Abstract

Background: Collaboration with other professions is essential in health care education to prepare students for future clinical teamwork. However, health care education still struggles to incorporate interprofessional education. Distance learning and virtual patients (VPs) may be useful additional methods to increase students' possibilities for interprofessional learning.

Objective: This study had two aims. The first was to assess if an interprofessional VP case could facilitate medical students' learning about team collaboration in online groups. The second was to assess how students experienced learning with the VP when remotely connected with their group.

Methods: A mixed methods design was used. The VP case was a 73-year-old man who needed help from different health professions in his home after a hip fracture. Questionnaires were answered by the students before and directly after each session. Qualitative group interviews were performed with each group of students directly after the VP sessions, and the interviews were analyzed using qualitative content analysis.

Results: A total of 49 third-year medical students divided into 15 groups participated in the study. Each group had 2 to 5 students who worked together with the interprofessional VP without a teacher's guidance. In the analysis of the group interviews, a single theme was identified: the interprofessional VP promoted student interaction and gave insight into team collaboration. Two categories were found: (1) the structure of the VP facilitated students' learning and (2) students perceived the collaboration in their remotely connected groups as functioning well and being effective. The results from the questionnaires showed that the students had gained insights into the roles and competencies of other health care professions.

Conclusions: This study demonstrates that an interprofessional VP enabled insights into team collaboration and increased understanding of other professions among student groups comprising only medical students. The interprofessional VP seemed to benefit students' learning in an online, remote-learning context. Although our VP was not used as an interprofessional student activity according to the common definition of interprofessional education, the results imply that it still contributed to students' interprofessional learning.

KEYWORDS

interprofessional learning; virtual patient; medical students; remote learning; distance learning; medical education

Introduction

Background

Effective interprofessional collaboration has shown a number of positive results for both patients and caregivers, such as increased patient satisfaction and the delivery of safe and patient-centered care [1,2]. Health care students' attitudes toward interprofessional teamwork are important and are formed from experiences and interactions. Different interprofessional learning activities may influence their future practices in their chosen professions [3]. Providing training in interprofessional care is crucial for health care students to acquire the skills needed for future clinical teamwork [2,4].

There are several barriers to interprofessional education (IPE), such as geographical distance, crowded timetables, and logistical difficulties [5], and it has always been a challenge to bring students from different health professions together, especially in primary health care settings [1]. The COVID-19 pandemic created further barriers to interprofessional learning at workplaces, and social distancing has affected the learning environment at medical universities.

Distance learning is not a new phenomenon in academia [6,7], and due to the COVID-19 pandemic, transition from on-campus learning to distance learning has been required at many universities. However, there are well-known challenges with distance learning, such as technological issues and the frequent association of distance learning with decreased student engagement [8]. Nevertheless, distance learning may facilitate high-quality health education in primary health care, where students are often geographically scattered during their clinical placements [6]. Distance learning with access to online learning materials, such as virtual patients (VPs), has shown great potential in previous studies to solve logistical problems in many health education settings [9,10]. Such materials, including VPs, are convenient for students to access at any time and from any location, which might also facilitate the use of such methods. VPs are computer-based simulations of patient encounters [11] that have been successfully used globally in different settings and with different purposes in medical education [11-15].

There have been some past studies of VPs that included students from different health care professions with the aim of exploring how VPs can contribute to IPE [10,16,17]. However, there is a knowledge gap regarding team collaboration and how students of the same profession learn about other professions using VPs. Prior to COVID-19, we had already received funding for a study to investigate how an interprofessional VP could prepare medical students for real home visits. The students were intended to work with the VP in an in-person setting as part of interprofessional groups. Due to COVID-19, all health care education had to be rethought and was shifted from in-person delivery to alternatives such as remote, online learning. Unfortunately, we could not arrange interprofessional student groups on such short notice.

In this study, the aim was to investigate how a VP designed for interprofessional student groups might be useful for groups

comprising solely medical students to gain insights into other professions' competencies and into team collaboration.

Aims of the Study

This study had two aims: (1) to assess if an interprofessional VP could facilitate medical students in learning about team collaboration in online groups and (2) to assess how students experienced learning with the VP when they were remotely connected with their group.

Methods

Study Design

This study was not interprofessional in the traditional sense, as we had students from only one profession participating in the study. Nevertheless, the VP used in this study was interprofessional in its design, and it had been previously studied by us in a setting with interprofessional student groups [16].

The study had a mixed methods design [18] that used both qualitative and quantitative approaches to strengthen the research findings. We performed group interviews with medical students and applied qualitative content analysis with an inductive approach to the data [19,20]. In addition, we used questionnaires to explore students' previous knowledge of different professions and investigate how the VP contributed to their understanding of other professional roles and teamwork ([Multimedia Appendix 1](#)).

The Interprofessional VP

The interprofessional VP case was a 73-year-old man who had recently returned home and received home care after surgery for a hip fracture. The case included 3 short illustrative video clips demonstrating individuals from 4 different health professions working together in home care with the intention to help the patient. The case also contained textual information about the roles and competencies of different health professions. During the case, students had to formulate and submit free-text answers to questions exploring their thoughts and further planning for the patient. After submission of their group reflections, the students received feedback from teachers as preprepared comments [16].

Context and Participants

Before the COVID-19 pandemic, all students in the third year of their medical program had a compulsory assignment in which they participated in a home care visit led by a clinician from another profession. During this assignment, the students interviewed the patient, the clinician, and the home care workers. The task for the students was to identify, describe, and reflect on the roles of the professionals who participated in the care of the patient and to describe how they collaborated with each other. Due to the pandemic, the students could no longer participate in home care visits or in physical group meetings. We had trialed our VP with interprofessional student groups in physical meetings in previous years, which we described in a previous paper [16]. We decided at the beginning of the pandemic to use the same interprofessional VP in a completely new context with groups including only medical students who were remotely connected to each other. Starting from May 2020,

all third-year medical students had to perform this new assignment and work with the VP case in remote group meetings as a replacement for the physical home visits.

Recruitment

Participants in this study were recruited via the learning platform for the course. After viewing a presentation on the compulsory assignment, the students received a written invitation to participate in the study. Students who were interested could click on a link to go to the study site, which was a page on the same learning platform. On the page, the students received more detailed information and were presented with the option to sign up. Participation in the study was voluntary. Students could sign up on given dates that were indicated on a calendar, and they were encouraged to choose 2 or 3 peers with whom they wanted to work and to sign up together. They had the choice to either initiate a new group or to join an already existing group. During the VP session, the students were instructed to be at separate physical locations of their choosing and to interact exclusively via an online communication tool (Zoom; Zoom Video Communications, Inc). One student in each group, the navigator, had to open the VP system on their computer and then share the screen with their peers. Each group had to decide at the beginning of their session which of them would be the navigator. The navigator had the role of navigating the VP system according to the wishes of their peers and submitting the group's reflections into the system. The majority of students were at home when working with the VP, while some were on campus. The students worked with the VP on their own without the presence of teachers.

Data Collection

The sessions were limited to a maximum of 2 hours. A Zoom link was sent to each group the day before their scheduled session with the VP, and each student was asked to answer separate questionnaires before and after the VP session ([Multimedia Appendix 1](#)). The before-VP questionnaire was filled in on the learning platform. The items in this questionnaire were measured on a 6-point Likert scale, ranging from 1 ("totally disagree") to 6 ("totally agree"). The questionnaire had demographic questions on sex, age, and prior experience of IPE activities. There were also questions about students' prior experience of learning activities with other health professions. After the VP session, as soon as the group interview was completed, the students received an email with the after-VP questionnaire. This questionnaire contained 2 additional questions, with free-text answers in which the students could describe what they had found especially valuable about the activity and what they would have preferred to be done differently. Directly after the session, each group was interviewed via the same Zoom link used for the session. Each interview lasted from 10 to 20 minutes and used an interview guide with the following open-ended questions: "How did you perceive working with the VP model remotely?" "How did the virtual patient help you in learning about other professions?" "Was there any other profession that you would have wished to get more information about?" and "How did you perceive working with each other remotely and only one person could navigate the VP during the whole session, how did that impact

your learning experience?" There was an interviewer and an observer present at each interview. A total of 11 of the 15 interviews were led by author CT while author ETP observed. The group interviews were recorded with the recording function of the Zoom app and transcribed verbatim by CT.

Data Analysis

Statistical Analysis of Quantitative Data

The statistical analysis of the students' answers to the before-VP and after-VP questionnaires was performed using Stata/BE (version 17; StataCorp LLC). Median scores with IQRs were calculated, and differences in scores before and after the learning activity were analyzed using the Wilcoxon signed rank test for paired measurements. *P* values less than .05 were considered statistically significant.

Qualitative Content Analysis

Qualitative content analysis was used for the analysis of the group interviews, inspired by the methods of Krippendorff [20] and Graneheim and Lundman [19]. The analysis focused on both manifest and latent content. The transcripts were initially read and reread to capture the content as a whole and were coded independently by authors CT, ETP, and HS. The material was coded manually. Meaning units relevant to the aim were identified, condensed, and labeled with codes and then discussed until consensus was reached. The various codes were interpreted and compared in a search for patterns, and codes with similar content were grouped into subcategories. The subcategories were then compared with each other and sorted into higher-level categories. The categories and subcategories can be seen as an expression of the manifest content of the text and describe the visible and obvious meanings in the text [19]. In the final stage, we tried to capture the essence of the material. A theme was formed that was considered to reflect the underlying meaning through condensed meaning units, codes, and categories on an interpretative level [19]. During the analysis process, CT, ETP, and HS moved back and forth between the whole and parts of the text. Finally, codes, subcategories, categories, and the theme were discussed until consensus was reached. Investigator triangulation was used to increase trustworthiness, and suitable quotes from different interviews were selected to illustrate the categories. In all transcriptions the students were coded, and the material was pseudonymized. Since new data did not add anything new in the last qualitative interviews, it was considered that sufficient information power was obtained for the qualitative interviews.

Ethical Considerations

Ethical approval was obtained from the Regional Ethical Review Board in Stockholm, Sweden (Dnr 2012/1011-31/5). Due to COVID-19 constraints, the request for informed consent and the subsequent responses were communicated in writing. Students could only sign up for participation via a link from the learning platform. They received the information that signing up on the calendar for a session with the VP meant that they gave their informed consent to participate in the study. Participation in the study was voluntary, and the students were informed that participation or withdrawal from the study would not influence their future studies or contact with the university.

ETP had contact with the students both as a teacher and an interviewer. HS was responsible for the primary care component of the study program in medicine. Ethical issues related to the double roles of ETP and HS were discussed, and the group interviews were mostly performed by CT.

Results

Quantitative Results

A total of 244 students were eligible for the study, 49 of whom signed up to participate, including 18 men and 31 women. They

formed 15 groups with 2 to 5 students in each. The median age of the participants was 25 (range 20-50) years. Of the 49 students, 46 answered the question about whether they had had experience of learning activities together with other professions, and 31 of these 46 (67%) had no previous interprofessional experience. There were 15 students who reported having had such experiences with nursing students. The results from the before-VP and after-VP questionnaires are presented in Table 1. The students reported having increased their understanding of the roles of the other professions presented in the VP case. The largest increase was in the perceived understanding of the role and competence of occupational therapists.

Table 1. The answers of students (N=49) to questionnaire items before and after working with an interprofessional virtual patient. Items were scored on a 6-point Likert scale, ranging from 1, (“totally disagree”) to 6, (“totally agree”).

Items	Before VP ^a session score, median (IQR)	After VP session score, median (IQR)	P value ^b
Items related to insight into the roles of various professions^c			
Family physician	3 (2-4)	5 (5-6) ^d	<.001
District nurse	3 (2-4)	5 (5-6) ^d	<.001
Physiotherapist	3 (1-4)	5 (5-6) ^e	<.001
Occupational therapist	2 (1-4)	6 (5-6) ^d	<.001

“I am familiar with using VPs and simulations for learning”	3 (2-4) ^g	N/A	N/A
“Working together with the VP remotely functioned well”	N/A	6 (5-6) ^d	N/A
“Our discussions contributed to my learning about the different professions’ roles in a home visit”	N/A	5 (5-6) ^d	N/A
“I perceive that working with the VP helped me to be better prepared for a real home visit”	N/A	5 (4-6) ^e	N/A

^aVP: virtual patient.

^bDetermined with the Wilcoxon signed rank test for paired measurements.

^cItem before the session: “I perceive that I have insight into the role of the following professions during a home care visit”; item after the session: “I perceive that I have a more in-depth insight into the role of the following professions during a home care visit.”

^dData missing from 2 students.

^eData missing from 3 students.

^fItem before the session: “I perceive that I have insight into the collaboration between...”; question after the session: “I perceive that I have a more in-depth insight into the collaboration between...”

^gData missing from 1 student.

^hN/A: not applicable. This question was not asked in this session.

Qualitative Results

From the analysis of the group interviews, we identified a single theme: the interprofessional VP promoted student interaction

and gave insight into team collaboration. Two categories were found: (1) the structure of the VP facilitated students’ learning and (2) students perceived the collaboration in their remotely

connected group as functioning well and being effective (Textbox 1).

Textbox 1. One theme, 2 categories, and 9 subcategories were identified from the 15 group interviews with medical students.

Theme: The interprofessional virtual patient promoted student interaction and gave insight into team collaboration.

For the category “the structure of the virtual patient facilitated students’ learning,” subcategories included the following:

- A mix of different methods with the virtual patient promotes learning.
- The virtual patient provides an understanding of the students’ own and other professionals’ roles and responsibilities.
- The virtual patient provides insights into the importance of collaboration between professions.
- The virtual patient provides as much information about handling the patient case as a real home visit.

For the category “students perceived the collaboration in their remotely connected group as well-functioning and effective,” subcategories included the following:

- Work with the virtual patient remotely was effective.
- Roles were distributed.
- It was good for the students to be able to choose who they wanted to work with.
- The students’ experiences of communication in the group during the session.
- The discussion would have been richer if there were other professions in the group.

The Interprofessional VP Promoted Student Interaction and Gave Insight Into Team Collaboration

This theme described how the interprofessional VP generated interactions between the students in several ways. The students felt that they could get help from each other by sharing their previous experiences and knowledge about other professions and in this way be able to help the patient in the VP exercise. The students had to formulate their thoughts about the patient’s situation and how they would help the patient and then had to submit their reflections in the system, which prompted them to discuss their thoughts and reflections within the group. The students reported that the mixture of video clips, text, and free-text responses in the structure of the VP prompted them to discuss and interact with each other regularly during the session. The students perceived that the VP case gave them insights into team collaboration by providing them with information about how different professions acted and collaborated in the case (via the video clips) and about those professions’ competencies in general (via the texts).

The Structure of the VP Facilitated Students’ Learning

All of the students appreciated the short video clips in the VP case because they felt that the clips helped them to obtain a detailed understanding of how other professions act in their roles during home visits. The students found the VP case to be realistic and that it gave a sense of meeting a real human being. The students also appreciated the texts in the VP that contained information about different professions’ competencies, because these texts complemented the videos. The students reported that it became clear to them from the case how different health professions contributed to helping the patient in an optimal way. This made the students understand the importance of collaboration:

How much one succeeds when there are several professionals working together depends on maybe several factors such as how you collaborate, how you

listen to each other, or how you can complement someone if someone has forgotten something. [Student group 15]

The students perceived having learned more about other professions by actively discussing the VP case in the group than if they had been listening to a lecture:

If you compare this way and think about all the professions compared to maybe sitting in a lecture where they talk about what different professions do during a home visit, then you would have zoned out immediately. But now you look and sort of discuss, laugh, and think as well. I think you learn a lot more this way. [Student group 10]

The students reported that they had gained insights into other professions’ roles and responsibilities by working with the VP. Several of the students mentioned explicitly that they had learned the differences between the roles of physiotherapists and occupational therapists. They also mentioned that it was new information for them that doctors can examine patients in their homes. The students found it valuable that the VP case provided them with information about professions that they would not have received if they had participated in a real-life home visit. Working with the VP made them feel more active in the patient consultation compared to a real home visit, during which they would typically listen passively to their supervisor:

This is an easier way to stay active throughout the task, and therefore to get more out of it than if you just sit passively next to someone and listen. [Student group 2]

Students Perceived the Collaboration in Their Remotely Connected Group as Functioning Well and Being Effective

In this category, the students described how using the VP remotely functioned well. They almost perceived being in the

same room together, because all of the participants in the group could follow the VP on their own screen:

I do not think there would be any major difference if we had been sitting together. This way we could all sit and watch the screen and follow along. [Student group 11]

Although only one of them acted as navigator and ran the VP, the students found it easy to work together. Indeed, some of them thought that it would lead to problems with teamwork if all of them could run the VP simultaneously. The students who navigated the VP needed to be responsive to their peers in the group discussions:

We discussed together what we should write and answer, so it was "B" who wrote everything, but we also said, like, "Ah, but you can write this and do it like this"...and so we always checked with each other by asking, "Are we ready click on the next section?" [Student group 14]

Those who did not run the VP felt that they were still actively involved in the group discussions. A spontaneous comment from some students was that they appreciated the opportunity to choose which peers they worked together with:

We could choose who we would be with, which also contributed to us...we all three know each other so we know a little about our dynamics, our prior knowledge, and that may be why it went so fast for us, too...ehh, because it will be a lot more efficient when you already know about the others, we have worked with them a bit before. [Student group 2]

However, the students stated that they would have appreciated working on the VP together with students from other professions. They wanted to know how students from other professions would have reasoned about the issues being discussed. In the absence of other professions, the students had to try to imagine the other professions' perspectives.

The students reported that their experience of working remotely was mainly positive, and they reported feeling more relaxed and saving travel time. However, the students also mentioned some difficulties working remotely, such as not being able to notice on the screen when someone wanted to speak. They also mentioned the importance of technology that functioned well, although they rarely experienced any technical problems.

A total of 44 students gave free-text responses about what they thought was especially valuable about the learning activity. The answers were in accord with the findings from the group interviews. They described how the short video clips helped them to better understand the roles and competencies of other health professions, and they also stated that they would like to work on the VP case with students from the other professions that were presented in the VP.

Discussion

Principal Results

To our knowledge, this is the first study that has assessed how an interprofessional VP can contribute to medical students'

learning about other professions and about team collaboration while remotely connected in online groups. The students perceived that the VP promoted learning and interaction in their groups and gave insight into team collaboration. The mixture of visual and textual information in the VP added valuable knowledge about the involved professions and was highly appreciated by the students. The students found that the VP functioned well and that it was effective to work with the VP while remotely connected to their groups. They stated that the digital communication tool allowed their conversations to flow smoothly, because they could see and hear each other on the screen. The students appreciated the video clips that demonstrated how different health professions collaborated with each other in home care, and they expressed the opinion that the video clips added greatly to their understanding of the roles and competencies of other professions.

Comparison With Prior Work

The finding that embedded video clips could facilitate students' interprofessional learning is in accord with our previous study [16], in which students worked with the same interprofessional VP case in face-to-face interprofessional student groups. Students in both studies reported similar perceptions about how the VP facilitated their interprofessional learning. The methods described in this study may not match the traditional notion of IPE because the student groups comprised only medical students, but our findings show that they still gained insights into team collaboration and a better understanding about other professions' competencies.

In a study by Edelbring et al [21], students could choose either to have a real-life meeting or to meet online in their interprofessional learning activity with a VP. The majority of the students chose to meet online and expressed the feeling that it worked well to have a digital meeting. The finding that the students appreciated working online is in line with our findings in this study.

Most published studies of IPE have involved at least two different health professions and have reported mostly positive findings, such as students stating that collaboration across professions benefits patients and helps to clarify professional roles [22-25]. We obtained similar results in our study even though we only had students from one profession. The VP case thus supported the students in understanding the importance of team collaboration to help patients.

Some students appreciated the opportunity to choose the peers they wanted to work with, and they found the discussions to be easier and more rewarding when working with peers they knew. Whether or not it is beneficial to be able to choose your working partners could, however, be questioned, and in their upcoming professional roles, new clinicians should be able to collaborate with people they are not familiar with. Our students appreciated being able to discuss the care of the patient with their peers and obtain immediate feedback from the VP system. In studies by Croft et al [26] and Dost et al [27], students reported barriers to online learning, such as not having peers for discussion and lacking immediate feedback from a teacher. The interprofessional VP described in this study cannot replace traditional IPE, but it could meet the challenges faced by every

faculty, such as logistical difficulties and the recent challenges of social distancing due to COVID-19. After this study was completed, the interprofessional VP was implemented as a permanent learning activity for all third-year medical students.

Limitations

A limitation was that the questionnaire used before and after the learning activity was not validated or pilot tested prior to its use, due to a lack of time at the start of the study. Another potential limitation is that two of the researchers were involved in the medical program as teachers; hence, the teacher-student relationship might have influenced the study participants' questionnaire answers. Additionally, the students were able to choose their peers for the groups by themselves, rather than being randomly assigned, and this could also be seen as a limitation. Furthermore, because the students in this study participated on a voluntary basis, it is not known how nonparticipating students would have perceived working with the VP online remotely in groups. On the other hand, 49 of the 244 eligible students participated in the study, and the findings may have been similar among students who did not participate,

because they performed exactly the same activity under the same circumstances and expressed a high level of appreciation in their course evaluation. In other words, the study was performed in a real-life context. Forty-nine of 244 eligible medical students may be considered a small sample size in quantitative research, but the sample size was large for a qualitative study. This study was also limited by the participation of medical students from a single university; therefore, the results might not be transferrable to medical students from other universities.

Conclusions

The results of this study demonstrate that the interprofessional VP gave insight into team collaboration and increased the understanding of other professions among student groups comprised only of medical students. The interprofessional VP seemed to benefit students' learning in an online, remote-learning context. Though our VP was not used as an interprofessional student activity according to the definition of IPE, the results imply that it still contributed to students' interprofessional learning.

Acknowledgments

The authors wish to acknowledge all the participating students.

Authors' Contributions

HS, ETP, and CT, together with UF, created the virtual patient (VP) model and the case. UF had the specific role of developing the VP system. UF also implemented the VP case into the VP system. ETP and HS planned the study and obtained funding. CT and ETP collected the data. CT, HS, and ETP carried out the data analysis and were deeply involved in all steps. CT drafted the first version of the manuscript. All authors revised and approved the final version.

Conflicts of Interest

None declared.

Abstract

Background: Zambia is facing a severe shortage of health care workers, particularly in rural areas. Innovative educational programs and infrastructure have been established to bridge this gap; however, they encounter substantial challenges because of constraints in physical and human resources. In response to these shortcomings, strategies such as web-based and blended learning approaches have been implemented, using virtual patients (VPs) as a means to promote interactive learning at the Levy Mwanawasa Medical University (LMMU) in Zambia.

Objective: This study aimed to evaluate the students' knowledge acquisition and acceptance of 2 VP medical topics as a learning tool on a Zambian higher education e-learning platform.

Methods: Using a mixed methods design, we assessed knowledge acquisition using pre- and posttests. In a randomized controlled trial setting, students were assigned (1:1) to 2 medical topics (topic 1: appendicitis and topic 2: severe acute malnutrition) and then to 4 different learning tools within their respective exposure groups: VPs, textbook content, preselected e-learning materials, and self-guided internet materials. Acceptance was evaluated using a 15-item questionnaire with a 5-point Likert scale.

Results: A total of 63 third- and fourth-year Bachelor of Science clinical science students participated in the study. In the severe acute malnutrition-focused group, participants demonstrated a significant increase in knowledge within the textbook group ($P=.01$) and the VP group ($P=.01$). No substantial knowledge gain was observed in the e-learning group or the self-guided internet group. For the appendicitis-focused group, no statistically significant difference in knowledge acquisition was detected among the 4 intervention groups ($P=.62$). The acceptance of learning materials exhibited no substantial difference between the VP medical topics and other learning materials.

Conclusions: In the context of LMMU, our study found that VPs were well accepted and noninferior to traditional teaching methods. VPs have the potential to serve as an engaging learning resource and can be integrated into blended learning approaches at LMMU. However, further research is required to investigate the long-term knowledge gain and the acceptance and effectiveness of VPs in medical education.

Introduction

Background

The critical need to enhance Zambia's health care workforce, particularly involving doctors, nurses, and other health care workers (HCWs), is driven by a substantial shortage of qualified HCWs. In this study, we define HCWs as individuals whose primary professional goal is to maintain or enhance the health of others, including those who provide patient care and diagnostic and treatment services across various clinical settings. The scarcity of HCWs is particularly acute in Zambia's rural areas, highlighting the importance of addressing this issue to ensure equitable access to health care and improved health outcomes across the country. Addressing this HCWs deficit is essential for enhancing public health outcomes and providing equitable care across the country. Exacerbating this situation are infrastructural obstacles such as the protracted process of developing educational facilities. The convergence of these factors impedes the capacity expansion and the enhancement of health profession training quality. Consequently, addressing these constraints is vital for improving public health outcomes and fostering a robust HCW workforce. These constraints contribute to adverse public health outcomes, including compromised disease treatment efficacy, increased child mortality, and poor maternal health [1]. In 2002, Zambia introduced medical licentiate practitioners (MLPs) through an initial 3-year diploma program, followed by a 2-year medical licentiate, to address the shortage of qualified HCWs, particularly in rural areas, and to upgrade the health care delivery scope of existing clinical officers. MLPs, who have a distinct role compared with traditional medical graduates, now complete a 4-year training program, for example, at the Levy Mwanawasa Medical University (LMMU), earning a Bachelor of Science (BSc) in clinical science [2-4]. This specialized training enables MLPs to perform a limited number of emergency surgeries, including cesarean sections, and to prescribe medications [2]. Their education focuses on 4 primary disciplines that align with the country's health priorities, particularly in rural areas: surgery, pediatrics, obstetrics and gynecology, and internal medicine [3,4]. The MLP training program comprises a balanced structure, including 2 years of theoretical instruction followed by 2 years of hands-on skills training acquired through rotational assignments at a diverse range of hospitals and health clinics across Zambia.

In low-resource learning environments, such as Zambia, e-learning and self-directed internet materials play a crucial role in overcoming the challenges posed by the scarcity of qualified HCWs, limited infrastructure, and constrained budgets. e-Learning allows for the expansion and enhancement of medical education by providing students with access to up-to-date information and resources regardless of their location. This approach is particularly beneficial for students in rural areas, where there may be a lack of qualified medical educators, limited access to learning resources, and inadequate infrastructure to support traditional face-to-face instruction [3,5].

Furthermore, self-directed internet materials encourage learners to take charge of their own education, allowing them to study at their own pace and focus on the topics most relevant to their professional development. This flexibility is crucial in low-resource settings, where e-learning can provide access to up-to-date information, reducing the reliance on on-site classes in areas facing a shortage of medical educators [3-5].

The integration of e-learning and self-directed internet materials into medical education programs in low-resource settings can help bridge the gap between theoretical knowledge and practical application, thus improving the overall quality of health care [6-8]. For example, virtual patient (VP) scenarios can provide students with a more interactive and engaging learning experience, enhancing their clinical reasoning skills and compensating for the scarcity of senior HCWs for face-to-face training [9]. By leveraging e-learning and self-directed internet materials, medical education programs in low-resource settings can better prepare students for the challenges they will face in their professional careers, ultimately leading to improved health care outcomes.

Interactive Medical Learning Through VPs

VPs are defined by the American Association of Medical Colleges as "a specific type of computer-based program that simulates real-life clinical scenarios" [10]. VPs offer the advantage of addressing multiple cognitive levels while enhancing the learning experience through supplementary channels such as visual and auditory information. Students may develop clinical reasoning skills by using VPs, which bridge the gap between theoretical clinical knowledge and practical clinical application [3-5]. Assuming the role of a clinician, VPs enable students to practice diagnostic, treatment, and follow-up procedures. This approach may bolster student motivation as they become more aware of the importance of practice [10-12], rather than solely focusing on academic performance or examination scores [13,14]. A systematic review conducted by Kononowicz et al [11] revealed that VPs are capable of improving skills and knowledge as effectively as, or even surpassing, other prevalent educational methodologies. They observed improvements in clinical reasoning, procedural skills, and a combination of procedural and team skills in both low-income and high-income settings [11]. Bediag et al [15] assessed the impact of VP training on the clinical skills of Cameroonian health care professionals and found that such training could contribute to the advancement of users' clinical operational skills [15].

In the Zambian context, implementing VPs as a learning resource can help mitigate challenges associated with the shortage of senior medical lecturers and infrastructure limitations. By integrating VPs into the existing e-learning platform, we can provide a more interactive and engaging learning experience, enhance clinical reasoning skills, and compensate for the scarcity of senior HCWs for face-to-face training. Furthermore, VPs can be accessed remotely, allowing students in rural areas or those with limited access to traditional

educational resources to benefit from this innovative learning approach [9]. To improve medical education at LMMU within the BSc clinical sciences program, we devised and assessed 2 VP scenarios. VPs could be a highly accepted and effective tool for integration into the existing e-learning platform for MLPs at LMMU, thus expanding the range of digital learning resources available. Our study specifically focused on examining 2 primary research questions that aimed to evaluate the effectiveness and impact of these scenarios on student learning and clinical reasoning skills. By addressing these questions, we sought to provide valuable insights into the potential benefits and limitations of implementing VP scenarios in medical education, particularly within the context of low-resource settings such as Zambia. Outcomes may differ from those in high-income countries because of differences in educational systems, infrastructure, and technological access. Evaluating the potential impact of VPs in a context such as LMMU can inform targeted interventions aimed at enhancing medical education, which may ultimately contribute to improved health care outcomes within such settings.

In the context of LMMU, our study aimed to address two primary research questions: (1) How effectively do VPs contribute to knowledge acquisition in comparison with the

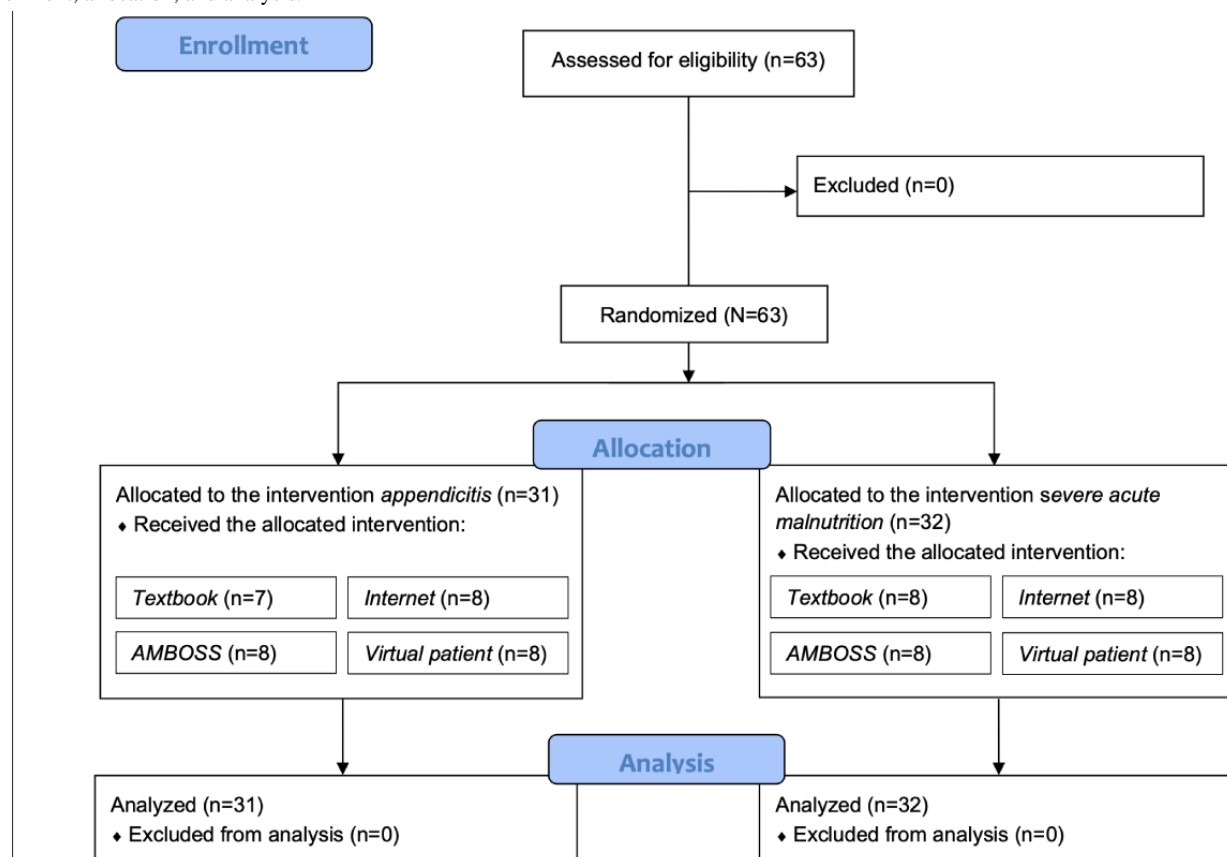

traditional learning resources prevalent in Zambia, such as learning from textbooks, using free internet searches, and accessing preselected static resources on a medical e-learning platform? and (2) How does student acceptance of VPs compare with their acceptance of traditional textbooks, internet searches, and a medical e-learning platform as learning tools?

Methods

Overview

We conducted a noninferior, randomized controlled trial with a mixed methods research design (convergent) to evaluate the effectiveness of VPs in terms of acceptance and knowledge acquisition (Figure 1). The analysis team was blinded to the study. The students, who were informed through a flyer distributed beforehand, were aware that the study aimed to investigate VPs as a learning method. The CONSORT (Consolidated Standards of Reporting Trials) checklist was used for reporting this study [16] (for the CONSORT checklist, refer to [Multimedia Appendix 1](#)). The study participants were recruited on November 29, 2021, and the study took place on December 10, 2021, at the main campus of LMMU in Lusaka, Zambia. All third- and fourth-year BSc clinical science students aged ≥ 18 years were eligible to participate in this study.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flow diagram detailing the randomized controlled trial, following the stages of enrollment, allocation, and analysis.

Randomization, Blinding, and Implementation

The study participants were recruited through digital messaging services, email, and the local university administration. A total of 63 third- and fourth-year BSc clinical science students aged

≥ 18 years were invited to participate in this study. Randomization was implemented in a 2-step process. Initially, participants were assigned to 1 of the 2 study groups (appendicitis or severe acute malnutrition [SAM]) based on their study ID. Subsequently, within each study group,

participants were stratified according to their academic year. We used stratified randomization to guarantee a balanced allocation of participants, considering the stratum of academic year. This procedure ensured an equitable distribution across study groups while addressing potential variations associated with participants' academic advancement. To maintain the integrity of the study, the data analysis team remained

independent of the data collection process. Only third- and fourth-year BSc clinical science students were asked to participate in the study, as they had previously been exposed to the 2 medical topics of appendicitis and SAM during their first 2 years of university training. The learning resources that the students were exposed to are presented in [Textbox 1](#).

Textbox 1. Students' learning resources.

- Interactive virtual patient (VP) medical topics
 - Severe acute malnutrition (SAM): The VP medical topic was developed using materials from the World Health Organization's country guidelines on managing SAM in infants and children [17], web-based resources [18,19], and relevant sections from Nelson's Textbook of Pediatrics [20] (refer to [Multimedia Appendix 2](#) for the detailed VP medical topic).
 - Appendicitis: The VP medical topic was developed using materials from the AMBOSS e-learning platform, specifically the website on appendicitis [21] (refer to [Multimedia Appendix 3](#) for the detailed VP medical topic).
- Textbook contents aligned with the Bachelor of Science clinical science curriculum
 - SAM: Nelson's Textbook of Pediatrics, 21st edition, pages 336-352 [20].
 - Appendicitis: Bailey and Love's Short Practice of Surgery, 27th edition [22].
- e-Learning materials were preselected from the medical e-learning platform AMBOSS [23], which was made available on a complementary basis to the Levy Mwanawasa Medical University faculty and students.
- Self-guided internet materials were made accessible to study participants, allowing them to independently investigate 1 of the 2 topics (appendicitis or SAM) using their own search terms. This approach facilitates autonomous exploration and information gathering on the subject through internet resources.

Both VP medical topics were uploaded to LMMU's Moodle e-learning platform [3] but remained inaccessible to participants until the day of the trial.

All participants, regardless of their assigned study group, completed a pretest before accessing their designated learning resource for a 30-minute period. After the intervention, a posttest identical to the pretest was administered to all the participants. Furthermore, each participant completed a questionnaire evaluating their acceptance of the respective learning resource ([Multimedia Appendix 4](#)). During the entire 4-hour study period, participants were explicitly instructed to refrain from communicating with one another.

Data Collection

To evaluate knowledge acquisition from the 4 learning resources, we administered multiple-choice question (MCQ) tests before (pretest) and after (posttest) the intervention. The appendicitis-related MCQ test comprised 20 questions (maximum score: 1000 points), whereas the SAM-related test contained 15 questions (maximum score: 720 points; refer to [Multimedia Appendix 5](#) for pre- and posttests). Each question was presented with 4 answer options, with 1 correct answer. All the groups received identical questions. An internal pilot study was conducted before the randomized controlled trial to ensure that participants could successfully pass the tests using any of the 4 learning resources. The pilot study involved a small sample of participants (n=6), including students (n=4) and faculty members (n=2), who were not part of the main study. The primary objective of this pilot study was to assess the clarity, comprehensibility, and effectiveness of the study materials, including the questionnaires and VPs. This preliminary testing helped to identify any potential issues,

ambiguities, or biases in the questions and to evaluate the overall efficacy of the questionnaire. By addressing these concerns, we aimed to enhance the validity and reliability of the study instruments and, ultimately, the quality of the data collected in the main study.

The pilot study addressed uncertainties regarding the effectiveness and time allocation of the various study methods. This facilitated the refinement of the learning materials and ensured appropriate time durations for each method, allowing for adequate knowledge acquisition. The pilot study also confirmed that each learning resource covered course objectives, preventing participants from focusing solely on pretest questions, and enabled the assessment of pre- and posttest questions to accurately measure knowledge acquisition across learning methods. By integrating the pilot study findings into the main study design, the research team mitigated concerns about the effectiveness of various study methods and the sufficiency of the time allocated for each approach.

The VPs were developed to be consistent with the Zambian context, incorporating relevant resources and guidelines, such as the World Health Organization's country-specific guidance on managing SAM in infants and children [17], and the curricular standards of LMMU. This method ensured that the VPs were customized to suit the requirements and expectations of BSc clinical science students as well as to address the specific demands of the local health care system.

Acceptance Questionnaire

We assessed the acceptance of the 4 learning resources using a questionnaire adapted from the study by Davis [24] on the technology acceptance model. The technology acceptance model

includes six dimensions: (1) perceived usefulness, (2) perceived ease of use, (3) attitude toward use, and (4) behavioral intention to use, (5) job relevance, and (6) perceived enjoyment. The original fifth component (actual system use) was excluded from our study's questionnaire, as it did not pertain to our research objectives. We incorporated 2 additional dimensions—(5) and (6)—based on the study by Salloum et al [25]. The questionnaire comprised 15 items, with responses recorded on a 5-point Likert scale.

Data Analysis

Before conducting the analyses, we examined all data for normal distribution using the Shapiro-Wilk test. *P* values <.05 were considered statistically significant. We analyzed both study groups separately. Descriptive statistics including frequency, percentage, mean, median, and SD were used to evaluate the distribution of age, sex, and prior medical knowledge within the groups. Here, prior medical knowledge refers to the participants' preexisting knowledge specifically related to appendicitis and SAM.

The pre- and posttest outcomes were evaluated through the following analyses:

1. We used an ANOVA test followed by a paired 1-tailed *t* test with Bonferroni correction as a post hoc test to assess any variations in prior knowledge across the 4 study groups for each of the 2 study groups' topics (appendicitis and SAM).
2. We applied the same approach described in the previous point to evaluate the differences in postintervention knowledge levels across the groups. This analysis aimed to identify whether there were any significant differences in the knowledge levels between the groups after exposure to different learning resources, which could indicate the relative effectiveness of each resource.
3. To assess within-group knowledge acquisition, we compared the pre- and posttest results for each group. We

used a Wilcoxon rank test for the 3 groups using textbook contents, e-learning materials, and self-guided internet materials. For the group using VP, we used a *t* test as the data were normally distributed. This analysis helped determine the extent of knowledge gain within each group after using their assigned learning resource.

The 5-point Likert scale was converted to numerical values (1=strongly agree, 2=agree, 3=neutral, 4=disagree, and 5=strongly disagree). We assessed acceptance across the 6 dimensions using descriptive statistics. To evaluate whether there was a statistically significant difference in the acceptability of the 4 learning resources among all intervention groups, we applied the Kruskal-Wallis test. As a post hoc analysis, we conducted a Wilcoxon rank test with Bonferroni correction.

Ethics Approval, Informed Consent, and Participation

This study was approved by the Heidelberg University Hospital Ethical Committee on August 30, 2021 (S-685/2021) and the LMMU Research Ethics Committee on November 29, 2021 (LMMU-REC 00005/21). We informed all potential and selected participants about the study's objectives and procedures as well as their right to withdraw at any time without consequences. Before participation, each individual provided written informed consent, ensuring their voluntary involvement in the study.

Results

Demographics

A total of 63 students consented to participate and were included in the study. The mean age of the participants was 39.56 (SD 6.05) years, with age ranging from 22 to 46 years. The sample consisted of 39 male students and 23 female students, with 1 participant identifying as "diverse." Regarding the participants' academic progression, 32 were in their third year of study, whereas 31 were in their fourth year (refer to Table 1 for a detailed breakdown).

Table 1. Overview of the study groups' composition and demographic characteristics (N=63).

Intervention group	Participants, n	Age (years), mean (SD)	Sex, n (%)			Study year, n (%)	
			Female	Male	Diverse	Third	Fourth
Study group 1—medical topic: severe acute malnutrition (n=32)							
Virtual patient	8	29.38 (1.77)	4 (50)	4 (50)	0 (0)	4 (50)	4 (50)
Textbook	8	27 (5.04)	3 (38)	5 (62)	0 (0)	4 (50)	4 (50)
Preselected e-learning materials	8	30,38 (6.82)	4 (50)	3 (38)	1 (12)	4 (50)	4 (50)
Self-guided internet materials	8	32.75 (9.66)	0 (0)	8 (100)	0 (0)	4 (50)	4 (50)
Study group 2—medical topic: appendicitis (n=31)							
Virtual patient	8	29.39 (4.57)	5 (62)	3 (57)	0 (0)	4 (50)	4 (50)
Textbook	7	29.17 (3.87)	2 (29)	5 (71)	0 (0)	4 (57)	3 (43)
Preselected e-learning materials	8	33.75 (4.74)	1 (13)	7 (87)	0 (0)	4 (50)	4 (50)
Self-guided internet materials	8	32.28 (7.51)	4 (50)	4 (50)	0 (0)	4 (50)	4 (50)

MCQ Pre- and Posttests

Pre- and Posttests for SAM

The pretest revealed a significant difference in knowledge between the *VP group* (mean score 480, SD 76.97) and the *textbook group* (mean score 456, SD 67.88) participants ($P=.01$) as well as a difference between the *VP group* and *self-guidedinternet group* ($P=.05$; refer to [Table 2](#) for detailed results). Participants in the *VP group* achieved the highest pretest scores, with a mean of 68% (43/63; mean score 480, SD 76.97) of the questions correctly answered, followed closely by the *e-learning group*, who correctly answered 63% (40/63) of the questions (mean score 456, SD 67.88). Students in the *self-guidedinternet group* scored 50% (mean score 360, SD 105.79), whereas students in the *textbook group* scored 48%

(mean score 342, SD 82.89). Although differences in scores between the groups persisted in the posttest compared with the pretest, the overall knowledge gap between the groups narrowed: The *VP group* scored 79% (mean score 570, SD 82.89), the *e-learning group* scored 68% (mean score 468, SD 132.7), the *self-guidedinternet group* scored 59% (mean score 426, SD 165.16), and the *textbook group* scored 59% (mean score 426, SD 82.89; refer to [Table 2](#) for details).

No significant increase in knowledge was observed in the *e-learning group* (mean score 468, SD 132.7) and the *self-guidedinternet group* (mean score 426, SD 165.16). However, significant knowledge growth was identified in both the *textbook group* ($P=.01$) and the *VP group* ($P=.01$; refer to [Multimedia Appendix 6](#) for details).

Table 2. Overview of the 4 exposure intervention groups that were exposed to the medical topic of severe acute malnutrition as well as their relative test scores (pre- and posttest) and average knowledge increase.

Intervention group (severe acute malnutrition)	Pretest score, mean (SD)	Posttest score, mean (SD)	Knowledge gain score, mean (SD)
Virtual patient	480 (76.97)	570 (82.89)	90 (90.48)
Textbook contents	342 (82.89)	426 (82.89)	84 (80.11)
Preselected e-learning materials	456 (67.88)	468 (132.7)	12 (114.02)
Self-guided internet materials	360 (105.79)	426 (165.16)	66 (122.88)

Pre- and Posttests for Appendicitis

The pretest for the medical topic of appendicitis did not reveal a significant difference in knowledge acquisition between the 4 intervention groups ($P=.62$; refer to [Table 3](#) for detailed results). Participants in the *e-learning group* achieved the highest pretest score, with a mean score 75% (mean score 750, SD 46.29), closely followed by participants in the *self-guidedinternet group* with 74% (mean score 735, SD

112.6), the *textbook group* with 74% (mean score 735, SD 146.3), and the *VP group* with 72% (mean score 718, SD 106.7). In the posttest, a difference was observed between the intervention groups, although this difference was not substantial ([Table 3](#)). On the basis of the individual learning curves, moderate knowledge acquisition was observed in all 4 groups, although these changes were not substantial (refer to [Multimedia Appendix 7](#) for details).

Table 3. Overview of the 4 exposure intervention groups that were exposed to the medical topic of appendicitis as well as their relative test scores (pre- and posttest) and average knowledge increase.

Intervention group (appendicitis)	Pretest score, mean (SD)	Posttest score, mean (SD)	Knowledge acquisition, mean (SD)
Virtual patient	718 (106.7)	800 (128.17)	81.25 (106.7)
Textbook	735 (146.3)	821.43 (128.64)	85.71 (85.22)
Preselected e-learning materials	750 (46.29)	887.5 (74.4)	137.5 (87.63)
Self-guided internet materials	735 (112.6)	850 (75.59)	112.5 (99.1)

Acceptance Questionnaire

We observed that the acceptance of learning resources varied depending on the medical topic. For the topic of SAM, the response to the statement “If given the opportunity, I would favor this learning resource over others” showed a significant difference between the *e-learning group* (mean 2.5, SD 0.33; $P=.01$) and the *self-guided internet group* (mean 1.25, SD 0.46). In contrast, the *VP group* had a favorable score (mean 1.62, SD 0.72). For the topic of appendicitis, the mean response to the same statement in the *e-learning group* was 1.38 (SD 0.52), which is significantly lower than the mean response in the *VP group* (mean 3.62, SD 1.41; $P=.02$).

Regarding the statement “I think this learning resource is a good instrument to acquire knowledge,” a difference between the *e-learning group* (mean 1.5, SD 0.53) and the *self-guided internet group* (mean 3.12, SD 1.13) with $P=.02$ was observed for the topic of appendicitis. This finding indicated that the *e-learning group* received more positive feedback than the *self-guided internet group* ([Table 4](#)).

One misinterpreted question in the study was removed because of its outlier status (question item: “Interacting with the learning mode required considerable effort.”).

Table 4. The acceptance questionnaire results for both study groups by intervention groups showing mean and SD.

Study arm and questions items (acceptance questionnaire)	Intervention groups, mean (SD)			
	Virtual patient group	Textbook group	Preselected e-learning materials	Self-guided internet materials
Study arm 1: severe acute malnutrition				
"I think this learning resource is a good instrument to acquire knowledge."	1.75 (0.89)	1.88 (1.13)	2.00 (0.76)	1.62 (0.52)
"If given the opportunity, I would favor this learning resource over others."	1.62 (0.74)	2.62 (1.19)	2.5 (0.53)	1.25 (0.46)
Study arm 2: appendicitis				
"I think this learning resource is a good instrument to acquire knowledge."	2.12 (0.64)	1.4 (0.89)	1.5 (0.53)	3.12 (1.13)
"If given the opportunity I would favor this learning resource over others."	3.62 (1.41)	2.00 (0.82)	1.38 (0.52)	2.75 (1.04)

Discussion

Principal Findings

In our study, we developed and assessed 2 interactive VP medical topics focusing on SAM and appendicitis, aiming to evaluate their effectiveness and acceptance compared with other prevalent learning resources at LMMU. The efficacy of transferring knowledge to students, and the precise impact of certain VP features, had previously been ambiguous. Our study aimed to address these aspects.

The primary aim of this study was to evaluate the acceptance and knowledge acquisition of BSc clinical sciences students at LMMU when using VPs as a learning resource in comparison with textbooks, preselected e-learning materials, and self-guided internet materials. A key finding of this study was that all 4 learning resources demonstrated their effectiveness in promoting knowledge gain within the study setting. Furthermore, VPs were well received by the students and proved to be noninferior compared with the other 3 learning methods.

Comparison With Prior Work

Knowledge acquisition significantly increased in the *VP* and *textbook groups* but not in the *e-learning* or *self-guided internet groups*. The differences in knowledge acquisition between these groups can be attributed to various factors. Each learning resource provides different levels of structure and guidance, with some students preferring visual or interactive content (eg, VPs) and others opting for text-based resources (eg, textbooks). These individual preferences may influence the effectiveness of each learning method, thus impacting knowledge acquisition across the groups. Motivation and engagement may also play a role, as VPs and textbooks potentially offer a more structured and engaging learning experience, which could lead to increased motivation and improved information retention. In contrast, general e-learning and self-guided internet materials may require a higher degree of self-discipline and motivation to effectively navigate and absorb the content. Another aspect to consider is the familiarity with learning resources. Students might be more familiar with traditional learning resources, such as textbooks, compared with newer methods, such as VPs or e-learning

platforms. This familiarity could influence the ease with which students can use and learn from these resources, thus affecting their knowledge acquisition. Finally, access to specific, targeted learning materials is essential. The *VP* and *textbook groups* had access to well-organized, systematic learning materials, making it easier for students to focus on relevant content and efficiently grasp key concepts. In contrast, participants in the e-learning and self-guided internet groups had to navigate and search for pertinent information independently. This process could be time consuming and challenging, as students might encounter a vast amount of information of varying complexity that is not always directly related to course objectives. Consequently, these students may have faced difficulties in identifying and assimilating the critical knowledge required for the subject matter, leading to a smaller increase in knowledge acquisition compared with their counterparts in the *VP* and *textbook groups*. However, this observation was not reflected in the acceptance questionnaire. In the second trial group (appendicitis), the pre- and posttest results revealed no significant differences in knowledge acquisition among participants in the intervention groups, although all 4 groups demonstrated an increase in knowledge. The acceptance questionnaires indicated similar responses for all 4 learning resources across 6 technology acceptance dimensions (perceived usefulness, perceived ease of use, attitude toward using, behavioral intention to use, job relevance, and perceived enjoyment) but showed mixed results when comparing the 2 medical subjects of SAM and appendicitis.

Participants exposed to the SAM VP intervention displayed a higher preference for this learning resource, which was not observed in the group exposed to the appendicitis VP. This difference could be attributed to the SAM VP's integration of more images and a visually appealing design, making it more engaging for students. The varying success of VPs for the 2 subjects may be attributed to differences in content and design. The appendicitis VP might have lacked the engaging elements found in the SAM VP, leading to a lower preference among participants. In addition, the participants' higher familiarity with or the lower complexity of 1 topic could have contributed to the observed differences in the success of the respective VPs. However, it is important to consider that the design of the 2 VP

medical topics may have acted as a confounding factor, potentially influencing the outcomes. As such, we cannot definitively attribute the observed differences solely to the subject matter or the VP medical topic design. Further research is needed to identify the specific factors that contribute to the success of VPs in medical education.

In the SAM group, the *preselected e-learning materials* (AMBOSS platform) received the lowest mean rating among all intervention groups. Conversely, the appendicitis group demonstrated a positive response to the AMBOSS platform but displayed indifference toward self-guided web-based learning materials. The disparity in the acceptance of the AMBOSS platform as a learning resource between the 2 study groups might be attributed to the platform's content, which primarily targets the global north.

The content of the AMBOSS platform may not be adequately tailored to the specific learning needs and objectives of the SAM group, possibly because of differences in guidelines, treatment protocols, or context-specific challenges in managing SAM between the United States and Zambia. In addition, the AMBOSS platform may use terminology, examples, or scenarios predominantly familiar to US-based learners, which could pose comprehension difficulties for Zambian students when addressing the specific topic of SAM. SAM is a pressing issue in Zambia, with treatment priorities and modalities that may differ from those in the United States. In contrast, appendicitis holds similar importance in both countries.

Pre- and Posttests

Upon comparing the pre- and posttest results of all study participants, the most substantial improvement was observed among fourth-year students. This finding aligns with the study by Kiesewetter et al [26], who reported that students with less prior knowledge experienced a greater cognitive load compared with those with more prior knowledge. A potential advantage of using VPs is their accessibility, as textbooks can be expensive, sometimes scarce, and may contain outdated content when published. Incorporating VPs into the curriculum can help overcome these limitations and provide students with up-to-date and readily available learning resources. Overall, our pre- and posttest findings indicate that VPs are as effective in promoting learning as other widely used learning resources. Previous research has indicated that the use of VPs leads to significant increases in knowledge, enhanced understanding, and improved problem-solving skills when compared with lecture-based small seminar groups [3,27,28]. These studies also evaluated long-term knowledge retention, revealing no discernible differences between the 2 groups over a 4- to 6-week period.

Acceptance Questionnaire

The observed disparity in the acceptance of VPs between the 2 study groups, SAM and appendicitis, could potentially be attributed to the differences in the design of the 2 VP medical topics. Peddle et al [29] conducted a study involving student interviews to better understand the acceptance of VPs and discovered that incorporating images improved student comprehension and facilitated knowledge retention. The study

emphasized the benefits of using short videos to promote knowledge acquisition.

In general, responses to the acceptance questionnaire were predominantly positive. Participants frequently selected responses that ranged from positive to neutral, whereas negative responses were rare. This pattern was also observed in other studies [30]. The study by Krumpal [31] described this phenomenon as individuals considering risks and losses when determining a response, as they seek social acceptability.

To address this potential bias, we communicated with the participants before the study, emphasizing that their responses to the questionnaires would be handled anonymously and would not affect their academic performance.

Future studies should carefully control for potential confounding factors, such as differences in design, when examining the effectiveness of VPs across different medical subjects. This would allow for a more accurate assessment of the impact of subject matter and case design on learning outcomes.

Strengths and Limitations

Our study, which encompassed a majority of students and investigated 4 distinct learning methods, provides valuable insights into how these approaches might improve student learning. However, several limitations of this study should be acknowledged.

First, the generalizability of our findings is limited because of the study population, which exclusively consisted of third- and fourth-year BSc clinical science students. Consequently, our results may not be directly applicable to other contexts, such as different disciplines.

Second, the content of the AMBOSS platform may not have been adequately tailored to the specific learning needs and objectives of SAM in Zambia. Disparities in the content and design of VP between the 2 case scenarios may also result in differences in the study outcomes. Future studies should consider developing a more robust method for comparing VP cases, such as using a larger sample of case scenarios or ensuring that the cases are matched in terms of difficulty and complexity.

Third, owing to a 1-hour delay at the study's onset caused by technical issues, some participants might have experienced time pressure during the later stages (posttest and acceptance questionnaire), potentially introducing bias. To mitigate this concern, we requested all participants to wait until the last participant completed the study. However, the delay could have resulted in increased fatigue among the participants, affecting their concentration, motivation, and overall performance during the learning sessions and the pre- and posttests. This factor could have potentially impacted knowledge acquisition, leading to lower scores across all intervention groups. Moreover, the delay may have induced stress or frustration that could have influenced their approach to the learning sessions and the pre- and posttests, resulting in less accurate or reliable data and affecting the overall interpretation of the study results.

Fourth, the study did not examine long-term knowledge retention or evaluate traits such as clinical reasoning using MCQs. Therefore, additional research is warranted to investigate

long-term knowledge acquisition, as this study concentrated solely on immediate knowledge gain.

Fifth, in our study, we acknowledge the possibility that participants may have been hesitant to provide negative feedback because of concerns regarding anonymity and potential implications for their academic performance. To address this concern, we implemented several measures to ensure anonymity of the data collected. These measures included (1) emphasizing the confidentiality of the study in the information provided to the participants, both verbally and in written form; (2) assigning unique participant identification numbers, which were not linked to personal information, to protect the identity of the participants during data collection and analysis; (3) ensuring that the questionnaires were completed individually and without peer or instructor influence; and (4) storing the collected data securely and restricting access to only the researchers directly involved in the study.

By implementing these measures, we aimed to minimize any potential bias arising from the participants' reluctance to provide negative feedback. Nevertheless, it is important to recognize that a certain degree of social desirability bias may still be present, which is common in self-reporting studies. Future research could explore alternative methods of data collection or use more indirect questioning techniques to further reduce the impact of such biases on the study results.

Future Directions

At present, LMMU is in the process of revising its e-learning strategy, with the aim of fully integrating e-learning into the curriculum in the future. In light of the findings from our study, it is important to consider potential methodological concerns, such as the content of the AMBOSS platform not being adequately tailored to the specific learning needs and objectives of SAM for Zambia, as well as disparities in the content and design of VP between the 2 case scenarios that may result in differences in study outcomes. Despite these concerns, the

updated e-learning strategy and our study results may support the potential inclusion of VPs within the curriculum as a means to enhance medical education at LMMU. Future research should address these methodological concerns to ensure that the implementation of VP scenarios is tailored to the specific needs and contexts of medical education in Zambia, ultimately leading to more robust and reliable outcomes.

Conclusions

The primary aim of this study was to assess the acceptability and effectiveness of VPs for knowledge acquisition in the BSc clinical science program at LMMU in Zambia, comparing their performance with 3 other prevalent learning resources: textbook content, preselected e-learning materials, and self-guided internet materials. In the context of a low-resource setting, our findings demonstrate that although VPs are well accepted, their effectiveness in terms of knowledge acquisition may vary depending on the specific case scenario and content design.

These results underscore the importance of adapting VP designs to Zambian needs and addressing the limitations observed in the appendicitis case before making broad statements regarding their comparability with other learning methods. When appropriately tailored to local contexts, VPs can function as an engaging and interactive learning strategy to enhance web-based or blended learning programs in settings with a high student-to-faculty ratio and limited teaching resources.

Nonetheless, further research on the acceptability and effectiveness of VPs is warranted, as the incorporation of additional VP medical topics into the blended learning program at LMMU for BSc clinical science students is planned. Expanding the evidence base will ensure that VPs continue to contribute positively to medical education in low-resource settings, support the ongoing development and refinement of these learning resources, and address potential disparities in content and design that may impact their effectiveness.

Abstract

Background: Teaching medicine is a complex task because medical teachers are also involved in clinical practice and research and the availability of cases with rare diseases is very restricted. Automatic creation of virtual patient cases would be a great benefit, saving time and providing a wider choice of virtual patient cases for student training.

Objective: This study explored whether the medical literature provides usable quantifiable information on rare diseases. The study implemented a computerized method that simulates basic clinical patient cases utilizing probabilities of symptom occurrence for a disease.

Methods: Medical literature was searched for suitable rare diseases and the required information on the respective probabilities of specific symptoms. We developed a statistical script that delivers basic virtual patient cases with random symptom complexes generated by Bernoulli experiments, according to probabilities reported in the literature. The number of runs and thus the number of patient cases generated are arbitrary.

Results: We illustrated the function of our generator with the exemplary diagnosis “brain abscess” with the related symptoms “headache, mental status change, focal neurologic deficit, fever, seizure, nausea and vomiting, nuchal rigidity, and papilledema” and the respective probabilities from the literature. With a growing number of repetitions of the Bernoulli experiment, the relative frequencies of occurrence increasingly converged with the probabilities from the literature. For example, the relative frequency for headache after 10.000 repetitions was 0.7267 and, after rounding, equaled the mean value of the probability range of 0.73 reported in the literature. The same applied to the other symptoms.

Conclusions: The medical literature provides specific information on characteristics of rare diseases that can be transferred to probabilities. The results of our computerized method suggest that automated creation of virtual patient cases based on these probabilities is possible. With additional information provided in the literature, an extension of the generator can be implemented in further research.

Introduction

Background

Education in medicine is a complex constellation of experienced teachers, instructive case studies supported by actual patients when possible, and motivated students. Teachers in medicine have at least two main roles: One role is their clinical practice, and the other role is teaching. In many countries, medical teachers are also expected to conduct research, which requires tight time management to accommodate all 3 roles [1]. However, teaching is complex work, and there are several criteria a teacher has to consider. An elaboration of these criteria can be found in the “seven-component-framework to enhance teaching effectiveness” [2] and include issues such as communication of goals, which is the basis for assessment [3]. Furthermore, especially in medical teaching, there are skills that cannot be taught in the classroom, such as clinical practice [3]. Teachers in medicine need to be experienced because medicine is, in contrast to many other subjects, an experience-based subject. However, experienced medical staff are usually severely time constrained by a variety of patient care tasks, a considerable amount of administrative or documentation duties, and other activities like meetings and organizing [4]. Additionally, increasing clinical obligations, partly due to economic constraints, and the lack of protected time resources (such as times for academic teaching or other nonclinical activities) make it more difficult for clinicians to fulfill academic tasks [5,6]. For teaching purposes, this staff must therefore be considered a limited resource that is not easily available. However, in addition to the severe time constraints on teachers, some other problems hamper the clinical education of students. When a particular disease is to be taught, patients with the corresponding diagnosis are usually not easily available. This applies especially for rare diagnoses. As a result, it may happen that there is a lack of adequate medical practice for medical students [7]. This is aggravated by the fact that the time patients stay in the hospital is reduced. Furthermore, some diagnoses (eg, tick-borne diseases) occur only seasonally and cannot be taught during the whole year [8]. Hence, there may be a gap in the training of especially rare but life-threatening diseases such as babesiosis, brain abscess, botulism, or abdominal aortic aneurysm rupture.

Further challenges in clinical teaching include competing demands where the needs of patients and students can conflict. This is encouraged by the fact that the clinical environment is not “teaching friendly,” as a hospital ward is not an ideal learning platform [9]. There are a lot of skills that cannot be learned in the classroom or from textbooks, as clinical knowledge can be better learned in a clinical setting. This requires a real patient or a patient simulation [3]. Patients play an important role in medical teaching; they can “tell their stories and show physical signs” [9].

Virtual patients as representatives of real patients in a computer-generated world are used as a solution for the gap in

sufficient medical practice for medical students [7]. Virtual patients can be implemented in simulated virtual clinical scenarios [10]. They are often used in e-learning environments and are usually based on real patient histories [11]. Other sources for the design and creation of virtual patients are reformatted data from electronic health records, respectively hospital information systems [12]. According to a systematic review, these virtual scenarios are well accepted in the education of medical students [12]. Virtual patient case studies used in teaching have been shown to improve medical student engagement [13]. Furthermore, case-based learning offers a promising method to assist students in learning the vast amount of clinical information, and the integration of virtual patients and cases can improve the effectiveness of education [14,15]. In addition, virtual patient cases offer the possibility of continuing education for physicians, which can be used especially for diagnostic training and medical decision-making [16]

Objectives

In our preliminary work, we focus on diagnosis, which is seen as one of the most important foundations in the training of future physicians [17]. Virtual patient cases can make an immense contribution here, especially with regard to the rare diseases already mentioned. Currently, virtual patients have to be elaborately created and filled with real patient data by the educator. Because of this, education using manually created virtual patients suffers from exactly the same problem as overall clinical education in medicine: the limited availability of experienced medical staff. To solve this problem, automated creation of complete virtual patients by a computer program is conceivable but is not yet available due to its complexity.

Automated creation of virtual patient cases may offer many advantages. It relieves some burden on medical staff, and, if evidence-based medical literature is used to create the virtual patient data, the quantity and quality of virtual patient cases can be significantly extended by basing their characteristics not on single subjective observations but on a comprehensive and generally agreed-upon medical consensus, available in a written form [18-20].

The accurate, comprehensive, and detailed description of diseases or disease profiles with all associated information forms the basis for automated creation of virtual patient cases. This information can be found in the medical literature, particularly in evidence-based major medical textbooks such as “Harrison’s Principles of Internal Medicine” [19] or “Mandell, Douglas, and Bennett’s Principles and Practice of Infectious Diseases” [20]. In order to use information from the textbooks, it must be available not only qualitatively, such as in terms of various symptoms of a disease, but also quantitatively, in the form of data on the frequency of their occurrence in that specific disease. For further detailed information or specifics, also related to pre-existing conditions, concomitant diagnoses, and special

population groups, an additional systematic search in medical databases can be considered.

Symptoms play a pivotal role in the diagnostic process because, together with the medical history, they form the basis for further diagnostic examinations like laboratory tests, computed tomography (CT), or magnetic resonance imaging (MRI). The presence of quantitative information regarding a diagnosis allows for random generation of patient cases with diagnosis-specific information. The core of the automated generation is the Bernoulli experiment, which can generate an assignment of diagnosis-specific properties for each patient case based on the quantitative information. In statistics, a random experiment in which there are only 2 possible outcomes (success or failure, or in the case of a symptom, its presence or absence) is defined as a Bernoulli experiment. Bernoulli experiments are also used in other areas of the medical field. Branson and Bind [21] described a framework for randomization testing for clinical trials and observational studies assuming an assignment mechanism that is based on a Bernoulli experiment. The random decision whether a patient receives a drug substance or the placebo can be modeled by a Bernoulli experiment with success probability of $P=.5$. In a simulation of the stroke-free period in at-risk patients with atrial fibrillation, the incidence of stroke was modeled as a Bernoulli experiment. The prediction of the stroke-free duration was used to estimate the risk of stroke in patients with atrial fibrillation [22]. Another application of Bernoulli experiments was reported in a method for modeling conception in fertility studies [23]. However, we could not identify any publications describing implementation of Bernoulli experiments in the context of medical training cases.

In this work, the following questions were investigated and tested for feasibility:

- Does the medical literature contain sufficient data that can be used to extract qualitative and quantitative information about diagnoses and the probabilities of correlated symptoms?
- How can this information be used to create virtual patient cases considering the different characteristics of diagnoses, such as specific occurrence of symptoms?

Methods

In accordance with the underlying research questions to test the feasibility of our concept as aforementioned, we first examined the literature data and then explored the possibilities of using the basic information obtained from the literature to automatically generate exemplary patient cases. We based our investigation on the example of the rare but life-threatening disease brain abscess, with incidences ranging from 0.4 to 0.9 cases per 100,000 population [24].

Information Retrieval

To extract evidence-based information about definite diagnoses, we examined which information about diagnoses is given in medical textbooks and how this information is structured. The results revealed that the textbooks contain detailed information about the occurrence of specific symptoms for certain diagnoses that could be used as the basis for the automated and random

creation of a template for virtual patient cases [19,20]. As an example, the symptom “fever” is described in 32%-79% of patients diagnosed with “brain abscess,” a very rare condition that must be diagnosed and treated as soon as possible [24]. In addition to the common symptoms, other diagnostic criteria, for instance, specific symptoms related to the location of the brain abscess or specific clinical characteristics regarding certain pathogens, are also provided in the textbooks.

Complementary to the basic, evidence-based information about a specific disease that can be obtained from medical textbooks, we conducted a systematic search for additional or more sophisticated information in the medical literature that may be used in the future to expand our program. To assess this potential for further supplementation of information from medical textbooks, our search focused on symptoms and diagnosis of brain abscesses and was performed in PubMed and Embase. Both databases were searched using specific key words (brain abscess, symptom, diagnosis, epidemiology) and Boolean operators to meet the requirements. The search strategy was then applied without restriction of language or time period.

Statistical Computing and Programming

The occurrence of a symptom of a single patient case can be modeled with a Bernoulli distribution. For this purpose, a Bernoulli experiment with the probability p for the occurrence of this symptom is performed, where p is the probability of success (outcome “1”). For example, the coin toss of a fair coin is a Bernoulli experiment with $p=1/2$ [25], and in our example here, a symptom with the probability p from the literature is given instead. However, since the data in the literature are always given as a range of the probability of a symptom occurring, a random number is generated from this range for the underlying probability p for each single Bernoulli experiment, in order to reflect the distribution and reach the respective variance of real-world data. Mean values were calculated from the given ranges to control the success of the generator. Hence, for each symptom of a case, a Bernoulli experiment is independently done, resulting in a series of Bernoulli experiments for each case (see Table 1). The first experiment in a series relates to symptom 1, the second experiment to symptom 2, and so on. These series are repeated until the desired number of cases is reached. Table 1 illustrates the method, where each row in the table represents 1 case with the associated symptoms.

To achieve this output, a random number generator was implemented in R, the programming language that is part of the free software of the R Foundation for Statistical Computing [26]. Here, we used the version R 3.6.1. To simulate the performance of Bernoulli experiments, the R function “rbinom” requires 3 arguments: (1) number of observations, (2) number of experiments per observation, (3) probability of success [27]. The last argument would be the probability retrieved from the literature [24]. With the help of the function “cbind” [28], after each individual run of the chain of functions, the respective outcomes are linked to each other, resulting in a series that represents the outcomes of the individual experiments with respect to the symptoms for each case (see Table 1).

Table 1. Arrangement of the Bernoulli experiments.

Case	Symptom 1 (Bernoulli experiments)	Symptom 2 (Bernoulli experiments)	...	Symptom m (Bernoulli experiments)
1	0	1	...	0
2	1	1	...	1
...
N	1	0	...	1

Results

Information Retrieval

With the current state of science, it is possible to extract reliable further information on diagnoses, such as the probabilities of the occurrence of various symptoms, from the medical literature. For example, the diagnosis “brain abscess” is described in a medical textbook with the symptoms and respective probabilities depicted in [Table 2](#) [24]. More usable information with regard to our example diagnosis (eg, on gender and age distribution, symptom constellation for diagnosis, and further diagnostic

information such as cerebrospinal fluid and blood parameters of infection) can also be found in the medical literature [24,29-31].

We conducted our systematic literature search in October 2022 and retrieved 50 results from PubMed and 60 nonduplicate results from Embase. The review of this literature revealed several cohort and review studies that addressed specific risk factors, symptoms, prognostic factors, changes over time, and population groups. By far, the largest proportion, however, was case reports and case series dealing with specific pathogens, rare causes and complications, or treatment trials.

Table 2. Probability of symptoms from the literature for the diagnosis “brain abscess.”

Symptom	Headache	Mental status changes	Focal neurologic deficit	Fever	Seizures	Nausea and vomiting	Nuchal rigidity	Papilledema
Range of probabilities	0.49-0.97	0.28-0.91	0.20-0.66	0.32-0.79	0.13-0.35	0.27-0.85	0.05-0.52	0.09-0.51
Mean value of the range	0.73	0.60	0.43	0.56	0.24	0.56	0.29	0.30

Statistical Computing and Programming

The probabilities in the literature were provided as a range, so the probability of success of each single Bernoulli experiment was drawn randomly from this range. Finally, all random successes were summed and divided by the number of drawings and are reported as the estimated probabilities in [Table 3](#).

Based on these data, an R script was implemented to randomly create sequences of symptoms representing possible patient cases. Details of the script are shown in [Figure 1](#).

The series of Bernoulli experiments was first simulated 10,000 times, resulting in 10,000 cases. For each case, the probability of success from [Table 2](#) for the corresponding symptom was used. [Table 3](#) contains the outcomes of the Bernoulli experiments.

For the generation of virtual patient cases, this means that, in case of success (outcome “1”), the corresponding symptom in [Table 3](#) is assigned to the case. This leads to the virtual patient cases depicted in [Figure 2](#).

With an increasing number of Bernoulli experiments, the relative frequencies of success and the average probabilities correspond more and more to the mean value of the range of probabilities from the literature (see [Table 2](#)). For example, the relative frequency for headache— $7267/10,000 = 0.7267$ (1. run)—rounded, is equal to the mean value of the range of the probability from the literature of 0.73.

Summing after 10,000 runs, this yields exactly the same ranges for the randomly drawn probabilities as in the literature.

The run of the R script can be repeated several times, with comparable results, as shown in [Table 4](#).

Table 3. Outcomes of performing 10,000 series of Bernoulli experiments for “brain abscess.”

Patient case	Headache	Mental status changes	Focal neurologic deficit	Fever	Seizures	Nausea and vomiting	Nuchal rigidity	Papilledema
1	0	1	0	0	0	1	0	0
2	0	0	1	0	0	0	0	0
3	1	1	0	1	1	1	0	0

Discussion

Principal Findings

In this work, we present a random number generator to generate virtual patient cases for a rare but fatal disease, for which missed diagnosis is an important prognostic factor [32]. The medical literature provides information on diseases with the associated spectrum of symptoms and the respective probability of occurrence of each symptom [20]. Using brain abscess as an example, a Bernoulli experiment was performed for each symptom with the probability of success based on the literature data. A series of experiments for the symptoms was started, and virtual patient cases with different symptom complexes were generated. We could show that the relative frequencies of the symptoms do not change significantly when the experiment is performed multiple times. The generator can create virtual patient cases at each start-up, which are different in their symptoms and, although these are random, they reflect the evidence-based probabilities from the medical textbooks.

A similar approach to ours using Bayesian networks has been applied to generate synthetic health data from real-world data in the field of heart disease and diabetes [33]. The external validity of the latter depends on the underlying sample, which is why we chose to use evidence-based basic information from the medical literature in our approach. However, a combined strategy may deliver the most realistic scenario.

Limitations and Strengths

The main limitation of our generator so far is that specific symptoms are not sufficient to characterize a patient case. Additional information must be provided, and this should include, for example, the following aspects: age, gender, origin, socioeconomic aspects, further diagnoses, further symptoms, risk factors, or predisposing conditions.

The strength of our work is the compilation of evidence-based information into a template for full virtual patient cases. Our generator could build the basis of a program that helps medical teachers to provide cases of rare but fatal diseases in order to train and improve their student’s knowledge and skills in this regard. Furthermore, a larger number of distinct virtual patient cases could be made available and provide students with elaborated training possibilities.

Future Possibilities

In our literature research, we were able to find information on several of these aspects [24,29-31], and medical textbooks are also rich with specific information that could be implemented in an automated generation of patient cases [19,20]. Our further literature research revealed that brain abscess, for instance, occurs more frequently in men (0.7/100.000) [34] and worse outcome is independently associated with Glasgow Coma Score on admission [35,36]. Hence, as an example, our generator could be expanded to determine gender as well, including a new Bernoulli experiment with the probability of success being 0.7 for male gender. The information on gender can then be added to the constellation of symptoms.

A further development of our generator can consider some of these other aspects in which patients differ. It would be of great benefit if a patient case with additional diagnostic criteria could be generated as a basic construct that would facilitate further elaboration. In the case of brain abscess, information on a predisposing condition like otitis media, sinusitis, or heart disease would be desirable. These conditions, together with the range of their relative occurrence, can also be found in the literature [34]. Moreover, a virtual patient should include laboratory data and media (like CT or MRI images), where necessary, as well as expert comments in the form of additional medical knowledge on a specific topic. For example, if there is a virtual patient with a suspected brain abscess, the expert

comment “MRI is the first imaging choice for a patient with a suspected brain abscess. A lumbar puncture should be performed with caution only when there is clinical suspicion of meningitis or abscess rupture” could be given according to the literature [24,37]. It is further possible that medical information is needed not only in binary (true/false) form but also in a quantitative form with numerical values. For example, for the symptom “fever,” in some medical contexts, the numerical value is needed (eg, 38.5 °C). If this information is required, the authors of virtual patients would have to add the value manually. However, for known distributions or ranges, methods of random generation of data can also be applied. In addition, even conditional probabilities could be simulated within and under control of the program.

So far, the generator presented here does not provide any further information, and manual editing of the generated patient case is necessary to add it. A more elaborated version of our generator could provide an extended construct that saves medical authors’ time, which they can use in their clinical work, but it does not yet create a complete virtual patient.

Virtual patients and virtual cases are an integral part of medical teaching, especially in e-learning systems, but their development is expensive and complex [7,11]. Often, virtual patients are based on real patient histories that are prepared for use in scenarios that are also virtual [11]. Little is known about the automated generation of virtual patient cases, and using statistical distributions of patient or disease characteristics seems to be a completely new field. Instead of using data from single real patients, we used statistical information on aggregated data as they are presented in textbooks or epidemiologic surveys. In this work, we could take a first step in this direction and show that it is possible to generate virtual training cases by performing Bernoulli experiments based on probabilities from the literature. Hence, we could show that research in this new field is possible

and should be further expanded. This can be a useful benefit, as medical staff, respectively medical teachers, are very busy, and the automated creation of virtual patient cases saves them time. As a result, medical teachers can spend more time with their real patients, and more virtual training cases are available. Furthermore, a shortage of cases of especially rare diseases can be avoided. In a continuation of this work, better-elaborated virtual training cases can be made available. This means that a constellation of symptoms and other data about a particular disease are presented, and the medical teachers can manually insert them into a virtual patient by adding further aspects such as expert comments, media, and feedback. As a result, the education of medical students can be improved.

Conclusions

The results suggest that automated creation of virtual patient cases with rare diseases is possible, but with regard to the limitation of symptom constellations, it is not yet suitable for professional use. Our literature search showed that, for our exemplary rare disease “brain abscess,” a plethora of information can be found in the medical literature that completes the information found in conventional textbooks. Based on this additional information, an extension of the generator can be implemented in further research. In addition to the symptoms, all criteria with given probabilities can be transferred to the generation of virtual patients using further Bernoulli experiments. Other diagnostic criteria (eg, examination results) for which specific distributions are provided in the medical literature can be randomly determined by integrating different statistical functions into the generator. Virtual patient cases with more detailed clinical information are then generated by the random generator and can be provided to medical teachers and further elaborated as desired and may help training students in the diagnosis of rare diseases.

Authors' Contributions

TK conceptualized and supervised the study. TK and CS designed the methodology. CS performed the programming. CS and DK wrote the original draft. TK, MH, and MW wrote, reviewed, and edited the manuscript. All authors have read and agreed to the final version of the manuscript.

Abstract

Background: Virtual reality has been gaining ground in health professions education and may offer students a platform to experience and master situations without endangering patients or themselves. When implemented effectively, virtual reality technologies may enable highly engaging learning activities and interactive simulations. However, implementation processes present challenges, and the key to successful implementation is identifying barriers and facilitators as well as finding strategies to address them.

Objective: This scoping review aimed to identify the literature on virtual reality implementation in health professions education, identify barriers to and facilitators of implementation, and highlight gaps in the literature in this area.

Methods: The scoping review was conducted based on the Joanna Briggs Institute Evidence Synthesis methodologies. Electronic searches were conducted in the Academic Search Elite, Education Source, and CINAHL databases on January 5, 2022, in Google Scholar on February 2 and November 18, 2022, and in PubMed database on November 18, 2022. We conducted hand searches of key items, reference tracking, and citation tracking and searches on government webpages on February 2, 2022. At least 2 reviewers screened the identified literature. Eligible studies were considered based on predefined inclusion criteria. The results of the identified items were analyzed and synthesized using qualitative content analysis.

Results: We included 7 papers and identified 7 categories related to facilitators of and barriers to implementation—collaborative participation, availability, expenses, guidelines, technology, careful design and evaluation, and training—and developed a model that links the categories to the 4 constructs from Carl May's general theory of implementation. All the included reports provided recommendations for implementation, including recommendations for careful design and evaluation, training of faculty and students, and faculty presence during use.

Conclusions: Virtual reality implementation in health professions education appears to be a new and underexplored research field. This scoping review has several limitations, including definitions and search words, language, and that we did not assess the included papers' quality. Important implications from our findings are that ensuring faculty's and students' competence in using virtual reality technology is necessary for the implementation processes. Collaborative participation by including end users in the development process is another factor that may ensure successful implementation in higher education contexts. To ensure stakeholders' motivation and potential to use virtual reality, faculty and students could be invited to participate in the development process to ensure that the educational content is valued. Moreover, technological challenges and usability issues should be resolved before implementation to ensure that pedagogical content is the focus. This accentuates the importance of piloting, sufficient time resources, basic testing, and sharing of experiences before implementation.

Introduction

Research on Virtual Reality

The implementation of technology is slow in higher education because of barriers to technology use, and the sharing of innovative and successful practices appears to be lacking [1]. This led to our interest in exploring how virtual reality is implemented in health professions and continuing education and which success factors exist.

Virtual reality is a broad concept. In the research literature, the term encompasses several categories: screen-based virtual reality, virtual worlds, and immersive virtual reality environments [2]. In this study, we defined virtual reality as a digital representation of a 3D environment. We focused on immersive virtual reality, wherein head-mounted displays are used to block out the real world, which coincides with the general understanding of what constitutes virtual reality [3-5]. Such virtual reality applications in higher education hold great promise for supporting students' learning and providing positive experiences in education programs [6]. They may also provide health care students with a platform to experience and master situations without endangering patients or themselves [7,8].

Until recently, virtual reality has mostly been used in technical higher education (eg, engineering, computer science, and astronomy) [9]. However, the use of virtual reality in health professions education is gaining ground and is starting to play an important role in competence development. Immersive technologies can provide learning gains similar to those provided by traditional educational modalities [10]. They can increase attention and enhance skills and confidence and seem to influence users' emotional responses to learning situations, which in turn increases learning motivation [11]. Furthermore, other outcomes, such as student satisfaction, self-efficacy, and engagement, may increase when using such technology, suggesting that it is a viable tool in health professions education [10]. A systematic review from 2021 examined the use of virtual reality to train nursing students and found it to be a feasible teaching strategy to improve knowledge acquisition when used to supplement, but not replace, conventional teaching methods [8]. Another systematic review concluded that virtual reality that aims to train health care professionals in soft skills (eg, teamwork and communication) is gaining ground as a promising prospect for health care professionals' continuing education [2]. When implemented effectively, virtual reality technologies enable highly engaging learning activities and interactive simulations [12].

Although recent research supports the use of virtual reality training in the context of health professions education, it also presents new challenges [8]. Several researchers have reported that students found virtual reality implementation to be insufficiently realistic, alleging that this was a result of the

limited time and available resources [4]. For faculty and students to use innovative technology in training, new ways of working are required for both parties. Therefore, implementing virtual reality requires changes to the organization or system within which the implementation is planned. To ensure successful implementation, it is necessary to identify barriers and facilitators as well as strategies to address them [13]. More and higher-quality research studies are required to explore the acceptability and effective implementation of this technology [11]. Thus far, qualitative studies have suggested easier uptake and more positive experiences among students with a high affinity toward technology [14], indicating that successful implementation relies on organizational as well as individual readiness.

Literature searches conducted for our study protocol [1] identified reviews concerning virtual reality in higher education, some of which reported on virtual reality in health professions education [2,8,15]. Virtual reality simulation training for disaster preparedness in hospitals has been covered by an integrated review [16]. The search also identified a scoping review protocol on virtual reality education for dementia care [17] and an integrative review on the applications of and challenges of implementing artificial intelligence in medical education [18]. However, no current or in-progress scoping review or systematic review reporting on virtual reality implementation in health professions education was identified [1]. To address this literature gap, this scoping review set out to identify literature on virtual reality implementation in health professions education to identify barriers to and facilitators of implementation as well as to highlight research gaps in this area.

Research Question

What recommendations for the implementation of virtual reality in health professions education are provided in the available literature?

Theoretical Background

In this paper, we define implementation as “the act of putting a plan into action or starting to use something” [19]. The implementation and embedding of innovative technology in higher education occurs in complex organizational environments, but other demands from busy work schedules may undermine this novel task. People need motivation to make things happen, such as using innovative technology such as virtual reality and changing their educational practices. The purpose of Carl May's general theory of implementation “is to help facilitate both prospective understanding of implementation processes and evaluation of their outcomes” [20]. This theory is intended to be a starting point for understanding and evaluating the implementation of complex interventions in health care practice. We found it conducive to use this theory in the higher education context, as this is also a complex organizational environment with many actors and systems

involved. According to May's theory, 4 constructs may be crucial for effective virtual reality implementation—*capacity*, *potential*, *capability*, and *contribution*—which concern both planning the implementation process and evaluating its progress and outcomes [20].

Virtual reality implementation in health professionals' education depends on faculty's and students' *capacity* to change their interactions as well as their assumed capability to use virtual reality. Social norms, roles, and material and cognitive resources are required to operationalize the intervention. Norms and roles are affected when incorporating innovative technology, such as virtual reality, into a social system (ie, the educational program in question). Moreover, informational and material resources shape practice and participants' accountabilities, influencing their capacity to use virtual reality. *Potential* concerns agency and motivation, which are antecedents of the dynamic and emergent conditions that follow virtual reality implementation. Individuals' intention and personal interest in virtual reality are important, but even more important is that the members of the organization collectively value the changes that the implementation process will elicit. If they value it enough, they will be committed to it. Individuals' intentions and shared commitment create readiness for virtual reality implementation. *Capability* concerns the workability of the technology at hand and the integration of the system into the given context. In this setting, capability concerns the ensembles of behaviors and practices around virtual reality objects and the procedures required to use virtual reality in education. Finally, *contribution* concerns how virtual reality implementation is a collective, coordinated, and collaborative social action. Joint action is necessary for the successful implementation of virtual reality in educational settings. When the involved actors contribute to implementation, they perform directed actions and perform the practices required to implement and embed virtual reality in their contexts. When actors agree on the technology and value it, they gain cognitive authority and their actions become meaningful, which are crucial to the implementation process [20].

Methods

Context

A challenge when implementing technologies such as virtual reality in higher education is to diminish the barriers' effects and enhance the facilitators' effects. Therefore, during the development phase of an educational project [21], we undertook this scoping review to systematically map the virtual reality implementation literature related to health professions education and to identify key concepts and sources concerning implementation, along with any literature gaps [22]. Considering that research on virtual reality implementation in health professions education is novel and groundbreaking, we present recommendations for the implementation of virtual reality in this setting. The scoping review has been reported based on the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses)—Extension for Scoping Reviews checklist (Multimedia Appendix 1) [23].

Literature Search

Keyword search refinement was conducted from November to December 2021 and is reported in the scoping review protocol [1]. A systematic literature search was performed on January 5, 2022, in the following databases: Academic Search Elite, Education Source, and CINAHL. Three keywords were used—"virtual reality," "higher education (health)," and "implementation"—as well as several synonyms and medical subject heading terms. The keywords were combined with "AND." We performed an additional search in PubMed on November 18, 2022, using the same keywords and medical subject heading terms. Refer to Multimedia Appendix 2 for the search strategy used.

The inclusion criteria for the search comprised articles published within the past 5 years (2017-2022); articles concerning higher education or health professions education, including medicine and continuing education; articles examining a particular age group (>18 years); articles concerning virtual reality or virtual reality simulation aspects; and articles written in English.

In Google Scholar, the following search combination was used on February 2, 2022: "implement* virtual reality health professional higher education," which was limited to articles published after 2017. This yielded 17,000 hits. The first author screened the first 50 articles, resulting in the identification of 3 (6%) articles that qualified for further screening [9,24,25]. Furthermore, we conducted hand searches of key items, reference tracking, and citation tracking, eliciting 1 article that qualified for further screening [8]. The first author performed an updated search in Google Scholar on November 18, 2022, which was limited to articles published in 2022. This yielded 16,900 results, of which the first 50 were screened. No new articles relevant to this review were identified through this search.

Through the literature search performed in January and February, 404 articles were included after duplicates were removed. The authors screened these articles (titles and abstracts) based on the inclusion criteria. Blind screening was conducted using the Rayyan (Rayyan Systems Inc) web tool [26], and at least 2 authors screened each article. The first author screened all 404 articles, and the coauthors divided the articles among themselves to ensure double screening of all articles. Before the screening process, we piloted the screening of 1.3% (5/404) of randomly chosen articles to ensure a similar understanding of the inclusion and exclusion criteria. This further aided in the screening process. Moreover, after screening the titles and abstracts, we discussed articles regarding which the decisions of the 2 authors who screened those were conflicting (17/404, 4.2%). After reaching a consensus based on the inclusion and exclusion criteria, 6.5% (26/404) of articles were included for full-text reading. An additional PubMed search conducted in November 2022 yielded 94 articles for screening. On the basis of the inclusion and exclusion criteria, 7% (6/94) of these were included for full-text reading, in addition to the previous 26 articles.

The first author conducted hand searches for white literature on Norwegian government web pages on February 18, 2022. The decision to search only Norwegian documents was made because

of this project's placement in a Norwegian higher education institution. The Norwegian keywords used in the search were "Implement*," AND/OR "virtual reality" (as the English term is commonly used in Norwegian), AND "teknologi"; the search included papers published in the past 5 years. Three white papers

were identified through these hand searches and included for full-text reading, along with 32 articles identified through literature searches of the databases. We considered eligible studies based on the criteria presented in [Textbox 1](#).

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria	
•	Participants: students, faculty, and health care professionals (adults)
•	Concept: implementation of virtual reality
•	Context: higher and continuing health professions education
Exclusion criteria	
•	Flatscreen simulation or 2D videos
•	Use for patients, clinicians, and children

Data Analysis

Following guidance for completing scoping reviews [27,28], all the authors extracted the following data from the included papers in a matrix before synthesis: author and country of origin, year of publication, aims and purpose, study population, methodology and sample description, concept, outcomes, and key findings related to the research objectives. The data extraction tool has been reported in our review protocol [1]. Data synthesis was conducted using qualitative content analysis [29]. First, the data were sorted according to the 3 factors in the data extraction form (facilitators, barriers, and recommendations). Second, the texts were grouped according to similarities and differences, and tentative categories were created. The categories were revised several times, and the content was shifted back and forth between categories until the authors reached a consensus on 7 categories that described the data's manifest content. Thus, the categories describe recommendations for virtual reality implementation in accordance with the research question.

Results

Overview

[Figure 1](#) is a PRISMA flow diagram that lays out the search and inclusion process [28]. It contains the results from the initial literature search conducted in January and February 2022 as well as those from the additional search conducted in November 2022. We included 7 (1.4% of the total 498 records screened) papers [30-36], and the key information from these papers is presented in [Table 1](#).

By conducting a content analysis of the data extracted from the included articles, we identified seven categories that describe the recommendations for virtual reality implementation provided in the included literature: (1) collaborative participation, (2) availability, (3) expenses, (4) guidelines, (5) technology, (6) careful design and evaluation, and (7) training. These categories relate to both the facilitators of and barriers to implementation and are described in detail in the subsequent sections to coordinate the findings and recommendations from the included articles.

Collaborative Participation

Overall, 3 concepts of collaboration were described in the included literature. *Collaboration in the design* of the virtual reality system, including user participation (students and faculty) in the design process, was essential to create usable and user-friendly applications, helped identify limitations, and played a critical role in successful virtual reality use [30,32]. *Collaboration by developers inside the virtual reality environment* for system design purposes was described by D'Errico [32]. This helped create realism and fidelity as well as identify errors. By being mutually immersed in the virtual world, the design team experienced the scenario together and efficiently identified solutions to problems [32]. The third and last concept of collaboration described was *collaboration inside virtual reality environments* by students (end users). Being able to move freely in the system using an active avatar provided a sense of reality and improved the sense of participation [34]. Such interactive elements promote user engagement and maximize the benefits of using virtual reality technology [36]. Students could practice examining patients, analyzing scenarios, and interacting with others in clinical situations in a virtual reality environment [33]. Such interactivity was described as facilitating implementation.

Availability

Availability concerns both the availability of virtual reality headsets and that of faculty and support staff during use. Successful virtual reality implementation depended on the suitable scheduling of the education programs [30]. Providing a system that allows students to borrow virtual reality headsets for 10 minutes facilitates the use of virtual reality [35]. Allowing repeated practice [34] and making virtual reality laboratories available to students 24/7 [33] were mentioned as facilitators.

Faculty availability during virtual reality use was also mentioned as being critical. On-site coordinators or facilitators for providing assistance in using the virtual reality system (address questions, brief students, and provide continuous feedback) were described as crucial to successful virtual reality implementation, both in preparation and actual use [34,36]. Moreover, using virtual reality in small tutorial groups rather than during lectures was advised [35].

Expenses

Virtual reality design and implementation are expensive because it takes time and resources to convert the current material into virtual reality [35]. The supply and costs of equipment are barriers to virtual reality implementation in health professions education [30,32,35]. In addition, virtual reality laboratories require space, which is also an expense for institutions. Training faculty and students to use virtual reality is time-consuming [30,35]. The time element is also crucial to expenses because virtual reality, owing to equipment costs, might not be feasible in large classes, at least not simultaneously [34,35]. Supplying enough equipment was mentioned as a barrier in several of the

included articles. One recommendation was to secure sufficient virtual reality headsets so that students would not fall behind [35]. Moreover, Saab et al [35] asserted that virtual reality should supplement conventional teaching, which also affects expenses considerably.

Guidelines

The reported barriers to successful virtual reality implementation included a lack of suitable standards, insufficient infrastructure, difficulties providing content, organizational culture, and a lack of management support [30]. The need for frameworks or guidelines to help implement virtual reality in health education was mentioned [30,31]. Therefore, developing and updating related laws, policies, guidelines, and standards, as well as using appropriate models in the design and implementation of virtual reality applications, could be beneficial for virtual reality implementation in health education [30,33]. In several European countries, the European Union's Vocational Qualifications Directive regulates nursing education programs. The directive regulates the duration of students' clinical placement, hindering the replacement of clinical practice with virtual reality simulation. This may create a barrier to the implementation of virtual reality laboratories in educational institutions. The Norwegian Ministry of Education has described the need for changes in regulations to enable the inclusion of simulation as a larger part of health education. Technical and pedagogical developments make it possible to implement teaching in new ways, with more student-active forms of learning and increased learning as the expected results [33].

Technology

Technological problems and usability difficulties were mentioned as significant barriers to successful virtual reality implementation [30,35,36]. People's IT skills (or lack thereof) and unfamiliarity with virtual reality hinder its use. Having a system for identifying and addressing technical limitations plays a key role in implementation processes.

The size, weight, and general clunkiness of the virtual reality headsets hinder some people in their use of the headsets. Others may experience sight problems, vertigo, dizziness, or motion sickness, which can hinder the use of virtual reality [35]. Some virtual reality systems, such as 360° videos, have little or no possibility of interaction or interactivity, which is also viewed as a barrier [32]. Incorporating more advanced technology into virtual reality, such as artificial intelligence and active avatars, to increase learners' sense of immersion would benefit the overall experience [34].

Careful Design and Evaluation

The careful design of virtual reality for health education is central [30,32,34,36]. To plan virtual reality training, instructors need to determine the overall objectives based on the expected outcomes. The pedagogics involved in the virtual reality learning experience were mentioned as being important for implementation and comprised the individual learner, learning

environment, context, and technology. Rim and Shin [34] recommended a template containing educational elements, virtual elements, and scenario outlines. The educational elements that are important to the planning of virtual reality training are learning objectives, course flow, and feedback strategies. The virtual elements and how they work are also central to the efficient designing of virtual reality. Moreover, careful planning of scenario outlines is crucial, and this includes the scenario, intended learning objectives, evaluation, mechanical support, and debriefing components. Evaluations should be conducted when using virtual reality in educational settings to ensure the program's efficacy and desired outcomes [34].

Training

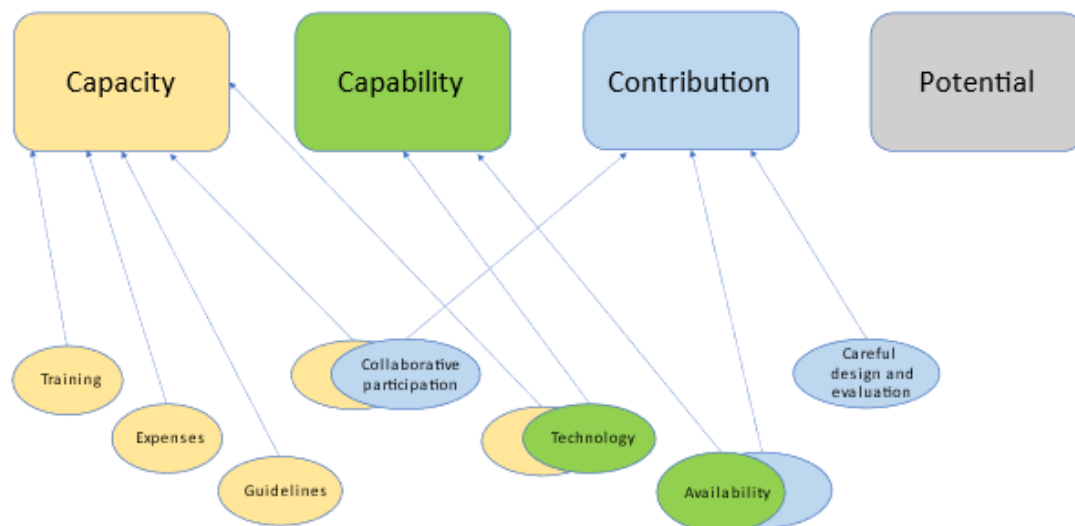

The training of end users was mentioned in several articles as one of the success factors for virtual reality implementation [30,34,35]. Practically using virtual reality, rather than being instructed theoretically, during training is valuable. Moreover, preparing students before use, assisting during use, and debriefing after use are viewed as crucial for successful implementation [34]. According to Barteit et al [31], virtual reality implementation benefits from using the Miller's Pyramid of Professional Competence—"See one, do one, teach one, and simulate one"—such that students are invited to facilitate simulation, after having participated themselves. Moreover, virtual reality applications in health education require a comprehensive manual that specifies how, where, and for whom this technology is appropriate [30], which is also relevant for providing training in and preparing for virtual reality use.

Discussion

Principal Findings

The purpose of this scoping review was to identify literature reporting on virtual reality implementation in health education and to explore which recommendations for implementation are provided in the available literature. On the basis of a systematic and thorough search and screening process and the inclusion and exclusion criteria presented, 7 papers were included—6 (86%) research articles and 1 (14%) government report. The fact that the number of papers deemed appropriate for inclusion is low indicates that research focusing specifically on virtual reality implementation is scarce. The articles that reported on facilitators focused primarily on human agents preparing for and performing within the virtual reality environment as well as the system's perceived convenience. Several barriers to virtual reality implementation were mentioned, particularly those concerning expenses, guidelines, and technology. All the included reports provided recommendations for implementation, particularly in the *Conclusion* section. These involve recommendations for careful design and evaluation, the training of faculty and students, and the presence of faculty during virtual reality use (as is also described under facilitators). Our model (Figure 2) links our categories to May's 4 constructs [20]. We have discussed our findings in the following section, considering both theory and earlier research.

Figure 2. Categories of implementation recommendations mapped onto May's general implementation constructs.

Comparison With Prior Work

Capacity

Our findings indicate that *training* for competency development is vital for enabling successful implementation and ensuring competent use among both students and faculty. Training as a prerequisite for successful virtual reality implementation relates to May's construct capacity [20], as it is necessary for both parties to have the capacity to use virtual reality. Our findings indicate that it could be useful for students to first observe, then conduct, and thereafter teach fellow students how to use virtual

reality simulations to obtain the necessary skills and confidence to use virtual reality gradually [31].

The faculty's lack of technological competence was mentioned as a barrier to successful virtual reality implementation in education [37]. According to May [13], norms and roles are affected when innovative technology is incorporated into an educational context. We may speculate regarding whether students have a greater capacity to use innovative technology than the faculty because most students within "Generation Z" are digital natives. This could affect social roles and norms and even change the power dynamics in the classroom setting. For

example, when using virtual reality in simulations, the faculty may need to take on less of an “expert role” and function more as facilitators [38].

However, we should be careful when assuming that all students are equally confident in using innovative technology. Training students and faculty is important because if students do not master virtual reality, they may not enjoy the possible pedagogical benefits that come from using it [39]. Implementing virtual reality in itself does not necessarily promote good teaching and learning for students [40]. Technology needs to be anchored firmly in the pedagogical approach; therefore, the knowledge of students’ and teachers’ training needs and experiences is important when implementing virtual reality. By securing well-planned training, cognitive resources can be ensured [20].

Related to this, and as our findings indicate, facilitating *collaborative participation* and providing *guidelines* are crucial for implementation. Guidelines that include informational and material resources provided to users are important and influence users’ capacity to use virtual reality. This corresponds to previous research suggesting that when using virtual reality in nursing education, clear guidelines and objectives for the applications are crucial to ensure successful use [41]. Moreover, virtual reality applications designed with consumer usability in mind are easier to use when training students and implementing virtual reality in higher education settings. Therefore, it is vital to ensure collaborative participation by including end users in the development process [42–44]. This is relevant to all institutions planning to implement virtual reality in their educational programs.

Training, collaborative participation, and the development of guidelines for proficient use can be time-consuming and expensive. Our findings indicate that expenses are a crucial aspect of virtual reality implementation in higher education. Expenses can also be related to May’s *capacity* construct. The supply and cost of equipment and the time and space required for virtual reality implementation are important aspects that need to be considered. When a program contains 300 students, using virtual reality as an educational method for all students is time-consuming, even if the institution has secured as many as 50 virtual reality headsets. Furthermore, storing several virtual reality headsets (eg, in a virtual reality laboratory) demands space in institutions, which also incurs high costs. Therefore, it could be of value to conduct cost-benefit analyses when implementing virtual reality in higher education [44], as Saab et al [35] argued that virtual reality should supplement, but not replace, the conventional teaching and learning methods.

Capability

Our findings indicate that availability is crucial and that it is necessary to provide sufficient time for both students and faculty to adjust when implementing and using virtual reality in health professions education. This builds on previous evidence that emphasizes the importance of a generous time window for successful virtual reality use in undergraduate programs [12]. Moreover, our findings suggest that ensuring that virtual reality technology is available to students is essential for its implementation. Woon et al [8] recommended that “virtual

reality training should consider self-guided, multiple short sessions in delivering procedural content using low-to-moderate immersion.” However, as mentioned in our findings, the presence of competent and experienced facilitators may be important for students’ potential for learning through virtual reality [34]. Facilitators’ presence is another factor in the *availability* category, which enables facilitators to brief students, answer questions, and provide continuous feedback. This contrasts with the recommendation for self-guided virtual reality use, as mentioned above, and it is important to explore this further in future research.

According to the presented theoretical framework, capability also concerns practices related to implementation [20]. Extant research has found that students prefer using new technologies in education if they make them experience emotions, such as motivation and enthusiasm, as well as provide experimental opportunities [45]. Faculty should strive to ensure that facilitators have the interpersonal, technical, and professional skills to create engaging virtual learning arenas for students [32,35], which may be a challenge. To make virtual reality useful in a higher education context, facilitators need sufficient time and clarification regarding their guiding educational and technical roles. Thorough behavioral and practical training of facilitators may reduce barriers to implementation and facilitate the creation of constructive learning arenas [20]. This can be used to prevent a so-called “implementation gap,” in which a lack of organizational readiness for change can lead to the unsuccessful implementation of new technologies [46].

Technological difficulties (eg, unfamiliarity and usability difficulties for facilitators) and practical barriers that hinder virtual reality users are major implementation barriers. Technological challenges should be resolved before implementation to ensure that pedagogical content is the focus, and not the technical barriers. This accentuates the importance of allotting sufficient time and resources to conduct basic testing and share experiences before implementation begins. It is important that the various parties involved in the process, both technical and educational, conduct constructive dialogues during the process [39]. Our findings indicate that a lack of knowledge about and experience with technology is an obstacle to virtual reality use. This builds on earlier research concerning the implementation of health technology, which concluded that even though users were motivated to learn how to use the new technology, a lack of information, sustainable infrastructure, and available resources hindered its implementation [46]. Our findings demonstrate the importance of having a system in place to identify and address the technical limitations when implementing virtual reality. Therefore, it is vital to develop a clear framework and action plan to address the different foci of the various stakeholders involved in the implementation process as well as to clearly define their roles and responsibilities.

Another barrier to the implementation and successful use of virtual reality is that some students experience sight problems, vertigo, dizziness, and motion sickness (also called virtual reality sickness) [35]. This is also related to the capability concept. Earlier research has described several ways to prevent virtual reality sickness, including moving the body and adding multisensory information (eg, music or aromas) [47]. These

suggestions may be of value when planning virtual reality implementation in higher education contexts.

Contribution

Our findings concerning collaborative participation, careful design and evaluation, and availability connect with May's construct contribution [20]. Implementing virtual reality is a collective, coordinated, and collaborative social and joint action in the context of higher education. The implementation of innovative technology depends not only on what can be done but also on the current stakeholders' attitudes toward and interest in new technological solutions. When the involved actors contribute to the implementation of virtual reality, they perform directed actions, continuously build and act on their functions, and perform the necessary practices to implement and embed virtual reality in their practice. For the implementation of virtual reality, it is crucial that the actors agree with and value it. This gives participants cognitive authority and adds meaning to their actions [20].

Our findings concerning collaborative participation and availability suggest that it is applicable to recruit student facilitators when implementing virtual reality as a learning methodology, as they may contribute to participation and competence. Although the time spent on training student assistants may be a challenge [48], the use of peer supervision can address the time-related challenges in the implementation of virtual reality simulation in health education settings. However, when students have too many demands placed on their time, they are more likely to experience a high cost of engaging in the activity [49]. This may negatively influence their motivation to participate; therefore, it may be useful to focus on creating and facilitating realistic timeframes for the involved students (and faculty) when implementing virtual reality in health professions education.

Collaborative activities with students as stakeholders and student assistants may also help strengthen students' competence in supervision, particularly if this is linked to formally obtaining supervisor competence [50]. Students normally do not have the same "expert knowledge" as faculty members, but it is conceivable that they may make a greater impact as motivators by virtue of being fellow students and relevant persons with whom other students can compare themselves. So far, little extant research has examined this, so it may be useful to explore this in future research. Common pedagogical solutions involving stakeholders may encourage employees, both internally and across universities and other academic institutions, to exchange experiences and inspire each other in a mutual learning process. This also has the potential to make pedagogical work easier [39].

Potential

A total of 7 categories emerged from the synthesis of the articles selected for this review, but we were unable to identify any links between them and the *potential* category, as May outlined [13]. *Potential* concerns individual interest, intention, and motivation and the collective valuation of and commitment to implementation. These processes are described as necessary antecedents for individual and collective behaviors [51-53] and,

therefore, are crucial to the success of any implementation [20]. Without persistent individual and collective drive among the users of the innovation, it is unlikely that it will be sustained over time. Nevertheless, our findings demonstrate that aspects relating to *potential*—individual and collective agency and motivation—have not been emphasized in the existing literature on virtual reality implementation in health professions education [30-35]. The social-structural prerequisites (capacity and contribution) for implementation and aspects of the technology itself (capability) have received considerably more attention. However, given the importance of agency and motivation in successful implementation, we encourage the researchers involved in future studies of virtual reality implementation in health professions education contexts to include this crucial aspect of the process. Such studies may include mixed qualitative and quantitative data collection strategies, with their quality relying on their ability to combine different types of data in meaningful ways [54]. However, agency should be studied in the context of the specific implementation process in question. For example, in line with Ajzen [51] and expectancy-value theory in general [55], faculty members are unlikely to be motivated to implement new technologies or teaching methods unless they perceive that the innovation has practical value. Thus, key stakeholders, such as faculty members, should be invited to participate from the start of the development process to ensure that the innovation's educational content is valued.

Limitations

This review has several limitations. First, it is possible that relevant literature was not included in this review, although several databases and government web pages were searched. We could have broadened our understanding of virtual reality and used other keywords (eg, "augmented reality" and "computer simulation") to obtain a wider overview of the existing studies. However, because of the scope of this study and the definition presented in the *Introduction*, we chose only immersive virtual reality in health professions education. This could be viewed as a limitation, as we excluded several articles that described virtual reality in a manner different from our definition and in other educational contexts. The concept of virtual reality is used in many ways, which poses a challenge for drawing conclusions based on virtual reality research. Having our definition of virtual reality broadened could have led us to include more articles, which might have influenced our findings. Moreover, it is a challenge when searching databases that the term virtual reality includes very different technologies. A common definition and use of *virtual reality* would be of value for the evidence base.

Furthermore, the quality of the included studies was not assessed as part of this scoping review because a scoping study does not seek to assess evidence quality and, consequently, cannot determine whether studies provide robust or generalizable findings [27,28]. However, this should be mentioned as a limitation of this study.

Moreover, searching for only English- and Norwegian-language papers limited this review's findings. However, this choice was made after careful consideration. Because of the language

knowledge in the research group, we conducted initial hand searches on Eastern European government web pages (Serbian, Croatian, and Bosnian Ministry of Education Government web pages) and in the Directory of Open Access Journals, using the keywords “Implementacija I/ili virtualne stvarnosti I/ili zdravstvenom strucnom obrazovanju.” Hand searches using these keywords were also conducted in 2 Eastern European scientific journals (*Hrcak* and *Nacionalna i sveucilisna knjiznica u Zagrebu*) on February 18, 2022. Owing to a lack of findings, these searches were excluded from the *Methods* section. We decided that focusing on the Norwegian and English languages was more relevant, as the project from which this scoping review was derived was conducted in a Norwegian higher education context [21].

Conclusions

This scoping review has provided an overview of the sparse literature on virtual reality implementation in health professions education. The included articles provided recommendations concerning collaborative participation, availability, expenses, guidelines, technology, careful design and evaluation, and training. These aspects can be connected to the 4 constructs in May's theory of implementation and are important to consider when planning virtual reality implementation in health professions education.

Recommendations for virtual reality implementation in health professions education aim to ensure faculty's and students' competence with the latest technology. By securing well-planned training for both faculty and students, cognitive abilities can be

improved. Collaborative participation by including end users in the development process can ensure the successful implementation of virtual reality in higher education contexts. To secure motivation and stakeholders' potential for using virtual reality, faculty and students could be invited to participate from the start of the development process to ensure that the innovation's educational content is valued. Moreover, technological challenges and usability issues should be resolved before implementation to ensure that pedagogical content is the focus, and not the technical barriers. This accentuates the importance of piloting, sufficient time resources, basic testing, and sharing of experiences before implementation. Furthermore, implementing virtual reality in education is currently expensive and time-consuming; therefore, cost-benefit analyses may be of value.

On the basis on our findings, virtual reality implementation in health professions education is a new and underexplored research field. As we could not identify results concerning potential, we argue that more studies investigating individual interest, intention, and motivation, as well as the collective valuation of and commitment to virtual reality implementation, are needed, as individual engagement is also crucial in implementation processes. Moreover, because of the scant research in this area, future research could further investigate viable and effective strategies for implementing virtual reality in health professions education. Finding a common definition and use of the term *virtual reality* would also be of value for the evidence base, as this would make it easier to examine implementation processes using similar education measures.

Acknowledgments

The authors thank Gunn Alice Brekke Valskår, a university librarian, for the development of the search strategy and assistance with the literature searches. The authors received no financial support for the research, authorship, or publication of this manuscript.

Abstract

Background: Single-choice items (eg, best-answer items, alternate-choice items, single true-false items) are 1 type of multiple-choice items and have been used in examinations for over 100 years. At the end of every examination, the examinees' responses have to be analyzed and scored to derive information about examinees' *true knowledge*.

Objective: The aim of this paper is to compile scoring methods for individual single-choice items described in the literature. Furthermore, the metric *expected chance score* and the relation between examinees' *true knowledge* and expected scoring results (averaged percentage score) are analyzed. Besides, implications for potential pass marks to be used in examinations to test examinees for a predefined level of *true knowledge* are derived.

Methods: Scoring methods for individual single-choice items were extracted from various databases (ERIC, PsycInfo, Embase via Ovid, MEDLINE via PubMed) in September 2020. Eligible sources reported on scoring methods for individual single-choice items in written examinations including but not limited to medical education. Separately for items with n=2 answer options (eg, alternate-choice items, single true-false items) and best-answer items with n=5 answer options (eg, Type A items) and for each identified scoring method, the metric expected chance score and the expected scoring results as a function of examinees' *true knowledge* using fictitious examinations with 100 single-choice items were calculated.

Results: A total of 21 different scoring methods were identified from the 258 included sources, with varying consideration of correctly marked, omitted, and incorrectly marked items. Resulting credit varied between -3 and +1 credit points per item. For items with n=2 answer options, expected chance scores from random guessing ranged between -1 and +0.75 credit points. For items with n=5 answer options, expected chance scores ranged between -2.2 and +0.84 credit points. All scoring methods showed a linear relation between examinees' *true knowledge* and the expected scoring results. Depending on the scoring method used, examination results differed considerably: Expected scoring results from examinees with 50% *true knowledge* ranged between 0.0% (95% CI 0% to 0%) and 87.5% (95% CI 81.0% to 94.0%) for items with n=2 and between -60.0% (95% CI -60% to -60%) and 92.0% (95% CI 86.7% to 97.3%) for items with n=5.

Conclusions: In examinations with single-choice items, the scoring result is not always equivalent to examinees' *true knowledge*. When interpreting examination scores and setting pass marks, the number of answer options per item must usually be taken into account in addition to the scoring method used.

Introduction

Multiple-choice items in single-response item formats (ie, single-choice items) require examinees to mark only 1 answer option or to make only 1 decision per item. The most frequently used item type among the group of single-choice items is the so-called best-answer items. Here, examinees must select exactly 1 (ie, the correct or most likely) answer option from the given answer options [1]. Often, best-answer items contain 5 answer options, although the number of answer options might vary ($n \geq 2$). Items with exactly 2 answer options are also referred to as alternative items (ie, alternate-choice items) [2]. In addition, single true-false items belong to the group of single-choice items. Examples of the mentioned single-choice items as well as alternative designations are shown in Figure 1.

Single-choice items have been used for more than 100 years to test examinees' knowledge. The use of these items began among US school pupils, who were given alternate-choice or best-answer items [3] or single true-false items [4] as a time-saving alternative to conventional open-ended questions (ie, essay-type examinations). Because of their character of only allowing clearly correct or incorrect responses from examinees, multiple-choice examinations were also called objective type examinations [5]. The term *new type examinations* was coined to distinguish them from previously commonly used open-ended questions [5,6].

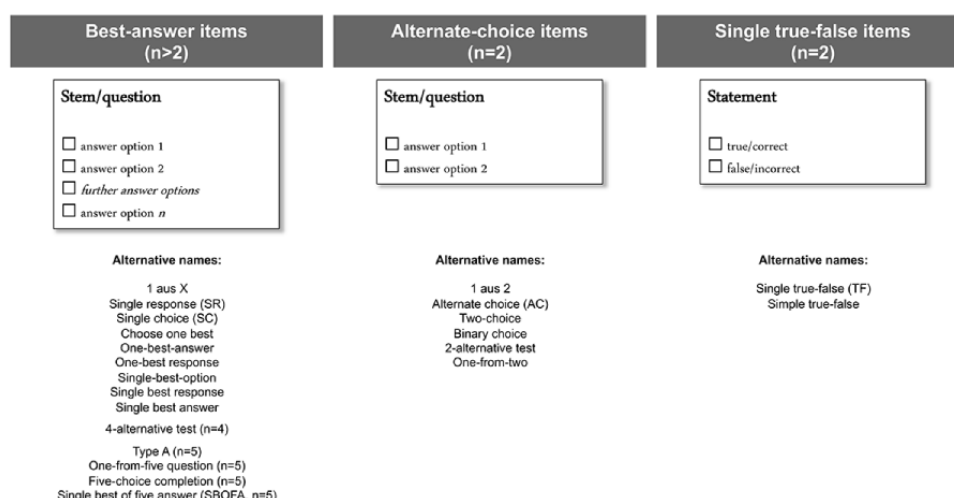

The use of multiple-choice items did not remain exclusive to the setting of high schools but also extended to examinations in university contexts [7] and postgraduate medical education [8,9]. Today, multiple-choice items are frequently used in examinations of medical and dental students (eg, within the *United States Medical Licensing Examination*). Besides their usage in individual medical or dental programs, different multiple-choice item types found their way into examinations for medical students by the *National Board of Medical Examiners* [10]: within the context of single-choice items, those with $n=5$ were particularly used and referred to as Type A items.

Examinations aim at assessing examinees' ability (ie, examinees' *true knowledge* [k]) regarding predefined learning objectives. The downside when using multiple-choice examinations is that examinees might also mark an item correctly by guessing or by identifying the correct answer option through recognition. Thus, an active knowledge reproduction does not necessarily take place, and correct responses are not necessarily resulting from examinees' *true knowledge*.

To grade examinees or to decide about passing or failing a summative examination based on a minimum required level of *true knowledge*, scoring algorithms are used to transfer examinees' responses (ie, marking schemes) into a score. To assess examinees' *true knowledge*, the obtained scores must either be reduced by the guessing factor, negative points (ie, malus points) must be assigned for incorrectly marked items, or the pass mark (ie, the corresponding cutoff score for the desired *true knowledge* cutoff value) must be adjusted based on the guessing probability [11]. The guessing probability for examinees without any knowledge ($k=0$, blind guessing only) amounts to 20% for single-choice items with $n=5$ and to 50% for alternate-choice items and single true-false items with $n=2$. Consequently, examinees without any knowledge score 20% or 50% of the maximum score on average, respectively [11]. However, it can be assumed that most examinees have at least partial knowledge ($0 < k < 1$) and that an informed guessing with remaining partial uncertainty occurs in most cases.

Since the introduction of multiple-choice items, numerous scoring methods have been described in the literature and (medical) educators are advised to choose an appropriate scoring method based on an informed decision. Therefore, the aim of this scoping review is (1) to map an overview of different scoring methods for individual single-choice items described in the literature, (2) to compare different scoring methods based on the metric *expected chance score*, and (3) to analyze the relation between examinees' *true knowledge* and expected scoring results (averaged percentage score).

Figure 1. Examples of 3 different multiple-choice items in single-choice format and alternative designations used in the literature (no claim to completeness).

Methods

Systematic Literature Search

The literature search was performed according to the PRISMA-ScR (Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews) checklist [12]. The checklist is available as [Multimedia Appendix 1](#). As this review did not focus on health outcomes, the review was not registered at PROSPERO (International Prospective Register of Systematic Reviews) prior to its initiation.

Eligibility Criteria

Potentially eligible sources were scientific articles, books, book chapters, dissertations, and congress abstracts reporting scoring methods for individual single-choice items in written examinations including but not limited to medical examinations. Scoring methods for item groups and scoring on examination level (eg, with different weighting of individual items, with mixed item types, or considering the total number of items per

examination) were not assessed. Further, scoring methods that deviate from the usual marking procedure (ie, a single choice of marking exactly 1 answer option per item) were not considered. These include, for example, procedures that assess the confidence of examinees in their marking (eg, confidence weighting), let examinees select the incorrect answer options (eg, elimination scoring), let examinees narrow down the correct answer option (eg, subset selection), or allow for the correction of initially incorrectly marked items (eg, answer-until-correct). No further specifications were made regarding language, quality (eg, minimum impact factor), or time of publication.

Information Sources

Four databases (ERIC, PsycInfo, Embase via Ovid, and MEDLINE via PubMed) were searched in September 2020. The search term was composed of various designations for single-choice items as well as keywords with regard to examinations. It was slightly adapted according to the specifications of the individual databases. The respective search terms for each database can be found in [Table 1](#).

Table 1. Search terms used for each of the 4 databases.

Database	Search term
ERIC	("single choice" OR "alternate choice" OR "single response" OR "one-best-answer" OR "single best response" OR "true-false" OR "Typ A") AND (item OR items OR test OR tests OR testing OR score OR scoring OR examination OR examinations)
PsycInfo	("single choice" OR "alternate choice" OR "single response" OR "one-best-answer" OR "single best response" OR "true-false" OR "Typ A") AND (item OR items OR test OR tests OR testing OR score OR scoring OR examination OR examinations)
Embase via Ovid	((("single choice" or "alternate choice" or "single response" or "one-best-answer" or "single best response" or "true-false" or "Typ A") and (item OR items or test or tests or testing or score or scoring or examination or examinations)).af.
MEDLINE via PubMed	("single choice"[All Fields] OR "alternate choice"[All Fields] OR "single response"[All Fields] OR "one-best-answer" OR "single best response" OR "true-false"[All Fields] OR "Typ A"[All Fields]) AND ("item"[All Fields] OR "items"[All Fields] OR "test"[All Fields] OR "tests"[All Fields] OR "testing"[All Fields] OR "score"[All Fields] OR "scoring"[All Fields] OR "examination"[All Fields] OR "examinations"[All Fields])

Selection of Sources

Literature screening, inclusion of sources, and data extraction were independently performed by 2 authors (AFK and PK). First, the titles and abstracts of the database results were screened. Duplicate results as well as records being irrelevant to the research question were sorted out. For books and book chapters, however, different editions were included separately. In a second step, full-texts sources were screened, and eligible records were included as sources. In addition, the references of included sources were searched in an additional hand search for further, potentially relevant sources. After each step, the results were compared, and any discrepancies were discussed until a consensus was reached. Information with regard to the described scoring methods was extracted using a piloted checklist.

Data Extraction

The following data were extracted from included sources using a piloted spreadsheet if reported: (1) name of the scoring method, (2) associated item type, and (3) algorithm for calculating scores per item. The mathematical equations of each

scoring method were adjusted to achieve normalization of scores up to a maximum of +1 point per item if necessary.

Data Synthesis

For all identified scoring methods, the expected scoring results in case of pure guessing were calculated for single-choice items with n=2 and n=5 answer options, respectively [13]. The *expected chance score* is described in the literature as a comparative metric of different scoring methods [11,13-15]. For its calculation, examinees without any knowledge (k=0) are expected to always guess blindly and thus achieve the expected chance score on average.

In addition, expected scoring results for varying levels of k ($0 \leq k \leq 1$) were calculated. For examinees with partial knowledge ($0 < k < 1$), a correct response can be attributed to both partial knowledge and guessing, with the proportion of guessing decreasing as knowledge increases. By contrast, examinees with perfect knowledge (k=1) always select the correct answer option without the need for guessing [11].

Examinees were expected to answer all items, and it was supposed that examinees were unable to omit individual items

or that examinees do not use an omit option. Furthermore, all items and answer options were assumed to be of equal difficulty and to not contain any cues. The calculation of the expected scoring result is shown in the following equation:

$$f \cdot x + (1-f) \cdot 0$$

where f are the credit points awarded for a correctly marked item ($i=1$) or an incorrectly marked item ($i=0$) depending on the scoring method used; k is the examinees' *true knowledge* [$0 \leq k \leq 1$]; n is the number of answer options per item; $x=1$ if the correct answer option is selected by *true knowledge*, otherwise $x=0$; in the equation shown, 0^0 is defined as 1.

MATLAB software (version R2019b; The MathWorks) was used to calculate the relation between examinees' *true knowledge* and the expected scoring results using fictitious examinations consisting of 100 single-choice items (all items with either $n=2$ or $n=5$).

Results

Overview

Within the literature search, a total of 3892 records were found through database search. Of these, 129 sources could be included. A further 129 sources were identified from the references of the included sources by hand search. The entire process of screening and including sources is shown in [Figure 2](#). Reasons for exclusion of sources during full-text screening are given in [Multimedia Appendix 2](#).

The included sources describe 21 different scoring methods for single-choice items. In the following subsections, all scoring methods are described with their corresponding scoring formulas for calculating examination results as absolute scores (S). In addition, an overview with the respective scoring results for individual items as well as alternative names used in the literature is presented in [Table 2](#). All abbreviations used throughout this review are listed at the end of this review.

Figure 2. Flow diagram of systematic literature search.

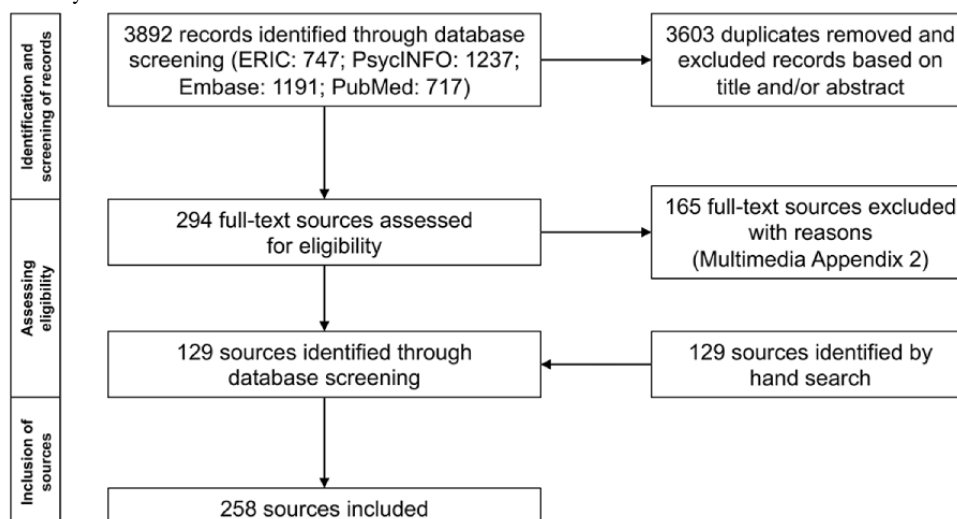

Table 2. Identified scoring methods and algorithms for single-choice items.

Method number and sources	Scoring method	Algorithm ^{a-c}

^af: resulting score per item.

^b $i=1$ if the item was marked correctly; otherwise $i=0$.

^cn: number of answer options per item ($n \geq 2$).

^d $o=1$ if the item was omitted; otherwise $o=0$.

^e $t_m=1$ if the statement is true; otherwise $t_m=0$.

^fNC: number correct.

^gN/A: not applicable (ie, no explicit name was previously introduced in literature).

^hCG: correct for guessing.

ⁱOnly described for $n=2$.

^jOnly described for single true-false items.

Scoring Methods Without Malus Points (0 to a Maximum of +1 Point per Item)

Method 1

One credit point is awarded for a correct response. Therefore, the examination result as absolute score (S) corresponds to the number of correct responses (R). No points are deducted for incorrect responses (W). The formula is $S = R$.

Method 2

One credit point is awarded for a correct response. In addition, $1/n$ credit points per item are awarded for each omitted item (O). No points are deducted for incorrect responses. The formula is $S = R + O/n$. This scoring method was first described by Lindquist [37] in 1951.

Method 3

One credit point is awarded for a correct response. For incorrect responses, $1 - 1/n$ credit points are awarded. The formula is $S = R + (1 - 1/n)W$. This scoring method was first described by Costagliola et al [154] in 2007 and named *fair penalty* by the authors. However, the term *penalty* is misleading because no points are deducted in case of incorrect responses.

Method 4

For each correct response, $1/(n - 1)$ credit points are awarded. Omitted items and incorrect responses do not affect the score. The formula is $S = R/(n - 1)$. For example, 1 credit point is awarded for a correct response on single-choice items with $n=2$ (ie, alternate-choice items, single true-false items) but only 0.25 credit points are awarded for a correct response on best-answer

items with $n=5$. This scoring method was first described by Foster and Ruch [181] in 1927.

Scoring Methods With Malus Points (Maximum –1 to +1 Point per Item)

Method 5

One credit point is awarded for a correct response. For incorrect responses, $1/[2(n - 1)]$ points are deducted. The formula is $S = R - W/[2(n - 1)]$. This scoring method was first described by Little [182] in 1962.

Method 6

One credit point is awarded for a correct response. For incorrect responses, $1/(n - 1)$ points are deducted. The formula is $S = R - W/(n - 1)$. This scoring method was first described by Holzinger [183] in 1924. For items with $n=2$, methods 6 and 13 result in identical scores; for items with $n=4$, methods 6 and 9 result in identical scores.

Method 7

For each correct response, $1/(n - 1)$ credit points are awarded. For an incorrect response, $1/(n - 1)$ points are deducted. The formula is $S = (R - W)/(n - 1)$. This scoring method was first described by Petz [226] in 1978.

Method 8

For each correct response, $(n - 1)/n$ credit points are awarded. For an incorrect response, $1/n$ points are deducted. Omissions do not affect the score. The formula is $S = [(n - 1)/n]R - W/n$. As a result, examinees achieve only 0.5 credit points for each correct response on single-choice items with $n=2$ and 0.8 credit points for each correct response on best-answer items with $n=5$.

This scoring method was first described by Guilford [41] in 1954.

Method 9

One credit point is awarded for a correct response. For incorrect responses, 1/3 points are deducted. The formula is $S = R - (1/3)W$. Originally, this scoring method was described by Paterson and Langlie [6] in 1925 with the formula $S = 3R - W$ for items with $n=2$ only. Later, the scoring method was also described for single-choice items with more answer options [88,203]. For items with $n=4$, methods 6 and 9 give identical results.

Method 10

One credit point is awarded for a correct response. For incorrect responses, 0.48 points are deducted. The formula is $S = R - 0.48W$. This scoring method was first described by Gupta and Penfold [229] in 1961 for single-choice items with $n=2$.

Method 11

One credit point is awarded for a correct response. Half a point is deducted for incorrect responses. The formula is $S = R - 0.5W$. This scoring method was first described in 1924 by Brinkley [18] and Asker [230] for single-choice items with $n=2$, but was later also used for single-choice items with more answer options.

Method 12

One credit point is awarded for a correct response. For incorrect responses, 0.6 points are deducted. The formula is $S = R - 0.6W$. This scoring method was first described by Gupta [231] in 1957 for single-choice items with $n=2$.

Method 13

One credit point is awarded for a correct response. One point is deducted for incorrect responses. The formula is $S = R - W$. For items with $n=2$, methods 6 and 13 result in identical scores. This scoring method was first described by McCall [4] in 1920 for single-choice items with $n=2$, but was later also used for single-choice items with more answer options.

Method 14

This scoring method results in 1 credit point for a correct response, 0.7 credit points for an omitted item, and -1 point for an incorrect response. The formula is $S = R + 0.7O - W$. This scoring method was first described by Staffebach [268] in 1930 for single-choice items with $n=2$.

Scoring Methods With Malus Points (Maximum -3 to +1 Points per Item)

Method 15

This scoring method results in 1 credit point for a correct response, 0.7 credit points for an omitted item, and -1.1 points for an incorrect response. The formula is $S = R + 0.7O - 1.1W$. This scoring method was first described by Kinney and Eurich [186] in 1933 for items with $n=2$.

Method 16

One credit point is awarded for a correct response. For an incorrect response, $n/(n-1)$ points are deducted. The formula

is $S = R - nW/(n-1)$. This scoring method was first described by Miller [20] in 1925. For items with $n=2$, methods 16 and 19 result in identical scores.

Method 17

For an incorrect response, 1.5 times as many points are deducted as credit points are awarded for a correct response. The original scoring formula is $S = 2R - 3W$. If a maximum of 1 credit point is awarded per item, 1 credit point is awarded for a correct response and 1.5 points are deducted for an incorrect response. This results in the following scoring formula: $S = R - 1.5W$. This scoring method was first described by Cronbach [259] in 1942 for items with $n=2$.

Method 18

One credit point is awarded for a correct response. For an incorrect response, 1.8 points are deducted. The scoring formula is $S = R - 1.8W$. This scoring method was first described by Lennox [203] in 1967 for items with $n=2$.

Method 19

One credit point is awarded for a correct response. For an incorrect response, $2/(n-1)$ points are deducted. The formula is $S = R - 2W/(n-1)$. This scoring method was first described by Gates [269] in 1921 with the scoring formula $S = R - 2W$ for items with $n=2$. Later, the scoring formula was also described for single-choice items [203,270]. In case of items with $n=2$, methods 16 and 19 result in identical scores.

Method 20

One credit point is awarded for a correct response. Three points are deducted for an incorrect response. The formula is $S = R - 3W$. This method was first described by Wood [17] in 1923 for items with $n=2$.

Specific Scoring Methods for Single True-False Items

Method 21

One credit point is awarded for correctly identifying the statement of true-false single items as true or false. If the statement presented is marked incorrectly, 62/38 points are deducted on true statements (W_t , incorrectly marked as false), but only 38/62 points are deducted on false statements (W_f , incorrectly marked as true). The scoring formula is $S = R - (62/38)W_t - (38/62)W_f$. This scoring method was first described by Cronbach [259] in 1942 for single true-false items and differentiates in the scoring of incorrectly marked true/false statements.

Expected Chance Scores of the Identified Scoring Methods

The expected chance scores of examinees without any knowledge ($k=0$) vary between -1 and +0.75 credit points per item for single-choice items with $n=2$. For single-choice items with $n=5$, expected chance scores show a larger variability. Here, the expected chance scores vary between -2.2 and +0.84 credit points per item, depending on the selected scoring method. A detailed list is shown in Table 3.

Table 3. Overview of scoring results for single-choice items with either n=2 or n=5 answer option.

Method number	Scoring formula ^{a-f}	n=2			n=5		
		Credit for incorrect responses ^h	Credit for correct responses ⁱ	Expected chance score	Credit for incorrect responses ^h	Credit for correct responses ⁱ	Expected chance score
1	$S = R$	0	1	0.50	0	1	0.20
2	$S = R + O/n$	0	1	0.50	0	1	0.20
3	$S = R + (1 - 1/n)W$	0.50	1	0.75	0.80	1	0.84
4	$S = R/(n - 1)$	0	1	0.50	0	0.25	0.05
5	$S = R - W/[2(n - 1)]$	-0.50	1	0.25	-1/8	1	0.10
6	$S = R - W/(n - 1)$	-1	1	0.00	-0.25	1	0.00
7	$S = (R - W)/(n - 1)$	-1	1	0.00	-0.25	0.25	0.15
8	$S = [(n - 1)/n]R - W/n$	-0.50	0.50	0.00	-0.20	0.80	0.00
9	$S = R - (1/3)W$	-1/3	1	1/3	-1/3	1	-2/30

Relation Between Examinees' true knowledge and the Expected Scoring Results

The relation between examinees' *true knowledge* and expected scoring results for single-choice items with n=2 and n=5 is shown in Figure 3. For all identified scoring methods, there is a linear relation between examinees' *true knowledge* and the expected scoring results. However, some scoring methods (ie, methods 4 and 7) award less than 1 point for correctly marked items if there are more than 2 answer options (n>2). One further method (method 8) awards less than 1 point for correctly marked items regardless of the number of answer options, so the

maximum score for these scoring methods might be less than 100%. Depending on the scoring method and the number of answer options, the y-axis intercepts (expected chance scores, k=0) and the slopes differ. A low expected chance score results in a wide range of examination results that differentiate different examinees' knowledge levels (ranging from the expected chance score as the lower limit to the maximum score as the upper limit). Only for methods 6 and 8 as well as method 7 in the case of n=2, the line starts from the pole (ie, examinees without any knowledge [k=0] achieve an examination result of 0%). Only for method 6, the relation between examinees' *true knowledge*

and the expected scoring results is independent of the number of answer options per item.

Figure 3. Relation between examinees' *true knowledge* (%) and the expected scoring results for examinations with 100 single-choice items (either $n=2$ or $n=5$ answer options per item). In each case, the expected scoring result at 50% *true knowledge* is shown with the associated 95% confidence interval. Method 21 is not shown because the relation depends on the proportion of single true-false items with true or false statements. O: number of omitted items ($O=0$); R: number of correct responses; S: examination result as absolute score (max. up to 100 points); W: number of incorrect responses.

Discussion

Principal Findings

In this review, a total of 21 scoring methods for single-choice items could be identified. The majority of identified scoring methods is based on theoretical considerations or empirical findings, while others have been arbitrarily determined. Although some methods were only described for certain item types (ie, single-choice items with $n=2$), most of them might also be used for scoring items with more answer options. However, 1 method is suitable for scoring single true-false items only.

All scoring methods have in common that omitted items do not result in any credit deduction. Some scoring methods even award a fixed amount of 0.7 points on omitted items (methods 14 and 15), which is, however, lower than the full credit for a correct

response, or the score to be achieved on average by guessing ($1/n$, method 2).

For the identified scoring methods, the possible scores range from a maximum of -3 to $+1$ points. A correctly marked item is usually scored with 1 full point (1 credit point). Exceptions to this are 3 scoring methods that only award 1 credit point in case of single-choice items with $n=2$ (methods 4 and 7) or that never award 1 credit point (method 8). These scoring methods are questionable because as the number of answer options increases, the guessing probability decreases. Further, a differentiation between examinees' marking on true and false statements (method 21) is not justified, because the importance of correctly identifying true statements (ie, correctly marking the statement as true) and false statements (ie, correctly marking the statement as false) is likely to be considered equivalent in the context of many examinations.

With the exception of method 6, the relation between examinees' *true knowledge* and the resulting examination scores depends on the number of answer options per item (n). Therefore, the number of answer options per item must usually be taken into account when examination scores are interpreted.

Examinations are designed to determine examinees' knowledge as well as to decide whether the examinees pass or fail in summative examinations. It can be generally assumed that examinees must perform at least 50% of the expected performance to receive at least a passing grade [271]. If examinees are to be tested on a *true knowledge* of 50%, adjusted pass marks must be applied depending on the scoring method used and the number of answer options per item. The theoretical considerations show that for an examination testing for 50% *true knowledge*, a pass mark of 0% or even negative scoring results might be appropriate, while other scoring methods would require pass marks up to 92%. Consequently, the examination's pass mark must be considered or adjusted when selecting a suitable scoring method. However, the pass mark might be fixed due to local university or national guidelines resulting in a limited number of suitable scoring methods.

Correction for Guessing

To account for guessing in case of single true-false items, the scoring formula $R - W$ (method 13) was originally propagated in the literature, where the number of incorrect responses is subtracted from the number of correct responses [4]. Since its first publication in 1920, this scoring method has been frequently criticized: the main criticism is that this scoring method assumes examinees to either have complete knowledge ($k=1$) or to guess blindly ($k=0$). However, especially in the context of university examinations, examinees are assumed to have at least some partial knowledge. Furthermore, the scoring method assumes that incorrect responses are exclusively the result of guessing. No differentiation is made between incorrect responses due to blind guessing (ie, complete lack of knowledge), informed guessing (ie, guessing with partial knowledge and remaining uncertainty), or other reasons (eg, transcription errors introduced when transferring markings to the answer sheet) despite complete knowledge. Because of the 50% guessing probability in case of alternate-choice items or single true-false items, it is assumed that for each incorrectly guessed response (W) 1 item is also marked correctly by guessing on average, so that the corrected result is obtained by the scoring formula $R - W$. Especially in the case of partial knowledge, examinees' marking behavior not only depends on their actual knowledge but also on their individual personality (eg, risk-seeking behavior) [272]. Consequently, the construct validity of examinations must be questioned when using the scoring formula $R - W$. Another criticism is that a correction by awarding minus points does not change the relative ranking of the results of different examinees if all examinees have sufficient time to take the examination and all items are answered [44,46].

Therefore, alternative scoring methods and scoring formulas emerged in addition to the already discussed scoring formula $R - W$. In this context, the literature often refers to formula scoring. However, the term *formula scoring* is not used uniformly: on the one hand, it is used as a general umbrella term

for various scoring methods to correct for the guessing probability. On the other hand, the term is used to refer to specific scoring methods (methods 2, 6, and 13). Using method 2, examinees receive $1/n$ points for each omitted item. This corresponds to the number of points they would have scored on average by blindly guessing. Method 6 is a generalization of the scoring formula $R - W$ for variable numbers of answer options. In case of n answer options, there are $n - 1$ times as many incorrect answer options as correct answer options and it is assumed that for each incorrectly guessed response (W) also $W/(n - 1)$ items are marked correctly by guessing on average. Therefore, the corrected score is given by the scoring formula $R - W/(n - 1)$. Consequently, methods 6 and 13 yield identical scoring results in case of items with $n=2$.

Strengths and Limitations

So far, the relation between examinees' *true knowledge* and the expected scoring result for single-choice items has been shown only for a small number of scoring methods [273]. Therefore, a systematic literature search was conducted in several databases as part of this review. As a result, a large number of different scoring methods have been identified and were compared in this review assisting (medical) educators in gaining a comprehensive overview and to allow for informed decisions regarding the scoring of single-choice items. However, limitations are also present: First, a number of assumptions (eg, equal difficulty of items and answer options, absence of cues) were required for simplification of the calculations and comparisons. However, these assumptions are likely to be violated in real examinations [15,274-276]. Second, calculations are based on classical test theory assumptions and did not employ item response theory models that might yield different results. Third, databases were already searched in September 2020 and potentially eligible sources published thereafter might not be included in this review. However, single-choice items have been used in examinations for over 100 years and further scoring methods are unlikely to have emerged in the past 2 years.

Comparison With Prior Work

Although some of the identified scoring methods might also be applied to other item formats (eg, *multiple-select items*), the presented equation for the calculation of the expected scoring result is limited to single-choice items. Analogous calculations for items in multiple-select multiple-choice formats with (eg, Pick-N items) or without (eg, Multiple-True-False items) mutual stochastic dependence have already been described in the literature [11,14].

Practical Implications

In practice, the evaluation of a multiple-choice examination should be based on an easy-to-calculate scoring method that allows for a transparent credit awarding and is accepted by jurisdiction. In this regard, scoring methods with minus points (ie, methods 5-21) may not be accepted by national jurisdiction in certain countries (eg, Germany) [277]. Furthermore, it does not seem reasonable to discourage examinees from marking an item by awarding minus points for the reasons already mentioned. Therefore, only 4 of the presented scoring methods

can be versatily used. Furthermore, it seems inconclusive to reward partial credit on incorrect responses or to refrain from awarding 1 credit point for correct responses in case of items with more than 2 answer options ($n > 2$). As a result, only a dichotomous scoring method (1 credit point for a correct response, 0 points for an incorrect response or omitted items) is recommended. Within the context of this review, the outlined scoring method is referred to as method 1.

The scoring of examinations with different item types, item formats, or items containing a varying number of answer options within a single examination is more complicated. Here, the individual examination sections would have to be evaluated separately or the credit resulting from the respective item type or item format would have to be corrected to enable a uniform pass mark. For example, in the single-choice format, credit

points resulting from items with $n=2$ would have to be reduced to compensate for the higher guessing probability compared with items with $n=5$ (ie, 50% vs 20% guessing probability).

Conclusions

Single-response items only allow clearly correct or incorrect responses from examinees. Consequently, the scoring should also be dichotomous and result in either 0 points (incorrect response) or 1 credit point (correct response) per item. Because of the possibility of guessing, scoring results cannot be equated with examinees' *true knowledge*. If (medical) educators interpret scoring results and determine suitable pass marks, the expected chance score must be taken into account, which in the proposed dichotomous scoring methods depends on the number of answer options per item.

Abstract

The role of artificial intelligence (AI) in radiology has grown exponentially in the recent years. One of the primary worries by medical students is that AI will cause the roles of a radiologist to become automated and thus obsolete. Therefore, there is a greater hesitancy by medical students to choose radiology as a specialty. However, it is in this time of change that the specialty needs new thinkers and leaders. In this succinct viewpoint, 2 medical students involved in AI and 2 radiologists specializing in AI or clinical informatics posit that not only are these fears false, but the field of radiology will be transformed in such a way due to AI that there will be novel reasons to choose radiology. These new factors include greater impact on patient care, new space for innovation, interdisciplinary collaboration, increased patient contact, becoming master diagnosticians, and greater opportunity for global health initiatives, among others. Finally, since medical students view mentorship as a critical resource when deciding their career path, medical educators must also be cognizant of these changes and not give much credence to the prevalent fearmongering. As the field and practice of radiology continue to undergo significant change due to AI, it is urgent and necessary for the conversation to expand from expert to expert to expert to student. Medical students should be encouraged to choose radiology specifically because of the changes brought on by AI rather than being deterred by it.

Introduction

A 2022 study found that half of medical students who consider specializing in radiology as 1 of their top 3 choices are concerned about the impact of artificial intelligence (AI) on the field [1]. This finding is contrasted by the optimism of leading radiologists from the Association of University Radiologists in 2020 toward AI, citing exciting developments in precision health, workflow efficiency, and decision support [2]. This contradiction highlights a lack of communication between the thought leaders in radiology and medical students regarding the promise of AI in radiology. If medical students only learn about the purported “dangers” and “threats” of AI on the radiology workforce from the media or from nonradiologist physicians,

they are at increased risk of believing such false claims, due to their lack of understanding of the complex and irreplaceable roles of the radiologist. The uncertain impact of AI on the future of radiology can further deter medical students from choosing radiology [3,4]. There is an unavoidable need to reconcile this misunderstanding between current physician AI experts and medical students currently in undergraduate medical education who are tasked to choose their specialty.

Yet, it is during this crucial time of transition in the field of radiology that there is an even greater and more urgent need for medical students to rise to the challenge as leaders and innovators. AI is reshaping the practice of radiology, just as picture archiving and communication system and magnetic resonance imaging did in previous decades [5,6]. This

reinvention of radiology can create new reasons for medical students to pursue the specialty. However, few articles have highlighted how AI can attract medical students toward radiology rather than scaring them away [7]. Even fewer articles about this topic have been written specifically for medical students, without much technical jargon, as the conversation is mostly *expert to expert* right now [8]. Beyond disproving the myth that AI is going to cause a negative disruption to the future radiology job market, this article encourages current and future medical students to not feel intimidated by AI, but rather be empowered to choose radiology especially because of it. To do so, 2 radiologists who are national leaders on AI and clinical informatics (SH and TC) and 2 medical student leaders (DL and KA) aim to provide a commentary that outlines several novel considerations related to AI that could attract medical students to radiology. Though the focus of this article is solely on radiology, as the influence of AI grows in other specialties, conclusions derived from this article can be applied to other specialties as well.

The Effect of AI in Radiology

AI is a broad category, encompassing multiple types of technology. The most popular category of AI in radiology is deep learning, which uses sophisticated neural networks to detect patterns in input data and produce outputs [9]. For example, deep learning can learn the relationships between pixels in a chest x-ray to detect findings associated with the presence or absence of pathologies such as cardiomegaly, emphysema, and atelectasis [9,10] at a level similar to practicing radiologists. Though this article will focus mostly on deep learning and pixel-based AI, it is important to note that AI includes natural language processing, which has been successfully applied to report creation, speech recognition, summarization, and text classification in radiology [11].

However, AI for radiology does not exist solely in research but has found its way to clinical utility too, with more than 200 Food and Drug Administration–cleared, commercially available AI software products for radiology available as of early 2023 [12,13]. Nonetheless, a majority of these products still need peer-reviewed publications clearly assessing their clinical utility [12]. However, as radiology research continues to be further polished and clinical use cases developed, it seems inevitable that AI will play a significant role in transforming the field of radiology [9,14]. Recognizing this imminent shift, radiology residencies are now encouraging increased AI literacy in their residents [15,16].

A Larger Impact on Patient Care

Medical students who want a career during which they can impact the care of the largest number of patients should strongly consider diagnostic radiology, a specialty that is unequivocally integral to the practice of medicine and would potentially benefit from AI. On top of reducing radiation exposure and doses of contrast agents, AI can increase workflow efficiency, improve organ quantification and disease detection, triage exams with urgent findings, and advance precision medicine [12,17]. For example, with an aging population and a greater reliance on

imaging in the United States and Canada, there has been significantly increased computed tomography (230%), magnetic resonance imaging (304%), and ultrasound (164%) imaging use within the last 2 decades [18]. The World Health Organization estimates that the percentage of the world's population that will be over 60 years old in 2050 will be nearly double what it was in 2015 [19]. To match the greater demand, AI can significantly improve the efficiency of the workflow of radiologists. For example, AI for bone age estimation resulted in up to 40% reduction in reading time [20]. Another AI to detect pulmonary metastases reduced reading time by 21% [21]. Furthermore, the World Health Organization data suggest that in 2050, two-thirds of the world's population over 60 will be in lower- and middle-income countries, increasing imaging volumes in these areas without a proportionate increase in radiologists and radiology trainees [19,22]. For students passionate about global health, RAD-AID is a global health initiative that provides AI tools and associated education to health care providers in lower- and middle-income countries [22]. For countries such as Guyana, which has 750,000 citizens but no in-country radiology programs, RAD-AID helped by starting residency programs and concurrently introducing AI education to help with the significant need to interpret high numbers of imaging examinations [22]. Finally, faster image acquisition by removing image noise [23] and improving image reconstruction [24], combined with decreasing necessary radiation exposure and contrast dose [25], can improve the imaging experience and decrease the risk of side effects for patients. Reducing barriers to imaging increases the value of radiology to both clinicians and patients and can accelerate the pace of diagnosis and treatment. The ability to play a role in the health care of a larger number of patients can give future radiologists a greater sense of meaning and a positive impact.

A New Need for Innovators and Researchers

AI has created a new space for innovators within radiology. When electronic medical records were introduced in the early 2000s, physicians were neither sufficiently consulted nor involved in the process and did not effectively or actively advocate for themselves and their patients [14]. The promise of data sharing and workflow improvements was not realized, and instead clinicians found themselves working harder—and for the computer, rather than the other way around—to deliver optimal care and create a healthy patient-physician relationship. Without the input of radiologists and physicians from other imaging specialties, such as cardiology, pathology, dermatology, and ophthalmology, the same could happen with AI. Instead, radiologists must lead AI innovations in their specialty [14] and guide data scientists and AI developers in building solutions that directly impact care delivery and improve patient outcomes.

There has been an explosion of radiology AI research in the past few years. Participation in AI research is not limited to radiologists with formal training in AI, computer science, or software development. In fact, the opposite is true; one criticism of radiology AI development has been that anyone with a graphics processing unit and some data can build a working

model. While this is technically true, building imaging AI models that make logical sense in the clinical workflow and address an unmet, relevant clinical need requires a domain knowledge that radiologists must provide. Imaging AI is a highly interdisciplinary field, consisting of experts from engineering, computer science, medicine, and informatics. The camaraderie and sharing of knowledge between these experts should be the norm in radiology AI research. For example, at Stanford's Center for Artificial Intelligence in Medicine & Imaging, leaders in medicine, education, business, computer science, ethics, and linguistics converge to form interdisciplinary teams dedicated to teaching AI and conducting AI research to solve health care issues [26-28]. This sharing of knowledge between fields of expertise creates ever-expanding areas of personal growth and discovery for the physician. Finally, for students who have an entrepreneurial spirit, the number of AI startups in radiology has significantly increased since the AI "boom" in the late 2010s. The 2021 global market size for AI in medical imaging is \$1.06 billion, with an expected compound annual growth rate of 46%, leading to a market size of \$10.14 billion by 2027 [29]. AI creates the opportunity for new exploration and innovation in various frontiers in medicine, and radiology stands to gain the most from these new developments. For medical students who desire to be creative, lead innovation, and conduct interdisciplinary research, radiology is a field that is filled with such new opportunities.

The Patient-Facing Radiologist

Radiology is also a highly technical field. Medical students perceive radiologists to have "little or no patient interaction" and think that radiology "is best suited for introverted people" [30]. AI can automate repetitive tasks currently performed by radiologists, such as screenings and lesion or organ measurements [9,14,31]. The hope is that this automation will create time for radiologists to meet and speak to patients face-to-face, to discuss the need for imaging, and to review the results and consult on the next steps in care. In total, 84% of surveyed patients have reported interest in meeting with a radiologist to discuss their imaging findings, with 57% of those willing to pay extra [32]. In 2022, the European Society of Radiology released a statement to encourage further radiologist-patient communication, in light of new technologies such as AI [33]. Although breast imaging and interventional radiology already afford these subspecialist radiologists face time with patients, AI may increase the likelihood that other subspecialties are able to interact with patients because of the time reduced from purely diagnostic work in front of a screen [24,34,35]. No longer just the "doctor's doctor," radiologists will be able to demonstrate their value as the patient's physician via direct patient interaction [35]. Patients will have the opportunity to learn about their diagnosis from the radiologist's point of view. Furthermore, with the passing of the 21st Century Cures Act, patients now have immediate access to their test results, including their radiology reports. This provides even more needs and opportunities for patients to connect with radiologists. Medical students who are concerned about the relatively secluded nature of the specialty should be encouraged

by the potential positive impact AI can have on increasing the quality and amount of patient interactions.

Becoming Master Diagnosticians and Information Experts

The practice of radiology requires the analysis of multiple sources of data and the integration of the presented information to identify a likely diagnosis. Rather, beyond patient history and the radiologist's clinical experience, output from AI will be a new source of data that adds to the richness of information presented to the radiologist as they exercise their clinical judgment. AI can also make simple but impactful changes, such as augmenting hanging protocols, which dictate how current and prior examinations (and now, AI results) are displayed to a radiologist for interpretation [17]. Medical students who enjoy becoming the epitome of an information specialist will find radiology augmented by AI to be one of the most intellectually stimulating fields in medicine. They will be expected to consolidate multiple additional sources of quantitative data in addition to reviewing the original reconstructed pixel data. Additionally, they will have the opportunity to translate this into actionable recommendations for both referring clinicians and patients. For example, an electronic health record-based AI can notify the radiologist about the patient's multiple pulmonary embolism history [36]. With this information, the radiologist will have a higher suspicion in diagnosing pulmonary embolism. Gathering these various sources of information and recognizing the potential for an underlying malignancy, the resident could report that concern so that the patient undergoes a more thorough checkup for potential malignancy. Already integral to the health care system, radiologists will become even more essential, which could improve the work satisfaction and sense of fulfillment of future radiologists.

For Medical Educators

Medical educators guide medical students as they decide on which specialty to pursue. Mentorship has been shown to be beneficial in a medical student's medical school experience and a significant factor for career path development for the past few decades [37]. Medical educators must have a holistic understanding of the potential effect of AI on certain specialties in order to disseminate unbiased information and properly advise medical students. Due to the COVID-19 pandemic, web-based learning has become a mainstay, and education on various topics is now much more readily available. For example, a working understanding of AI and its impact on medicine can be gained from free massive open online courses [8]. Additionally, many articles have been recently published to introduce the concept and promises of AI at a level for medical professionals with minimal prior understanding of AI [14,38,39]. To better guide medical students, it would be wise for medical educators to be cognizant of changes in the medical field by staying in touch, by reading and keeping up to date with these new review articles. However, the bottom line is that medical educators should lead by example for medical students by approaching the topic of AI in medicine with a healthy optimism and with

critical thinking, given the significant role they can play in informing the future of their medical students.

Conclusion

Radiologists who embrace AI are unlikely to be replaced by the technology. Instead, AI is poised to positively transform the field. This will create a greater demand for radiologists who are innovators, multidisciplinary researchers, and empathic physicians who take pride in being information specialists. Medical students considering what specialty to choose should be aware of these changes, especially as misinformation spreads

about the future impact of AI on the field of radiology. Medical educators should also be cognizant of these changes to properly mentor medical students in deciding their future specialty. Though the current medical student community seems hesitant in pursuing radiology due to AI [1], the positive changes to the field of radiology due to AI can actually create new reasons that may attract medical students toward this specialty. Radiology is currently undergoing a process of transformation. Thus, it is in this crucial time that correct guidance has to be given to encourage current medical students to choose radiology and become both leaders and advocates for positive change.

Abstract

When facing a health decision, people tend to seek and access web-based information and other resources. Unfortunately, this exposes them to a substantial volume of misinformation. Misinformation, when combined with growing public distrust of science and trust in alternative medicine, may motivate people to make suboptimal choices that lead to harmful health outcomes and threaten public safety. Identifying harmful misinformation is complicated. Current definitions of misinformation either have limited capacity to define harmful health misinformation inclusively or present a complex framework with information characteristics that users cannot easily evaluate. Building on previous taxonomies and definitions, we propose an information evaluation framework that focuses on defining different shapes and forms of harmful health misinformation. The framework aims to help health information users, including researchers, clinicians, policy makers, and lay individuals, to detect misinformation that threatens truly informed health decisions.

KEYWORDS

misinformation; social networks; decision-making; information validation; policy; health information; web-based

Introduction

Almost 3 quarters of people (72%) use the internet first when they need health-related information [1]. Web-based information helps people to prepare for conversations with clinicians, facilitates self-care, and improves adherence to physicians' advice and recommended medication use [2]. However, the benefits of web-based information come with challenges. To find credible information, individuals often need to sort through misinformation, which may include posts about potentially harmful practices, unproven alternative therapies, pseudoscientific explanations, rumors, and misappropriations [3,4]. Misinformation, in fact, has an overwhelmingly high prevalence—up to 40% of posts on social media contain health misinformation related to vaccinations; eating disorders; treatments; and chronic diseases, including cancer [5].

Health misinformation could mislead health-related decisions and result in harmful outcomes. A recent physician evaluation of popular social media posts found frequent health misinformation and identified that almost a third (31%) of such posts could lead to individuals delaying standard treatment or engaging in potentially toxic, expensive, and futile therapies [6]. Decisions driven by misinformation can lead to emotional damage, false hopes, financial loss, and more importantly, physical damage that hastens death [7-9]. Although a comprehensive evaluation of the negative effect of misinformation on patient outcomes has not been completed, multiple case reports describe individuals who have suffered negative consequences after they followed web-based misinformation [10], including prominent cases with public figures, such as Steve Jobs [11] and William Hurt [12]. Perhaps the most devastating effect of misinformation is that it sows doubt in medical science. In extreme cases, such doubts can lead to social movements advocating decisions that threaten

public safety. For instance, motivated by misinformation that was spread by antivaccine supporters, a substantial proportion of people in the United States chose not to receive vaccines against the COVID-19 virus despite their proven safety and effectiveness [13,14].

To date, no comprehensive system can reliably detect and neutralize harmful health misinformation, partially because harmful misinformation takes multiple shapes and forms. More than 50 distinct types of misinformation are described in the literature, such as fake news, manipulation, rumors, fabrication, and click bites [15-17]. The most common definitions of misinformation are developed based on a single information characteristic, such as truthfulness or author motivation (disinformation) [18,19], including two definitions specifically related to health misinformation [20,21]. As a result, certain types of harmful health misinformation are not covered by these definitions. For instance, one of the most common definitions suggests that misinformation is information that contradicts truthful facts, where truth is defined as a fact or opinion that is aligned with the expert consensus or the best scientific evidence available at that time [18]. This definition does not cover cases in which truthful facts are exaggerated, misinterpreted, or used in the wrong context. For instance, SanSentinel [22] distributed a story about a physician dying after receiving a COVID-19 vaccination. The chronology of the events was truthfully described in the article. However, the connection between the physician's vaccination and death was never established. Despite the cause of death not being verified, the news ignited a misinformed public discussion about the dangers of vaccination. The story reached almost 50 million views on Facebook [23]. Some proportion of those individuals who viewed the Facebook message were likely motivated to reject or delay vaccination, which, in turn, prolonged the damage of COVID-19 to public health.

More inclusive definitions usually consist not of one but a composite of information characteristics. However, frequently, these characteristics are not considered from a user point of view and may be challenging to evaluate. For instance, author motivation is a common characteristic that is used in misinformation definitions. The core issue is that authors could

be motivated by a mixture of positive, negative, and selfish interests. For example, an author could have financial interests in posting an advertisement for medication with unknown outcomes but also may genuinely intend to help treat a condition. In this and other similar situations, author motivation is difficult to discern, even for experts in the field.

The overarching purpose of this viewpoint is to propose a composite framework that covers the substantial proportion of harmful health misinformation but is simple enough to be applied by health information users, including researchers, clinicians, policy makers, and lay individuals. The development of the framework is guided by the practical goal of helping users identify and prevent the negative impact of misinformation on decisions related to various aspects of health, including preventive medicine, therapeutic care, and lifestyle behaviors. Therefore, we focused the framework on misinformation that has the potential to cause harm to health-related decisions, inclusive of physical, emotional, social, and financial harm.

Misinformation Characteristics

The characteristics of misinformation are defined in this framework as abstract rules that can be used to judge the quality of information [24]. We used 3 criteria to suggest the characteristics of misinformation that could be helpful in detecting harmful health misinformation. First, characteristics should be observable. In other words, a user should be able to evaluate a characteristic on their own or in consultation with an expert (clinician). As alluded to above, motivation tends to be an unobservable characteristic. Second, information characteristics should be generalizable across multiple contexts and media. Taxonomies and examples specific to media (eg, click bites) were not included. Third, characteristics of information should be simple. Thus, characteristics that contained branching logic and subcategories were excluded. According to these criteria, we chose the following key characteristics of misinformation for the framework: actionability, verifiability, and facticity. The examples of misinformation taxonomies that we used to choose misinformation characteristics are provided in Table 1 [15-17,25-34].

Table 1. Summary of the characteristics of misinformation.

Articles	Characteristics of misinformation as identified by the authors	Reasons for not including some characteristics
Kapantai et al [15], 2020	Motivation, verifiability, and facticity	Observability: motivation or intention
Southwell et al [25], 2019	Actionability and audience exposure	Observability: audience exposure
Tandoc et al [26], 2018	Level of facticity and authors' intention to deceive	Observability: motivation or intention
Zannottou et al [17], 2019	Types of misinformation (eg, fabrication and propaganda) and motivation	Generalizability: types of misinformation; Observability: motivation or intention
Kumar et al [27], 2018	Opinion based (eg, fake reviews), fact based, and with intention to deceive	Observability: opinion-based information (fake reviews) as well as motivation or intention
Gabarron et al [28], 2021	Myths, sarcasm, and humor	Generalizability: types of misinformation
Jamison et al [29], 2020	Antivaccine conspiracies and provaccine promotions	Generalizability: specific context
Paquin et al [30] ^a , 2022	True claim, misleading claim (ie, implicit misinformation), and false claim (ie, explicit misinformation)	Observability: implicit misinformation
Wardle et al [31], 2017	Disinformation (false information to harm), misinformation (false information), and malinformation (true information that is used to harm)	Observability: disinformation and malinformation
Lemieux et al [32], 2018	Inaccuracy, unreliability, and inauthenticity	Simplicity: unreliability and inauthenticity
Dhoju et al [33], 2019	Reliable media and unreliable media	Generalizability: type of media
Molina et al [16], 2021	Real news, fake news, commentary (opinion), misreporting (accidentally not true), polarized and sensationalist content, citizen journalism, satire, and persuasive information	Generalizability: type of article
Wang et al [34], 2022	Intentions, perception of the information or relevance ^a , benchmarks of facticity, and scope	Observability: motivation or intention as well as scope

^aPerception of information is defined as the perceived usefulness of information in a problem-solving information search. We interpret this concept as whether users perceive information as worth acting upon; in other words, whether they evaluate information as actionable.

Actionability

Actionability of information is defined by whether the information can lead a person to change their attitude or action (doing or not doing something), which they would not have done without learning the information. One could evaluate actionability by considering to what extent the information is useful for solving a specific health problem [35]. Not all information is actionable [25,35]. In some cases, the actionability of information is defined by users' perspectives. Information might motivate behavior change among some populations but not others. For instance, messages related to screening for sex-related cancers, such as breast or prostate cancer, may not be relevant for health information users of the opposite sex. Similarly, misinformation about medication related to heart diseases [36] might be judged as actionable by older populations more than younger populations.

In other cases, actionability of information is defined by the nature of information. Certain types of information might be irrelevant for health-related problems. An example of such information might be a hoax disclosing a cancer diagnosis by a celebrity [37]. Without a further discussion of the celebrity's previous lifestyle or medical choices, this information is nonactionable. Other examples could be honest errors in attributing information to a wrong source [25] or some forms of click bites, which are attractive titles that are not supported by information in the text. The misleading titles could be debunked when one engages in reading the article [19].

Actionable information may contain a direct call for action, including recommendations to buy medication; engage in therapy; change diets and lifestyle behaviors; or repost the information itself. Actionable information could hide in opinions and personal stories. A notable example is the story of Belle Gibson. In her web-based blog, she disclosed her experience of treating brain cancer with ayurvedic medicine, oxygen therapy, as well as a gluten and sugar-free diet [38]. She claimed to reach a complete cure via these actions. Before it became known that she had faked her diagnosis, she built a profitable business selling futile dieting as a cancer cure to her followers [39]. Not only personal stories but also simple opinion statements may have a dramatic effect on public health. For instance, at the beginning of the COVID-19 pandemic, President Donald Trump stated that people have a choice whether to wear masks for protection; he also claimed that he personally decided not to wear a mask. According to the epidemiological model proposed by researchers from Emory University, if the President's statement reduced mask use by 25%, it caused 4244 deaths in the United States alone [40].

As such, we propose that health information users sort information based on whether the information prompts them to change attitudes or take a particular action with regard to solving a health-related problem. Evaluation of actionability could reduce the cognitive load of information evaluation, allowing users to ignore nonactionable information while beware of the influence hidden in personal stories and opinions. If information users detect that the information is likely to result in behavior

or attitude change, the information needs to be flagged for further assessment of facticity.

Facticity

Facticity is formally defined by whether the information is consistent with the evidence or consensus of the scientific community at the time of evaluation [18]. Factual information usually originates from data, scientific reports, rigorous clinical trials, observational studies, or documented agreements of field experts. Facticity is a key component that underlines identifying harmful information. Decisions that are based on nonfactual information have unknown, and at times, harmful outcomes. For individuals with medical conditions and those who receive standard medical therapies, this path is especially precarious. Some complementary supplements, diets, and alternative therapies may not be harmful when used independently but may become toxic in combination with standard therapies [41].

Multiple recommendations have been developed to guide health information users in their evaluation of information facticity [42-46]. Although recommendations vary in complexity, the majority of them ask users to do the following:

- Identify authors and their credentials
- Understand authors' conflicts of interest
- Learn about funding sources
- Identify and evaluate original sources of information
- Compare information among different sources
- Determine the date of posting

The evaluation of facticity is an arduous task. First, many health information users might not be equipped to implement some of the recommended steps. For instance, the recommendation "evaluation of original sources" may require users to have some scientific knowledge in interpreting data and expertise in determining the quality of scientific reports. The second challenge is that information frequently presents a mixture of true and false statements that occur due to honest errors, misunderstanding, and sometimes because of authors' motivated intentions. For instance, a recent news report stated that "a vaccine wiped out cancer from a patient" [47]. The report described a clinical trial that enrolled patients with breast cancer and a patient who stated that her cancer was gone. The report delivered partially truthful information. A clinical trial for vaccination against breast cancer is ongoing, but the conclusion about the effectiveness of the vaccine was premature and false. In fact, several years of surveillance are required before the effectiveness of this vaccine can be reported [48]. Such partially factual reports may motivate patients' decisions, which will likely result in financial loss, false hopes, and disappointment. The third challenge is that facticity might change over time if new scientific evidence becomes available and alters the balance of benefits and harms [18]. For instance, a medication for hypertension, Mibefradil (Posicor), was approved as effective and safe. Later, it was discovered that in combination with other medications, it increased the risk of death. According to some sources, Mibefradil caused more than 100 deaths before it was recalled [49].

Although complex, establishing facticity is an important task for health information users, which needs to be conducted

continuously due to the possibility of changes in scientific evidence. If the evidence is established or consensus among experts is reached, facticity could be determined [18]. However, if evidence and experts' opinions remain emergent or are controversial, it is difficult to establish facticity. In this case, we suggest that the information should be flagged as unverifiable.

Verifiability

Verifiability is a characteristic of information that is defined by the availability of evidence or scientific agreement that could support a piece of information. Whether information is verifiable could be established during facticity evaluation, although some types of information may be judged as unverifiable preemptively. Such types of information range from personal stories to articles describing newly discovered "breakthrough" medicine, for which rigorous scientific studies have not been conducted.

Personal stories on social media and patient testimonies are common examples of unverifiable health information. Health information users might find personal stories helpful because stories allow them to learn medical terminology, visualize different processes of treatment, and understand how side effects feel [50]. However, personal stories could not be reliably verified, as the author might fake the diagnosis or describe a unique rare case that falls outside the scientific evidence, and therefore, will not be relevant to other patients' experiences.

Flagging information as unverifiable could help health information users to assign a lesser weight to such information when a decision needs to be made, remain doubtful and open-minded about the subject, and adjust their decisions if an expert's opinion or new evidence becomes available. If unverifiable information needs to be used to inform health-related decisions, health information users need to treat it as nonfactual and take necessary precautionary steps, such as careful estimation of potential harms and benefits as well as thorough consultation with clinical experts.

Framework for Defining Harmful Health Misinformation

The challenge of misinformation is a daunting one, and unfortunately, it is a problem that is here to stay. With the advent of social media and the ease of sharing web-based information, false and misleading health information spreads rapidly and has significant consequences for public health. Despite the ongoing efforts of researchers, public health officials, and technology companies, misinformation continues to persist and is becoming increasingly difficult to combat. This complex issue requires a multifaceted approach involving education, technology, and policy interventions. To create effective strategies and mitigate the negative impacts of misinformation, we must prioritize interventions that are both evidence-based and realistically implementable. This requires a systematic approach that includes classifying different types of misinformation. Gaining a comprehensive understanding of the various manifestations of misinformation enables us to develop targeted interventions

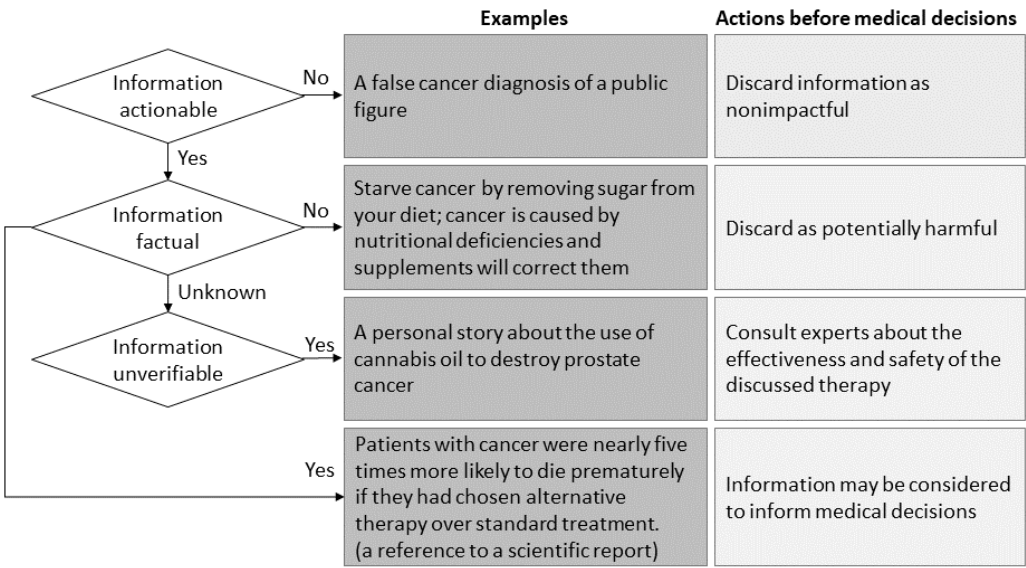

that systematically address persistent issues and effectively curtail the dissemination of false or harmful information.

The framework presented in [Figure 1](#) is designed to assist health information users in classifying information and guide them on how to approach verifying health information that could mislead their decisions. The framework focuses on 3 characteristics of information: actionability, facticity, and verifiability. If something is not actionable, it may be considered unimportant and can be discarded. Facticity is an essence that information users aim to achieve. However, identifying facticity can be challenging, and in some cases, it may be impossible due to the lack of available evidence or knowledge. Therefore, the third component—unverifiability—is included in the framework. To address unverifiable information effectively, it is recommended to seek expert opinions on the potential risks associated with the information. In contrast to other frameworks, our approach is founded on the principle of observability and strikes a balance between comprehensiveness and simplicity.

Thus, this framework is user-friendly and could be applied by various stakeholders to combat health misinformation. For instance, individual users can learn from the framework that if they are unsure about the accuracy of information, they should label it as unverifiable and seek expert opinion instead of continuing to search for more information, which may lead only to confusion or false confidence. Researchers developing

algorithmic detection of misinformation can flag both nonfactual and unverifiable information to safeguard health information users from futile verification attempts. Clinicians can use the framework during patient encounters to initiate conversations on how to approach information evaluation and identify harmful misinformation. They can encourage patients to consider not only facticity but also information’s actionability and verifiability to help patients prioritize the strategies of information vetting. Further, they could emphasize the uncertainty of outcomes behind unverifiable information to ensure that patients make truly informed decisions. With this framework, policy makers are better equipped to introduce the concept of uncertainty behind scientific evidence that informs public health policies. Specifically, policy makers can provide clarifications on which aspects of information should be deemed actionable and which aspects are currently unverifiable. The approach will enable the public to remain receptive and amend their decisions in response to new evidence. Overall, the framework aims to unite health information users, researchers, clinicians, and policy makers in their effort to develop a comprehensive system that helps detect and combat health-related misinformation. This systematic approach enables us to create a more informed and empowered society, one that is better equipped to identify and combat the negative effects of health misinformation.

Figure 1. Health information classification.

Acknowledgments

We thank Brian Southwell, PhD, and Dmitry Fridman, MD, for their comments and ideas. We are thankful to University of North Carolina patient advocates for their feedback on the proposed framework.

Conflicts of Interest

JEL receives grant funding from Genentech. The other authors declare they have no conflicts of interest.

Abstract

Digital health is an expanding field and is fundamentally changing the ways health care can be delivered to patients. Despite the changing landscape of health care delivery, medical trainees are not routinely exposed to digital health during training. In this viewpoint, we argue that thoughtfully implemented immersive elective internships with digital health organizations, including start-ups, during residency are valuable for residents, residency programs, and digital health companies. This viewpoint represents the opinions of the authors based on their experience as resident physicians working as interns within a start-up health navigation and telehealth company. First, residents were able to apply their expertise beyond the traditional clinical environment, use creativity to solve health care problems, and learn from different disciplines not typically encountered by most physicians in traditional clinical practice. Second, residency programs were able to strengthen their program's educational offerings and better meet the needs of a heterogeneous group of residents who are increasingly seeking nontraditional ways to learn more about care delivery transformation. Third, digital health companies were able to expand their clinical team and receive new insights from physicians in training. We believe that immersive elective internships for physicians in training provide opportunities for experiential learning in a fast-paced environment within a field that is rapidly evolving. By creating similar experiences for other resident physicians, residency programs and digital health companies have a key opportunity to influence future physician-leaders and health care innovators.

Introduction

Digital health is an expanding field and promises to be a significant disruptor of health care delivery [1]. Although the use of technology in health care has been percolating for several decades, the field of digital health has exponentially grown with new medical technology, creation of health policy innovation centers, and invigorated private sector interest in health care. The global digital health market is projected to grow from US \$183 billion in 2020 to US \$509 billion by 2027 [2], and in the

United States, digital care and telehealth have the highest compound annual growth rate among all segments of digital health [3]. This boom in digital health is fundamentally changing the ways health care can be delivered to patients.

Despite the changing landscape of health care delivery and practice, medical trainees have not traditionally been exposed to digital health during training, and residency programs have not kept pace with opportunities to train physician-innovators in digital health. Currently, digital health education in medical training appears to be sparse, and it primarily takes the form of

elective curricula for medical students [4,5]. This lack of exposure during the formative years of shaping medical practice can limit awareness of the changing landscape of practicing medicine.

The inherent flexibility of using an elective internship to learn more about digital health aligns well with the ever-changing digital health care landscape. However, immersive experiential learning opportunities like this, which go beyond traditional medicine, are uncommon in residency.

Resident physicians are uniquely positioned to benefit from an immersive elective internship at this point in their medical training; they have more substantial clinical experience than medical students, but they are not yet fully ingrained in the traditional health care system’s mindset and still maintain some level of career path flexibility. In this viewpoint, we argue that immersive elective internship experiences with a digital health company should be considered by resident physicians eager for unique, hands-on learning opportunities in care delivery transformation outside of usual residency training. We share our experiences in setting up an elective internship program for resident physicians at a start-up digital health company and summarize the benefits and learnings of the experience for resident physicians, residency programs, and digital health companies.

The Implementation and Structure of 3 Immersive Elective Internships Within a Digital Health Start-Up Company

We designed an immersive elective internship for 3 resident physicians from the University of California, San Francisco with interests in digital health and care delivery transformation. The internship involved working experientially as clinical strategy interns within a start-up telehealth and health care navigation company (Included Health). Participants included 2 internal medicine residents and 1 pediatrics resident. These 3 internships took place between April 2019 and January 2022, in 4- to 6-week rotations.

The origins of this internship program arose organically from conversations between the resident physicians and a leader in

this digital health organization who is also an adjunct faculty member at University of California, San Francisco. Through sharing interests, experiences, and common goals, we found that there was an opportunity to set up an internship at this digital health organization in the clinical strategy group.

To establish the internship program, we worked closely with the leadership of the residency program and the digital health organization to develop a proposed elective structure and curricular objectives. The curricular objectives were designed to align with fulfilling core competencies outlined by Accreditation Council for Graduate Medical Education, as summarized in Table 1 [6]. Our residency program leadership worked with the digital health organization and our institution’s Office of Graduate Medical Education to enable internships structured as elective rotations in residency. Residency program graduation requirements and medical responsibilities of a hospital limited the internship to 4-6 weeks in duration.

We also made efforts to identify a dedicated internal mentor within the digital health organization for the resident physicians participating in the program. The mentor was a physician-leader in the organization who inherently understood the background, knowledge, and skills of resident physicians. This was beneficial for optimizing the learning experience and ensured that the resident physicians were efficiently deployed to well-scoped projects. The mentor met with the participating residents before each internship to shorten the onboarding learning curve and worked closely with the residents throughout the duration of the internship to guide them in their work.

All 3 internship experiences were designed to meet the outlined curricular objectives. The specific content of each internship experience was significantly shaped by the digital health organization’s strategic and operational priorities during the respective period of each individual internship. The initiatives worked on by the resident physician interns included the development of pediatric care management programs, the design of integrating pharmacy services into telehealth primary care, the analysis of clinical patterns for telehealth primary care and behavioral health services, and the clinical vetting of telehealth and hybrid primary care service competitors. This work often entailed data analysis, clinical shadowing, secondary research, stakeholder interviews, and various other tasks.

Table 1. Designed curricular objectives aligned with Accreditation Council for Graduate Medical Education (ACGME) Core Competencies for resident physicians interning for 4-6 weeks at a digital health start-up organization.

Objectives	ACGME Core Competencies
Deepen knowledge of patient-facing challenges in health care navigation and access to care and apply to outpatient and transition-of-care clinical practice	<ul style="list-style-type: none">• Medical knowledge• Patient care
Learn the practice of implementing and assessing new interventions to affect downstream patient outcomes	<ul style="list-style-type: none">• Practice-based learning and improvement
Develop knowledge of health care navigation ecosystem and resources	<ul style="list-style-type: none">• Systems-based practice
Work effectively with interdisciplinary, cross-functional members and create deliverables for relevant stakeholders associated with the assigned project	<ul style="list-style-type: none">• Interpersonal and communication skills• Professionalism

The Value of Immersive Elective Internships During Residency

Based on our experience and supporting research, we believe there are multiple benefits of an immersive elective internship experience in digital health for residents, residency programs, and digital health organizations, including start-ups.

Benefits and Learnings for Resident Physicians

All participating resident physicians agreed that the experience provided abundant hands-on learning in a fast-paced environment during a short time and that they were able to apply their knowledge of patient care delivery to their internship experiences. Moreover, all concurred that the internship was highly formative in influencing how they considered next steps in their careers as practicing clinicians. Voluntary qualitative feedback by participating resident physician interns highlighted the following key lessons learned by residents during the internship that can be applied to their future careers.

First, the immersive internship allowed resident physicians to recognize how physician-leaders can apply their expertise in many ways beyond the traditional clinical environment. Participating residents worked with physician-leaders in the organization who played various roles, ranging from setting clinical strategy to leading clinical care delivery. According to one resident, “What struck me the most was the variety of ways that physicians can lend their clinical expertise to create impact within different functions.”

Second, residents learned to collaborate with a diverse range of disciplines to solve health care problems. This experience provided the first opportunity for most residents to work closely with individuals from disciplines that are not typically encountered in the traditional clinical practice of a physician. From data scientists, product managers, designers, and engineers, residents learned about opportunities and challenges for designing solutions for patients and clinicians. Although many large health systems often employ individuals with backgrounds in these fields, physicians rarely have the opportunity to closely interact and collaborate with these disciplines on a daily basis to work toward a common goal. This immersive internship allowed physicians in training to enhance their skills in team-based professionalism and communication [6].

Third, residents were able to experience how creativity can be used to approach health care problems in new ways. Traditional training in medicine tends to emphasize the role of repetition, pattern recognition, and clinical reasoning based on a repertoire of memorized facts and knowledge. Participating resident physicians agreed that they could see how novel approaches and design thinking were employed to approach problems in health care, such as improving patient messaging and clinical workflows to be more patient-centric and user-friendly. According to one resident, “I saw more discussions asking ‘what if?’ and ‘how should we?’ rather than ‘how can we make this

work within existing constraints?’ and it felt like a shift in the default mindset that I am used to.”

Benefits and Learnings for the Residency Program

Residency programs that develop an opportunity for an immersive elective internship program at digital health start-ups may strengthen their program’s educational offerings and development of their resident physicians in several ways. First, residents may be able to gain valuable skills applicable to residency training from an immersive elective experience. A recent survey of residency program directors found that more than two-thirds of respondents believed that physicians in training can gain communication and leadership skills, organizational and team-based skills, and the ability to innovate from start-up experiences [7]. Second, an increasing number of residency program applicants are entering residency with entrepreneurial experience and interest in digital health [7,8]. Providing the opportunity for an elective internship at a digital health start-up during the course of residency training can help programs meet the interests of an emerging generation of physicians in training. Finally, offering this opportunity for cross-functional training outside of the traditional clinical setting aligns with an increasingly broader call for new training opportunities in leadership for physicians. Some argue that traditional settings are no longer sufficient for developing physician-leaders and that it is crucial for leaders to engage today’s physicians in training in experiential learning to embrace their eagerness for innovation and ultimately encourage system transformation [9-11].

Benefits and Learnings for Digital Health Organizations

Digital health organizations, including start-ups, can benefit from a resident physician immersive internship program. Physicians in training can bring a new perspective to the company by applying their up-to-date knowledge of clinical practices, recent experiences of care delivery, and intimate knowledge of both physician and patient needs [10]. For example, one resident physician was able to provide examples in her internship for how certain patients with specific disease processes may benefit from interacting with chatbots to triage clinical concerns. Resident physician interns also provide the digital health organization with the advantage of expanded capacity to tackle specific, time-bound projects of high priority. As another example, having a resident physician involved in the design of pharmacy service integration into telemedicine-based primary care services proved beneficial by providing the perspective of a clinician who may prescribe medications in various scenarios.

Creating Opportunities for Immersive Elective Internship Experiences During Residency

As the field of digital health is constantly evolving and rapidly changing, elective internships for physicians in training provide opportunities for immersive experiential learning in a fast-paced

environment. The impact of the internship can stretch far beyond the dedicated immersive experience alone; it can influence career steps and serve as a launching point for cultivating physician-leaders who can meaningfully engage across the traditional and digital health landscapes. By creating more experiences like this for other resident physicians, residency programs and digital health organizations have a key opportunity to influence physician-leaders and health care innovators of the future.

Abstract

Background: The COVID-19 pandemic altered how residency interviews occur. Despite 2 years of web-based interviews, these are still perceived as inferior to in-person experiences. Showcasing a program and location is critical for recruitment; however, it is difficult to highlight the program's location and community digitally. This article presents the authors' viewpoints on designing and implementing a virtual second look for residency applicants.

Objective: Our objective was to host a web-based event to feature the benefits of living in Winston-Salem, North Carolina, for residency applicants, enhance recruitment efforts, and ensure a successful residency match. The goal was to cover topics that interested all applicants, highlight how Winston-Salem is a special place to live, involve current residents, and engage community members.

Methods: Three programs—child neurology, neurology, and family medicine were chosen for a pilot virtual second look. All residency program directors' were asked to recommend community contacts and help identify residents and faculty who may serve as content experts on one of the topics in the panel discussions. A total of 24 community leaders from restaurants, venues, schools, and businesses were contacted, and 18 agreed to participate. The panel discussions included living in and raising a family in Winston-Salem, experiencing Winston-Salem arts and music, where to eat and drink like a local, and enjoying sports and outdoors in the area. The 2-hour event was hosted on Zoom. Postevent feedback assessments were automatically sent to each registrant through Research Electronic Data Capture (REDCap). This study was deemed exempt from Wake Forest University Health Sciences institutional review board review (IRB00088703).

Results: There were 51 registrants for the event, and 28 of 48 registrants provided postevent feedback, which was positive. The authors found in the MATCH residency results that 2 of 2 child neurology positions, 4 of 6 adult neurology positions, and 1 of 10 family medicine positions attended our second look event. One adult neurology resident who did not participate was an internal candidate. All respondents agreed or strongly agreed that the session was valuable, well organized, and met their expectations or goals. Furthermore, all respondents gained new information during this web-based event not obtained during their interview day.

Conclusions: The virtual second look event for residency attendees featured the benefits of living in Winston-Salem, and the perspectives of current residents. Feedback from the session was overall positive; however, a top desire would be devoting more time for the applicants to ask questions directly to the community leaders and our resident trainees. This program could be

reproducible by other institutions. It could be broadened to a graduate medical education-wide virtual second look event where all medical and surgical programs could opt to participate, facilitating an equitable opportunity for prospective applicants.

Introduction

Background

In March 2020, the COVID-19 pandemic disrupted typical medical education operations. Only 6 days after declaring a global pandemic, the Association of American Medical Colleges (AAMC) recommended ceasing all medical student clinical rotations [1,2]. In addition, by May 2020, AAMC announced the recommendation of web-based interviews for the 2021 match season [3].

Social media swiftly became an essential focus in digital recruitment, with a significant rise in residency program social media accounts during the pandemic [4-6]. Programs used social media to offer glimpses into the day-to-day life of residents, provide resident spotlights, share resident wellness initiatives, and advertise web-based open houses. In addition, programs developed web-based events before and during interview dates. These often featured program leaders and residents, video overviews of the community, or hospital tours to highlight the lifestyle and location in their regions.

Social interactions, work-life balance, and location culture are priorities for applicants [7]. Applicants felt social media created transparency, relayed values, and potential fit of the program. However, a survey of child neurology residency programs suggested web-based interviews were still perceived as inferior to in-person experiences. Additional challenges occur for programs in smaller or midsize towns that applicants may be less familiar with or have never visited. Showcasing the program and location becomes more critical for recruitment; however, it is difficult to highlight the program's location and community in the web-based setting [8,9].

Wake Forest University School of Medicine (WFUSOM), headquartered in Winston-Salem, North Carolina. Since the founding of the medical school in 1902 and the medical center in 1923, Wake Forest has grown into a nationally recognized academic medical center and health care system. The catchment area is a 24-county region, including western North Carolina and Southwest Virginia, extending to Tennessee and West Virginia. The hospital is the largest tertiary care center for the Piedmont region of the Southeast. However, Winston-Salem is a midsize city with an estimated population size of 250,000 [10].

The AAMC recently recommended a third season of web-based recruitment [11]. However, how do programs adequately reflect the culture and locale through a digital lens? To address this gap, we created a virtual second look event for our institution's child neurology, neurology, and family medicine applicants. This article presents the authors' viewpoints on designing and implementing a virtual second look for residency applicants.

Objective

The Graduate Medical Education (GME) Committee at WFUSOM recognized that there was a need to feature the benefits of living in Winston-Salem to applicants. Therefore, the GME invited one program's leadership (authors LDS and JMM) to plan a web-based pilot event with 3 residency programs. Our aim was to host a successful web-based event to feature the benefits of living in Winston-Salem for residency applicants, enhance recruitment efforts, and ensure a successful residency match. Each program has hundreds of applicants, so the event would need to be scalable to a larger potential audience in the future if the initial session was a success. The web-based offering would cover topics that interest applicants, highlight how Winston-Salem is a special place to live, involve current residents from various programs, and engage community members.

Methods

Program Development

LS, an executive member of the GME and program director of the child neurology residency, presented to the GME in the August of 2021 to propose objectives, dates, and timelines. All residency programs were invited, and the first 3 programs that responded were included in the pilot: child neurology, neurology, and family medicine. A planning committee was formed, including authors JMM, NC, and LDS and GME specialist Mikell White. Four themes were identified from collective feedback following a presentation at a GME meeting with program directors and from discussions with adult neurology and child neurology residents (1) living in and raising a family in Winston-Salem, (2) experiencing Winston-Salem arts and music, (3) where to eat and drink like a local, and (4) enjoying sports and outdoors.

A planning committee was formed with GME and program leaders. As a result, a date was chosen on a Friday in February 2022 to not conflict with interview dates and to reflect a typical working day for community members. Additionally, this date was chosen to allow programs to have submitted their rank list yet allow applicants to have time to adjust their decisions. Logistically, this also allowed enough time to finalize an agenda and attendees from the community.

Program directors from all residency programs were asked to recommend contacts for the community and help identify residents and faculty who may serve as content experts on one of the topics in the panel discussions. The event was free. None of the participants or community partners were compensated for their time.

Authors LDS and JMM partnered with a local tourism company to identify a speaker to introduce the Winston-Salem tourism industry and develop contacts for the community leaders and organizations. A final agenda, including panelists, was reviewed for content with our GME executive team. The GME had already held a successful web-based Diversity and Inclusion event led (led by authors AKB and NDT) for invited underrepresented minorities, so careful consideration was made not to overlap in content ([Multimedia Appendix 1](#)). Our Accreditation Council for Graduate Medical Education (ACGME)-designated institutional official and associate dean of GME for the WFUSOM (author MS) were invited to present about the GME programs and shared resident resources.

A total of 24 community leaders from restaurants, venues, schools, and businesses were contacted, and 18 agreed to participate as panelists. Individual meetings were arranged with each community leader to share the prospective resident interests and help narrow the focus of their discussion during the panel session. This connection helped answer questions about the target audience and why we recruit them. The authors also used this time to propose questions and learn about opportunities in the community for residents. Consent was received from all community leaders to include their organization's brand in our advertisements and communications with invited applicants.

This process took several weeks and occurred between November 2021 through January 2022. The authors added faculty moderators (n=4) from the school of medicine and resident panelists (n=4) from neurosurgery, neurology, child neurology, and family medicine residency programs.

A web-based brochure included photos, bios, social media contacts, and website resources. This brochure was an aid for the moderators to learn more about panelists and a guide shared with all applicant attendees to learn more about the community. The brochure was reviewed with all participants before being shared with applicants.

The session ([Textbox 1](#)) was designed to be short and fast-paced over 2 hours to optimize applicant attendance. The session was hosted within the Zoom videoconferencing platform with 2 GME program coordinators available for technical support. The panelists were expected to check in 15 minutes before their panel discussion and stay for the duration of their discussion, keeping their commitment time to less than 1 hour. A full agenda was shared with moderators, including a full script of anticipated questions for panelists. Panelists received their questions over email the week of the event to allow them to anticipate their area of focus. Each panelist received guidance on the length of time per question and was given 1-2 questions.

Textbox 1. Outline of the virtual second look program.

Welcome presentation (30 minutes)

- Introduction: Child Neurology Program Director
- Welcome: Wake Forest University School of Medicine's Graduate Medical Education Designated Institutional Official
- History of Winston-Salem: Local Visitor Center Director of Marketing and Communications
- Schedule introduction: Child Neurology Associate Program Director

Panel 1: Living in and raising a family in Winston-Salem (30 minutes)

- Panelists: family medicine resident, child neurology resident, resident spousal association leader, local gymnasium president, local sports chief executive officer, city's recreational special events coordinator
- Moderator: Adult Neurology Program Director

Panel 2: Experiencing Winston-Salem arts and music (20 minutes)

- Panelists: conductor of the local medical orchestra and current medical student, local boarding school teacher, local music venue owner and cofounder, University of North Carolina School of the Art director of media relations and communications, local arts council director
- Moderator: Adult stroke neurologist

Panel 3: Where to eat and drink like a local (20 minutes)

- Panelists: neurosurgery resident, local restaurateur, local restaurant and bar assistant general manager, local vineyard co-owner, local brewery manager
- Moderator: Child Neurology Program Director

Panel 4: Enjoying sports and outdoors (20 minutes)

- Panelists: Family medicine resident, University sports executive associate athletic director, Winston-Salem Open Tournament director, area minor league baseball president and general manager, city parks and recreation special projects coordinator, local district director for community relations
- Moderator: Child Neurology Associate Program Director

Wrap-up: All moderators (5 minutes)

To minimize bias of attendance on the rank list, the adult and child neurology program submitted their finalized rank list before the web-based event. The family medicine program director was not present at the event nor given a list of attendees. Applicants present were not required to turn on their cameras or show their names, although many applicants opted to do so.

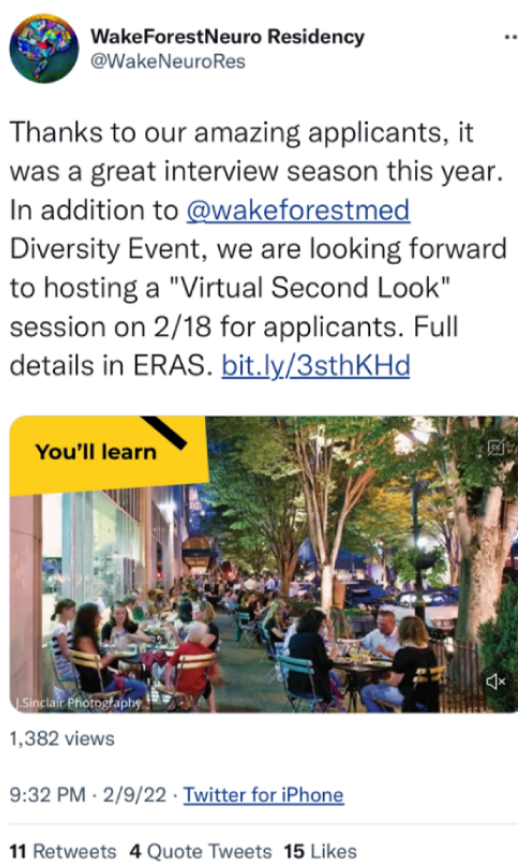

A welcome room allowed necessary audio or visual testing to minimize disruption. All moderators and panelists had their cameras turned on with listed names and organizations.

Advertising Methods

Finalizing the panelists and general agenda was necessary before advertising to applicants, which led to a shorter advertisement period. The event was advertised on social media and through

an Electronic Residency Application Service (ERAS) communication. On February 09, 2022, an ERAS communication was sent by the program directors of the included programs inviting all interviewed applicants to register. ERAS invites were sent to 50 child neurology, 100 adult neurology, and 167 family medicine applicants. On the same day, a promotional PowToon video created by JMM was posted on the Wake Forest Neurology Residency Twitter account @WakeNeuroRes (Figure 1). This is a combined adult and child neurology social media account run by LS. The post had 11,100 impressions, 15 likes, 4 quote tweets, 11 retweets, 1398 video views, and 8 link clicks. While the family medicine program does have a Twitter account, it was not promoted by social media as this account is not frequently used.

Figure 1. Twitter advertisement of virtual second look event.

Assessment Methods

Applicants were emailed a Zoom link for the event upon successful registration through Research Electronic Data Capture (REDCap), which included demographics, which residency program they were applying to, the applicant's goals for the event, and how the applicant heard about it (Multimedia Appendix 2). Registrants could opt in to have their deidentified data included in the results.

Postevent feedback assessments were automatically sent through REDCap to each of the registrants. The initial feedback request was sent immediately after the web-based event. Automatic weekly reminders to complete the feedback were sent through REDCap for 1 month following the event. Feedback assessments

(Multimedia Appendix 3) evaluated the presenters, the content organization, the degree to which expectations were met, and the value of each session and the overall event (Kirkpatrick Level 1). We also evaluated whether new information was gained from the web-based session compared to the web-based interview day (Kirkpatrick Level 2). Applicants were asked to rate each question on a 1-5 Likert scale, with 1=strongly agreed and 5=strongly disagreed. Additionally, applicants provided their top 3 highlights for the events and any suggestions for future improvements.

Ethical Considerations

This study was deemed exempt from Wake Forest University Health Sciences institutional review board review (IRB00088703).

During event registration, participants were asked “Do you consent to us using your deidentified data for future event planning and research purposes? This will not affect your ability to register or participate in the event.” Registrants could opt-in to have their deidentified data included in the data analysis. Written consent was not obtained. Study results were published in lieu of providing individual subjects with additional information regarding the study. Participants were not compensated.

Confidentiality was protected by collecting only information needed to assess study outcomes, minimizing to the fullest extent

possible the collection of any information that could directly identify subjects, and maintaining all study information in a secure manner.

Results

Demographics

Between initial advertising and the event date (February 9-18, 2022), there were 51 registrants for the event. Forty-eight consented to have deidentified data included for future event planning and research purposes (Table 1). Most registrants heard about the event through ERAS communication rather than other modalities. Thirty-eight registrants requested a complimentary informational packet about the area through the local visitor center. A heat map using the provided zip codes is included in Figure 2. Most registrations resided in the Southeast; however, some registrants digitally attended nationwide.

Figure 2. Heat map of registrants.

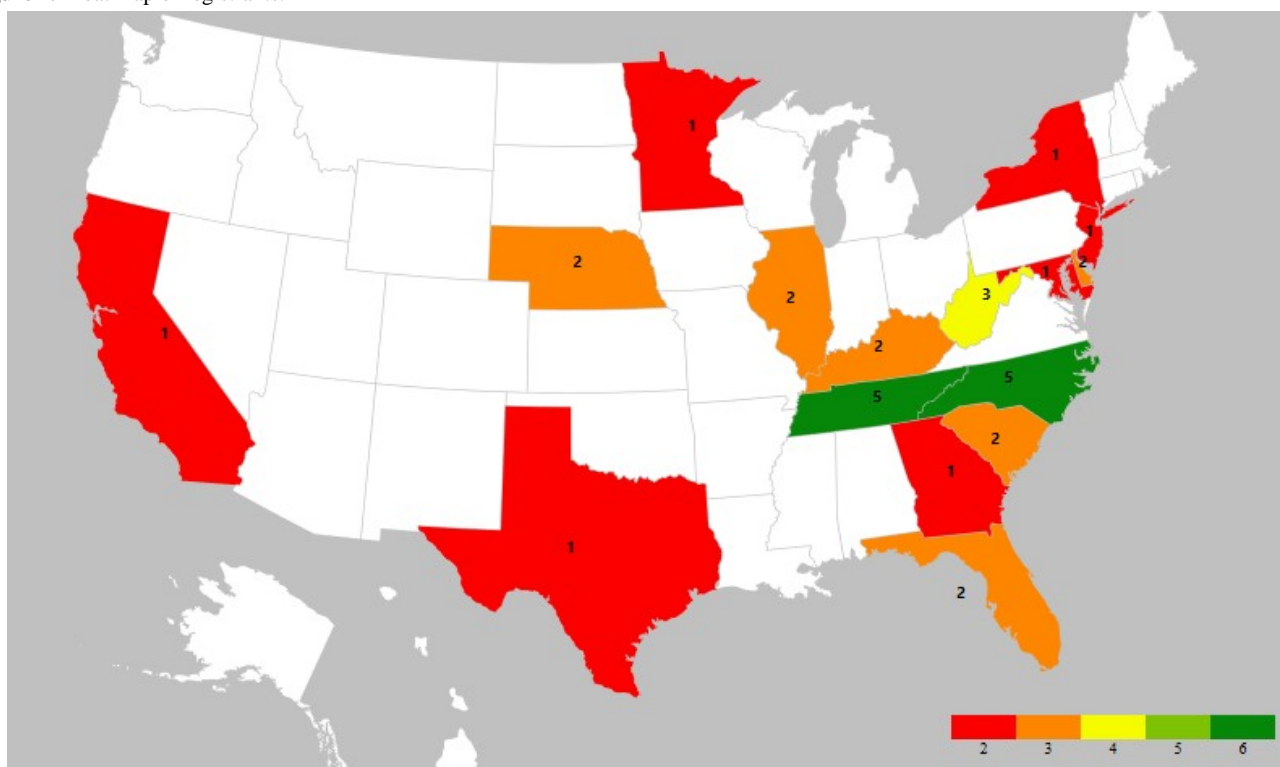

Table 1. Demographics of registrants (n=48).

Characteristics	Participants, n (%)
Age (years)	
20-30	45 (93.8)
31-40	3 (6.3)
41-50	0 (0)
≥51	0 (0)
Race	
American Indian or Alaska Native	0 (0)
Asian	12 (25)
Black or African American	6 (6.3)
Native Hawaiian or other Pacific Islander	0 (0)
White	32 (66.7)
Not disclosed	1 (2.1)
Ethnicity	
Hispanic or Latino	0 (0)
Not Hispanic or Latino	44 (91.7)

Social Media	1 (2.1)
Email	14 (29.2)
Word of mouth	4 (8.4)

^aERAS: electronic residency application service.

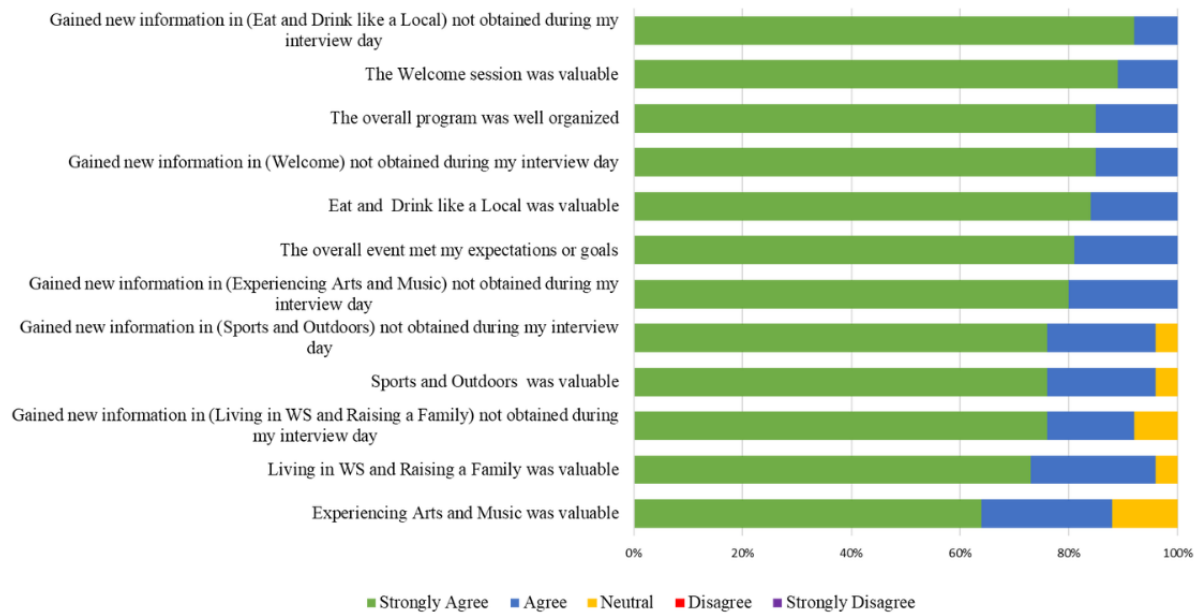

Pre-Event Expectations or Goals

Registrants indicated their goals for attending the virtual second look event during registration. Most attendees wanted to learn more about living in the community (45/48, 94%) and learn from current residents about their experience (42/48, 88%). However, learning about the culture of Winston-Salem (34/48, 71%) and restaurants, bars, and wineries (33/48, 69%) were other top priorities for attending the event. Learning about raising a family in the Winston-Salem community was rated the lowest, with only 21% (10/48) of registrants identifying it as a goal for attending the event.

Postevent Feedback

We received a postevent feedback response rate of 58% (28/48) of registrants. Overall, the feedback was overwhelmingly positive. All respondents (28/28, 100%) agreed or strongly agreed that the session was valuable, well organized, and met expectations or goals. Additionally, all respondents (28/28, 100%) agreed or strongly agreed that new information was gained during the event about restaurants, bars, arts, music, and the welcome session that was not provided during the interview days. While it still felt valuable, there were more mixed responses to the arts and music panel and the living and raising a family in the area panel (Figure 3). On a scale of 1-10, 1=not effective and 10=very effective, respondents reported a mean of 8.6 level of effectiveness for this event (minimum 7, maximum 10, median 8).

Figure 3. Postevent feedback. WS: Winston-Salem.

Qualitative Feedback

Respondents also provided their top 3 highlights and suggestions for future event improvements. JMM developed a codebook of relevant concepts and emerging themes. Two team members coded all comments (JMM and RAC), and coding discrepancies were discussed and resolved. We analyzed the comments using deductive thematic content analysis practices to identify themes and subthemes [12].

The top 3 themes for event highlights included hearing about entertainment or things to do, the living and culture of Winston-Salem, and personal experiences (Table 2). Respondents predominantly highlighted learning about local food and drink options. They also enjoyed personal experiences, particularly from residents. The overall organization, energy, and variety of the event were positive.

Table 2. Top themes from respondents on event highlights.

Themes	Supportive quotes
Entertainment or things to do	<ul style="list-style-type: none">I appreciated hearing about the local places for foodHearing of the food options, common places to live, and great places to take family should residents have children.I enjoyed hearing from the business owners from the area. I feel like this is unique to Wake Forest and this second look. I appreciated hearing about the local places for food. I am very interested in visiting the llama winery!
Living in and the culture of Winston-Salem	<ul style="list-style-type: none">It gave us an idea of where people like to live and also how connected the community isExperiencing the culture of Winston-Salem and hearing about why it is a special place to liveInclusivity of potential schooling, gyms, and other amenities required for residents with families
Hearing personal experiences	<ul style="list-style-type: none">The personal experiences of everyone living in Winston-SalemFirst, it was extremely valuable to hear a resident state the location of a popular area for incoming residents to live in (Ardmore discussion).The different conference sessions, particularly asking current residents questions
Variety of community speakers and topics	<ul style="list-style-type: none">The involvement of so many members of the community and their direct point of view. All the people seemed very nice and welcoming.Involvement of people from the community outside of the hospital and school, learning about music and art events and learning about how diverse Winston-Salem isJust hosting this was a standout compared to the other programs. Including community members and talking about life in Winston-Salem in different stages was great and really helped show either how well Wake Forest is regarded or how community-focused the town of Winston-Salem is.
The energy of the event	<ul style="list-style-type: none">The interests of everyone who attended allowed for a very organic conversation during presentations.Seeing the people of Winston-Salem being so enthusiastic about promoting the city!I enjoyed everyone's positive attitude.

The event feedback was overwhelmingly positive. The top theme for feedback was allowing more time for questions. While

respondents did have the option to use the chat function for questions, this was not used. Additional improvement themes

included increased interaction or breakout sessions, hearing more from residents, and more visuals of the hospital or area (such as web-based tours, photographs, etc).

Match Results

The authors recognize that the second look event likely attracted a group of applicants more interested in the participating programs. We found in the MATCH residency results that 2 of 2 child neurology positions, 4 of 6 adult neurology positions, and 1 of 10 family medicine positions attended our second look event. One adult neurology resident who did not participate was an internal candidate.

Discussion

Principal Results

The recent transition to web-based interviewing has increased interest in developing and expanding web-based content for applicants in various interactive and passive formats. Through this interactive pilot program, we learned that there was high interest from many residency programs to have a GME-led effort on commonly shared needs. Enthusiasm was high for this program even in the first year, making limiting it to only 3 programs in our pilot challenging. Although the content was generalizable to all residency programs, there must be careful consideration of possible challenges in scaling up the number of programs included. A higher volume of attendees could add unanticipated difficulties. In addition, several matches, including the medicine specialty match and fellowship matches, occur throughout the year, so expansion of programming would need to be mindful of timing.

We heard from program directors, residents, and applicants that this was a unique opportunity to add resident and faculty voices that may not be present on an individual program's web-based interview day. The authors note smaller programs can leverage partnerships with more extensive residency programs. A positive effective resident communicator could help recruit for other residency programs.

Previous in-person and most web-based interview days do not typically include interactive participation from the GME. Our model allowed the GME to share resources directly with applicants. The GME leader spoke about our training institutions' health, growth, and variety.

Community partners also found the experience to be mutually beneficial. This was seen as a way to help advertise and showcase their opportunities directly to the end user. Most community partners connected us with the owner, the lead of marketing or communication, or the head of programming. Some applicants may choose our health system for residency. However, community leaders saw this as a way to promote our city for future travel or encourage residents to consider our health system again for future fellowship or faculty positions.

Additionally, our faculty reported that it was engaging to see the community partners share their experiences as experts in that content area and cater to a broader audience of varied interests. Program leadership or interviewing faculty may need to learn the answers to some applicant questions because of

their interests or community experiences. Of note, although we invited several daycares and preschools, unfortunately, we could not have representation due to the time chosen.

We used REDCap for our invitation and sharing of content, including our web-based brochure and event surveys. REDCap had additional benefits as it allowed registering attendees to sign up without involving our GME staff as it was automated. It also created a list of all those registered that allowed us to follow up on Match and the possible effects of the second look on recruitment. Careful consideration must be given to confidentiality and minimizing the risk of bias on rank list decisions. Options could include finalized rank list submissions for participation in the virtual second look event or blinding the programs from participants.

We had several residents and programs ask to share the content following the event so it could continue in the future as a passive format option to expand our reach. Unfortunately, we did not plan on recording the event and could only make the welcome presentation available. A recording of the event may prove valuable in faculty or resident onboarding.

The majority of the feedback for the sessions was positive. However, some feedback included that the sessions on raising a family and sports and outdoors could have been more valuable. Raising a family was a lower priority for many individuals attending the session initially, likely reflective of different stages of their lives. No specific narrative comments were provided on either of these sessions in the feedback for suggested improvements. The art and music session was also not rated as valuable as the other sessions. In the future, we could modify the types of community members and organizations invited to the sessions to engage and entertain a diverse audience of all ages and stages of life.

The advantages of this event are that it is cost and time efficient for applicants and allows applicants not to take time off from their clinical rotations at their home institution. In addition, having a virtual second look decreases barriers among prospective applicants by giving everyone an equitable opportunity to learn about WFUSOM and the Winston-Salem community.

Limitations

There were several limitations to this study and event. This is the experience and viewpoints of the authors at an academic center in a moderate city. This may not be generalizable or meet the needs of all institutions. One limitation is the applicant's ability to access reliable internet and the appropriate technology to attend the event. It also requires time off from clinical duties for the duration of the event. Despite being a high-yield overview of Winston-Salem, it may not highlight the desired aspects for all applicants. Additionally, although virtual second looks facilitate equity, some applicants may prefer to travel to the area to learn more about Winston-Salem.

Regarding the feedback, selection bias may be a limitation. Most of the feedback was positive, and those who enjoyed the event were often more likely to provide feedback. Although narrative comments were requested, there could be more purposeful questioning as to why specific sessions were rated

higher or lower. Feedback on the event was requested during a period when programs were submitting their rank lists. While both the adult and child neurology programs had submitted their rank list and the attendee list was not shared with the family medicine program directors, being more transparent with this process may reduce concerns about attendance influencing programs' rank list. Alternatively, the feedback survey could be sent after the ranking was closed balancing timing to the event to risk the loss of survey participation.

Additionally, those more interested in WFUSOM may have been more likely to attend the virtual second look in the first place. As the child and adult neurology program leadership were involved in creating the event, they could promote the event during their interview season and advertise it on social media. This may have influenced more attendees from these 2 programs over family medicine for the first year. Furthermore, as we waited for a finalized agenda before promoting the event, the advertising period needed longer. This affected the number of applicants and programs we were involved in during our first year of the virtual second look event. Longer and more strategic advertising would increase the reach of recruitment of applicants to attend the virtual second look. Additionally, broadening to a GME-wide virtual second look event where all medical and surgical programs could opt to participate would facilitate an equitable opportunity for prospective applicants.

Conclusions

The virtual second look event was valuable for child neurology, neurology, and family medicine attendees. It featured the benefits of living in Winston-Salem and the perspectives of current residents. It filled a gap faced in the web-based environment of how to showcase a city and institution. The program has the potential to be expanded to more residency programs at the WFUSOM with the advantages of decreasing barriers among applicants, including the cost of travel and time away from clinical rotations at home institutions.

Future Directions

Feedback from the session was overall positive; however, a top desire would be devoting more time for the applicants to ask questions directly to the community leaders and our resident trainees. In our first year, we had most of the questions scripted; however, with continued partnership with our community leaders, preparing for open questions in future years would be easier. In addition, time could be set aside for applicants to ask questions directly to the panelists, making the session more interactive for applicants, community leaders, and resident trainees. Future sessions could be recorded so applicants unable to attend could still receive the information and benefits of the session.

Future evaluations of the second look event could assess whether registrants are attending because they are precontemplative, contemplative, and already familiar with the area. Additional areas of interest would include how such an event influences their rank-list decision-making, their decision to attend in-person second look events, and granular feedback about the event itself. Furthermore, comparing the demographics of web-based event attendees to program interviewees, applicants, or the GME demographics as a whole to evaluate the effect of the program on these factors over time would be valuable.

There could be other ways to advertise to increase registration. We learned from our recruitment data that most applicants discovered the event through regular ERAS communication from the programs. Suppose the date is selected far in advance. In that case, it could be shared with applicants during the interview season through web-based interview day discussions, the residency program website, and the GME website. The session could also be scheduled earlier in interview season so applicants could learn more about the Winston-Salem community before ranking their residency choices and help highlight the benefits of our residency program. However, this would need to be carefully balanced bias towards or against applicants while rank lists were open. Last, this program could be expanded to more specialties at the WFUSOM, aiding residency recruitment.

Acknowledgments

We especially thank residents Travis Keaton Bryan, Daniel Lapid, Hanna Smith, Kyle Townsend, Arthur Washington, Keli Jones, and faculty Tamra Ranasinghe for agreeing to participate in the first pilot.

Conflicts of Interest

JMM has no disclosures relevant to the manuscript. However, within the past 2 years, she has received speaker honoraria from the Tourette Association of America and the American Academy of Neurology. She also receives research support from the Tourette Association of America and the American Board of Psychiatry and Neurology. RAC, SIO, AKB, NDT, EP, NC, MS, and LDS have no disclosures relevant to the manuscript. However, within the past 2 years, SIO has received research support from the NIH or NINDS.

Abstract

Peer teaching in medicine is a valuable educational approach that benefits students and tutors alike. The COVID-19 pandemic has significantly impacted the advancement of remote education in the medical field. In response, the Cerrahpasa Neuroscience Society organized a web-based, volunteer-based peer tutoring program to introduce students to central nervous system tumors. This viewpoint examines our peer mentoring experience in medical education. We discussed how we shaped the course, its positive effects, and the flexible nature of the course, which brought medical students from different regions together. In addition to evaluating academic results, we examined the social relations made possible by this unique teaching method by analyzing student feedback and test scores. Finally, we discussed the promise of global web-based mentoring, highlighting its significance in the dynamic and global context of medicine.

KEYWORDS

COVID-19; distance learning; medical education; mentoring; peer teaching; web-based tutoring

Background

Peer teaching in medicine is an increasingly recognized and valuable educational approach that benefits both students and tutors [1]. Using understandable language and relevant examples, this teaching strategy creates a stimulating and productive learning environment for medical students by leveraging the power of shared cognitive abilities and similar knowledge levels highlighted in the cognitive congruence hypothesis [2]. Students can gain insights into potential pitfalls and challenges by observing and discussing their peers' mistakes and misconceptions, allowing them to fine-tune their own learning strategies. Moreover, students develop essential communication and teamwork skills through collaboration,

which are critical for success in the health care field [3]. Furthermore, positive learning environments enhanced by peer interactions benefit medical education, as social congruence theory suggests that peers and near-peers are less threatening and better understand the stresses of the curriculum [1]. Another advantage of medical student peer education is that it provides relatable role models for professional development [1]. Tutors benefit significantly from peer education in medicine as well. Teaching others has been shown in studies to improve retention of material because it requires active engagement and a deeper understanding of the subject matter [4]. Tutors are likely to cultivate leadership abilities, which might be further enriched by their involvement in the course's administrative facets.

The COVID-19 pandemic has significantly impacted the advancement of remote education in the medical field. As social distancing and lockdowns became prevalent worldwide, institutions quickly adapted to web-based learning platforms to ensure continuity in medical education [5]. This shift increased access to educational resources and sparked the development of novel teaching methods, such as simulations [6-8].

As members of the Cerrahpasa Neuroscience Society, we diligently contributed to the advancement of remote education during this challenging period. Throughout the pandemic, we organized fully remote webinars [9], student-led web-based journal clubs [10], and, finally, a web-based peer tutoring program. Instead of focusing on exam preparation or grade improvement, our first peer tutoring program aimed to introduce students to nervous system tumors. As a result, the course was entirely volunteer based, with tutors who were genuinely interested in and knowledgeable about the subject offering fresh insights into understanding the topic more thoroughly. To maintain a dynamic and responsive learning environment, tutors prioritized incorporating feedback into their planning processes, which was then used to refine the structure of subsequent sessions. In this viewpoint, we tackle an exploratory journey through the application of peer tutoring in medical education. We share the developmental process, positive impact, and practical flexibility of a peer-tutored course that connected medical students across Turkey, based on our experiences as tutors and organizers. We intend to assess not only the possible academic benefits but also the social advantages realized through this unique educational model through a detailed examination of tutee feedback, quiz results, and the personalized approaches adopted by the tutors. As we delve into the facets of this program, we highlight the broader potential for remote international mentorship, emphasizing its resonance with today's ever-changing and interconnected medical landscape.

Course Design, Implementation, and Assessment

The Cerrahpasa Neuroscience Society is a student-led organization that was founded in 2018 at the Cerrahpasa Faculty of Medicine, Istanbul University-Cerrahpasa. The Cerrahpasa Faculty of Medicine is an Istanbul-based public medical school that is one of Turkey's oldest and most prestigious medical schools. The first 3 years of medical school at the Cerrahpasa Faculty of Medicine are preclinical, with clinical clerkships taking place in the 4th and 5th years. The sixth and final year is a pregraduate internship year.

A comprehensive neuroscience course, "Pathology and Radiology of Nervous System Tumors," was scheduled to run from March 16 to May 11, 2021. Participants had to meet 2 requirements for earning a completion certificate: attend at least 80% of the classes and score a minimum of 80% on the final exam. The course was led by 2 experienced fifth-year medical

students (BBO and MK), who served as the president and vice president of the Cerrahpasa Neuroscience Society. The course was divided into 5 lectures, with MK teaching the pathology topics and BBO covering the radiology aspects. We divided the lectures into five titles: (1) gliomas, (2) meningiomas and peripheral nervous system tumors, (3) central nervous system metastasis and primary central nervous system lymphoma, (4) childhood brain tumors, and (5) other nervous system tumors.

The program was open to applications from medical students of any grade and school due to the web-based format of events, which allowed a wide range of attendees. Attendance at the lessons, completion of quizzes, and acquisition of the certificate were provided at no cost. The course was promoted through the Cerrahpasa Neuroscience Society's newsletter subscription, as well as the society's website and social media platforms.

The 5 lectures were given over 9 weeks, with 2 weeks between the lectures. All lectures were held on the same weekday, starting at 5 PM on the Google Meet (Google LLC) platform. Lectures lasted approximately 2 hours, including a quiz and feedback. A few days before each session, participants would receive an email with resources to study beforehand to become familiar with the content of the week's lecture. These emails would include both the English and Turkish versions of the resources, as well as the option to view the material in a simplified or detailed format. Given that not all tutees were at the same level of medical school and that many had not yet studied nervous system tumors, this was critical in preparing them for the lesson.

The first 4 sessions shared a consistent format: the material, which focused on a specific tumor subgroup, began with an explanation of the pathology from macro- to micropathology. To solidify understanding, emphasis was placed on visual materials and numerous examples. Next, the second tutor delved into the same topic through the lens of radiology, outlining how radiologic images should be interpreted. The second part of each session followed a similar lecture style. Notably, the first lecture centered on defining terminology and techniques in radiology, establishing a foundation for subsequent sessions. After the lectures, tutees tackled related medical cases under the tutors' guidance. Students solving cases either volunteered or were selected by the tutors in the absence of volunteers.

Each session concluded with a 10-question multiple-choice quiz on the lecture content. The quiz encompassed both visual and verbal case questions, drawing from the provided resources and lecture information. Following the quiz, participants were presented with a feedback form to evaluate the tutors. This form incorporated a 5-point Likert scale to assess specific criteria, as well as open-ended questions designed to gather insights on strengths and weaknesses in order to improve future sessions (Table 1). Attendance was tracked based on the quiz and feedback form completion.

Table 1. Feedback form distributed to students after every lesson.

Question number	Question	Question type
1	“Preparation for the lesson”	5-point Likert scale
2	“Specifying the goals of the lesson”	5-point Likert scale
3	“The organization of the content”	5-point Likert scale
4	“Command of the subject matter”	5-point Likert scale
5	“Maintaining interactivity in the lesson”	5-point Likert scale
6	“Feedback given to the interacting students”	5-point Likert scale
7	“Maintaining the interest in the topic throughout the lesson”	5-point Likert scale
8	“Specifying the takeaway points”	5-point Likert scale
9	“What do you think was well done regarding the lesson?”	Open ended
10	“What would you like to see done in the upcoming lessons?”	Open ended
11	“If you have any additional comments or questions, please write them.”	Open ended

Although the fifth lecture was initially planned to follow the same structure, the tutors opted for a fully interactive session, with each participant solving at least one medical case. This revision-style approach, prompted by numerous suggestions, served as a comprehensive course review. Consequently, the final tumor subgroup lecture, which was not group-specific, was replaced with a recap of previous sessions through medical case resolution.

A total of 2 weeks after the lectures concluded, tutees with over 80% attendance received an exam question sheet through email and were asked to submit their answers within an hour. On evaluating the responses, tutees who scored above 80% were awarded course certificates.

This study was conducted in line with the principles of the Declaration of Helsinki. All participants provided informed consent after being fully informed about the lectures' and surveys' purpose and benefits. Ethical approval was deemed unnecessary by the institutional board because the survey responses were anonymous and stemmed from the Cerrahpasa Neuroscience Society's peer-tutored courses, which were conducted remotely and independently of the university.

A total of 65 students from various medical schools throughout Turkey enrolled in the course. The Cerrahpasa Faculty of Medicine was the most represented institution, accounting for half of the participants.

The number of attendees gradually decreased over time, with 35 participants in the first lecture and only 12 in the final session. SPSS Statistics (version 26; IBM Corp) was used for descriptive statistical analysis. No bivariate analysis was conducted. The average quiz score improved throughout the course, with the exception of the final quiz, which had the lowest average grade (61.9 out of 100).

Figure 1 displays the average scores of the tutors based on Likert-type questions after all lectures. Meanwhile, Figure 2 illustrates the average scores of the tutors for individual lectures, also based on Likert-type questions. Over the course, the highest average tutor rating was 4.88, which corresponded to “preparation for the lesson.” In contrast, the lowest average rating was 4.57, associated with “specifying the takeaway points.” The average of the 8 ratings for each tutor after each lecture fluctuated and did not display a consistent pattern.

Figure 1. Mean tutor evaluation scores for each question, with ratings using a 5-point Likert scale (1=very poor and 5=excellent). The corresponding questions for the question numbers are given in Table 1. BBO: Burak Berksu Ozkara; MK: Mert Karabacak; Q: question.

Figure 2. Mean tutor assessment scores for each session, listed in sequential order. Ratings are derived from a 5-point Likert scale (1=very poor and 5=excellent). BBO: Burak Berksu Ozkara; L: lecture; MK: Mert Karabacak.

Open-ended questions revealed that tutees primarily requested the inclusion of medical cases in the lectures. This suggestion was made by various tutees across multiple sessions, with the frequency decreasing as tutors incorporated more cases into their lectures. In earlier sessions, tutees requested more text-heavy slide organization and a slower pace. Once these needs were addressed, such feedback was no longer received.

Over time, the number of suggestion-based comments decreased while expressions of appreciation for the tutors increased.

Out of the 7 tutees who submitted answers to the final exam, all surpassed the 80% threshold and qualified for a completion certificate. Comparing the quiz averages of these 7 tutees with the 28 who did not complete the course, the former group consistently achieved higher average scores in each quiz.

Bridging Gaps in Pandemic Times

The COVID-19 pandemic has significantly impacted education, leading to obstacles in delivering quality instruction for medical students and exacerbating feelings of social isolation due to physical distancing. We introduce a peer-tutored course designed to not only enhance learning but also promote social interaction among participants. The responses from the participants suggested that the tutors may have fulfilled their roles satisfactorily, potentially creating a course that could have bridged the geographical and social gaps between a diverse group of Turkish medical students. During a period when quarantine may have contributed to feelings of isolation or had a negative impact on the psychological health of medical students, this initiative may have served as more than an educational tool, possibly fostering a sense of community and connection [11]. In doing so, it provides a valuable platform for these students, who are among the groups most affected by self-quarantine measures [12]. A student said,

As someone who felt quite alone during the pandemic, this course was a relief.

Tailoring Lessons Through Feedback

Throughout the course, tutors maintained a dynamic lecturing style that readily adapted to students' needs. A chronological analysis of the weekly feedback reveals that tutors diligently reviewed the scores and comments using them to tailor subsequent sessions. For example, after the first week where tutees reported insufficient interaction, tutors enhanced interactivity, leading to open-ended feedback that praised the increased engagement and usefulness of the case-solving sessions. In response to the subsequent week's criticism of lesson organization, tutors revamped the third session's slideshow by incorporating text alongside images, as suggested by the tutees. A tutee said,

As we previously desired, examining a large number of radiology images has been very positive for us, especially in terms of ingraining the pathologies we have reviewed into our minds. Discussing the finer points of radiological examinations has also been very beneficial for us. Thank you for taking our feedback into consideration.

This strategy and the flexibility of the lesson plans demonstrated how minor adjustments made in class can potentially boost student satisfaction. Having peer students as tutors and designing the course to be entirely volunteer based, naturally, may have allowed this flexibility to be practiced more smoothly. Nonetheless, there could be a lesson to take away from this demonstration, considering the integration of student feedback and requests within the application of the curriculum in medical school.

Grades, Engagement, and Feedback

On examining the quiz averages, a general increase in topic comprehension may not be a coincidence. From our perspective, this improvement is likely attributable to the students who

completed the program, likely due to their program satisfaction and success. The gradual grade progression is not observed on the final exam, which may be attributed to the detailed qualities of the questions covering the entire course. Nonetheless, this overall improvement should not be overlooked, as it may suggest that students are benefiting from a supportive environment. According to the test results, consistent participation may correlate with higher grades. The contrast between the 7 mentees who completed the course and the 28 who did not reveals the potential benefits of constant engagement and feedback. While we recognize that these results may be influenced by the individual characteristics of the students who chose to complete the course, our observations indicate a possible relationship between student engagement, feedback, and learning outcomes. While the limited number of students constitutes the primary limitation of our observations, it should not diminish the potential relevance of these insights. Additional research could strengthen these insights, revealing more about the interplay between these educational components.

Peer Tutoring: Enhancing Education and Professional Growth

Despite the absence of empirical data, we, as tutors and authors of this paper, would like to emphasize the substantial benefits we have derived from the tutoring approach delineated by Ten Cate and Durning [1]. Considering that physicians must assume the role of educators, our tutoring experiences have significantly enhanced our preparedness and enthusiasm for this critical aspect of our profession. In addition to tutoring, our comprehensive involvement in organizing and administering the course from inception to completion has cultivated our leadership abilities and bolstered our confidence. Furthermore, this experience has solidified our commitment to prioritizing education as a fundamental component of health care. Currently, we continue to mentor several students from the course, an ongoing relationship that has allowed us to refine and augment our supervisory skills. Additionally, we believe that this experience enhanced our understanding of the topics we covered. Beyond the personal and professional growth, we have experienced, we believe that this peer-teaching model has positive implications for the education process itself. Peer teaching offers students a unique perspective on subject material as compared with a traditional curriculum. Tutors frequently draw on their own learning experiences, making it simpler for tutees to grasp the subject matter [13-15]. Having already mastered the core concepts, tutors can effectively guide their peers in focusing on what truly matters. We believe that these insights and experiences are not just theoretical concepts but tangible benefits that we have personally witnessed and experienced through our involvement in peer tutoring.

Global Mentoring

After the COVID-19 pandemic, the normalization of remote communication paved the way for a more interconnected world, possibly allowing international remote mentors to play an increasingly important role in student education. These global mentors, who come from various cultural and professional

backgrounds, can offer students invaluable insights and guidance that cross geographical boundaries, fostering a deeper understanding. Students can gain a fresh perspective on their academic pursuits while also developing the skills needed to navigate the interconnected and rapidly evolving world they will eventually enter as professionals by tapping into the wealth of knowledge that remote mentors bring to the table. As members of the Cerrahpasa Neuroscience Society, we are grateful to be receiving support from author SB, whose inspiration led us to establish this peer tutoring course.

Importance of the Course

In the ever-changing landscape of web-based medical education, it is essential to emphasize what makes our peer-taught course distinctive. To the best of our knowledge, web-based radiology-pathology courses tailored to the Turkish context are scarce. Our course is the first ever free radiology-pathology correlative course taught by students in Turkey. This distinction is significant, particularly in light of the limited context-appropriate web-based resources available to Turkish medical students, especially while many Turkish medical students perceived themselves as having inadequate radiology skills [16]. Moreover, the fully peer-taught model of our course is a novel approach in our region. This method gained even more importance during the challenging times of the COVID-19 pandemic. While some may believe that our course's research foundation and methods are comparable to those of other global web-based teaching initiatives, it is essential to consider the context in which our course was conceived and implemented. This paper's primary objective is not to delve into methodologies but to highlight the innovation in addressing a distinct gap for

Turkish medical students during a global pandemic by using peer-led strategies.

Future Directions and Limitations

Our experiences with peer tutoring, though enlightening and inspiring, are not without their limitations. This paper's conclusions are primarily based on qualitative feedback and subjective observations, as opposed to a comprehensive empirical framework. This lack of extensive data limits our ability to make broad generalizations; therefore, this paper is classified as a viewpoint piece emphasizing personal insights and contextual interpretation. The decreasing number of students was another concern. This could be due to a variety of factors. Even if the web-based activities were helpful, the pandemic made many people feel exhausted [17]. Even though our course was organized to help students, it was challenging due to the difficult medical topics covered. As attendance was voluntary, some students may not have felt pushed to remain. Technical difficulties with web-based sessions may have discouraged some. Last, personal issues may have impacted their decision to continue during this difficult time. In addition, the program's voluntary nature may have resulted in selection bias, as more motivated students were more likely to participate, potentially skewing the results. Future research could address these limitations by integrating better evaluation methods, involving various educational settings, and increasing the number of participants. Examining the long-term effects of such peer-tutoring initiatives on tutors and tutees and the integration of similar approaches into traditional curricula could provide a deeper understanding of the numerous advantages of these educational techniques.

Abstract

Continuing medical education (CME) is a requirement for medical professionals to stay current in their ever-changing fields. The recent significant changes that have occurred due to the COVID-19 pandemic have significantly impacted the process of providing and obtaining CME. In this paper, an updated approach to successfully creating and administering CME is offered. Recommendations regarding various aspects of CME development are covered, including competitive assessment, marketing, budgeting, property sourcing, program development, and speaker and topic selection. Strategies for traditional and hybrid CME formats are also explored. Readers and institutions interested in developing CME, especially in the setting of the ongoing pandemic, will be able to use these strategies as a solid framework for producing CME. The recommendations and strategies presented within this paper are based on the authors' opinions, expert opinions, and experiences over 13 years of creating CME events and challenges brought about due to the COVID-19 pandemic.

(*JMIR Med Educ* 2023;9:e49825) doi:[10.2196/49825](https://doi.org/10.2196/49825)

KEYWORDS

continuing medical education; post COVID-19 pandemic; content development; collaboration; audience; marketing; budgeting; accreditation; evaluation and outcomes; competitive assessment; education; development; assessment; continuing education; medical education; framework

Introduction

Continuing medical education (CME) is a requirement for medical doctors and various other health care professionals to remain competent within their respective fields [1-3]. CME is most effective when it is interactive, involves multiple exposures, and focuses on topics that clinicians view as important and timely [4]. When properly delivered, CME offers numerous benefits, including enhancing clinician knowledge, skills, and attitudes, improving patient outcomes, and lowering health care costs [5-10].

For many health care professionals, the COVID-19 pandemic upended many aspects of daily life, including professional obligations and the process of obtaining and delivering CME. The dynamic nature of the pandemic produced numerous challenges to the status quo of health care (clinical, education, and research) obligations. Given the travel restrictions, need for social distancing, and fear of "super-spreader events," many in-person live CME courses were canceled outright across the country. In 2020, a study of CME planners demonstrated that 87% canceled their events due to the pandemic [11]

As the COVID-19 pandemic progressed to an endemic state, it became clear that given the ongoing need to fulfill professional

licensure requirements, changes were necessary in the delivery of CME. The uncertainty of the pandemic and constantly changing policies catalyzed a need for flexible, on-demand continuing education for health care professionals, while still

ensuring participant safety [12]. As a result, some CME events reemerged offering nontraditional formats, while others were eliminated entirely (Table 1) [13].

Table 1. Potential course formats [13-16].

Course format	Advantages	Challenges
Web-based course (enduring materials)	<ul style="list-style-type: none"> • Learners complete at their pace • Continuous revenue stream • Flexibility for learner and expert 	<ul style="list-style-type: none"> • Accreditation requirements • Content only valid as of date of recording • Gauging audience response to content
In-person course	<ul style="list-style-type: none"> • Networking with learners • Gauging audience response 	<ul style="list-style-type: none"> • Cost • Space limitations
Livestream course	<ul style="list-style-type: none"> • Reduced travel costs • Flexibility for speakers and learners 	<ul style="list-style-type: none"> • Technology issues and costs • Professional image, that is, quality of the stream, branding • Gauging audience response to content is more difficult without camera on livestream learners
Hybrid course (synchronous in-person and livestream)	<ul style="list-style-type: none"> • Appeal to multiple learning styles • Networking with learners • Interaction with some learners during presentation • Gauging audience response to content with learners in-person 	<ul style="list-style-type: none"> • Technology issues and costs • Professional image, that is, quality of the stream, branding • Engaging dual audiences • Livestream audience has a feeling of being “left out”

Despite the importance of CME and the ongoing need for education, there is limited information on how to develop CME in the setting of the postpandemic era which includes many traditional and new formats such as conferences, workshops, enduring materials, or web-based and hybrid courses [14,15,17]. To close this gap, this paper puts forth an approach for creating and administering a CME event, including best practices for designing, implementing, and evaluating CME. Given that courses or conferences are the most popular format of CME, recommended strategies for conference-based traditional and hybrid formats will be reviewed, using published evidence and expert consensus informed by the new practices impelled by the COVID-19 pandemic [14].

Before You Create a CME Course

Foundational Aspects of Collaboration and Communication

For a CME event to be successful, appropriate stakeholders must be identified [18]. Stakeholder support can vary greatly, from time, resources, expertise, mentorship, program and topic development, administrative assistance, and financial investment. CME requires a collaborative effort, supported by health care professionals, content experts, speakers, nonclinical support, and divisional or departmental or institutional leadership [19]. By incorporating other individuals with a shared passion and different skill sets, one will be able to efficiently strengthen the event across all stages.

Collaboration and open communication are fundamental factors throughout all stages of the CME. Course directors and speakers will need allocation of time away from their usual clinical practices to develop and take part in the event. Nonclinician support (program manager, CME specialist, public relations specialist, audiovisual experts, and other administrative staff)

will also be needed. Depending on the size of one's institution and the proposed CME, many of these roles could be combined. However, though it is possible to hire an external audiovisual support (either privately or from the destination property itself), using audiovisual support from one's own institution and engaging them early in the planning process will ensure a successful event and cost control. Engaging with CME or event associations, such as the Alliance for Continuing Education in the Health Professions (ACEHP or Alliance), can provide resources to ensure compliance, templates, and staying up-to-date with best practices.

Institutional support and collaboration can be further secured by aligning the educational endeavor with one's institutional needs [20]. Strategic needs can be measured using hard or soft data [20]. Hard data include financial and attendance goals, ability to meet educational objectives as measured via various evaluation methods, or clinical referrals to one's institution. Soft data include the perceptions and opinions of the attendees gathered by word of mouth, open-ended comment sections on a standard evaluation, and anecdotal observations. By properly aligning the CME with the needs of one's institution, one will be able to demonstrate the importance of the CME and the potential return on investment for the endeavor [21].

General Needs Assessment

Once you have the foundational support, determine whether or not the proposed event or course is necessary or will add anything to the current educational landscape. The majority of successful CME come directly from the needs of those on the front lines of health care due to challenging cases or conditions, newly released guidelines, significant clinical practice changes, or the emergence of a novel subject [22]. As such, the proposed idea should be focused on, imparting new information or

challenging previous knowledge, of interest to health care professionals, and impactful to the direct care of patients [22].

Knowing Your Audience

Intended Audience

Identifying the intended audience is key to developing an effective CME. The planned audience will influence all aspects of the educational activity, from modalities to property location and credit types offered. Knowing the audience in conjunction with the learning gap, will also allow one to be able to formulate various aspects of the CME; this includes learning objectives, course content, marketing strategies, overall goals of the event, and preferred learning styles. A well-tailored instructional design is paramount as a recent study of CME preferences demonstrated significant differences in learning style preferences based on gender and medical specialty [23]. These variations in learning styles emphasize the recommendation to combine different educational modalities in a single CME event, which would allow greater educational flexibility for the attendees and better meet the needs of the audience related to the learning objectives [23,24]. It is worth noting, there is controversy regarding the validity of using learning styles when designing adult education; further research is needed to further explore the merits and limitations of learning styles [25].

Predicting the intended audience will also help in selecting the ideal location and venue destination for the CME. Health care professionals choose to attend a conference for multiple reasons, often traveling with nonconference participants (that is, family or friends). Thus, selecting a destination that has a distinguishable name brand and providing attractive activities for the nonconference participants, can positively impact course registrations. When selecting the location and creating the event program schedule it is crucial to consider the ease of access of the area (flight itineraries and ground transportation) and the local attractions and amenities that the venue and the surrounding area offer to participants and nonparticipants.

Competitive Assessment

When creating CME, one must explore the current educational marketplace [26]. To achieve this, perform a competitive assessment; a competitive (“needs”) assessment is a strategic tool, exploring the current state of the marketplace (that is, competition) [26]. A competitive assessment will help to identify the types of consumers that would most likely be interested, what the perceived positive traits in CME offerings are, and the strengths and weaknesses of the current competition. By researching the competition, one will be better able to differentiate the proposed event from the others, by focusing on specific details or gaps that are present in the marketplace.

The key to performing a competitive assessment is to identify what specific and actionable questions need to be answered

[27]. By asking the “right” questions, a competitive assessment will also highlight the preferred modalities of the educational offering, associated operating costs, support or funding opportunities, and current industry standards for pricing of the CME.

Most of the information for the competitive assessment can be obtained from analyzing previous similar course programs, web-based searches, or by using companies that coordinate CME offerings [27]. Once the necessary information has been gathered, create an easy-to-read report that highlights the findings. The report should also provide actionable recommendations and foreseeable challenges. The competitive assessment should be updated (at least annually) in order to continually innovate the CME, mitigate risk, and be aware of changes in the competition [27].

Sourcing Properties and Event Timing

Determining the actual location and timing of the CME depends on accurately predicting the intended audience. By knowing the target audience, you will be in a far better position to select preferred destinations, timing options, program topics, and educational credit types that would attract a wide array of attendees.

While reviewing the competitive assessment, attention should be given to the timing of the proposed CME, the timing of similar educational offerings, and the timing of holidays. It is best to avoid offering a CME event during the week of a national holiday, spring break, or faith observance, as well as to keep several weeks of buffering between the proposed CME and related well-established, high impact CME offerings (such as national meetings).

In a recent survey, CME attendees indicated that they preferred to have courses during the work week, in the mornings, rather than during the weekend (personal communication by ABM, MD, Mayo Clinic Updates in Internal Medicine attendee survey, October 2020). As a result, the day of the week, time of day, and time zones should all be considered when determining the timing of the CME. Time zones are also especially important when incorporating a digital component to an event; a significant time zone difference can deter learners from attending hybrid, synchronous (simultaneous in-person and digital offerings) events that start early or end late in the digital learner’s time zone. Incorporating asynchronous (previously recorded) content would permit learners to review content at their own pace [28].

In terms of venue sourcing, this can be done by either contacting properties (hotels, resort, and conference centers) directly or using a property sourcing company. [Textbox 1](#) outlines the key factors when sourcing properties.

Textbox 1. Key factors when sourcing properties.**Access**

- Closest large airport
- Car rental
- Additional lodging in area
- Additional activities for nonconference time
- Desirable location or weather

Event space

- Space to accommodate fluctuating audience size
- Proximity of breakout and meal rooms
- Proximity to guest rooms
- Food and beverage space

Hotel and guest rooms

- Ratio of guest rooms sufficient for event space
- Complimentary Wi-Fi
- Complimentary or reduced self-parking
- Waive resort fees
- Number of bathrooms in or near event space

Audio or visual

- Contract with hotel
- Reduced Wi-Fi expense
- Bring own equipment and technologists if possible
- Plan set up time with hotel at least 1 day in advance
- Plan clean up time at least 4 hours before next event set up begins

By using a sourcing company, one would be able to capitalize on any available resources and preexisting industry relationships that the sourcing company has with different sites or brands as well as bulk-price negotiation. Leveraging their expertise within the industry will help one negotiate lower rates and determine ideal properties and destinations best suited for the intended audience. Sourcing companies will provide one with a report enabling a quick comparison across multiple properties, brands, destinations, and dates. Another benefit to using a sourcing company is that in the event there are issues onsite, the sourcing company is able to intervene and help resolve issues promptly.

Creating a CME Course

Focused Needs Assessment

Course Objectives

Creating course objectives is the next step in developing a CME. By using the information from your general needs and competitive assessment, one should formulate the overarching goals of the CME program and objectives. Objectives should be specific, actionable, measurable, and relatable to the intended audience. It is recommended to create simple objectives, typically only 1 learning verb followed by a discrete knowledge

or skills that springs from the gap analysis [22]. When writing measurable objectives, clearly indicate how the CME will measure the change in knowledge, behavior, or attitude.

Accreditation

While planning a CME course, one needs to consider the accreditation agencies specific to the target audience. Health care professionals are governed by different licensure board agencies, based on the respective specialty, which can have vastly different accreditation requirements and costs (Table 2) [22,29-32].

In addition, each state could have different regulations, guidelines, and CME requirements. To combat this variability, many of the specialty boards are now organized under the joint accreditation system of Accreditation Council for Continuing Medical Education (ACCME), which helps to streamline regulatory and accreditation procedures for interprofessional education [33]. All accrediting agencies require formulating course objectives, as well as educational and practice gap statements [29-32]. The educational gap statement highlights the overall educational need for the content being delivered. The practice gap is designed to describe and compare what *is* currently being practiced with what *should* be practiced. Clearly

written educational and practice gaps are designed to guide the program development to achieve the documented objectives [22]. One should create this foundational component of the course, identifying what is the problem that the education offerings want to address, why this problem exists and how the education will help fill this gap.

The decision of which types of credit to offer is entirely dependent upon the intended audience. A course that offers multiple credit types (such as American Medical Association, American Board of Internal Medicine Maintenance of Certification, and American Academy of Family Physicians) can attract various subspecialties to the same CME.

Table 2. Commonly used United States accreditation bodies and credit type.

Name of organization	Credit
Accreditation Council for Continuing Medical Education (ACCME)	AMA ^a PRA ^b Category 1 Credit
AMA	AMA PRA Category 1 Credit
American Board of Internal Medicine (ABIM)	Maintenance of Certification (MOC) points
American Academy of Family Physicians (AAFP)	Family medicine
American Osteopathic Association (AOA)	Doctor of osteopathy
American Nurses Credentialing Center (ANCC)	Nurse or nurse practitioner
American Academy of Physician Assistant (AAPA)	Physician assistant
American Association of Nurse Practitioners (AANP)	Nurse practitioner

^aAMA: American Medical Association.

^bPRA: Physician Recognition Award.

CME Content Development

Selecting Topics to Meet Your Objectives

The educational program is based on the overall purpose of the event, specific learning objectives, and clinical knowledge or practice gaps. The topics must be innovative, timely, and fill an educational gap that currently exists [34]. Using an iterative process with multiple stakeholders (course directors, CME administrators, and content experts) present, create a comprehensive list of potential educational topics and then discuss the benefits and limitations of each. This is particularly important while creating education for an interdisciplinary multispecialty audience. As the individual merits of each topic are assessed, ensure that each fulfills the course objectives and fits into the larger construct of the educational purpose and offering [22]. Topics that align with one's objectives can be grouped together in a logical order, which will help to form a cohesive educational itinerary or program. Topics that do not meet these thresholds should be eliminated from the program.

Speaker Selection

Once the course objectives and educational topics are finalized, move on to speaker selection. Many factors are involved with speaker selection, including identification of content experts, content delivery skills, inclusion and diversity, institutional priorities, and scheduling availabilities [35]. Be mindful of any gender or racial disparities in the speaker roster. Furthermore, sending an announcement to gauge the level of interest that individuals at your institution might have for future speaking opportunities can lead to additional potential speakers and content experts. Faculty evaluations completed by the course participants can also assist in determining future speakers that resonate with the attendees.

Planning the CME

Budget

CME is an expensive undertaking with a very large overhead. Upfront resource identification and allocation is needed for developing and operationalizing the educational event. Many expenses (including deposits, marketing strategy, and printing educational materials) are incurred prior to the event. However, the 2 largest expenses, food or beverage and audiovisual, are not incurred until the CME begins [36]. By comparing data from previous events with similar audience demographics, one can create a realistic budget and effectively manage expenses. In fact, the initial step to position a course for successful budget management occurs during the competitive assessment. It is during the competitive assessment that resources such as CME planning staff, audio visual staff, accreditation fees, marketing fees, and clinical course leadership time should be assessed.

The post-COVID-19 era is characterized by more diverse types of educational offerings, with web-based and hybrid CME events becoming much more common [37]. Budgeting for a web-based or hybrid synchronous event should include the cost of the additional technology necessary to successfully deliver the content digitally. Initially, there will be some upfront additional expenses, given that many CME courses have never had a web-based presence. After the initial purchase of the equipment, ongoing expenses will include continued maintenance and operation of the equipment and upgrading the technology as needed. Though there exists a perception among attendees that web-based events should be offered at a lower cost due to the reduction of travel and food, a high-quality web-based or hybrid CME will require greater resources and technology, which will ultimately drive up the costs of producing the CME [38]. It is important to develop and provide a high production value for hybrid or live streaming educational events.

Marketing

Marketing strategies should be reviewed throughout the life cycle of the activity. Marketing expenses can be one of the more expensive aspects of hosting a CME event [36]. Types of marketing include email, direct mail, website, paid search, web-based calendar, print and web-based journals, industry specific organizations, and social media. Careful consideration of the intended audience will help to identify the most effective marketing strategies. The intended audience's marketing preferences can differ based on the specific course and audience demographics. According to a recent physician survey, 84% of physicians report email and direct mail as the top 2 marketing techniques leading to course registration [39].

The above survey also noted that physicians received marketing information 2-3 times before deciding to attend a CME event [39]. This highlights the need to develop a multiphase, multimodal media (that is, email, web links, brochure, and social media) strategy. When deploying a multimodal marketing campaign, use similar messaging in the different marketing approaches [40]. Further, word-of-mouth marketing can be influential. Word-of-mouth marketing can be face-to-face or via social media. A recent study demonstrated that word-of-mouth via social media was more influential than direct face-to-face communication [41].

Marketing strategies should also be tailored, based on generational demographics of the target audience [42]. In general, there are 3 generational demographics that most likely attend CME events: baby boomers (born 1955-1964), Gen X (born 1965-1976), and millennials (born 1977-1992) [43]. Understanding generational similarities, differences, and preferences can guide the marketing strategies. According to a 2018 study, millennials prefer email (77%) and web-based searches (65%) as sources for event information, while Gen X prefer print media via direct mail (65%), followed by email (59%), and web-based searches (59%) [44]. Though millennials

are most likely to engage in social media sites, digital activity by Gen X and baby boomers continues to grow [44]; thus, it is important to target these groups digitally as well. Furthermore, while Gen X is a smaller population compared to millennials or baby boomers, they actually have the largest CME-related spending power, making it a highly sought-after demographic group [44].

In order to track this information, one should implement conversion tracking for digital marketing tactics. Conversion tracking identifies how well an advertising campaign is performing by tracking web-based traffic from digital marketing that leads to actual registrations. Furthermore, it is recommended to ask how the attendee learned about the event during the registration process; this information can then be used to guide future marketing strategies [39].

Course Website

The overall goal of your marketing campaign is to increase registrations. Thus, the course website and web-based registration platform are an integral part of the marketing campaign. The website will function as a centralized space from marketing, to registration, through claiming credit. Figure 1 is an example of the layout of a course website. Textbox 2 offers various effective suggestions when creating a CME course website [45].

Disorganized or incomplete websites reflect poorly on the course and could deter attendees from registering. The participant's interaction with the course website can influence the overall perception and success of the course as it would be the first (general information and registration) and last (evaluation and credit claiming) impression an individual would have with the CME [45]. Multiple vendors exist in the domain of website development and administration for CME activities, however it is essential for the organizers and owners of the content to keep close supervision of the branding and functionality of the platform.

Figure 1. Example of course website layout.

A Systematic Approach to Medically Unexplained Symptoms 2023

Westlake Village, CA US
August 9, 2023 to August 12, 2023

[Overview](#) [Program](#) [Location](#) [Faculty](#) [Accreditation](#) [Exhibitors](#)

[Register](#)

This course will offer Live (in-person) and Livestream (virtual) attendance options

Course Directors - [Arya Mohabbat, M.D.](#), [Sanjeev Nanda, M.D.](#), and [Elizabeth Wight, M.D.](#)

August 9 - 12, 2023 - Four Seasons Westlake Village - Westlake Village, California

This course provides a diagnostic framework/template for medically unexplained conditions with shared etiologies and presentations. Subsequently, more specific management strategies for each condition is provided, along with various clinical pearls. The program covers various medically unexplained conditions seen throughout the scope of internal medicine, selecting from a variety of pertinent general and subspecialty-derived conditions. Expert faculty present evidence and case-based clinical approaches.

Registration Fees

General Session	
MD, DO, PhD	\$995
Resident, Fellow, NP, PA, Allied Health Professional, Retiree	\$925

Target Audience

This course is intended for general internists, internal medicine subspecialists, family medicine physicians, physician assistants, nurse practitioners, and other primary healthcare professionals who practice in or have a special interest in treating medically complex patients.

Learning Objectives

Upon completion of this activity, participants should be able to:

1. Describe the pathophysiological process of central sensitization
2. Define the relationship between central sensitization and various medically unexplained symptoms
3. Integrate diagnostic and treatment strategies in chronic headaches
4. Identify diagnostic and treatment strategies in gastrointestinal symptoms
5. Describe evidence-based treatment strategies for fibromyalgia and chronic fatigue syndrome

Attendance at any Mayo Clinic course does not indicate or guarantee competence or proficiency in the skills, knowledge or performance of any care or procedure(s) which may be discussed or taught in this course.

Event starts: 08/09/2023 - 7:30am

Event ends: 08/12/2023 - 12:35pm

[Save For Later](#)

Textbox 2. Strategies for creating course website.**Website**

- Clearly state value proposition of course
- Easy to navigate
- Mobile friendly
- Internet search results link directly to desired information
- Organic results appear after an internet search has been initiated
- Based on “ranking” (relevancy of search term to course listing)
- Enhance using search engine optimization (SEO)

Details needed

- Location
- Description
- Start and end times (include time zone)
- Program schedule
- Registration platform
- All course materials
- Syllabus
- Speaker list
- Digital delivery details and links (as needed)
- Accreditation requirements
- Claiming credit

Search engine optimization (SEO)

- Consistent web address with multiple pages
- Static (unchanging) pages
- Specific year-to-year course changes
- Meta title—appear as the results of internet search
- Concise
- Meta description—appear under the meta title
- Clearly describe the value of the course
- Keyword targeting
- Terms potential audience is using to locate desired event
- Strategic and unique to course

Digital delivery tips

- Consistent across portfolio
- Software for digital delivery
- Consistent access point
- Flexible
- Tested prior to event
- Available throughout the event
- Enhance digital user experience
- High quality production value
- Responsive video platform
- Provide opportunity to interact with speakers and be engaged

Commercial Support

Commercial support is often sought to offset the expense of planning, marketing, and running the CME. Commercial support can be in several forms, including grants, scholarships, vendor displays, sponsored events, or in-kind contributions. Each commercial entity has their own application process to apply for funds. Leveraging established relationships and contact points between one's institution and industry could significantly facilitate this process.

This expense mitigation however comes with an implicit appearance of commercial bias and conflicts of interest [46]. To prevent overt bias or conflicts, all team members should follow the ACCME Standards for Integrity and Independence in Accredited Continuing Education policies, that put forth strong regulations when involving commercial support [47]. Compliance with these policies and formal documentation of mitigating plans are required by all accrediting agencies. Additionally, policies under the 2010 "Sunshine" provisions require extensive disclosure reporting for speakers, event planners, authors, and other participants; all relationships and conflicts of interest must be documented, made available, and resolved prior to the educational event [48].

Running and Evaluating the CME

Onsite Strategies

The CME organizers should build a positive operating relationship with the venue and technology managers in order to ensure a professionally delivered experience. This relationship begins with clear communication of the needs and expectations and what they in turn can expect from the CME organizers [49]. These communications will usually occur over a period of months, in the form of phone calls, emails, digital platforms, and potentially a pre-event onsite visit. Once at the venue, a preconference meeting should be scheduled with the venue managers; this allows for an opportunity to clarify any questions about the program and audience, verify safety and security measures, and review the layout of the hotel and conference space areas. For a web-based event, the technology and CME organizers should review the electronic set up, identifying the support structure for the attendees, and discuss strategies to minimize or resolve any potential technological issues.

For an onsite event, the setup of the conference room reflects on both the CME organizers and the venue. Each event will need multiple separate spaces, each serving its own purpose [49]. Specific areas will be needed for the registration desk, networking, formal educational sessions, audiovisual or technical support, refreshments, and commercial support. Room set up should allow for smooth traffic flow and allow for easy access to refreshments, restrooms, and the registration desk, all while providing for appropriate social distancing. Regulations by ACCME forbid the coexistence of educational and commercial activities in the same physical space unless they are separated by a considerable amount of time. Conference materials should be made available for quick access by attendees and flow directly into the educational space or have them easily available from a web-based depository.

The refreshment area should be in a location close to, but separate, from the educational space; this will allow for a more relaxed environment for breaks, discussions, and networking, while not disrupting the educational offerings. When designing the seating arrangement in the educational space, select a room set up that encourages the goals of the event. Classroom style seating provides space to use electronic devices and note taking; crescent or full round tables encourage engagement between attendees; theater style maximizes space to accommodate large groups [50]. When determining the layout, identify if tablespace is needed for audience note-taking, the need for charging outlets, or the ability to stand during the learning sessions.

Pandemic-related health and safety precautions will vary based on the local governance and will impact the layout of the educational space. The Centers for Disease Control's recommendation for social distancing of 6 feet has greatly reduced the capacity and layout of the learning environment [51]. It should also be noted that some institutions and venues will have their own policies. In addition, social distancing creates a challenging situation for professional networking. Conference sites may also recommend numerous modifications to their facilities to limit the amount of people passing through specific areas. These precautions will impact the flow, timing, and set up of the event. As a result, additional noneducational ("break") time will need to be built into the schedule to allow for appropriate distancing, while still fostering a welcoming and collegial environment. Despite the recent normalization of regulations around in-person events, it is prudent to expect unforeseen medical and social events that can rapidly change policies and impact the operations around the educational offering.

Opportunities for direct communication between attendees and CME representatives (course directors, speakers, and administrators) should be carefully reviewed. The CME organizers will need to provide customer support and be readily available to resolve questions or concerns throughout the lifecycle of the CME. This is true both for in-person and web-based events. In total, 1 event member should be at the registration desk at all times at a destination event to provide customer support for the attendees and serve as a security measure for the event materials. Furthermore, course directors and faculty members should be located in the educational space, moderating the conference, communicating any changes in the program or timing to the organizers and technology staff, and facilitating introductions and question and answer sessions. Close communication will provide for seamless transitions between sessions, facilitate any timing adjustments, and resolve any urgent issues. The advent of web-based-only and hybrid events creates a clear need to allocate enough resources, often a designated administrative staff, focused on the needs and particularities of the digital offerings. Issues with livestreaming, web-based troubleshooting, accessibility, and overall good-customer support mandate that as much attention be paid to the in-person customers as well as to digital ones.

Course Evaluations and Outcomes

What constitutes whether an event has been successful or not should be determined during the initial planning stages and

documented, allowing you to directly compare the event's performance to specific objective and subjective metrics. Performance metrics could include registrations, attendance, financials, marketing, hotel block occupancy, institutional referrals, and course evaluations.

Course evaluations are more subjective than the other performance metrics mentioned. However, all attendees should have the opportunity to evaluate the course, assessing its impact on their knowledge gaps and patient outcomes. Course evaluations can be created using different formats, depending on what is being measured [22]. Surveys, questionnaires, pre- or posttests, and reflective questions are just a few examples [22]. The course evaluation should capture the satisfaction of the learning event, indicate if course objectives were met, and reporting of likely changes to their practice due to the CME [52]. The course evaluation can assess not only the impact on the clinician to remain competent within their respective field, but could also be used to solicit recommendations for future topics or locations. All evaluations and suggestions should be combined into a report and reviewed by the CME organizers. As previously mentioned, postactivity evaluations are very important to inform the effectiveness of the education, the achievement of the learning objectives, and to provide several data points to appraise the success of the course or web-based activity.

Summary

Principal Findings

CME is a requirement for health care professionals to stay current in their ever-changing fields. The COVID-19 pandemic

significantly impacted the process of creating and administering CME. To successfully provide CME in the post-COVID-19 pandemic era, an institution and its programs must not only understand their audience and educational goals, but more importantly, appreciate and use the novel formats and delivery platforms. By doing so, one will be able to determine the most appropriate modality, timing, location, and marketing strategies. A CME event requires collaboration between stakeholders, accreditation agencies, and commercial support; clear communication and realistic expectations are vital when developing CME. Given the post pandemic-related challenges, CME providers are faced with significant uncertainties moving forward. The long-term impact of this transition on learning preferences and knowledge retention has yet to be determined. Nevertheless, given these changes, institutions will need to quickly adapt on how best to encourage ongoing CME participation and improve both the web-based and traditional destination experience for their attendees.

This viewpoint paper does have several limitations that should be highlighted. First, the strategies are based on a combination of author and expert opinion, as well as our collective experience with CME development and administration. As such, there can be selection and recall bias, as well as limitations in generalizability. Second, our institution is a large tertiary academic medical center based in the United States; this could limit the generalizability and applicability of our recommendations. Third, it should also be noted that there is increasing discussion regarding the utility and validity of adult learning style or theory and its application in CME. We acknowledge this dispute, but also note that our institution does rely and use adult learning theory principles in CME development.

Data Availability

All data generated or analyzed during this study are included in this published paper [and its supplementary information files].

Authors' Contributions

DB, CS, TA, AB, DC, JTR, and ABM wrote the original draft, reviewed and edited this paper.

Abstract

As we progress deeper into the digital age, the robust development and application of advanced artificial intelligence (AI) technology, specifically generative language models like ChatGPT (OpenAI), have potential implications in all sectors including medicine. This viewpoint article aims to present the authors' perspective on the integration of AI models such as ChatGPT in clinical medicine and medical education. The unprecedented capacity of ChatGPT to generate human-like responses, refined through Reinforcement Learning with Human Feedback, could significantly reshape the pedagogical methodologies within medical education. Through a comprehensive review and the authors' personal experiences, this viewpoint article elucidates the pros, cons, and ethical considerations of using ChatGPT within clinical medicine and notably, its implications for medical education. This exploration is crucial in a transformative era where AI could potentially augment human capability in the process of knowledge creation and dissemination, potentially revolutionizing medical education and clinical practice. The importance of maintaining academic integrity and professional standards is highlighted. The relevance of establishing clear guidelines for the responsible and ethical use of AI technologies in clinical medicine and medical education is also emphasized.

KEYWORDS

ChatGPT; clinical research; large language model; artificial intelligence; ethical considerations; AI; OpenAI

Introduction

Accelerated by advancement of computing technology, the use of artificial intelligence (AI) in clinical medicine has seen many remarkable breakthroughs from diagnosis and treatment to prediction of disease outcomes in recent years [1]. As new technological applications continue to emerge, ChatGPT, a generative language model launched by OpenAI in November 2022 has essentially revolutionized the IT world.. What makes ChatGPT a promising tool is the vast amounts of

data used in its training and its ability to generate human-like conversations covering diverse topics.

Over the past few years, AI involving various techniques have gained significance in clinical medicine, whereas the use of chatbots has been documented in the published literature, even before the launch of ChatGPT. For example, one study reported the use of a chatbot in the diagnosis of mental health disorders [2]. In another study, Tudor et al [3] reported various applications of chatbots and conversational agents in health care, such as patient education and health care service support.

Many of these applications can be delivered via smartphone apps [3].

The use of AI in medicine, including the use of generative language models, is often accompanied by challenges and contentions. Some common challenges include privacy, data security, algorithmic transparency and explainability, errors and liability, as well as regulatory issues associated with AI medicine [4]. Lately, the use of generative language models in scientific writing has also stirred up controversies in the academic and publishing communities. Some journals have declined ChatGPT as a coauthor, whereas others have happily accepted manuscripts authored by ChatGPT [5].

Currently, numerous reviews on the use of generative language model in the field of clinical medicine have been reported, but mainly in the context of academic writing [6] and medical education [7]. However, viewpoints on that relate the use of ChatGPT in clinical medicine, and its implications for medical education are lacking. The inexorable march of technological innovation, exemplified by AI applications in clinical medicine, presents revolutionary changes in how we approach medical education. With the advent of AI platforms like ChatGPT, the landscape of pedagogical methodologies within medical education is poised for unprecedented change. This model's vast training on an array of data and ability to generate human-like conversations is particularly compelling.

Despite earlier uses of AI and chatbots in clinical medicine, the introduction of highly advanced models such as ChatGPT necessitates a rigorous examination of their potential integration within medical education. Understanding the challenges that coincide with AI use, such as privacy, data security, and algorithmic transparency, is crucial for a comprehensive, informed, and ethically grounded exploration of AI in medical education. Hence, this article aims to provide a perspective on ChatGPT and generative language models in clinical medicine, addressing the opportunities, challenges, and ethical considerations inherent in their use, particularly their potential as transformative agents within medical education.

Generative Language Models and ChatGPT

Generative language models such as ChatGPT are trained on a massive amount of text data to understand natural language and

generate human-like responses to a wide range of questions and prompts (instructions). “GPT” stands for “Generative Pretrained Transformer.” ChatGPT is an enhanced version of previous generations of GPTs (GPT-1, -2, -3, and -3.5) and a sibling model to InstructGPT (OpenAI). It is an AI-based language model designed to generate high-quality texts resembling human conversations [8]. The technology underpinning ChatGPT is known as transformer-based architecture, a deep machine learning model that uses self-attention mechanisms for natural language processing. The model was first introduced by a team at Google Brain in 2017 [9]. Transformer-based architecture allows ChatGPT to break down a sentence or passage into smaller fragments referred to as “tokens.” Relationships among the tokens are then analyzed and used for new text generation in a similar context and style as the original text.

A detailed discussion of the technology used in ChatGPT is beyond the scope of this viewpoint article. Briefly, ChatGPT is a fine-tuned model belonging to the GPT 3.5 series. Compared to earlier versions of GPT, some strengths of ChatGPT include its ability to admit errors, ask follow-up questions, question incorrect assumptions, or even decline requests that are inappropriate. There are 3 main steps in the training of ChatGPT. The first step involves sampling of a prompt (message or instruction) from the prompt library and collection of human responses. The data are then used in fine-tuning the pretrained large language model (LLM). In the second step, multiple responses are generated by the LLM following prompt sampling. The responses are then manually ranked and are used in training a reward model to fit human preferences. In the last step, further training of the LLM is achieved by reinforcement learning algorithms based on supervised fine tuning and reward model training in the previous steps [8].

Currently, the research preview version of ChatGPT is available to the public at no cost. Although ChatGPT is helpful in data sourcing, and some users speculate that ChatGPT will replace search engines like Google, it is noteworthy that several key differences exist between a chatbot and a search engine [10]. Table 1 summarizes the differences between a chatbot and a search engine.

Table 1. Differences between a chatbot and a search engine.

	Chatbot	Search engine
Purpose	To generate natural language text responses	To index and retrieve information from the internet
Input	Questions and queries raised by users	Keywords entered by users
Output	Natural language text in the form of human-like conversations	List of links to web pages and relevant information
Output	Responses generated are personalized and conversational	Retrieved information is factual and objective
Information type	In the form of conversational text	Web-based contents in the form of text, images, and videos
Technology	Transformer-based neural network architecture	A combination of technologies (eg, machine learning, natural language processing, and web indexing).

Opportunities for Using Generative Language Models

Studies have reported the use of ChatGPT in several medical education–related areas. In one study, ChatGPT passed the United States Medical Licensing Examination (USMLE) [11] and in another, it outperformed InstructGPT in the USMLE, achieving a passing score equivalent for a year 3 medical student [12]. Fijačko et al [13] reported that ChatGPT generated accurate answers and provided logical explanations to Basic Life Support and Advanced Cardiovascular Life Support examination questions but was unable to achieve the passing threshold for both examinations. Savage [14] described the potential use of ChatGPT in drug discovery.

It is worth mentioning that researchers have explored the use of generative language models in health care prior to the launch

of ChatGPT. For example, a generative language model has been used in COVID-19 public health response [15], explanation of treatment process to stakeholders [16], patient self-management [17], mental health screening [18], research participant recruitment [19], research data collection [20].

At present, the ability of ChatGPT’s to perform complex tasks required of clinical medicine awaits further exploration [21]. It has been shown that the performance of ChatGPT decreases with increased complexity of the task. For example, Mehnen et al [22] reported that the diagnostic accuracy of ChatGPT decreased with rare diseases when compared to that with common diseases. Despite current limitations, a growing body of research suggests that ChatGPT and other chatbots can be trained to generate logical and informational context in medicine. Some potential applications of ChatGPT in clinical medicine and medical education are summarized in Table 2 [12,19,23–28].

Table 2. Potential applications of ChatGPT in clinical medicine and medical education.

Area of research	Potential applications	Example	Study (year)
Learning in medical education	ChatGPT as a source of medical knowledge	ChatGPT could pass the USMLE ^a , showing its ability in generating accurate answers	Mbakwe et al [11] (2023)
Patient engagement and education	Provide information to patients, caretakers, and the public	Use of chatbots in prostate cancer education	Görtz et al [23] (2023)
Disease prevention	Provide counseling and gather information (eg, risk factors) for health screening	Use of chatbots in symptom screening for patients with autoinflammatory diseases, with high patient acceptability	Tan et al [24] (2023)
Participant recruitment	Analyze information from potential participants through conversations and medical records and streamlined information gathered	Comparing recruitment of research participants using chatbot versus telephone outreach	Kim et al [19] (2021)
Data collection	Review large volumes of data through conversations and medical records, use data collected (eg, medical history, investigation findings, and treatment outcomes) for pattern recognition in diseases, and correlate data (eg, demographics and risk factors) with diseases	Use of a chatbot (Dokbot) for health data collection among older patients	Wilczewski et al [25] (2023)
Clinical decision support and patient management	Review data on medical history, investigation findings, etc, and provide treatment recommendations, and support clinical decision-making by providing supplemental information	Application of ChatGPT in making diagnoses and patient management using clinical vignettes	Rao et al [26] (2023)
Drug discovery and development	Review large volumes of scientific data on drugs and identify gaps and potential targets	Use of pretrained biochemical language models for targeted drug design	Uludoğan et al [27] (2022)
Medical writing	Assist in medical writing and publication	Application of ChatGPT in case report writing	Hedge et al [28] (2023)

^aUSMLE: United States Medical Licensing Examination.

Drawbacks of Using Generative Language Model

Information accuracy and authenticity are a great challenge for using chatbots. In one study, researchers asked ChatGPT to generate 50 abstracts from selected medical publications. The study reported that ChatGPT could generate convincing abstracts that escaped plagiarism detection. Further analysis showed that scientists had difficulties in differentiating the fabricated abstracts from the original ones [29]. In another instance, researchers asked the researchers observed that the ChatGPT produced nonexistent or erroneous references [30]. From these

examples, it is worrisome to learn that chatbots can generate fabricated and incorrect information, or what is known as “artificial hallucination.” These “hallucinations” have significant implications, especially when it comes to life-and-death matters in the clinical setting.

Based on its performance in a parasitology examination, a Korean study reported that ChatGPT showed lower knowledge and interpretation ability when compared to medical students [31]. Therefore, ChatGPT may need further training and enhancement on its ability to interpret medical information. In addition, the uncertainty on how ChatGPT and other AI applications derive their information and the black box problem

have always been a big challenge in AI medicine [32]. This further raises concerns of transparency and trust, which are 2 crucial elements in medicine.

The training period of ChatGPT was between 2020 and 2021. As of this writing, ChatGPT was unable to provide information beyond the training period. For example, based on the authors' experience, ChatGPT failed to describe the Turkey-Syria earthquakes that took place in February 2023. This implies that further training is necessary for ChatGPT to provide up-to-date information, whereas training a large-scale AI model like ChatGPT is expensive and time-consuming. Moreover, it involves feeding ChatGPT with high volumes of information, which requires highly skilled personnel.

Ethical Considerations

The use of AI models like ChatGPT may give rise to social, ethical, and medico-legal issues. This section discusses these challenges and the potential pitfalls associated with the use of ChatGPT.

Privacy, Confidentiality, and Informed Consent

Patient privacy and confidentiality, as well as data protection are common issues of debate in AI medicine [33]. Integration of existing health care systems and medical records with ChatGPT may lead to such issues. Informed consent must be obtained from the patients before ChatGPT accesses their data. The requirements of informed consent may vary depending on the situations. Some additional elements may need to be included when obtaining informed content for application of AI in medicine. Some examples include the disclosure of algorithmic decision support, a description of the input and output data, an explanation on the AI training, as well as the right of a second opinion by a human physician [34]. It is important that physicians ensure privacy and data security, as a breach of confidentiality may lead to a breach of trust, which can negatively impact the doctor-patient relationship.

Accountability, Liability, and Biases

Accountability and liability are other ethical considerations. As some medical errors are life-threatening, physicians and researchers must ensure safety and accountability when using AI to support diagnosis, clinical decision-making, treatment recommendations, and disease predictions. Other ethical issues include biased and inaccurate data, leading to unfair and discriminatory results. Therefore, it is important to ensure that AI applications used in research and clinical medicine are trained on representative and diverse data sets to avoid such biases.

In the context of generative language models, bias may be viewed as systematic inaccurate representations, distortions or assumptions that favor certain groups or ideas, perpetuate stereotypes or any incorrect judgments made by the model based on previous training. Biases in generative language models can

be introduced through various sources, such as the training data, algorithms, labeling and annotation, as well as product design decisions and policy decisions. On the other hand, different types of biases can occur, which include demographic, cultural, linguistic, and political biases [35].

Using LLMs like ChatGPT in clinical decision-making may lead to other unintended consequences such as malpractice and lawsuits. The use of traditional decision support tools like clinical practice guidelines allow physicians to assess the reliability of information according to the source and level of evidence. However, AI models like ChatGPT may generate biased and incorrect output with a lack of transparency in data sourcing. AI models may treat all sources of data equally and fail to differentiate the data based on evidence levels [36]. Depending on how the question is phrased, ChatGPT may provide different answers for the same question. Hence, the physicians should take these issues into consideration and use ChatGPT with caution in clinical decision-making.

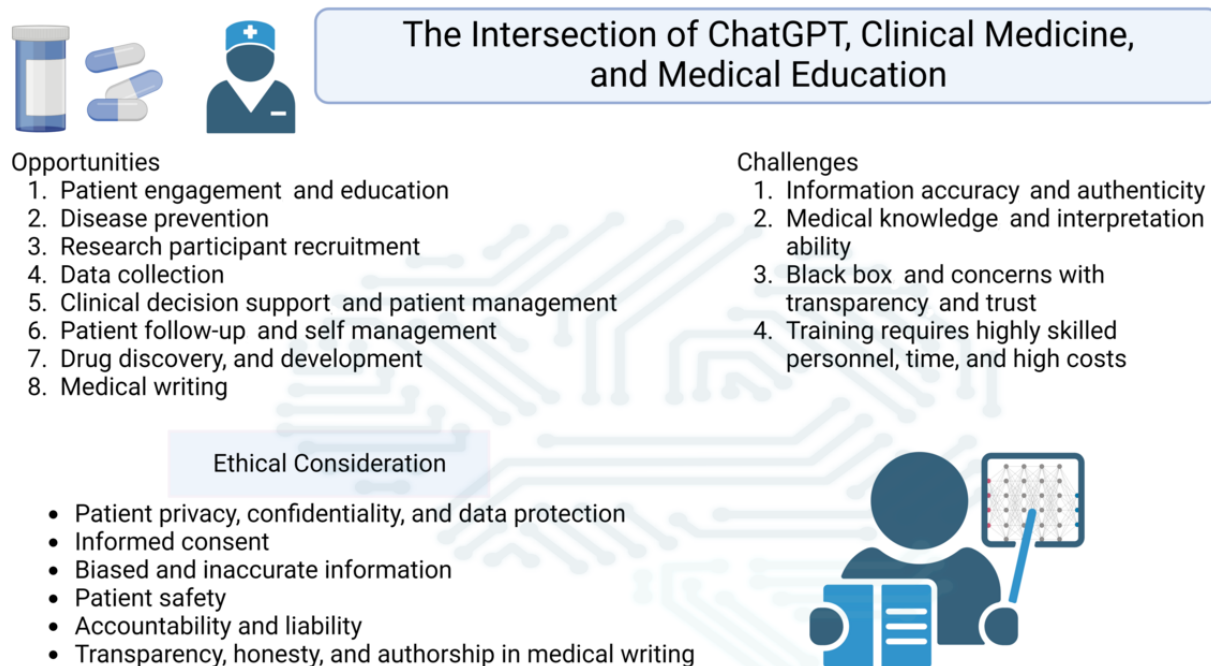

Regulation of the Use of AI in Medicine

With the emergence of social, ethical, and legal issues associated with applications of AI in health care, there is a need to impose regulatory measures and acts to address these issues. The regulation of AI medicine varies in different parts of the world. For example, in the United States, a regulatory framework and an action plan were published by the Food and Drug Administration in 2019 and 2021, respectively. In the United States, the responsibilities of AI lie with the specific federal agencies [37].

On the contrary, the European Commission proposed a robust legal framework (the AI Act) that regulates applications of AI in not only medicine but also other sectors. AI applications in medicine must meet the requirements of both the AI Act and the EU (European Union) Medical Device Regulation [38]. Some areas under such regulation include lifecycle regulation, transparency to users, and algorithmic bias [37]. The European Union also regulates the data generated by AI models via the GDPR (General Data Protection Regulation). Under the GDPR, solely automated decision-making and data processing are prohibited [39].

Academic Dishonesty

The use of ChatGPT in medical writing must be transparent, as it raises issues on academic dishonesty and fulfillment of authorship criteria, with some disapproving ChatGPT from being listed as an author in journal publications [5,40,41]. While the use of ChatGPT in clinical medicine and medical education allows easy access to a vast amount of information, it may raise issues like plagiarism and a lack of originality in scientific writing. Overreliance on ChatGPT may hinder the development of skills in original thinking and critical analysis. [Figure 1](#) summarizes the use of ChatGPT in clinical medicine.

Figure 1. Overview of the use of ChatGPT in clinical medicine and medical education.

Impact of Using AI Models in Clinical Medicine on Medical Training

As the use of AI models such as ChatGPT becomes more common in clinical medicine, it is likely to reshape the landscape of medical education and affect how medical students learn and handle information [42]. Some of the applications mentioned in Table 2 may also be applied in medical education. For instance, the use of ChatGPT in making diagnoses and patient management using clinical vignettes may enhance student learning experience and increase accessibility to learning resources [26]. The use of ChatGPT as a supportive tool in medical writing [28] may also have an impact on medical education. On the other hand, with the integration of AI models in medical education, medical educators will need to address certain issues such as accuracy and reliability of the information, as well as academic dishonesty.

Furthermore, while medical educators and physicians continue to explore the use of AI models in the clinical and research settings, there is an emerging need to introduce new elements in the teaching of medical ethics and medico-legal issues [43]. Whether medical educators readily embrace AI or approach it with caution, the growing presence of AI in our daily lives and the medical field cannot be denied. Therefore, it is time that medical educators re-evaluate the existing medical curriculum and incorporate these elements to prepare medical graduates for effective and ethical use of AI in their medical career.

Conclusions

Generative language models have revolutionized the world. With its current state of technology, we believe that this new AI application has great potential in clinical medicine and medical education. “Garbage in, garbage out” is a common adage in computer science. Like any AI application, the key to the efficient use of ChatGPT depends on the quality of the training data. Given the fact that it can generate inaccurate and nonexistent information, generative language models still have room for improvement. Therefore, when using ChatGPT, physicians and medical students must always verify the information with reliable and evidence-based sources such as practice guidelines, peer-reviewed literature, and trusted medical databases.

While clinical researchers and physicians may use ChatGPT as a supportive tool, its role in replacing humans in complex data collection, analysis, and validation remains uncertain. Hence, the integration of AI in clinical medicine warrants further investigation. After all, when the chatbot makes mistakes, the ultimate responsibility lies with the human user. The use of generative language models in clinical medicine and medical education should also be ethical, taking into consideration patient safety, data protection, accountability, transparency, and academic honesty. When incorporating AI models in medical education, it is crucial that medical educators establish guidelines on the responsible and ethical use of applications such as ChatGPT. The importance of academic integrity, originality, and critical thinking should be emphasized to ensure that medical students uphold the highest professional standards throughout their medical education journey and their future clinical practice.

Abstract

Innovation in medical education is not only inevitable but a requirement. Manikin-based simulation is currently the gold standard for supplemental clinical training; however, this modality requires significant equipment and personnel to operate. Virtual reality (VR) is emerging as a new method of delivering medical simulation sessions that requires less infrastructure but also allows for greater accessibility and flexibility. VR has slowly been integrated into the medical curriculum in some hospitals; however, more widespread adoption would transform the delivery of medical education for future clinicians. This tutorial introduces educators to the BUILD REALITY (begin, use, identify, leverage, define, recreate, educate, adapt, look, identify, test, amplify) framework, a series of practical tips for designing and implementing a VR-based medical simulation environment in their curriculum. The suggestions are based on the relevant literature and the authors' personal experience in creating and implementing VR environments for medical trainees. Altogether, this paper provides guidance on conducting a needs assessment, setting objectives, designing a VR environment, and incorporating the session into the broader medical curriculum.

KEYWORDS

virtual reality; innovation; digital health; simulation; medical education; medical training; tutorial; how-to; curriculum

Introduction

Medical education is transforming. Currently, manikin-based simulation is the gold standard used for clinical training, yet, despite being effective, it is quite resource-intensive. Manikin-based simulation requires dedicated space, equipment, and personnel to run simulation sessions for medical trainees [1,2]. Often, the educational facility will need simulation specialists to oversee the simulation and medical facilitators to debrief participants to support learning.

Virtual reality (VR) is emerging as a new, flexible method of delivering simulation sessions that allows for educational standardization. Central to VR is the concept of immersion,

which is defined as the perception and belief of being present in a simulated world [3]. VR is a computer-generated world that involves immersion and sensory feedback. VR-based medical simulation offers benefits for both medical learners and educators by providing various means of delivering learning content [3-5]. VR is standardized, accessible, and can have assessment metrics and feedback built into the VR environment. Moreover, the medical trainee can go through the VR environment remotely, at any location or time of day. VR allows learners to make mistakes safely and then learn through deliberate practice to improve their performance without harming any patients [6].

The successful application of VR in medical education requires careful planning and implementation. Through our experience

launching VR-based clinical simulation sessions in hospitals such as the Sunnybrook Health Sciences Centre, the Hospital for Sick Children, and the Sunnybrook Canadian Simulation Centre, this tutorial aims to provide educators with a series of practical suggestions for designing and implementing VR-based medical education sessions ([Textbox 1](#)). Throughout this paper, we will outline the BUILD REALITY (begin, use, identify, leverage, define, recreate, educate, adapt, look, identify, test, amplify) framework and use our experience from the

development and implementation of our VR environment as a case study to further reinforce our suggestions. The VR-based medical simulation environment we developed is (1) being used in the Sunnybrook Simulation Centre and (2) being tested in a clinical trial (Clinicaltrials.gov NCT04451590) to assess whether it can enhance the decision-making skills of medical trainees during an airway injury crisis scenario ([Multimedia Appendix 1](#)).

Textbox 1. The BUILD REALITY (begin, use, identify, leverage, define, recreate, educate, adapt, look, identify, test, amplify) framework for designing and implementing a virtual reality-based medical simulation environment.

Design

- Begin with a needs assessment
- Use the needs assessment to set objectives
- Identify the best virtual reality (VR) modality
- Leverage and build content based on learning theory
- Define and support the cocreation of the VR environment
- Recreate diversity and accessibility within the VR environment

Implementation

- Educate users with a prebriefing
- Adapt and test the VR environment with learners and educators
- Look for VR simulation champions
- Identify barriers
- Test the impact of the VR tool
- Amplify VR in the 21st century: value within the broader curriculum

Design

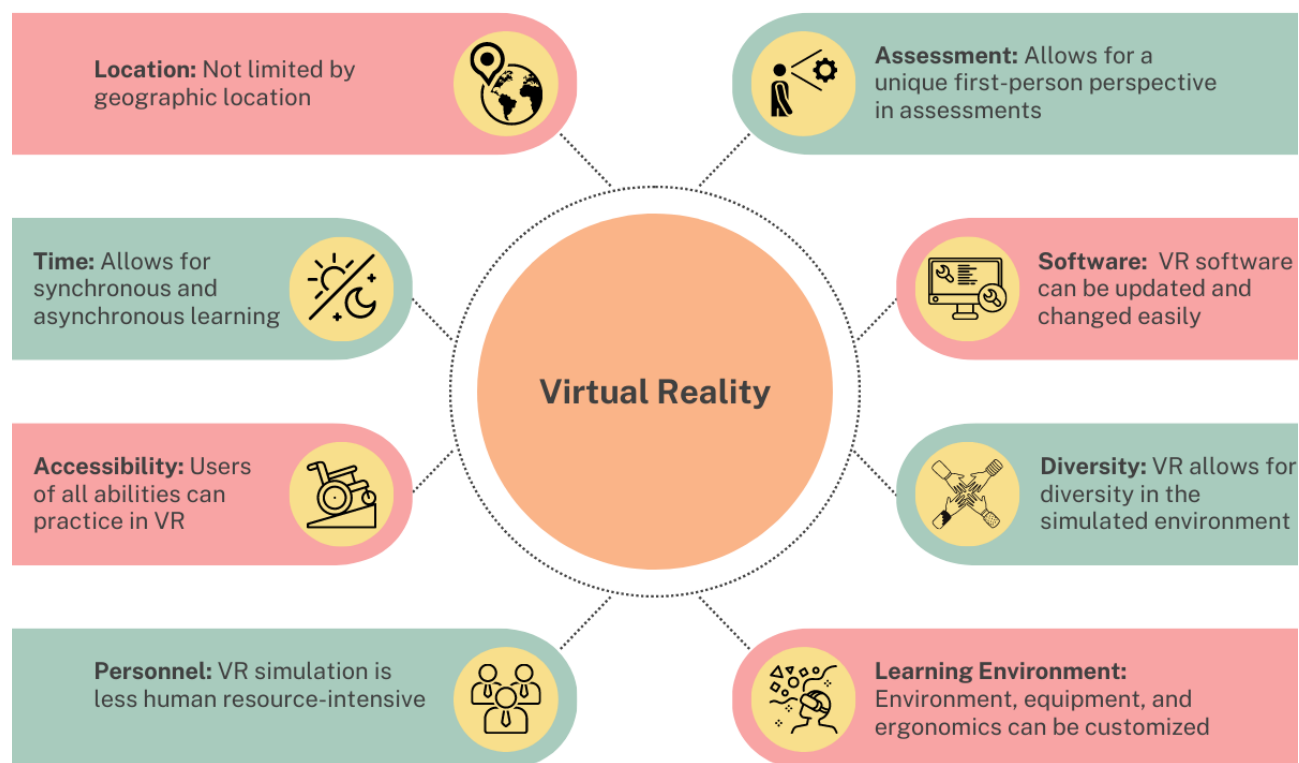

Begin With a Needs Assessment

Before creating a new VR clinical environment, it is important to involve all stakeholders and conduct a needs assessment. The stakeholders that should be involved include the end users, human factor specialists, content experts, and software design technical experts. The team should conduct interviews, use focus groups, and make real-life observations to identify an unmet problem in the medical education system.

As shown in [Figure 1](#), there are certain factors to consider in a needs assessment that may promote creating a VR-based medical environment over another teaching modality. These factors include location, time, accessibility, assessment, personnel, software, diversity, and learning environment [4-6]. Compared to manikin simulation, VR simulation is not geographically constrained and allows for asynchronous learning. VR environments can be designed to be accessible to the user, especially for individuals with mobility constraints, and they require less intensive use of hospital and human resources than manikin simulation. Compared to other teaching modalities, the learning-by-doing nature and first-person perspective of VR

allows for new forms of assessment and evaluation. The VR environment can easily be updated and changed as new medical guidelines are released and diversity can be built in through various avatars and virtual patients. Finally, the learning environment can be customized to replicate any environment (eg, an operating room or a trauma center), including simulated equipment and ergonomics.

If the needs assessment identifies a gap requiring a standardized, accessible, or self-regulated solution, then VR is an up-and-coming technological solution [6]. In the past, VR environments have been created for procedure education support, anatomy training, and clinical decision-making. VR can be used to educate patients, medical students, residents, other health care providers, and interprofessional teams [7-10]. Before creating a VR environment, one should perform thorough market research to see if another laboratory or commercial entity has already created a VR environment that satisfies the educational requirements. If this is the case, the VR assets or environment can be shared and downloaded onto the VR platform used. If it is decided that a VR environment should be developed, budget support should be considered for both the technical and nontechnical expenses of the project.

Figure 1. Factors to consider in a needs assessment that promote the use of virtual reality. VR: virtual reality.

As part of the needs assessment for our VR airway scenario, we collected feedback through focus groups from various program directors, nurses, medical learners, trauma physicians, and anesthesiologists. Additionally, we conducted clinical observations of manikin-based simulation sessions and real-life airway trauma cases to identify gaps that could be addressed through VR.

Use the Needs Assessment to Set Objectives

The objectives should be aligned with an education evaluation model, such as the Kirkpatrick model [11]. The Kirkpatrick model is used to evaluate the effectiveness of a learning program and allows for objective setting early in the development pipeline. For instance, with a VR-based simulation environment, the Kirkpatrick model objectives related to the anticipated reaction, learning, behavior, and results [12] should be set out during the design stage of the VR environment. With these objectives in mind, the team can work to select certain parameters, such as the type of VR headset and environment. The objectives should be aligned with the latest medical textbooks and reviewed with stakeholders and end users. In helping to formulate the objectives, one should involve an interprofessional group of educators—this ensures all professional perspectives can be drawn upon [13]. Based on the use case of the VR environment (eg, memorization or decision-making), the group should set objectives based on

knowledge acquisition, application, and core decision-making steps that need to be conveyed.

For instance, for our airway crisis management scenario, we created objectives related to the content, technical skills, and nontechnical skills that needed to be conveyed ([Multimedia Appendix 2](#)).

Identify the Best VR Modality

Once the needs assessment and the objectives are set, the interprofessional team should determine the level of immersion, interactivity (passive vs active), and the modality required for the environment. It should be noted that immersion can include sound, eye tracking, VR controllers, and haptic feedback, among other features. Interactivity in VR is often on a spectrum where passive VR is similar to watching an engaging movie and active VR is when one can manipulate an environment, similar to our airway environment ([Multimedia Appendix 1](#)). Once these parameters are decided upon, the hardware can easily be selected. The options include a screen-based or a stand-alone VR headset ([Table 1](#)) [14,15].

Based on our airway crisis scenario needs assessment and objectives, we wanted an immersive and active environment that simulated a trauma bay. Therefore, we used a stand-alone VR headset with sound, eye tracking, and controllers to allow learners to make decisions and physically practice their clinical decision-making.

Table 1. Comparison of screen-based and stand-alone virtual reality headsets.

	Screen-based virtual reality	Stand-alone virtual reality
Description	Interacting with a computer monitor, a smartphone, or a smartphone inside a lightweight, portable headset	Stand-alone headset with integrated processors and sensors
Price range	Low	Medium-high
Immersivity	Low-medium	Medium-high
Resolution	Low-medium	High
Motion tracking	Low	High
Equipment examples	Computer-based games, YouTube 360, Google Cardboard	Oculus Quest, Pico 4, HTC Vive Pro

Leverage and Build Content Based on Learning Theory

VR can simulate environments that enhance learning while also being interactive and immersive. To maximize the effectiveness of the VR environment, it should be built on sound learning theories, such as constructivism and self-regulated learning. For example, with constructivism, knowledge is constructed in a learning-by-doing fashion. Therefore, a VR-based simulation that allows the trainee to actively participate in the environment through navigation and manipulation is extremely beneficial [16].

An advantage of VR compared to manikin-based simulation is that it can be performed without access to a simulation center, which requires specialized personnel. VR is a modality that could provide a lower cost of learning where assessment and feedback processes can be preprogrammed into the VR environment and thus promote self-regulated learning [17]. This aspect ensures that the learner can go over key concepts at their own speed and practice as many times as needed [18]. The LOOP (learning theory, objectives, outcome, and output) framework is a design framework used for immersive VR environment development that is based on sound learning theory and objectives to create the VR output [19].

In our VR environment, the medical trainee goes through the core decision-making steps in an airway trauma to save a patient. While our scenario requires rapid decision-making, which presents a challenge for medical trainees, the trainee can go through the scenario as many times as needed. Each time, the algorithm provides feedback to promote self-regulated learning. Overall, we built the VR environment following self-regulated learning and constructivism learning theories.

Define and Support the Cocreation of the VR Environment

Cocreation occurs when learners and educators work collaboratively with one another to create educational resources [20]. An interprofessional team must be established to use the objectives to create a suitable VR environment. This will include individuals previously involved in the needs assessment and additional software developers, animators, human factor specialists, medical education researchers, and clinicians [21]. Together, they will provide the software background, curriculum content, and educational design input needed to effectively achieve the project outcomes. Any team must clearly define research questions, identify roles and responsibilities, set attainable goals, and communicate frequently.

The interdisciplinary team should follow three steps: (1) Create an outline, program goal, and detailed flowchart for the VR program. This skeleton should then link key educational goals and objectives with the visual elements in VR. (2) Use the outline as a building block for the developers and animators to create the first prototype of the VR environment. They will create these assets themselves or purchase assets. A game engine such as Unity or Unreal should be used when bringing together the assets, 3D models, 2D graphic designs, video elements, and voices [22]. (3) Test the initial iterations meticulously and evaluate both the VR environment and its use by learners; this is important in the design process.

We brought together an interprofessional team for our VR airway scenario, including software developers, learners (first to third years of medical education), program directors, medical educators, and health care professionals. A flowchart for the VR airway scenario is provided in [Multimedia Appendix 3](#).

Recreate Diversity and Accessibility Within the VR Environment

Creating a new VR environment for the medical curriculum is a great opportunity to uphold the medical community’s commitment to inclusion, diversity, and equity. This can be done by creating patient and clinician avatars with diverse characteristics, such as age, height, weight, race, ethnicity, sex, gender, and health conditions. Since the VR environment can be repeated with ease, different patient or clinician avatars can be introduced in the medical trainees’ simulation curriculum. This opportunity for diversity is unique to VR when compared to traditional simulation-based medical education, where the purchased manikin is of the same sex and skin color for all medical trainees [23].

Additionally, VR allows the user to interact with the environment in multiple different ways. Users can teleport across the virtual room with a controller instead of walking, which is extremely beneficial for people who have physical disabilities. The room scale can be adjusted to eye height for individuals who need to be seated or are in a wheelchair [24]. These inherent accessibility elements should be introduced in the design of the VR environment to allow for increased utility.

In our case, the VR airway scenario included diverse avatars and various built-in features for accessibility needs. For instance, the medical trainee could use the controller to teleport across the trauma bay instead of walking, and they could move the

virtual hospital bed up or down based on their height and reach ([Multimedia Appendix 1](#)).

Implementation

Educate Users With a Prebriefing

Prebriefing is extremely important for both manikin and VR-based modalities. With manikin-based simulation, the facilitator summarizes the objectives of the environment, orients the participant to the environment, and provides a clear description of the participant's role in the scenario [25]. Through VR, the prebriefing can be embedded within the VR environment as an acclimation room to avoid the need for specialized personnel and resources.

For many medical trainees and even educators, it could be their first time going through a VR environment. Therefore, the prebriefing session should include orientation for both technology and objectives. For example, once the headset is turned on, the orientation session should include how to navigate in the VR environment, how the hand tracking or controllers are used, and which objects can be manipulated.

For the VR airway environment, we prebriefed the objectives beforehand through email with the medical trainees. The technology prebriefing was delivered entirely through a VR acclimation room where the user was shown how to teleport in the virtual trauma bay and how to use the controllers to manipulate certain objects.

Adapt and Test the VR Environment With Learners and Educators

Once the prototype of the VR software is created, it should be piloted with the end user to receive feedback on content validity and VR usability. Effective usability testing does not have to be burdensome; typically, 5 to 6 sessions for any type of user is enough to reveal 95% of usability issues [26]. This process will help identify and resolve any errors. The entire setup should be tested at this stage, as follows: (1) Pre-VR: this stage includes selecting a designated VR area (eg, hospital, examination room, or home), setting up the VR equipment, introducing the technology to the users, and providing a prebriefing on how to navigate through the VR environment. (2) During VR: for immersive headsets, it is important to ensure that the user can teleport if they are in a large room or have enough space if they are walking around. The audio should be tested, and the environment should be clearly visible. It is also important for members outside the medical community, including developers and animators, to test the VR environment. All areas of the VR environment should be viewed and explored to uncover any problems. (3) Post-VR: a cleaning protocol should be determined for the VR headset and other equipment. Multiple options exist, including VR ultraviolet cleaning boxes and disinfectant wipes compatible with the brand of the VR headset. Logistics should be considered; for example, where the headset will be stored, how medical trainees can access the headset, if personnel are needed at the hospital, and if the trainees can take the equipment home.

Similar to manikin-based simulation, validity can be assessed through a pretest followed by a training session and a posttest.

Furthermore, an independent rater can watch an end user interact with the VR environment and evaluate the effectiveness of the tool [27].

For our VR trauma environment, we used an iterative testing process and made changes over 18 times to the setup and VR software. The scenario was tested on a wide demographic, including medical staff, students, residents, developers, research staff, and individuals outside the medical community. We validated the tool through pre- and posttests, and independent raters evaluated medical trainee performance.

Look for VR Simulation Champions

With any new technological innovation, it is important to find interprofessional champions to advocate for the adoption of the VR environment [21]. These individuals can help recruit medical trainees, integrate sessions into the curriculum, and engage administrators and clinical colleagues.

Through experience, we would recommend involving program directors, clinical administrators, medical educators, and other health care providers interested in advocating for the adoption of the technology. Clinician investigators conducting research using virtual and augmented reality are another valuable resource. They can provide resources and tips on ways to implement the VR environment more widely in the hospital and medical education curriculum.

Our VR simulation champions were program directors, site leads and investigators, residents, medical students, and the anesthesia research team. Furthermore, since our use case was filling a gap for trauma physicians and anesthesiologists, they became champions to help incorporate our VR environment into the curriculum.

Identify Barriers

With the implementation of any innovation, challenges related to technical and nontechnical factors need to be considered. Teams should be ready to adapt or switch technologies based on uncovered restraints from a technical standpoint. VR glitches should be carefully documented and relayed to developers and animators involved in the project. One must also monitor for adverse side effects related to the VR environment, including motion sickness, nausea, dizziness, and headache [28].

From a nontechnical standpoint, there can be challenges related to the logistics and adoption of the VR environment. One concern involves determining who will finance the VR program and which health care team members will have access to the environment. Some basic considerations, such as where the equipment will be stored, who is responsible for cleaning and charging the equipment between uses, and how users will book VR training sessions should be determined. On a larger scale, for VR-based simulation to be used effectively, the setup and assessments must be standardized and reproducible. We recommend organizing training tutorials with both end users and facilitators and carving out dedicated clinical time in the medical curriculum.

The technical challenge that we faced was switching from a bulky VR headset that required connection to a gaming laptop and sensors on tripods to a stand-alone VR headset. This

transition allowed us to run the scenario on the VR headset itself. On the nontechnical side, we used the simulation center and hospital research department as the hub for the VR program.

Test the Impact of the VR Tool

It is important to validate the impact of the VR tool based on the objectives created previously using an educational evaluation model. Following the Kirkpatrick model [11,12] includes answering questions about reactions (“Did the learners react favorably to the VR environment?”), learning (“Did the learners acquire the intended knowledge and skills?”), behavior (“Did the VR education change behavior?”) and results (“Did the VR education influence clinical performance?”).

With VR, it should be decided which evaluations will be embedded in the VR environment and which will be completed through other means (eg, paper or online questionnaires). The VR tool should undergo utility and usability testing throughout the development process; the tool can also be scrutinized during research studies, such as randomized controlled trials. Through these various evaluation metrics, the VR environment may be regarded by teaching hospitals and medical bodies as a more valuable educational tool and lead to easier uptake.

We assessed the VR airway decision-making scenario through usability testing with developers and through clinical trials with medical students, residents, and physicians. Currently, as a group, we are gathering this data to showcase the influence of the VR environment on knowledge acquisition, clinical behavior, and performance.

Amplify VR in the 21st Century: Value Within the Broader Curriculum

VR has been shown to be beneficial for anatomy training [8], procedure education [9,10], and clinical decision-making [29]. However, the VR environment should be embedded in the broader medical curriculum and still be supported by grand rounds, quality assurance meetings, e-learning modules, and simulation center visits. These educational tools, coupled with real patient encounters, can lead to the next generation of clinically competent health care members.

It is the responsibility of the interprofessional team to ensure that supplemental resources, such as prebriefings and assessments, are available for the medical trainee, as this will allow for greater implementation of the VR environment within the medical curriculum. During the global pandemic, where social distancing and remote education present challenges for clinical learning, VR enables medical trainees to continue participating in engaging and interactive training. Importantly, VR can also be incorporated in underresourced and rural communities as a supplemental teaching modality.

In our case, we have already begun using the VR airway scenario with medical students and anesthesia residents in our clinical teaching curricula (Multimedia Appendix 1). VR breaks down geographic barriers, which allows us to easily test and implement the environment in other medical education departments around the world.

Conclusion

Technological advances and VR in health care are beginning to have practical applications in medical education programs. VR is an accessible, standardized, and safe medical tool that allows medical trainees to practice skills without patients or hospital infrastructure. The opportunity to repeatedly practice anywhere without real consequences to a patient is one of the main advantages of VR technology. This aspect, coupled with the minimal resources involved in facilitating a VR environment, is a driving force behind the adoption of this technology in the medical curriculum. The foundation of a successful VR-based medical simulation environment requires a strong interprofessional team to establish the VR objectives, select the VR modality, and cocreate the VR environment. Once a prototype is designed, the VR environment must be tested meticulously and incorporated into the medical curriculum through VR simulation champions. The implementation of VR is challenging, but through this tutorial, we provide educators with a framework (BUILD REALITY) that can be used to design and implement VR-based medical education training in their curricula.

Acknowledgments

The authors thank the members of the Department of Anesthesia at the Sunnybrook Health Sciences Centre and Sunnybrook Canadian Simulation Centre for their support and guidance. We also thank Dr Andrew Fleet for proofreading the final manuscript.

Authors' Contributions

SG and FA designed the tutorial, SG compiled and analyzed the literature, and SG wrote the original draft of the manuscript. SG, LK, CM, JW, KW, and FA read and revised the manuscript. SG, FA, and LK edited the final version of the manuscript. All authors read and approved the final manuscript.

Abstract

The use of virtual reality (VR) stimulation in clinical settings has increased in recent years. In particular, there has been increasing interest in the use of VR stimulation for a variety of purposes, including medical training, pain therapy, and relaxation. Unfortunately, there is still a limited amount of real-world 360-degree content that is both available and suitable for these applications. Therefore, this tutorial paper describes a pipeline for the creation of custom VR content. It covers the planning and designing of content; the selection of appropriate equipment; the creation and processing of footage; and the deployment, visualization, and evaluation of the VR experience. This paper aims to provide a set of guidelines, based on first-hand experience, that readers can use to help create their own 360-degree videos. By discussing and elaborating upon the challenges associated with making 360-degree content, this tutorial can help researchers and health care professionals anticipate and avoid common pitfalls during their own content creation process.

Introduction

In recent years, there has been an increasing interest in using immersive virtual reality (VR) technology in the clinical setting. This is a continuously growing field, and applications within the clinical setting include, among others, preparedness and medical training for staff, familiarization with the hospital setting, pain treatment, and anxiety treatment [1-8]. Specifically in the intensive care unit, the majority of research done using VR has examined its use with patients as a tool for relaxation [9]. This is followed by its use for delirium prevention in patients; however, the approaches were similar in that they also used VR as a relaxation tool [9].

Due to the increased interest and numerous potential applications for this technology, a group of 21 international VR experts recently worked together to develop a set of standards for best practices [10]. The standards aim to provide guidance when attempting to conduct VR treatments in health care as well as translate findings from VR research into practical applications [10]. The Virtual Reality Clinical Outcomes Research Experts (VR-CORE) committee defined 3 phases that should be used when designing VR clinical studies, starting with content development [10]. The VR-CORE members specifically suggested the use of human-centered design, emphasizing that patients and providers should be involved. This is related to the finding that personalization—allowing the participant to make

decisions on various aspects of VR content—can contribute to the level of relaxation and engagement experienced by the user [11]. Furthermore, previous studies have found that the effects of VR across a variety of applications, such as pain therapy and relaxation, are greater when using immersive VR technologies compared with other media such as television screens or headphones [12–16]. Consequently, the application of VR technology ideally requires 360-degree videos that are tailored to their intended purposes.

While specialized companies can be hired to create custom 360-degree videos to suit the specifications of a given project, these concepts and technologies are still relatively new, and their services often come at a premium. Alternatively, immersive content can be purchased on the internet, but this option has its fair share of limitations. While more affordable, users of web-based content must consider the potential licensing issues and royalties associated with its use. Furthermore, videos purchased on the internet may also have limited customizability, such as the length of the content (which is typically restricted to a few minutes), or the location depicted. It may also not be possible to customize certain aspects of the purchased videos, such as the addition of audio tracks (eg, voice-guided meditation) [17,18]. Thus, one potential way of overcoming these limited options is to generate user-created 360-degree video content.

While previous tutorials have outlined how to create 360-degree VR content for training and environmental familiarization, they are limited in their applicability as well as the robustness of the methods described [2,4]. Specifically, these tutorials assume that the creator has access to a controlled environment with minimal risk of interaction with uncontrollable environmental

factors. Additionally, these tutorials have failed to address certain steps that are vital for working with 360-degree videos and instead outsourced these steps or used the built-in software provided with the device as a workaround. The limited scope of these existing tutorials, especially in light of the recommendations of the VR-CORE group, highlights a gap in the literature regarding the creation of customizable in-house VR content that does not require the user to outsource certain aspects of the work or hire expensive companies.

The goal of this tutorial paper is to provide readers, be they researchers or health care professionals interested in applying VR in a clinical setting, with a pipeline that can be used to create custom 360-degree videos. Moreover, the goal is that the pipeline can be used for a variety of applications across various levels of expertise and multiple target populations. The methods and advice provided in this paper are based on the study team's first-hand experience of creating 30-minute, 360-degree nature videos that were subsequently shown to patients with critical illness in an intensive care unit using a head-mounted display (HMD). While the focus of our work was the creation of relaxing scenes that featured nature, the steps outlined below can be easily generalized and used to record content that is more suitable for different purposes, such as pain therapy or distraction, in which the 360-degree exploration of a given setting is desired [5,6,8,19–23].

Editing Pipeline

Overview

The pipeline presented in this paper focuses on 5 main aspects that must be considered when creating 360-degree videos (Figure 1).

Figure 1. Proposed pipeline for creating and using 360-degree videos.

The first aspect is the planning and designing of the content, which requires making decisions on a variety of parameters, such as the duration of the content, as well as its visual and auditory components. The second aspect covers the auditory and visual equipment necessary as well as how to record the footage. The third aspect involves the creation and processing of the final footage, with a specific focus on how to combine the recorded content into a single 360-degree video and postprocessing considerations. The fourth phase discusses the hardware that should be used for deployment and visualization; it includes considerations regarding the visualization of the 360-degree content, the choice of VR device, and hygiene precautions. Finally, this tutorial discusses how to evaluate the VR experience. Additional detailed descriptions of the experimental setup as well as potential use cases following this pipeline can be found in [Multimedia Appendix 1](#).

Planning and Designing of the Content

Overview

Before beginning to record any content, it is important to know what types of scenes should be recorded and their duration; this will depend on the overall purpose of the VR content. For example, if planning to use VR for relaxation purposes in patients with critical illness, the literature suggests that the duration should ideally be around 10–15 minutes [24]. On the other hand, if VR is to be used as a meditation tool to improve sleep in patients with critical illness, then a duration of 30 minutes may be better suited to that purpose [17]. Relevant points to consider are the visual content, the auditory content, and the duration of the content.

Visual Content

The types of scenes to be recorded will depend on the purpose of the content. Specifically, if the content is intended to provide a distraction, then engaging content such as cartoons or interactive scenes, as have been used for pain therapy, may be

the best choice of content [12,13,22]. If, however, someone wants to be relaxed, a calm nature scene may be more suitable than an urban environment [19,20,25]. Based on this, Table 1 outlines several important questions that should be considered when deciding what type of content should be recorded.

Table 1. Questions and considerations related to the visual content of the videos.

Questions	Considerations
What type of activity should be present? (eg, human activity, animal activity, nonhuman activity)	<ul style="list-style-type: none">• Some activity should be present, or the video may look like a still image.• The type of activity will depend on the individual goals of the VR^a stimulation (eg, distraction and relaxation). For example, natural settings are more relaxing than urban settings, so in this case, limit human activity.• For scenes involving human activity, local filming laws should be consulted.
How much activity should be present? (eg, constant activity, intermittent activity)	<ul style="list-style-type: none">• Too much activity, and the viewer can become overwhelmed.• Too little activity, and the viewer can become bored [26].• The ideal amount of activity depends on the target population and the goals of the content.
How quickly should the activity be occurring or should the scene be changing?	<ul style="list-style-type: none">• Content that is too repetitive or does not change enough may be boring.• Content that changes too much or too quickly can be confusing or disorienting.
Should the recording be static or dynamic?	<ul style="list-style-type: none">• Dynamic recordings may be more engaging.• Dynamic recordings may increase the risk of cybersickness [27].
What about cybersickness?	<ul style="list-style-type: none">• There are 5 main contributors to cybersickness: content, interaction, human, hardware, and experimental factors [27].• Some risk factors cannot be controlled (eg, age), while other factors can be accounted for (eg, static versus dynamic content).

^aVR: virtual reality.

Auditory Content

Like visual content, the type of auditory content that should be included is dependent on the goals of the video (eg, voice-guided meditation or relaxing nature sounds) [17,18,28]. Table 2 outlines several important questions that should be considered when recording and postprocessing 360-degree content.

Table 2. Questions and considerations related to the auditory content of the videos.

Questions	Considerations
What type of auditory content should be presented?	<ul style="list-style-type: none">• The addition of music can be challenging as it is very personal [24].• Sounds recorded together with the visual content are both easier to include and will more reliably engage the user [14,24].• Audiobooks or podcasts could be used depending on the goal of the stimulation (eg, nature scene with guided meditation).
Should the auditory input be monophonic or stereophonic?	<ul style="list-style-type: none">• Stereophonic audio creates a multidirectional perspective on the horizontal or vertical plane (eg, birdsong coming from the left or right).• This may depend on the recording equipment available (eg, a built-in camera microphone may restrict the user to monophonic).• Spatial audio creates sounds in a 3D space, with the listener in the middle.• Spatial audio can be programmed to respond to head movements.
At what volume should the auditory input be presented?	<ul style="list-style-type: none">• Volume should be regulated throughout and across content.• Individuals may have different listening preferences or be hard of hearing.• It may not always be feasible for the user to adjust the volume level themselves.

Duration of the Content

A final component to consider is the length of the content as well as how it relates to both the visual and auditory content. The ideal video duration is dependent on how the final video will be used as well as the content itself. For example, if the goal is to distract people, as is often the goal in pain therapy [23], then individual videos could be shorter. In contrast, if the goal of the video is to induce a relaxation effect—for example, by showing them a sunset—then the video should be long enough to capture this event. In general, the overall length of the video can be adjusted by adding or removing video footage. Alternatively, the length can be adjusted by ensuring that it can be looped, that is, the end of the video can seamlessly transition into the start of the video without a perceptible difference in the content. In this way, the duration of the footage can be adapted at a later stage (eg, during postprocessing), adding another layer of personalization.

Equipment and Recording of the VR Content

Visual Equipment

As the technology available for recording 360-degree videos continues to evolve, there are an increasing number of commercially available cameras. There are 2 main types of cameras: monoscopic and stereoscopic cameras. Monoscopic VR uses multiple monoscopic cameras attached to a rig to film multiple fields of view that are stitched together in the postprocessing stage. Stereoscopic VR also uses multiple cameras to film multiple fields of view, with the exception being that, in stereoscopic cameras, there is a lens assigned to each eye. In this way, stereoscopic cameras can generate 3D content that cannot be achieved using a monoscopic rig unless special postprocessing techniques are used.

In addition to the camera itself, there are additional accessories that are required. Videos recorded using 360-degree cameras can be extremely large depending on the resolution, frame rate, and duration of the recording and may require additional storage solutions as well as a powerful computer for processing. The exact specifications will depend on the camera used and the video files generated; a more detailed example can be found in [Multimedia Appendix 1](#). The camera may also require

supplementary batteries or an additional power source if outdoor scenes are being captured. The environmental conditions may also necessitate the purchase of additional accessories related to wind or rain protection.

Finally, as this setup may appear intriguing to passing individuals, it may be useful to consider some protective measures. Specifically, it may be useful to attach signs to the camera tripod, warning individuals to refrain from approaching or touching the camera, as this may disrupt the recording and have a disorienting effect on the viewer. Florescent cones can also be placed around the base of the tripod to prevent individuals from approaching the camera or accidentally knocking the camera down ([Figure 2](#)). Any person or object that comes close to the camera can cause discomfort for the end user, as they might feel that the object approached too close to them. Lastly, as the camera captures footage of its entire surroundings, there is no way for someone who does not wish to be filmed to pass by undetected. To prevent problems associated with this issue, it can be useful to place signs at an appropriate distance from the camera that warn passersby that they will be filmed if they continue on this path. Individuals who do not wish to be filmed can then choose an alternative route.

Figure 2. Examples of on-location shooting using fluorescent cones to make passersby aware of the tripod and camera.

Recording Perspective

When filming on location, the easiest and most flexible way of positioning the camera to capture scenes is through the use of a camera tripod. There are two recommended heights that should be used to guarantee a natural viewing experience: a height that

is comparable to someone who is standing or a height that is comparable to someone who is seated on the ground. Selecting 1 of these 2 heights will increase the likelihood that the user will experience the scenes as if they were truly present at that location ([Figure 3](#)).

Figure 3. Camera setup and examples. (Left) Camera setup while filming on-location. (Top right) Screenshot of the final postprocessed video as it would be seen using the VR headset. (Bottom right) Insta360 Pro II camera (Arashi Vision Inc) showing the control panel. VR: virtual reality.

Audio Equipment

There are 4 main methods by which auditory content can be added to 360-degree videos. First, one may choose to film the visual content using devices that have built-in microphones. This option allows for the most seamless combination of visual and auditory content. However, recording the auditory content may not be straightforward, depending on the equipment available and used. For example, cameras that have a built-in cooling fan may result in poor-quality audio recordings. Additionally, it is impossible to customize microphones that are built into the camera; users may wish to use an external microphone to record the soundscape.

There are many different devices available depending on budget and the desired specifications, which will be dependent on the content considerations discussed above. Care must be taken to find a recording device with a suitable range that is capable of picking up on activities in close proximity but not extraneous sounds, such as sounds from a distant highway [29]. Additional characteristics that should be considered include the power supply (ie, cabled or battery-powered), internal storage capabilities, and wind protection. The latter is particularly important for outdoor recordings, as even the slightest gust of wind can be heard on audio recordings [29]. If the video content is expected to include a vocal track—for example, to allow for a guided meditation routine or to act out a scene—it may be important to consider how this voice will be captured by the device. A better solution may be to record these audio tracks separately and add them to the video during postprocessing.

In cases where it is not possible to record sounds on location, sound clips can be stitched together using dedicated software such as Audacity (Audacity, Inc). However, finding available sound sources and creating an audio clip is not always easy. Furthermore, ensuring that transitions between clips are undetectable and ensuring proper fading can be challenging. Discrepancies that cannot be heard during postprocessing may be noticeable when played on higher-quality devices. This makes creating high-quality audio clips difficult and time-consuming.

Therefore, a final option for adding auditory content to the videos is the purchase of professionally recorded sounds. As with the video content, longer-duration, nonlooping content may be limited, though it is not impossible to obtain. It should be noted that the misalignment of audio and video is detectable by a trained ear, and certain viewers may be perturbed if actions such as footsteps can be seen but not heard [30].

The Creation and Processing of the Final 360-Degree Footage

Recording the desired content using a 360-degree camera is only part of the process. The stitching and postprocessing of the footage are both equally important components of video creation and may require special consideration, as outlined below.

Stitching and Auto-Stitching

As 360-degree VR recordings use multiple cameras, as described above, stitching is an important part of the postprocessing step. During stitching, the videos recorded from each camera are merged into a single file, such that there is no clear start or end to the visual field as the user turns around. However, the process

of merging these videos is not trivial, as the recorded videos have overlapping fields of view. This means that each lens captures a portion of the surrounding environment that is also captured by a neighboring lens. The video must, therefore, be properly overlapped to avoid double vision. This process is easily accomplished for still pictures or videos with little activity and becomes more challenging with increasing activity as objects can pass over these stitch lines.

As this process can be difficult and time-consuming, many 360-degree cameras now come with proprietary software that automatically stitches the footage together. Such software can produce relatively good results, particularly when there is limited activity or when objects and activity take place further from the camera. The recommended minimum distance that should be maintained between all activity and the camera to ensure the best result is defined in the camera's user manual (typically 1.5 m).

Finally, if the proprietary software is unable to generate smooth stitch lines, more advanced programs such as Mistika VR (Soluciones Graficas Por Ordenador SL) can be used to improve the final video. These programs allow the stitch lines to be visualized and manually adjusted through edge points so that they do not run directly through moving objects or elements that are important to the video. Valuable written advice and video tutorials made by content creators as well as the developers of these different stitching programs are available on the web; these resources describe the steps needed to improve the stitching of a video in great detail.

Postprocessing

Postprocessing is an important step that allows the user to add external audio tracks, improve lighting, make color adjustments, and remove unwanted objects. Various programs can be used for postprocessing; some require the purchase of a paid license, while others are free. A detailed description of programs used by the study team can be found in the example provided in [Multimedia Appendix 1](#).

If the camera's built-in microphone is used, then the video and audio files will be automatically loaded into the program simultaneously. Alternatively, if the audio files are recorded using an external device, stitched together, or purchased, then they must be added to the video file separately. This can be done before or after editing the visual content, as these files are independent of each other.

Lighting and color adjustments can also be made during postprocessing. By following photographic principles, the lighting and colors in the video can be adjusted to convey a specific tone, mood, and atmosphere. The user may also wish to remove certain objects from the recorded footage, such as the camera's tripod. Alternatively, it may be easier to cover an object rather than edit it out, for example, with a company logo. Generally, video editing programs allow users to cut out unwanted objects or color over them. If this approach is taken, then it should be noted that, depending on the duration of the video, the lighting in the scene may change. Therefore, the process of editing or removing objects may need to be done in multiple steps to ensure that the lighting and colors match. Additionally, with longer-duration videos, there is also a higher likelihood of objects in the surrounding environment interfering with the recording, such as insects landing on the camera lens. These can also be edited out during postprocessing.

In the final postprocessing step, certain settings may have to be altered to ensure that the final video is compatible with the hardware used to display it ([Table 3](#)). Within the postprocessing software itself, it may also be necessary to indicate that the content is for VR purposes and, subsequently, whether the content is monoscopic or stereoscopic. The resolution, frames per second, and necessary codecs can also be adjusted at this stage. The playback device may also require filenames to be formatted in a specific way so that the device can recognize 360-degree content. [Multimedia Appendices 2 and 3](#) contain examples of video clips exported using the settings listed in [Table 3](#).

Table 3. Video export settings for playback using a Pico G2 4K virtual reality headset (PICO).

Attribute	Setting
Codec	H.264
Width (pixels)	5760
Height (pixels)	2880
Frame rate (frames per second)	24
Aspect ratio	Square pixels
Bitrate	Variable
Virtual reality mode	Monoscopic (360° × 180°)
Time interpolation	Free sampling
Metadata	Enabled

Hardware for Deployment and Visualization

Choice of Device

Once the video files have been exported, the 360-degree videos can be played on a computer, mobile phone, or VR headset.

Videos on a computer or mobile device may require specific software or can be viewed directly through YouTube (YouTube, LLC) or Facebook (Meta Platforms, Inc), assuming that the video was properly uploaded for 360-degree playback on these platforms. On these devices, the virtual environment can be

explored by panning around the scene. On mobile devices, the user can explore the scene by pointing the device in the direction they wish to look. This is similar to VR headsets, in which the scene rotates as the user moves their head, immersing the user in the virtual environment. In this way, exploration of the scene using VR is achieved very naturally.

Currently, there are several commercially available HMDs for displaying immersive VR content. They can all be split into 2 main categories: tethered and untethered devices. Tethered devices use a cabled connection to a powerful computer to acquire and display the VR content and often require additional equipment such as base stations and lighthouses for tracking. In contrast, untethered devices are less powerful and may require a wireless connection to transmit and receive content, but they are cable-free. This has the advantage of making the user feel less restricted in their movements and can make the device easier to use as there are no external components to consider. Another aspect that may be relevant for use in a clinical or research setting is the ability of devices to launch in what is known as kiosk mode. This mode allows the device to run a specific application when turned on, thus requiring less hands-on manipulation of the interface.

In addition to ease-of-use considerations, the internal specifications of the device need to be considered. Devices with better specifications often cost more; more expensive devices tend to offer higher image quality, resulting in a more realistic virtual environment. This is important, as it can increase the users' sense of presence [31]. For this reason, specifications such as the resolution per eye, refresh rate, field of view, and display type all play a role in the user experience and should be considered.

In addition to the internal specifications of the device, there are also physical components to consider. To improve user enjoyment and increase immersion within the virtual environment, the HMD should be as unobtrusive as possible [31]. This means that aspects such as weight, counterbalance, padding, and adjustability, to name a few, should be considered when selecting an appropriate device. Wearing a heavy device that does not provide adequate counterbalance (usually located at the back of the user's head) can result in discomfort on the wearer's nose. However, while the addition of a counterbalance may alleviate pressure on the user's nose, it may increase their discomfort when leaning their head against a support. The material and amount of padding, as well as the ability to adjust

the tightness of the device, can also play a role in the user's overall comfort. Additionally, the ability to adjust the device's internal lenses can allow for a clearer and more focused image to be achieved.

A final aspect that should be considered is the auditory output of the device. Some devices have integrated speakers, whereas others do not. While integrated speakers may be suitable for VR gaming, they may be less desirable if the goal is to envelop the user in the virtual environment. In this case, one may choose to use external headphones (preferably noise-canceling), which can be connected to the device, typically through a cabled connection. In general, there are no special requirements to be considered in terms of compatibility between the headphones and the VR device; any commercially available headphones can be used.

Hygiene

Hygiene is of particular importance when using HMDs in a clinical setting. All parts of the device must be disinfected when switching between users, and these considerations must also be accounted for when selecting a device. Devices with a plastic outer covering can be wiped clean with hospital-grade disinfectant wipes. However, some devices, such as the first-generation Oculus Quest (Meta Platforms, Inc), have a fabric covering. To overcome this limitation, a custom-made fabric cover that can be disinfected may be required (Figure 4). It should be noted that the lenses of the headset cannot be disinfected with any product that contains alcohol. For such components, a UVC disinfection box (Cleanbox Technology, Inc) can be used; this allows any VR device, including its lenses, to be safely disinfected in 60 seconds (Figure 4). Such a disinfection box can also be used to disinfect over-the-ear headphones that often contain a fabric lining inside their earpieces. Headphones can also be covered with a disposable sanitary earpiece protector to improve hygiene (Figure 4).

Arcades and specialized gaming centers are also concerned with hygiene problems but are often less strict with their requirements. These centers often use silicone covers that can be disinfected with alcohol-based wipes or disposable pads that can be placed on the portion of the headset that touches the user's face. Although these solutions are plausible, sweating can cause silicone covers to become uncomfortable while also dampening disposable pads, causing them to slip out of place. If considering long-term use, the financial aspect of using disposable pads may also need to be considered.

Figure 4. Examples of potential hygiene measures for the hardware used for deployment. (Left) Hygiene covers for over-the-ear headphones. (Middle) UVC disinfection box which can be used for head-mounted displays and headphones. (Right) Custom-made hygiene cover with fabric that can be disinfected on a first-generation Oculus Quest (Meta Platforms, Inc).

Evaluation of the VR Experience

Conducting research using VR is not limited to content; research surrounding VR also focuses on understanding the user experience, specifically as it pertains to presence and immersion within a virtual environment. There are 3 main validated questionnaires that are used to measure presence. The most cited test is a 32-item presence questionnaire developed by Witmer and Singer [32], followed by the 6-item presence questionnaire known as the Slater-Usch-Steed questionnaire [33], and the 13-item iGroup Presence Questionnaire developed by Schubert et al [34,35]. Similarly, there are validated questionnaires concerned with immersion, such as the one developed by Tcha-Tokey et al [36], which is based on the Immersive Tendencies Questionnaire developed by Witmer and Singer [32].

In addition to measuring presence and immersion, it is important to quantify any negative side effects, known as cybersickness, caused by the virtual world [27]. These may include, but are not limited to, symptoms such as nausea, dizziness, headache, and eye strain [37]. These symptoms can be assessed by the validated Simulator Sickness Questionnaire [38]. However, care should be taken to record baseline symptoms in clinical subpopulations [37].

Finally, if the goal is to conduct a scientific study using VR, researchers may wish to consider including eye and head tracking. This could provide information about what parts of the video the user was focusing on and how much they explored their virtual environment. However, eye and head tracking are not supported by all HMDs; these requirements should be considered when selecting an appropriate HMD.

Discussion

Overview

Creating custom 360-degree videos for use in VR-focused research is not an easy task. Unfortunately, due to the relative

novelty of the technology and its use in displaying such content, there is a lack of clear resources available, particularly for those unaccustomed to video editing. Therefore, the goal of this tutorial was to provide information pertaining to the creation, playback, and evaluation of 360-degree videos, with several concrete examples provided in [Multimedia Appendices 2 and 3](#). This expands on existing tutorials, which provide a narrower and less complete scope of information [2,4,39].

While the use cases discussed here refer to the clinical setting, with relaxing 360-degree content provided as an example, there are also nonclinical applications for which the current tutorial could be useful [16,18,40]. As referred to throughout the tutorial, 1 nonclinical use case could involve the use of VR for guided meditation [17,18]. Another example could include using VR to explore and study architecture or improve the general well-being of individuals without access to nature [41,42]. In both of these cases, 360-degree VR content is used. Therefore, using the information provided in the tutorial, the same principles can be used to create content suited to those purposes, thereby extending the target population beyond researchers and health care professionals. In this way, this tutorial can act as a reference for anyone looking to create their own content.

Challenges

Based on our own experiences creating 360-degree VR content, one of the greatest challenges related to creating 360-degree virtual reality content is the length of the recordings. While shorter videos that last less than 5 minutes can be recorded quite easily, there are several equipment- and environment-related issues that must be considered when longer videos are required, especially in environments that are exposed to uncontrollable factors. Not only is there an increased chance of environmental interference, such as insects landing on the lenses or individuals approaching the camera, but there are also technical challenges that must be overcome. This includes overheating and battery life, which must be considered before filming. Additionally, issues associated with file storage capacity and computational

power become important when conducting postprocessing on longer videos.

Another challenge to consider when producing 360-degree videos is the content. The team associated with this study focused on recording calm scenes based on the natural environment, as the goal was to achieve a relaxation effect [13,14,41,43-45]. As such, heavy equipment often had to be brought to remote locations in a backpack. It was also difficult to find the correct balance of activity and nonactivity based on the goals of the project. For example, although the footage was intended to relax the viewer, there still needed to be enough activity to ensure that the video did not appear to be a still picture and that there was enough change in the environment to retain the viewer's interest. Additionally, when filming in a public location, filmmakers must consider the legality of filming individuals who enter the frame of the camera. This problem is particularly relevant when recording 360-degree footage, as there is no way for an individual to avoid being filmed once they enter the camera's field of view. One option to increase the amount of activity in a scene without running afoul of legality issues is to hire actors to create an engaging scene that is appropriate for the purposes of the content.

Future Research

To address some of these concerns, future studies using 360-degree videos should conduct a prestudy that examines the

suitability of their content for their intended purposes. In this way, the reaction of the target population can be examined at an early stage, before the investment of time and resources that are required to make all of the content. However, the suitability of the content will, to some extent, always depend on the individual. Another aspect that could be further investigated is the inclusion of different sounds. Specifically, the overall influence that the choice of sound has on the feeling of immersion within the VR environment could be examined. In this way, the user's experience could potentially be improved.

Conclusions

This tutorial provides users with a pipeline for the creation of customizable 360-degree videos based on first-hand experience. As the field of VR research and use continues to grow and the technology becomes more accessible to the general public, this paper will hopefully guide users through the process of creating content that is suited to their individual needs while avoiding common pitfalls associated with content creation. In doing so, this tutorial fills a gap in the literature and expands upon previously published tutorials focused on the creation of 360-degree videos by explaining 5 key considerations associated with the creation, deployment, and evaluation of 360-degree VR content.

Acknowledgments

The authors would like to acknowledge Carina Röthlisberger for her assistance in recording and troubleshooting the first videos. The authors would also like to thank Listening Earth for sharing their expertise regarding sound recordings and allowing us to use their recordings in our research.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed for this tutorial paper.

Authors' Contributions

ACN undertook the conceptualization, methodology, writing of the original draft, review, and editing of this manuscript. MMJ, SMJ, RMM, and TN took part in the conceptualization, supervision, writing of the original draft, review, and editing of this paper.

Conflicts of Interest

None declared.

Multimedia Appendix 1

Document outlining the details of the pipeline that the study team implemented while recording their nature videos.

[[DOCX File, 179 KB](#) - [mededu_v9i1e42154_app1.docx](#)]

Multimedia Appendix 2

A 2-minute, 360-degree-enabled video. The 360-degree scene can be explored by panning around the video.

[[MP4 File \(MP4 Video\), 181075 KB](#) - [mededu_v9i1e42154_app2.mp4](#)]

Multimedia Appendix 3

A 50-second video clip of a screen capture of a 360-degree-enabled video. Exploration of the scene was done using the cursor. Note that exploration within a HMD would appear smooth. HMD: head-mounted display.

Abstract

Background: The number of new HIV diagnoses in the United States continues to slowly decline; yet, transgender women and men who have sex with men remain disproportionately affected. Key to improving the quality of prevention services are providers who are comfortable broaching the subjects of sexual health and HIV prevention with people across the spectrum of gender identities and sexual orientations. Preservice training is a critical point to establish HIV prevention and sexual health education practices before providers' practice habits are established.

Objective: The study aimed to develop participative web-based educational modules and test their impact on HIV prevention knowledge and awareness in future providers.

Methods: Sexual health providers at an academic hospital, research clinicians, community engagement professionals, and New York City community members were consulted to develop 7 web-based educational modules, which were then piloted among medical students. We assessed knowledge of HIV and sexually transmitted infection prevention and comfort assessing the prevention needs of various patients via web-based questionnaires administered before and after our educational intervention. We conducted exploratory factor analysis of the items in the questionnaire.

Results: Pre- and postmodule surveys were completed by 125 students and 89 students, respectively, from all 4 years of training. Before the intervention, the majority of students had heard of HIV pre-exposure prophylaxis (122/123, 99.2%) and postexposure prophylaxis (114/123, 92.7%). Before the training, 30.9% (38/123) of the students agreed that they could confidently identify a patient who is a candidate for pre-exposure prophylaxis or postexposure prophylaxis; this increased to 91% (81/89) after the intervention.

Conclusions: Our findings highlight a need for increased HIV and sexually transmitted infection prevention training in medical school curricula to enable future providers to identify and care for diverse at-risk populations. Participative web-based modules offer an effective way to teach these concepts.

KEYWORDS

HIV prevention; medical education; sexual health education; pre-exposure prophylaxis; PrEP

Introduction

Background

Since 2017, the overall rate of new HIV diagnoses in the United States has declined each year owing to HIV testing, treatment as prevention, and advances in biomedical prevention such as pre-exposure prophylaxis (PrEP) and postexposure prophylaxis (PEP). However, transgender women and men who have sex with men are disproportionately represented in new HIV diagnoses each year [1,2]. The reasons for these disparities are multifactorial, but key to improving access to, and quality of, HIV prevention services are knowledgeable providers who are comfortable addressing topics of HIV prevention and sexual health concerns across gender identities, sexual orientations, and age. Providers frequently serve as key facilitators to accessing prevention services. Focus group meetings among lesbian, gay, bisexual, transgender, and queer (LGBTQ) individuals conducted previously by our group identified that an important factor in accessing prevention services and participating in HIV prevention research studies was receiving information from providers experienced in providing care to gender-diverse individuals [3]. When LGBTQ individuals such as minoritized Black men who have sex with men are stigmatized by health care providers, this leads to distrust of providers, lack of sexual orientation disclosure, delays in seeking needed medical care, and incomplete disclosure of risk-taking behaviors related to HIV [4-10]. A survey of 120 American internal medicine residents revealed that only 2.3% had ever prescribed PrEP, with the top barrier being lack of familiarity, likely because of a lack of provider education and training [11]. Discomfort with sexual history taking and genital examinations was identified as a barrier to sexually transmitted infection (STI) testing [12,13] and decreased the likelihood of prescribing PrEP [14-16].

Objectives

Education can change providers' intentions and practices [17]. We propose that for lasting impact, it is important to start HIV prevention and sexual health education before inadequate practice habits are firmly established. Therefore, medical students are an important group to train to shape future HIV prevention practices and knowledge. Data about knowledge of, and attitudes toward, HIV prevention among medical students are fairly limited but reveal concerns about inadequate preparation for future practice [18-20]. A recent survey of medical students found that only 37.6% felt adequately trained to address sexual health concerns of patients, and other surveys revealed that students do not feel fully prepared to care for LGBTQ patients [21-24]. Focused training on HIV prevention, gender identity, and sexual orientation and behaviors provided early in medical education may remove barriers and

stigmatization for LGBTQ patients. We proposed to address this need by creating participative educational modules adapted for medical students. Novel approaches such as web-based platforms that permit participative learning, incorporate feedback, and use role-playing have proven extremely successful when used by infectious diseases faculty at an academic medical center to teach medical students general infectious diseases and virology [25]. This investigation built on the expertise of the research team to create participative modules that focus on topics of HIV prevention, sexual health, risk reduction, and the biomedical prevention research pipeline. We tested the impact of these modules on knowledge of STI and HIV testing as well as PEP and PrEP in a cohort of first- through fourth-year medical students.

We hypothesized that participative web-based modules would increase medical students' knowledge of PrEP and PEP, increase confidence in identifying candidates for HIV prevention services, and serve as acceptable learning tools for medical students.

Methods

Primary Outcome Measures

Our main outcome measures were student-reported comfort and confidence in engaging with LGBTQ patients, student-reported sexual history-taking abilities, and confidence in identifying patients who are candidates for PrEP and PEP (5-point Likert scale). We also assessed general knowledge of HIV and STI screening and prevention (10-point scale).

Module Development

The educational modules were developed between September 2018 and January 2019 using *Articulate Storyline* (Articulate Global, LLC). Sexual health providers, research clinicians, and community engagement volunteers at a large urban tertiary care academic medical center located in a predominantly Latinx (72%) and foreign-born (47%) community in New York City were consulted for expertise and supplemental materials on risk reduction counseling, prescribing, and monitoring patients on PrEP and PEP, as well as biomedical prevention research studies [26]. These materials were used to develop unique clinical narratives and cases that were web based and participative. The finalized module content is presented in [Textbox 1](#).

After initial drafts of the modules were constructed, the same sexual health providers, research clinicians, and community engagement volunteers who were consulted before module creation were asked to offer feedback on content accuracy, language, and organization. The modules were hosted on a web-based secure server established by the research team. These modules can be viewed at [Stick2PrEP](#) [27].

Textbox 1. Finalized module content.**Seven 5- to 10-minute modules**

1. A postexposure prophylaxis (PEP) module on the indications and evidence behind PEP and how to monitor a patient on PEP
2. PEP cases where students engaged with 4 distinct clinical cases based on the foundational knowledge and skills learned in the PEP module
3. A pre-exposure prophylaxis (PrEP) module on laboratory testing, prescribing, and clinical indications for PrEP
4. PrEP cases where students applied the knowledge learned in the PrEP module by navigating 4 patient cases
5. A sexually transmitted infection testing module focused on special considerations when screening and treating diverse patient populations such as cisgender men who have sex with men, geriatric populations, patients living with HIV or AIDS, and transgender women
6. A sexual health algorithm about the appropriate terminology to use when interacting with gender and sexually diverse patients, creating a welcoming environment for lesbian, gay, bisexual, transgender, or queer patients, and gendered pronoun use, with concepts supplemented by 2 clinical cases
7. Research concepts that explored HIV prevention in the research setting, such as preventive vaccine and antibody studies, topical microbicides, and long-acting injectable PrEP

Advisory Group

Community members aged ≥ 18 years who lived in the New York City metropolitan area and had seen a provider more than once in the last 12 months for unspecified medical reasons were invited to provide contact information to participate in a community advisory group about their HIV and STI testing experiences and provide feedback on initial versions of the educational modules. Gender and sexual minorities were strongly encouraged to participate. Community members were recruited via Craigslist, Facebook, and physical flyers posted on the medical center campus. Of the 116 eligible community members who responded to the advertisements, up to 16 (13.8%) were contacted for each advisory group, with gender identity, sexual orientation, risk factors for HIV and STI infection, and clinical experiences being relevant to the selection process. After we obtained informed consent from all participants, 2 advisory group meetings were conducted in November 2018. Two members of the research team, MAA and WG, facilitated these meetings. All community members were reimbursed US \$25 for their time and thoughtful contributions. These advisory group meetings followed a prepared script, and audio recordings of both meetings were transcribed. Two research team members identified reoccurring themes from the transcripts, which were then used to further inform the content of the modules. Two

iterations of the modules based on advisory group feedback occurred, incorporating feedback from the first group (iteration 1) and the second group (iteration 2).

Medical Student Questionnaires

We used 20 items to assess student confidence, knowledge, and perception of sexual health, which were assessed before and after completion of the educational modules. To our knowledge, no validated survey instruments exist to measure these concepts. Thus, the survey instrument was developed based on a review of published literature and clinical experience of the investigative team. Question content and phrasing were developed collaboratively by authors WG, MAA, CC, JZ, and MEK. The remaining members of the research team offered feedback on an initial draft of the questionnaire. The questions used in the assessment are presented in [Textbox 2](#). The first 10 questions were assessed on a 5-point Likert scale, ranging from 1=*strongly disagree* to 5=*strongly agree*. The next set of 10 questions, based on HIV and STI screening and prevention knowledge, was presented in a multiple-choice format and graded for correctness on a scale of 0 to 10, with each question weighted equally. The students were asked to provide demographic information to capture relevant educational and social variables (ie, age, gender, race, sexual orientation, and familiarity with PrEP and PEP).

Textbox 2. Medical student questionnaire. LGBTQ: lesbian, gay, bisexual, transgender, and queer; PEP: postexposure prophylaxis; PrEP: pre-exposure prophylaxis; STI: sexually transmitted infection.

Likert-scale questions: comfort with taking a sexual history and with sexual and gender minorities, as well as identifying candidates for postexposure prophylaxis and pre-exposure prophylaxis (questions 6, 7, 8, and 9 were removed from the pre- vs postintervention analysis based on factor structure determined via exploratory factor analysis)

1. I feel comfortable asking patients about their sexual orientation e.g. gay, bisexual.
2. I feel comfortable discussing sexual health problems with patients of different gender identity than my own.
3. I feel comfortable taking a sexual history from a patient who identifies as LGBTQ.
4. I feel comfortable asking patients about their sexual practices e.g. "Are you sexually active?", "Do you practice vaginal sex?"
5. I find taking a sexual history easy.
6. I have adequate skills to take a sexual history.
7. I have enough exposure as a medical student to take a sexual history from a real patient.
8. I have enough exposure as a medical student to take a sexual history from a simulated patient.
9. I feel that there is not enough training in medical school on how to discuss sexual health problems with patients.
10. I feel confident identifying a patient who is a candidate for PrEP, PEP, and other HIV and STI prevention services.

Multiple-choice questions: HIV and sexually transmitted infection screening and prevention knowledge (for the multiple-choice questions, students were presented with 4 options not shown here; they did not receive correct-response feedback)

1. How often should all sexually active gay, bisexual, and other men who have sex with men (MSM) be screened for HIV, syphilis, chlamydia, and gonorrhea?
2. According to the CDC, annual chlamydia screening is recommended for all sexually active women under the age of ____, as well as older women with risk factors such as ____.
3. 4th generation HIV tests detect ____ in blood specimens.
4. PrEP, when used daily and with condoms, has been shown to reduce the risk of HIV infection in those who are high risk by up to ____.
5. Which of these individuals would benefit from PrEP use?
6. At time of initiation of a PrEP regimen, how many days of medication should you prescribe at the first patient visit?
7. How many days of medication should you prescribe at an initial PEP visit?
8. How many hours after HIV exposure should PEP be started?
9. Which of these individuals would be a candidate for PEP (assume within appropriate time window)?
10. True or False: HIV negative recipients of an HIV vaccine may test positive on some HIV antibody tests for the duration of a vaccine study and possibly thereafter.

Completion of the survey was anonymous and not time restricted. The questionnaire was administered using Qualtrics survey software and was open only to medical students at the institution where the modules were developed. Informed consent was obtained using the cover page of the survey. Electronic invitations to participate in the survey were distributed using class listserve accounts. Administrative permission was obtained before sending invitations to student listserve accounts. Participant eligibility and inclusion criteria were defined as currently enrolled first- through fourth-year medical students. Medical students at the recruitment site (approximately 150 per class) participate in a 4-year curriculum, with full-time classroom-based teaching for the first 1.5 years (3 semesters) of the curriculum, after which they begin their clinical rotations. Exposure to HIV and STI testing occurs during the infectious diseases unit in the third semester and as is relevant during clinical rotations. Some fourth-year students were recruited for participation via a month-long residency preparedness course taken just before the intern year. The questionnaire and

participation were offered as voluntary supplemental learning opportunities.

After completion of the premodule survey, the students were routed to another Qualtrics survey whereby they could provide an email address to receive a URL link to the learning modules. Students were given up to 2 weeks to complete the 7 learning modules to facilitate focused learning and to allow knowledge gained from one module to be applied to the next. At the end of the final module, participants received a link to complete an anonymous postmodule Qualtrics survey.

The postmodule questionnaire was used to assess the same domains included in the premodule questionnaire and used the same 20-item assessment. It also contained a space for free-text entry to provide general thoughts and comments on the modules. However, the postmodule questionnaire did not include demographic information in an effort to maintain student anonymity. For this reason, the pre- and posttest surveys could not be linked at the individual level. Local institutional review board approval was obtained before starting the study (refer to

the *Ethics Approval* section), and all methods were performed in accordance with the Declaration of Helsinki. Grant funding was used to reimburse students US \$50 for completing the modules.

Statistical Analysis

Exploratory factor analysis (EFA) was conducted to investigate the factor structure of the Likert-scale questions of the questionnaire. As a first step, parallel analysis, minimum average partial, and a scree plot were used to determine the number of factors to extract for the EFA. Subsequently, several models with different numbers of factors, suggested by the initial analysis, were fitted via weighted least squares (WLS). We anticipated that the underlying factors were intercorrelated. Therefore, oblimin and promax oblique rotations were used and their results compared.

Each model was evaluated by examining whether it exhibited salient pattern loadings (loadings ≥ 0.32), showed an approximate simple structure, and contained considerable intercorrelations among the factors. A root mean squared residual (RMSR) of ≤ 0.08 was considered an acceptable model fit. The proportion of residual coefficients that exceeded absolute values of 0.05 and 0.10 were also examined. Finally, the Cronbach α reliability coefficient for each subscale had to approach a value of .90 for a model to be deemed acceptable.

For the resulting factor model, median scores with IQRs were calculated both before and after the intervention. *P* values for comparing pre- and postmodule responses were determined using Wilcoxon rank sum tests. For HIV and STI screening and prevention knowledge, percentage correct was calculated for each question, and *P* values were determined using the 2-sample binominal test for proportions using normal theory methods with continuity correction. *P* values were Bonferroni corrected. Median HIV and STI screening and prevention knowledge scores were compared via Wilcoxon rank sum tests. Given the paired nature of the data, we intended to use Wilcoxon signed-rank tests; however, without means of linking the

premodule and postmodule questionnaire responses, the individual-level data could not be paired. The purpose of keeping the premodule and postmodule responses unlinked was to maintain the anonymity of the students in accordance with the institutional review board protocol. All data were analyzed using RStudio 2022.02.2+485 *Prairie Trillium* release (Posit Software, PBC) and Microsoft Excel (version 16.62).

Ethics Approval

This investigation was conducted in accordance with the Declaration of Helsinki and was approved by the institutional review board at Columbia University Irving Medical Center (AAAR8304). Informed consent was obtained from all medical student participants via the premodule web-based questionnaire and from all community members who participated in the advisory groups.

Results

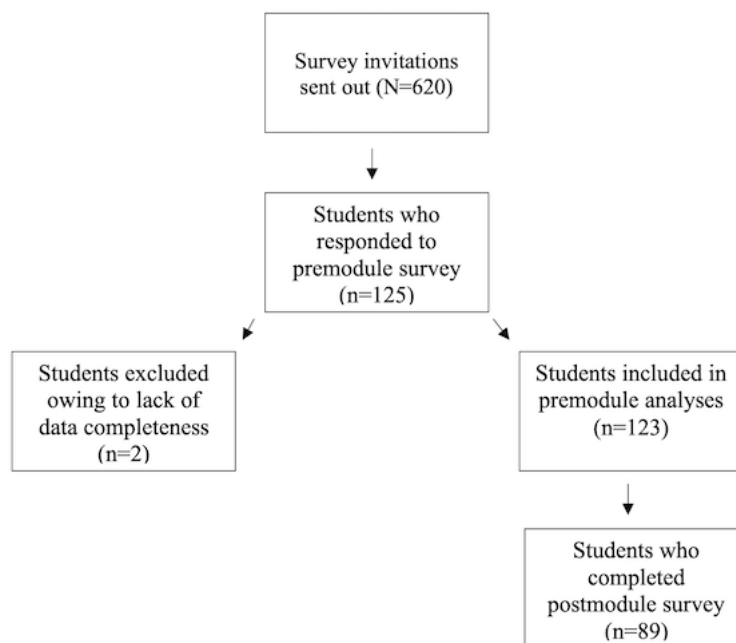

Survey Response and Demographics

A total of 620 survey invitations were sent to medical students via email or the institution offering the residency preparation course; we received responses from 125 individuals, representing a 20.2% response rate. Two responses were excluded from data analyses owing to lack of data completeness. The mean age of the 123 students in the final sample was 26.5 (SD 2.4) years, and fourth-year students were most represented among all student cohorts (51/123, 41.5%). The majority of students identified as White (62/123, 50.4%), heterosexual (96/123, 78.1%), and women (71/123, 57.5%), whereas 22% (27/123) identified as lesbian, gay, bisexual, or other or did not provide a response. Most students had heard of PrEP and PEP before the educational modules (122/123, 99.2%, and 114/123, 92.7%, respectively). Complete participant characteristics are summarized in [Table 1](#). A total of 89 students also completed a postmodule survey. The overall completion rate was 71.2% (89/125). [Figure 1](#) summarizes study participation and completion.

Measurement Psychometrics

Of the 10 Likert-scale questions presented in [Textbox 2](#), question 9 was removed from the analysis because it did not correlate with any other question (no Pearson r values >0.3) and had the lowest item-total correlation ($r=-0.17$); hence, it would not have contributed meaningfully to the analysis. The initial analysis using the previously described factor extraction methods and incorporating the remaining 9 questions suggested a 1- to 2-factor model. A 2-factor model was most appropriate (RMSR=0.034) but had increased complexity resulting from question 6 loading almost equally on both factors (complexity=1.97, WLS1=0.465, WLS2=0.413). Upon further inspection, the wording of question 6 was noted to be highly similar to that of question 5; therefore, question 6 was removed too. In subsequent models with 8 questions included, questions 1, 2, 3, 4, 5, and 10 loaded on the first factor, whereas questions 7 and 8 loaded on the second factor. Given that any factor should comprise at least 3 contributing questions, the 2 questions loading on the second factor (questions 7 and 8) were removed from the analysis [28]. In sum, of the 10 Likert-scale questions, 6 were deemed appropriate for inclusion in the pre- to postintervention statistical analysis. Those removed are noted in [Textbox 2](#).

Parallel analysis, the scree plot, empirical scree tests, and the minimum average partial all suggested an EFA with a single factor, henceforth referred to as factor 1. The RMSR for the resulting single factor model was 0.041, which is below the a priori cutoff of 0.08. Factor loadings for the 6 questions that comprise factor 1 ranged from 0.490 to 0.799. In this model, there were no residuals >0.10 and only 27% >0.05 . The Cronbach α value for factor 1 was .87 (95% CI 0.82-0.90), and reliability did not increase when any individual factor was dropped, thus supporting the 1-factor structure and inclusion of these 6 questions.

Pre- to Postintervention Analysis

For factor 1, although the median score did not change, the IQR increased, given a median of 4.0 (IQR 3.0-4.0) before the intervention and 4.0 (IQR 4.0-5.0) after the intervention ($P<.001$; [Figure 2](#)). The frequency of the score of 5 (*strongly agree*) increased from 15% to 35%. Specifically for confidence identifying a candidate for PEP or PrEP, the median score increased from 3.0 (IQR 2.0-4.0) to 4.0 (IQR 4.0-5.0; $P<.001$). The frequency of the score of 4 (*agree*) increased from 22% to 53%, and the frequency of the score of 5 (*strongly agree*) increased from 9% to 38%. These data are summarized in [Multimedia Appendix 1](#).

Although 4 questions were removed from the factor analysis, some of these questions demonstrated statistically significant increases from before to after the intervention; for example, when asked to rate agreement with question 7 (“I have enough exposure as a medical student to take a sexual history from a real patient”), the median score increased from 3.0 (IQR 2.0-4.0) to 4.0 (IQR 3.0-4.0; $P=.02$). Agreement with question 6 (“I have adequate skills to take a sexual history”) also increased from 4.0 (IQR 3.0-4.0) to 4.0 (IQR 4.0-5.0; $P<.001$).

The median HIV and STI screening and prevention knowledge score also increased from a baseline of 6.0 (IQR 6.0-7.0) to 8.0 (IQR 7.0-9.0; $P<.001$; [Figure 3](#)). Pre- to postintervention changes in the scores for the 10 individual questions on HIV and STI screening and prevention knowledge are summarized in [Table 2](#); the questions are presented in [Textbox 2](#). Although there was an increase in the percentage of correct responses for all questions after the educational intervention, 4 of the 10 questions met our criteria for statistical significance ($P<.005$ after Bonferroni correction). All statistically significant changes in correct responses involved prescribing, monitoring, and evidence behind PrEP and PEP. This perhaps reflects a collective gap in knowledge within this clinical domain as well as a substantial increase in knowledge of this subject after the intervention.

Figure 2. Factor 1 before and after the educational intervention (premodule survey: n=123 and postmodule survey: n=89). Data are shown as box-and-whisker plots with the lower and upper limits (bounds) of the box representing quartile 1 (25th percentile) and quartile 3 (75th percentile), respectively. The median (quartile 2, 50th percentile) is represented by the bolded horizontal line within each box. Whiskers, shown as vertical lines extending from the boxes, extend to 1.5 times the IQR. IQR: interquartile range.

Figure 3. Pre- and posteducational intervention HIV and sexually transmitted infection screening and prevention knowledge (premodule median scores: n=123 and postmodule median scores: n=89). HIV and sexually transmitted infection screening and prevention knowledge scores are on a scale of 0 to 10 and represent general sexual health screening and prevention questions scored for correctness. Data are shown as box-and-whisker plots with the lower and upper limits (bounds) of the box representing quartile 1 (25th percentile) and quartile 3 (75th percentile), respectively. The median (quartile 2, 50th percentile) is represented by the bolded horizontal line within each box. Whiskers, shown as vertical lines extending from the boxes, extend to 1.5 times the IQR.

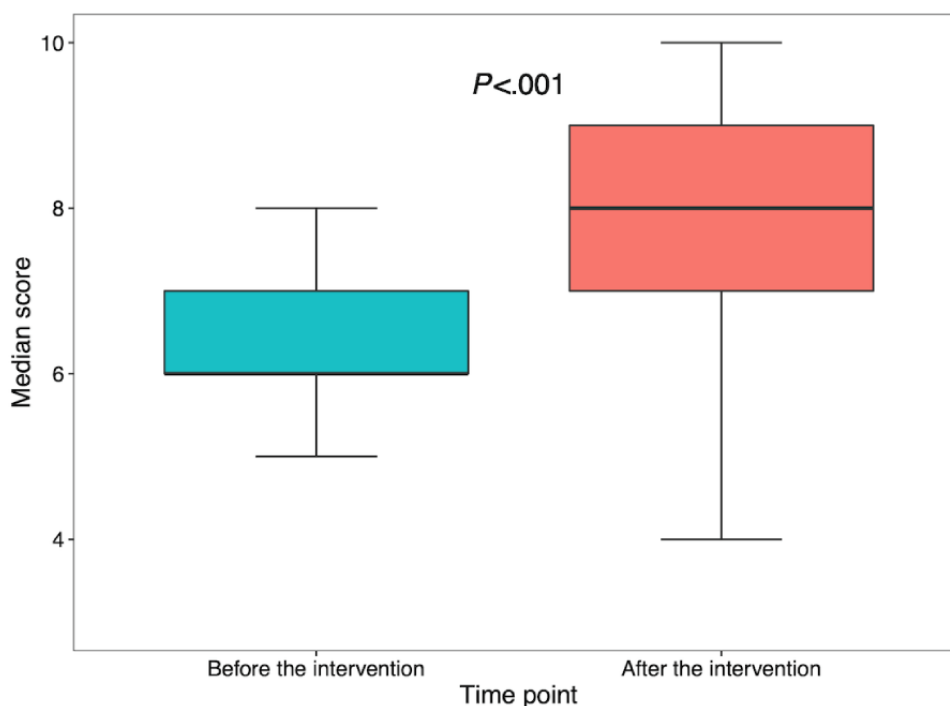

Table 2. HIV and sexually transmitted infection screening and prevention knowledge percentage of correct answers by question.

	Preintervention survey (% correct), n=123	Postintervention survey (% correct), n=89	P value ^a

Narrative Feedback

Narrative feedback from medical students, collected as free-text entry within the postmodule survey, was overwhelmingly positive. A student stated as follows:

Great modules. This is the first time in my medical school program to learn about PEP, as well as my first formal education module on PrEP. Keep it up and make it more available to future healthcare providers. [Participant 1]

Another student provided the following feedback:

Really useful modules, especially the PEP module as I received no education on post-exposure prophylaxis, as well as how to prescribe it to my patients throughout the entirety of medical school. These modules should become an integral part of our clinical training. [Participant 2]

A third student stated as follows:

This was great learning. I wish it was integrated into the medical curriculum. [Participant 3]

Several individuals commented that the modules were the appropriate length and that they provided useful information even for those already familiar with PrEP and PEP.

Advisory Groups

Regarding the advisory group meetings, of the 6 community members, 2 (33%) attended the first meeting, and 4 (67%) attended the second. The first and second advisory group meetings lasted 90 minutes and 120 minutes, respectively. Demographic characteristics of the advisory group participants are summarized in Table 3. Three key themes were identified from the meetings, which were used to inform module content and are summarized in Table 4, with supporting quotations (the quotations were selected, verbatim, from audio-recorded transcripts; language was not abridged or manipulated; and transcription was performed by Transcripts 4 North America). In addition, prompted by the advisory meetings, we modified module content language to further enhance inclusivity and reorganized the workflow of several modules to improve clarity.

Table 3. Advisory group participant demographic information.

Advisory group meeting	Age of participant (years)	Race	Gender identity ^a	Sexual orientation	Heard of PEP ^b	Ever taken PEP	Heard of PrEP ^c	Ever taken PrEP
1	31	Mixed race (did not specify)	Woman	Heterosexual	Yes	No	Yes	No
1	24	Black, non-Hispanic	Man	Heterosexual	No	No	Yes	No
2	37	Black, non-Hispanic	Man	Gay	Yes	No	Yes	Yes
2	56	Black, non-Hispanic	Man	Bisexual	Yes	Yes	Yes	Yes
2	— ^d	White, non-Hispanic	Woman	Heterosexual	Yes	No	Yes	No
2	40	Black, non-Hispanic	Man	Heterosexual	Yes	Yes	No	No

^aWoman refers to cisgender woman and Man refers to cisgender man. There were no participants identifying as transgender in either advisory group.

^bPEP: postexposure prophylaxis.

^cPrEP: pre-exposure prophylaxis.

^dParticipant did not provide response within free-text response box.

Table 4. Advisory group themes with supporting quotations from participants.

Themes	Illustrative quotes
Bias and stereotype in patient-provider interactions	“But maybe to not use—I don’t necessarily feel like you have to speak to minorities, gay men, or people who live in maybe impoverished neighborhoods like we are high risk just because of those factors.” [Participant 1]
Diversifying standard clinical practices	“I think they should have like a checklist of things, you know. I’ve never been to a primary care doctor that—maybe I filled it out on paper—that asked me if I’m bisexual, if I’m heterosexual, whatever. I’ve never really experienced that before.” [Participant 2]
Openly promoting access to innovative prevention services	“You know, you don’t see signs in the office that says PrEP or anything like that. You go to these community-based places and you see PrEP everywhere, you know? But you don’t see it in no primary care doc, you know, about that.” [Participant 3]

Discussion

Principal Findings

This study evaluated medical students’ knowledge and confidence regarding HIV and STI prevention concepts across the spectrum of gender identity and sexual orientation. Our findings suggest that there is a need for increased HIV and STI prevention training in standard medical school curricula, particularly given the recent Centers for Disease Control and Prevention recommendation that all sexually active adolescents and adults should be informed by their providers about PrEP [29]. This conclusion is supported by our findings that although most of the students had heard of PrEP (122/123, 99.2%) and PEP (114/123, 92.7%), only 30.9% (38/123) felt confident identifying patients who were candidates for these prevention therapies. Before the intervention, relatively few students could identify the number of days of medication that should be prescribed at an initial visit for PrEP (48/123, 39%) and PEP (31/123, 25.2%). Others have demonstrated that both web-based and in-person educational curricula can effectively teach sexual history taking and increase confidence in working with LGBTQ patients among first- and second-year medical students, but they did not include students in later years of medical education in these interventions [30-33]. Our study found that HIV and STI prevention knowledge was similar across years of medical education. Fourth-year medical students preparing to begin residency did not feel more confident than their juniors at identifying candidates for prevention services; nor did they report the highest confidence in their perception of their sexual history-taking abilities or confidence in interacting with LGBTQ patients. This highlights a lack of effective curricula for medical students related to sexual health and emphasizes the need for this content to not only be taught early in medical school but also be reiterated in the final years of medical education.

Many prior studies have used interventions that require in-person sessions or web-based group meetings, whereas this study demonstrates that completely self-paced web-based educational modules are an effective and easy-to-implement method of increasing medical student knowledge [30-35]; for example, the percentage of students who felt confident in identifying a candidate for prevention services increased by 60%—from 30.9% (38/123) to 91% (81/89)—after completion of the educational modules. In addition, comfort providing sexual health care to LGBTQ individuals and perception of sexual history-taking abilities, both of which are encompassed in factor 1, increased after the intervention. These findings support the

use of innovative educational modules as practical and accessible learning tools to increase medical students’ knowledge.

The students’ free-text comments from the postmodule survey demonstrated that the modules were well received by participants and were viewed as an important addition to their medical education. Their comments underscored that this content was not covered elsewhere in their education and affirmed that there is a need for increased HIV and STI prevention training in standard medical school curricula. Given the positive feedback and interest from the students, these modules have now been incorporated into the second- and fourth-year medical student curricula at the institution where they were developed.

Strengths and Limitations

This study includes several strengths. The educational modules were designed in part by sexual health clinicians who provided clinical expertise, with subsequent refinement via input from diverse community members. The use of EFA allowed for progress toward a validated instrument to measure medical student confidence in taking a sexual history and working with LGBTQ patients. The self-paced web-based nature of the modules is also a great strength of this study because it allowed for students to flexibly engage with this content at times that were most suitable for them in terms of the learning experience.

Our study is not without limitations. Pre- and postmodule questionnaires were completed anonymously, and we did not provide students with a study-specific ID or linking identifier between the pre- and postintervention responses. This limited our ability to make statistical inferences from our analyses, which had a pre-post paired design. Instead, unpaired aggregated differences were generated through our analyses. The study may have limited generalizability because the baseline characteristics of the students who completed the study do not necessarily reflect the characteristics of medical students or providers throughout the region or nationally; for example, 22% (27/123) of the students who completed the premodule survey identified as lesbian, gay, bisexual, or other in terms of sexual orientation, which is above the estimated average for the US adult population (4.5%) [36]. Some students may also have learned about HIV prevention, PrEP, and PEP through public health campaigns and other external sources in New York City; in other words, their knowledge may not be attributable to the educational modules. In addition, given that the data were gathered by self-report, it is possible that the students provided socially desirable responses and misestimated their own abilities

during survey completion. If our recruitment attracted students with specific social or educational variables, this may have been a confounding element; for example, participants were not recruited in equal numbers across all years of medical school. Some students may have been drawn to the study owing to monetary compensation and may not have meaningfully engaged with the content before completing the postmodule survey. We also recognize that this analysis is exploratory in nature. We hope to repeat this study with a larger sample size and additional postmodule survey time points to further validate the survey instrument, perform a confirmatory factor analysis, and

demonstrate long-term knowledge retention after module completion.

We demonstrated that web-based educational modules on the subject of HIV prevention are easy to design and implement, are viewed favorably by learners, and effectively increase medical students' knowledge of STI testing, HIV prevention strategies, and confidence in taking a sexual history. Broader implementation of such modules in medical school curricula could enhance HIV prevention services offered by the next generation of medical providers.

Acknowledgments

The authors would like to thank the administrative staff at New York-Presbyterian Hospital and Columbia University Irving Medical Center Division of Infectious Diseases for their continual support. The authors would also like to thank the medical students who completed the educational modules and community members who participated in the advisory groups. This study would not have been possible without them. This research was supported by the HIV Vaccine Trials Network Research and Mentorship Program. Research reported in this publication was also supported by the National Institute of Allergy and Infectious Diseases of the National Institutes of Health (UM1AI069470, K23AI150378, and L30AI133789). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Data Availability

The data sets generated and analyzed during this study are not publicly available because they are protected by the institutional review board at Columbia University Irving Medical Center but are available from the corresponding author on reasonable request.

Authors' Contributions

WG, MAA, JB, CC, JZ, and MES participated in study conceptualization. WG and MAA were the primary creators of the educational modules. RJG provided instruction on the software used to create the modules. CC, JZ, BG, RJG, and MES reviewed the module content and offered feedback. WG and CAS completed the data analysis. MAA, JB, and WG conducted the advisory groups and identified key themes from interview transcripts. WG and MAA drafted the manuscript with feedback from CAS, JZ, and MES. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The potential for digital health technologies, including machine learning (ML)-enabled tools, to disrupt the medical profession is the subject of ongoing debate within biomedical informatics.

Objective: We aimed to describe the opinions of final-year medical students in Ireland regarding the potential of future technology to replace or work alongside general practitioners (GPs) in performing key tasks.

Methods: Between March 2019 and April 2020, using a convenience sample, we conducted a mixed methods paper-based survey of final-year medical students. The survey was administered at 4 out of 7 medical schools in Ireland across each of the 4 provinces in the country. Quantitative data were analyzed using descriptive statistics and nonparametric tests. We used thematic content analysis to investigate free-text responses.

Results: In total, 43.1% (252/585) of the final-year students at 3 medical schools responded, and data collection at 1 medical school was terminated due to disruptions associated with the COVID-19 pandemic. With regard to forecasting the potential impact of artificial intelligence (AI)/ML on primary care 25 years from now, around half (127/246, 51.6%) of all surveyed students believed the work of GPs will change minimally or not at all. Notably, students who did not intend to enter primary care predicted that AI/ML will have a great impact on the work of GPs.

Conclusions: We caution that without a firm curricular foundation on advances in AI/ML, students may rely on extreme perspectives involving self-preserving optimism biases that demote the impact of advances in technology on primary care on the one hand and technohype on the other. Ultimately, these biases may lead to negative consequences in health care. Improvements in medical education could help prepare tomorrow's doctors to optimize and lead the ethical and evidence-based implementation of AI/ML-enabled tools in medicine for enhancing the care of tomorrow's patients.

Introduction

Background

According to economists and futurists, traditional health care will become increasingly disintermediated by innovations in digital technology, including advances in artificial intelligence (AI)/machine learning (ML) [1-3]. These views are also held by many AI experts and health care informaticians, many of whom are physicians, who predict that ongoing developments in AI/ML will revolutionize the delivery of health care [4-7]. Moreover, digital innovations and AI/ML-enabled tools already play roles in health care by helping patients to monitor and manage their symptoms, supporting patient triage decisions via chatbots, informing clinical decisions, offering treatment recommendations via clinical decision support tools, and supporting health care resource management [8]. Despite these developments, in surveys, many medical professionals are skeptical about the impact and value of digital and AI/ML tools on their job, with surveyed physicians doubting the scope of technological innovations to replace clinicians in fundamental medical tasks [9-11]. Emerging surveys among students enrolled in a range of health care training programs, including medicine, dentistry, and clinical psychology, also revealed divergent opinions about the impact of AI/ML on their chosen profession, with participants reporting limited formal education on these topics [12-18].

Objectives

We sought to explore the opinions of final-year medical students in Ireland on the impact of future technology on the job of general practitioners (GPs). We performed a brief scoping review of the literature using the terms “artificial intelligence,” “machine learning,” “education,” and “training” in the search engines of PubMed and Google Scholar, and explored the grey literature. Only a few surveys, which were conducted in Europe, the United States, and South Korea, explored the attitudes of medical or health care students about the encroachment of AI/ML in medicine, and most were single-site studies [12-18]. Our objective was to explore the opinions of final-year medical students across Ireland to obtain a better understanding of their forecasts about the capacity of future technology to fully replace or to partner with physicians in undertaking key components of the work of GPs. In addition, our aim was to explore both students’ longer-term predictions and comparatively shorter-term forecasts (25 years from now) about how technology might impact the work of GPs.

Methods

Study Population

Participants in this convenience sample paper-based survey were final-year medical students at 4 of Ireland’s 7 medical schools (after survey administration, in August 2021, a new 8th medical school at the University of Ulster began enrolling

students). Using the study team’s contacts, we sought to administer the survey in the country’s 4 geographical provinces. Between April 2019 and March 2020, the anonymous survey was distributed by lecturers after compulsory final-year classes at each institution to increase responses.

Ethics Approval

Institutional review boards at University College Cork (protocol #2018-188), National University of Ireland Galway (protocol #19-Dec-15), Queen’s University Belfast (protocol #19.28), and University College Dublin (protocol #LS-19-89) approved the study at their respective sites. Participation was voluntary, and all students who decided to participate provided written consent.

Survey Instrument

The survey (Multimedia Appendix 1) was divided into 5 parts (Sections A to E). Section A requested demographic information. In Section B, the study team replicated and also extended components of a survey instrument originally devised to investigate the views of UK GPs about the potential impact of technology on the primary care profession [9]. The survey by Blease et al [9] formulated a generic list of tasks common to primary care, including “analyze patient information to reach diagnoses,” “analyze patient information to predict the likely course of the patient’s illness,” “evaluate when to refer patients to other health professionals,” “formulate personalized treatment plans,” “provide empathic care to patients,” and “provide documentation (eg, update medical records) about patients,” and requested that respondents rate the likelihood of these tasks being replaced by future technology. An additional goal was to compare students’ responses with those in the original UK survey.

Replicating the original survey, the first set of 6 survey items in Section B opened with a brief statement: “Some people believe that machine learning/artificial intelligence will lead to significant changes in medical practice and that machines will one day replace the work of physicians; others deny that new technologies will ever have the capacity to replace this work.” We then asked respondents their opinion on the likelihood that, “future technology will be able to fully replace and not merely aid human doctors in performing each task as well as or better than the average GP.” Employing 4-level Likert items, we included the following response options: “extremely unlikely,” “unlikely,” “likely,” and “extremely likely.” Participants who responded that replacement was “likely” or “very likely” were asked a follow-up question about how soon in their estimation would technology have the capacity to perform the task as well as or better than the average GP, and were provided with a list of 5 response options: “0-4 years from now,” “5-10 years from now,” “11-25 years from now,” “26-50 years from now,” and “more than 50 years from now.” In all closed-ended questions in the survey, we avoided “don’t know,” “neutral,” or “no opinion” options on the grounds that participants often conflate these answers [19].

The study team also extended and developed the original survey instrument by asking students 2 additional questions in Section B. One question was “In 25 years, of the following options, in your opinion what is the likely impact of artificial intelligence/machine learning on the work of GPs?” Students were offered 1 of 4 response options: “no influence (GPs’ jobs will remain unchanged),” “minimal influence (GPs’ jobs will change slightly),” “moderate influence (GPs’ jobs will change substantially),” and “extreme influence (GPs’ jobs will become obsolete).” Participants who answered that there would be minimal, moderate, or extreme influence were then asked the following open comment box question: “Please briefly describe the way(s) in which you believe artificial intelligence/machine learning will change GPs’ jobs in the next 25 years.”

While Section B explored opinions about the potential capabilities of future technology to fully replace GPs on specific tasks, the aim of Section C was to explore students’ views about routine partnership between “man and machine,” that is, GPs and digital tools, in performing various tasks in primary care. Specifically, our aim was to explore students’ predictions about the roles of technology in triage decisions, clinical decision support, remote monitoring of symptoms, and patients’ access to their records. Using a 6-point Likert scale we asked students their level of agreement about the following 6 scenarios: “25 years from now...” (1) “...technology (eg, smartphone apps) will be used to decide when patients need to see a GP,” (2) “...GPs will routinely work in partnership with artificial intelligence/machine learning to diagnose patients,” (3) “...GPs will routinely work in partnership with artificial intelligence/machine learning to determine the likely course of a patient’s illness,” (4) “...GPs will routinely work in partnership with artificial intelligence/machine learning to devise patient treatment plans,” (5) “...remote monitoring of patients’ vital signs will be more common than in-person check-ups of vital signs with GPs,” and (6) “... patients will have greater access to their own medical records than they do today.”

Section D of the survey focused on students’ views about the potential benefits and harms of AI/ML in medicine, and Section E focused on students’ experiences and opinions about formal teaching of AI/ML in their medical degree program. The results of Section D will be published elsewhere, and the results of Section E have now been published [20].

The survey was devised in consultation with Irish, British, and American primary care physicians, and we piloted the survey with physicians in Ireland and the United Kingdom (n=6), and final-year medical students in the United Kingdom (n=5) to ensure face validity. The feedback process was conducted via one-on-one consultations involving think-aloud methods with primary care physicians and medical students.

Data Analysis

Quantitative Component

After survey collection, quantitative survey responses were entered into Excel (Microsoft Corp), and descriptive statistical analysis was carried out using JASP (0.9.2; University of

Amsterdam) and SPSS (version 27; IBM Corp). CIs were calculated using the package “REdaS” and function “freqCI,” with the CI level set at 0.95. We used descriptive statistics to examine students’ characteristics and their opinions about the impact of future technology to replace the current tasks of GPs in primary care, whether they believed AI/ML would impact the work of GPs 25 years from now, and whether GPs would routinely partner with AI/ML. For comparisons, students intending to become GPs and internists were grouped together as “planned nonspecialists,” while the remaining categories were grouped together as “planned specialists.” We also embedded into the survey the term “internists” (which is less common in Ireland and the United Kingdom), as we anticipated a high proportion of nonnative student respondents. Due to the ordinal nature of the dependent variables, group comparisons (across males versus females and planned specialists versus planned nonspecialists) were performed using the Mann-Whitney *U* test where the *U* value refers to the difference in the summed ranks.

Qualitative Component

Survey responses were uploaded to the software QCMap (coUnity Software Development GmbH) for analysis. Thematic content analysis was used to investigate students’ responses, and transcripts were read by AK and CB to achieve familiarization with the responses. Owing to limitations with the data set (short phrases or fragments of sentences), full thematic analysis was not applicable [21]. One coder (AK) undertook the thematic analysis. A process was employed in which brief descriptive labels (“codes”) were applied to comments, and multiple codes were applied if comments presented multiple meanings. Following this process, revisions and refinements of codes were undertaken by CB, and AK and CB met to discuss coding decisions. Afterwards, first-order codes (“categories”) were grouped into second-order themes based on commonality of meaning, and AK and CB met to review and refine the final themes.

Results

Results of the Quantitative Survey

Survey Participants

Data collection at 1 medical school (University College Dublin) was terminated in March 2020 because of teaching disruption due to COVID-19, and survey data from this site was excluded from the analysis. A total of 43.1% (252/585) of final-year students across the 3 remaining medical schools responded (raw data are presented in [Multimedia Appendix 2](#)). Among all respondents, 62.6% (157/251) were female and 90.7% (223/246) were born in 1992 or later ([Table 1](#)). Participants were nationally diverse, with 57.9% (114/197) from Ireland, 12.2% (24/197) from Malaysia, 12.7% (25/197) from the United Kingdom, and 8.1% (16/197) from Canada. Among the respondents, 69.9% (165/236) identified as White and 27.1% (64/236) identified as Asian. Almost half of all participants (116/247, 47.5%) planned to specialize in general practice or internal medicine ([Table 2](#)).

Work of GPs in the Long Term: Opinions About Technological Replacement

Around two-thirds of participants (158/251, 62.9%) reported it was “very unlikely” or “unlikely” that technology would ever be able to fully replace GPs in reaching diagnoses (Table 3). Among the remaining 37.1% (93/251) who thought it was “likely” or “very likely,” only 22% (20/93) estimated that the

capacity for replacement would emerge in 0-10 years, with many (38/93, 41%) estimating a time scale of 11-25 years (Table 4). Similarly, most participants (157/245, 64.1%) reported it was “very unlikely” or “unlikely” that future technology would be able to fully replace GPs in formulating personalized treatment plans. Among those who believed this was likely or very likely, however, 41% (36/87) estimated that the technological capacity to do so would emerge in 11-25 years.

Table 3. Opinions about the likelihood of future technology replacing general practitioner tasks.

Task	Opinion							
	Very unlikely		Unlikely		Likely		Very likely

^aParticipants were only asked to indicate time scale if they first indicated it was likely or very likely that future technology will fully replace human doctors in each task as well as or better than the average general practitioner. As such, some data are not provided (missing n=159, 138, 121, 165, 234, and 38 for tasks 1, 2, 3, 4, 5, and 6, respectively).

^bLower bound CIs have been set to 0.

^cN/A: not applicable.

Participants were divided about the technological capacity to fully replace GPs regarding prognoses or referrals. For prognoses and referrals, 54.9% (136/248) and 48.8% (120/246), respectively, indicated replacement was “likely” or “very likely,” and a majority of these participants believed that the timeframe for this capacity for prognoses and referrals was 11-25 years (53/128, 38.4% and 48/121, 39.7%, respectively). In contrast, 85.9% (212/247) predicted technology would be able to fully replace GPs in undertaking documentation, and among them, 64.5% (138/214) predicted this capacity would emerge within 10 years. Finally, participants were least expectant about the potential for technology to replace GPs in providing empathetic care, with 93.5% (231/247) predicting this was “very unlikely” or “unlikely.”

Work of GPs in 25 Years: Opinions About the Impact of AI/ML

Around half of the surveyed students (127/246, 51.6%) believed AI/ML would have a moderate or extreme influence on the work

of GPs in the next 25 years (Figure 1). Around 1 in 10 (25/246, 10.2%) believed it would have no influence, with the work of GPs remaining unchanged.

When asked to reflect on what, specifically, might change 25 years from now, around one-third “moderately” or “strongly” agreed that technology (eg, smartphone apps) would be used to decide when patients need to see a GP (79/244, 32.2%), with similar proportions predicting GPs would routinely work in partnership with AI/ML to diagnose patients (90/244, 36.9%), determine the likely course of a patient's illness (90/244, 36.9%), or devise patient treatment plans (86/244, 35.2%) (Figure 2). More than 4 in 10 (107/244, 43.9%) “moderately” or “strongly” agreed that in 25 years from now, remote monitoring of patients' vital signs will be more common than in-person check-ups of vital signs, with the majority (169/244, 69.3%) “moderately” or “strongly” agreeing patients will have greater access to their own medical records than they do today.

Figure 1. Predicted impact of artificial intelligence/machine learning on the work of general practitioners in the next 25 years. AI: artificial intelligence; GP: general practitioner; ML: machine learning.

Figure 2. Predicted impact of artificial intelligence/machine learning on health care in the next 25 years. AI: artificial intelligence; GP: general practitioner; ML: machine learning.

Correlates of Opinions

Male students in our sample rated it more likely that future technology would fully replace GPs in undertaking diagnoses (Mann-Whitney $U=6137.5$; $P=.02$), prognoses ($U=5254$; $P<.001$), and empathy ($U=6108$; $P=.02$), compared with female students. No other gender differences were observed in participants' forecasts. The likelihood of future technology replacing GPs for referrals was rated higher by students who planned to specialize in medical professions other than general practice or internal medicine ("planned specialists") than by those who planned to enter primary care professions (Mann-Whitney $U=5501$; $P<.001$). Similarly, making forecasts about the impact of technology on the work of GPs 25 years from now, planned specialists thought that AI/ML would have a large impact ($U=5972.5$; $P=.02$), more strongly agreed that technology would be routinely used to decide when patients need to see a GP ($U=5343$; $P=.001$), and agreed that GPs would

routinely work in partnership with AI/ML to diagnose patients ($U=5445$; $P=.003$) and determine the likely course of a patient's illness ($U=5207$; $P<.001$). Finally, compared with aspirant nonspecialists, planned specialists more strongly predicted that 25 years from now, patients will have greater access to their own medical records ($U=5656.5$; $P=.01$).

Results of the Qualitative Survey

In total, 60.7% (153/252) of students left comments describing the ways in which they believed AI/ML will change the work of GPs 25 years from now. Comments were short and had a mean of 7.21 (SD 6.96) words. Following inductive analysis (see above), 4 major themes emerged (see [Textbox 1](#)). Illustrative examples of themes and categories are provided below. For more elaborate comments, participant number, gender, year of birth, and chosen medical specialty have been mentioned (the latter information was provided by the respondents).

Textbox 1. Themes and categories.**Administrative effects**

- Reduction/removal of administrative tasks and workload
- “Better administration culture”
- Greater efficiency of care
- Improved communication within health care
- Artificial intelligence/machine learning (AI/ML) will assist with documentation
- Increased use and/or quality of patient health records

Clinical judgement

AI/ML will ...

- Triage
- Assist in diagnosis
- “There will be less expected of general practitioners (GPs)”
- Replace GPs
- Not replace GPs
- Assist decision-making
- Decrease error rate

Care management and access

AI/ML will ...

- Assist in treatment and/or management
- Enable patient self-monitoring
- Increase telemedicine
- Monitor/analyze disease progression
- Assist medication prescribing
- Make some technologies more accessible
- Gather data outside consultation
- Introduce financial challenges

Relational aspects

AI/ML will ...

- Increase time with patients
- Reduce time with patients
- Better human interaction
- Not replace empathy
- Not impact patient-doctor relationship
- Introduce ethical issues
- Not replace human interaction
- Impact patient-doctor relationship

Administrative Effects

Students envisaged changes to administrative work because of AI/ML as having the biggest effect on the work of GPs, with 33.9% (108/319) of all coded passages belonging to this theme. Two-thirds of the coded phrases within the theme described a

reduction or complete removal of administrative tasks and workload (40/108, 37.0%), or assistance with documentation (31/108, 28.7%). Students frequently forecasted “less paperwork” and “easier paperwork” as likely, with some comments suggesting AI/ML would reduce the time needed to process documents requested by patients (eg, “sick letters” or

“referral letters”). When predicting how technological advancements would assist with documentation, few students elaborated beyond describing it as “better” or “easier.” Some examples referred to automation with respect to notetaking (“automatic dictation instead of typed/written notes” [Participant #165, female, born 1997, internal medicine specialty]) both for referrals and appointment summaries.

Greater efficiency in care (22/108, 20.4%) was also a common category within this theme. Students described several ways in which they believed AI/ML “may streamline care” [Participant #242, male, born 1993, psychiatry specialty], for example, by optimizing resource allocation or the referral infrastructure:

Better links between primary and secondary care - information from both will be better shared.
[Participant #230, female, born 1995, anesthesiology specialty]

Students also expected better time management as a result of automation of simple tasks like filing referrals or reviewing basic information from examinations, for example, “Gathering and collating data will become easier and assist GPs in their work.” [Participant #195, male, born 1996, general practice specialty].

Improved use of patient health records was another category, and students predicted AI/ML would provide easier access to the records both among GPs and other specialists, as well as assist in populating the records (“updating records and summarizing consultation” [Participant #127]).

Clinical Judgment

A second major theme was clinical judgment (94/319, 29.5% of all coded passages), which encompassed predictions about how GPs’ clinical decision-making may be affected by AI/ML. Assistance in diagnosis was a major concern among students, with half (47/94, 50%) of the coded passages in this theme describing various AI/ML applications. Students envisaged AI algorithms that will provide “diagnosis based on symptom consultation” [Participant #93, female, born 1996, general practice specialty], particularly when it comes to dermatology, hematology, radiology, and other medical imaging. Some described a degree of sophistication:

data interpretation according to data banks may play a larger role [Participant #207, female, born 1995, internal medicine specialty]

providing differential diagnoses [Participant #56, female, born 1996, other surgery specialty]

Others were more reserved and were more doubtful about the impact of AI/ML:

In terms of diagnosis, medicine is as much an art as a science. I find it difficult to believe that a computer can appreciate the value of a clinical decision based on observation and relationships with a patient.
[Participant #215, female, born 1995, internal medicine specialty]

Predictions about the effects of AI/ML tools on decision-making (10/94, 11%) and triage (15/94, 16%) were also common, and forecasts included the idea that AI/ML might serve as support

tools for GPs by “reducing waiting lists,” “helping screen patients,” or “reviewing appointments.” Some suggested that in 25 years, “there will be less expected of GPs” [Participant #19, male, born 1990, emergency medicine specialty], with some disagreement on the scope of AI/ML to replace them altogether. There were concerns that “GPs could be entirely supplanted by artificial technology in 25 years” [Participant #167, male, born 1996, internal medicine specialty], which may lead to a “lack of jobs” [Participant #163, male, born 1995, obstetrics specialty]. One student perceived developments in AI/ML as a threat to the GP profession only:

In terms of providing empathy or communicating directly with patients, nurse practitioners are already a less expensive and equally as knowledgeable alternative to GPs that could work in tandem with AI to render the GP entirely obsolete. [Participant #167, male, born 1996, internal medicine specialty]

A few believed that technology will, in the words of 1 participant, “function as an adjunct rather than replacement” [Participant #166, female, born 1997, anesthesiology specialty].

Care Management and Access

Another theme was care management and access (94/319, 29.5% of all coded passages). Within it, the leading prediction was that AI/ML would aid in treatment or management (34/94, 36%) of care, including “formulating treatment plans” and “referral pathway suggestions.” Some were cautious, limiting their predictions to “simple conditions, eg, common cold” [Participant #162, female, born 1996, psychiatry specialty], while others saw significant potential. One student mentioned that AI/ML “could help organize patients’ treatment regime based on multiple factors such as compliance” [Participant #186, female, born 1995, general surgery specialty]. Medication prescribing was also perceived as likely to be impacted by AI/ML (29/94, 31%). From automatic prescribing and renewal to contraindication analysis and error detection, students commonly forecasted a role for AI/ML in medication management. Several commenters predicted timely personalized prescribing based on “test results,” “guidelines,” and “adverse effects reviews.”

Predictions about approaches to treatments enabled by technology were further reflected in the category monitoring/analysis of disease progression (10/94, 11%). Patient “disease course prediction” was expected to be supplemented through “vitals and timeline analysis” enabled by AI/ML advances. Remote health care tools were also referenced (5/94, 5%) via “pre-examination before consultation” [Participant #23, female, born 1994, general medicine specialty] and patient self-monitoring (3/94, 3%). Only a few comments (7/94, 8%) discussed telemedicine, forecasting “less in-person visits” [Participant #171, female, born 1997, pediatrics specialty] and “video consultations” [Participant #229, female, born 1991, general medicine specialty]. Similarly, a minority (4/94, 4%) considered that the implementation of AI/ML would make care more accessible 25 years from now, though some believed it would also introduce financial challenges.

Relational Aspects

The smallest emergent theme encompassed the impact of AI/ML on relational aspects of care (23/319, 7.2% of all coded passages), which focused on opinions about how technology might change the patient-GP relationship. Within this theme, students were divided about whether technological advancements might increase (3/23, 13%) or decrease (4/23, 17%) time spent with patients. Students, however, were skeptical about the replacement of human interactions by AI/ML within 25 years, particularly regarding empathy provided by GPs:

Machines will perform logical work whereas GPs would manage the humanity side of the medical work, ie, empathy, support, encouragement. [Participant #154, male, born 1995, hospital management specialty]

Students described the patient-doctor relationship as follows: “key importance for patients’ benefit and it is therapeutic” [Participant #114, female, born 1993, unsure about specialty], with only 2 (9%) respondents predicting it could be enhanced through advances in AI/ML. Only 1 person (4%) predicted a negative relational effect of AI/ML stating “poor rapport” [Participant #189, male, born 1997, internal medicine specialty]. A similar minority (4/23, 17%) of codes pertained to the ethical implications of adopting AI/ML in health care. Only 1 (4%) participant described concerns about patients’ privacy as a consequence of AI/ML innovations.

Discussion

Summary of the Major Findings

Few studies have explored the views of medical students about how AI/ML will impact the future of their job. This mixed methods study specifically explored forecasts of final-year Irish medical students about how future technology might influence the work of GPs. When requested to forecast the impact of AI/ML on the work of GPs 25 years from now, students were divided, with around half of all surveyed students believing the work of GPs will change minimally or not at all. Notably, students who did not intend to enter primary care predicted that AI/ML would have greater impact.

With regard to specific tasks, around one-third of students moderately or strongly agreed that 25 years from now, technology (eg, smartphone apps) would be used to decide when patients need to see a GP. Similarly, around one-third moderately or strongly agreed that GPs would routinely work in partnership with AI/ML to diagnose patients, determine the likely course of a patient’s illness (“prognosis”), or devise patient treatment plans. About 4 in 10 students moderately or strongly agreed that 25 years from now, remote monitoring of patients’ vital signs would be more common than in-person check-ups for vital signs, with 7 in 10 students agreeing that patients would have greater access to their medical records. Again, students who did not intend to enter primary care were more likely to forecast that AI/ML would impact key aspects of the work of GPs, including formation of decisions about when patients should see GPs, assisting GPs in diagnoses and

prognoses, and helping patients obtain greater access to their medical records.

Results from the qualitative section of the survey supported and partially elaborated on these predictions. The dominant perspective was that 25 years from now, there would be a reduction in GPs’ workloads with less paperwork and greater efficiency in primary care. Other common themes encompassed forecasts that AI/ML-enabled tools would aid clinical judgment but only for a narrow range of symptoms, mostly pertaining to imagery. Another theme was the potential for AI/ML to aid with treatment and care management, including automatic prescribing. Fewer students envisaged a role for AI/ML in patient self-monitoring, and only a minority predicted an increase in telemedicine or patient access to health care. Although participants were divided about whether AI/ML might have an impact on the time GPs would spend with patients, most were skeptical about whether technological tools could ever replace the empathy provided by GPs.

Offering forecasts on the capacity for future technology to fully replace core aspects of the job, around 2 in 3 students believed it is unlikely or very unlikely that GPs would ever be fully replaced by AI/ML tools in performing diagnoses or formulating personalized treatment plans for patients. Students were split over whether prognoses or triage could ever be fully replaced. Consistent with the qualitative component, however, students were most skeptical about the scope of future technology to replace GPs in providing empathic care, with more than 9 in 10 predicting this was unlikely or very unlikely. In contrast and in keeping with predictions about the impact of technology over the next 25 years, students were most expectant about the scope of future technology to fully replace GPs in undertaking the role of documentation, with more than 8 in 10 believing this was likely or very likely. Among them, around 2 in 3 predicted this would happen in the next 10 years. Finally, we also found correlations between gender and students’ opinions, with male respondents more likely to believe future technology would fully replace GPs in undertaking diagnostics and prognostics, and in the provision of empathy. Students who did not intend to enter primary care professions were more likely to believe GPs would be replaced by future technology in making referral decisions to other specialists.

The results of this study mirror other recent medical student and GP surveys, which demonstrated a wide range of opinions among participants about the impact of AI/ML on health professions [14,17,18]. Conspicuously, students’ opinions about the prospects for technology to fully replace various primary care tasks revealed some similarities but also intriguing differences with the findings in a recent survey conducted with GPs in the United Kingdom [9]. Final-year medical students in Ireland and experienced GPs offered similar predictions about the capacity for future technology to replace GPs in key tasks; however, students tended to be more cautious and conservative in their estimations of time scales for when AI/ML advances might arise. Although these divergences might be associated with sampling effects, we noted that the original UK GP study [9] reported a weak correlation between respondent age and opinions, with younger GPs more skeptical about the imminence of technological advances.

The reasons behind associations between younger age/inexperience and relative technoskepticism are not fully understood, though 2 hypotheses might be considered. First, it is reasonable to hypothesize that, compared with established GPs, younger respondents may be more AI/ML savvy and less susceptible to hype about AI/ML, and as a result, they may be more reserved in their forecasts. However, a growing number of student surveys now indicate that there is scarce formal training in AI/ML in medical schools [12-18,20]. Indeed, in previously published findings that emerged from the present survey, 4 in 10 final-year students reported that they had not heard of the term “machine learning,” with 2 in 3 reporting spending no time learning about AI/ML during the entire period of their medical degree [20]. Therefore, it is unlikely that greater awareness about technology influenced comparatively more conservative predictions among our student respondents. A second and more plausible hypothesis is that younger age/inexperience and technoskepticism might be associated with well-documented optimism bias, which is the tendency of people to believe that they will not be affected by negative events. In short, student participants may be susceptible to interpreting information on AI/ML in ways that support the prospects of their own long-term career in medicine. Tentative support for this hypothesis comes from differences in opinions related to students’ choices of medical specialty, with those intending to enter primary care less likely to believe AI/ML would impact the work of GPs. Further support comes from the finding that students predicted that the administrative burdens of updating documentation would be outsourced to technology.

Like other studies, including those among psychiatrists [10], male respondents were more likely to predict that future technology will be able to fully replace GPs in some key tasks. The reasons for this difference are not fully understood, though findings from social psychology demonstrate sex differences when it comes to risk aversion [22]. It may be that males are slightly less cautious on average compared with females in offering professionally threatening predictions. It is worth emphasizing, however, that other surveys have not reported gender differences [9]. Only one-third of our respondents were male. For many years in Ireland, there has been a trend of more male medical students than female medical students [23]. Therefore, it is possible that gender disparities in respondents’ opinions in the present study might have been an artifact of sampling limitations.

We also observed contrastive predictions among our students compared with informaticians and other experts working in health care AI/ML and related fields. A Delphi poll of international health informatics experts reported consensus that in 10 years (by 2029), advances in AI/ML would prompt workforce changes within primary care, with a shift toward computing and engineering in the educational backgrounds of students entering medical school, and increasing demands on students to work with AI/ML-enabled tools in health care [24]. In contrast, when asked to reflect on what might change 25 years from now, a minority of students forecasted that GPs would partner with AI/ML tools in supporting clinical decision-making. However, such advances are already underway. In countries with electronic health records (EHRs)

in primary care, the availability and uptake of clinical decision support systems, which are tools that link patients’ personal information held in EHRs to clinical software to inform patient-specific assessments or recommendations, appear to be widespread [25]. These tools are being increasingly powered by ML, and they use computerized reminders, alerts, and prompts linked to patients’ electronic records to help inform recommendations. Prescription alerts, for example, warn doctors about harmful dosing or risks of drug interactions, and clinical decision support systems have the potential to help standardize guideline adherence, and support diagnostic and prognostic decisions [26].

Other predictions associated with access to primary care and patient management of their care also diverged from expert predictions and current trends. For example, when asked to predict what might change 25 years from now, a minority of students agreed that technology, such as smartphone apps, would be routinely used to decide when patients need to see a GP, a finding supported by qualitative analysis. Although partly accelerated by COVID-19 and stay-at-home measures, so-called “digital first” gateways to online triage, such as AskMyGP, Engage Consult, and eConsult in the United Kingdom, are being increasingly adopted in primary care [27]. Although these systems are implemented with the goal of mitigating increased work burdens, it is important to note that there is scarce evidence such systems, as currently embedded into work practices, do in fact improve efficiencies, and they may even exacerbate pressures on physicians by identifying greater patient needs [28,29]. It is worth emphasizing, however, that predictions about increasing implementation of AI/ML tools in medicine are not the same as gauging views about their adequacy, safety, or ease of use, especially with respect to integration into GPs’ workflows. Notwithstanding, students’ predictions did appear to contrast with growing prepandemic secular trends.

A larger proportion (107/244, 43.9%) of students, though still a minority, moderately or strongly agreed that remote monitoring of vital signs will be more common than in-person check-ups in the near future. Nonetheless, few students elaborated on this in the qualitative section of the survey. Although students could not have predicted how the pandemic would catalyze an uptick in telemedicine, including the use of electronic communication to track, monitor, or manage symptoms or chronic conditions [30], interest and uptake in remote patient monitoring has grown in recent years [31,32]. Increasingly via smartphone photos, blood pressure cuffs, heart rate monitors, portable electrocardiography systems, and a host of other devices, patients can manage their health from their home with real-time readings relayed instantly to the patients and the clinical team. Moreover, there is evidence that so-called mobile health may improve precision [33-36] while driving down health care expenditure, including hidden travel costs, related to in-person appointments [37-39].

Finally, 1 prediction was fully in line with recent health care developments. Almost all students expected that access to medical records would increase in the next 25 years. Currently, in around 20 countries, including Australia, Canada, the Nordic countries, and the United States, patients are offered rapid online access to at least some of their EHRs, a practice that is growing.

Strengths and Limitations

A major strength was soliciting the opinions of a diverse range of medical students from institutions in geographically distinctive regions of Ireland. The survey offered insights into students' forecasts about the potential impact of technology on the work of GPs both in the medium term during their own career span and in the longer term with regard to replacement of doctors. Going further than other investigations [9], the present study examined students' views about the likelihood of full technological replacement of GPs in specific core roles while also examining participants' predictions about the extent to which GPs might partner with machines in a variety of tasks. Combined with the mixed methods approach, the study permitted more nuanced students' opinions about the impact of AI/ML on the work of GPs.

The survey has several limitations. We used a nonprobability convenience sample, limiting generalizations about the opinions of all final-year medical students in Ireland. In addition, the moderate response rate (43%) raises questions about representativeness, though this is a very strong response rate for survey research where participants do not receive compensation. It is also unknown whether the decision to complete the survey was influenced by prior awareness about AI/ML or whether response biases were influenced by participants who were more enthusiastic or more skeptical about the effects of AI/ML on primary care. Because of the limitations of open comment boxes, participants' responses were often vague or truncated, and it was not possible to probe the views of students in depth. The survey was administered prior to the COVID-19 pandemic, which has been associated with considerable developments and attention regarding the role of AI/ML-enabled tools in digital epidemiology and public health. Conceivably, if the survey had been undertaken after the pandemic, participants' views might have differed. Nonetheless, to date, no medical school included in this survey has modified their curriculum to include greater education about AI/ML.

Further survey research and curricular analyses could explore the extent to which medical students receive training about existing clinical decision support tools and their implementation in clinical work. Qualitative research methods, such as interviews and focus groups, could provide more nuanced findings on aspects of students' views and understanding about the impact of AI/ML on medicine. Finally, future studies could explore the views of medical faculty about the impact of AI/ML-enabled tools on medicine, including their awareness, understanding, and appreciation of the scope for these applications and limitations associated with these applications. Such work might help illuminate potential obstacles to curricular advancement on these topics within medical education.

Conclusions

This mixed methods survey provides insights into what final-year medical students in Ireland think about the impact of AI/ML on primary care. A broad spread of opinions was apparent, with many forecasts contrasting with the considered opinions of health informaticists. Ireland is ranked as a leading technology capital in Europe [40], with the fastest growing technology workforce on the continent [41]. This survey combined with previously published findings [20] suggests that training regarding AI/ML in Irish medical education may be lagging behind advances in the field. We caution that without a firm curricular foundation on advances in AI/ML, students may rely on extreme perspectives involving self-preserving optimism biases that demote the impact of advances in technology on their choice of specialty on the one hand and technohype on the other. Ultimately, these biases may lead to negative consequences in health care. Improvements in medical education could help prepare tomorrow's doctors to optimize and lead the ethical and evidence-based implementation of AI/ML-enabled tools in medicine for enhancing the care of tomorrow's patients.

Acknowledgments

The authors thank Dr Cliona McGovern for assisting with data gathering prior to the termination of the study at University College Dublin due to COVID-19, and Drs Catherine DesRoches, John Halamka, and John Kelley for early discussions about the content of the survey.

Abstract

Background: Advanced practice nurses (APNs) are in high demand in critical care units. In Norway, APNs are educated at the master's degree level and acquire the competence to ensure the independent, safe, and effective treatment of patients in constantly and rapidly changing health situations. APNs' competence embraces expert knowledge and skills to perform complex decision-making in the clinical context; therefore, it is essential that educational institutions in nursing facilitate learning activities that ensure and improve students' achievement of the required competence. In clinical practice studies of APN education, face-to-face reflection group (FFRG) meetings, held on campus with the participation of a nurse educator and advanced practice nursing students (APNSs), are a common learning activity to improve the competence of APNSs. Although FFRG meetings stimulate APNSs' development of required competencies, they may also result in unproductive academic discussions, reduce the time that APNSs spend in clinical practice, and make it impossible for nurse preceptors (NPs) to attend the meetings, which are all challenges that need to be addressed.

Objective: This study aimed to address the challenges experienced in FFRG meetings by implementing virtual reflection group (VRG) meetings and to explore the experiences of APNSs, NPs, and nurse educators in VRG meetings as an active learning method supported by technology to stimulate students' development of the required competence to become APNs in critical care.

Methods: This study adopted a qualitative explorative design with 2 focus group interviews and used inductive content analysis to explore the collected data.

Results: The main finding is that reflection group meetings supported by technology resulted in a better-structured active learning method. The VRG meeting design allowed APNSs to spend more time in clinical practice placements. The APNSs and NPs experienced that they participated actively and effectively in the meetings, which led to a perceived increase in competence. The APNSs also perceived an improved learning experience compared with their prior expectations.

Conclusions: Users perceived that the implemented novel teaching design supported by technology, the VRG meeting, was a more effective method than FFRG meetings on campus to develop APNSs' required competence in critical care. The VRG was also perceived as an improved method to solve the challenges encountered in FFRG meetings. Specifically, the APNSs felt that they were prepared to undertake complex decision-making with a higher level of analytic cognition in a clinical context and to lead professional discussions in the ward. This developed teaching design can easily be adapted to diverse educational programs at various levels of professional education.

Introduction

Overview

Worldwide, health care institutions' treatment of patients has become increasingly complex because of the rapidly aging population [1,2]. In addition, treatment and technological developments allow chronically ill patients to manage their diseases at home longer than before so that when they need to be treated in health care institutions, their health situation is worse and more complex than that of patients a few years ago [3]. The recent global COVID-19 pandemic presented an unexpected situation in which many infected persons required acute critical care, but knowledge of treatment was scarce, creating an urgent desire for the ability to address the situation rapidly and critically [4]. These developments highlight the need to prepare advanced practice nurses (APNs) in their education to face contemporary challenges in critical care. The role of an APN requires expert knowledge and skills to make complex decisions in a clinical context [1].

To become an APN in Norway, registered nurses must attend and complete a master's program of 120 European Credit Transfer and Accumulation System points. The curriculum is designed to guide an advanced practice nursing student (APNS) to acquire the expected competence. To educate APNs in critical care, it is essential to offer learning activities that promote the development of professional competence needed to care for acutely or critically ill patients. The main competencies that APNSs must acquire in their education are biophysical knowledge, technical skills, communication skills, intra- and interprofessional teamwork skills, leadership skills, and guidance and coaching skills as well as knowledge of evidence-based practice [5,6]. Furthermore, it is essential for APNSs to develop core qualities and competencies for patient safety [5,7]. Overall, nurses' greater educational qualifications are associated with better patient outcomes [8]. APNs are in great demand in critical care units (CCUs) because they can ensure independent, safe, and effective practices in constantly and rapidly changing situations [1,2,5,9].

Background

The APN master's program at Norway's Lovisenberg Diaconal University College (LDUC) provides theoretical and clinical practice studies over a period of 2 years. The clinical practice studies are distributed over a period of 8 weeks in the first term, 12 weeks in the second term, and 9 weeks in the third term. In each term, APNSs study various theoretical subjects before and after their practical period. In the last term, they focus on their master's thesis.

A crucial part of nursing education is helping students to develop a strong foundation of evidence-based practice skills and apply them in clinical practice [10]. Therefore, the LDUC's advanced practice nursing master's program in critical care uses reflection group (RG) meetings as a learning activity. The RG meetings aim to train students to reflect on their experiences during the clinical practicum period, supporting their reflections with evidence. In this process, called *reflective practice*, students critically consider and assess their practical experiences to gain knowledge and learn how to improve their competencies and

skills [11,12]. Analyzing clinical problems in evidence-based practice through critical reflection demands combining the best available research evidence, expert opinions, and patients' individual preferences [13]. Nurses who learn to reflect on their practical experiences develop professional competence to solve problems and provide more flexible, individualized, and holistic care to patients [14].

RG meetings at LDUC have recently been held on campus, with APNSs participating in 3 group sessions of 3 hours in each practicum. During the meetings, which included up to 10 APNSs, each student presented a patient case from clinical practice and a related research paper, providing evidence as recommended by Straus et al [13]. RG meetings aim to stimulate reflection and facilitate APNSs' achievement of their expected competence. The structure of face-to-face RGs (FFRGs) led to several challenges, however, including reduced time in clinical practice placements (as the APNSs had to meet the nurse educator [NE] and fellow students at LDUC campus), unproductive professional discussions (as the APNS were often unprepared for meetings), the impossibility of involving nurse preceptors (NPs) in organized professional discussions (as they could not leave the clinical practice for a long period because of their responsibility for patient care), and a perceived low achievement of learning outcomes, as underlined in the assessment meeting of APNSs in clinical practice. In addition, the FFRG format of each student giving a short presentation often leads to repetition in academic discussions.

To address these challenges, the FFRG meeting concept was redesigned according to the LDUC's strategy of using active learning methods based on technology. The new design, called the virtual RG (VRG) meeting, was better structured and held remotely via the Zoom meeting platform rather than in person. The first course to use the VRG meeting design was the Management of Complex Patient Conditions, the main learning outcome of which was analyzing and managing complex clinical situations based on professional experience, research, and knowledge. APNSs must gradually develop situational awareness and action skills in complex patient situations. Specifically, they must collaborate with the preceptor to gradually act independently using evidence-based practice. The VRG meeting aimed to increase the students' time in clinical practice placements, to better organize professional discussion and reflection, to optimize and facilitate the participation of the students' preceptors in RG meetings, and to improve the APNSs' achievement of expected learning outcomes [15]. Constructive alignment [16] was applied as a theoretical approach in developing the new design, ensuring a connection between learning outcomes, learning activities, and the assessment of clinical practice [15].

Throughout the clinical practice period, the NE, NPs, and APNSs attended VRG meetings, which comprised three meetings of 45-minutes each that were executed over 3 days (see Table 1). Before the meetings, APNSs were assigned roles with specific tasks and responsibilities, giving them time to prepare. The roles were distributed as follows in each meeting session: 1 APNS assumed the role of "responsible student," another was the "respondent," and the remainder were ordinary "participants." The responsible student's role was to prepare a

session of 45 minutes in collaboration with their NP by choosing a patient case and related research paper. The respondent APNS was responsible for critically assessing the research paper, and the remaining students were responsible for being prepared for the meeting by reading the case and research paper. It was also expected that during the discussion, the remaining students actively participated by reflecting on and sharing their own

experiences with similar cases with their peers. A structured approach to RG meetings with the participation of an experienced NP can enable nursing students to reach a deeper level of assessment and a higher level of cognition [12,14]. Table 1 provides an overview of the main differences between the FFRG and the VRG.

Table 1. Comparison of face-to-face and virtual reflection group meeting design.

Objectives

This study aims to address the challenges experienced in FFRG meetings by implementing VRG meetings and to explore the experiences of APNSs, NPs, and NEs with VRG meetings as

an active learning method to stimulate students' development of the competencies needed to become APN in critical care.

Research Questions

The research questions are as follows:

1. How did VRG meetings address the challenges experienced in FFRG meetings?
2. In comparison with FFRG meetings, what were the experiences of APNSs, NPs, and NEs with VRG meetings as an active learning method to stimulate the students' perceived development of the competencies needed to become an APN in critical care?

Methods

Design

This study adopted a qualitative explorative design using focus group interviews. An exploratory design is useful for identifying views and experiences [17] regarding, in this setting, users (NSs, NPs, and NEs) participation in VRG meetings.

Participants

The participants recruited for this study were APNSs, NPs (from the CCUs where the students carried out their clinical practice), and NEs from the master's program in APN in critical care. The APNSs were recruited from 2 cohorts (autumn 2018 and autumn 2019). To be eligible for the study, the participants (APNSs and NEs) had to have had experience with the previous FFRG meeting design before participating in the VRG meetings. The course coordinator and associate professor (MTS) and the assistant professor (Ørjan Flygt Landfald) were responsible for the concept and organization of the VRG meetings.

Data Collection

Information about the study and invitations to participate were disseminated to the APNSs and NEs via the Canvas (Instructure, Inc) learning platform. The NPs were contacted via email because they had no access to Canvas. Informational meetings were also arranged after the users' participation in the VRG meetings to recruit informants for the focus group interview. Polit and Beck [17] recommend that participants should feel no pressure to participate in research studies, so those interested in participating in focus group interviews had to contact the researcher (Ørjan Flygt Landfald). The researcher (Ørjan Flygt Landfald) had no previous contact with the APNSs or NPs, thus avoiding a potential influence on the recruitment of participants or the content of the collected data.

Data Generation and Setting

To inform the focus group interviews, the research team developed an interview guide with open-ended questions about participants' (APNSs, NPs, and NEs) experiences with the VRG (Textbox 1). The research team was trained in advance to conduct the interviews. A total of 2 focus group interviews were conducted immediately after the students' clinical practice periods: the first in October 2019 (third semester) and the second in April 2020 (second semester). The first focus group interview was held in a conference room on the LDUC campus. Participants were seated around a table to indicate an equal position in the discussion. The second focus group was web based because of the COVID-19 pandemic.

Textbox 1. The interview guide.

- Main question
 - Can you talk about your experiences of participating in virtual reflection group (VRG) meetings as compared with the face-to-face reflection group meetings?
- Supporting questions
 - What are the benefits and limitations of the VRG meetings?
 - What was your experience of following a guide for conducting VRG meetings?
 - What competencies did you develop from the VRG meetings regarding your role as an advanced practice nurse (APN)?
 - How did the professional discussion contribute to your development as an APN in critical care?
- Different roles are included in the implementation of a VRG; what expectations did you have in advance regarding:
 - leading the professional discussion when conducting a VRG?
 - including the nurse preceptor in the discussion to share their experiences?
 - your role as a respondent?

Research shows that the manner in which an interview is conducted crucially determines the quality of the collected data and relies on the moderator's proficiency [17]. The moderator in this study (AAGN) was an experienced researcher with a PhD. In the interviews, 2 members of the research group were observers (Irene Rød and Ørjan Flygt Landfald) and were allowed to make comments and follow-up questions if they perceived a need for them. In the first interview, Irene Rød observed and took notes on the group's interactions to supplement the verbal transcript and enable a fuller analysis, as

recommended by Polit and Beck [17]. In the second interview, Ørjan Flygt Landfald participated and organized technical support and audio file recording. The moderator was familiar with the required competencies of APNSs and encouraged the informants to actively participate in the conversation. The participants freely commented on each other's views and experiences of VRG meetings as an active and effective teaching method. The focus group sessions lasted 60 minutes and were audiotaped and subsequently transcribed verbatim by MTS using the HyperTRANSCRIBE tool.

Ethics Approval

The project was approved by the Norwegian Center for Research Data (reference number: 132520). After the participants (APNSs, NPs, and NEs) expressed interest in participating, the course coordinator and associate professor (MTS) again provided verbal and written information about the study, after which the participants provided written informed consent. Before signing the informed consent, they were made aware that participation in the study was voluntary, that they could withdraw their consent at any time without giving a reason, and that doing so would not affect their study conditions at LDUC. The NPs and NEs were assured that their participation in the study would not affect their work conditions. The collected data were treated confidentially and used as described for the purpose of the

project. The data were anonymized, making it impossible to identify individuals.

Data Analysis

All authors participated in the data analysis, first reading the transcripts several times to gain insight into the content. We used inductive content analysis as described by Graneheim and Lundman [18] to explore APNSs’ perceived achievement of the required competence in critical care after participating in VRG meetings. Next, the text was condensed into meaning units with descriptions close to the text, and codes were inductively developed by reading and rereading the meaning units. We had several discussions and finally agreed on categorizing the results into subthemes and themes (Table 2). During the analysis, we moved forward and backward between themes and subthemes, as recommended in the literature [18,19].

Table 2. Examples of the analysis process from meaning unit to theme.

Raw data divided into meaning units	Condensed meaning unit description close to the text	Interpretation of the underlying meaning	Subtheme	Theme
NP ^a 5: We had a difficult case that the student chose to take up, which involved several people in the unit, so we talked. Both I and the student and several others also talked about the case before she presented it [in the VRG ^b meeting]. And after the VRG, it also was talked about, because it was a case that many thought was a bit difficult, and it became a learning situation for the students, of course, but also for the colleagues in the unit. So, it was actually quite a useful method and there were more people who benefited by learning from it then.	The preceptor described that the student chose to discuss a difficult case in the VRG meeting that led to a great involvement of colleagues working in the CCU ^c . Both APNSs ^d and colleagues on the unit learned from the discussions.	The VRG meeting is organized in a way that led to a great deal of involvement and increased the competence of students, the preceptor, and employees in the CCU.	Improved focus on evidence-based practice in the clinical environment	Synergy in competence development
Moderator: Several of you have said that it is scary. What is scary? APNS 5: It was probably what was supposed to happen, because you shall lead the meeting for an entire hour, which none of us has done before. You will welcome, then you will present a case, then you will present an article, then you have questions [the fellow students] what do you think...and what do you think? You have to “hold it all the time.” Then, it’s not as simple as someone has mentioned earlier here, that you just talk as you can in a normal discussion, but that you actually have to “name drop” the other students as I did. If no one is talking, then I “name drop” in a way [laughs] so that there will not be such silence. So, yes, there was a bit of that about being a leader, which was scary, but it was very educational.	The APNS thought it was both scary and educational to be responsible for leading the meeting for 45 minutes the first time. Their charge was to welcome the participants, present a case and an article, and include all the students and preceptor in the discussion so that they all actively contributed to the discussion instead of participating in silence.	The role of leading a meeting and presenting a case and research article while making sure that all the students participated was quite scary the first time but at same time very educational.	Increased leadership skills	Developed intrapersonal and professional skills

^bVRG: virtual reflection group.
^cCCU: critical care unit.
^dAPNS: advanced practice nurse student.

Trustworthiness

Participants (APNSs, NPs, and NEs) were divided into 2 groups. Each group was interviewed by the moderator, who was an associate professor (AAGN) who led the group discussions

according to the prepared guide. Moderator bias was minimized, as both the moderator and observer were not involved in teaching the APNSs and were completely unknown to the participants [17]. Data saturation was achieved in the second interview, as no new information was obtained and redundancy

of the collected data was achieved. These findings reflect a deep understanding of the data because of the authors' diverse areas of expertise. MTS is an associate professor, is a coordinator of APN master's education, and has experience in critical care; AAGN is an associate professor in nursing undergraduate education with clinical experience with chronically ill patients; SC is an assistant professor and was the head LDUC librarian; and ALS is an associate professor, is the head of the master's department at LDUC, has for several years completed training in practice guidance, and has clinical experience in hospital and nursing home medical departments. In addition, 3 of the authors had extensive research experience with qualitative design and data analysis. All the authors have agreed on the final results.

The NEs were responsible for delivering the intervention through VRG meetings but were not involved in student

recruitment or data collection. The researchers responsible for data collection had no previous contact with the APNSs to avoid possible bias connected to students being afraid that positive or negative feedback in the interviews could influence their grades.

Results

Overview

The eligible participants comprised approximately 35 APNSs, 10 NPs, and 3 NEs who participated in VRG meetings as a part of learning activities in advanced clinical practice (Table 3).

To ensure anonymity, references to individual participants' statements used nonidentifying numbers to represent the individuals (Table 4).

Table 3. Participants in the study.

	Focus group 1 (in person), participated/invited	Focus group 2 (web-based), participated/invited	Total, participated/invited
Students	6/8	3/27	9/35
Preceptors	4/5	2/5	6/10
Educators	2/2	2/2 ^a	4/4
Total	12/15	7/34 (–1) ^a	19/49 (–1) ^a

^aOne educator guided the groups in 2 different clinical practice periods; therefore, this educator participated in both focus group interviews 1 and 2.

	Focus group 1 (in person), participant identifier	Focus group 2 (web-based), participant identifier
Students	1-6	7-9
Preceptors	1-4	5 and 6
Educators	1 and 2	3 and 4

An overall finding of this study is that technology-supported RG meetings led to a better-structured active learning method. The VRG design allowed APNSs to spend more time in clinical practice placements and promoted active and effective participation of APNSs and NPs in the meetings. Participating in the VRG meetings increased the perceived competence of APNSs and NPs. The APNSs also perceived an improved learning experience compared with their own expectations. The

findings are presented according to overall themes, followed by subthemes.

The results of this study revealed 3 main themes. The first theme reflects the importance of a well-structured learning activity in creating learning opportunities, whereas the second and third themes reflect how APNSs perceived the achievement of the general required learning outcomes and their expected professional competence as APNs in critical care (Table 5).

Table 5. The findings categorized into overall themes and subthemes.

Themes	Subthemes
Preparation process encouraging learning	<ul style="list-style-type: none"> Importance of a defined teaching design Importance of clearly determined roles
Developing intrapersonal and professional skills	<ul style="list-style-type: none"> Increased learning focus Increased responsibility and commitment Increased leadership skills
Synergy in competence development	<ul style="list-style-type: none"> Increased collaboration between students and preceptors Improved focus on evidence-based practice in the clinical environment Improved professional interaction skills

Preparation Process Encouraging Learning

Importance of a Defined Teaching Design

The VRG meetings were conducted based on a rigorous guide, which the students evaluated as “very good.” One of the NEs experienced that the design of the VRG meetings led to better focus, which she perceived as an advantage, especially for the students. Several APNSs thought that the VRG meetings were more structured and effective than the FFRG meetings they had previously experienced (Table 1). The APNSs reported that FFRG meetings resulted in a lack of learning focus after half an hour. All interviewed participants (APNSs, NPs, and NEs) agreed that the newly designed structure for RGs based on virtual meetings improved the participants’ learning experience. In addition, all the NPs in both focus group interviews were very positive about the flexibility and scheduled times of the VRG meetings. The virtual meeting enabled the participation of the users (APNSs, NPs, and NEs) independent of their geographic location, and a shorter meeting allowed the APNSs to spend more time in their clinical practice placement. In addition, the NPs experienced gaining academic competence in both the preparation phase with the APNSs and during VRG meetings. Although the NPs perceived that their academic contribution to the VRG meetings was modest, they perceived a high value in their practical experience in clinical practice and their role as preceptors in support of the APNSs.

The NEs and APNSs from both focus group interviews experienced that the VRG stimulated learning, as patient cases were distributed to the participants before each meeting. This new RG meeting structure led to a perceived improvement in the participants’ focus when compared with the previous design. One student said as follows:

I felt that it led to more learning because it was a completely different way of having a reflection group meeting, and what was presented was more evidence based. We were supposed to present the case and the research in such a way that it was easier to discuss it instead of just sharing our own experiences and opinions. [APNS 7]

Another student added the following:

So we come into [the meeting] and we have to just start. We have only 45 minutes, and we have a lot to get through during that time. It became much more academic [with virtual meetings] than when we met face to face; then, it was more like, “Hi, how are you doing?,” and then you maybe lose 10 to 15 minutes talking about what’s been going on and that we haven’t seen each other. We can log in and talk together before the meeting starts if we want to have a chat. [APNS 9]

Importance of Clearly Determined Roles

An NE pointed out that APNSs were supposed to be on a clinical practicum to learn and that it was important that APNSs, NPs, and NEs understood their roles. One student emphasized the importance of the design in clarifying roles:

Each week, I felt that my role as a student was emphasised; it was easier for me to say, “I’m here to learn new things and to find good learning situations.” [APNS 6]

Another student added:

It is important for us that the NP knows what we’re up against, so I think that a good thing about the meetings is that the NPs who have taken part in the VRG meetings know a little bit more about it. [APNS 3]

One of the NPs said:

I have understood that the student is the one who takes responsibility, and the preceptor gets involved when the article is found and gets involved with the discussion that takes place before the VRG meeting. [NP 1]

Overall, the NPs perceived that they helped as much as they could during the RG meetings. One of the preceptors experienced that everybody had a role to play and that she learned a lot by listening to the respondent giving feedback. One of the educators pointed out:

It is important to involve the clinical preceptor, because it benefits both the student and the preceptor. [NE1]

Developing Intrapersonal and Professional Skills

Increased Learning Focus

The students expressed that they spent more time preparing for the VRG meetings than for FFRG meetings. Accordingly, they perceived that they had developed better skills in finding research articles and presenting patient cases. When preparing for the VRG meetings, the APNSs experienced increased learning, as they studied their fellow student’s patient case, demonstrating more committed to being prepared for VRG meetings than for FFRG meetings. They perceived that preparing for the VRG meetings and participating in the patient case discussions stimulated their critical thinking. One of the NPs expressed surprise at the APNSs’ skills:

They [the students] knew the literature well; I had also prepared in advance. The good thing about having these VRG meetings is that they require more preparation of participants when compared with FFRG meetings. Now you have the chance to go a bit more in depth, you can spend more time at the ward, discuss with the NE, discuss with others in your surroundings and other fellow students on the subject, and it means that you maybe develop more insights into the studied subject than before. [NP 2]

The VRG meeting was perceived to be evidence based, and the students experienced that each meeting they participated in gradually improved their skills in reading research articles and searching the database. One student said:

I felt that I learned much more than before, because it was a very structured design. I also felt that all the students were well prepared each time. We discussed

only the articles that we presented, in addition to which there were different topics each time, not like earlier, where all the students presented the same subject [case], and there was a lot of repetition [before], I felt. [APNS 1]

Increased Responsibility and Commitment

There was a general agreement among the participants in the focus group interviews that the students participated more in the discussions during the VRG meetings than in the FFRG meetings. The VRG meeting guide stated that all students had to participate actively during the meeting. One student felt that the discussion part of the VRG was uncomfortable, because all the students were to speak in turn, and no student was allowed not to participate in the discussion. However, many other focus group participants experienced the discussion section of the VRG as positive, leading to an increased perception of achieved learning outcomes. It had been easier for the APNSs not to participate in the discussion during FFRG meetings, which negatively affected their learning experience:

You didn't have to say anything unless you were asked a question. In the virtual meeting, everyone was required to take part, everyone had to prepare, and I think it was good for us as students that you had to take more responsibility in that setting. [APNS 3]

The NEs felt that they had a more passive role, as the responsible students and their peers were charged while continuing the discussion. In the VRG meeting, the NEs were able to sit and take notes, which they could then use to provide a summary at the end, which they could not do in the FFRG meetings.

Using a strict guide was also perceived as useful by students who did not like to speak up and therefore would become passive in the previous RG meeting design. One student pointed out:

In the meetings we had on campus, I have noticed that it's often the same people who take part in the discussions; it's the same people who speak up, the same who take part in the follow-up discussions, and there are always some who don't take part. And I think it becomes even more obvious when you are sitting at a screen in a Zoom meeting. [APNS 7]

Increased Leadership Skills

Some students found it challenging to lead the VRG meetings, feeling that they were outside their comfort zone. The APNSs described diverse experiences related to leading meetings, but they all agreed that it was nerve racking:

The experience of leading a meeting was a bit scary to start with, but I think it would have been just as scary or exciting if I had been in a physical meeting; being on Zoom didn't make it scarier. Physical meetings could have been scarier. It went very well altogether. [APNS 8]

A few students felt it was difficult to encourage their fellow students to discuss the case:

It is scary being the meeting leader for a whole 45 minutes, which none of us have done before. You have to welcome everybody, present a case, then present your research article; then, when you are finished—then—what do you think, and what do you think? You have to carry on the whole time. So it's not as simple as someone here said earlier, that you can just talk like you do in a normal discussion, but you have to "name drop" like I tend to do; if nobody talks, then I just sort of "name drop" [laughs] so it isn't just silence. So, yes, it was a bit, being the leader, that was scary but also very educational. [APNS 5]

Both APNSs and NEs felt that the VRG meetings were suitable preparations for the role of an APN. For APNSs, it was meaningful to choose a professional topic and discuss it. Some of the APNSs took part in several meetings before they assumed the role of a responsible student:

I managed to prepare myself and learn from the others before I had to do it myself in the end, so I think it [leading a meeting] went OK. [APNS 4]

Several of the students experienced enhanced leadership skills by participating in the VRG meetings:

I think we were good at keeping the VRG meeting going. We learned from having to take turns to speak, to include everyone and to ensure that everyone got to say something about their own thoughts and experiences. [APNS 8]

The APNSs felt supported by their NPs when performing the leader role:

The students managed to pass on the baton to the other students without it seeming embarrassing; it went quite well. And my role was really, I felt, to support my student through the meeting. [NP6]

One student summarized the significance of developing competence in professional leadership:

I felt that the biggest advantage was that we learned to lead a meeting, how to steer it and how to argue. Yes, we are going to become intensive care nurses, but we are also going to become APNs, who will have a slightly different role, so it helped me to see that we will need to be able to lead that type of meeting in a work environment, to be able to take up problems out in the field, try to make changes or show something new; this was a good way of practicing that. [APNS 3]

The NEs assumed that the VRG meeting was well structured and promoted APNSs' development of leadership skills:

Each student practiced leading the professional discussions, and the discussions became very good, and everyone was well prepared. [NE3]

Synergy in Competence Development

Increased Collaboration Between Students and Preceptors

The students experienced the NPs' participation in the VRG meetings as positive. They pointed out that preceptors could not participate in the FFRG meetings because they were unable to leave the ward. The collaboration between NPs and APNSs in the VRG meetings was also seen as positive:

When it came to finding a research article, we had a lot of good conversations about what we wanted to discuss together; we went through several different subjects and found in the end a case that we both found interesting. [APNS 5]

In the previous RG design, such cooperation was not possible. Another APNS said:

We discussed a case before the VRG meeting and discussed the results we had found in the article I had chosen. So it was more than what I previously experienced in clinical practicum, where I hadn't even mentioned the choice of a research article to my preceptor. [APNS 7]

Improved Focus on Evidence-Based Practice in the Clinical Environment

The NPs experienced that collaborating with the APNSs in the VRG meetings led them to be updated with new knowledge from research publications. Usually, the NPs felt it was challenging to remain up to date on science in their research field because of their hectic, practically orientated daily work. Cooperation between NPs and APNSs stimulated their engagement in evidence-based knowledge:

There is something about the knock-on effects, which are also great when you go about your daily tasks and don't have much time for additional work as well. [NP1]

I think it is important. You get insights into what the students need to learn. You can update yourself, and, as [NP 1] says, there isn't much time normally to find the newest research, so I think I learned a lot by being a preceptor. [NP2]

The NPs also mentioned that the organizational structure of the VRG meetings led to a great deal of involvement, academic interest, and discussions on various topics:

Both I and the student, along with several others, also discussed a difficult case before the student presented it [at the VRG meeting]. We talked about the case afterwards, because there were many who thought that the case was difficult, and, in a way, it became a learning situation for the students but also for us on the ward. So, the VRG meeting was actually a useful method, and there were more people who got something useful out of it. First, the student wrote down the case. I got it as an email, so I could read it on my own time and think about it, and then we all

spoke about it on the ward. I think it was a good way of doing it. [NP 5]

Improved Professional Interaction Skills

For the VRG meetings, the APNSs were instructed to share documents with one another before the meetings, which they perceived as useful. In each meeting, one of the APNSs assumed the role of respondent and had the task of giving the responsible student critical feedback on the chosen research article. The experience of receiving feedback from a fellow student was described as follows:

You get feedback [from the respondent] on how you have appraised the article, and, for me, it was informative and something I can take with me when I am finished. Because you know that you will also use this knowledge later in working life. [APNS 9]

One of the NPs felt that the VRG meetings were perfect for cooperation with the APNSs, saying that even though it could be perceived as stressful to read a research article on a busy working day, the preparations for the VRG meetings energized them and helped them give more guidance to the APNSs. The preceptors experienced closer cooperation with the students, as they had a specific task:

You have it in the back of your mind all the time that you have to find a discussion topic together, so there are more professional discussions and learning situations that arise. [NP3]

Discussion

Principal Findings

The primary findings of this study pertain to the perceived benefits of a structured, active learning approach supported by technology, namely, VRG meetings. When the teaching method is well structured, it generates positive consequences, as shown in our results. The VRG meeting design inspired well-prepared participants because of their well-defined roles and responsibilities, and the APNSs perceived increased competencies related to intrapersonal and professional skills. The VRG meetings also led to increased synergy and collaboration between APNS, NPs, and NEs and, consequently, to perceived enhanced APNS and NP competence.

The Participants' Experiences of VRG Meetings

To participate in the VRG meetings, the APNSs had to be prepared, which stimulated their responsibility and commitment to learning. Furthermore, they found that VRG meetings were more effective and focused more on evidence-based knowledge than FFRG meetings. Each week, some APNSs felt that their role as a student was recognized by the NPs, who perceived the APNSs to be more prepared for the meetings and took more initiative and responsibility for diverse learning activities in their clinical practice placement. Providing APNSs with structured, active learning has been found to enable their reflective process and improve their professional practice, and consequently, patient outcomes [12].

The VRG meeting is a pedagogical method that, in line with Vaz de Carvalho and Bauters [20], fosters active involvement

of students in their learning process. According to Agarwal and Kaushik [21], web-based teaching methods should be a part of postgraduate training if they are relevant to students' learning needs in their clinical practice. Using Zoom as a technological tool in the VRG meetings better established the APNSs' learning process, as they had to be prepared and could not hide behind others. The use of supportive technology to ensure an active learning process is in line with a recent study by Nes et al [22]. Learning is an active process that requires motivation and engagement from all students, so these elements must be considered when a specific discipline, course, or program aims to guide students toward achieving the required learning outcomes [23]. Higher education programs must be designed to accommodate a new generation of technological learning tools that promote learners' autonomy, collaboration, and critical analytical ability to foster the active construction of complex knowledge and skills [12,24]. Active learning occurs in interactions between individuals, such as fellow students, who share experiences and knowledge with one another [25]. Our study showed that VRG meetings actively engaged APNSs in the learning process, which is an important finding, as active engagement is crucial in collaborative learning according to Zhang and Cui [24].

The APNSs and NPs who participated in the VRG meetings experienced stimulated critical reflection based on patient cases and available evidence in research articles. APNSs require critical reflection to turn their experiences into learning, for which a structured teaching approach, as implemented in this study is recommended [26]. Critical reflection has also been associated with using analytical cognition in students' development of problem-solving skills [27]. APNSs need to apply their knowledge to manage complex decision-making in an intensive critical care context. To make the right decision in complex situations requires that APNSs in critical care exercise critical reflection at a high level of analytical cognition because as the Hammond [28] theory of cognition contends, a high level of intuitive cognition may inspire poor decisions. Hammond [28] cognitive continuum theory describes the levels of analytical and intuitive cognition in task management, with task properties varying from poorly to well structured [29]. Analytical cognition is associated with cognitive control, slow data processing, and conscious awareness and confidence, which are often induced when managing a well-structured task. However, ill-structured tasks such as complex patient situations in critical care often induce intuitive cognition, which involves less cognitive control, less conscious awareness, and low confidence [28,29]. By attending the VRG meetings, the students turned their experiences into learning using critical reflection with analytical cognition, discussing difficult cases, sharing knowledge, and reaching a deeper level of assessment and a higher level of cognition, as recommended by Miraglia and Asselin [12] and Scheel and Bydam [14].

The Main Perceived Improved APNS Competencies Resulting From VRG Meetings

Our results indicate that participating in VRG meetings was experienced as a good preparation for the role of an APN, primarily with regard to the development of intrapersonal and professional skills, which embrace a nurse's capability to

understand, deal with emotions, and practice self-discipline [30]. In this study, the APNSs dealt with emotions (feeling outside their comfort zone) by leading and actively participating in VRG meeting discussions. In addition, the meetings contributed to greater responsibility and commitment of the APNSs in terms of preparation and participation when compared with FFRG meetings. In the professional role of an APN in critical care, the meaning of competence is feeling sufficiently safe and secure to efficiently manage decision-making in life-threatening patient situations [31]. Our findings clearly show that the APNSs perceived the VRG meetings as meaningful, and they reported that choosing a patient case and relevant research study, leading the meeting, and being required to argue increased their self-discipline and self-confidence. Furthermore, by participating in the VRG meetings, the APNSs gradually gained the confidence in presenting their point of view, which contributed to the development of an autonomous role and advanced knowledge in clinical decision-making in critical care, as expected from an APN [32,33]. Implementing VRG meetings in the clinical practice of master's education programs may positively enhance APNSs' personality traits, which affect their conscientiousness and openness to experience in developing their competence and are important factors in nursing education in critical care [31].

Another important finding of this study was students' ability to develop their leadership skills, a core competency required in the APN role [6,32]. Essential leadership skills in APNs include competence in self-awareness, self-management, social awareness, and relationship management [6]. In this study, the responsible student ensured that everyone attending the meeting had the opportunity to express their thoughts and experiences. These discussions became very positive, increasing the synergy and competence development among the APNSs. The VRG meetings also influenced the clinical practice environments of the clinical placements at both the individual and organizational levels. At the individual level, reflection leads to enhanced knowledge and transforms the assumptions. At the organizational level, reflection empowers nurses to explore concerns and make changes [12]. The results of our study are in line with those of Ljungbeck et al [32], who described leadership skills as an important competence for APNSs in critical care. The results of this study regarding APNSs' perceived achievement of leadership skills may be transferable to the clinical practice context, potentially enabling them to develop professional leadership skills in the ward.

Strengths and Limitations

This innovative study used technology to improve the teaching approach (RG meetings) routinely used in clinical practice for nursing education. The data were collected from all parties (APNSs, NPs, and NEs) involved in clinical practice education, increasing the trustworthiness of the intervention evaluation. Data were collected from 2 different groups at different stages of the APN education program. Moreover, the developed VRG meeting can easily be adapted to several educational programs and to various levels of professional education.

As a limitation, we experienced a slight drop out of possible informants in the second focus group interview. One reason for

this may be that we invited a larger number of students, as VRG meetings were implemented in a greater number of CCUs (Table 3). Another reason may be that the interview was in a web-based format because of the COVID-19 pandemic (although we found this perplexing, as the informants were used to attending virtual meetings). However, the low number of participants in the second interview confirmed that the informants felt no pressure to participate in this study, which was positive. Furthermore, VRG meetings depend on appropriate and functional technical tools, and participants must have access to devices, such as computers, tablets, or smartphones.

Conclusions

The participants perceived the VRG meeting—a structured, active learning approach supported by technology—as being more effective than FFRG meetings on campus in developing APNSs' required competence in critical care. The VRG meeting was also perceived as an improved approach for solving several challenges previously experienced in FFRG meetings. On the basis of participants' experiences, we conclude that VRG meetings contribute to increasing APNSs' competence, specifically by preparing them to exercise complex decision-making with a higher level of analytical cognition in a clinical context. VRG meetings may also inspire professional discussions in the ward, increasing professional interaction.

Acknowledgments

The authors wish to acknowledge Ørjan Flygt Landfald, who contributed to the conception and design of the study, was the observer in the second interview, and actively contributed to the completion of the study. The authors also acknowledge Irene Rød, who was the observer in the first interview.

Abstract

Background: Many individuals with posttraumatic stress disorder (PTSD) first present to primary care rather than specialty mental health care. Primary care providers often lack the training required to assess and treat patients with PTSD. Virtual trainings have emerged as a convenient and effective way of training primary care providers in PTSD assessment and communication methods (ie, motivational interviewing [MI]).

Objective: The aim of this study was to conduct a pilot randomized controlled trial of a synchronous Virtual Worlds (VW; a virtual world where learners were immersed as avatars) training versus an asynchronous web-based training on PTSD and MI, comparing the feasibility, acceptability, usability, and preliminary efficacy of 2 different training platforms among primary care providers.

Methods: Participating primary care providers were randomized to a VW and a web-based PTSD training. Outcomes were collected at baseline, posttraining, and 90-days follow-up. Standardized patient interviews measured participants' communication skills in assessing and managing patients with PTSD symptoms.

Results: Compared to the web-based training, the VW training platform achieved larger learning gains in MI (ie, partnership and empathy) and in discussing pharmacotherapy and psychotherapy for PTSD. Both VW and web-based trainings led to increases in PTSD knowledge and primary care providers' self-confidence.

Conclusions: The asynchronous web-based PTSD training improved PTSD-related knowledge and self-confidence but was not as effective as the VW immersive experience in teaching MI or clinical management. Because VW training is synchronous and new for many learners, it required more time, facilitation, and technical support. As computer technology improves, VW educational interventions may become more feasible, particularly in teaching clinical skills.

Introduction

Rates of posttraumatic stress disorder (PTSD) among veterans of Iraq and Afghanistan are estimated to be as high as 30% [1,2]. Veterans underuse Department of Veterans Affairs (VA) mental health services due to factors such as poor access, beliefs about psychotherapy, and stigma [3-7]. Veterans more frequently present to VA primary care providers (PCPs) with symptoms of PTSD (eg, sleep disturbance); however, PCPs often fail to associate these symptoms with PTSD. In a prior study [8], PCPs in VA primary care accurately identified PTSD in only half of veterans. In a national survey of PCPs [9], participants answered only 41% of PTSD knowledge questions correctly. Failure to detect and manage PTSD symptoms in primary care patients hinders early intervention and puts patients at risk for chronic PTSD symptoms. Motivational interviewing (MI) is an evidence-based communication method designed to enhance motivation for change [10], including treatment engagement for mental health disorders, such as PTSD.

Given cost constraints, scheduling challenges, geographic barriers, and concern about in-person gatherings (during the COVID-19 pandemic), health care systems increasingly use web-based and virtual reality trainings for continuing medical education (CME) and medical education [11,12]. A meta-analysis of over 200 web-based CME trainings demonstrated large effect sizes in improving self-reported knowledge and clinical practice behaviors, compared to no education [13]. CME programs that included interactive activities and skills practice had the largest effect ($d=0.67$) [14], yet few web-based CME programs achieved high levels of interactivity or immersion.

This appears true both in general and for PTSD training specifically. For example, our team previously developed and piloted an asynchronous, web-based PTSD training for PCPs [15], which included clinical vignettes demonstrating PTSD assessment and management using MI [10]. The results of this study indicated that PCPs' PTSD knowledge and perceived self-efficacy improved compared to baseline, and PCPs experienced few technical challenges with the web-based training. However, they commented on the lack of interactivity and skills practice [15]. A more engaging platform uses Virtual Worlds (VW), a 3D computer-based multiuser multimedia environment. A VW platform offers graphical representation of a physical space, where individuals use avatars (digital self-representations) to interact with each other and objects [16]. Studies demonstrate that VW training enhances learning outcomes beyond what is provided by web-based or face-to-face learning activities [12,16-18]. However, there is little research on VWs' potential efficacy for the assessment and management of PTSD.

In this study, we developed a synchronous VW PTSD and MI training for PCPs that was interactive and immersive, simulated trauma and PTSD symptoms, and allowed learners to interact

with instructors and each other. The VW also allowed for real-time feedback, as participants practiced new MI and PTSD assessment and management skills with standardized patients (SPs). Using prior asynchronous web-based training with similar content, this pilot randomized controlled trial (NCT03898271) assessed the feasibility, acceptability, usability, and preliminary efficacy of the VW training in improving PTSD-related assessment and management as well as MI skills among PCPs. We hypothesized that those PCPs who participated in the VW PTSD and MI training would demonstrate greater PTSD assessment and MI communication skills, greater self-reported improvements in PTSD assessment and MI communication skills, and greater satisfaction with VW training, compared to participants in the control group who underwent asynchronous web-based training.

Methods**Participants, Recruitment, and Randomization**

PCPs (ie, physicians, nurse practitioners, or other trainees) from the VA, other community health care systems, and university affiliates across the United States were recruited via email. PCPs with at least five military service veterans on their panels were eligible; PCPs lacking adequate computer or internet speeds to support VW technology were excluded. Following baseline self-report assessments and SP interviews, consenting PCPs were randomized to either the VW training (intervention) or the web-based training (control).

Ethical Considerations

The study was approved by the Institutional Review Board of the University of California, San Francisco, and the Research Protection Program of the San Francisco VA Health Care System (IRB number 14-15004). All participants provided consent for their participation in this study. Participants received a gift card valued up to US \$50 and the opportunity to earn up to 5.75 CME credits for participation (the remuneration amount varied depending on whether the participant opted to receive CME credit). Participants also received US \$20 if they participated in a qualitative interview at the end of the study. All study data have been deidentified in this manuscript.

Study Overview

The overall goal of this pilot randomized controlled trial was to assess the feasibility, acceptability, usability, and preliminary efficacy of a VW training format, compared to an asynchronous web-based training in improving PTSD-related assessment and management as well as MI skills among PCPs. PTSD assessment skills were measured by participant self-report measures. PCP skills were assessed via standardized behavioral coding and participant self-report measures. The feasibility and acceptability of the training formats (ie, VW and web-based training platforms) were evaluated in qualitative interviews with participants.

Training Conditions

VW Training in PTSD Assessment and MI

The VW training was developed as a collaboration between the research team (content expertise), virtual educational consultants, and a technical build team. The VW training was iteratively refined based on feedback and input from a series of semistructured interviews and focus groups with project stakeholders (ie, PCPs, VA leadership, medical educators, Department of Defense partners, and IT experts). The final VW training consisted of a VW orientation and 2 synchronous 90-minute training sessions 2 weeks apart.

Session 1 began in a simulated VA medical center lobby containing informational posters about war-related PTSD. Learners met Alex, a young war veteran with PTSD symptoms who was interviewed by a PCP in the VW environment. Alex only disclosed his symptoms after the VW PCP adopted an MI-consistent communication style. Next, as avatars, learners were virtually teleported to Alex's apartment, where they assumed Alex's identity. As "Alex," participants toured Alex's apartment for PTSD-related symptoms or "clues" (eg, empty beer bottles, concerned wife, and unused sporting gear). Next, participants were teleported to Alex's classroom, where they observed his physiological reactivity to innocuous triggers (eg, loud noise) via simulated electronic vital signs monitor. As

"Alex," participants observed how the loud noise triggered Alex's memory of the battlefield (ie, a flashback of Alex crawling through the battlefield). Next, learners navigated their avatars into an amphitheater for a live, instructor-led didactic session on PTSD symptoms and MI. Finally, learners entered a virtual breakout room where they practiced new MI communication skills by interviewing SPs (also avatars), assessing for PTSD symptoms, and receiving personalized feedback from trained MI experts. [Figures 1-4](#) show screenshots of the VW training.

Session 2 opened with a virtual obstacle course simulating the common barriers to accessing mental health care. From there, participants were teleported to a virtual "Modalities to Care" room, which exhibited 4 multimodal approaches that could be combined to manage Alex's PTSD symptoms. These approaches included medication, psychotherapy, complementary and integrative health, as well as valued activities. Learners practiced creating SMART (specific, measurable, action-oriented, realistic, and timebound) treatment goals based on patient histories that incorporated a multimodal approach. Learners then entered an amphitheater for a didactic session on PTSD symptom management, including indications for referrals and the use of MI for mental health treatment engagement. The training session again concluded with learners practicing with SPs and receiving feedback on PTSD symptom management and MI skills.

Figure 1. Virtual Worlds screenshot of amphitheater.

Figure 2. Virtual Worlds screenshot of Alex in classroom.**Figure 3.** Virtual Worlds screenshot of Alex at the doctor.

Figure 4. Virtual Worlds screenshot of multimodal care with participants.

Web-Based PTSD Training

The updated asynchronous web-based training (control) was 70 minutes and consisted of an introductory module and 4 web-based narrated video training modules (assessment of PTSD, comorbid conditions and related problems, pharmacological management of PTSD in primary care, and psychotherapeutic interventions for PTSD) [14]. It included didactic content, case presentations, and videotaped clinical vignettes of PCPs interacting with patients with PTSD symptoms using MI communication techniques. Audience polling with questions was added after each module to make the web-based training more comparable to the highly interactive VW training.

PCP Self-Report Measures

PCP participants were emailed a link to complete the web-based baseline and posttraining self-report measures 1 week and 90 days after training completion. Outcome assessment domains included sociodemographic or clinical practice characteristics (baseline only), PTSD knowledge (8 items) [14], PTSD clinical skills self-confidence, System Usability Scale (SUS) [19-21], and participant feedback on the training.

SP Interviews and Coding

SPs were trained actors portraying 1 of 6 randomly assigned cases of veterans with PTSD symptoms. Participants completed a telephone interview with an SP at baseline, posttraining, and 90-days follow-up. Interviews were coded to evaluate PCPs' communication and PTSD-related clinical skills in the following domains: (1) shared decision-making and patient engagement, (2) PTSD symptom assessment and symptom management, and (3) MI skills. Each domain included subcategories that were coded on a 5-point global rating scale. The MI domain measured PCP partnership and empathy from the Motivational Interviewing Treatment Integrity behavioral coding system [22].

Other coding domains were developed specifically for this project (Multimedia Appendix 1).

All coders received training and attended weekly coding meetings. SP interviews were deidentified, and coders were blinded to session order (ie, baseline, posttraining, and 90 days). Roughly 20% of interviews were randomly selected for double coding to calculate interrater reliability (IRR).

Qualitative Interviews With PCP Learners

Qualitative semistructured interviews were conducted with a subset of PCPs to learn more about their experiences with either training platform. Each interview was analyzed by 2 trained analysts using rapid qualitative analysis. Analysts listened to each interview and created a summary of interview content to identify themes with exemplary quotations.

Data Analysis

Using paired (2-tailed) *t* tests, within-treatment group change in the proportion of correct PTSD knowledge responses were compared from baseline to posttraining and follow-up. A difference-in-differences analysis compared the mean change over time between treatment groups for knowledge or self-confidence and standardized patient coding scores. Coded items were grouped into concepts that measured the same underlying psychometric construct and standard *t* tests compared constructs within study arms. IRR analyses evaluated consistency between coders [23]. Participant feedback was evaluated by comparing mean responses in SUS between groups using standard *t* tests.

Results

Demographics and Training Completion

Recruitment and enrollment of PCP participants in the trial is shown in Figure 5. Of 200 eligible PCPs, 99 were randomized

to the VW (intervention) training and 101 to the web-based PTSD training (control). In the VW condition, a total of 51 participants received training, and 48 did not receive training for various reasons. Specifically, 23 PCPs dropped out or had no contact before the training, 14 dropped out due to a lack of time, 4 had IT barriers, and 7 cited other reasons; [Figure 5](#)). In the web-based training, 51 participants received training, and

50 participants did not receive training. Among those who did not receive training, 43 dropped out or had no contact before the training, 2 had no contact after the videos were sent, and 5 cited other reasons for not participating. In sum, a total of 102 PCPs (51 in each arm) completed training. Characteristics of study participants are shown in [Table 1](#).

Figure 5. CONSORT (Consolidated Standards of Reporting Trials) diagram of participant enrollment.

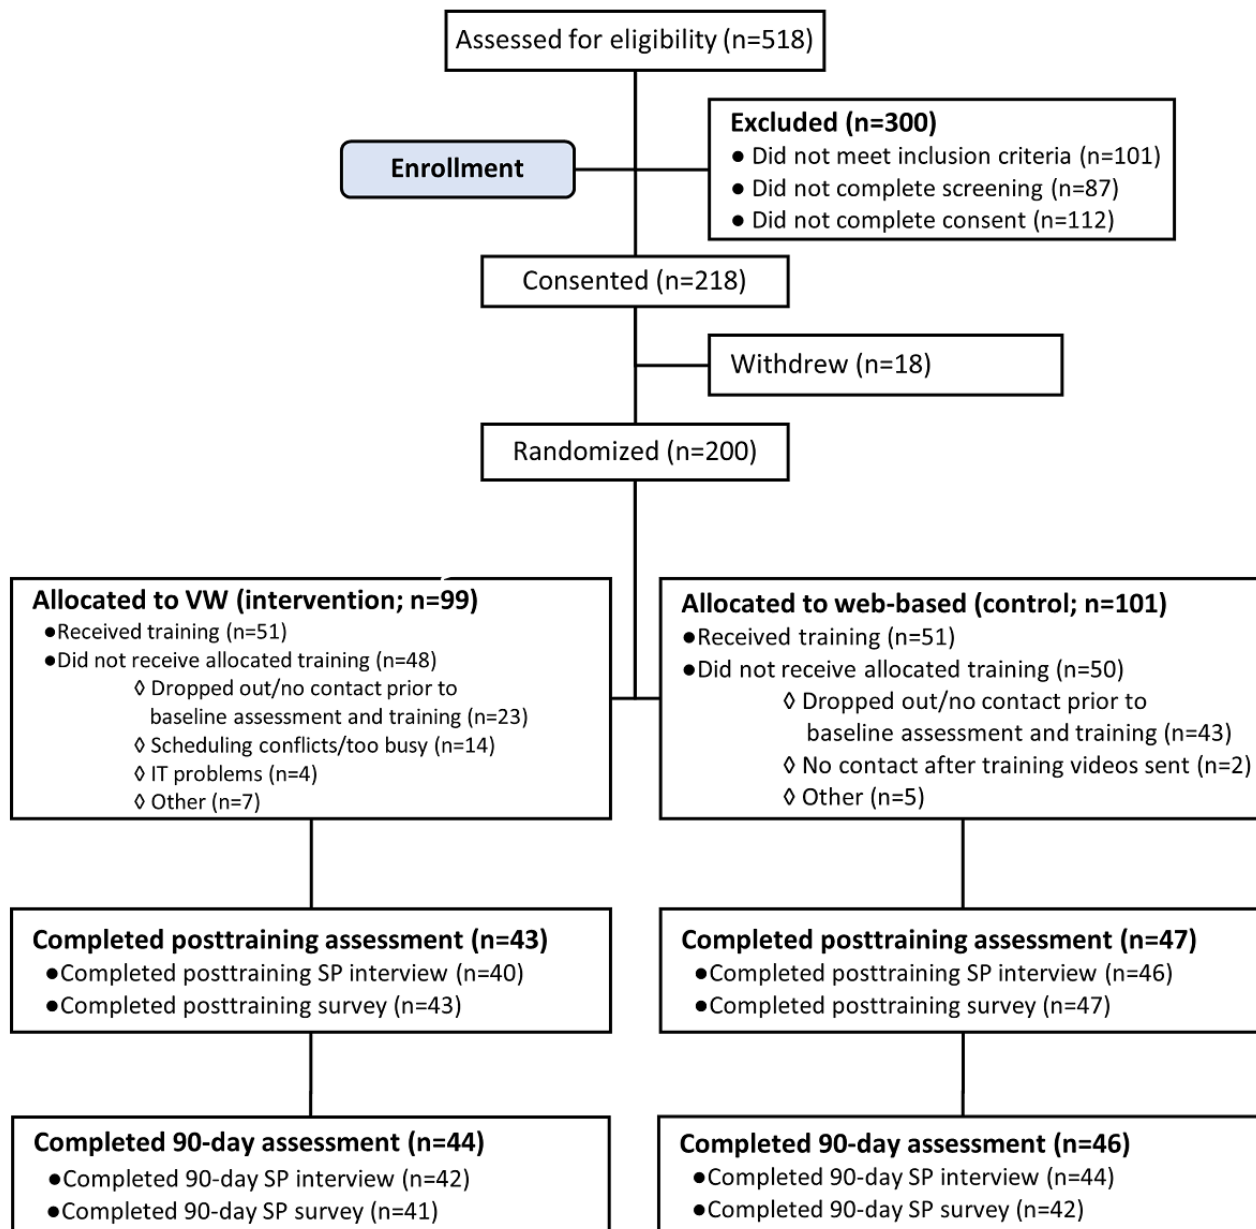

Table 1. Respondent demographic and baseline characteristics by treatment arm (Virtual Worlds [VW] vs web-based training).

Characteristics	Overall (n=107), n (%)	VW training (n=51), n (%)	Web-based training (n=56), n (%)
Gender (female)	72 (68)	32 (64)	40 (71)
Profession

Participant Self-Report Items

There was a significant increase in PTSD knowledge post training among participants in both the web-based training condition (Cohen $d=0.7$) and the VW training condition (Cohen $d=0.6$). This increase was maintained at the 90-day follow-up (web-based condition Cohen $d=0.3$ and VW condition Cohen

$d=0.7$). Similarly, there was a significant increase in self-confidence in PTSD clinical skills in both the web-based condition (Cohen $d=1.4$) and the VW condition (Cohen $d=1.2$) at posttraining and at the 90-day follow-up (web-based condition Cohen $d=1.3$ and VW condition Cohen $d=1.5$), with no statistically significant difference between groups at either time point (Table 2).

Participant Self-Report of Training Usability From SUS

Participants in the web-based training reported significantly greater usability (mean 86.9, SD 17.5; [Multimedia Appendix 2](#)), compared to participants in the VW group (mean 56.8, SD 21.7), yielding a large effect size (Cohen $d=1.5$).

SP Interviews

The IRR between coders was moderate for most items (range 0.4–0.7; [Table 3](#)). There was a significant within-group increase in the VW group in discussions of pharmacotherapy and

psychotherapies from baseline (mean 2.9, SD 0.9) to posttraining (mean 3.4, SD 0.8; Cohen $d=0.6$; [Table 4](#)) and follow-up (mean 3.3, SD 1.0; Cohen $d=0.4$; [Table 5](#)). There were also significant within-group increases in the domains of partnership and empathy for the VW group from baseline (mean 2.9, SD 0.9) to posttraining (mean 3.3, SD=0.7; Cohen $d=0.5$) and follow-up (mean 3.2, SD 0.8; Cohen $d=0.4$), compared to the web-based group, which remained the same at baseline, posttraining, and follow-up. Between-group differences in partnership and empathy for the VW group, compared to the web-based group, approached significance ($P=.08$; Cohen $d=0.4$) from baseline to posttraining.

Qualitative Findings From PCP Learners

PCPs reported mixed perspectives on the value of the VW platform and whether this mode of delivery was worth the time required to install or set up the program and navigate using their avatars. Several participants described the VW as “clumsy” or “inefficient.” Nevertheless, participants overwhelmingly found the content of the VW training memorable and valuable. The interactive and applied components of the training distinguished it from other trainings. Because the VW training incorporated a variety of immersive audio-visual experiences in different virtual settings, participants felt the VW modality was especially strong in accommodating different learning styles. Perspectives were mixed on whether they would choose the VW format again. Some liked the interactive aspects of the VW format, while others liked the greater flexibility and reduced time commitment of the more traditional web-based option. Some participants agreed that any provider who interacts with patients with a history of trauma could benefit from this training, from PCPs to emergency department providers and specialists. Some

noted that even though mental health providers are likely to have had training in PTSD, they might not have had as much training in MI and could still benefit from the interactive MI training.

Discussion

Principal Results

Results from this pilot randomized controlled trial of a synchronous VW versus an asynchronous web-based training indicate participants in the VW condition achieved greater gains in some dimensions of MI (ie, partnership and empathy) and in their discussions of pharmacotherapy and psychotherapy treatment options with individuals with PTSD. The positive findings regarding the impact of the VW training on MI skills in this study is consistent with other trials of VW training formats to improve PCPs' MI skills and suggest that this training platform warrants further study [24]. In this study, the web-based training was viewed as more usable compared to the VW format. Nonetheless, both methods of training were successful in

increasing PCPs' knowledge of PTSD assessment and management. These results occurred even though most PCP participants had more than 10 years of professional experience, including experience in caring for patients with trauma. This highlights the importance of ongoing and accessible training in PTSD assessment and management for PCPs.

Data from the SP interviews showed increases in each of the PTSD- and MI-related learning domains measured, many of which were sustained over time. These increases were larger among PCPs who participated in the VW compared to those in the web-based training, but the difference between groups was not significant. Notably, PCPs participating in the VW training achieved significantly higher and sustained MI scores of partnership and empathy. Thus, the VW immersive and interactive activities and practice as well as the real-time feedback may have yielded significantly higher skill levels in engaging patients through empathy and partnership and in discussions about PTSD symptom management using medication and psychotherapy.

Despite the significant increase in PCPs' pharmacotherapy or psychotherapy discussions and MI skills in the VW training group, participants viewed the synchronized virtual platform as less usable compared to those in the web-based training condition. This gap between the efficacy of the VW platform and its ease of use highlights the need for greater efforts in improving usability, particularly in terms of navigating avatars through virtual spaces using a standard personal computer and keyboard or mouse, as opposed to video game systems designed specifically for virtual world navigation.

Limitations

This study's findings are limited due to the attrition rate (approximately 50% in each group) from randomization to

training as well as the small sample size. Nevertheless, the rates of dropout among PCP participants were similar across the 2 conditions. Moreover, high rates of attrition are common in studies of frontline clinical providers [25]. This suggests that future trials should provide greater incentives, include less burdensome study assessments, and plan for potential attrition in sample size calculations.

Conclusions

The asynchronous web-based PTSD training was not as effective as the VW immersive experience in teaching PCPs to use MI skills in assessing and managing patients with PTSD but was viewed as more usable among PCPs. Participants in both platforms demonstrated increased PTSD-related knowledge and self-confidence in assessing and treating PTSD.

Improving PCP knowledge of trauma and PTSD and their MI communication skills is important to better engage patients in treatment and can serve as a vital gateway to specialty mental health treatment, given the high utilization rate of health care among individuals with PTSD [26]. Nonetheless, prior research indicates that PCPs require training in MI and PTSD assessment to increase PCP competence and comfort. VW training in PTSD and MI shows promise but requires moderate facilitation and technical support. As computer technology improves, immersive and interactive VW educational interventions may become more feasible and useful, particularly in teaching clinical and communication skills.

Abstract

Background: Engaging men in psychotherapy is essential in male suicide prevention efforts, yet to date, efforts to upskill mental health practitioners in delivering gender-sensitized therapy for men have been lacking. To address this, we developed Men in Mind, an e-learning training program designed to upskill mental health practitioners in engaging men in therapy.

Objective: This study involves an in-depth analysis of the user experience of the Men in Mind intervention, assessed as part of a randomized controlled trial of the efficacy of the intervention.

Methods: Following completion of the intervention, participants provided qualitative (n=392) and quantitative (n=395) user experience feedback, focused on successes and suggested improvements to the intervention and improvements to their confidence in delivering therapy with specific subpopulations of male clients. We also assessed practitioner learning goals (n=242) and explored the extent to which participants had achieved these goals at follow-up.

Results: Participants valued the inclusion of video demonstrations of skills in action alongside the range of evidence-based content dedicated to improving their insight into the engagement of men in therapy. Suggested improvements most commonly reflected the desire for more or more diverse content, alongside the necessary adaptations to improve the learning and user experience. Participants also commonly reported improved confidence in assisting men with difficulty articulating their emotions in therapy and suicidal men.

Conclusions: The evidence obtained from this study aids in plans to scale Men in Mind and informs the future development of practitioner training interventions in men's mental health.

Introduction

Men's Mental Health and Help-Seeking Experiences

The intersection between men's mental health outcomes, particularly suicide, and masculine gender socialization has drawn increasing research attention [1]. In many countries, traditional gender norms that dictate that men should be emotionally stoic and self-reliant are thought to manifest as barriers to men's help-seeking for mental health care [2]. Such barriers are thought to subsequently amplify men's vulnerability to suicide [3]. To date, much of the empirical literature has focused on tackling the issue of improving men's access to targeted and tailored evidence-based interventions [4,5]. In doing so, one of the keys to improving care is tailoring practitioner training within a larger landscape of culturally adapted treatments [6,7].

Prior research highlights that men seeking help for depression often receive insufficiently engaging services that can exacerbate shame or feelings of alienation in the therapy environment, leading to high rates of premature dropout [8,9]. This mismatch is also reflected in suicidal men who seek help, with treatment often neglecting men's agency and autonomy, thereby not meeting their needs and directly affecting their efforts and desire to seek further support [10,11]. Research exploring the experiences of mental health practitioners substantiates common challenges when working with men, including, for example, a lack of preparedness to tap into traditionally masculine men's emotional worlds [12]. Importantly, interventions aiming to lever men's rigid adherence to traditional masculine norms to promote help-seeking have been shown to increase help-seeking intentions [13]. Public health promotion campaigns aimed at affirming men's help-seeking behavior have also demonstrated positive effects by increasing help-seeking intentions (eg, Man Up [14]), awareness, and behavior (eg, Man Therapy [15] and Real Men. Real Depression [16]). However, with this intended increase in male help seekers, comparable efforts are needed to ensure that practitioners working with men in therapy are equipped to sensitize their treatment to better reach, respond, and retain men in all their diversities. Indeed, this is even more critical in the case of suicidal men, where practitioners may only have a short window of opportunity to effectively engage their male clients [17].

Practitioner Education for Engaging Men in Therapy

Currently, guidelines for engaging men in therapy do exist [18], alongside case studies documenting the sensitization of therapy for men [19]. The existing literature has so far provided consistent recommendations for working with men in practice, advocating for practitioners to have an awareness and understanding of how gender socialization impacts male client presentation and the therapeutic relationship, to self-reflect on their own gender biases and socialization, and to implement specific microskills around communication and treatment structures that adapt their practice to be more male oriented [6]. However, the field currently lacks a synthesis of these findings into accessible and scalable training initiatives for the mental health workforce [6].

To address this gap, Seidler et al [20] created Men in Mind, a web-based training program designed to upskill mental health practitioners (eg, psychologists, counselors, and social workers) to engage and respond effectively to men in psychotherapy. Men in Mind was initially evaluated through a pilot trial among 196 Australian practitioners, with the results providing evidence for the acceptability, feasibility, and potential efficacy of the program [21]. Subsequently, a randomized controlled trial (RCT) [22] was conducted among 587 practitioners with results showing that Men in Mind was effective at increasing practitioners' self-reported efficacy to engage and respond to men in psychotherapy to a large effect (Cohen $d=2.63$, 95% CI 2.39-2.87; $P<.001$).

Men in Mind: Next Steps

Importantly, efficacy alone does not ensure real-world applicability or feasibility, which must be a core consideration when designing and evaluating interventions for subsequent scaling and dissemination. Indeed, meta-analytic evidence suggests that learning experiences in web-based environments can moderate the differences between learning outcomes when comparing web-based and face-to-face learning [23]. These results also suggest that web-based learning may increase student performance when compared with face-to-face instruction. This is particularly significant given the potential for e-learning training programs (web-based learning initiatives [24]) to be efficient and easily scalable. However, it is rare for e-learning evaluation studies to conduct dedicated in-depth analyses of learners' experiences beyond simple user experience feedback [25]. This is a notable gap when considered alongside mixed evidence regarding knowledge retention in web-based learning formats: improving web-based learning experiences could be critical to practitioner knowledge retention. Specifically, Burn et al [26] found that web-based practitioner training for engaging fathers in parenting interventions led to decreases in practitioner competencies at follow-up (where the same decreases were not observed in in-person training). If Men in Mind is to be scaled across international markets to assist practitioners, it is essential to understand participants' experiences of the successes and shortcomings of the intervention via dedicated analysis. This will complement prior quantitative evidence of the efficacy of Men in Mind to provide a detailed understanding of how and why the intervention improved practitioner self-efficacy, thereby informing broader international efforts to achieve knowledge translation in the development of gender-tailored mental health interventions for men [27]. The expectations and goals of the practitioners undertaking the training are also of value here. Clarifying whether the learnings of Men in Mind are in line with practitioner expectations and whether they will help them achieve their goals is critical in ensuring motivation and engagement with the program. To address these gaps in user experience, this study aims to provide an in-depth report of participant experience during the Men in Mind trial, reporting our qualitative evaluation of participants' experiences of the intervention, quantitative e-learning feedback, and learning implementation goals.

Methods

Study Design

This study involved the analysis of training feedback and goal assessment outcomes of the Men in Mind RCT, a web-based RCT with 2 parallel groups, a Men in Mind group (who underwent the Men in Mind training program) and a waitlist control group (who underwent the training program after the Men in Mind group). The RCT examined the efficacy of Men in Mind in improving practitioners' clinical competencies related to engaging with and responding to male clients in therapy. The protocol for this trial has been described in detail elsewhere [28], with the primary and secondary quantitative outcomes forthcoming. All relevant documentation regarding the trial was preregistered and available at the Australian New Zealand Clinical Trials Registry (ACTRN12621001669886).

Ethical Considerations

Ethics approval was obtained from the University of Melbourne Psychology, Health, and Applied Sciences Human Ethics subcommittee (22618). All participants provided informed consent at the beginning of the web-based survey before participating. All data provided was deidentified. No financial compensation was provided to participants for taking part in this study; their free access to the Men in Mind training intervention was considered adequate compensation for their time.

Participants and Procedure

Participants were Australian-based mental health practitioners who were recruited into the Men in Mind RCT. All the participants were fluent in English and were currently delivering psychotherapy to male clients. A "mental health practitioner" was defined as a client-facing mental health professional currently delivering psychotherapy (eg, psychologists, psychiatrists, counselors, or social workers). Participants were recruited from a pool of interested practitioners who registered an interest in the study via a web-based portal following advertisements (delivered via Facebook and the website of Orygen, the study sponsor) and presentations by the research team. Participants were excluded if they were an undergraduate student at the time of the trial. Informed consent was provided by the participants via the web before the first data collection point and was required for participation.

There were 3 data collection points in the trial: baseline, primary end point (6 weeks following randomization), and follow-up

(12 weeks after the primary end point for the Men in Mind group and 6 weeks after completion of the Men in Mind group by those in the waitlist control group). Follow-up occurred at different time points for both groups as it was designed as a follow-up assessment for the Men in Mind group and a comparative postintervention assessment for the waitlist control group (to be compared with the primary end point for the Men in Mind group). This paper focuses on feedback and goal assessment data regarding the Men in Mind intervention from both groups, across the primary end point and follow-up data collection points.

Intervention

Regarding the intervention itself, Men in Mind is a self-led web-based training program for mental health practitioners, which aims to upskill their self-reported clinical competencies related to engaging and responding to male clients in therapy. The content of Men in Mind comprises five modules: (1) "Rebranding Masculinity"—which offers in-depth understandings of men's gender socialization, masculinities, and connections between masculine norms and men's mental health; (2) "Your Gender, Your Practice, Your Rules"—lobbying practitioners to reflect on their gender socialization and how this might impact on their engagement of male clients; (3) "The Hook: Engagement and Motivation"—details strategies for engaging and motivating male clients, alongside tools for assisting men experiencing difficulty identifying or articulating their emotions; (4) "The Depressed Man"—aims to equip practitioners with the tools to identify externalizing profiles of male depression, particularly responding to anger and irritability; and finally, (5) "The Suicidal Man: Saving Those Thousand Lives"—shares connections between masculine socialization and men's suicide, highlighting warning signs and tools for therapeutically engaging suicidal men. These modules, along with all content within Men in Mind, are all evidence based and have been iteratively developed through past research, which has included a Delphi expert consensus study [29], qualitative research exploring male clients and practitioners' perspectives [9,30], and a scoping review regarding engaging men in psychological treatment [31].

Outcomes

Overview

Sociodemographic characteristics of the participants were collected at baseline. Table 1 specifies the outcome assessment procedures across time points of the trial.

Table 1. Timing of outcomes assessed across trial end points.

	Men in Mind group		Waitlist control group
	T2 (post) ^a	T3 (follow-up)	T3 (post) ^a
Five-item quantitative feedback	✓	✓	✓
Three-item qualitative feedback	✓		✓
Goal assessment outcomes			
Learning goals	✓		
Goal achievement		✓	

^aThe Men in Mind group had their postintervention assessment at T2 (6 weeks after baseline), while the waitlist control group started the program immediately after T2 and had their postintervention assessment at T3 (12 weeks after baseline). For the Men in Mind group only, T3 (follow-up) occurred 18 weeks after baseline.

Quantitative Feedback Items

To assess their experience of the Men in Mind training, participants completed 5 training program feedback experience items adapted from previous e-learning evaluation studies [32]. On a scale from 1 (strongly disagree) to 7 (strongly agree), participants were asked the following items: “I believe my current clinical practice will improve as a result of completing Men in Mind”; “I would recommend Men in Mind to other mental health professionals/colleagues”; “After completing Men in Mind, I feel more equipped to work with male clients in therapy”; “After completing Men in Mind, I am looking forward to working with more male clients”; and “After completing Men in Mind, I have been better able to retain male clients who have agreed to a course of therapy.” Participants completed these items after the intervention. Participants in the Men in Mind group also completed a repeat of 2 of the feedback items (“My current clinical practice has improved as a result of Men in Mind,” and “After completing Men in Mind, I have been better able to retain male clients who have agreed to a course of therapy”) at follow-up to assess for any changes in these items over the 12 weeks after the intervention.

Qualitative Feedback Items

After the intervention, the participants were asked to respond to 3 free-text entry items to gauge their experience of the training program. This survey occurred following completion of the intervention for both groups (ie, 6 weeks following randomization for the Men in Mind group and 12 weeks following randomization for the waitlist control group).

Participants were asked, “In your own words, what was the best thing about the training program for you?” “In your own words, what do you think could be improved about the training program?” “In your own words, which population(s) of male clients do you feel more confident working with now, as a result of completing Men in Mind?” (eg, men experiencing suicidality, men experiencing difficulty with emotional communication, and sexual minority men).

Goal Assessment Outcomes

At the primary end point, participants in the Men in Mind group were asked to respond to the following open-text item: “Now that you’ve completed Men in Mind, what are your three main goals for implementing the training into your practice?” These

goals were then presented back to the participants at follow-up. They were then asked to indicate whether they met their goals by responding with “No progress yet”; “Making progress”; or “Achieved” (coded as 1, 2, or 3, respectively).

Data Analysis

Bivariate analyses (a chi-squared test for categorical variables and an independent samples 2-tailed *t* test for continuous variables) were conducted to examine any differences between participants who responded to the relevant items and those that did not for the quantitative, qualitative, and goal assessment data. Responses to the quantitative items were analyzed using SPSS Statistics (version 27; IBM), with descriptive statistics presented for each of the 5 quantitative items.

Responses to the 3 open-ended qualitative items were analyzed using inductive thematic analysis. This involved a 6-stage process of coding and theme development in accordance with the guidelines by Clarke et al [33]. The responses were first read in detail to gain familiarity with the data, with all responses being downloaded into a spreadsheet for analysis. Initial codes were then identified using open coding by 2 authors (MJW and RB), and codes were developed to encompass similar responses. Cross-comparison of 10.2% (40/392) of the responses for each of the 3 items was undertaken by 2 authors (MJW and RB), with any disagreements being discussed and resolved. These initial codes were then sorted and merged into broad themes to form preliminary findings. Subsequent themes were then reviewed by the lead author (ZES) and were appropriately named and condensed. Throughout this process, selected themes (particularly those produced with low-frequency codes) were subsumed under higher-order themes to better represent the underlying thematic content. Finally, consensus on the themes and illustrative quotes was reviewed by all authors through meetings and collaborative writing of this paper.

For the goal assessment data, qualitative content analysis was used to form the overall goal categories [34]. This analysis involved the analytic stages of preparation (in-depth immersion in the data), organizing (initial coding and grouping of similar responses; collation of overlapping codes), and reporting (development of a conceptual map to represent the data). One author (MJW) conducted the content analyses of the goals data. The proportion of progress made by the participants was reported in simple frequencies.

Results

Sample Characteristics

A total of 587 participants were included in the original Men in Mind RCT (300 assigned to the Men in Mind group and 287 assigned to the waitlist control group) with demographic characteristics comparable across both groups (Table 2). Once the intervention had been completed, 395 participants completed the 5-item quantitative training program feedback (210 participants from the Men in Mind group and 185 participants from the waitlist control group), with a further 190 participants (Men in Mind group only) completing the additional 2 items at the follow-up assessment point (12 weeks after the intervention). Comparatively, 392 participants completed the qualitative feedback and 204 participants in the Men in Mind group completed the goal assessment data (waitlist control group did not undergo goal assessment). Bivariate analyses were

conducted to examine any potential demographic differences between participants who completed the quantitative, qualitative, and goal assessment data and the original 587 participants. These analyses found no differences in variables of gender, profession, employment load, qualifications, workplace, or region (Multimedia Appendix 1). A significant difference was found in the years of experience (as a practitioner) variable for both the quantitative data ($\chi^2_3=8.02$, $N=587$; $P=.046$), and qualitative data ($\chi^2_3=9.40$, $N=587$, $P=.02$), with those who completed the feedback being more experienced. An independent samples 2-tailed t test revealed a significant difference in the age variable for completers compared with the noncompleters, with the completion group being older, for the quantitative completers ($t_{585}=3.38$; $P=.001$), the qualitative completers ($t_{585}=3.31$; $P=.001$), and the goal assessment completers ($t_{585}=2.25$; $P=.02$).

^cTAFE: technical and further education.

Quantitative Feedback

Overall, the participants demonstrated a high level of agreement on the positive impact of Men in Mind (Figure 1) across the following items (combined group means): (1) improved clinical practice because of Men in Mind (mean 6.40, SD 0.92), (2) their likelihood of recommending the program (mean 6.63, SD 0.78), (3) feeling more equipped to work with male clients (mean 6.25, SD 0.96), and (4) increased desire to work with more men in therapy (mean 6.21, SD 0.99). These 4 posttraining feedback

items (maximum score of 7) showed notable stability between the items and between the groups. For the last item, (5) being better able to retain male clients, the scores were lower (mean 5.18, SD 1.30), although they still demonstrated a moderate level of agreement and remained stable at the 12-week follow-up. There was a slight drop in the mean score for the improvement item at follow-up (mean 5.64, SD 1.13). There were no significant differences between the intervention and waitlist control groups, except for item 1 after the intervention ($t_{393}=2.04$, $P=.04$).

Figure 1. Five-item quantitative feedback of practitioners in the Men in Mind group and the waitlist control groups after the intervention and the Men in Mind group at follow-up.

Qualitative Feedback

Best Elements of Men in Mind

The most highly favored element of Men in Mind, among the 392 respondents, concerned the 40 video depictions (Figure 2) of the 4 male clients' presentation and progress in therapy, alongside demonstration of "skills in action" to complement written content (Table 3). Participants' appreciated the practical

"examples of how to vocalise some of these important questions and conversations with clients in new ways," coupled with informative comparisons between a "typical and then alternative strategy for working with the client" and the diversity of presenting issues and challenges depicted using the case studies: "seeing the four different role plays and the outcomes from them has given me the tools and information to work with client's that present with any issue."

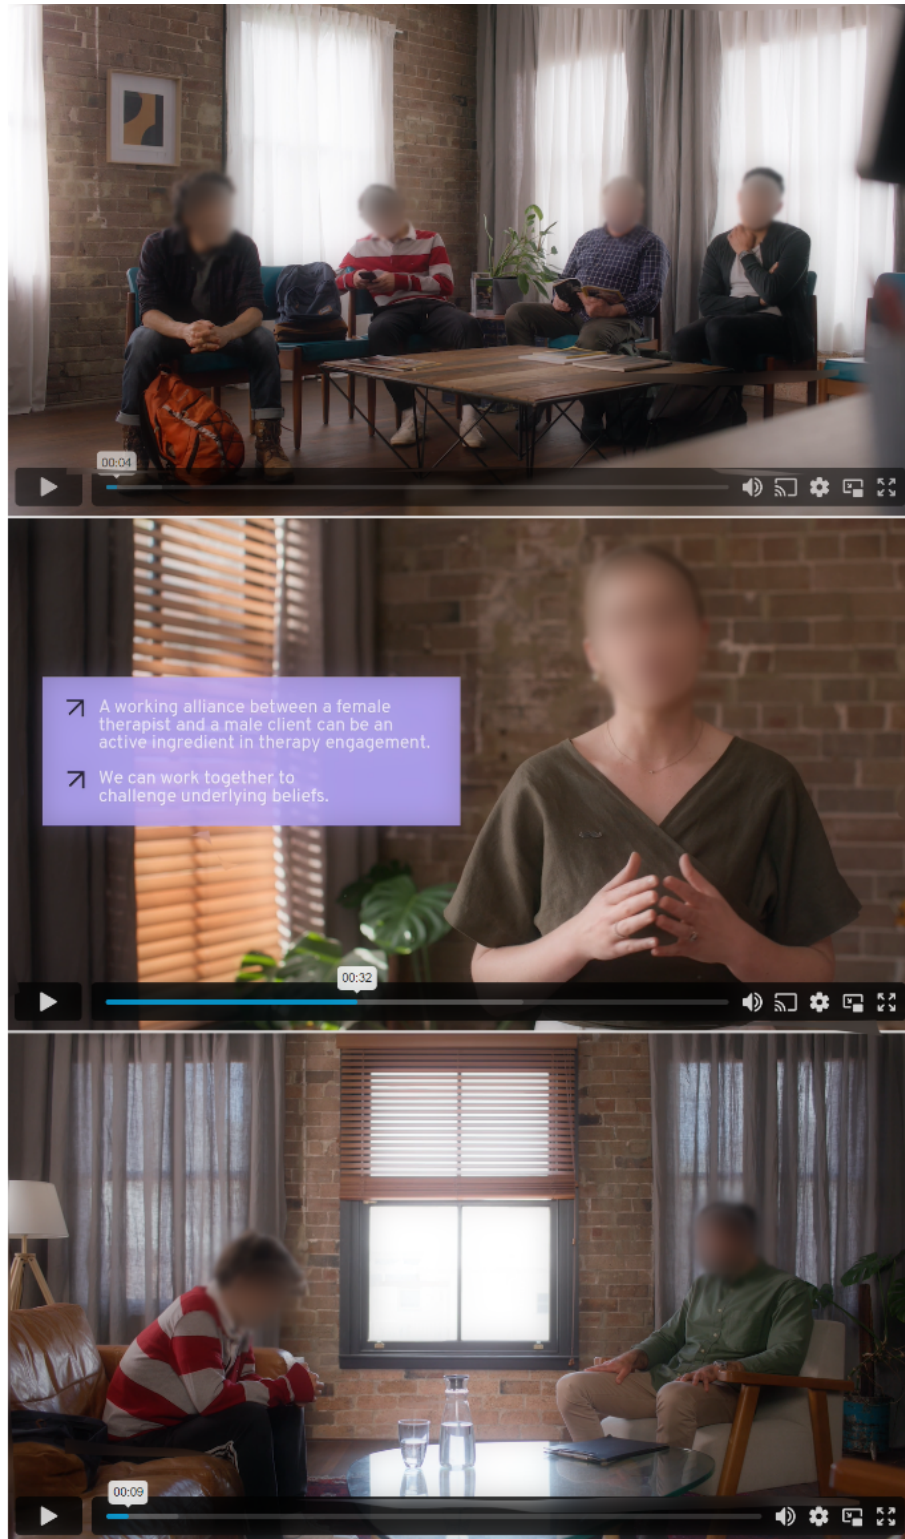

Figure 2. Depictions of the video content included throughout Men in Mind.

Table 3. The thematic analysis map of participants' responses to "What is the best thing about the training program for you."

Group	Responses, n (%) ^a
Facilitated demonstrations and video content	
Role-play videos of skills in action	146 (37.2)
Diverse client video examples	38 (9.7)
Better equipped to engage and respond to men	
Improved insight into therapy with men	76 (19.4)
Better understanding of masculinity and gender (in general)	78 (19.9)
Better equipped to engage men	25 (6.4)
Male suicidality content	17 (4.3)
Male depression content (eg, MDRS ^b)	13 (3.3)
Content filled a gap	
Evidence-based and expert-delivered content	67 (17.1)
Relatable and relevant content	41 (10.5)
Practical skills	34 (8.7)
Validated existing learning	15 (3.8)
Engaging learning experience	
Worksheets and toolkit exercises	58 (14.8)
Engaging presentation and platform	58 (14.8)
Simple to work through	51 (13)
Prompted reflection and practice	27 (6.9)
Self-paced	17 (4.3)
Variety of learning formats	12 (3.1)

^aPercentage represents the percentage of participants who responded to the qualitative items (n=392) rather than the full RCT sample (N=587).

^bMDRS: Male Depression Risk Scale.

Depictions of the Video Content in Men in Mind

The next category encompassed participants' reflections on the apparent outcome of the training, in which many felt better equipped to engage and respond to men in therapy. A general sense of improved insight into the "male experience of therapy" by feeling better equipped to apply a "gender lens" was noted here. In particular, participants appreciated education regarding "strategies that are specifically [targeted] at men rather than generic counselling practices" and content that guided them on leveraging their gender to assist male clients. Practitioners (both men and women) also valued learning about the ways in which their own gender could be leveraged and positioned to assist male clients: "Deeper reflection on own gender – biases, gendered thinking, own experiences of masculinity growing up."

The responses next suggested Men in Mind addressed a previously unmet need and filled a content gap. This included participants valuing the evidence-based nature of the content, alongside the provision of supplementary research to allow participants to expand on their learning: "links to the research articles—my male clients love it when I refer to or send them research." Specifically, information on male depression screening, including how to use the Male Depression Risk Scale,

was mentioned by many researchers [35]. Participants valued the "practical strategies" taught in Men in Mind, including "examples of what language to use and how to implement the theories in sessions," which facilitated implementation: "I began to use this training in my practice immediately."

Finally, the participants appreciated the engaging learning experiences provided throughout Men in Mind. The most highly favored aspects of the learning experience included the worksheet exercises ("the resource pack at the end was perfect"); alongside the presentation of the training content, which was described as "very aesthetic and engaging." Furthermore, the training was described as simple to work through, with content that progressed logically ("logical flow from theory to assessment to engagement to intervention") at an accessible pace that allowed completion "in [their] own time."

Suggested Improvements to Men in Mind

Regarding improvements to Men in Mind, while the most commonly occurring code (93 participants) reflected praise of the program and a lack of areas for improvement (eg, "nothing—this was one of the best, most clearly informative and practically useful courses I have undertaken"), the 392 respondents to this item nonetheless suggested numerous areas for improvement (Table 4).

Table 4. The thematic analysis map of participants' improvement responses.

Group	Responses, n (%) ^a
General content improvements	
Greater quantity of content	62 (15.8)
Greater depth of content	22 (5.6)
Course format	
Unrealistic time allocation	49 (12.5)
Note-taking improvements	34 (8.7)
Improvements to learning aids (eg, worksheets)	63 (16.1)
Technological issues (eg, saving progress and downloading files)	17 (4.3)
Video improvements	
More (or longer, more diverse) video content	42 (10.7)
Staged video or acting improvements	11 (2.8)
Improvements in therapeutic techniques of practitioners in videos	6 (1.5)
Subtitles on videos	6 (1.5)
Unscripted (or more natural) videos to analyze	6 (1.5)
Access and follow-up	
Unlimited or longer access to the training (after completion)	18 (4.6)
Group learning or supervision; question and answer with facilitators	15 (3.8)
Follow-up platform with emerging evidence or resources	13 (3.3)
Ensure course is recognized by more organizations	8 (2)
Content population focus	
More content on specific presentations (eg, alcohol or substance use, anxiety, PTSD ^b , ASD ^c , relationships, and IPV ^d)	15 (3.8)
More content on gender and sexual diversity	9 (2.3)
Specific modules for different age groups	8 (1.3)
More cultural diversity	5 (1.3)
More content on suicidality	6 (1.5)
Content on male-specific presentations of resistance	2 (0.5)

^aPercentage represents the percentage of participants who responded to the qualitative items (n=392) rather than the full RCT sample (N=587).

^bPTSD: posttraumatic stress disorder.

^cASD: autism spectrum disorder.

^dIPV: intimate partner violence.

The first subtheme regarding content improvements was related to suggested additional content regarding subgroups or presentations among men. Most commonly this not only referred to the need for more sexual and gender diversity (eg, "More focus on varied gender and sexual identities, e.g., transgender males, gay, etc.") but also pertained to men of varying age groups (eg, "more content of and for adolescent males," "additional age ranges") and cultures ("Further emphasis on unique issues faced by men of colour..."). In addition, participants noted the potential for further content focused on a range of presenting issues among men, including suicidal thoughts or behaviors (eg, "I think it would be good to spend more time on suicide intervention, as Module 5 really could have been separated into two modules") and men's perpetration of abuse or interpersonal violence (eg, "didn't really touch on any kind of abuse, violence, or offending behaviours which

might be extremely difficult to respond to without prior training").

Furthermore, common across responses was a suggestion to include additional content in specific forms (eg, "more visual and lecture-based content," "more role plays and scripted techniques") or provide greater depth regarding what some participants perceived to be a relatively simplistic depiction of men and masculinity: "The information felt a bit cliché to a particular stereotype of a very blokey Australian man and some of the tips and interventions then also felt they served kind of to reinforce this stereotype... I see quite a lot of men in my practice and some of the issues/themes only seemed relevant to a very small subset of these: very closed off, sporty, blokey, angry (for which they were extremely helpful by the way)."

Suggestions for improving the videos were also common across responses. This primarily concerned the suggestion for more videos, along with longer (eg, “Even more video examples, with different options or what is helpful to say or not say given the diverse clients presented”) or more varied scenes for participants to reflect on; “The videos/scenarios could represent more varied situations, not just a therapeutic setting. Such as support worker roles, social workers etc.” Some suggestions were also offered to improve the authenticity of the videos, “I’m just never a huge fan of staged session videos,” alongside accessibility improvements; “I think for accessibility purposes, the videos could include captions and also the feature to be sped up.”

Subsequently, improvements were made regarding the overall presentation and learning experience offered to the participants. This primarily concerned improvements regarding participants’ capacity to consolidate and retain their learning (eg, “Some forced recall might help me to integrate the knowledge,” “More quizzes and ways to check understanding and application of the content along the way”). Some participants noted the need for more time to engage with the training in greater depth (eg, “Higher allocation of time. It took me about twice as long as estimated”) with others suggesting improvements regarding the somewhat “clunky” in-built note-taking feature (“I think it would be great to leave space in the modules themselves for people to write responses”). A small number of participants mentioned issues surrounding the saving of their progress or the capacity to download provided readings or learning aids.

Finally, suggested improvements concerned the desire for opportunities to engage with the training material in more depth

by discussing learnings and practicing skills with other practitioners (eg, “It would be awesome if there was an interactive component eg. Webinars and activities with other people, not just with recorded content and papers”). Participants suggested there would be value in additional “follow-up” or “refresher” training to aid in implementation of learning over time.

Confidence Following the Completion of Men in Mind

Finally, while it was common across responses for the 392 respondents to report universally improved confidence when working with men (67 participants; eg, “all men,” “most men actually”) participants reported improved confidence working with a variety of subgroups of men in therapy following the training. The most common category referred to improved confidence in working with men experiencing difficulty with emotional literacy and expression (eg, “Men who fit the stereotypical profile that limits emotional expression and authentic communication”), where participants often reflected a sense of improved confidence to unlock the internal world of “emotionally numb” men. Encouragingly, participants also reported improved confidence when “working with men in high risk/crisis situations,” particularly being more aware of signs of suicidality that “might not be expressed verbally by the client.” Improved confidence to respond to men’s reactivity, particularly anger, was also common (eg, “men who others see as having ‘anger issues’”), along with working with men with depression or anxiety (eg, “men who may not show the typical signs of depression”). Other specific subgroups of men were also mentioned ([Table 5](#)).

Table 5. The thematic analysis map of participants' confidence responses.

Group	Responses, n (%) ^a
Men with emotional difficulties or mental health issues	
Men experiencing difficulty with emotional communication or regulation	190 (48.5)
Men experiencing suicidality	107 (27.3)
Angry men, men with difficulty with aggression	43 (11)
Men with depression or anxiety	21 (5.4)
Other specific types of men	
Men with traditional (masculine) attitudes; gender role strain	32 (8.2)
Sexual minority men	31 (7.9)
Men from different cultural backgrounds	5 (1.3)
Incarcerated or violent men	5 (1.3)
Men of different ages	
Old or older men	29 (7.4)
Adolescent or young men	27 (6.9)
Middle-aged men or fathers	16 (4.1)
Men across the life span	2 (0.5)
Resistant or unmotivated men	
Detached, indifferent, ambivalent, or unmotivated men	17 (4.3)
Resistant, ambivalent, or reluctant men	15 (3.8)
Men impacted by significant life events	
Men struggling with role transitions (eg, job, relationship, and schooling)	12 (3.1)
Men experiencing trauma or abuse	3 (0.8)
Men experiencing chronic illness or physical losses	2 (0.5)

^aPercentage represents the percentage of participants who responded to the qualitative items (n=392) rather than the full RCT sample (N=587).

Goal Assessment Data

Participants in the Men in Mind group (n=204) provided up to 3 goals at T2, resulting in a total of 603 goal responses. Of these 603 individual goal responses, a further 453 were matched with self-reported goal achievement scores at follow-up. [Figure 3](#) presents the 5 goal categories, frequencies, and the corresponding achievement ratings. The 5 goal categories related to goals aimed to *leverage masculinities in therapy* (exploring masculinity and the impacts of gender socialization), *improve engagement or retention* (specific male-oriented engagement strategies), *work better with men's emotions* (strategies to assist men experiencing difficulty identifying or articulating their

emotions), and *consolidate learning* (goals relating to retaining knowledge from the training). [Multimedia Appendix 2](#) provides a more detailed description of these categories along with participant examples for each. Goals coded as belonging to the *improve engagement or retention* category were achieved at a higher rate than any of the other 4 categories. Similar, but slightly lower, achievement scores were noted for the *leverage masculinities in therapy* category. In contrast, goals coded under the *consolidate learning* category had the lowest achievement rates. Overall, 85.4% (387/453) of the goals with achievement ratings were rated as "achieved" or "making progress" at the 12-week follow-up.

Figure 3. Achievement percentages for each of the 5 goal categories (N=603), as follows: A) Leverage masculinities (n=162), B) Improve engagement or retention (n=153), C) Men's emotions (n=60), D) Men's suicidality or depression (n=118), and E) Consolidate learning (n=110).

Discussion

Principal Findings

This study investigated participants' experiences of a web-based training program, Men in Mind, in depth, addressing previous gaps in intervention evaluation and collating data to assist in real-world scaling and implementation of this intervention. This study also aligns with international recognition of the value of mental health practitioner development in the psychology of men and masculinities to aid their practice and provides a concrete avenue to achieve this end [27]. Findings across the qualitative feedback items highlighted the current strengths of Men in Mind, particularly in terms of the value of video vignettes of skills in action, improved insight into the connections between traditional masculinity and the therapy environment, and the engaging learning experience provided. Suggested improvements largely reflect the need to expand the training material with more inclusivity, diversity, and equity-tailored content, along with necessary improvements to the provided learning aids and novel content areas to include in future iterations. Encouragingly, participants reported improved confidence in assisting men struggling with emotional communication and suicidal men. Complementing participants' qualitative data, results from the quantitative feedback items

showed consistency across domains of practitioner self-efficacy as having improved after Men in Mind, and importantly, that practitioners felt improvements in engaging and retaining men in their practice. Altogether, these findings indicate necessary improvements before the scaling of Men in Mind, while also informing viable components of practitioner e-learning interventions focused on men's health service engagement.

Qualitative Feedback

Successes of Men in Mind

According to participants, the 40 professionally produced role-play videos were the most enjoyable aspect of the program. This reflects the value of providing guided demonstrations, particularly when video content is segmented into clearly defined sections and key takeaways are highlighted via accompanying text [36]. The desire among therapist learners for observational learning has also been documented in prior research [37]. Coupled with the sourcing of topic areas for the videos directly from past evidence of practitioner challenges working with men [30], these factors likely contributed to the authenticity and resonance of the video content in Men in Mind. This was confirmed by broad feedback that Men in Mind was an engaging learning experience, reflecting the efforts that went into the program to incorporate best practice learning design

methods [38-40]. For example, participants' endorsement of the value of providing multiple learning tools (ie, videos, supplementary reading material) accords with prior research documenting the diversity in adult learning styles and the capacity of e-learning platforms to appropriately cater to this [41]. Finally, and perhaps most importantly, practitioners valued the improved insight into therapy with men provided by the Men in Mind intervention. This substantiates the identified gap in training for mental health practitioners, particularly regarding the sensitization of therapy for help-seeking men [6].

Suggested Improvements to Men in Mind

A key recommendation for improving Men in Mind was feedback to increase the amount and depth of the current content, integrating more targeted content for specific subgroups of men, as well as men who operate outside of traditional masculine norms. This is an important critique, as there is growing recognition of the essential role of intersectional approaches to men's health promotion [42]. Diversity in the intersections of gender and other factors (eg, culture, socioeconomic status, age, and sexuality) in influencing men's mental health outcomes (eg, suicide rates) was acknowledged throughout the training. However, specific recommendations for working with demographic subgroups of men were beyond the scope of this iteration of Men in Mind. Regarding intersectionality and men's mental health, there is a lack of evidence-based approaches to educate practitioners in balancing the recognition of individual diversity while also targeting therapeutic engagement strategies based on clients' social group membership without re-entrenching stereotypes. It is important to contextualize the unique dichotomy arising here, whereby men's mental health is situated as a "specialized" area of practice yet relates to clinical considerations for a vast and diverse group (almost half of the global population). Future iterations of Men in Mind will aim to build on the current content to explore practice adaptation recommendations when working with particular subgroups of men, as informed by lived experience and expert consensus (eg, First Nations men and gender and sexual minority men). Moreover, while some practitioners suggested the need for more specific content, others referred to the length of the course as a barrier to completion, highlighting a point of tension. Providing a course that is sufficiently generalist to capture the interests and needs of many practitioners will ultimately fall short of practitioners looking for more specialist information. However, a significant part of the course length feedback was related to the time estimates provided for the program being referenced as inaccurate and potentially unrealistic. Therefore, more realistic time estimates at the start of the course could ease the tension between these 2 contradicting areas of feedback. Providing continued or unlimited access to the modules (after the 6-week period) was also pointed out by practitioners as a potential solution. Regardless, the feedback emphasized the need for learning materials in this area to expand from the baseline understanding provided by Men in Mind to specialist content focusing on male priority subgroups of interest.

Confidence to Work With Different Groups of Men

Participants most often reported improved confidence to assist men having trouble identifying or communicating their

emotional experiences. This finding reinforces the common challenge experienced by practitioners in delivering therapy to male clients who ostensibly lack the emotional literacy deemed a requisite for engagement [30,43-46]. The emotional restraints socialized by traditional masculinities have been considered a critical factor in therapy being deemed the "antithesis of masculinity" [47]. That participants reported improved confidence in this domain reflects the value of emphasizing the onus on practitioners to appropriately sensitize their therapy for men, taking on available recommendations for effective strategies to improve men's emotional literacy [48]. Participants also commonly reported improved confidence to respond to men's anger. These findings potentially reflect Men in Mind's predominant focus on traditionally masculine identifying men, for whom difficulty with emotional expressions of distress via anger can be common [49]. While this was intentional given evidence substantiating traditional masculine norms as barriers to mental health service engagement [50-52], it is important for future iterations of Men in Mind to further emphasize inclusivity and plurality in masculinities to assign a diversity of agency in response to wide-ranging structures and masculine norms [53,54]. In addition, considering the evidence of high rates of mental health service contact before suicide in men [55], participants also reported improved confidence in assisting men experiencing suicidality. This is particularly reassuring given previous evidence that many practitioners feel less competent to work with suicidal men (relative to women [56]). As many practitioners grapple with a small window of opportunity to work with suicidal men, compromised due to delayed presentation to health services [57], improving practitioner confidence to capitalize on men's engagement is essential.

Participant Goals and Achievement Scores

Likely reflecting the novelty of applying a "gender lens" to their therapy engagement strategies, the most commonly observed category of participants' goals following completing Men in Mind was to leverage masculinity to engage their male clients. This is noteworthy given the extent to which traditional masculinity has often been pathologized in existing modes of therapeutic engagement as a unitary construct categorically incompatible with psychotherapy [18]. The appetite among participants to implement their learning in this domain, evident in their goals to leverage masculinity, is encouraging in light of long-standing recommendations for mental health systems and services to adapt to men rather than vice versa [58]. Participants also consistently reported goals to improve their engagement strategies, likely reflecting the vast range of strategies offered to engage men, derived from prior research [31]. In addition, goals to consolidate learning likely reflected the broad array of supplementary reading provided in the intervention, suggesting an appetite among participants to broaden their familiarity with men's mental health literature.

In terms of goal achievement ratings overall, it was most common for participants to report achieving goals related to improving their engagement and retention strategies. Perhaps these goals were more readily achieved because of the highly practical nature of the training material: participants are presented with a logical framework of engagement strategies to facilitate seamless implementation. Similarly, the practical

strategies offered to engage male clients in discussions around the potential intersection between traditional masculine norm adherence and their mental health likely facilitated participants' achievement of their goals around leveraging masculinity. Notably, the goals made regarding consolidating learnings from the course had the lowest rates of achievement. While the other 4 goal categories centered around improvements for working with men in therapy, the learning consolidation category focused on improving and retaining knowledge from the course. This could signify that it was challenging for participants to retain theory-based knowledge around the course, a factor inhibiting the integration of these frames into practice. This aligns with the qualitative feedback regarding the best elements of Men in Mind where practitioners commonly highlighted the role-plays and practical demonstration of skills as the most compelling part of the program.

Implications

Previous findings in the field of e-learning suggest that centering on learner experience in the development of e-learning interventions can be a critical component of engagement [59]. In the case of practitioner training for engaging and responding effectively to help-seeking men, the uptake of training material was critical in light of the lack of available avenues to address established disconnects between practitioner training and men's mental health service engagement. The positive user experience feedback results found in this study, when considered alongside the high level of engagement and improvements in practitioners' clinical competencies [22], reinforce the critical value of learning and user experience design input alongside extensive user testing with the practitioner group when developing e-learning interventions. This is particularly relevant when considering the rollout and implementation of e-learning programs on a broader scale, with the efficacy of Men in Mind supporting claims that having this design input and user testing can be essential to ensuring user desirability and long-term integration into clinical practice [59]. The findings also suggest the value of adopting learnings from the Men in Mind model to develop more widespread practitioner training in other areas of neglected focus for boys and men's mental health promotion, particularly when masculine norm adherence is thought to play a role in the exacerbation of poor outcomes. Examples include engaging boys and men in therapy to assist recovery from childhood sexual abuse, where often vast delays in help-seeking can arguably increase the necessity for practitioners to effectively capitalize on early windows to establish therapeutic alliance [60].

Three key areas of interest could be improved in future iterations of the program. First, we aimed to improve the expectation setting at the start of the program, specifically with regard to more realistic time estimates for completion, and how the program should be contextualized (ie, as a foundational course for working with men generally, before pursuing further information regarding the range of subgroups within men). This is directly in response to feedback regarding improving content depth and course length, where most participants were happy to complete a longer course but were unaware of what they

perceived as an unrealistic time estimate. Second, we aim to improve access to the program by improving the depth and variety of the take-home materials practitioners who are given after completion of the program. Accessibility is a critical component of web-based learning, and extended access to course content would allow for further repeated use of the content, reinforcement of information and practice, and the ongoing implementation support necessary to ensure implementation fidelity [61]. Finally, to assist participants in their shared learning and implementation of the Men in Mind content, there is likely value in the establishment of a community of practice to facilitate group supervision and ultimately contribute to a gender-sensitive practitioner workforce more broadly.

Limitations and Future Directions

The limitations of this study include its reliance on participants' self-reports and the use of novel questionnaire items. This limits the extent to which we can infer tangible changes in practitioner behavior; however, our approach was intentional, given the qualitative design and aims to obtain an in-depth understanding of participants' experiences with Men in Mind. Therefore, the reliance on self-report data could also be considered a strength of the study, in that practitioner self-report is an effective way to tap into the depth of user experiences. There was also a significant difference in age and experience for participants who provided feedback and goal assessment data compared with our original RCT sample. This may imply that the results of this study are not representative of younger, less-experienced practitioners, which is a limitation considering that younger and less-experienced practitioners might be most amenable to behavior change via e-learning interventions. An obvious gap also concerns the extent to which improvements to practitioner confidence and their achievement of learning goals translates to improvements in outcomes among male clients (eg, improved engagement in care). Our demonstration of the efficacy of Men in Mind via RCT [22], coupled with qualitative evidence from this study of participants' favorable experiences with the intervention, solidifies the testing of client outcomes as a viable next step. Indeed, consultation with male clients [9] has confirmed that health services and practitioners not responding appropriately to the needs of male clients is a critical problem in this field. Ensuring that Men in Mind is successfully addressing this problem, from the perspective of the male clients themselves, is essential.

Conclusions

In this study, we have reported in-depth experiences with the Men in Mind training intervention, including the best elements and those in need of improvement. Participants reported improved confidence in engaging a range of help-seeking men and encouragingly reported clear goals for implementing their learning into practice. Our findings substantiate the need for effective knowledge translation efforts that bridge the gap between evidence and practice. When focusing on mental health service delivery, such approaches do due justice to the complex and often systemic issues that can stymie mental health service engagement and outcomes.

Acknowledgments

The creation and development of Men in Mind was funded by the global men's health charity Movember, while its evaluation (the randomized controlled trial) was fully funded by the Australian Government's Medical Research Future Fund, Million Minds Mental Health Research Mission.

Data Availability

The data sets generated during this study are not publicly available due to ethical restrictions, but data are available from the corresponding author upon reasonable request and with ethics approval for secondary analyses.

Authors' Contributions

ZES contributed to conceptualization, funding acquisition, investigation, methodology, writing the original draft, and reviewing and editing the manuscript. RB contributed to formal analysis, investigation, methodology, visualization, writing the original draft, and reviewing and editing the manuscript. MJW contributed to formal analysis, investigation, methodology, visualization, writing the original draft, and reviewing and editing the manuscript. JF, JLO, and JO contributed to validation and reviewing and editing the manuscript. SR contributed to supervision and reviewing and editing the manuscript.

Conflicts of Interest

The lead author, ZES, was partially employed by Movember, who funded the creation and development of Men in Mind. However, the evaluation research of the program was fully funded by the Australian Government's Medical Research Future Fund, Million Minds Mental Health Research Mission.

Abstract

Background: Patients' perspectives and social contexts are critical for prevention of hospital readmissions; however, neither is routinely assessed using the traditional history and physical (H&P) examination nor commonly documented in the electronic health record (EHR). The H&P 360 is a revised H&P template that integrates routine assessment of patient perspectives and goals, mental health, and an expanded social history (behavioral health, social support, living environment and resources, function). Although the H&P 360 has shown promise in increasing psychosocial documentation in focused teaching contexts, its uptake and impact in routine clinical settings are unknown.

Objective: The aim of this study was to assess the feasibility, acceptability, and impact on care planning of implementing an inpatient H&P 360 template in the EHR for use by fourth-year medical students.

Methods: A mixed methods study design was used. Fourth-year medical students on internal medicine subinternship (subI) services were given a brief training on the H&P 360 and access to EHR-based H&P 360 templates. Students not working in the intensive care unit (ICU) were asked to use the templates at least once per call cycle, whereas use by ICU students was elective. An EHR query was used to identify all H&P 360 and traditional H&P admission notes authored by non-ICU students at University of Chicago (UC) Medicine. Of these notes, all H&P 360 notes and a sample of traditional H&P notes were reviewed by two researchers for the presence of H&P 360 domains and impact on patient care. A postcourse survey was administered to query all students for their perspectives on the H&P 360.

Results: Of the 13 non-ICU subIs at UC Medicine, 6 (46%) used the H&P 360 templates at least once, which accounted for 14%-92% of their authored admission notes (median 56%). Content analysis was performed with 45 H&P 360 notes and 54 traditional H&P notes. Psychosocial documentation across all H&P 360 domains (patient perspectives and goals, mental health, expanded social history elements) was more common in H&P 360 compared with traditional notes. Related to impact on patient care, H&P 360 notes more commonly identified needs (20% H&P 360; 9% H&P) and described interdisciplinary coordination (78% H&P 360; 41% H&P). Of the 11 subIs completing surveys, the vast majority (n=10, 91%) felt the H&P 360 helped them understand patient goals and improved the patient-provider relationship. Most students (n=8, 73%) felt the H&P 360 took an appropriate amount of time.

Conclusions: Students who applied the H&P 360 using templated notes in the EHR found it feasible and helpful. These students wrote notes reflecting enhanced assessment of goals and perspectives for patient-engaged care and contextual factors important to preventing rehospitalization. Reasons some students did not use the templated H&P 360 should be examined in future studies. Uptake may be enhanced through earlier and repeated exposure and greater engagement by residents and attendings. Larger-scale implementation studies can help further elucidate the complexities of implementing nonbiomedical information within EHRs.

Introduction

The posthospitalization period is a particularly vulnerable time for patients as they may need to adjust to new or evolving diagnoses, modify medication regimens, navigate new mobility limitations, and implement new lifestyle changes. To facilitate care transitions, reinforce chronic disease management, and prevent rehospitalization, it is essential to understand patient perspectives as well as patients' unique social context. The presence of unmet social needs has been strongly linked with inferior health outcomes [1] as well as a higher risk of rehospitalization [2-4]. Despite this connection, patient perspectives and social context are not systematically assessed with the traditional history and physical (H&P) examination. While the World Health Organization supports inclusion of social, economic, and political aspects of health in the training of medical students globally [5], and the Institute of Medicine has recommended collection of social determinants of health in the electronic health record (EHR) [6], psychosocial documentation remains limited. The fundamental history-taking framework through which physicians approach diagnosis and management has changed very little over the past 50 years. Physician documentation still focuses more on biomedical domains rather than on the psychosocial context [7,8]. Consequently, graduating medical students and residents are not prepared to ask critical questions related to the psychosocial context [9].

The H&P 360 is a revised template for conducting an H&P that applies a 7-domain biopsychosocial framework, integrating assessment of patient perspectives and goals, mental health, and an expanded social history (behavioral health, social support, living environment and resources, and functional status) with collection of biomedical information (see [Multimedia Appendix 1](#)) [10]. This template has shown promise in increasing psychosocial documentation in standardized evaluation settings, including a one-time-point use in an inpatient subinternship (subI) [10] and an Objective Structured Clinical Examination exercise during which third- and fourth-year medical students were randomized to use of the H&P 360 or the standard H&P [11]. However, potential uptake and impact with more routine use of the H&P 360 in usual clinical teaching settings remain unknown.

Given the ubiquity and ease of developing templated notes to facilitate documentation within the EHR among practicing clinicians, residents, and students in many countries, creation of a templated note guiding students through the H&P 360 domains could be one approach to promote uptake. EHR-based template studies to date have focused on inpatient resident and faculty subjects with primary endpoints including note quality, quality of care, and time to note completion [12-14]. However, few studies have evaluated the use of templates to intentionally improve documentation related to patient perspectives and social

and behavioral determinants of health [15,16]; most such initiatives have centered on interprofessional team members rather than on promoting psychosocial documentation within a physician's scope of work [17,18].

The objective of this study was to assess the feasibility, acceptability, and impact on care planning of implementing an inpatient H&P 360 template in the EHR for use by fourth-year medical students during their internal medicine subI.

Methods

Study Design

This implementation study included fourth-year medical students (MS4) completing their internal medicine inpatient subI at the University of Chicago (UC) during the 2020-2021 academic year. The evaluation plan was based on the Kirkpatrick model (Reaction, Learning, Behavior, Organizational Performance), building on prior work with standardized patients ("can do") to use in usual clinical settings ("does") [19]. Student reaction and learning were assessed through a postintervention survey. Behavioral change and organizational performance were assessed by measuring utilization of the EHR template and through content analysis of student notes.

Ethics Approval

The UC Institutional Review Board granted the student survey an exemption under quality improvement status. The UC Institutional Review Board (IRB19-1800; IRB21-0571) granted exemption approval for the review and qualitative analysis of student clinical notes. A waiver of informed consent was granted due to the retrospective design and patients and students being unavailable for consent.

EHR Template Development

A team composed of 2 general internists (one of whom was the course director for the internal medicine subI) and 2 hospital medicine physicians (one of whom was also a bioinformatics fellow) adapted the H&P 360 for use with inpatients and created the EHR templates [11]. The full H&P 360 template included components of a traditional H&P with expanded sections specific to the H&P 360 domains (see [Multimedia Appendix 2](#)). Under history of present illness, the template included prompts for: (1) patient understanding of health, (2) self-assessed control, (3) patient-identified strengths, (4) patient-identified barriers, (5) patient priorities and goals, and (6) psychosocial problems and concerns. Under social history, the template included prompts for documentation under the following domains: (1) behavioral health, (2) social support, (3) living environment and resources, and (4) function. Finally, under the assessment and plan, in addition to the typical headings prompting documentation of evaluation and management of acute and chronic biomedical problems, there was an added heading for interdisciplinary resource needs.

The team engaged a group of 4 fourth-year medical students participating in internal medicine subIs to pilot various iterations of the template to improve usability. Based on feedback from the students, who desired maximum flexibility with documentation, the decision was made to allow free-text responses under each domain rather than using drop-down response options. In addition, while some students preferred to use a full de novo H&P 360 template, others preferred to insert unique H&P 360 elements into other existing templates. As a result, two templates were created to accommodate flexibility in documentation: one that could be used as a complete H&P and another that allowed integration of only the unique H&P 360 domains into any H&P template or progress note. Students also suggested that we create a visual reminder for the H&P 360 domains that could be referenced during history-taking; based on this feedback, we created and offered cards for student ID badges listing the H&P 360 domains and relevant content areas.

Participants

UC Pritzker School of Medicine fourth-year medical students participate in a 4-week inpatient subI of their choosing. SubIs in internal medicine choose to rotate in general internal medicine, clinical cardiology, or the medical intensive care unit (ICU) (all at UC) or at an offsite community hospital teaching affiliate. SubIs are on call every 3-4 days and may admit up to three patients per call day.

Between August 2020 and April 2021, 24 internal medicine subIs were enrolled in the H&P 360 educational program. Prior to their subI month, students received an orientation email from the course director (author IJA) describing the H&P 360 model and providing the note templates, smart phrases for pulling up the templates, and use expectations. The two H&P 360 templates were shared with the students via the EHR. One could be used as a full H&P note template ([Multimedia Appendix 2](#)). The second template contained only the elements unique to the H&P 360 and excerpts could be merged into any traditional H&P template ([Multimedia Appendix 3](#)). SubIs were asked to use one of these H&P 360 templates in at least one admitting note per call cycle. Students also received cards for their ID badge listing the H&P 360 domains to reference during the patient encounter. The on-service attending physicians were informed of the expectations via email and provided with informational materials about the H&P 360 and rationale for use. During a monthly subI noon conference with author IJA, students were invited to informally discuss their experience using the H&P 360 template.

Utilization of the H&P 360 Template

H&P 360 template usage was measured to understand its feasibility and acceptability. Research coordinators conducted an EHR query to retrospectively identify all admission notes written by students during their subI in general internal medicine or cardiology at UC during the 2020-2021 academic year (n=13 students). Notes written by subIs in the ICU were excluded because of expected admission note differences in this setting and competing priorities for ICU patients at admission. SubIs at the affiliate health care system conducted documentation in a separate, inaccessible EHR, thereby precluding collection of

their notes. The research coordinators identified all subI admission notes utilizing an H&P 360 template; all other admission notes were labeled as utilizing traditional (ie, any non-H&P 360) templates. The proportion of all notes written using the H&P 360 template was calculated per student and in total.

Content Analysis

Content analysis was performed to assess the impact of the H&P 360 template. For purposes of qualitative comparison of note content, research coordinators collected and deidentified all of the H&P 360 notes and a sample of the traditional notes. The sample of traditional notes was drawn by attempting relatively balanced representation across students. Specifically, each student could contribute no more than 5 traditional notes to the total sample; for those with more than 5 traditional notes, a random subsample was selected for inclusion.

The content analysis team was composed of three internists involved in medical education (JWT, VGP, IJA) and one medical student (EYR). Throughout the process of analysis, team members discussed their preconceived notions and biases from their roles in education and patient care. The team began with a set of a priori content domains based on the H&P 360 template (eg, mental health, behavioral health, social support). The team members independently reviewed a set of notes—four from the H&P 360 group and four from the traditional group—to clarify the definition of the content domains, add additional de novo content domains as needed, and improve consistency between coders. Subsequently, for each of the notes, two team members extracted relevant text and entered it into a Research Electronic Data Capture (REDCap) template under the appropriate content domain. Discrepancies in coding were reviewed and resolved through email correspondence. The text from each content domain was then aggregated into a document and reviewed by two members of the team to identify themes within each content domain and to assess whether there were qualitative differences in the content between the H&P 360 and traditional templated notes. Each content domain was discussed at the weekly group video meeting. The number of notes categorized under each content domain was counted for the H&P 360 and traditional templated groups.

Student Survey

A student survey was used to assess student perceptions of feasibility, acceptability, and impact of the H&P 360. Survey items assessing student perception of the H&P 360 were developed in collaboration with the American Medical Association H&P 360 Implementation Grantee team. The survey consisted of 14 5-point Likert-scale questions assessing feasibility, perceived impact on patient care, and perceived impact on educational experience. Short-response items elicited useful and challenging aspects of the H&P 360 and student recommendations ([Multimedia Appendix 4](#)).

At the conclusion of the educational program, all subIs (n=24 students) were asked to complete the survey anonymously. Percentages of students who selected 5 (strongly agree) or 4 (somewhat agree) on the Likert scale were tabulated. Open-ended responses were read by two members of the

research team and common statements (defined as reported by three or more students) were identified and summarized.

Results

Utilization of the H&P 360 Template

Utilization of the H&P 360 could be directly measured among the 13 subIs rotating on the UC general medicine or cardiology services during the 2020-2021 academic year. This group authored a total of 164 admission notes in the EHR. Of all admission notes, 45 (27.4%) were written with an H&P 360 template (Multimedia Appendix 5). As mentioned above, subIs

rotating in the ICU or at the community hospital teaching affiliate were excluded from this analysis.

Of the 13 subIs, 6 (46%) students authored at least one admission note using an H&P 360 template. These H&P 360 templated notes accounted for 14%-92% of their authored admission notes (median 56%). Seven students (54%) never authored a note using the H&P 360 templates.

Content Analysis

Content analysis was performed with 45 H&P 360 notes and 54 traditional H&P notes (Table 1).

Table 1. Documentation of content domains across the history and physical (H&P) 360 and traditional H&P notes.

Content domain	H&P 360 notes (n=45), n (%)	Traditional H&P notes (n=54), n (%)
Patient perspectives and mental health		
Patient understanding of health	23 (51)	16 (30)
Patient priorities and goals	18 (40)	4 (7)
Mental health	15 (33)	8 (15)
Expanded social history		
Behavioral health (nonsubstance use)	32 (71)	23 (43)
Social support	44 (98)	28 (52)
Living environment and resources	16 (36)	10 (19)
Function	42 (93)	31 (57)
Impact on patient care		
Needs identified	9 (20)	5 (9)
Education and counseling	12 (27)	13 (24)
Interdisciplinary resource coordination	35 (78)	22 (41)

Patient Perspectives and Mental Health

Patient Perspectives

Text was coded for patient understanding of health and patient priorities or goals. Some H&P 360 notes retained and responded directly to the EHR template prompts for these elements within the patient subjective history, while others spontaneously integrated this content into other areas of the note.

While 7% (4/54) of traditional notes documented patient priorities or goals, this was documented in 40% (18/45) of H&P 360 templated notes. Qualitative differences between groups were also identified in the content coded for this domain. H&P 360 notes discussed priorities related to decreasing pain, increasing function, determining the cause of one's symptoms, wanting to improve chronic disease management, and wanting to go home.

Patient priorities and goals: Would like to make sure no underlying etiology of current a-fib [atrial fibrillation] episode. Pt [patient] reports h/o [history of] diagnosis of T2DM [type 2 diabetes mellitus] and is trying to improve w/ lifestyle modification and does not like to take medications. [H&P 360 note, Student F]

In contrast, for traditional notes, the only documented priorities or goals related to the patient wanting to leave the hospital: "She wants to go home." [Traditional note, Student N]

Patient understanding of health was documented in 51% (23/45) of H&P 360 notes and in 30% (16/54) of traditional notes. Documentation across both groups related to patient perceptions as to the cause of their symptoms or patient familiarity with their medications: "He states he has recurrent episodes of Afib [atrial fibrillation] since 2013 w/ similar symptoms (he has a watch that alerts him)." [Traditional note, Student K]

Among H&P 360 notes, some also included information from the perspective of the patient or clinician of the patient's level of understanding of their diagnoses, medications, or disease etiology.

Patient understanding of health: Pt [patient] understands the reason that she required her extensive surgery, and she has a clear understanding of the reasons for her various medications. Patient self-assessed control: Pt reports feeling like her health status is currently "out of [her] control." She states that her health is "in the lord's hands." [H&P 360 note, Student C]

Mental Health

Overall, 33% (15/45) of H&P 360 notes and 15% (8/54) of traditional notes included the mental health domain. Across both groups, there was documentation regarding psychiatric diagnoses and related treatment, anxiety, stress, substance use, or documentation that there were no relevant concerns in this domain. Qualitative differences between groups were not identified. One such example was: "...increased stress related to her brother's condition and the need to pay for his medical expenses." [Traditional note, Student G]

Expanded Social History

Behavioral Health (Nonsubstance Use)

A majority of notes in both groups contained autopopulated text related to tobacco, alcohol, and drug use. Since it was unclear whether this information was input by the author of the note or had been documented in the EHR from a prior encounter, this information was not included for the purposes of this analysis. The behavioral health domain (excluding information about tobacco, alcohol, and drug use) was present in 71% (32/45) of H&P 360 notes versus 43% (n=23/54) of traditional notes. Across both groups, text coded for behavioral health frequently documented patient adherence to medications. Physical activity and nutrition behaviors were also described across both groups. Qualitative differences in the coded text were not identified: "States takes meds regularly and doesn't miss... States his wife cooks-does not use salt. Does little physical activity like stairs." [H&P 360 note, Student D]

Social Support

Information about the patient's social network was documented in 98% (44/45) of H&P 360 notes and in 52% (28/54) of traditional notes. The social support domain included information about the patient's cohabitants, other important relationships, and presence of home health workers. Across both groups, there was also information about how the patient's social network assisted in their care. No qualitative differences were observed in the coded text: "The patient currently lives with her daughter. her medications are managed at home by her son, who is a nurse." [Traditional note, Student A]

Living Environment and Resources

Overall, 36% (16/45) of H&P 360 notes and 19% (10/54) of traditional notes documented information about patient's access to housing, transportation, food, insurance, or financial resources. The coded content was qualitatively similar across both groups.

Previously living with friend, but patient denies living with anyone currently. Does not offer further details of living arrangements. Patient seems to be living independently, but is not clear as to whether she is living with others or receives help. [H&P 360 note, Student G]

Function

Patient functioning prior to hospitalization was documented in 93% (42/45) of H&P 360 templated notes and in 57% (31/54) of traditional notes. Across both groups, this domain was

qualitatively similar. Both groups documented activities of daily living, instrumental activities of daily living, mobility, assistive devices, cognitive functioning, and occupation.

At baseline, patient uses powerchair for mobility since 2010. She is able to eat and use the bathroom on her own but requires assistance to cook, clean, shower, and do her home leg therapy. [H&P 360 note, Student H]

Impact on Patient Care

Needs Identified

Resource needs were identified in 20% (9/45) of H&P 360 templated notes and in 9% (5/54) of traditional notes. Needs were commonly related to placement due to concerns about safety, insufficient caregiving in the home setting, or housing instability. Identified needs also commonly included insurance issues, medication refills, or outpatient follow up. In qualitative comparison, text from the H&P 360 notes contained more detail about resource needs. Plans for addressing needs were usually but not always explicitly described. The plans often involved acquiring equipment or involving social work. In situations where a plan was not stated, it was unclear if it was assumed that it would be addressed or if it ultimately was not addressed.

Per pt's [patient's] niece, concern for abuse and neglect at pt's home. Pt endorses verbal abuse/threats from daughter; denies any physical harm. - SW [social work] following, contacted elder abuse hotline, case assigned to Center for New Horizons who will f/u [follow up] with pt and family members. [H&P 360 note, Student C]

Needs PCP [primary care provider]- no insurance, SW [social work] consult to help establish with Medicaid. [Traditional note, Student L]

Education and Counseling

Patient education or counseling was described in 27% (12/45) of H&P 360 notes and in 24% (13/54) of traditional notes. Across both groups, documented counseling most often involved nutrition, physical activity, and substance use, while some notes documented patient education regarding management options. There was little detail in excerpts from either group. No qualitative differences were identified: "Encourage elevation of legs during sitting and during bedtime. Compression stockings as outpatient." [Traditional note, Student O]

Interdisciplinary Resource Coordination

Interdisciplinary resource coordination was documented in 78% (35/45) of H&P 360 notes and in 41% (22/54) of traditional notes. This code included inpatient and outpatient referrals to social work, physical or occupational therapy, nutrition, podiatry, and medical specialties. Across both groups, a majority of the documentation was simply noting that physical or occupational therapy services were ordered for the patient. There was not much detail in either group. Qualitative differences were not identified: Social work consulted on prior admission. Consider referral for inpatient vs outpatient rehab services. [Traditional note, Student C].

Student Survey

Of all subIs in internal medicine (N=24), 11 (45%) completed the survey regarding their experience with the H&P 360 (Table 2). Regarding feasibility of the H&P 360, the majority of respondents strongly or somewhat agreed that the H&P 360 took an appropriate amount of time to complete and strongly or somewhat agreed that it was easy to use. However, few respondents strongly or somewhat agreed that presentations

using the H&P 360 were well-received by the clinical team. Regarding perceived impact on patient care, respondents strongly or somewhat agreed that the H&P 360 helped them better understand patient goals, facilitated a stronger provider-patient relationship, changed some of the questions they asked during the encounter, and added valuable information that they would not have known about the patient. Few students strongly or somewhat agreed that the H&P 360 helped them to create a more comprehensive problem list (Table 2).

Table 2. Survey respondents somewhat agreeing or strongly agreeing with statement (N=11).

Statement regarding H&P ^a 360	Agree with statement ^b , n (%)
Feasibility	
Took an appropriate amount of time to complete	8 (73)
Was easy to use	7 (64)
Could be incorporated into every patient interaction	6 (55)
Presentations were well-received by my clinical team	3 (27)
Perceived impact on patient care	
Helped me better understand patients' goals	10 (91)
Facilitated a stronger provider-patient relationship	9 (82)
Changed some of the questions I ask patients during the encounter	10 (91)
Added valuable information that I would not otherwise know about the patient	9 (82)
Facilitated care planning that included other health professionals	7 (64)
Helped improve the care I provided to my patients	6 (55)
Was able to incorporate information into management plans	5 (45)
Helped create a more comprehensive problem list	4 (36)
Perceived impact on education	
Helped me learn to be a better clinician	7 (64)
Plan to use elements during other rotations	7 (64)

^aH&P: health and physical.

^bSurvey prompts were answered on a 5-point Likert scale. Responses were dichotomized as agreeing with statement if 5 (strongly agree) or 4 (somewhat agree).

In open-ended prompts on the survey, five students shared that the H&P 360 served as a prompt to further explore or document social history. One student wrote:

It provided examples for what to ask in order to learn more information about patient's social and home life...It alerted me to important things that we often don't ask or miss when taking care of inpatients.

Three students stated that the template helped them clarify patient goals.

Regarding areas for improvement, four students noted the time that it took to complete the H&P 360. One of these students recommended having the option for shorter, drop-down answers available in the template.

Three students shared that they thought patients were surprised to be asked about some of the topics covered in the H&P 360. One student wrote:

I think the biggest challenge is that patients aren't used to being asked some of these questions (their

goals, their self-perceptions of their health) during these admissions. It can be a delicate subject.

Finally, three students reported concerns about deviating from the note template typically used on their clinical service. Two students specifically reported receiving negative feedback from their clinical team. One wrote:

...at times I would get feedback from my residents that they wished the information was incorporated elsewhere. It was also cumbersome to be expected to document so much info that oftentimes is nice and useful to know, but that my team did not necessarily want to hear about.

Discussion

Principal Findings

In this inpatient implementation study of the H&P 360 EHR template, psychosocial documentation was more common across virtually all H&P 360 content domains among admission notes

using the H&P 360 template compared to the traditional H&P note template. Importantly, documentation was also more common with respect to social needs identification and interdisciplinary collaboration. However, the overall impact of the tool was diminished by limited and variable uptake of the H&P 360 note template by the subI students.

While students generally provided positive feedback about the potential of the H&P 360 to improve understanding of patient goals and to enhance the patient-provider relationship, students less often reported that this added information changed treatment plans or improved care. There are several potential reasons for this apparent paradox. First, students are already including health-related social needs in care planning closer to the time of discharge (not captured in admission notes). Alternatively, they gather information but do not apply it (potentially due to barriers related to time, resources, or interdisciplinary support).

Many students did not use the H&P 360 template. Open-ended survey feedback suggested that a barrier to use may be the time required to complete the expanded H&P. Drop-down menu responses could increase ease of template use; however, these may also limit detailed communication of the patient's context or preferences. Pacing collection of psychosocial information throughout the hospital stay beyond the admission day, perhaps through triggered alerts or reminders, could decrease and spread out the time required; this pacing may in some cases improve perceived relevance and acceptability to students and patients as acute biomedical issues have abated.

In addition to time constraints, several students also noted negative feedback from some team members who felt that the psychosocial information presented within the context of the H&P 360 appeared to deviate from expected convention. Students have strong incentives to assimilate with their team and thus likely felt pressure not to use the H&P 360 template even if they found it useful. The lack of interest among other team members in patients' contextual information likely relates in part to the historical focus physicians have had on biomedical information. Further, the timing of presenting this information may have been a factor as students' perceptions of the relative value of this contextual information may be lower in informing initial treatment and stabilization plans at admission as compared with the longer-term planning that occurs nearer to discharge.

This pragmatic implementation provided only a low-intensity orientation to the H&P 360 for faculty in the form of emailed materials. Future efforts will need to increase and improve orientation of faculty to the H&P 360 as well as include training for resident physicians. Student uptake of the H&P 360 EHR template may be further enhanced through exposure in the preclinical years in settings such as free clinics and clinical preceptor groups.

Comparison With Prior Work

To date, EHR tools and templates have predominantly been leveraged to enhance biomedical documentation, targeting quality metrics, and optimizing reimbursement [13,20-22]. Our study represents an important contribution to this literature as there is limited research on use of EHR templates to improve psychosocial documentation or to intentionally elicit patients'

perspectives and goals. Several initiatives in the United States call for improved integration of screening of social determinants of health into health care delivery and the need for standardized methods for capturing this information in EHRs [6,23,24]. Systematic documentation of patients' needs and goals during hospitalization has the potential to not only improve the care of individual patients (personalizing care, supporting shared decision-making, aiding discharge planning), but can provide critical context for health systems in designing programs and determining staffing needs to meet the needs of the patient population they serve [23,25].

While most interventions to promote psychosocial documentation in the EHR have focused on the completion of expanded checklists and screening tools primarily by nonphysician team members, we intentionally chose to include psychosocial documentation within the physician note template [17,18,26]. This choice was made to match the usual workflow for students and residents at our institution and to promote this documentation as a part of the physician's sphere of work (rather than an area delegated to social workers, nurses, or others).

While EHR templates have been found to improve documentation of key measures, some studies suggest that this may occur at the expense of patient-centered care, prioritizing the clinician's agenda above that of the patient [27]. However, in contrast to many EHR templates, the H&P 360 promotes a domain-based approach to discussing psychosocial concerns with patients (rather than a checklist-based approach) and further intentionally solicits patients' goals and perspectives. Integration of patient-centered questions within templates used by general practitioner practices in England was actually found to increase the perception of patient-centeredness [16].

Limitations

There are several important limitations to note. First, while we found that psychosocial documentation was more common in the H&P 360 notes as compared with traditional notes, our study design did not allow for rigorous statistical testing. Second, the low and variable uptake of the EHR template meant that our sample of representative H&P 360 notes was drawn from a small number of students, thus limiting the generalizability of our findings. Third, students self-selected when to use the H&P 360 as compared with traditional note templates. Consequently, it is possible that there may have been systematic differences among patients represented in each group (eg, ability to engage, presence and number of needs), which may have biased the results. Fourth, we focused solely on initial admission H&P notes and did not include review of progress notes or discharge summaries. As a result, we may have missed instances in which psychosocial information was documented later during a patient's hospital course. Fifth, we did not survey patients or interdisciplinary team members about their experiences with the H&P 360 and did not collect any other objective systems-level data on the impact of the H&P 360 on discharge planning or resource provision. As a result, our findings are limited by the accuracy and completeness of subI documentation. Lastly, the survey response rate was low, in part due to inclusion of students on their ICU rotation who were unlikely to utilize the H&P 360 owing to competing acute

priorities. While the response rate was overall lower than ideal, the students who did complete the survey likely represented a large majority of those who utilized the EHR template.

Conclusions

Integrating the H&P 360 framework into templated notes in the EHR is feasible, and may increase assessment of goals and perspectives for patient-engaged care and contextual factors important to prevention of rehospitalization. Uptake of the note

template may be enhanced through earlier and repeated exposure, encouraging paced usage over the course of a hospitalization, and greater engagement by residents and attendings. Larger-scale implementation studies with learners and practicing clinicians, paired with robust evaluation efforts involving patients, clinicians, and interprofessional staff, are needed to better understand the complexities of implementing nonbiomedical information within EHRs and the usual flow of care.

Abstract

Background: Prospective physicians are expected to find artificial intelligence (AI) to be a key technology in their future practice. This transformative change has caught the attention of scientists, educators, and policy makers alike, with substantive efforts dedicated to the selection and delivery of AI topics and competencies in the medical curriculum. Less is known about the behavioral perspective or the necessary and sufficient preconditions for medical students' intention to use AI in the first place.

Objective: Our study focused on medical students' knowledge, experience, attitude, and beliefs related to AI and aimed to understand whether they are necessary conditions and form sufficient configurations of conditions associated with behavioral intentions to use AI in their future medical practice.

Methods: We administered a 2-staged questionnaire operationalizing the variables of interest (ie, knowledge, experience, attitude, and beliefs related to AI, as well as intention to use AI) and recorded 184 responses at t_0 (February 2020, before the COVID-19 pandemic) and 138 responses at t_1 (January 2021, during the COVID-19 pandemic). Following established guidelines, we applied necessary condition analysis and fuzzy-set qualitative comparative analysis to analyze the data.

Results: Findings from the fuzzy-set qualitative comparative analysis show that the intention to use AI is only observed when students have a strong belief in the role of AI (individually necessary condition); certain AI profiles, that is, combinations of knowledge and experience, attitudes and beliefs, and academic level and gender, are always associated with high intentions to use AI (equifinal and sufficient configurations); and profiles associated with nonhigh intentions cannot be inferred from profiles associated with high intentions (causal asymmetry).

Conclusions: Our work contributes to prior knowledge by showing that a strong belief in the role of AI in the future of medical professions is a necessary condition for behavioral intentions to use AI. Moreover, we suggest that the preparation of medical students should go beyond teaching AI competencies and that educators need to account for the different AI profiles associated with high or nonhigh intentions to adopt AI.

Introduction

Background

Artificial intelligence (AI), which is broadly defined as the use of a computer to model intelligent behavior with minimal human intervention [1], has the potential to transform or even revolutionize medicine [2]. In his seminal book, entitled “Deep Medicine: How Artificial Intelligence Can Make Health Care Human Again,” Topol [3] highlighted AI’s potential to improve the lives of physicians and patients. The promise of clinical AI algorithms ranges from image-based diagnosis in radiology, ophthalmology, and dermatology [4–6] to patient monitoring in cardiology and endocrinology [7,8] to the prediction of cardiovascular and kidney diseases [9,10], to name a few. In these areas, AI could offer valuable diagnostic and predictive insights concerning subtle changes to cue prospective physicians to initiate preventive measures as well as timely and accurate interventions [2,11].

For the potential benefits associated with AI use to materialize to their full potential, both current and future generations of physicians must be able to navigate with ease in an ever-changing digital environment. Accordingly, a growing academic literature has emerged on the attitudes of physicians toward AI, most of which concerns radiologists. According to these studies, the perception of AI among this group of specialists ranged between acceptance with enthusiasm and skepticism owing to the fear of being displaced by the technology [12,13]. Other surveys concerned all physicians, irrespective of their specialty. For instance, Oh et al [14] surveyed 669 physicians practicing in South Korea. Although most respondents considered AI useful in medical practice, only 5.9% (40/669) said that they had good familiarity with this technology. The ability to analyze vast amounts of high-quality, clinically relevant data in real time was seen as the main advantage of using AI, and a vast majority of the respondents (558/669, 83.4%) agreed that the area of medicine in which AI would be the most useful is disease diagnosis.

More recently, Scheetz et al [15] conducted a web-based survey of 632 fellows and trainees of 3 specialties (ophthalmology, radiology or radiation oncology, and dermatology) in Australia and New Zealand. Findings revealed that 71% (449/632) of the respondents believed that AI would improve their field of medicine, and 85.7% (542/632) felt that medical workforce needs would be affected by AI within the next decade. Improved disease screening and streamlining of monotonous tasks were identified as key benefits of AI. Finally, Paré et al (Paré, G, unpublished data, March 2022) investigated the assimilation of digital health technologies by Canadian family physicians to further understand the breadth and depth of their use in clinical practice for the diagnosis, treatment, and prevention of diseases and for the monitoring of chronic patients. A slight majority (422/768, 54.9%) of the respondents indicated that they were open to using AI for medical diagnosis purposes.

Although education has been identified as a priority to prepare future physicians for the successful implementation of AI in health care [15,16], to our knowledge, only a few studies have investigated medical students’ attitudes toward AI and their

beliefs concerning the relevance of introducing AI-related material as a standard part of the curriculum. For instance, Sit et al [17] explored the attitudes of 484 United Kingdom medical students regarding training in AI technologies, their understanding of AI, and career intention toward radiology. Findings revealed that medical students do not feel adequately prepared to work alongside AI but understand the increasing importance of AI in health care and would like to receive formal training on the subject. Another example is the study by Park et al [18] that surveyed 156 radiology students in the United States. Over 75% (117/156) of the students agreed that AI would play a major role in the future of medicine, and 66% (103/156) of the students believed that diagnostic radiology would be the specialty most greatly affected by AI. Approximately half of the students (69/156, 44.2%) reported that AI made them less enthusiastic about radiology as a medical specialty.

In light of the aforementioned information, little empirical knowledge is available on medical students’ views on, familiarity with, and intention to use AI-based health technologies (AIHTs), including big data analytics and machine learning–based applications that are promised to have profound medical and societal impacts (eg, the study by Galetsi et al [19]). Further, prior studies mainly surveyed radiology students (eg, the study by Park et al [18]) or focused on students’ intention to use a specific AI-based application (eg, the study by Tran et al [20]). Importantly, prior surveys soliciting medical students’ opinions were conducted before the COVID-19 pandemic and are highly descriptive and atheoretical in nature. This study aims to fill these gaps. More precisely, we adopt a *configurational* perspective [21] to investigate the AI profiles of prospective physicians, that is, to identify the different configurations of factors that characterize these individuals with regard to AI. In addition, this study aimed to identify the AI profiles that are associated with a strong intention on the part of prospective physicians to use AIHTs in their future medical practice.

As explained in the *Theoretical Foundations* section, the configurational approach is based on the premise that there are specific combinations of prospective physicians’ AI knowledge, experience, attitudes, and beliefs that positively influence their intention to use AIHTs in medical practice [22]. Therefore, the first research question answered by this study is the following: *In a medical school context, what are the different AI profiles of prospective physicians that are associated with a strong intention on their part to use AIHTs in their future medical practice?* Additionally, given that the configurational approach allows for causal asymmetry, the second question is as follows: *What are the different AI profiles that do not allow these individuals to have a strong intention to use AIHTs in their future practice?*

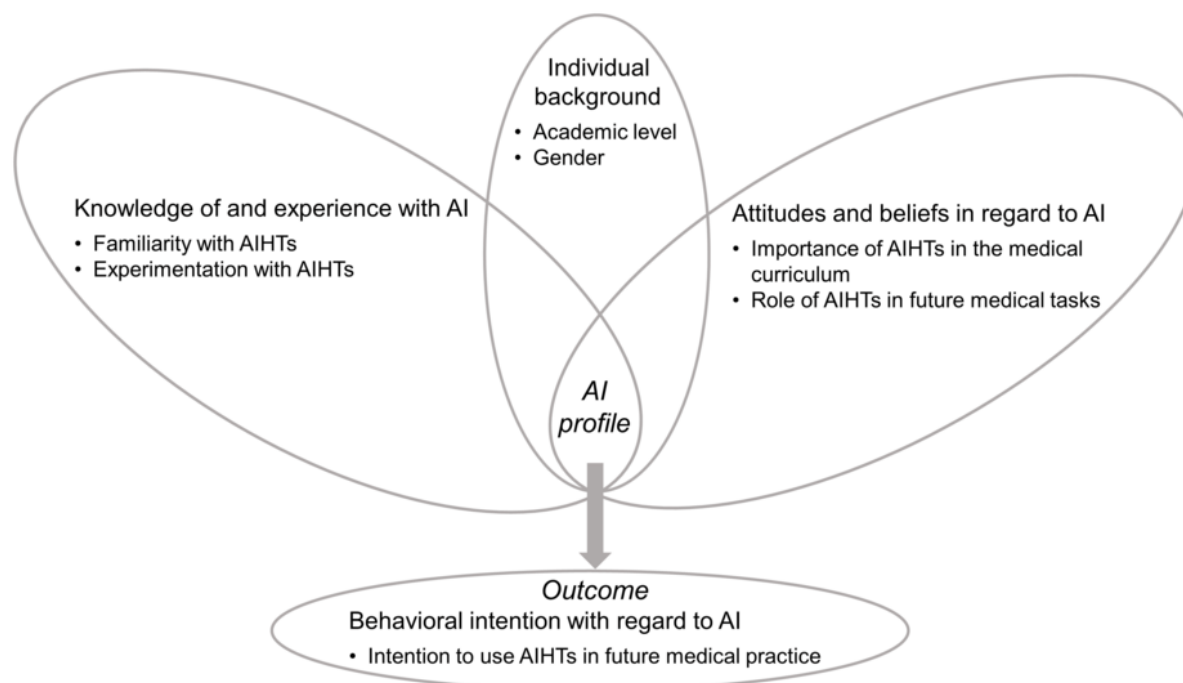

Theoretical Foundations

The configurational model of prospective physicians’ behavioral intention with regard to AI, empirically investigated in this study, is presented in Figure 1. This model first assumes that the AI profiles of prospective physicians are made up of two main components: (1) knowledge of and experience with AI and (2) attitudes and beliefs with regard to AI. Our model also

assumes that different AI profiles will be associated with different levels of behavioral intention with regard to AI. This assumption is based on the basic tenet of configurational theory, which follows the *systems* (rather than *variance*) approach [23]

and seeks to further explain complex societal, organizational, group, and individual phenomena by identifying synergistic combinations of interacting causal conditions [21].

Figure 1. Configurational model of prospective physicians' behavioral intention with regard to artificial intelligence (AI). AIHT: AI-based health technology.

The first component of our configurational model refers to prospective physicians' familiarity and experimentation with AIHTs. In the present context, familiarity with AIHTs is mainly within a medical student's own control (endogenous factor). It is closely related to the concept of computer self-efficacy [24], which is included in many IT adoption models. For its part, experimentation with AIHTs is largely influenced by external factors (exogenous factor). It is associated with the concept of *facilitating conditions* included in the technology acceptance model (TAM), a theory that models how potential users come to adopt a new technology [25]. Facilitating conditions are external factors that influence an individual's perceptions of the difficulty with which a task (eg, use of AIHTs) may be performed [26]. In medical teaching, facilitating conditions such as digital skills training would thus enhance students' assimilation of instructional technologies [27]. In this study, facilitating conditions are operationalized as medical students' level of hands-on experimentation with AI-based tools during their medical education.

Next, the second configurational component refers to prospective physicians' attitudes and beliefs with regard to AI. According to Triandis' [28] theory of interpersonal behavior, individuals' behavioral intention is influenced by their attitudes and beliefs with regard to the behavior. On the one hand, attitudes toward technology use have mainly been conceptualized through the "perceived usefulness" component of the TAM, defined as the degree to which individuals deem that using a particular technology would enhance their work performance [25]. Adapted to this study's context, perceived

usefulness refers to prospective physicians' perceptions of the greater importance that should be afforded to AIHT training within their medical studies. On the other hand, beliefs concerning technology use have mainly been conceptualized through the "perceived consequences" of such use [28], that is, through individuals' perceptions of the value expected from the intended behavior [29]. In this study, we assessed medical students' belief in the role that AIHTs are expected to play in support of their future medical tasks such as the prevention and diagnosis of illnesses.

Following prior research on digital health training (eg, the study by Vossen et al [30]) as well as various studies testing the TAM (eg, the study Venkatesh [31]), 2 individual factors were included, namely, gender and academic level, as individual background variables to add a contextual component to our configurational model. Here, we simply assume that these factors are likely to be associated with the prospective physicians' AI profile, which, in turn, will be associated with their behavioral intention with regard to AI.

Whereas the theoretical background of our study is constituted by the previously mentioned configurational theory and by behavioral theories such as Triandis' [28] theory of interpersonal behavior and the TAM, the theoretical foreground is founded upon the theorization of the task-technology fit concept. This last theory's basic tenet is that a technology will be adopted to the extent that it is perceived to be well suited to the work tasks of the individuals whom it is meant to support, that is, suited to their tasks' complexity, uncertainty, interdependence, and

autonomy [32]. In our case, the notion of *fit* implies an understanding of how best to match AI-based tools with specific medical tasks (eg, diagnosing an illness) in specific medical contexts (eg, in emergency care) [33]. This led us to propose that the prospective physicians' intention to use AIHTs in their future practice would primarily depend on the perceived consequences of such use, that is, on the prospective physicians' belief that using AI-based tools will render them more effective in accomplishing their medical tasks. In turn, we also assume that such beliefs would be primarily conditioned by the prospective physicians' evolving knowledge of and experience with AIHTs and by their concomitantly evolving attitude toward the AI training received during their medical studies [34].

Methods

Overview

This study was conducted at the University of Montréal's medical school in Canada. During the 5-year long undergraduate medical curriculum, no formal digital health education or training is provided to students. However, students have access to the EDUlib web-based training platform that offers educational content on a variety of subjects, including health and information technologies, as well as to symposia and conferences on different aspects of digital health. The study population consisted of 1367 medical students from the University of Montréal. The survey questionnaire was administered in 2 phases: an initial survey (t_0) in February 2020, before the COVID-19 pandemic, and a replication survey (t_1) in January 2021, during the pandemic.

As we were unable to locate any preexisting questionnaire that assessed the variables included in our research, we developed our own measurement instrument. The items broadly align with those used in related contexts (eg, the study by Zigurs and Khazanchi [33]). The survey design underwent several rounds of iteration, and final validation was performed with a group of 10 medical students from the University of Montréal who were excluded from the sampling population.

The measurement of the research variables was based on the abovementioned literature on medical education in AI-enabled digital health technologies. The "experimentation with AIHTs," "familiarity with AIHTs," and "importance of AIHTs in the medical curriculum" variables were each measured with three 5-point scales (AI, machine learning, and big data analytics). The "role of AIHTs in future medical tasks" variable was measured with five 5-point scales pertaining to the potential effect of AIHT on medical tasks (prevention, diagnosis, treatment, prognosis, and patient-physician relationship). The outcome variable, "intention to use AIHT in future medical practice," was measured through the summation of 8 dichotomous scales (yes or no) pertaining to the use of AIHTs in support of medical activities (radiological image analysis, photographic image analysis, pathological image analysis, diagnosis, prognosis, therapeutic planning, patient history data analysis, evaluation, and the monitoring of patient-physician communication). The full measurement instrument is presented in [Multimedia Appendix 1](#).

To analyze the AI profiles associated with high or nonhigh intentions to use AIHTs, we performed fuzzy-set qualitative comparative analyses (fsQCA) [34,35] in combination with analyses of necessity [36]. In a nutshell, fsQCA is a second-generation configurational analysis method that uses Boolean algebra for determining different configurations of elements that generate the same outcome [37]. In this method, each configurational element (or causal condition) is considered a *fuzzy set*. Consistent with the configurational theory, fsQCA allows for equifinality and causal asymmetry [22]. Specifically, in explaining prospective physicians' behavioral intention toward AI adoption, the configurational approach allows us to account for complex and nonlinear relationships among the knowledge, experience, attitudes, and beliefs of these individuals with regard to AI as well as to account for *equifinality*. In this study, equifinality is the possibility for prospective physicians to have an equally strong intention to use AIHTs while showing different AI profiles, that is, through different configurations of conditions that *cause* the intention [38]. In other words, equifinality allows configurational elements (ie, the elements forming the prospective physicians' AI profiles) to be combined in multiple ways to equally produce the outcome of interest (ie, a high level of behavioral intention), which means that the same element might be present in one *high-intention* AI profile but might be absent in another. Thus, the same configurational element (or causal condition), for example, a high level of familiarity with AIHTs, could be associated with high intention in one profile but not in other profiles, in which the prospective physicians' intentions depend on how the familiarity is configured with the other elements that form the AI profile. This approach also allows for *causal asymmetry*, that is, the possibility that the AI profiles associated with the presence of a strong intention to use AIHTs differ from the profiles associated with the absence of such an intention [22].

In line with the methodological guidelines for fsQCA [39,40], we completed the steps of calibration, necessity analysis, truth table construction, and sufficiency analysis, as explained in the *Results* section. The fsQCA was conducted with the QCA (version 3.0) software [41].

Ethics Approval

The survey questionnaire was approved by the ethics committee at the University of Montréal on October 29, 2019 (#CERSES-19-108-D). Informed consent was obtained from all participants. All methods were executed in accordance with relevant guidelines and regulations.

Results

Overview

Of the 1367 students, 184 (13.46%) students responded to the initial survey at t_0 , whereas 138 (10.1%) responded to the replication survey at t_1 . As shown in [Table 1](#), most participants were women (119/184, 64.7% at t_0 and 96/138, 69.6% at t_1), and the number of participants in their third year or later of medical training (108/184, 58.7% at t_0 and 78/138, 56.5% at t_1) was more than the number of participants in their first or second year.

Table 1. Profile of the respondents.

Medical students' background	t_0 (n=184), n (%)	t_1 (n=138), n (%)
Academic level		
Preparatory year (year 1)	40 (21.7)	28 (20.3)
First year preclinical (year 2)	36 (19.6)	32 (23.2)
Second year preclinical (year 3)	43 (23.4)	56 (40.6)
First year internship (year 4)	33 (17.9)	8 (5.8)
Second year internship (year 5)	32 (17.4)	14 (10.1)
Gender		
Women	119 (64.7)	96 (69.6)
Men	65 (35.3)	42 (30.4)
Age (years), mean (SD; range)	22.9 (3.5; 18-38)	22.6 (2.7; 18-35)

The reliability and descriptive statistics of the research variables for the 2 samples (t_0 and t_1) are presented in Table S1 of [Multimedia Appendix 2](#). Note that, overall, the sampled prospective physicians showed rather low levels of knowledge of AIHTs and experience with AIHTs. When comparing the variable means between the t_0 and t_1 samples, a significant difference ($P=.047$) was found for a single variable, indicating that the prospective physicians at t_1 (peri-COVID-19 pandemic) were less familiar with AIHTs, albeit slightly, than those at t_0 (pre-COVID-19 pandemic). Overall, these 2 samples thus appeared to be quite similar, notwithstanding the advent of the COVID-19 pandemic after the initial survey. The correlation matrices of the research variables (t_0 and t_1) are presented in Table S2 of [Multimedia Appendix 2](#).

With respect to the measurement properties of the research variables, one must first note that our measure of the outcome variable, intention to use AIHTs, is of the “index” rather than “scale” type. In contrast to scale measures, index measures tend to follow a Poisson type rather than a normal distribution and regroup elements not expected to be highly intercorrelated, hence the inappropriateness of using the Cronbach α coefficient to assess the internal consistency of such measures [42]. As shown in Table S1 in [Multimedia Appendix 2](#), all α coefficients above the 0.80 threshold confirm the internal consistency of the 4 scale measures, and the average extracted variance of these measures confirm their convergent validity (average extracted variance > 0.50).

Next, we examined the correlation matrix of the 4 scale variables to ascertain whether any 2 of these correlated above the 0.71 threshold, as this would indicate a strong risk of common method bias (CMB) in our data [43] and a lack of discriminant validity [44]. As shown in Table S2 in [Multimedia Appendix 2](#), this was not the case. The “marker variable” CMB detection technique was also called upon [45]. The recommended procedure for applying this technique post hoc was used; that is, the smallest correlation among the scale variables (0.08 at t_0 and 0.06 at t_1) was used as a reliable estimate of common method variance (CMV) to calculate CMV-adjusted correlations [46]. Given that many of these adjusted correlations (33% at t_0 and 66% at t_1) were nonsignificant ($P .05$) and that the originally

significant correlations among the variables remained significant when adjusted for CMV [47], it further appeared that CMB was not a major threat in this study.

Consistent with the configurational theory [21] and as opposed to covariance-based or component-based structural equation modeling techniques such as partial least squares regression, the configurational analysis method implemented in fsQCA assumes complex, nonlinear causality [22] and allows for equifinality and causal asymmetry [48]. The principal contribution of fsQCA lies in its ability to evaluate the relation between a configuration of elements and an outcome. The analysis of our configurational model was preceded by a direct fuzzy-set *calibration* of 5 of the 7 research variables, as it is recommended when Likert-type scales and indexes are used for variable measurement [48]. For each of our research variables, we thus identified the 3 points of fuzzy-set membership (fully-in, crossover, and fully-out) using percentiles, as recommended in the fsQCA literature [49]. For their part, the individual background variables—academic level and gender, measured as binary variables—constituted “crisp” sets (fully-in=1 and fully-out=0).

Although we first described fsQCA with regard to the relationship between the desired outcome and the case sets built for each causal condition (or configurational element), the main advantage of this technique lies in its capacity to analyze relationships between configurations (ie, combinations of causal conditions) and the outcome [37]. As the configurations are built through Boolean addition of individual causal conditions, a condition's fuzzy-set score indicates its degree of membership in the solution.

The fsQCA technique starts its configurational analysis by creating a truth table of 2^k rows, where each row represents a possible configuration combining k individual causal conditions [50]. This table is sorted on the basis of the frequency and consistency, where frequency represents the number of observations for each possible configuration, and consistency estimates “the degree to which cases correspond to the set-theoretic relationships expressed in a solution” [22]. Given our large-sized sample, we set the frequency threshold at 3; hence, all configurations with a frequency of ≤ 2 were deleted

from further analysis. Furthermore, we applied the recommended threshold of 0.80 for consistency [51], which is also the default value in the fsQCA version 3.0 software used in this study. Hence, for configurations below the consistency threshold, the outcome variable was set at 0 and for the rest at 1, given that these configurations are the ones that fully explain the outcome [50].

Configurational Analysis (t_0)

Overview

The first step in fsQCA is the analysis of the configurational elements that are deemed *necessary* for the outcome (Table 2). Generally, the necessity of a causal condition is assessed by its consistency, that is, by the extent to which members in this condition (eg, prospective physicians believing the role of AIHTs in their future medical tasks to be highly important) show membership in the outcome (eg, prospective physicians

having a high intention to use AIHTs in the future). Within fsQCA, a causal condition is deemed to be necessary for an outcome when its consistency score exceeds the threshold of 0.90 [37]. However, necessary condition analysis (NCA) provides a more suitable approach, especially for the necessity analyses of fuzzy-set conditions (derived from continuous variables). NCA is better suited for our data set because it is more aligned with in-degree necessary conditions, relying on ceiling line calculations that are more flexible than the dichotomous bisection underlying fsQCA necessity analyses [49]. The NCA analyses reported in Multimedia Appendix 3 suggest that prospective physicians' strong beliefs in the role of AIHTs in their future medical tasks is a necessary condition for behavioral intentions. This finding is also corroborated by the occurrence of the same condition across all high-intention configurations, which is considered indicative of a necessary condition in fsQCA approaches [49].

Table 2. Analysis of the necessary configurational elements (t_0)

Configurational element	High intention ^a (to use AIHTs ^b in future practice)		Nonhigh intention ^c (to use AIHTs in future practice)	
	Consistency	Coverage	Consistency	Coverage
Knowledge of and experience with AI^{a,d}				
Familiarity with AIHTs	0.023	0.983	0.999	0.450

^dAI: artificial intelligence.

^eCrisp set: fully-in=1 and fully-out=0.

The next step in fsQCA allows one to analyze the configurational elements that, together, are *sufficient* to produce the chosen outcome [37]. That is, using Boolean algebra and counterfactual analysis, fsQCA effectuates a logical reduction of the truth table into 3 types of solutions that combine the causal conditions that are deemed sufficient to achieve the desired outcome: parsimonious solutions, intermediate solutions, and complex solutions. Owing to its difficult interpretation and poor applicability, the complex solution—which produces all possible configurations of conditions—is simplified into the parsimonious and intermediate solutions. The intermediate solution is obtained through a counterfactual analysis of the complex and parsimonious solutions. The parsimonious solution yields the “core” conditions, whereas the “peripheral” conditions are those that are included in the intermediate solution but not in the parsimonious solution [37]. Therefore, the “core” conditions are those found to strongly influence the outcome

and cannot be left out from any configuration, whereas the “peripheral” conditions have lesser influence on the outcome and, therefore, may be exchangeable (with other peripheral conditions) or even expendable. For interpreting results, it is recommended to combine the parsimonious and intermediate solutions to identify the core and peripheral conditions in the resulting configurations [22]. Now, the peripheral conditions may be regarded as “complementary” or “contributing” configurational elements in that they make sense as important causal conditions; they may thus be removed from a configuration only if one is willing to make assumptions that run counter to the existing theoretical and substantive knowledge [37].

Configurations for High Intentions to Use AIHTs in Future Medical Practice (t_0)

In demonstrating equifinality, the results of the fsQCA-based sufficiency analysis identify 3 intermediate solutions, that is, 3 causal configurations equally associated with a high intention to use AIHTs in future medical practice ($HI1_0$, $HI2_0$, and $HI3_0$). The overall solution coverage indicates the proportion of cases that are covered by all reported configurations, whereas the overall solution consistency assesses the degree to which the

configurations are subsets of the outcome. Note that, as shown in Figure 2, we use the notation introduced by Ragin [37]: black circles represent the presence of a condition, circles with a cross-out indicate the absence of the condition, large circles represent core conditions, small circles represent peripheral conditions, and blank spaces represent an immaterial condition (or a situation characterized by a “don’t care” in which one condition may be either present or absent without altering the outcome). The 3 intermediate solutions derived from fsQCA appear as follows in Figure 2:

Figure 2. Configurations for the presence and absence of a high intention to use artificial intelligence (AI)-based health technologies (AIHTs) in future medical practice (t_0). HI: high intention; med.: medical; NHI: nonhigh intention.

Configuration Configurational element	High Intention (to use AIHT in future med. pract.)			Nonhigh Intention

Nota. Intermediate solutions (consistency threshold = 0.80, frequency threshold = 3)					

- The first high-intention configuration, $HI1_0$, highlights the need for prospective physicians to have a strong belief in the role of AIHTs in supporting their future medical tasks (core condition) and, secondarily, to have a favorable attitude toward the importance of AI in the medical curriculum (peripheral condition). Furthermore, $HI1_0$ is under the (core) condition that these individuals be in their first or second year of medical education.
- The second configuration, $HI2_0$, also highlights the need to have a strong belief in the role of AIHTs in future medical tasks (core condition) and, secondarily, a favorable attitude toward the importance of AI in the medical curriculum (peripheral condition). However, $HI2_0$ also includes a sufficient level of experimentation with AIHTs as a (core) condition for prospective physicians to have a

- strong intention to use AIHTs in their future practice, irrespective of their academic level and gender.
- The last configuration, $HI3_0$, is the most parsimonious, in that it only includes (as a core condition) having a strong belief in the role of AIHTs in future medical tasks under the added condition that the prospective physician be a woman (core condition) and that they be in their third or later year of medical education (peripheral condition).

Thus, at t_0 , there appears to be 3 different ways (or *causal recipes*) for prospective physicians to develop a strong intention to eventually use AIHTs in their future medical practice.

Configurations for Nonhigh Intention to Use AIHTs in Future Medical Practice (t_0)

In addition to equifinality, the configurational approach taken here allows for causal asymmetry, that is, the possibility that the causal conditions for the presence of the preferred outcome will differ from those for its absence [22]. As this approach allows for nonlinearity in causation, the same configurational element may have different causal roles within different configurations. In demonstrating causal asymmetry (Figure 2), further results of the fsQCA analysis identify 2 causal configurations associated with nonhigh intention to use AIHTs in medical practice ($NHI1_0$ and $NHI2_0$), that is, with the absence—rather than the presence—of a strong intention on the part of prospective physicians. Here, the absence of a strong belief in the role of AIHTs in prospective physicians' future medical tasks is the core condition that is shared by both

non-high-intention configurations, thus reinforcing the necessity of this last configurational element. However, asymmetry is observed because the lack of experimentation with AIHTs is also a core condition that is shared by the 2 configurations. These last 2 core conditions may thus be considered as necessarily “preventing” prospective physicians from having a strong intention to use AIHTs in their future practice.

Configurational Analysis (t_1)

Overview

Similar to the results of the necessity analysis of the t_0 data and as presented in Table 3, results of such an analysis of the t_1 data indicate that no configurational element appears to be individually necessary for prospective physicians to have a high intention to use AIHTs.

Table 3. Analysis of the necessary configurational elements (t_1).

Configurations for High Intention to Use AIHTs in Future Medical Practice (t_1)

Similar to the results of the sufficiency analysis of the t_0 data, results of the sufficiency analysis of the t_1 data identify 4

intermediate solutions, that is, 4 causal configurations equally associated with a high intention to use AIHTs in future medical practice ($HI1_1$, $HI2_1$, $HI3_1$, and $HI4_1$). The 4 intermediate solutions derived from fsQCA are shown in Figure 3.

Figure 3. Configurations for the presence and absence of a high intention to use artificial intelligence (AI)–based health technologies (AIHTs) in future medical practice (t_1). HI: high intention; med.: medical; NHI: nonhigh intention.

Configuration Configurational element	High Intention (to use AIHT in future med. practice)				Nonhigh Intention

Nota. Intermediate solutions (consistency threshold = 0.80, frequency threshold = 3)								

- The first high-intention configuration, $HI1_1$, highlights the need for prospective physicians to have a strong belief in the role played by AIHTs in their future medical tasks (core condition) and to have positive attitudes toward the importance of AI in the medical curriculum (core condition). Furthermore, $HI1_1$ is under the (core) condition that these individuals be in their first or second year of medical training.
- The second configuration, $HI2_1$, also highlights the need for prospective physicians to have a strong belief in the role of AIHTs in their future medical tasks (core condition) and positive attitudes toward the importance of AI in the medical curriculum (core condition). However, $HI2_1$ also includes a sufficient level of familiarity with AI technologies as a (core) condition for prospective physicians to have a strong intention to use AIHTs in their future practice, irrespective of their academic level and gender.
- The third configuration, $HI3_1$, is the most parsimonious, in that it only includes (as a core condition) having a strong belief in the role to be played by AIHTs in supporting prospective physicians' future medical tasks under the added condition of the physicians being in their third or later year of medical training (core condition) and being women (peripheral condition).
- The last configuration, $HI4_1$, highlights the need to have a strong belief in the supporting role played by AIHTs in future medical tasks (core condition) and to have a high familiarity with AIHTs (core condition) under the

(peripheral) condition that the prospective physicians be women.

At t_1 , there appear to be 4 different "causal recipes" for prospective physicians to develop a strong intention to use AIHTs in their future medical practice. Moreover, it is worth noting that, notwithstanding the prior analysis of necessary conditions, a strong belief in the role of AIHTs in support of future medical tasks appears to be a necessary condition because it is present in all 4 high-intention configurations [49].

Configurations for Nonhigh Intention to Use AIHTs in Future Medical Practice (t_1)

Demonstrating causal asymmetry in a fashion similar to what was done for the t_0 data and as presented in Figure 3, further results of the fsQCA analysis of the t_1 data identify 4 causal configurations associated with nonhigh intention to use AIHTs in medical practice ($NHI1_{1a}$, $NHI1_{1b}$, $NHI2_1$, and $NHI3_1$). Note that the first 2 configurations share the same core conditions and thus may be considered as "second-order" solutions with regard to equifinality [22]. The absence of a strong belief in the role of AIHTs in support of future medical tasks is the core condition that is shared by all 4 configurations and is thus a condition that would be detrimental to the future use of AIHTs in prospective physicians' medical practice.

Comparative Analyses (t_0 and t_1)

A comparative look at Figures 2 and 3 allowed us to make the following observations regarding the high intention

configurations identified in the replication study (peri-COVID-19 pandemic, t_1 ; $n=138$), as compared with those identified in the initial study (pre-COVID-19 pandemic, t_0 ; $n=184$):

- The $HI1_1$ configuration is nearly identical to $HI1_0$, as only the individual background conditions vary in importance (core vs peripheral condition).
- The $HI2_1$ configuration substitutes the familiarity with AIHTs (core) condition for the experimentation with AIHTs (core) condition, that is, substitutes AI knowledge for AI experience when compared with $HI2_0$.
- The $HI3_1$ configuration is nearly identical to $HI3_0$, as only the individual background conditions vary in importance (core vs peripheral condition).
- The $HI4_1$ configuration includes the familiarity with AIHTs (core) condition and excludes the academic level (peripheral) condition when compared with $HI3_0$.

With regard to the nonhigh intention configurations, differences between the configurations at t_0 (Figure 2) and t_1 (Figure 3) may be tentatively attributed to the significant differences between the 2 samples (Table S1 in Multimedia Appendix 2), that is, to the lesser familiarity and experimentation with AI of the students at t_1 when compared with those at t_0 and not to the differences in their individual background.

These observations are indicative of the robustness of our results and overall validity of the configurations that emerged from this study.

Discussion

Principal Findings

Our study first shows that a strong belief in the role of AIHTs in future medical tasks consistently figure as part of sufficient configurations and as the only individually necessary condition for future (intended) use of AI (Figures 2 and 3). This condition is also the only one that is causally symmetric, that is, the students who have a low intention to use AI are the students who do not believe AI will play an important role in their future profession. With regard to the other conditions, we uncover distinct AI profiles, that is, configurations, that describe equifinal sufficient solutions associated with the outcome of high intention toward AI. For the most prevalent profile of students in the early years of medical education, the core condition of a strong belief in the role of AI was sufficient, together with the condition that they have favorable attitudes toward the importance of AI (peripheral at t_0 and core at t_1). For the second major AI profile, which applies across academic levels and genders, a favorable attitude toward AI and a form of knowledge or experience with AI (experimentation in t_0 and familiarity in t_1) were conditions for the outcome of high behavioral intention. Finally, for a distinct profile of women participants with a high intention to use AI, a strong belief in the role of AI remained the only additional core condition (complemented by familiarity with AIHTs in the second sample). This last profile was mostly observed for students in their later years of medical education.

Beyond these nuanced findings, an additional fundamental insight is that being familiar with AI and having experimented with AI, considered individually, are not necessary conditions for students' intention to use AI in their future practice. This was confirmed by both forms of analysis, the fsQCA and NCA. As Hanckel et al [39] noted, identifying such conditions that—against conventional expectations—are not individually necessary for the outcome can be seen as a key strength of fsQCA. With prior research and discourse primarily focusing on curriculum design and the teaching of AI competencies (ie, knowledge and familiarity), our findings show that these efforts are expected to be ineffective in shaping medical students' behavioral intentions. Instead, the evidence from our study suggests that their belief regarding the role of AIHTs deserves more attention.

In interpreting the findings from this study, one should also appreciate the fsQCA method and its unique strengths. Originally applied to comparative policy analyses, that is, small sample size, noninterventional contexts involving complex causal relationships, QCA is increasingly valued in health care contexts [39]. The benefit of fsQCA, compared with traditional, regression-based approaches, is that it deals with profiles, or configurations of conditions, instead of assuming population homogeneity, independence of variables, and constant marginal effects. In our context, the fsQCA method was capable of capturing nuanced findings, including the findings that (1) the intention to use AIHTs is only observed when prospective physicians have a strong belief in the role of AI (individually necessary condition); (2) certain AI profiles, that is, combinations of knowledge and experience, attitudes and beliefs, and academic level and gender, are always associated with high intentions to adopt AI (equifinal and sufficient configurations); and (3) profiles associated with nonhigh intentions cannot be inferred from AI profiles associated with high intentions (causal asymmetry). Furthermore, the findings displayed in Figures 2 and 3 also indicate that the sufficient configurations depend on the academic level and gender, offering starting points for more targeted educational initiatives.

Implications

A key implication for medical education is that the intention to adopt AI is observed only when students have a strong belief in the role of AI in medicine. Prior research offers suggestions of requisite AI-related skills and selections of corresponding curricular contents [52-55]. In our work, we emphasize that beyond teaching basic AI skills, the medical curriculum should also consider the roles of attitudes, beliefs, and behavioral intentions. To accomplish this, medical schools may foster an environment in which prospective physicians can explore, discuss, and develop their views with peers and expert practitioners early on. It would be fair to provide students with accurate information and access to experts to assist the formation of attitudes related to AIHTs and to facilitate the self-selection into medical specialties. In a nutshell, educational efforts should avoid producing students with AI-related skills but no intention of using AIHTs. Furthermore, we advise educators to adapt their teaching approaches to the different AI profiles, taking into consideration that students in the early years may want to appreciate the importance of AI in their future profession,

whereas students in the later years may use AI when they have acquired enough knowledge. Ideally, educational initiatives should be adapted to the AI profiles related to AI attitudes and beliefs as well as AI-related familiarity and experimentation.

Limitations

This exploratory study has a few limitations that can serve as a starting point for future research. First, the scope of our study was restricted to a single medical school in Canada, and our findings may not be generalizable to other medical education contexts, especially when the career paths of physicians, country's development levels, health care systems, or regulations related to the medical profession differ. Second, although our sampling frame aimed to cover a broad variety of cases, several theoretical cases (ie, combinations of conditions) were not observed in the truth table. However, the highest number of cases corresponding to a single configuration do not reflect >10% of the data set, suggesting that the data set provides a strong empirical foundation for our findings [40]. Given that QCA, as an analytical method, is appropriate for small samples (eg, 10 to 30 cases), it is essential that there are no single configurations that represent large parts of the data set and to consider the logical remainder in the truth table when interpreting the results [40]. Third, the data collection instrument was created for this study and relies on the general terms such as AI, machine learning, and big data analytics. Future research could take this as a starting point to develop more specific

operational definitions, not only of AI in the context of health care but also of AIHTs. Fourth, the survey is an observational and noninterventional data collection method. Further research is needed to ascertain the degree to which selected variables may change through intervention or the extent to which the efforts to inform medical students about the expected impacts of AI on their future practice enable them to self-select into the different specialties.

Conclusions

The future of medical practice is expected to feature AI technologies, raising the question of how prospective physicians are best prepared for the new demands of the profession. Considerable work has been done related to the selection of AI topics and AIHT competencies for curriculum redesign. However, being competent in the use of AIHTs does not necessarily coincide with the behavioral intent to adopt these technologies. In this context, our work explains behavioral intent based on fsQCA, which identifies strong belief in the role of AIHTs as the only necessary condition, and dissociates different AI profiles as sufficient configurations. A replication showed that the findings remained stable, even after the advent of the COVID-19 pandemic. Going forward, these insights suggest that educators should go beyond teaching AIHT competencies and consider students' beliefs and attitudes, which are intricately related to the intended adoption of AIHTs in their future practice.

Abstract

Background: The use of artificial intelligence (AI) in medicine is expected to increase significantly in the upcoming years. Advancements in AI technology have the potential to revolutionize health care, from aiding in the diagnosis of certain diseases to helping with treatment decisions. Current literature suggests the integration of the subject of AI in medicine as part of the medical curriculum to prepare medical students for the opportunities and challenges related to the use of the technology within the clinical context.

Objective: We aimed to explore the relevant knowledge and understanding of the subject of AI in medicine and specify curricula teaching content within medical education.

Methods: For this research, we conducted 12 guideline-based expert interviews. Experts were defined as individuals who have been engaged in full-time academic research, development, or teaching in the field of AI in medicine for at least 5 years. As part of the data analysis, we recorded, transcribed, and analyzed the interviews using qualitative content analysis. We used the software QCAmap and inductive category formation to analyze the data.

Results: The qualitative content analysis led to the formation of three main categories (“Knowledge,” “Interpretation,” and “Application”) with a total of 9 associated subcategories. The experts interviewed cited knowledge and an understanding of the fundamentals of AI, statistics, ethics, and privacy and regulation as necessary basic knowledge that should be part of medical education. The analysis also showed that medical students need to be able to interpret as well as critically reflect on the results provided by AI, taking into account the associated risks and data basis. To enable the application of AI in medicine, medical education should promote the acquisition of practical skills, including the need for basic technological skills, as well as the development of confidence in the technology and one’s related competencies.

Conclusions: The analyzed expert interviews’ results suggest that medical curricula should include the topic of AI in medicine to develop the knowledge, understanding, and confidence needed to use AI in the clinical context. The results further imply an imminent need for standardization of the definition of AI as the foundation to identify, define, and teach respective content on AI within medical curricula.

Introduction

Background

Artificial intelligence (AI) has been of broad scientific interest in medicine for over a decade. This is reflected in the publication of more than 18,000 scientific publications mentioning AI-related terms in that time. AI is expected to revolutionize health care systems around the world. Apart from the economic benefits, AI is expected to make health care more efficient for both patients and health care professionals [1]. Improvements are expected to reduce clinician's workload and leave more time for patient-practitioner interaction [1,2].

With increased public and scientific interest, research into the potential challenges of AI is becoming more commonplace. Recent developments in the use and handling of algorithms in AI applications have raised highly relevant ethical concerns that need to be addressed, in addition to crucial questions regarding patient safety and data [3]. These include questions regarding potentially biased decision-making, the liability in case of any mistakes, and effects on the physician-patient relationship [4].

Researchers propose that addressing potential challenges regarding the use of AI in medicine requires adequate knowledge of the technology [5,6]. Furthermore, studies have shown that early acquisition of knowledge and competencies can increase the acceptability of new technology like AI [7,8]. Recent publications suggest that since medical education is considered to be the basis of the medical profession, integration of AI into the curriculum must occur early and comprehensively [9].

To prepare future generations of physicians for the use of AI within the rapidly changing health care system, education needs to adapt to the new challenges. As the development of new curricula modules and teaching content is a time-intensive and complicated process due to traditional structures and accreditation procedures, significant research is needed to define relevant competencies and teaching content regarding AI in medicine.

Defining AI

AI has been a topic of interest in computer science since the 1950s [10]. However, due to the often-prevailing heterogeneity in the definition of AI on the part of science and the public, it is essential to present the definition of AI on which this publication is based. This will facilitate not only the interpretation of the following results but also the discussion that follows.

A distinction can be made between so-called strong AI and weak AI. "Strong AI" defines an AI whose intellectual abilities are comparable to those of humans [11]. However, a uniform definition of AI is hampered by the lack of a uniform definition of intelligence as such, which also affects the feasibility of "strong AI" [12]. The term "weak AI" is used to define an AI that is capable of performing certain tasks that may be comparable to humans due to its selective and specific "intelligence" [13]. The "weak AI" can be further divided into the so-called symbolic AI and statistical AI [13]. While "symbolic AI" is based on rules or instructions predefined by humans for the execution of a certain task, "statistical AI" aims

to establish correlations that can be established from patterns in the analyzed data itself.

The application areas of "symbolic AI" in medicine mainly include rule-based expert systems, where the rules to be followed by the AI have been previously defined by experts. Clinical decision support systems can be used in patient care, for example, to support doctors in diagnosis and treatment [14]. The subfield of "statistical AI" also includes so-called machine learning (ML), which is the focus of scientific research, especially in the field of medicine. The core of ML is the ability to learn from data without being explicitly programmed to do so. ML also includes the subarea of so-called deep learning, in which artificial neural networks are used to develop information processing similar to that of the human brain [13]. Current application areas of ML in medicine include, for example, the analysis of image-based data in terms of detecting skin cancer or suspicious lesions in mammograms [1,15]. Although there is research interest in developing applications based on "strong AI" to be used in the field of medicine, there are currently no established use cases [16].

The present publication is based on the definition of "weak AI" with its subdomains and all results should be interpreted against this background.

Objective

The study was conducted to explore essential knowledge and understanding regarding AI in medicine, relevant to define curricula teaching content within medical education. The results should provide the foundation for the improvement of the education of medical students and the medical curriculum.

Methods

The following section of this study aims to provide a detailed description of the study design, data collection, and data analysis techniques used in this research. The methods used in this study were chosen to ensure the validity and reliability of the results and to ensure that ethical standards were met.

Study Setting

The study, conducted from September to November 2022, aimed to identify relevant knowledge and understanding of AI-related teaching content in medical education using semistructured expert interviews. From the total of 68 initially identified and contacted experts in the field of AI in medicine and health care (including information technology, medical informatics, and medicine), we were able to include 12 in this study. Most experts were based in Germany (n=10), with 2 experts being included from Austria. For the qualitative data collection, we defined experts as individuals who have been engaged in full-time academic research, development, or teaching in the field of AI in medicine for at least 5 years.

Experts were recruited by email and personal recommendation by the participants. Of the total of 12 included experts, half were primarily working in the field of research and practical development of AI-based applications in the field of medicine (eg, a researcher at the German Research Centre for Artificial Intelligence). The remaining 6 experts were primarily associated

with teaching and research in the field of medical informatics, AI, and digital medicine as part of the medical curriculum (eg, professor for medical informatics). As the experts were primarily recruited by email, an email address that was not publicly accessible through a web-based search was an exclusion criterion.

Additional exclusion criteria were no or less than 5 years of experience in the field of AI in medicine, a lack of consent to the transcription or voice recording as well as a missing current or recent involvement in projects related to the research, development, or teaching of AI in medicine.

Ethics Approval

The Research Committee for Scientific Ethical Questions (RCSEQ) of the UNITI TIROL – Private University for Health Sciences and Health Technology, Hall in Tirol, Austria, granted ethical approval for the study.

Data Collection

Web-based interviews were conducted, using the Cisco Webex Meeting application. The meetings were recorded using an analogous voice recorder. We obtained consent from the participants before conducting the interviews, including their agreement to be recorded and their data to be used for research purposes. As part of the interview, a semistructured guideline was used. The guideline included questions about the experts’

education and experience in AI, the anticipated impact of AI in medicine, as well as key competencies required for use of AI in medicine, and possible teaching content (please see the supplementary information for the interview guideline). On average, the interviews lasted for 35 minutes.

Data Analysis

The recorded interviews were transcribed manually with the help of the transcription software f4transkript and a transcription service provider was used to transcribe some of the transcripts. Transcription followed the established rules of Dresing and Pehl [17]. To analyze the transcripts, qualitative content analysis by Mayring with inductive category formation was used with the help of the software QCAmap (version 1.2.0) and Microsoft Excel (version 16.66) [18]. The data were coded and categorized based on themes related to the objective of this study.

Results

As a result of the qualitative content analysis, we defined 3 main categories (“Knowledge,” “Interpretation,” and “Application”) with a total of 9 subcategories. Each of the subcategories is defined by quotes from the participants to highlight the procedure and the original meaning. An overview of the 3 main categories with all associated subcategories is shown in Table 1.

Table 1. Overview of the 3 defined main categories with the associated 9 subcategories.

Main categories	Subcategories
Knowledge	<ul style="list-style-type: none">• Basic understanding of artificial intelligence• Statistics• Ethics• Data protection and regulation
Interpretation	<ul style="list-style-type: none">• Critical reflection• Associated risks• Data basis
Application	<ul style="list-style-type: none">• Practical skills• Trust

First Main Category: “Knowledge”

Based on the results of the qualitative content analysis, the first main category was defined. Given the interdisciplinary data collection, the “knowledge” main category summarizes suggested knowledge, which medical students should learn regarding the topic of AI in medicine as part of their education.

Subcategory 1: “Basic Understanding of AI”

The first subcategory “basic understanding of AI” highlights the need for basic knowledge and definitions, without an in-depth understanding:

But that's not, in my opinion, about people really understanding the technology down to the smallest detail and being able to implement and train on things themselves. I don't think they need that. [Interview 7]

Subcategory 2: “Statistics”

The second subcategory “statistics” relates to the good statistical knowledge needed to understand AI, which was mentioned by half of the experts.

The basis is statistics. (...). So that's the basis, because these learning AI methods are all based on statistics. [Interview 5]

This subcategory should also account for the importance of understanding probabilities and their application within medicine. Especially with AI-based applications, statistical knowledge will play a key role in the interpretation of results, which will be further addressed in the second main category.

Subcategory 3: “Ethics”

Half of the interviewed experts mentioned the need for an understanding of ethical competencies related to the use of AI in medicine, which is captured in the third subcategory “ethics.”

And then just ethical competencies and I think that has a high requirement (...) [Interview 10]

The use of AI-based applications in medicine requires adequate ethical competencies to address the new challenges arising through the interaction with patients and the usage of their data. This does not only refer to the well-known “black-box” phenomena of deep learning or potential bias through unrepresentative training data but rather addresses the topics like the medical self-image or the physician–patient relationship too. Although ethics has a long tradition within medical curricula, it also needs to adapt to new technological developments in medicine to address associated challenges and discussions.

Subcategory 4: “Data Protection and Regulation”

The last subcategory “data protection and regulation” of the first main category summarizes the need for an understanding of data protection laws and regulations concerning the use of AI in the clinical context, mentioned by 4 of the interviewed experts.

(...) where we have to have a good idea of how we can use it, but also what the legal limitations of the whole thing are. [Interview 10]

The need for an understanding of data protection laws does not only apply to the use of AI in medicine but is of increasing significance due to the accelerated digitalization of medicine. An understanding of the regulation regarding the use of AI in medicine can help to prevent uncertainties and potential disapproval by users.

Second Main Category: “Interpretation”

The second main category “interpretation” accounts for the high importance to interpret and evaluate the results provided by AI-based applications in medicine. This main category summarizes the statements related to the evaluation of results and should highlight the importance of sufficient knowledge and competencies needed to address all associated challenges.

Subcategory 1: “Critical Reflection”

The first subcategory “critical reflection” addresses the need for adequate knowledge and understanding to question the results yielded from AI-based applications critically.

(...) also of the possibilities to critically question these things. [Interview 4]

The ability to critically reflect and question the results shows the importance of adequate teaching of content relating to AI in medicine. As with any traditional technology or application, AI-based applications are not free of mistakes, which in the clinical context can have significant consequences.

Subcategory 2: “Associated Risks”

As users need to be aware of potential consequences and risks associated with the results provided by AI, the second subcategory “associated risks” reflects the answers of 5 of interviewed experts:

(...) also what are the, yes, risks? What can go wrong? Well, the AI also makes mistakes, of course. [Interview 2]

One of the most mentioned risks was related to false-positive results provided by AI. Without any critical questioning of the results, this can lead to unnecessary treatments for the patients. Although this might be of minor significance in the case of additional physical examination, it could lead to additional exposure to radiation or punctations. Although false-positive results can lead to more imminent negative consequences, the mentioned consequences of false-negative results can be of major significance too in case a disease is not recognized and treated. False-negative or positive results highlight the need to be aware of the associated risks related to the results of AI-based applications in medicine. Furthermore, critical reflection of the results is not only connected to potential associated risks, but rather to an understanding of the data that were used to train AI applications.

Subcategory 3: “Data Basis”

The third subcategory of the second main category “data basis” represents the statements of 4 of the experts and describes the need for a good understanding and reflection of the data used in the development process of the AI-based application.

And, of course, you also have to think about the data that might be fed into it now, do they make sense? Are they representative? [Interview 2]

Both are important requirements to interpret the results and are closely associated not only with the other subcategories of this main category but rather with the subcategories from the first main category too. Without a basic understanding of statistics and how AI-based applications work, it is hard to understand the need for representative data samples. Potential bias makes ethical competencies necessary to interpret and critically question the results based on the data basis. This subcategory does not only refer to the need for an understanding of whether the data basis is representative of the current patient, but rather the imminent need to understand that current AI applications have very narrow use cases. To prevent false diagnosis and associated consequences, it is necessary to critically reflect on the unreliable results that can arise from deviation from the specific use case.

Third Main Category: “Application”

Analysis of the interviews yielded a third main category named “application.” This category comprises 2 subcategories and summarizes the requirements to apply AI-based applications in clinical practice.

Subcategory 1: “Practical Skills”

The first subcategory “practical skills” addresses the practical skills required, to use AI-based applications of any kind.

In clinical practice, the most important thing is actually the practical application. [Interview 1]

This subcategory further includes basic technological understanding and skills needed, to apply any software application. Based on the feedback from half of the interviewed experts, this includes for example competency to use hardware

like desktop computers, including keyboard and mouse or operating software used in the clinical context. Moreover, this subcategory summarizes the knowledge and understanding needed to apply AI software within the clinical workflow. Users need to understand whether it makes sense to use the applications and how they can be used to improve the workflow in clinical practice.

Subcategory 2: “Trust”

The second subcategory “trust” represents a base layer needed to use any technology. This subcategory relies on adequate knowledge (first main category) and teaching within the medical curricula. The absence of teaching as part of the medical curriculum could further lead not only to the lack of trust and potentially the disapproval of the application, but could also lead to a blind trust, which can have significant consequences as part of the interpretation of results.

Creating trust, but not blind trust. [Interview 12]

Creating trust not only concerning the use of AI-based applications but rather trust regarding the own competencies in the process of applying AI-based applications within the clinical context is one of the challenges that can be addressed as part of medical education.

Discussion

Principal Findings

The results indicate the significance of the integration of teaching content regarding AI as part of the medical curriculum. All experts interviewed agreed on the importance of teaching AI content in the medical curriculum, which echoes the current state of literature [6,8,19]. Although an interdisciplinary approach to data collection was chosen, there was significant agreement on the relevant knowledge and competencies required to use AI in the clinical context.

This agreement is reflected through the definition of the 3 main categories (“Knowledge,” “Interpretation,” and “Application”). Most experts recommended that medical students should only receive basic knowledge of current AI models and terminology, as they will not be required to develop or train AI-based applications themselves, which is also in line with recommendations of current publications [6,20]. However, the experts disagreed about the definition of the knowledge that medical students should acquire as part of medical education. For example, some experts were convinced that the responsibility of ensuring the ethical and unbiased development of AI-based applications falls on developers and companies, rather than on medical students, and therefore the need for teaching ethical aspects of AI in medicine is considered to be low. Current publications suggest that even though developers of AI-based applications should do their best to consider ethics during the whole development process, users must be aware of potential ethical issues and challenges arising through the use of AI in medicine [21-23].

The practical challenges and barriers of implementing new teaching content, such as the need for the renewal of accreditation or sufficient knowledge of the teaching staff,

further reinforce the recommendations of the experts to only facilitate a basic level of knowledge acquisition of AI as part of the medical education [24]. The experts interviewed for this study agree on the need for opportunities to specialize in AI based on the student’s interest and the requirement for ongoing training programs and extracurricular activities suggested by current publications [7,20,25]. The transfer of knowledge on the topic of AI in medicine is required to build an understanding and competencies needed to interpret the results provided by an AI-based application and apply the new technology within the clinical context.

For many of the interviewed experts, the ability to interpret results provided by AI applications concerning the data basis and the associated risks is highly important when it comes to preferred teaching outcomes. The results from this study confirm the imminent need for an early and conscientious implementation of curricula teaching content on AI, as suggested by earlier studies [9,26,27]. For example, a study published in 2021 found that >90% of medical students anticipate new social and ethical challenges related to the use of AI in medicine [28]. Moreover, current publications on the knowledge and perception of medical students concerning AI show that the overall level of confidence and knowledge is comparably low, given the anticipated impact in the field of medicine [28-30].

Lack of Standardization

The experts’ statements reveal a disagreement and lack of standardization in the definition of AI. Recent publications on the integration and teaching of AI within medical education commonly lack a specific and dedicated definition of AI [6,8,19]. Given that the definition of AI should be considered the necessary foundation to identify, define, and teach respective content on AI within medical curricula, the lack of standardization has further limited the comparability of current scientific publications significantly. For example, the demanded awareness of potential limitations, risks, and opportunities within the scientific literature and the experts’ statements of this study may vary depending on whether applications based on statistical or symbolic AI are considered [6,19].

The need for standardization in the definition of AI as a foundation for related teaching content is further emphasized by the potential ethical challenges and issues that may arise from the use of different types of AI in a clinical context. For example, in the context of bias, clinical decision support systems can be subject to bias arising from the unintended transfer of existing bias on the part of the developers [31,32]. Focusing on applications based on ML as part of statistical AI per definition, there is an imminent risk for bias originating from unrepresentative data sets used in the training process of the applications [33]. This highlights the importance of clearly defining and distinguishing between the various types of AI (eg, statistical or symbolic AI) to effectively address these ethical issues.

Although the integration and teaching of AI as part of medical education have been of increased scientific interest in recent years, further highlighting the need for early and adequate education of medical students, the available research is still limited [6,8,19,34]. The comparability and practical implications

of current research are further limited not only due to a lack of standardization in terms of the definition of AI and possible teaching content but rather due to differences in the structure of medical education between different countries in general [19]. In Germany for example, there has been an increasing effort to define and implement AI-related competencies and learning objectives as part of medical education [35]. The recommended AI-related learning objectives are well aligned with the results of this study. Especially, the need for basic knowledge about AI models and the importance of an understanding of the data basis as well as the practical application can be confirmed by our findings [35]. But due to the lack of a uniform definition of AI within the scientific literature, the experts' statements regarding AI models and the recommended teaching content as well as associated competencies varied in this study. Agreement on the terminology of AI and the related teaching content is especially important, as medical education should aim to provide a comparable level of knowledge and competencies for all students.

The results of this study highlight the need for comparability, as the experts' statements not only confirm the results of current literature but further specify and highlight the importance of awareness of associated risks, critical questioning of the results, as well as the significance of basic technical and technology skills [20,25,36]. Furthermore, the results presented highlight the importance of medical education to create trust for AI-based applications, which is associated with the acceptance of the technology by its users. The highlighted significance of trust as a requirement for acceptance and the importance of being able to interpret the results is also a distinguishing feature in comparison with other publications [5,8]. Because of the significance of trust in AI on the part of the users, the need for standardization in defining and teaching AI within medical education becomes imminent, as inconsistency can lead to uncertainty and potential disapproval of the technology.

Limitations

There are several limitations of this study. Using qualitative research methods, the level of generalization is limited due to a small sample size. Although we sought an interdisciplinary approach to the data collection, the results of the study still represent the subjective opinions of the participants. Furthermore, the results are likely to be subject to a selection

bias, as no randomization was used and participants were recruited through recommendation. As only a limited number of standardized questions within the data collection were used, interviewer's bias is also possible. Additionally, as the data collection was conducted through a web-based service provider, technical difficulties may have affected the quality of the collected data.

Conclusions

This study aimed to explore and define relevant knowledge and understanding concerning the subject of AI in medicine as part of the medical curriculum. The results of the study, based on qualitative content analysis of expert interviews, indicate that knowledge and understanding of the fundamentals of AI, statistics, ethics, and privacy and regulation should be part of medical education. Furthermore, medical students need to be able to interpret and critically reflect on the results provided by AI, considering the associated risks and data basis. The development of trust in AI as well as the acquisition of related practical skills, including the need for basic technological skills, should be an indispensable part of medical education.

As AI in medicine is likely to become increasingly significant in the future, medical users will need adequate knowledge and understanding to use it effectively. Due to the new opportunities and challenges associated with the use of AI-based applications in medicine, medical education needs to adapt to those changes, to provide future generations of physicians with the necessary knowledge and competencies. The research aims to emphasize the importance of integrating teaching content related to AI into the medical curriculum. The results provide implications for the creation of new teaching content based on interdisciplinary data collection. Furthermore, the results further imply a need for standardization in the definition of AI as a foundation for associated teaching content and the integration of AI into medical education. Subsequent research should explore the practical implications of this study and how the results can be transferred into the medical curriculum. Furthermore, research and the development of tools are needed to assess the current knowledge and competencies of medical students regarding the use of AI in medicine. This will not only have practical implications for the creation of new teaching content but will rather allow an assessment of the success of new teaching content in the future.

Abstract

Background: The high school-to-medical school education transition is a significant milestone in the students' academic journey, which is characterized by multiple stressors. Although this crucial transition has been repetitively explored, the concept of proactively intervening to support this transition is still novel.

Objective: In this study, we investigated the efficacy of a web-based multidimensional resilience building intervention in developing selected soft skills that are believed to drive the learner's success in any learning setting. The association between the students' academic performance over time and their proficiency in selected modules addressing skill sets, including Time Management, Memory and Study, Listening and Taking Notes, and College Transition, was also assessed to test the impact of the intervention on the students' learning.

Methods: A longitudinal study was conducted on 1 cohort of students of a Bachelor of Medicine, Bachelor of Surgery program (MBBS). The medical students were offered a learning intervention around 4 skill sets during the first year of the 6-year program. Quantitative analyses were conducted using deidentified data, relating to the students' proficiency in the 4 skill sets and to the students' academic performance: grade point average (GPA). Descriptive analyses constituted computing an overall score of skill sets' proficiency (of all 4 selected skill sets). The mean and SD (and percentage of the mean) were also calculated for each skill set component, independently, and for the overall score of skill sets' proficiency. Bivariate Pearson correlations were used to assess the extent to which the academic performance of the students can be explained by the corresponding students' level of proficiency in each skill set component and by all 4 sets together.

Results: Out of the 63 admitted students, 28 participated in the offered intervention. The means and SDs of the annual GPA of the students for years 1 and 2 (GPA range 1-4) were 2.83 (SD 0.74) and 2.83 (SD 0.99), respectively. The mean and SD of the cumulative GPA toward the end of year 2 was 2.92 (SD 0.70). Correlation analysis showed that the overall score of skill sets proficiency was significantly associated with the annual GPA of year 1 ($r=0.44$; $P=.02$) but was not associated with their annual GPA of year 2. The cumulative GPA (toward the end of year 2) appeared to be significantly associated with the overall score ($r=0.438$; $P=.02$).

Conclusions: Developing purposefully selected skill sets among medical students holds the potential of facilitating the high school-to-medical school education transition and is likely to improve their academic performance. As the medical student progresses, the acquired skills need to be continuously reinforced and effectively built upon.

KEYWORDS

transition; undergraduate; medical; education; academic performance; self-regulated learning

Introduction

High school-to-medical school education transition is a significant milestone in the students' academic journey. The transition entails a physical and mental multidimensional adaptation to higher education frameworks and their expectations, self-regulated behaviors, and sociocultural and environmental influences [1]. A teacher-driven structured, planned, monitored, and evaluated school program leaves the school-leaver unprepared for becoming an independent autonomous sophomore, and for inhabiting an open campus with a potentially experimental lifestyle [2]. This highlights the importance of self-regulated learning (SRL), and of crafting nurturing environments that inspire and empower students to create their own learning pathways. SRL relates to 5 elements of the individual students: cognitive and metacognitive, behavioral, and motivational and emotional [3]. Self-regulated students are recognized as active learners, managing their own learning via monitoring and the use of metacognitive strategies [4]. Multiple transition points in health professions' education, first at admission to medical school, second from preclinical to clinical years of learning, and finally from clinical years to practice, demand adaptation by the students and nurturing by the educators and by other environmental support mechanisms [5-10].

The students' perception of their capabilities of coping with their workload affects their ability to achieve their academic goals [11,12]. A framework for comprehensive and coherent development of learning proposes a preinduction web-based course followed by a carefully designed induction phase with increasing personal tutor support and constant self-reflection by the student [13,14].

The difficulties students confront are variably coped with depending upon the entry level of a medical program (ie, undergraduate or graduate) and on individual-level characteristics. In all cases, unfavorable impacts can range from suboptimal academic performance to adverse health outcomes, requiring attempts at prevention, early detection, and mitigation [15]. Although this crucial phase of the educational transformation is both documented and has earned scientific exploration, programs that bridge and support the high school-to-medical school education leap are a recent phenomenon [14]. Outcomes of such interventions have also not been extensively published, discussed, or translated into policy [2]. A "learning to learn" framework supported moving away from the deficiency model of focusing on remedying missing skills during the high school-to-medical school education transition [2]. Instead, a "holistic subject-specific approach" that supports the engagement and commitment of academic teachers to ensure the growth of independent learners was proposed.

This study was therefore undertaken to implement and analyze the impact of a web-based multidimensional resilience building foundational program, designed to foster students' SRL. This intervention ran synchronously during the first curricular year of an undergraduate Bachelor of Medicine, Bachelor of Surgery program (MBBS). Through this study, we investigated the efficacy of this intervention. We also analyzed the association between the students' proficiency of 4 purposefully selected sets of skills and their academic performance over time. Accordingly, our research question was: is the proficiency in the selected skill sets associated with the students' academic performance?

Methods

Ethical Considerations

The ethics approval for this study was granted by the Mohammed Bin Rashid University of Medicine and Health Sciences-Institutional Review Board (MBRU-IRB-2021-58). Informed consent was obtained from all the participants. All methods were performed in accordance with relevant guidelines and regulations. Consent for publication was not applicable as there are no individual details, images, or videos.

Context of the Study

The study was conducted at the College of Medicine at the Mohammed Bin Rashid University of Medicine and Health Sciences (MBRU) in Dubai, United Arab Emirates, on a cohort of undergraduate medical students. Students are admitted into the MBRU 6-year MBBS directly from high school with no premedical foundation year. The MBBS is divided into 3 phases, each of which has several components (phase 1: 1 year; phase 2: 2 years; and phase 3: 3 years). Student progression to the next phase is subject to successful completion of the progression requirements along with the achievement of a minimum cumulative grade point average (cGPA) at the end of the preceding phase.

Description of the Intervention and Study Participants

In the academic year 2018-2019, a total of 63 students (52 females and 11 males) were admitted to the MBBS at MBRU. The cohort intake was homogenous with respect to age and academic credentials, given the standardized admission selection processes and procedures to test cognitive and noncognitive abilities. To ease the transition of the high school students admitted to the medical school, and to enable personal, academic, and professional development, the students were offered a web-based multidimensional resilience building intervention, which is a proprietary commercial program (Pearson College and Career Readiness Solution-2018) [16].

The adapted intervention was developed by the system provider in alignment with the personal and social capabilities framework. This framework pinpoints crucial sets of soft skills that are believed to increase the users' awareness, happiness, empathy,

and resilience. All of which are necessary for a successful high school-to-medical school transition [17]. The tool's developer identified 6 common categories of soft skills that can drive the learner's success in any learning setting: (1) collaboration and teamwork; (2) communication; (3) critical and creative thinking; (4) leadership; (5) self-management/initiative and mindset; and (6) social responsibility [18]. The proposed digital tool consists of 19 web-based modules listed in Figure 1. Multimedia Appendix 1 provides a detailed description of the tool.

The implementation of the intervention was spearheaded by an Advising Group composed of a selection of students' academic advisors from the MBBS (all of whom are faculty members), in addition to professional administrative and technical members from the MBRU. The intervention was implemented in alignment with the SRL theories. Accordingly, the adaption occurred in 3 phases that are common across the main theories of SRL: preparatory, performance, and appraisal [19,20].

Each student was given a unique number and access code to the web-based tool on the orientation day at the start of the respective academic year. The use of the tool was not mandated. The students were offered an information session conducted during the orientation day to introduce the tool and to address the students' queries. The participants' first exposure was during the new students' orientation at the beginning of the academic year, where representatives of the advising group facilitated the

students in the initiation of the preparatory phase. Thereafter, the students were enabled to deploy the 4 components integral to SRL: task definition, goal setting and planning, enacting study tactics and strategies, and metacognitively adapting studying [4]. Throughout the performance phase, the academic members of the advising group played the role of mentors, where they assumed that the students are self-directed, intrinsically motivated, have previous knowledge and experience, will form mental models through this learning and development experience, and use analogical reasoning as their knowledge base evolves [21]. Thus, throughout the assigned 6 weeks, 3 reflection sessions (1 every 2 weeks) were conducted. This was done to foster SRL in the context of collaborative learning [22]. Four out of the 19 modules of the adapted web-based program were prioritized and purposefully selected as part of this transition. The selection was based on the perceived deficiencies identified at the same learning stage in previous intakes of the respective MBBS. Accordingly, the selected modules addressed the following skill sets: Time Management (TM), Memory and Study (MS), Listening and Taking Notes (LTN), and College Transition (CT). The tool is supplemented with pre- and postassessments, and each module has learning objectives where the attainment of the corresponding objectives is gauged by the post-assessment. The outcome of the assessment is reflected on a "Mastery Report" generated for individual students as the *appraisal phase*.

Data Collection

Data related to the students' proficiency in the 4 selected sets of skills were extracted from the reporting dashboard (from the corresponding "Mastery Report"). This is linked with grade book, embedded in the software of the web-based tool and corresponds to the learning outcomes of the courses (Figure 1). Each set of skills corresponds to a module, with a list of preset learning objectives. Attainment of a learning objective is represented with "1" (versus "0"). The number of learning objectives varies from one module to another. For the set of skills under investigation, the number of learning objectives was as follows: 8 for TM, 9 for MS, 8 for LTN, and 9 for CT.

As for the data related to the students' academic performance, the cumulative or semester grade point average (GPA) for the students was retrieved from the student information self-service. The extracted information from the students' records was retained in such a manner that subjects cannot be identified. Data were coded and linked through identifiers to the subjects.

Data Analysis

The quantitative data were analyzed using SPSS for Windows (version 27.0; IBM Corp).

The descriptive analysis constituted computing an overall score of skill sets' proficiency (of all 4 selected skill sets). The highest

possible score is 34 (ie, the sum of the learning objectives, where attaining the respective objective corresponds to “1” and failing to attain it corresponds to “0”) and the least possible is 0. Then, the mean and SD (and percentage of the mean) were calculated for each skill set component, independently, and for the overall score of skill sets’ proficiency. The validity tests of Cronbach α and the principal component analysis (PCA) of the Kaiser-Meyer-Olkin and Bartlett’s test were performed to ensure the internal consistency and check the external variance, respectively, of the overall score of skill sets proficiency, and that of each skill set component independently (since each component is comprised of a set of skills; Figure 1).

To select the appropriate comparative analysis tests, a test of normality (Kolmogorov-Smirnov) was conducted for the annual GPA of years 1 and 2 and of cGPA. The data of the annual GPA

of year 1 and that of the cGPA turned out to be normally distributed ($P=.11$ and $P=.15$, respectively). As for the data of the annual GPA of year 2, it turned out to be nonnormally distributed ($P=.005$). Given the fair sample size, the bivariate Pearson correlations were used to assess the extent to which the academic performance of the students (GPA1, GPA2, and cGPA) can be explained by the corresponding students’ level of proficiency of each skill set component and by all 4 sets together (ie, the overall score of skill sets’ proficiency).

Results

Out of the 63 admitted students, 28 (27 females and 1 male; 44.44%) participated in the above-mentioned intervention (ie, 44.44%). Table 1 presents the participants’ demographic details.

Table 1. Participants’ demographic details (N=28).

Items	Values, n (%)

Non-UAE	16 (57)
High school classification	
Private	28 (100)
Government	0 (0)
Curriculum	
American	17 (60)
British	5 (18)
Indian	3 (11)
International Baccalaureate	3 (11)

^aUAE: United Arab Emirates.

The reliability score of Cronbach α for the overall score of skill sets’ proficiency was 67%. When each skill set component, TM, MS, LT, and CT was analyzed independently, and Cronbach α scores were 93%, 88%, 69%, and 81%, respectively. The percentage of the total average of the overall score of skill sets’ proficiency turned out to be 32.15%, as per Table 2. According

to the PCA (Kaiser-Meyer-Olkin Measure of Sampling Adequacy), most of the variance can be explained by the instruments of each skill set component and the overall score of skill sets proficiency, which means this instrument is not only reliable but also, according to Bartlett’s test of Sphericity, valid to measure what it is intended to measure ($P<.001$).

Table 2. The percentage of the mean and SD for each skill set component and for the overall score of skill sets' proficiency.

Module	Items (ie, highest possible score), n	Mean (SD)	Percentage of the mean
TM ^a	8	2.46 (2.82)	30.75
MS ^b	9	3.36 (2.87)	37.33
LTN ^c	8	2.39 (1.93)	29.88
CT ^d	9	2.71 (2.42)	30.11
Overall	34	10.93 (7.20)	32.15

^aTM: Time Management.^bMS: Memory and Study.^cLTN: Listening and Taking Notes.^dCT: College Transition.

The mean and SDs of the annual performance of the students for years 1 and 2 on a GPA range of 1-4 were 2.83 (SD 0.74) and 2.83 (SD 0.99), respectively. The mean and SD of the cGPA at the end of year 2 was 2.92 (SD 0.70). In Table 3, the bivariate Pearson correlations showed that the overall score of skill sets proficiency was significantly associated with annual academic performance of the students in year 1 ($r=0.44$; $P=.02$) but was

not associated with their annual academic performance in year 2 ($r=0.327$; $P=.09$). Yet, the cGPA (toward the end of year 2) appeared to be significantly associated with the overall score ($r=0.438$; $P=.02$). Also, the performance of the students seemed not to be associated with their proficiency scores in each of the components, independently.

Table 3. The output of the bivariate Pearson correlations.

Discussion

Principal Findings and Comparison With Prior Work

The start of the educational journey in medical schools requires building of resilience through early mastery of time management, modification of study methods to cope with quantum of cognitive burden, and evolution toward higher levels of analytical thinking [6,7]. It entails the recognition of the need for self-reliance and peer collaboration, reorientation to resources, and development of the capacity to handle success

and reverses. The medical novice with little prior exposure to disease and death requires a framework of resilience within which they develop a new professional identity [8,9]. Tests of knowledge, skills, and competencies in a medical curriculum require both proficiency and test understanding, which are key to success and contribute to perceived self-worth [10].

In a scoping review of learning support intervention programs, during the first year of medical school, it was found that interventions could be identified as proactive or reactive addressing deficits or promoting development [14]. The interventions addressed knowledge, personal and professional

learning skills, and program learning elements and were delivered through a variety of institutional stakeholders and student-centered initiatives. This study showed that the intervention of developing the following skill sets, TM, MS, LTN, and CT, constituted an efficacious bridge in terms of facilitating high school-to-medical school transition. The proficiency of the students in the respective skill sets, altogether, was significantly associated with enhanced performance in the first year (ie, annual GPA-Y1) and cumulatively toward completion of the second year of the MBBS (ie, cGPA-Y1 and Y2). The results show that entry to an undergraduate medical program entails a transition that calls for students' adaptation to the medical curriculum and a process of professional identity building [8,23]. In fact, this study established that developing the combination of all 4 selected skill sets is what adds value (together and not in isolation) toward adapting to this transition, as reflected in the participants' academic performance. Therefore, the web-based intervention under investigation offered a holistic, multipronged solution to a compounded transition challenge, where it was evident that the integrated whole, in terms of the educational offerings, was more than the sum of its individual components.

The intervention, investigated in this study, appeared efficacious in the first year (ie, annual GPA-Y1) but not in the second year (ie, annual GPA-Y2). In other words, the proficiency in the selected skill sets successfully predicted academic performance in the first year. However, as the students progressed to the second year, the true, intended effect of the intervention appeared to have dissipated. This finding supports the provision of a refreshing course to reinforce the benefits initially accrued. It would also be helpful to offer the students complementary learning opportunities of more advanced and focused skill sets, appropriate to their next stage of learning. Of note, study time and study habits are known to have a variable relationship to performance [6]. In a previously conducted study, student performance in medical school appeared to be better correlated with learning *approaches* rather than learning *styles* [24]. Thus, focusing on adaptive techniques that encourage strategic and deep learning approaches is likely to be most effective in supporting students as they progress in their educational trajectory.

This study also showed that having the intervention was better than not having it. Although the intervention was not efficacious in the second year (ie, annual GPA-Y2), adapting this intervention was still considered beneficial for the students given that the cGPA was significantly associated with the overall skill sets' proficiency. The tools used in the current study, overall and for each skill set (ie, TM, MS, LTN, and CT), independently, all turned out to be internally consistent or reliable and externally valid. In other words, the components of the tools defined by the web-based intervention under investigation (Figure 1) are worth leveraging as a means of evaluating the proficiency of high school graduates in the selected skill sets and their readiness to transition to universities, in general, and medical schools, in specific. This finding reinforces the importance of basing initiatives aimed at high school-to-university transition on SRL theories, which requires fostering the students' motivation and commitment to learn

[25]. It would also add value to consider not only the persons but also their behaviors and environments, as indicated in the triadic analysis of SRL [19].

The efficaciousness of the intervention under investigation encourages medical educators to think of innovative ways to proactively facilitate not only the entry into medical school transition but also the ones that follow. Next, preclinical to clinical transitions bring novel disruptors due to perceived or actual stress of inadequacies or incompetence which demand tackling through nurturing and empowerment [26]. Finally, transition programs to internship, for example, address "professional reflection, consolidation of knowledge, and social, emotional, and ethical growth" beyond the overt curriculum [27]. Transition-to-residency pilot programs have been hailed as acceptable and feasible mechanisms to make the final transition to graduate studies smoother [28]. With this in mind, we propose an adapted framework of transition support that aligns the timing of the transition support and its context in a stepwise and sustainable fashion. In the context of the MBBS, the early transition support could employ tools that boost communication and a self-management or initiative mindset. In the following preclinical years, increasing levels of critical thinking and collaboration are required as enablers for professional growth. Integrated with clinical years and postgraduate training, social responsibility and leadership would determine the development of the persona of the mature health professional along with academic accomplishment and competency in skills. Accordingly, based on the evidence gathered from this study, we propose a stage-appropriate adaptation support system contextualized to a stepwise transition-mitigation approach to supporting student resilience and progression in a medical education degree program.

Limitations and Future Directions

This study has several limitations. First, the intervention (in alignment with the ethical principle of autonomy) was not mandatory but made optional. Thus, it was entirely up to the students whether, or not, they wanted to sign up for the offered opportunity. Although it would have been ideal to obtain a higher engagement rate, it is apparently not uncommon for a good proportion of any 1 student body not to sign up to optional learning opportunities [29,30]. This might have introduced a bias, where, for example, those who chose to take part in the experience were the ones who were more competent and perhaps better at self-directed learning. Second, the participants constituted a sample of a single cohort (with a low response rate). Hence, the generalizability of this study's findings is limited. The findings of this study, however, can be transferred to student populations that are characteristically similar to those under investigation. It will be worthwhile to conduct follow-up studies that compare several such programs across multiple institutions, preferably in different countries. Finally, our study did not focus on nonscholastic aspects of the student experience, which could help evaluate noncurricular stressors that either contribute to or aggravate student nonprogression. Such variables could be of relevance given the complementarity of the social, cultural, symbolic, and economic capitals to the student's capital in determining both the intent to join medical school and the achievement of goal posts (while navigating

medical graduation) [30,31]. A study of such parameters would help in designing a 360-degree plan of action that begins before entry into the medical program, molds to the progression level needs, and in later years, provides seamless support to transit to graduate medical education and the health professions workspace.

Conclusions

This study highlights the importance of developing a contextualized, evidence-driven intervention to proactively nurture purposefully selected skill sets among medical students

to facilitate their education transitions, and in turn their academic performance and progression. Such an intervention should not be perceived as a 1-time learning bridge around high school-to-medical school but rather a series of initiatives that address the specific needs of medical students, depending on the stage of their educational trajectory. This cascade of events will build upon each other, continuously reinforcing the acquired knowledge and skills. We recommend for all such activities to focus on empowering medical students and fostering their capacity for SRL.

Abstract

Background: YouTube is considered one of the most popular sources of information among college students.

Objective: This study aimed to explore the use of YouTube as a pathology learning tool and its relationship with pathology scores among medical students at Jordanian public universities.

Methods: This cross-sectional, questionnaire-based study included second-year to sixth-year medical students from 6 schools of medicine in Jordan. The questionnaire was distributed among the students using social platforms over a period of 2 months extending from August 2022 to October 2022. The questionnaire included 6 attributes. The first section collected demographic data, and the second section investigated the general use of YouTube and recorded material. The remaining 4 sections targeted the participants who used YouTube to learn pathology including using YouTube for pathology-related content.

Results: As of October 2022, 699 students were enrolled in the study. More than 60% (422/699, 60.4%) of the participants were women, and approximately 50% (354/699, 50.6%) were second-year students. The results showed that 96.5% (675/699) of medical students in Jordan were using YouTube in general and 89.1% (623/699) were using it as a source of general information. YouTube use was associated with good and very good scores among the users. In addition, 82.3% (575/699) of medical students in Jordan used YouTube as a learning tool for pathology in particular. These students achieved high scores, with 428 of 699 (61.2%) students scoring above 70%. Most participants (484/699, 69.2%) reported that lectures on YouTube were more interesting than classic teaching and the lectures could enhance the quality of learning (533/699, 76.3%). Studying via YouTube videos was associated with higher odds (odds ratio [OR] 3.86, 95% CI 1.33-11.18) and lower odds (OR 0.27, 95% CI 0.09-0.8) of achieving higher scores in the central nervous system and peripheral nervous system courses, respectively. Watching pathology lectures on YouTube was related to a better chance of attaining higher scores (OR 1.96, 95% CI 1.08-3.57). Surprisingly, spending more time watching

pathology videos on YouTube while studying for examinations corresponded with lower performance, with an OR of 0.46 (95% CI 0.26-0.82).

Conclusions: YouTube may play a role in enhancing pathology learning, and aiding in understanding, memorization, recalling information, and obtaining higher scores. Many medical students in Jordan have positive attitudes toward using YouTube as a supplementary pathology learning tool. Based on this, it is recommended that pathology instructors should explore the use of YouTube and other emerging educational tools as potential supplementary learning resources.

KEYWORDS

pathology; medical students; YouTube; social media; medical education; online resources

Introduction

YouTube, which launched in 2005, gained tremendous progressive popularity as an online video-sharing website, and it remains the most popular social media platform in the world, with more than 8.5 billion monthly visitors. In addition, YouTube.com is the most visited website. Over 2 billion users log in to YouTube each month, and the users consume over 1 billion hours of content daily [1].

Although YouTube was invented as a video-sharing platform for the everyday user, the tendency for educational use has not gone unnoticed. Over time, scores of colleges and universities have established a presence and created their own tips on YouTube by using their own video-sharing web pages called YouTube channels. In March 2009, YouTube announced the launch of YouTube EDU, which was a highly organized collection of YouTube channels synthesized by college and university partners. At the end of YouTube EDU's first year, YouTube EDU had grown to include more than 300 colleges and universities with more than 65,000 videos of lectures, news, and campus life available freely for the public view [2].

Currently, YouTube is considered one of the most popular sources of information among college students. In addition to YouTube videos providing students with immediate information freely, using YouTube videos is noted to improve students' engagement, increase their perception of learning efficacy, enhance and sharpen critical thinking, and aid their deep understanding and visualization of the viewed materials [3,4]. However, traditional teaching using boards, laptop screens, and projectors is progressively declining and becoming more boring to many students. This is becoming obvious, especially with the emergence of different highly interactive technology-based educational and learning tools [5]. Several studies postulated that an effective educational role could be played by technology-based tools such as social media websites including YouTube [6].

Pathology is the study of disease, and it is the bridge between basic and clinical sciences for medical students. It concerns every aspect of patient care, from diagnosis to treatment, and it is an essential science for the clinical practice of future doctors. Given that pathology material is full of gross and microscopic images, it is expected that learning pathology requires more visual methods like YouTube videos and other attractive technology methods that increase visual engagement to enhance learning. A continuously increasing number of

pathology-related videos are available on YouTube. These videos include many recorded lectures, animations, microscopic and gross illustrations, tutorials for gross dissection of anatomical organs, and much more. As previously noted, with a well-organized video, anatomical footage of live patients along with cadavers, medical imaging, plastic models, and diagrams can be used to enhance and solidify the understanding of 3D structures [7]. Additionally, a UK case study about the use of YouTube videos in learning and teaching an introductory course concluded that the use of YouTube was an effective method of supporting learning and surmised that YouTube helps students learn by providing alternative views and opinions on subjects, a variety of delivery mechanisms, and the use of everyday examples to illustrate points [8]. Such reports suggest that the efficient use of YouTube videos as a student learning aid might also be very helpful for building pathological knowledge that is very important for clinical practice.

This study was designed to confirm that medical students in Jordan recognize YouTube as an important medical and, in particular, pathology educational tool. Consequently, this could positively affect student scores in the pathology course. Moreover, we report some challenges faced by students while using YouTube and suggest some recommendations to adopt YouTube as an educational tool in the pathology curricula of universities.

Methods

Study Design and Participants

This descriptive, cross-sectional study was conducted using an online questionnaire targeting second-year to sixth-year medical students in all public universities in Jordan. We followed the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) in conducting this study [9]. Data were collected using web-based questionnaire software (Google Forms). Participants were recruited from August 2022 to October 2022 through social media (Facebook) by posting an invitation to complete the questionnaire after providing a brief description of the study. The link to the questionnaire was included in the invitations that were posted on pages and groups commonly accessed by medical students in Jordanian public universities (eg, university-related pages, study group pages).

Items in the Questionnaire

We used a 10-minute online questionnaire created in Google Forms that was based on current scientific literature by referring

to the literature and included main ideas and primary items relevant to our topic. The face and content validity of the questionnaire were established by review of the questionnaire by 5 experts in the field who provided their feedback and suggested necessary changes. The reliability of the questionnaire was established through pilot testing by collecting data from 20 medical students who were asked to provide their feedback. These students were not included in the study sample.

The questionnaire consisted of 6 attributes. The first section collected participant demographic data, including gender, university, and level of study. The second section included 4 questions on the general use of YouTube and recorded material. The remaining 4 sections targeted the participants who used YouTube to learn pathology including using YouTube for pathology-related content. The second section included a comparison of content and presentation between recorded pathology material (lectures or videos) provided by the faculty of medicine at the student's university and pathology-related YouTube videos viewed by the participant. The comparison used ratings of excellent, good, acceptable, and poor, with an option to choose "not applicable." The third section assessed the prevalence of the use of YouTube for pathology-related content and learning pathological sciences and systems with "YES" and "NO" answers available. The fourth section included 12 questions on perceived value, challenges, and recommendations for using YouTube as a learning tool for pathology. Students were also asked about time spent watching YouTube videos when preparing for pathology-related examinations and reasons for using YouTube as a learning tool for pathology.

Sample Size and Sampling Technique

The sample size was calculated using epiinfoTM v.7.2.4.0 (US Centers for Disease Control and Prevention) [10], a database and statistics program for public health professionals, considering a previous study performed in Jordan with a sample population proportion of 68% [11]. Using a cross-sectional study design, where n is the required sample size ($n = Z^2 (\alpha/2)^2 pq/d^2$), we calculated the sample size based on the following parameters: prevalence of 68%, precision of 0.04, 99% CI, and 5% margin of error. We estimated 577 as the minimum sample size required to represent the true population. A convenience sampling size ($n=699$) was used in this study.

Data Analysis

Frequencies and proportions were used to summarize the data. Comparisons between categorical variables were analyzed using the Pearson chi-square test. In order to examine the factors linked to students' pathology exam scores in terms of YouTube utilization, binary logistic regression analysis was performed. Scores above 70% were considered a sufficient level of proficiency in pathology (true), and scores lower than 70% were considered an insufficient level of proficiency in pathology (false). Statistical significance was set at $P=.05$. SPSS version 26 (IBM Corp) was used to conduct the statistical analysis.

Ethics Approval

Ethics approval was obtained from the Yarmouk University institutional review board (Ref R D\119\12\3460). All study

procedures were conducted according to the principles of the World Medical Association Declaration of Helsinki and its amendments [12]. Participants were informed prior to starting the questionnaire that it was completely anonymous and voluntary and that all data would be treated as confidential.

Results

As of October 2022, a total of 699 Jordanian medical students responded and completed the survey. Of the 699 responses, 445 (63.7%) were collected in Arabic, while the rest were in English. Over 60% (422/699, 60.4%) of the participants were women, and approximately 50% (354/699, 50.6%) of the participants were second-year students. A very good score (81%-90%) in the pathology course was the most often reported score (209/699, 29.9%), followed by 202 good scores (71%-80%). Table 1 describes the demographic characteristics of the participating medical students.

In terms of using YouTube for learning and its relationship with pathology scores, a large proportion of students included in this study (675/699, 96.5%; $P=.31$) acknowledged using it. Similarly, among students who used YouTube in general, very good and good scores were the most frequently described (405/699, 57.9%). Fewer students (623/699, 89.1%) reported using YouTube as a source of general information, with students with very good and good scores being the most frequent to answer this way. Among students who did not use YouTube as a source of learning, using recorded material (lectures or videos) provided by the faculty of medicine at their universities was the least often mentioned source of information (198/699, 28.3%). However, among the students who used the recorded material (lectures or videos) provided by the faculty of medicine, better scores were reported, with very good and good being the most commonly reported scores. When asked if they used YouTube as a learning tool for pathology, the majority of the participants (575/699, 82.3%) responded affirmatively. A comparison of the 2 results (affirmative and negative) revealed that the scores of the students who used YouTube as a source of pathology learning tool were higher, with 428 students scoring above 70%, particularly in comparison with only 90 students scoring the same result but without the use of a YouTube learning source. The detailed results are shown in Table 2.

Concerning the content of the recorded lectures or videos offered by their universities, 233 students rated it as good, a similar number ($n=199$) stated that it was acceptable, and a slightly smaller number ($n=145$) described it as poor. Further, students reported comparable results on the presentation quality of the recorded material for the pathology course (lectures or videos) provided by the college of medicine, with approximately 56% (395/699, 56.5%) reporting that the presentation quality was acceptable or good. However, when asked about the pathology-related YouTube videos, 376 and 424 students evaluated them as "excellent" in content and presentation, respectively. Table 3 shows the perceived value of using university pathology lectures compared with YouTube lectures.

When comparing the attitudes of students toward university pathology lectures with their attitudes toward YouTube lectures,

most participants found that YouTube lectures are more interesting (484/699, 69.2%), contain a lot of animations and pictures (537/699, 76.8%), and could enhance the quality of learning (533/699, 76.2%). In addition, 68% (475/699) of students answered with “yes” when asked if university pathology lectures are not attractive to all students. Table 4 shows the students' attitudes toward university pathology lectures and YouTube lectures.

In terms of the association between the actual use of YouTube to study pathology and students' grades, 323 students said they had been confused when choosing the appropriate pathology information. However, of the 323 students, 193 received good or very good scores, while a few (n=8) received only a 50% score. Only 99 students, on the other hand, claimed that they had not been confused when selecting the appropriate pathologic information. Most of the students (524/699, 75%) achieved a score higher than 70%. Furthermore, when asked if it would be helpful if your instructor chose appropriate pathological YouTube videos in his lectures, most students who had an overall score in the pathology course >70% agreed. Table 5 summarizes the student opinions on the effectiveness of using YouTube in combination with instructor lectures.

Binary logistic regression analysis was used to correlate the factors that influence students' scores. These factors were divided into 3 questions: the first regarding the studied module, the second regarding the type of content, and the third question regarding the time spent watching YouTube videos while preparing for pathology exams. Overall, the majority of these variables were indeterministic and statistically insignificant. Nevertheless, studying the central nervous system via YouTube videos was associated with higher odds of achieving higher scores (odds ratio [OR] 3.86, 95% CI 1.33-11.18; $P=.01$). YouTube-assisted study of the peripheral nervous system, on the contrary, was related to lower odds of achieving higher scores (OR 0.27, 95% CI 0.09-0.8; $P=.02$). Similarly, watching pathology lectures on YouTube was related to a better chance of attaining higher scores (OR 1.96, 95% CI 1.08-3.57; $P=.03$), but watching study tips and pieces of advice were correlated with a decreased likelihood of achieving higher scores (OR 0.47, 95% CI 0.29-0.77; $P=.01$). Surprisingly, spending more time watching pathology videos on YouTube while studying for examinations corresponded with lower performance, with an OR of 0.46 (95% CI 0.26-0.82; $P=.01$). Table 6 shows the binary logistic regression analysis results for the factors that contributed to students' exam performance.

Table 1. Demographic characteristics of the participating medical students (n=699).

Discussion

Principal Findings

The findings of our study are in harmony with those of previous studies published in the literature: that YouTube has evolved into one of the most popular social media platforms utilized by many people worldwide for many general purposes and as a learning tool for students in particular [5,13-17]. This was indicated in our study, as 96.5% of the medical students who participated in the survey in Jordan acknowledged using YouTube, and this was reflected in their scores: Very good and good scores were the most frequently described scores (57.9%). There are many published articles about students using YouTube as a learning tool in different specialties [4,6,8,18], with anatomy as a particularly good example [5,13,19,20]. This led us to explore how medical students use YouTube for pathology

especially because there have been few previous reports about this topic and because pathology and anatomy share many similarities, particularly in terms of visual engagement [5]. The study showed that 82.2% of the students were using YouTube to learn pathology and that the scores of the students who used YouTube as a tool to learn pathology were higher, with 428 students scoring above 70%. Therefore, based on the results of this study and other studies [5,6,13,18,21], YouTube can be a helpful and preferable educational tool for students, and it should be utilized in a very effective way in universities.

YouTube was used mostly to watch pathology lectures and animated pathology videos. In addition, medical students used it to enhance their understanding of gross and microscopic images. Moreover, students were using YouTube to watch surgical operations to see the pathological organs. These examples were not the only viewed content; students indicated

that they were also using YouTube to access study tips and advice videos as well as videos about pathology questions and answers. Further, as in a previous study for anatomy [5], students appear to use YouTube more often to learn about certain topics related to body systems and regions. In our study, students were using YouTube mainly for hematopoietic and lymphoid systems, cardiovascular systems, and other body systems. This might reflect the difficulty of learning these topics and, accordingly, the need to use additional educational resources including YouTube videos. It is worth mentioning that watching YouTube videos to study the central nervous system was associated with higher odds of achieving higher scores but was related to lower odds when studying the peripheral nervous system. This could be attributed to the difficulty of the content in the peripheral nervous system course, the difficulty in memorizing the details of nerves and their distribution, and the possible poor quality of YouTube videos. Surprisingly, spending more time watching pathology videos on YouTube while studying for examinations corresponded with lower performance, and this might be explained by distraction caused by watching many videos, focusing on materials not related to their curricula, watching without memorization, and loss of concentration.

Medical students seem to have a very positive attitude toward YouTube as a pathology learning tool. Almost all the students agreed that they found useful pathology-related information on YouTube and that YouTube helped understand pathology topics, memorize and recall pathological information, and achieve higher scores in pathology-related exams. This combination of memorization, understanding, and visualization is needed for successful learning in most courses, especially those including pictures and images such as anatomy and pathology in medical schools [5,22]. Actually, videos are suggested to have a positive impact on these mental processes. This is fortified by the results of a study in which videos uploaded to an anatomy YouTube channel were reported to be helpful in creating memorable visual images [13]. Moreover, most of the students in our study encouraged their faculty members to make their own pathology YouTube channels to be a reference for them and their colleagues in the future.

Comparison With Prior Work

The content and presentation of pathology-related YouTube videos were found to be superior to those of recorded pathology lectures or videos. This was mainly attributed to including animations and pictures and using a variety of methods for illustrations. Moreover, medical students perceived pathology lectures on YouTube as more attractive, informative, and interesting, and they enhanced the quality of pathology learning, which is consistent with many previous studies [4,5,13-17]. This indicates the importance of the available online platforms including YouTube as a supplementary educational tool. However, it should be noted that, although YouTube can offer educational value, it should not be solely relied upon for pathology learning, passing pathology exams, and obtaining the needed information for the curricula, as supported by many students in our study and a previous study on embryology and histology [13] that found that 34.2% and 25% of students were hesitant to use YouTube to learn embryology and histology, respectively. This suggests that labeled images, true

histopathological slides, and virtual microscopy are preferred over videos.

Moreover, although the recorded material (lectures or videos) provided by the faculty of medicine at their universities was the least often mentioned source of information (198/699, 28.3%), students who relied only on this material still received very good and good scores. This suggests that pathology educators could benefit from creating their own YouTube channels and incorporating them into their face-to-face lectures, as this approach has been found to improve the learning process [5,23].

It is worth noting that YouTube videos are of variable quality and are, accordingly, of varying educational value, which might be challenging and time-consuming for students, as indicated in our study and another corresponding study about anatomy [5]. Students were confused regarding which content to rely on when using YouTube for learning, and the available content-related material or course did not correspond with their learning phase, despite achieving good or very good scores. On the other hand, most of the students who claimed that they were not confused when selecting the appropriate pathologic information achieved a score higher than 70%. As explored in our study, this could necessitate the help of instructors by using some YouTube videos in their lectures, guiding the students on the relevant pathology content to follow on YouTube, and providing them with suggested links that meet the course objectives and match the student's level of knowledge.

Overall, this study adds to the existing literature on the potential use of YouTube as an effective supplementary pathology learning tool. It also emphasizes the importance of using a variety of methods and sources to ensure comprehensive education in pathology.

Strengths, Limitations, and Future Directions

Recommendations

In light of this, pathology educators at Jordanian universities may consider the potential benefits of using YouTube as an educational tool. This could be achieved by providing their students with educationally effective pathology channels while also admitting the possible limitations and drawbacks of this approach.

Moreover, pathology educators could consider the creation of a pathology YouTube channel for Jordanian universities that prompt discussion and sharing of information while ensuring students' privacy and academic integrity.

Limitations

Although this study has provided explorative information about the use of YouTube to learn pathology, it has some limitations. First, the questionnaire was general and did not include questions that evaluated students' satisfaction with specific YouTube channels that are frequently used by the students. Future research could consider using a mixed methods approach that includes both self-reported data and objective measures to investigate this issue in addition to investigating the usefulness of creating new YouTube channels for Jordanian universities. Second, although the study included an adequate sample size, generalization of the results must not be easily assumed, since

some universities had much greater participation than others (nearly 50% of the participants were from Yarmouk University), and some groups had higher participation rates (second-year students). Future studies could consider recruiting students with near equal proportion from different universities at different levels of medical study. Third, this study only focused on the use of YouTube as a supplementary learning tool, and other aspects such as the videos' quality, level of engagement, or learning preferences of the students were not investigated. Future research could explore these factors to provide a more comprehensive understanding of the use of YouTube as a learning tool. Fourth, since we conducted our study amid the COVID-19 era, not considering the effect of the COVID-19 pandemic on students' education is considered another limitation of this study. Therefore, we recommend other investigators study the effect of COVID-19 lockdowns on the online learning process in general and using YouTube channels in particular.

Last, this study did not address any limitations pertaining to copyright laws or other ethical issues associated with using open-source content on YouTube. Future studies could also consider addressing these ethical considerations to ensure that utilizing YouTube as a resource for learning is legally and ethically sound.

Conclusion

The results of this study suggest that YouTube may play a role in enhancing pathology learning, and aiding in understanding, memorization, recalling information, and obtaining higher scores. Many medical students in Jordan have positive attitudes toward using YouTube as a supplementary pathology learning tool. Based on this, it is recommended that pathology instructors should explore the use of YouTube and other emerging educational tools as a potential supplementary learning resource.

Abstract

Background: Teaching hospitals have been regarded as the primary settings where doctors teach and practice high-quality medicine, as well as where medical students learn the profession and acquire their initial clinical skills. A percentage of instruction is now done over the internet or via electronic techniques. The present COVID-19 epidemic has pushed distance electronic learning (DEL) to the forefront of education at all levels, including medical institutions.

Objective: This study aimed to observe how late-stage medical students felt about DEL, which was put in place during the recent COVID-19 shutdown in Jordan.

Methods: We conducted a prospective, cross-sectional, web-based, questionnaire-based research study during the COVID-19 pandemic lockdown between March 15 and May 1, 2020. During this period, all medical schools in Jordan shifted to DEL.

Results: A total of 380 students responded to a request to fill out the questionnaire, of which 256 completed the questionnaire. The data analysis showed that 43.6% (n=112) of respondents had no DEL experience, and 53.1% (n=136) of respondents perceived the DEL method as user-friendly. On the other hand, 64.1% (n=164) of students strongly believed that DEL cannot substitute traditional clinical teaching. There was a significant positive correlation between the perception of user-friendliness and the clarity of the images and texts used. Moreover, there was a strong positive correlation between the perception of sound audibility and confidence in applying knowledge gained through DEL to clinical practice.

Conclusions: DEL is a necessary and important tool in modern medical education, but it should be used as an auxiliary approach in the clinical setting since it cannot replace conventional personal instruction.

(JMIR Med Educ 2023;9:e42354) doi:[10.2196/42354](https://doi.org/10.2196/42354)

KEYWORDS

COVID-19; distant electronic learning; medical; medicine; school; medical school; medical education; clinical skill; teaching hospital; questionnaire; distance learning; distance education; web-based education; web-based learning; medical student

Introduction

Residents and medical students must be educated and trained in a teaching or university hospital, where they will have direct

contact with actual patients and be exposed to real-life scenarios [1]. This concept faces ever-increasing challenges as new medical schools emerge, more students enroll, and medical specialties become more complex and require interdisciplinary

teaching [2]. As a result, remote or distance electronic learning (DEL) has long been a topic of debate, and some medical schools have already made measures to construct certain electronic and virtual reality learning modules [3]. Moreover, platforms and tools have already been designed to address medical problems and requirements [4], such as videos, mobile monitoring apps [5], simulation labs [6], and wearable devices [7].

The emergence of the COVID-19 pandemic has placed an immense burden on the health care system in Jordan, resulting in an unprecedented level of stress. As a consequence, this has presented unique and complex challenges within the learning environment, both in terms of practicality and logistics. These challenges have the potential to leave a significant and enduring impact on medical education [8,9]. Web-based education holds considerable promise in terms of expanding access to education and improving efficiency; however, it does not necessarily surpass the effectiveness of traditional classroom-based approaches. The effectiveness of web-based education largely hinges on the successful integration of instructional designs that align with sound learning principles [10]. While distance education is easily implemented in theoretical courses and has been done for decades through specialized web-based platforms (eg, Coursera, EdX, and others), it is more difficult in areas that require hands-on experience. Medicine is one of these areas, and the pandemic has had a significant influence on both students and staff at medical schools, particularly in the later stages [11].

The implementation of DEL necessitates the presence of adequate digital infrastructure within each country to support and sustain these activities. This includes the necessary technological resources and systems required to facilitate effective remote learning. However, the global outbreak of COVID-19 has accelerated the widespread adoption of digital technologies in public sectors, presenting a significant challenge for governments worldwide, in addition to the health crisis [12]. Not all countries were equally equipped and prepared to address this digital transformation, exposing the varying pace of digital evolution. Societies have been compelled to adapt to this digital revolution with varying degrees of readiness. Therefore, the implications of DEL extend beyond education and encompass broader societal and ethical considerations that humanity must urgently confront and resolve, particularly given the ongoing pandemic.

This study examined the perceptions of senior medical students regarding DEL implemented during Jordan's COVID-19 shutdown. The primary objective was to extract valuable insights that can contribute to the improvement and integration of DEL into conventional medical education, ultimately transforming it into an effective teaching tool. By exploring the experiences and feedback of medical students during this unprecedented period of remote learning, this study aimed to shed light on the strengths, weaknesses, and potential enhancements of the DEL approach in medical education.

Methods

Study Design

This cross-sectional study was conducted during the COVID-19 pandemic lockdown in Jordan, which lasted from March 15 to May 7, 2020. The study aimed to assess the perceptions of medical students regarding the implementation of DEL during this period.

Participants

The target sample included fourth-, fifth-, and sixth-year medical students from all 6 medical schools in the country, encompassing various training specialties. The total estimated number of eligible participants in the national sample was around 3500-4000 students. The sample size for the study was calculated using Raosoft software. The study population (n=700) was entered into the software, and the recommended sample size was 245. In this study, a total of 700 students were given the questionnaire. Out of these, 256 students completed the survey and provided their responses, equaling a response rate of 36.6%.

Questionnaire Development

Content with face validity is defined as that which "simply looks relevant to the person taking the test. It evaluates the appearance of the questionnaire in terms of feasibility, readability, consistency of style and formatting, and the clarity of the language used" [13]. To gather data, we developed a comprehensive questionnaire. The questionnaire underwent a face validity assessment by 5 independent academic members from our medical school who were not involved in the study. The questionnaire was improved based on the suggestions provided by the experts. They provided their feedback by proposing some modifications, deletions, and additions. We documented all these proposed amendments, performed them, and then adopted them to conduct the study. Additionally, feedback from 20 clinical students was incorporated into the final version. We further ensured that the questionnaire, as a tool for data collection, was delivered to the participants without errors or ambiguity. The questions included were directly collected after the responses were sent from the participants. All these approaches accommodated the validity and reliability of the instrument adopted.

The questionnaire consisted of 5 sections addressing the following different aspects of the student's experiences with DEL:

1. Past DEL experiences: Participants were asked to rank their previous experiences with DEL on a 4-point scale (none, little, adequate, or excellent).
2. Applications used: Students were provided with a list of applications commonly used by various medical schools during the lockdown, including Microsoft Teams, Zoom, WhatsApp, Skype, Google Forms, Face Life, PowerPoint with sound effects, Moodle, Videos and YouTube, and Lark. They were asked to indicate which applications they used.
3. Perceptions of the DEL method: This domain focused on the student's perceptions of the quality and value of the

DEL method. They assessed aspects such as user-friendliness, audio-visual quality, clarity, utility, and the potential for DEL to replace live or traditional teaching or be integrated into the future curriculum. Participants responded using a 5-point Likert scale.

Validity and Reliability

The reliability of the questionnaire was tested using Cronbach α , and the value of the stability coefficient was calculated to be .871, which was acceptable.

Data Collection

The verified questionnaire was distributed via the formal social networking sites used by all medical students in the country (including Facebook, LinkedIn, and Instagram) 4 weeks after the implementation of DEL. The survey remained open for 8 weeks, and a reminder email was sent 2 weeks after the initial launch to encourage participation.

Data Analysis

The data analysis involved analyzing the participants' perception of the quality and value of the DEL applications using SPSS Statistics version 22 (IBM). The responses on the Likert scale were analyzed by calculating the percentages of agreement for each statement. Correlation analysis was performed to examine the relationships between the different variables. The statistical measure used was the Spearman correlation test (r_s), and significance levels were indicated with 2-tailed P values. The Spearman correlation test is not limited to continuous data; it can be used to test ordinal or categorical data. Since this study comprises a categorical data set, Spearman correlation was performed.

Ethical Considerations

This study was approved by the ethical committee of the medical school of Al-Balqa Applied University (MD/56/41/1381) and was conducted according to the Declaration of Helsinki. Informed consent was signed by each participant after a clear understanding of the study objective was provided. The Institutional Review Board ensured that the study adhered to ethical guidelines and standards, protecting participants' rights, confidentiality, and welfare.

Results

The demographic information of the participants is presented in Table 1. The majority of the participants were men ($n=129$, 50.4%) and aged between 24-26 years ($n=126$, 49.2%). The students were asked to rate their past learning experience with DEL on a 4-point scale (none, little, adequate, excellent). Most participants ($n=114$, 45.4%) ranked their DEL experience as none, and 95 (37.8%) participants selected little. Only 16 (6.4%) students had excellent learning experiences with DEL.

Table 2 shows the perceptions of the participants toward DEL. Among the 256 respondents, 150 (58.6%) participants reported that the DEL method was user-friendly. Additionally, 162 (63.3%) participants stated that the sound was audible, and 145 (56.6%) participants mentioned that the images and texts used in the DEL applications were clear and helpful. However, it is worth noting that 64 (25%) participants had a negative perception, and an additional 110 (42.9%) participants had a somewhat negative perception regarding the technical aspects. Furthermore, 113 (44.1%) participants found the entire DEL experience enjoyable and beneficial, and 116 (45.3%) participants expressed their willingness to try it in the future. On the other hand, 150 (58.6%) participants disagreed that DEL can replace traditional teaching methods. Interestingly, despite the convenience offered by DEL, only 105 (41%) participants perceived it as helpful for applying clinical knowledge to patients.

Table 3 shows the correlation coefficient test between the perception of quality and the learning experience of the participants. The findings of the correlation coefficient analysis demonstrated that the tested variables had a positive and significant correlation. The audibility of sound and clinical examinations through videos and the participants' learning experience were moderately correlated, which showed that the better the audio and video quality, the better and more enjoyable the students' experience and the more likely students were to express zeal and eagerness to try DEL in the future. The perception of user-friendliness was also positively associated with learning experience. The comfortability and enjoyment of using DEL were positively correlated with learning experience. Moreover, the application of clinical knowledge to patients was strongly correlated with learning experience. Students perceived encouragement in applying their acquired knowledge in clinical practice. The results were evident in the students' satisfaction with adopting DEL in teaching for medical schools (Table 4). The responses were most significant when students were asked for their consent to adopt DEL for further implementation of electronic learning teaching applications ($P=.006$).

Furthermore, the user-friendliness of DEL also had a significant impact on acquired knowledge ($P=.02$). Moreover, the responses of students were also satisfactory when they were asked about the substitution of clinical teaching with DEL, which significantly impacted acquired knowledge ($P=.02$). The responses were insignificant when the students were asked whether the images and text used helped them acquire knowledge ($P=.23$). The visualization of images and text also did not have a significant impact on acquired knowledge ($P=.40$). Similarly, audibility of sound ($P=.09$), clinical examination through videos ($P=.07$), understanding of the topic with videos ($P=.10$), the enjoyability of the DEL experience ($P=.06$), and the application of clinical knowledge to the patient following DEL ($P=.29$) had no satisfactory influence on acquired knowledge.

Table 1. Demographics and distance electronic learning experiences of the participants (n=256).

Category	Participants, n (%)
Age (years)	
18-20	15 (5.8)
21-23	115 (45)
24-26	126 (49.2)
Gender	
Women	127 (49.6)
Men	129 (50.4)
Learning experience	
None	114 (45.4)
Little	95 (37.8)
Adequate	25 (10)
Excellent	16 (6.4)
Application used	
Microsoft	39 (15.5)
WhatsApp	8 (3.2)
Skype	1 (.4)
Zoom	70 (27.9)
PowerPoint	3 (1.2)
Face Live	3 (1.2)
Moodle	7 (2.8)
Google	5 (2)
Lark	9 (3.6)
E-learning	1 (.1)
Videos and YouTube	28 (11.2)
Multiple apps	42 (16.7)

Table 2. Perceptions of the quality and value of distance electronic learning (DEL) applications (n=256).

Statement	Strongly disagree, n (%)	Disagree, n (%)	Neutral, n (%)	Agree, n (%)	Strongly agree, n (%)
DEL method was user-friendly	36 (14.3)	14 (5.6)	44 (17.5)	64 (25)	86 (34.3)

Discussion

Principal Findings

The main findings of this study regarding the influence of DEL on senior medical students during the COVID-19 shutdown in Jordan are as follows. First, a large number of participants ($n=114$, 45.4%) had no prior experience with this type of learning and were compelled to pursue it due to the circumstances. Despite being relatively unfamiliar with remote learning, the low number of unfavorable responses suggested that the students were willing to try this new teaching style or at least acknowledge its necessity and usefulness. It is worth noting that Jordanians have a high level of computer literacy, with a significant portion of the population owning smartphones and using social media platforms.

The results demonstrated that there was a significant and positive correlation between the perception of quality and the learning

experiences of students. The audio and video quality was moderately associated with learning experience, while the application of clinical knowledge obtained through DEL to patients was strongly correlated with learning experience. Furthermore, enjoyable and comfortable experiences of DEL were strongly associated, and students were eager to try DEL in the future.

Comparison to Prior Work

Given the mainly unfamiliar audience, the low number of unfavorable replies suggests that students were eager to attempt the new teaching style or at the very least appreciated its necessity and use. Furthermore, Jordanians are computer savvy, with 38% of the population owning a smartphone and 84% using social media sites, such as Facebook and Twitter [14]. Still, the participants in our study almost exclusively used Microsoft Teams and Zoom despite the wide variety of options.

On the subject of usefulness, the participants were rather reluctant, with only 42% rating the usefulness of DEL as positive or rather positive, while 36% rated it as negative or rather negative. They seemed fearful of incorporating this methodology into their “normal” curriculum. This was also depicted in the negative stance of 64% of students to the possibility of substituting classic teaching with DEL. The negative and positive responses were equally divided regarding both the enjoyment of the experience and the possibility of trying it in the future (roughly 40% of each group for each question).

The transformation of education from formal person-to-person classroom interactions to web-based informal meetings has greatly impacted medical education worldwide. Students are not accustomed to this type of learning, so it is not surprising that only 30% maintained a “regular” studying schedule, while 40% admitted that their schedule was upsetting. Studying is an integral part of medical education, with top students studying 6-8 hours per day in the preclinical stage [15]. Nevertheless, it is essential to diversify the concept of learning and incorporate the ever-changing conditions, either in the form of advancement or in the form of disruption [16].

Aside from the academic value of face-to-face learning, returning to traditional, on-site teaching provides much-needed social interaction for youths. When we analyzed student-patient relations, 60% missed direct in-person interactions and 77% missed their hospital-based clinical rounds. In a similar study in Singapore, two-thirds of medical students of all stages favored returning to the classrooms rather than continuing remote learning [17]. Another study of Swiss students before and after the COVID-19 lockdown showed increased levels of stress, anxiety, loneliness, and depression, with female students experiencing the symptoms more intensely [18].

Overall, the first attempt at medical teaching through DEL has received a positive note, both on a technical level as well as on the content. Luckily, digitization in Jordan is extensive and the infrastructure is in place to ensure technical efficiency throughout the country [19]. In terms of content, the migration of the course to a digital form did not reduce its quality and educational value. However, in terms of clinical value, the results were worrisome since only one-third of the students felt they could apply their knowledge to actual patients [20].

Apart from the theoretical knowledge medical students receive, they also are taught, through the example of their mentors, how to interact with patients. Clinical rounds help them familiarize themselves with medicine-in-practice in everyday situations. Additionally, peer discussions with fellow students are an effective method of deep learning in 81% of male and 89% of female students [15]. Clinical practice is based on observation, examination, investigation, and critical assessment to identify proper differential diagnoses, diagnose, treat, and sometimes operate on patients. All these skills can only be obtained by hands-on application and live peer interaction. This is the reason why only 39% of students were comfortable with the knowledge gained from DEL. Maybe more digital interaction should be implemented as a mandatory course or training to make the students more familiar with modern technologies and prepare them for the future when digital health will become mainstream.

Strengths and Limitations

This study highlights the technical capability of Jordan to support digital medical training and recognizes the value and significant contribution of DEL in continuing medical education during the COVID-19 pandemic. However, the findings indicate that the students in this study showed reluctance and fear toward digitization, suggesting the need for further efforts to familiarize them with this educational approach. While DEL cannot fully replace traditional clinical teaching, it should be integrated as an integral part of medical education, serving as a complementary tool in the clinical setting. This study conducted a comprehensive data analysis, exploring multiple dimensions of DEL, such as prior experience, user-friendliness, and the potential for substitution of traditional clinical teaching. This thorough analysis provides a nuanced understanding of students' attitudes and perceptions regarding DEL. Furthermore, the study's focus on a timely and relevant topic, namely, the impact of DEL during the COVID-19 pandemic, highlights its practical implications for medical education. The findings shed light on the role of DEL as a necessary and valuable tool in modern medical education, while also emphasizing the need to address students' concerns and integrate DEL as an auxiliary approach in the clinical setting. By offering valuable insights and recommendations, this study has the potential to inform and guide educational strategies in similar contexts.

This study has several limitations that should be acknowledged. First, the research was conducted during the COVID-19 pandemic lockdown, which created an unprecedented and unique educational context. The findings may be influenced by the specific circumstances of the pandemic and the abrupt shift to DEL, limiting their generalizability to other periods or nonpandemic situations. Moreover, the study relied on a self-report questionnaire, introducing the possibility of response bias. Participants may have provided answers that they believed were expected or socially desirable, potentially affecting the accuracy and reliability of the data. Third, the study focused on senior medical students in Jordan, which may limit the generalizability of the findings to other populations or educational settings. The cultural, institutional, and educational context of Jordan may have specific influences on students' perceptions and experiences with DEL that differ from those in other regions. Additionally, the study did not assess the long-term effects or outcomes of DEL on students' learning and clinical skills, which could provide further insights into the effectiveness and limitations of this educational approach.

Future Directions

DEL is rapidly infiltrating medical schools, and this fact should be considered while designing the curriculum for future physicians. Because of their lack of experience, the students in this study were hesitant and worried about shifting to digital medical education. We are confident that calculated gradual, modest encounters will be of great benefit to clinical teaching. Future longitudinal studies are needed to evaluate all aspects of digital learning in clinical teaching for medical students. Moreover, future research and initiatives should aim to address students' concerns and optimize the implementation of DEL to enhance the overall medical education experience.

Abstract

Background: Prolonged grief disorder (PGD) is a newly recognized mental disorder characterized by pervasive intense grief that persists longer than cultural or social expectations and interferes with functioning. The COVID-19 epidemic has resulted in increased rates of PGD, and few clinicians feel confident in treating this condition. PGD therapy (PGDT) is a simple, short-term, and evidence-based treatment developed in tandem with the validation of the PGD diagnosis. To facilitate the dissemination of PGDT training, we developed a web-based therapist tutorial that includes didactic training on PGDT concepts and principles as well as web-based multimedia patient scenarios and examples of clinical implementation of PGDT.

Objective: We aimed to evaluate user satisfaction with the tutorial and whether the tutorial increased trainees' knowledge of PGDT principles and procedures. Moreover, we included a small number of pilot questions to evaluate the PGDT-related clinical skills.

Methods: This study evaluated tutorial learning using a pre- and poststudy design. Participants were recruited from professional organization mailing lists, announcements to graduates of the Columbia School of Social Work, and through word of mouth. After signing consent, participants completed a brief demographic survey, a 55-item multiple-choice prestudy test on the concepts and principles of PGD and PGDT covered in the tutorial, and a 4-item pilot web-based prestudy test to gauge PGD clinical implementation skills. The link to the course content was then activated, and participants were given 8 weeks to complete the 11-module tutorial containing information, web-based exercises, simulated patient and video examples, and self-tests.

Results: Overall, 406 clinicians signed consent, and 236 (58.1%) started the tutorial. Of these, 83.1% (196/236) completed all 11 modules. Trainee scores on our PGDT assessment improved substantially from pretraining to the postmodule assessment, with the total number of correct answers increasing from a mean of 29 (SD 5.5; 52.7% correct) to 36.7 (SD 5.2; 66.7% correct; $t_{195}=18.93$; $P<.001$). In addition, the trainee's implementation scores on 4 clinical vignettes increased from 2.6 (SD 0.7) correct out of 4 to 3.1 (SD 0.4) out of 4 ($t_{188}=7.02$; $P<.001$). Effect sizes (Cohen d) were 1.44 (95% CI 1.23-1.65) for PGDT assessment and 1.06 (95% CI 0.84-1.29) for implementation. Trainees found the tutorial interesting, enjoyable, clearly presented, and useful for professional development. They endorsed a mean score of 3.7 (SD 0.47) on a 1 to 4 scale of agreement with recommending the course to others and feeling satisfied with the tutorial, and a mean of 3.3 (SD 0.57) with feeling able to apply the skills with clients.

Conclusions: This pilot study provides support for the usefulness of this web-based training for teaching clinicians how to administer PGDT. The addition of patient scenarios for clinical implementation strategies holds promise for increasing the effectiveness of PGDT training and other evidence-based treatments.

Trial Registration: ClinicalTrials.gov NCT05121792; <https://www.clinicaltrials.gov/ct2/show/NCT05121792>

Introduction

Background

Prolonged grief disorder (PGD) is a new diagnosis in the Diagnostic and Statistical Manual of Mental Disorders (DSM) fifth edition text revision [1], and the World Health Organization's International Classification of Diseases 11th edition (ICD-11) in 2019 [2]. PGD is characterized by persistent pervasive intense grief that interferes with functioning for a period that exceeds expectations of the person's social, cultural, or religious groups and is at least 6 months after the loss in the ICD-11 and at least 12 months in the DSM fifth edition. The disorder is characterized by persistent intense yearning, longing, or preoccupation with the person who died, accompanied by at least 3 of 8 associated symptoms, also persistent and pervasive to a clinically significant degree and occurring daily for at least the past month: the loss of a sense of identity, marked sense of disbelief about the death, avoidance of reminders that the person has died, intense emotional pain such as anger or sadness related to death, difficulty reengaging with others or with one's own life, a feeling of emotional numbness, feeling that life is meaninglessness because of death, or intense loneliness as a result of death. Studies have found that PGD is associated with major impairment in social, occupational, and leisure activities [3,4]; increased risk for suicide [5] (rates higher than depression [6]); and negative health consequences, for example, cancer and cardiovascular disease [3].

The introduction of a new mental disorder begs the question of available treatments. In the case of PGD, PGD therapy (PGDT; formerly called Complicated Grief Therapy) was developed [7] and tested in 3 randomized controlled trials with a total of 641 participants [8-10] before the inclusion of PGD as an official diagnosis. This treatment research initiative paralleled and contributed to the research that validated the criteria for new diagnosis [11,12]. Each of the 3 studies, sponsored by the National Institute of Mental Health, compared PGDT to a proven efficacious treatment for depression, either interpersonal psychotherapy in 2 of the studies or antidepressant medication in the third. PGDT produced an average response rate of 71%, compared with 33% for depression treatment. Importantly, depression is most often confused with PGD [8,9,13].

PGDT Overview

PGDT is a short-term (16 sessions) integrated psychotherapy targeting adaptation to loss. PGDT is based on research-informed principles and evidence-based methods from cognitive behavioral therapy, interpersonal psychotherapy, motivational interviewing, positive psychology, and psychodynamic psychotherapy. Attachment theory is used to understand bereavement and grief and to define the treatment goal of facilitating adaptation to loss. Following the dual-process model of coping with bereavement [14], adaptation is conceptualized as entailing the acceptance of the reality of the loss and restoration of the capacity for well-being. The

foundational premises of PGDT are that grief is a stress response and a form of love that emerges naturally and finds a place in our life. Although everyone grieves and adapts in their own way, there are commonalities. Adapting to loss progresses naturally if it does not become derailed. Derailers are naturally present during early grief and can get in the way of adapting if they persist over time and gain too much prominence in mental functioning [15]. PGD therapists use active listening and personalized interventions, as they work through a planned sequence of sessions and a series of well-specified psychological exercises. These exercises provide experiential learning opportunities for each of the 7 themes that operationalize the process of adapting to loss, understanding and accepting grief, managing grief-related emotions, seeing a future with promise, strengthening relationships, narrating a coherent story of death, living with reminders, and feeling connected with memories (Figure 1). The first 2 themes help patients understand and manage grief; the next 2 focus on restoring the capacity for well-being using the self-determination theory goals of autonomy, competence, and relatedness [16]. The last 3 themes help patients to accept the reality of the loss and establish a sense of connection with the person who died. For more detailed information, refer to the study by Shear [16].

The critical shortage of clinicians trained in evidence-based treatment has been amplified by the pandemic. The rate of psychiatric disorders has increased [17], with more patients seeking help [18]. This has already put a strain on clinicians who are unlikely to be knowledgeable about PGD or PGDT. This means that a large number of therapists will need to be trained in a short amount of time. One way to facilitate access to training is through the use of digital technologies.

Internet-based training, both synchronous and asynchronous, can be available to any clinician with internet access. Asynchronous training is unconstrained by enrollment limitations, trainer availability, and time limitations, as busy clinicians can work at their own pace [19]. Using the principles of instructional design, such as high interactivity and multimodal learning, enhances the quality of training and increases knowledge retention [20]. Web-based technologies have been used to successfully train clinicians in several evidence-based treatments such as interpersonal psychotherapy for depression [21], cognitive therapy for adolescent depression [22], anxiety disorders [23], and drug abuse [24]. Web-based training has also been used to help train non-mental health clinicians to deal more effectively with mental health issues, such as emotional trauma [25] and adolescent mental health [26]. While no web-based therapist training for treating grief has been reported, several web-based self-help interventions for grief have been published [27-30].

In a review of the use of technology to train clinicians in evidence-based treatments, Singh and Reyes-Portillo [31] found that technology-based training can be just as effective as traditional training and has the potential to facilitate the adoption

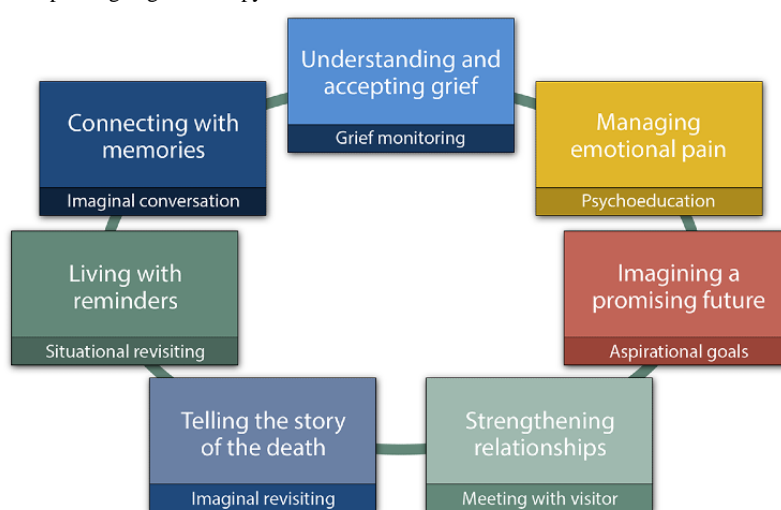

of evidence-based practice. Fairburn and Wilson [32] suggested that internet-enhanced technologies might provide the only scalable solution to the challenge of disseminating clinician training on evidence-based treatments as well as supporting the actual use of skills in clinical settings after completing training. Internet-based training can also provide opportunities for ongoing updates, specific steps to prevent drift, retesting, and monitoring. In addition, we have had positive experiences combining synchronous and asynchronous training methods.

A major issue in training clinicians on evidence-based treatments is not only how to facilitate the uptake of conceptual knowledge but also how to teach and assess effective clinical implementation of the treatment. Several studies have found that web-based training is more effective when followed up by clinical consultation [33-35]. However, live supervision is costly, time-consuming, and not easily scalable. To help make this aspect of training scalable, German et al [36] used a *train the trainer* approach, where a cohort of clinicians within a setting were trained by experts, using in-person workshops followed by live supervision. Once trained, these clinicians used their expertise to train new clinicians within the group [36] using a combination of web-based training followed by live supervision. They found that the combination of web and live training was as effective in producing clinical competency as training performed entirely by clinicians. Murphy et al [37] used web-based video playback technology (mPath) to help

trainees reflect upon their interpersonal counseling skills in specific therapy sessions. In our previous studies, we used live remote observation via videoconference for training on applied skills using standardized patients [38] or trainers playing the parts of the patient while providing live feedback [21,23,39,40]. These studies found that live remote training improved not only didactic knowledge but also applied clinical skills and led to successful treatment outcomes [22,23]. However, this approach is still costly and does not solve the scalability problem.

In the tutorial, we included a small pilot component to address clinical implementation strategies using web-based multimedia patient scenarios with animated vignettes or previously produced actors with scripted videos. This approach allows for repetitive practice and immediate feedback in a safe and structured environment. To pilot this effort, users observed an actor-therapist interacting with an actor-patient (or an animated therapist interacting with an animated patient). This scenario portrayed a challenging clinical situation that clinicians might encounter when performing PGDT. Users indicated one of several possibilities for how they would respond to a situation. Through practice and feedback, clinicians can learn ways to engage in similar conversations with actual patients. The use of similar actor-patient scenarios to train clinicians has been reported for suicide risk assessment [41] and the treatment of major depression [42], alcohol [43], and substance use disorders [44].

Figure 1. Themes and processes in prolonged grief therapy.

Aim of This Study

The purpose of this study was to report on trainees' experiences and their learning outcomes after completing our recently released web-based therapist training tutorial on PGD and PGDT. Specifically, we measured (1) trainee satisfaction with the tutorial, (2) improvement in trainee knowledge of the principles and procedures used in PGDT, and (3) improvement in trainee choice of clinical implementation strategies in delivering PGDT.

Methods

Study Participants

Participants were therapists with a mental health-related degree or graduate students in a mental health program, recruited between October 2021 and May 2022. Study participants were recruited from electronic mailing lists of licensed psychologists in New York State, announcements to persons on e-newsletter lists from the Columbia Center for Prolonged Grief, announcements to individuals who had previously taken a course at the Center for Telepsychology, announcements to graduate students at the Columbia School of Social Work, and by word of mouth. Interested individuals reviewed the web-based

information sheet consent form and indicated that they freely agreed to participate in the study. Those agreeing to participate were provided a username and password and linked to a brief demographic survey, a 55-item multiple-choice pretest on the principles and concepts of PGD and PGDT, and a 4-item web-based pretest to assess PGD clinical implementation strategies. Once the demographic survey and pretests were completed, the link to course content was activated.

Description of PGDT Tutorial

The web-based PGDT tutorial contains didactic information, web-based exercises, simulated patient scenarios, animated graphics, ongoing web-based self-tests, and video examples of patient role-plays in a multimodal, multimedia, and web-based learning approach that research has found to enhance learning efficacy [20] ([Multimedia Appendix 1](#)).

The tutorial contains 11 modules covering the following topics: the nature of grief, an overview of PGD and PGDT, pretreatment assessment, a module for each of the 7 PGDT themes, and a final module that provides a summary of the treatment progress and addresses treatment termination. As PGDT is a *measurement-based* approach (ie, an intervention that includes regular structured assessment with simple validated instruments) [45], the tutorial reviews the assessment tools used in PGDT and how to integrate them into treatment. Each module is approximately 20 to 40 minutes long.

Trainees work through the tutorial at their own pace. However, they are encouraged to space out the time they work on it rather than take it in a few long sessions, as spaced learning increases knowledge retention [46]. A posttest is given immediately after completing each module, as testing performed closer to when the material was learned improved retention [47]. Consistent with continuing education guidelines, successful completion requires an overall score of 80% on the posttests. Users can retake the module until a passing score is obtained. The participants in this study were given 8 weeks to complete the training.

Study Assessment Instruments

Evaluation of User Satisfaction

We used three measures to evaluate user satisfaction with this tutorial: (1) rates of course completion, (2) scores on a satisfaction questionnaire, and (3) ratings on whether course objectives were achieved.

Course Completion

Course completion was defined as the completion of all 11 modules, including the quizzes. The number of dropouts per week and study module was also examined.

User Satisfaction Questionnaire

User satisfaction was evaluated using an 8-item User Satisfaction Questionnaire. This scale is similar to that used in prior web-based clinician training studies [38,48-53].

User Rating of Learning Objectives

User satisfaction was also evaluated based on the percentage of trainees who felt that the learning objectives of the tutorial

were met. The learning objectives for each module are stated at the beginning of each module. There were 46 learning objectives across the 11 modules. After completing each module, the trainees were asked to indicate whether they agreed that the specific learning objectives were met on a scale of 1 to 4 (1=strongly disagree, 2=disagree, 3=agree, and 4=strongly agree).

Evaluation of Trainee Knowledge of Principles and Procedures Used in PGDT

We developed a set of 55 questions, including 5 questions related to each of the 11 training modules. The participants answered a 55-item questionnaire at baseline before being given access to the tutorial. They were then asked to answer 5 of these questions at the end of each tutorial module ([Multimedia Appendix 2](#)). After posting their answer to each question, the participants were given feedback with the best answer and rationale. Finally, to progress to the next module, trainees were required to repeat any of the 5 items until they correctly answered at least 4 of the 5 questions. We used the first answer for all questions as the end-point measure in the analyses described here. However, repeated testing with feedback is part of the educational process; thus, we believe this is a conservative estimate of the participants' actual learning.

Evaluation of Trainee Clinical Implementation Strategies in Delivering PGDT

We developed a series of animated vignettes and used previously produced scripted role-play videos using actors that demonstrated a series of challenging scenarios. After viewing a video segment, the trainee was presented with several possible therapist responses and asked to select one that they thought would be best. After providing their answers, they received feedback on their choices. To evaluate whether this experience influenced the trainee's implementation strategies in delivering PGDT, we used four intervention choice points as a pre- and posttest: (1) a discussion during review of grief monitoring, (2) a patient questioning the value of monitoring grief, (3) a scenario in which there was a derailer present in a discussion of aspirational goals, and (4) setting up an avoidance hierarchy for situational revisiting. These are examples of common kinds of challenges a therapist might encounter in PGDT ([Multimedia Appendix 3](#)).

Statistical Methods

This study used a pre- and poststudy design. Paired *t* tests (2-tailed) were used to measure the pre- to posttest changes in PGDT knowledge and clinical implementation strategies. The effect sizes (Cohen *d*) were calculated to examine the magnitude of the changes. The McNemar chi-square test was used to test the differences in percentages. Descriptive statistics were calculated for user satisfaction and learning objectives data.

Ethics Approval and Informed Consent

The study was reviewed and approved by the Columbia University Institutional Review Board on October 13, 2021 (registration number: AAAT7389). The approval process also obliged us to register this study at ClinicalTrials.gov. All

participants provided written informed consent before being given access to the tutorial.

Results

Demographic and Professional Characteristics of Tutorial Users

The demographic characteristics of the participants who completed the tutorial are presented in [Table 1](#). The sample was

primarily female (178/196, 90.8%) and White (159/196, 81.1%), with a mean age of 48.9 (SD 13.7; range 22-79) years. The sample predominantly included social workers and psychologists with a smattering of other mental health professions. Therapists had a mean of 2.7 (SD 11.0; range 0-44) years' experience doing therapy. Most (115/196, 58.7%) reported having had prior grief training, and 85.7% (168/196) reported having personally experienced grief.

Table 1. Demographic and professional characteristics of the participants (n=196).

Characteristics	Values
Age (years), mean (SD)	49.9 (13.7)

User Satisfaction

Tutorial Completion

A total of 6538 recruitment emails were sent. Of these, 6.2% (406/6538) expressed interest in the study and signed consent forms within a few days. At that point, we closed recruitment, as the study enrollment goals were met. Of those who signed

the consent form, 58.1% (236/406) completed the questionnaires and began the tutorial. Of the 236 who started the tutorial, 196 (83.1%) completed it. The numbers of dropouts per module are listed in [Table 2](#). Module completion rates fell gradually but minimally from 236 to 196, that is, from module 1A and 1B and then from 2 to 11.

Table 2. Pre- to posttest improvement in participants' knowledge of prolonged grief disorder therapy concepts by module (score range per module is 0-5).

Tutorial module	Values, n	Prestudy test, mean (SD)	Poststudy test, mean (SD)	<i>t</i> test (<i>df</i>)	<i>P</i> value
All 10 modules	196	29 (5.5)	36.7 (5.2)	18.93 (195)	<.001
1A. The nature of grief	236	2.5 (1.2)	4.1 (0.9)	17.1 (225)	<.001
1B. Overview of prolonged grief disorder	227	1.7 (1.0)	2.7 (1.3)	10.1 (225)	<.001
2. Pretreatment assessment	213	2.4 (1.1)	4.3 (0.9)	23.7 (212)	<.001
3. Understanding and accepting grief	210	2.6 (1.1)	3.5 (1)	10.8 (208)	<.001
4. Managing emotional pain	208	2.7 (0.9)	3.5 (0.9)	9.8 (206)	<.001
5. Imagining a promising future	203	2.6 (1.1)	3.4 (1.1)	7.5 (201)	<.001
6. Strengthening relationships	200	3.1 (1.2)	4.2 (0.8)	11.6 (198)	<.001
7. Telling the story of the death	200	2.4 (1.1)	3.8 (1)	14 (199)	<.001
8. Living with reminders	199	2.3 (1)	4.0 (1)	19.2 (197)	<.001
9. Connecting with memories	198	1.5 (1)	3.4 (1.2)	19.1 (197)	<.001
10. Putting the treatment together and managing its ending	196	2.6 (0.9)	2.8 (0.7)	2.3 (195)	.031

User Satisfaction Questionnaire

Trainees (n=192) scores on the 8 user satisfaction questionnaires were uniformly high. They scored between 3=agree and 4=fully agree on 6 of the 8 questions, including material presented in an interesting manner, concepts presented clearly and easy to understand, would recommend this course to others, enjoyed taking the tutorial, and felt able to apply these skills to clients. They said that they learned a lot and found information useful for their practice. Finally, they endorsed the feeling that the learning objectives were achieved ([Multimedia Appendix 4](#)).

Learning Objectives

The average learning objective was reported as being met (ie, "agree or strongly agree") by 96.9% (182/188) of clinicians. A list of all 46 learning objectives, their mean ratings, and percentage of trainees rating the objective as being met can be found in [Multimedia Appendix 5](#).

Evaluation of Trainee Knowledge of Principles and Procedures Used in PGDT

As shown in [Table 2](#), trainee scores on PGDT concepts and procedures ratings showed statistically significant improvement from pretraining to the postmodule assessment, with the total number of correct answers increasing from 29 (SD 5.5; 53% correct) to 36.7 (SD 5.2; 67% correct; $t_{195}=18.93$; $P<.001$; [Figure 2](#); effect size: Cohen $d=1.44$; 95% CI 1.23-1.65). The largest increases in scores were found in modules 2 (pretreatment assessment) and 8 (living with reminders), and the smallest increase was found in module 10 (putting the treatment together and managing treatment ending). While those with prior grief training scored slightly higher on the pretest than those without prior grief training, 29.9 (53%) versus 27.6 (50%; $t_{194}=2.93$, $P=.004$), the mean change was 7.7 for both groups. Not surprisingly, there was a difference between the mean change for graduate students (n=16;  1=5.8; SD 5.9) and licensed clinicians (n=179;  1=7.9, SD 5.7; $t_{194}=1.41$, $P=.19$).

Figure 2. Histogram of pre- and posttest scores on prolonged grief disorder treatment concepts and procedures.

Evaluation of Trainee Clinical Implementation Strategies in Delivering PGDT

The mean change in trainees’ scores on the pilot clinical implementation assessment increased substantially, from 2.6 (SD 0.7; 65%) correct out of 4 to 3.1 (SD 0.4; 78%) out of 4

($t_{188}=7.03$; $P<.001$). The standardized effect size was $d=1.05$ (95% CI 0.84-1.29). The changes in each response are presented in Table 3. There was no major difference in this measure between those with and without prior grief training ($t_{186}=0.98$; $P=.32$) or between clinicians and graduate students ($t_{193}=1.40$; $P=.16$).

Table 3. Pre- to posttest improvement in prolonged grief disorder therapy clinical decision-making skills (n=188).

Skill	Participants prestudy test (%)	Participants poststudy test (%)	Chi-square test (df)	P value
1. Reviewing grief monitoring	70.4	95.2	40.1 (1)	<.001
2. Questioning the value of monitoring grief	89.9	98.9	15.2 (1)	<.001
3. Dealing with derailers in aspirational goals	12.73	14.3	0.5 (1)	.64
4. Setting up a fear hierarchy for situational revisiting	92.6	97.98	6.3 (1)	.01

Discussion

Principal Findings

The principal findings of this study support the growing body of literature supporting the helpfulness of asynchronous web-based technologies for training clinicians in evidence-based treatments [31,54,55]. Scores on trainee ratings on our PGDT assessment measures increased substantially, as, to a lesser extent, did our trainee clinical implementation strategy assessment. In addition, the high response rate to our recruitment notices, as well as the unusually large percentage who completed the tutorial, suggests a high level of interest in this tutorial. Higher user satisfaction was further supported by the User Satisfaction Questionnaire scores and the percentage of trainees reporting that the learning objectives were met. The high completion rate we obtained was notable and may be related to the appeal of this program, including appealing interactivity, novelty, animated and video clinical examples, and the novelty of a new DSM diagnosis that already has a well-validated treatment approach. User satisfaction is especially important in asynchronous web-based training, where there is a high risk of discontinuing training.

Given the recent introduction of PGD in ICD-11 and DSM fifth edition text revision, as well as a marked increase in persons

with prolonged grief owing to the pandemic, rapid dissemination of training on effective PGD treatment is needed. Over 6 million people died worldwide during the pandemic. A total of 1.1 million people died of COVID-19 in the United States [56], adding substantially to the 2.8 million deaths per year. A recent US demographic study estimated that each death leaves about 9 bereaved relatives [57], which suggests that the bereaved outnumber the deceased by nearly 10-fold [58]. Overall, the rates of PGD among all bereaved individuals have been estimated to be approximately 10% [59], with higher rates for more difficult deaths. Circumstances of pandemic deaths have been especially challenging and thus qualify as particularly difficult deaths that are likely to be associated with elevated rates of PGD.

Notably, 85.7% (168/196) of the trainees reported having experienced a major loss. Many therapists become interested in grief therapy after experiencing their own grief. Life experience is a good way to understand the experience of a patient, so this may be a benefit. Alternatively, a personal loss may sensitize a therapist in a way that might make therapy more challenging. However, we found no difference in responses to this tutorial among those who did or did not report an important grief experience.

Therapists with prior grief training scored substantially higher on our pretest than those without this training, but the difference was only a few points. The scores of both groups showed a reliable increase on our assessment questionnaire after taking the tutorial. This suggests that even experienced therapists and those with prior personal grief experience or prior grief training can benefit from this training on PGD and its treatment. However, a mean score of 67% indicates that more learning is required to achieve optimal training results.

We included 4 pilot questions related to the use of PGDT clinical implementation skills, which mostly showed improvements in these assessments, suggesting that this is a promising extension of web-based training that might be further developed. Live role-plays with immediate feedback and clinical supervision may still be the best way to support the development of clinician skills [33-35]. However, given that PGD is a new disorder, there are not yet sufficient numbers of PGDT trainers to meet the needs of a large number of clinicians needing this training, and the observation of the trainee's role-plays (either live or remote) is not yet scalable. Web-based technology can offer a useful tool to augment didactic training. Web-based patient scenarios provide an alternative in which trainees may gain comfort in implementing and experimenting with new skills. This may be a more comfortable way to receive feedback on their performance, especially in the early stages of training. Future work should continue to build methods for the effective asynchronous practice of clinical skills.

Study Limitations

This study has several limitations. First, we recruited individuals through internet announcements to a wide range of professionals, but those who signed up were mostly more experienced therapists, and the majority had already had grief training. It is important to know how therapists who are less comfortable or knowledgeable about grief would respond to this tutorial. Second, perhaps the most important limitation of this study is that there are no patient outcomes and no measures of therapist adherence when providing therapy. Thus, it is unclear whether

training improves treatment efficacy. Third, although we showed large pre-post effect sizes in our measured outcomes, our conclusions are limited by the lack of information about the reliability and validity of the test items. In addition, posttests were conducted immediately after the material was presented. Whether the knowledge gained was retained is unknown. Fourth, the therapists in our sample were primarily White (159/196, 81.1%). Most concerning, only 6.1% (21/196) self-identified as Black compared with the population prevalence of 13% in the United States and the elevated rates of both yearly death rates and PGD among people of color. This low rate may be due to failure to reach Black professionals; failure of Black therapists to be interested in the tutorial; or perhaps most concerning, a low level of Black professionals trained as therapists. A secondary analysis of our most recent intervention efficacy study showed no difference in response rates between individuals who self-identified as White or Black. Clearly, more work is needed to ensure that efficacious evidence-based treatment is available to people of different cultures [60].

Conclusions

This preliminary study provides support for the effectiveness of web-based training in teaching clinicians to recognize PGD and administer PGDT. The inclusion of a web-based multimedia tutorial for didactic training and simulated patient scenarios to develop PGDT-related clinical skills holds promise for increasing the effectiveness of web-based training. The model and components used in this tutorial model may also be helpful in the dissemination of training for other evidence-based treatments. Web-based training may help facilitate training in evidence-based treatments by overcoming barriers owing to limited trainer capacity, time, and scheduling constraints [61,62]. Further studies are warranted to determine the reliability and validity of the tutorial outcome measures and explore the optimal use of web-based training in the context of other approaches to PGDT training. Such studies would provide data that would enable a cost-benefit analysis of the best ways to integrate each approach into the training of grief therapists.

Acknowledgments

This study was funded by the National Institute of Mental Health of the National Institutes of Health under the Small Business Technology Transfer Award (R41MH118126), jointly awarded to the Center for Psychological Consultation (principal investigator: KK) and Columbia University Center for Prolonged Grief (principal investigator: MKS). The content is the sole responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health. The videos in the tutorial were produced by the Columbia University Center for Teaching and Learning under a Columbia University Provost Grant to the Center for Complicated Grief, 2018.

Data Availability

Deidentified data files are available on Dropbox over internet [63].

Conflicts of Interest

KK, The Center for Prolonged Grief, and Columbia University have a financial interest in the web-based therapist training program described in this study.

Abstract

Background: Near-peer teaching (NPT) is becoming an increasingly popular pedagogical tool in health professions education. Despite the shift in formal medical education from face-to-face teaching toward encompassing web-based learning activities, NPT has not experienced a similar transition. Apart from the few reports on NPT programs hastily converted to web-based learning in light of the COVID-19 pandemic, no studies to date have explored web-based learning in the specific context of NPT.

Objective: This qualitative study examined the nature of interactions among peer learners (PLs), peer teachers (PTs), and the learning content in a student-led, web-based NPT program for medical students.

Methods: A 5-month-long voluntary NPT program to support first- and second-year medical students' biomedical science learning in the undergraduate medical curriculum was designed by 2 senior-year medical students and delivered by 25 PTs with 84 PLs participating. In total, 9 PLs and 3 PTs underwent individual semistructured interviews at the end of the program to explore general NPT experience, reasons for joining NPT, the effectiveness of NPT, the demand and importance of NPT, and the feasibility of incorporating NPT in the formal curriculum. Interview transcripts were analyzed using a thematic analysis approach.

Results: The first general theme focused on the nature of student-student, student-teacher, and student-content interactions. Although PLs were engaged in web-based NPT, there was minimal interaction between students, as most PLs preferred to learn passively and remain anonymous. PLs believed the web-based NPT learning process to be a unidirectional transmission of knowledge from teacher to learner, with the teacher responsible for driving the interactions. This was in sharp contrast to PTs' expectation that both parties shared responsibility for learning in a collaborative effort. The second general theme identified the advantages and disadvantages of delivering NPT on a web platform, which were mainly convenience and teaching skills development and poor interactivity, respectively.

Conclusions: Student-led, web-based NPT offers a flexible and comfortable means of delivering academic and nonacademic guidance to medical students. However, the web-based mode of delivery presents unique challenges in facilitating meaningful interactions among PLs, PTs, and subject content. A blended learning approach may be best suited for this form of student-led NPT program to optimize its efficacy.

Introduction

Overview

Medical education has seen a gradual shift toward web-based learning in recent decades [1], even before the COVID-19 pandemic hastened this transition [2]. In contrast, medical education initiatives such as near-peer teaching (NPT) programs have typically been conducted as in-person activities, wherein near peers—students “one or more years senior in training on the same level of the medical education spectrum” [3]—act as peer teachers (PTs) to teach junior students, peer learners (PLs).

Compared with same-level PTs, near peers have a better understanding of the knowledge that students are expected to acquire and potential pitfalls [3]. Meanwhile, they are better equipped to communicate information at an appropriate level and empathize with students than faculty members [3]. Thus, NPT as a pedagogical approach in an increasingly digitalized medical education landscape is an important area of study.

Although there has been extensive literature published on the outcomes of web-based medical education in general [4], the use of web-based means to conduct NPT has been understudied. It was not until the COVID-19 pandemic that NPT programs were forced to take place on the web, leading to several publications commenting on the feasibility, merits, and challenges of delivering NPT on the web to meet the educational demands during the pandemic [5,6]. However, the implementation of NPT under such crisis-ridden circumstances represents “emergency remote teaching,” which should be distinguished from programs intentionally designed to be delivered entirely on the web [7].

This study focused on a voluntary student-designed and student-delivered initiative. To date, to the best of our knowledge, no research has explored in detail medical students’ experiences of student-led NPT purposely delivered on the web.

Background

The sudden transition of medical education to a web-based setting during the COVID-19 pandemic occurred for both formal teaching and NPT around the globe. Institutions conducted web-based NPT to deliver didactic teaching, clinical clerkships, subinternships, and mentorships during this time [8–11]. Jeong et al [6] developed a web-based peer teaching elective “born of necessity” during the pandemic and found it to be a feasible supplementary learning medium that benefited both PLs and PTs. Meanwhile, Hampshire et al [12] reported that the web-based format of NPT for teaching immunology and microbiology content increased student engagement. Similarly, near-peer surgical teaching for junior doctors using a web-based platform was perceived by trainees as an effective alternative to classroom teaching in terms of overall quality, relevance, and usefulness [13].

However, the emergency adaptation of face-to-face teaching to a web-based mode of delivery faced several challenges. From medical students’ perspectives, barriers to web-based learning include quality assurance of content delivery, educators’ lack of experience in web-based delivery, learners’ acceptance of new learning modalities, and levels of engagement in web-based classes [14]. In a letter to the editor of the journal *Medical Education Online*, Roberts et al [5] reflected on the challenges of restructuring their peer-led teaching sessions into a web-based format during the COVID-19 pandemic. These included maintaining learner engagement, managing learner passivity, and raising the technological skills level of tutors [5].

The limitations of emergency remote teaching and web-based NPT have led to mixed evaluations of their value and efficacy as a pedagogical tool. Although objective outcomes of student performance were equivalent in in-person NPT and web-based NPT established during the pandemic, students perceived web-based NPT of anatomy and radiology to be less effective as a learning tool and felt that PTs were ill-prepared for the small-group sessions [8]. Similarly, students at the University of Malta found web-based, small-group tutorials for anatomy teaching to be ineffective [15]. In contrast, student examination scores, engagement in teaching activities, and evaluations of a web-based pediatric clinical clerkship based on hybrid learning principles and NPT were similar to in-person clerkship outcomes [9].

Optimal strategies to engage students in web-based NPT and student preferences for web-based interaction have not been extensively investigated [16]. Rosenthal et al [16] explored the enjoyment, comfort, engagement, and learning associated with 5 different methods of class participation in a web-based NPT program for emergency medicine developed during the pandemic. They found that calling on students in groups of 3, using web-based group polling software, and asking for volunteer responses in the videoconference platform’s “chat” feature maximized student learning and engagement without compromising enjoyment and comfort. However, the perspectives of PTs were not addressed, which are important in student-led NPT initiatives as the sustainability of such programs relies on participation by the PTs in addition to learners.

No studies have explored the attitudes and perceptions of PLs and PTs toward a carefully planned web-based NPT experience. The instructional design and planning process required for effective web-based learning is absent in a majority of emergency remote teaching intended to be a temporary shift of delivery mode during a crisis [7]. Thus, the expectations, experiences, and challenges faced in the implementation of a web-based NPT program *intentionally* designed to be delivered on the web may differ from those reported in the existing literature. This study focuses on the student-student (SS), student-teacher (ST), and student-content (SC) interactions

exhibited among PLs and PTs during a student-led, web-based NPT program.

Methods

Developing an NPT Initiative at the University of Hong Kong's Li Ka Shing Faculty of Medicine

The abrupt transition to web-based learning in November 2019, because of social unrest in Hong Kong and the subsequent COVID-19 pandemic, was a challenge for all students but in particular for second-year medical students, as year 2 is recognized as one of the most demanding years of study in the Bachelor of Medicine and Bachelor of Surgery curriculum. Traditionally, senior-year medical students had supported these students on an informal ad hoc basis. However, the NPT program aimed to deliver student-led teaching in a systematic, pedagogically robust manner at this time of need to supplement the formal curriculum by adding value and extending the concepts learned. The fifth-year students who led the NPT initiative collaborated with faculty members to identify the most challenging areas of the year-2 curriculum to identify areas of focus for the NPT sessions. In total, 25 PTs participated in the program, of which 6 (24%) were male and 19 (76%) were female, and 10 (40%) had previous teaching experience (eg, private tutoring). The PTs were provided with a briefing session, a handbook, and optional training opportunities to prepare them for their role. Two training options were co-designed by the student organizers and university staff, namely a course on "Peer-Teaching in Higher Education" delivered by the University of Hong Kong Centre for the Enhancement of Teaching and Learning and a web-based training session on pedagogical approaches and skills for small-group learning run by the Bau Institute of Medical and Health Sciences Education. Both training programs focused on strategies particularly aimed at web-based teaching. Interactive tutorials were held on the web using Zoom (Zoom Video Communications) in small groups of 1 or 2 PTs with 5 to 10 PLs. Each session lasted between 1 and 2 hours.

Throughout the second semester of the 2020 to 2021 academic year, PTs scheduled tutorials on core topics of the year-2 organ system-based preclinical curriculum according to their availability. The tutorial schedule was made available to the year-2 Bachelor of Medicine and Bachelor of Surgery cohort via a social media platform in advance of the sessions and was updated biweekly. Students enrolled in tutorials on a first-come-first-serve rolling basis. Over the 5-month teaching period, 84 PLs participated in the program, of which 38 (45%) were male and 46 (55%) were female. Of these 84 participants, 68 (81%) and 16 (19%) participants were non-degree holders and degree holders, respectively.

Study Population and Research Questions

A qualitative study was undertaken in which PLs and PTs were identified through purposive sampling to participate in semistructured interviews upon completion of the 5-month-long NPT program. An information sheet and consent form were provided to participants, and 9 PLs and 3 PTs agreed to participate in the study. The overall research questions were as

follows: How do students behave in a web-based NPT context? and How does student behavior impact web-based NPT?

Ethics Approval

Before the data collection, ethics approval was obtained from the University of Hong Kong's Human Research Ethics Committee (reference EA200224).

Theoretical Framework

This small study was conducted using semistructured interviews within the research paradigm of narrative inquiry. As stated by Mertova and Webster [17], narrative inquiry is situated within human stories. It is a research method that captures how we as humans experience and perceive events. There is no scientific "validity" attached to the collected data, as there is no attempt to generalize findings. The way we as humans experience a situation is unique to each one of us. Within this paradigm, the researcher investigates experiences of particular events and looks for patterns or themes in the ways participants perceive situations. Through the semistructured interviews, the researchers entered a dialogue with the PLs and PTs to capture their particular experiences in participating in NPT.

Data Collection

Semistructured interviews were conducted using Zoom and audio recorded. An interview guide was developed for PLs and PTs (Multimedia Appendix 1) to elucidate their thoughts on NPT across five domains as follows: (1) general NPT experience, (2) reasons for joining NPT, (3) the effectiveness of NPT, (4) the demand and importance of NPT, and (5) the feasibility of incorporating NPT in the formal curriculum. Each interview lasted approximately 20 minutes and was transcribed verbatim and anonymized by a third party with no vested interest in the study.

Data Analysis

Two members of the research team analyzed the transcripts using a thematic analysis approach, which involves 6 phases: familiarization with the data, generating initial codes, searching for themes, reviewing themes, defining and naming themes, and producing the report [18]. They independently applied inductive coding over multiple readings to identify recurrent themes, which were subsequently reviewed and revised, with differences resolved by consensus. Associated quotations were extracted to illustrate the key agreed-upon themes. Once key themes were identified, they were categorized according to the Moore [19] framework of the 3 forms of desirable interactions in distance education (ie, SS, ST, and SC interactions) to examine the nature of PT and PL interactions in web-based NPT and the advantages and disadvantages of web-based NPT.

Results

Overview

A total of 9 PLs and 3 PTs were interviewed. Among the 9 PLs, 3 (33%) were male and 6 (67%) were female. Among the 3 PTs, 1 (33%) was male and 2 (67%) were female. The semistructured interviews revealed participants' perceptions of web-based learning and the nature of the interactions among PLs, PTs, and

tutorial content. The themes identified from the thematic analysis are summarized in [Textbox 1](#). Overall, SS interaction was limited in comparison with ST and SC interaction, and PLs and PTs had differing views on what constituted “interaction” in a

web-based setting. However, web-based NPT provided a comfortable environment for PLs to learn and PTs to develop their teaching skills.

Textbox 1. Summary of themes (global theme, organizing theme, and basic theme).

Types of interactions in web-based near-peer teaching (NPT) [19]

- Student-student
 - Individualistic learning approach
 - Students’ perceptions of the level of expertise of their peers and near peers
- Student-teacher
 - Preference for anonymity and privacy
 - Discrepancy in expectations regarding the roles and responsibilities of peer learners and peer teachers
- Student-content
 - Passivity in learning
 - Learning priorities
- Advantages and disadvantages of web-based NPT
 - Web-based learning environment
 - Skills development for web-based teaching

Nature of Interactions in Web-Based NPT

SS Interaction

Both PTs and PLs noticed a lack of SS interaction during the tutorials. Some PLs adopted a passive approach to learning and refrained from speaking aloud or showing their face on camera:

The students weren’t very willing to verbally communicate on Zoom or turn on their cameras or speak to each other. [PT-3]

Not all of the students will participate actively in the session, [some] keep muted and keep their camera closed all the time. [PL-2]

However, the PLs may not have felt that such a lack of interaction hindered their learning during the session. Most PLs perceived NPT as a means to learn from their near peers solely through the direct transmission of knowledge from those in the senior years rather than an opportunity to collaborate with their immediate peers to develop knowledge together in a collective learning process:

I wouldn’t say that [the lack of student-student interaction] would affect the atmosphere, because I mean we are here to learn, and I [am] just focusing on the tutor but not our classmates. It doesn’t really affect me that much. [PL-4]

ST Interaction

PTs and PLs generally felt a greater degree of ST interaction than SS interaction, although this was still largely limited to participation by PLs via anonymous platforms or written

communication or one-on-one private interactions between the PL and PT:

They [PTs] were kind of making more interaction [with us and would] give us time to ask questions. [PL-6]

Especially when we did activities like Kahoot or online games, they [PLs] were very actively participating...I also was pleasantly surprised by how many questions they sent, like a lot of them private messaged me questions about topics they were confused about. [PT-3]

Regarding the use of web-based quiz platforms, such as Mentimeter, to promote ST interaction, one of the PLs stated the following:

Most importantly it’s anonymous...so people can’t see who is answering, so I think they will be more brave and interacting. Rather than typing on the chat box on Zoom, I think [it’s] definitely helping [interaction]. [PL-5]

However, some PLs did not desire or experience much ST interaction in their sessions:

I want to go there and learn so it’s like a peer teacher teach and I listen kind of mode. [PL-1]

There is not much interaction. And I think there isn’t much in normal lectures either, so it didn’t really matter because I personally just watch the recorded [lecture] videos...there’s no difference to me. [PL-4]

On the other hand, some students preferred more ST interaction than what was available, such as longitudinal interactions spanning beyond the tutorial itself:

The tutor could do more to get to know us and perhaps [offer] some sort of support for our study after the tutorial because...now it's more like, "Oh, we have like a lecture or a tutorial and then, oh, bye bye." I think there could be follow-up after the tutorial. [PL-3]

SC Interaction

The PLs and PTs felt that the PLs were engaged in web-based tutorials, with certain learning activities (such as applying knowledge to clinical scenarios and web-based quizzes) being more effective in encouraging PLs to interact with the subject matter than others. However, the PLs believed that the PT was responsible for driving their engagement with the content instead of it being a self-motivated process:

We tried to come up with a couple of different clinical cases in the form of multiple choice questions to get them to really think about: "Oh, so if you have a patient scenario what might they have? How might you manage them?" A piece of feedback that we received was that the students really enjoyed these kinds of questions and...knowledge synthesis. [PT-1]

I always do anticipate that some students will not answer our quizzes [and] not want to participate, so I was really surprised by everyone answering...and all the questions we got really showed that they were listening. [PT-3]

Although not many students are participating or actively speaking, but some of the teachers can make us more active in the form of using Menti. [PL-2]

PLs had varied opinions toward the modalities used to assess their understanding of the tutorial content. Anonymous quiz platforms were favored over asking and answering questions verbally or in a written format wherein PLs' identities would be revealed:

Some people are still afraid of having their answers on the chat publicly wrong [but] I think [NPT is] more interactive than the actual lectures. [PL-5]

Despite the passivity of certain PLs, their voluntary participation in the extracurricular NPT sessions suggests their engagement with the content:

The schedule of a medical student is really harsh so sometimes one to two hours could be the other time for us to revise. [That was] the first hesitation for us when we first heard of it [NPT], [but after the first session] I think it's good...that's why I keep going. [PL-6]

Conceptualization of Web-Based "Interaction" by PLs and PTs

Although some students hoped to learn passively from the PTs, others recognized the importance of interaction in learning and provided feedback that NPT could be improved by integrating more interactions. However, some PLs viewed "learning" as acquiring strategies for memorizing information rather than attaining a deeper understanding of concepts:

If the session is more interactive it would leave a larger impression like it will help us to better memorize all the stuff mentioned in a session. [PL-2]

I [thought] it might be good to attend and see what the seniors do to recite [the cranial nerves], and I think that they really shared some tips that will help me to recite this better. [PL-4]

Furthermore, there was a discrepancy in expectations between PLs and PTs regarding the nature of the interaction by PLs during web-based NPT. PTs expressed disappointment in the PLs' unwillingness to interact through their cameras and microphones:

The first session didn't really meet my expectations...because I expected them to be even more interactive. [PT-2]

It's quite difficult to teach if they do not open the cameras...I invited them [to] open the camera so it's more interactive so I can see them nod or see if they understand what I'm talking about. [PT-2]

I haven't really been able to visually see the people I'm kind of tutoring or coaching which is a little bit of a bummer but I completely understand, I mean like 8 or 9pm I don't really want to be turning my camera on either...without these visual cues, perhaps with their facial expressions or body language, it can be quite difficult to gauge whether we're getting the point across or whether they find it as engaging as we hope it is...I think some of that feedback would help. [PT-1]

Although PLs switched off their cameras and empathized with the increased difficulty this posed to the PTs, they did not believe this hindered interaction overall or their level of engagement and learning in NPT. Evidently, PLs and PTs held contrasting views regarding what constituted student "interaction" in web-based learning, with PLs perceiving a distinction between "interaction" and "engagement" in web-based NPT:

Students don't like opening their cameras, so the teachers can't really see us...It affects the teacher more than the student because I guess the student actually is quite interactive in terms of asking questions on the chat or even opening their mic. [PL-5]

[The NPT sessions are] quite engaging...so I don't think that [PLs not turning on their cameras] is a problem. [PL-6]

In addition, PLs expected PTs to drive the interactions in web-based NPT:

The tutor could ask us questions and then we'll answer it. [PL-3]

I just wanted them to go through maybe or let me know what the...key points in that topic [are]. [PL-5]

The senior will demonstrate the correct approach [to the question] and their recommended approach is the key thing to the session. [PL-9]

One PT shared the belief and felt it was the role of the teacher to entertain PLs during the session, whereas another PT anticipated NPT sessions to be a shared learning process with equal contribution by PLs and PTs to the discussion:

Before the session, I was really nervous because...I thought it would be quite boring and some students may not like the interaction through Zoom. [PT-2]

There is that sort of element of responsibility from the student's perspective to be responsible and take charge of their own learning. [PT-1]

Advantages of Web-Based NPT

For most PLs, web-based NPT was “flexible” and “convenient” in terms of timing and location as “you can just log on from anywhere” (PL-7). Compared with face-to-face sessions, web-based NPT is more casual and enjoyable, as the web-based format “lessens the stress” (PL-1) and “you can actually enjoy the session more comfortably because you can [be at] home” (PL-6).

PTs concurred with the “time and efficiency” (PT-1) advantages of web-based NPT compared with in-person teaching. They also commented on the more comfortable and safe learning environment on the web, especially with the option of remaining anonymous, which may alleviate PLs’ stress associated with interacting with PTs:

[Students are] a little bit more open to asking questions online...So I think that [teaching online] has made it a little bit more comfortable in terms of creating an open and welcoming learning environment for them...It [also] alleviates some of the pressure and the burden of...if I were to raise my hand up in class and everybody [knows] that it's me. [PT-1]

Online [NPT] makes students who would be shy or unwilling to show up in-person come to a class online because they're able to turn off their camera and mic and...be as disengaged as they want...I think some people do like to study...in their own environment where they're comfortable and [have] a choice to be anonymous. [PT-3]

With web-based teaching, PTs have fewer logistical concerns and more teaching tools available at their disposal to optimize the learning experience for PLs:

I don't have to think about...how I'm going to hook up my computer to a projector [because] I can easily do that with screen sharing...so I think the technology is really great and really has allowed us to benefit from online teaching and in fact I think it really works well with this kind of Zoom learning. [PT-1]

Moreover, web-based NPT provided PTs with opportunities to practice skills unique to web-based teaching and experience teaching in a virtual setting:

It was very good hands-on to see...how to teach in a Zoom format...It allowed me to kind of see the perspective of our professors. [PT-3]

I [applied] some skills that I've never thought would be useful, especially through online teaching...to trigger some interest of students and to invite any questions. [PT-1]

Disadvantages of Web-Based NPT

However, conducting web-based NPT has its disadvantages too, particularly in terms of hindering SS and ST interaction:

People are less active when the session is not face-to-face. [PL-1]

It's quite quiet during the Zoom meeting because we don't want to talk on Zoom and we like to type in the chat...In the future, they can have some face-to-face sessions with the juniors so that the juniors can attend and interact with them. [PL-8]

It would have been nice if the group was more interactive with us and with each other...Them interacting with one another [would] probably be easier in-person. [PT-3]

Discussion

Overview

Although e-learning and NPT separately have become popular pedagogical methods used in the setting of medical education [1,20], there have been few reports on the implementation and outcomes of a student-led NPT program *purposely* designed to be delivered on the web. This qualitative study offers an insight into medical students’ experiences of web-based NPT either as PTs or PLs, in particular, the perceived nature of interactions during tutorials and the advantages and disadvantages of a web-based medium of instruction. Our findings have implications for educators in medicine and other fields seeking to engage students in NPT on web-based platforms by highlighting key considerations, pitfalls, and opportunities for facilitating interactions in web-based NPT.

Principal Findings

Interaction Between Students on the Web

Our study demonstrates that web-based NPT sessions facilitated interactions among PLs, PTs, and subject content to varying degrees. The lack of SS interactions witnessed during NPT was similarly reported in the context of web-based learning by Wut and Xu [21] and Ng [22] among university students and tutors in Hong Kong and by Banna et al [23] in the United States. In addition, Wut and Xu [21] found that web-based classrooms posed challenges to students’ teamwork and group discussion, peer learning through the process of asking questions and formulating solutions, and establishing social presence.

This phenomenon may be explained by the Transactional Distance theory [24], which considers the impact of various types of interaction on the sense of distance a learner feels during web-based learning encounters, and consequently, their engagement and behavior. The absence of face-to-face human contact in web-based settings is likely to increase the transactional distance experienced by the student, thus reducing their sense of belonging and willingness to participate [23].

Other possible factors accounting for limited SS interaction include the unfamiliarity of students with one another, their different learning paces, and the depth of understanding of course material [22]. The students' personality may also hinder SS interaction. For example, introverted students may prefer to learn on a web-based platform over a face-to-face classroom but enjoy web-based activities that involve working alone rather than in a collaborative manner [25].

However, the importance of SS interaction in learning, such as student satisfaction and performance, is still under debate. Small-group learning has been shown to benefit student achievement considerably more than individual learning [23]. On the other hand, Moore et al [26] reported that most students did not like or want SS interaction in distance education classes, whereas Kuo et al [27] demonstrated that SS interaction was not a substantial predictor of student satisfaction, in contrast to SC and ST interactions. The value and perceived importance of SS interaction in web-based learning may further depend on contextual factors, such as whether collaborative activities or group projects are needed [27].

Interaction Between ST and SC

Regarding ST and SC interactions, this study found that PLs mainly adopted a passive learning approach with minimal interaction or interacted with PTs through communication channels that guaranteed anonymity from other PLs. This behavior was surprising to some PTs, who expected PLs to be more open to interacting through their cameras and microphones. Wut and Xu [21] noted similar challenges with university students in Hong Kong being reluctant to openly share their views, ask questions, and request clarifications. Various factors affect students' reluctance to exchange information in web-based settings. Knowledge-sharing behavior, which may be explicit (eg, sharing documents) or implicit (eg, sharing know-how), has been shown to be lacking in web-based environments compared with face-to-face learning [28]. Using the Transactional Distance theory to understand how web interactions affect knowledge-sharing behavior, Yilmaz [29] reported that higher-quality SS, ST, and SC interactions (among others) reduce individuals' sense of transactional distance in a web-based environment, which subsequently improves knowledge-sharing behavior.

Culture further impacts knowledge-sharing behavior and one's predilection for anonymity. In a study of multinational and cross-cultural web-based classes involving students from Hong Kong, Beijing, and the Netherlands [28], the cultural dimensions identified by Hofstede [30] affected knowledge sharing, which included collectivism and individualism (the extent to which individuals in a society are integrated into groups), power distance (the degree of acceptance and expectation of unequal power distribution by less powerful members of society), uncertainty avoidance (how threatened members of a society feel about uncertain or unknown situations), Confucian dynamism (having a long-term or short-term orientation in life), and concern for face (concern over the image of oneself, another party, or both parties). Cultural values may further explain students' preferences for anonymous peer review, as students from Asian backgrounds (eg, Mainland China, Taiwan, and

Hong Kong) are reluctant to criticize their peers' work to preserve group harmony [31].

In addition, students' preference to remain passive, private, and anonymous in ST and SC interactions may be related to personality factors, such as being shy or embarrassed to ask questions publicly or being concerned about making mistakes in front of other peers [21]. Alternatively, their behavior may reflect their *surface* approach to learning, aimed at merely reproducing learning material in the absence of reflection about the purpose of knowing the information or formation of connections between the information [32]. This was apparent in 4 PLs who expected NPT to be an act of the PT transmitting knowledge in a unidirectional manner to the PLs who received it passively and "learning" to occur from rote memorization of facts rather than understanding the information. In contrast, PTs unanimously adopted a "deep" learning approach by finding patterns in the knowledge and explaining the principles underpinning information, which they anticipated PLs would emulate but did not in practice. Mirghani et al [32] similarly reported that first- and second-year medical students preferred a "surface" learning approach, whereas senior-year students were more likely to adopt a "deep" learning approach. Considering that the learning environment and culture plays a role in shaping students' learning approach, this finding is not surprising because the heavy workload and examination-based assessment of preclinical medical education makes "deep" learning difficult for students [32]. Nevertheless, PLs' passive "surface" learning approach has implications for the academic outcomes of web-based NPT, as this approach is associated with poor academic performance [33,34].

However, although extensive ST and SC interactions by active students who reveal their identities represent tangible indicators of the individual's engagement and are assumed to enhance learning, anonymous interactions or the absence of visible activity do not equate to disinterest or disengagement with web-based learning [35]. "Lurkers" who are present but remain inactive in web-based discourse with their peers and instructors are nevertheless still learning, despite not visibly participating [36,37]. Furthermore, there is no substantial difference between active and passive activities on student engagement levels in web-based courses, although active means of interaction may offer additional benefits, such as strengthening students' social presence and potentially reducing social isolation [38]. This may be an important consideration for NPT programs that aim to offer social support, in addition to academic guidance.

Advantages and Disadvantages of Student-Led, Web-Based NPT

Implementing a student-led NPT program using a web-based platform has its unique advantages and disadvantages. Flexibility and comfort level are commonly cited strengths of web-based education, especially in uncertain circumstances such as during the COVID-19 pandemic [39,40]. Besides tutoring, web-based, student-led NPT platforms may also be used to provide psychological support and nonacademic advice [41,42]. However, web-based environments may still be less conducive to sharing socioemotional information than in person [43]. In addition, web-based NPT develops the teaching skills and

technological literacy of PTs, which are essential professional competencies in the modern era of medicine, given the likelihood for web-based learning pedagogy to persist in the future [21,44].

Comparison With Prior Work: Outcomes of Student-Led, Web-Based Learning and Face-to-Face Learning

Evaluation of learning should encompass not only the extent of information acquired by students but also the social interaction and “connectedness” that students feel throughout the process. As Gilbert and Moore [45] emphasized, there is a need to assess both “informational/instructional interactivity” and “social/organizational interactivity” when comparing traditional and web-based instruction. Future research should compare web-based and face-to-face delivery of NPT with regard to the academic and nonacademic facets of students’ learning experiences. On the other hand, a study conducted by Foo et al [2] on medical students from the same institution as this study found that students performed significantly worse in problem-based learning tutorials conducted on the web than in person from the perspective of the tutors, specifically in the domains of participation, communication, preparation, critical thinking, group skills, and total score. More research is needed with regard to student performance in the context of NPT and with students’ perceptions (such as satisfaction) taken into consideration.

Specific aspects of the learning experience that are better supported by web-based or in-person interactions should be clarified. Paechter and Maier [43] highlighted that the students undertaking courses at Austrian universities had clear preferences for web-based or face-to-face learning depending on the particular learning objective or learning process. Students favored web-based communication for SS interactions that merely involved the dissemination of information to peers but face-to-face communication in situations that required higher cognitive presence (such as cooperative learning, agreeing on a shared meaning with other learners, or reaching a joint solution) [43]. For ST interactions, web-based communication was deemed more appropriate for the rapid exchange of information with tutors (such as receiving feedback), whereas face-to-face interaction was preferred in situations in which tutors developed the knowledge of students (eg, by facilitating the acquisition of knowledge) [43]. To establish positive SS and ST social relations, students advocated for face-to-face interaction [43]. It is uncertain whether such appraisals of preferred interactions are applicable to informal NPT settings dominated by synchronous learning activities. Research focusing on students’ preferences for specific aspects of NPT in the context of medical education is necessary.

Future Directions

Moving forward, student-coordinated NPT programs for medical students in Hong Kong should be delivered in a manner that balances convenience and flexibility without compromising social and organizational interactivity, informational and instructional interactivity, and program sustainability [45]. Considering the results of this study and students’ preferences for web-based or face-to-face interaction, depending on the

learning objective [43], NPT may benefit from a blended learning approach that incorporates traditional face-to-face learning and e-learning.

Blended learning is already widely implemented in formal medical education, with meta-analyses demonstrating significantly improved knowledge acquisition and outcomes compared with traditional learning in health education [46,47]. It may similarly be optimal to conduct student-led NPT tutorials using this method, as the factors restricting SS, ST, and SC interactions in NPT, as identified by this study, are likely explained by the limited social and organizational interactivity offered on the web compared with in-person interaction, resulting in students’ heightened sense of transactional distance, unfamiliarity with their peers, lack of belonging, and reluctance to actively participate [23]. NPT in particular is heavily centered on collaborative learning and has the secondary aim of developing students’ social support network; thus, face-to-face elements are suggested and preferred by students to facilitate their cooperation on tasks and share socioemotional information [43], improve social presence and relations, and reduce social isolation [38].

In addition, the web-based component of student-led NPT should be retained as its convenience, efficiency, and comfort level reduce students’ barriers to participation as a PL or PT, hence ensuring the sustainability of the program. e-Learning for health professions is associated with equivalent or even superior outcomes than traditional learning in terms of knowledge, skills, attitudes, and satisfaction [4]; hence, the quality of learning in NPT should not be inferior to face-to-face learning if conducted on the web. Strategies such as creating anonymous quizzes [35] or assigning roles to each student in small-group discussions [48] can maintain student engagement on the web. PTs should be trained in such web-based teaching strategies to facilitate interactions that enable effective learning and standardize the quality of teaching. PTs should remind PLs of their shared responsibility for learning and their expected active contribution to tutorials [23]. Moreover, the web-based elements of NPT can be extended beyond the delivery of tutorials. Asynchronous measures such as a web-based discussion forum or a group created on social networking sites can promote interaction, collaboration, active participation, the sharing of knowledge and resources, and critical thinking [23]. PLs can be assigned to groups that are kept the same throughout their study to strengthen group cohesiveness and longitudinal relationships.

Limitations

First, a limitation of this study is the lack of a comparison group of students participating in face-to-face NPT and comparison of web-based NPT with web-based classes that are a part of the formal curriculum. Consequently, the findings regarding the nature and outcomes of SS, ST, and SC interactions may not be a result of the web-based format of NPT alone but rather influenced by other elements of NPT implementation, such as group size, educational distance between PTs and PLs, teaching skills of PTs, or the students’ personalities. Future studies should compare interactions among students in web-based and face-to-face NPT, exploring in further detail the specific aspects of near-peer education that benefit most with either the mode

of instruction and the underlying causes of the learning behaviors that shape interaction. Second, although the qualitative research methodology used enables a detailed understanding of participants' perceptions and feelings about NPT to inform student-centered pedagogical design, it does not allow for an objective assessment of learning outcomes for PLs (such as academic performance, satisfaction, and engagement) and PTs (such as teaching competencies and academic performance). A quantitative study with a larger sample size would allow such outcomes to be explored to guide future NPT programs.

Conclusions

This study reveals the nature of the SS, ST, and SC interactions that take place in student-led NPT tutorials conducted on the

web for medical students, designed and delivered by medical students. Despite the web-based learning environment being convenient and comfortable, students refrained from participating in active and collaborative ways. Nevertheless, web-based NPT can serve as a useful supplement to formal medical education by providing an easily accessible platform for PLs to receive academic and psychosocial support and for PTs to develop their competencies as educators in a digital era. Future directions of NPT should make use of the strengths of both web-based and face-to-face modalities to foster meaningful interactions and maximize learning, whereas further research should explore the subjective experience and objective outcomes of web-based versus face-to-face NPT.

Acknowledgments

The authors would like to thank the students who participated in the near-peer training program; Dr Kendrick Shih (Department of Ophthalmology), Dr Mei Li Khong (Li Ka Shing Faculty of Medicine), and Dr Tomasz Cecot (School of Biomedical Sciences) for their support and guidance; and Ms Joyce Tsang (Department of Family Medicine and Primary Care) for her assistance with data collection. This work was supported by a Teaching Development Grant from the University of Hong Kong (project number 811).

Abstract

Background: UK medical graduates can apply for specialty training after completing a 2-year internship (foundation training). Postfoundation training application requirements vary depending on specialty but fundamentally require key skills such as teaching, research, and leadership.

Objective: This study investigated whether medical student demographics impact their self-reported familiarity with the Post-Foundation Training Pathways (PFTP) and Post-Foundation Application Process (PFAP).

Methods: This was a cross-sectional study using a Bristol Online Survey. We invited all UK medical students to answer a range of questions about their demographics. Students were then asked to rank their familiarity with PFTP and PFAP on a scale of 1 to 5 (1=least familiar and 5=most familiar). The responses were collected between March 2022 and April 2022 and exported for further analysis. Statistical analysis was conducted in Stata (version 17.1; StataCorp) using chi-square tests.

Results: A total of 850 students from 31 UK medical schools took part. There was a significant difference between gender and self-reported familiarity with PFTP ($P<.001$) and PFAP ($P<.001$), with male students expressing higher familiarity. Similarly, there was a difference between ethnicity and self-reported familiarity with PFTP ($P=.02$) and PFAP ($P<.001$), with White students more likely to express higher familiarity than their Black, Asian, or Mixed Ethnic counterparts. Lastly, there was an overall difference between medical background and age and self-reported familiarity with PFTP and PFAP (all $P<.001$), with students from medical backgrounds and older students being more likely to express higher familiarity.

Conclusions: The impact of gender, ethnicity, age, and medical background on students' self-reported familiarity with PFTP and PFAP is significant. Further studies are required to evaluate the impact of these factors on tested knowledge of PFTP and PFAP and whether this impacts the success rate of postfoundation applications.

Introduction

In the United Kingdom, medical training starts with students spending between 4 and 6 years at the undergraduate level. Following this, all UK medical students must complete the foundation training program, a 2-year paid internship rotating through 6 different placements, before starting specialty training [1].

Postfoundation training lasts between 3 and 8 years, with many doctors taking years out of training before entering a specialty training program. Recruitment to specialty training programs varies between specialties. It might include a combination of a Multi-Specialty Recruitment Assessment (MSRA) exam score [2], a portfolio [3], as well as interviews.

Candidates can often prepare for the MSRA and the interview components of these postgraduate recruitments in the months leading up to the start of the application cycle. However, the portfolio part of the selection process often takes many years to develop. The portfolio includes components such as teaching experience, involvement in research, taking on leadership roles, and additional qualifications. The longer preparation time for those components could create an unfair advantage for candidates who know about the application process earlier in their undergraduate careers and, in turn, limit candidates' specialty selection.

The need for a diverse, well-balanced medical workforce is an established concept. Numerous studies have shown improved outcomes when patients match the gender and ethnicity of their physicians [4,5]. A diverse medical workforce is essential for patients and good for bringing a range of experiences together, paving the way for innovation and improvement of services. The primary aim of this study was to investigate any difference between medical students' demographics and their self-reported familiarity with Post-Foundation Training Pathways (PFTPs) and Post-Foundation Application Process (PFAP). The secondary aim was to investigate the difference between demographics and training pathway choices.

Methods

Study Design and Compiling the Questionnaire

This was a cross-sectional study using a web-based questionnaire. Bristol Online Surveys (University of Bristol) was used to collect responses.

The authors designed the survey to include questions about the participants' demographics, including gender, ethnicity, medical background, age, and training stage, as well as questions on self-reported familiarity with PFTPs and PFAPs. The questionnaire also assessed participants' preferred training programs out of a selection of common pathways, including acute care common stem (ACCS), core surgical training (CST), general practice, internal medical training (IMT), neurosurgery,

obstetrics and gynecology, ophthalmology, psychiatry, and radiology. The survey involved a range of question styles, including Likert scale, multiple choice, and free text (Multimedia Appendix 1).

This was an open, voluntary survey, and participants were required to complete all the questions before being able to submit their responses. When relevant, participants were given response options such as "not applicable" or "rather not say." The Bristol Online Surveys prevented participants from submitting multiple responses using web-based cookies.

Recruitment Process

All current UK medical students were eligible to take part. To maximize the reach of the questionnaire, local collaborators were recruited from several universities across the country to promote the study and assist in collecting responses (see "Acknowledgments" section). The collaborators and authors carried out a trial run to ensure the functionality and usability of the electronic questionnaire before the national opening.

This study was advertised through social media channels as well as locally placed printed posters. In order to incentivize participation, students were offered a chance to enter a draw to win a £50 (US \$61) Amazon voucher, which was self-funded by the authors. If the participants opted for entry into the draw, they were asked to enter their email address for the prize allocation. This was collected separately and not linked to the rest of the questionnaire. After prize allocation, all email addresses were deleted.

The data collection took place over 2 months, between March 2022 and April 2022. The data were stored safely on the Bristol Online Survey's servers and was anonymously exported for further analysis.

Definitions

The following definitions were given to the participants to standardize their answers.

Coming from a medical background was defined as having a family member or close friend with a medical degree.

Self-reported familiarity with PFTPs was defined as understanding the number of years involved in the desired training pathway and whether the training pathway was run through or required multiple applications (eg, 2 years of CST followed by another application cycle for 4-5 years of higher surgical training).

Self-reported familiarity with PFAP was defined as an understanding of the current criteria for candidate selection (eg, use of MSRA, portfolio, and interviews) and the content of the said criteria (eg, portfolio and interviews assessing qualities such as leadership, academics, and teaching).

Analysis

For familiarity with PFTPs and PFAP, respondents were asked to express their responses based on a 1-5-point Likert scale, which ranged from the lowest level of familiarity (1) to the highest level of familiarity (5), with the average response being in the middle. Respondents were also asked to indicate what their preferred training pathway after the foundation program would be if they were to choose at this point in time.

The data were analyzed using Stata (version 17.1; StataCorp). Overall differences between demographics and self-reported

familiarity were analyzed using chi-square tests. As our contingency tables are larger than 2 by 2, we then used Pearson-adjusted residuals to examine where any significant differences lie. A residual is the difference between the observed and expected values for a cell. The larger the residual, the greater the contribution to the overall chi-square value and significance. Adjusted residuals are Pearson residuals divided by an estimate of their SE, $P < .05$ represents residuals of ≥ 1.96 (indicated by relevant footnotes in Tables 1-3), and a more conservative $P < .01$ represents residuals of ≥ 2.58 (indicated by relevant footnotes in Tables 1-3).

Table 1. Illustrates the Pearson residual values for students self-reported familiarity with Post-Foundation Training Pathways and asks the question “How familiar are you with training pathways of doctors after foundation training?” Chi-square and associated P values refer to overall significance between the variables tested and the Pearson adjusted residuals illustrate where significant differences lie.

Variables	Self-reported familiarity with Post-Foundation Training Pathways out of 5 (1=least familiar and 5=most familiar)					Chi-square (df)	P value

Ethical Considerations

The project was reviewed by the Faculty of Health Science Research Ethics Committee at the University of Bristol, and ethical approval was also granted (reference number: 9858). All participants were informed about the aims of the study, the average length of time required to fill out the survey, and the members of the investigating team. This information was included in all promotional material about the survey as well as the first page of the web-based survey. All the data were collected anonymously.

Results

Overview

A total of 850 UK medical students from over 31 medical schools completed the web-based questionnaire. IMT, CST, general practice training, and ACCS were the most popular training pathways that students expressed an interest in at this point of their university training (24.8%, 19.6%, 18.6%, and 14.8%, respectively).

Gender

A total of 584 female, 245 male, and 11 nonbinary, nonconforming students took part. Also, 10 participants

preferred not to declare their gender. Due to small sample sizes, the nonbinary, nonconforming students, and those who preferred not to mention their gender were excluded from further gender-based analyses. There was an overall significant difference between gender and self-reported familiarity with PFTPs (*P*<.001), where 40% (98/245) of the male students expressed high familiarity (4 or 5 on the Likert scale), compared to 26.5% (155/584) for female students (Figure S1-A in [Multimedia Appendix 2](#) and [Table 1](#)). Similarly, there was an overall significant difference between male and female medical students and their self-reported familiarity with the PFAP (*P*<.001), where 67.1% (392/584) of the female students expressed low familiarity (1 or 2) compared to 44.1% (108/245) for male students. Significantly more male students expressed a higher familiarity (4 or 5) with the application process (male: 26.5% vs female: 10.3%; Figure S1-B in [Multimedia Appendix 2](#); [Table 2](#)).

Lastly, there was a significant overall difference between genders and chosen training pathway (*P*<.001), where male students were more likely to choose radiology and neurosurgery training and female students more likely to choose obstetrics and gynecology as their potential training pathway (Figure S1-C in [Multimedia Appendix 2](#) and [Table 3](#)).

Ethnicity

A total of 458 students were of White ethnicity, while 377 were of Black, Asian, or Mixed Ethnic (BAME) backgrounds. Furthermore, 15 participants selected unknown or preferred not to declare their ethnicity. Due to a small sample size, this group was excluded from further ethnicity-based analyses. There was a small overall significant difference between self-reported familiarity with PFTP and ethnicity ($P=.02$; Figure S2-A in [Multimedia Appendix 2](#)). BAME students were more likely to choose a 2 and less likely to choose a 3 on the Likert scale compared to White students ([Table 1](#)). There was a stronger and more significant difference between White and BAME students and their self-reported familiarity with PFAP. White students reported to be more familiar with PFAP (4 or 5) compared to their BAME counterparts (White: 19.8% vs BAME: 9%; Figure S2-B in [Multimedia Appendix 2](#); [Table 2](#)).

When asked about training pathways that the students might choose at the time of the survey, there was a significant overall difference between White and BAME students ($P<.001$), where more White students (19.7% vs 9.5%) chose ACCS. This was reversed for radiology (White: 1.1% vs BAME: 4%), although the overall numbers for radiology were low (20 out of 850). There was no significant difference between the other training pathways and ethnicity (Figure S2-C in [Multimedia Appendix 2](#) and [Table 3](#)).

Medical Background

A total of 255 out of 850 students came from a medical background, defined as having a family member or close friend with a medical degree. There was a significant difference between medical background and self-reported familiarity with PFTPs ($P<.001$). A significantly higher proportion of students with no medical background expressed low familiarity (1 or 2) with the training pathway (no medical background: 41.1% vs medical background: 20%). Those with a medical background were also much more likely to answer a 4 (Figure 3A-A in [Multimedia Appendix 2](#) and [Table 1](#)).

There was also a significant difference between coming from a medical background and self-reported familiarity with PFAP ($P<.001$). A higher proportion of students with no medical background expressed low familiarity (1 or 2) with the application process (no medical background: 69.1% vs medical background: 40%). Comparably, more students from a medical background indicated higher familiarity (4 or 5) with the application process (no medical background: 9.2% vs medical background: 28.2%; Figure 3-B in [Multimedia Appendix 2](#); [Table 2](#)).

A total of 85% (217/255) of those who had come from a medical background thought that this had a positive impact on their familiarity with PFTPs and PFAPs.

There was no overall significant difference with medical background and selection of the training pathways ($P=.05$), except for obstetrics and gynecology (no medical background: 9.4% vs medical background 3.5%; Figure 3-C in [Multimedia Appendix 2](#); [Table 3](#)).

Age

The participants were from various training stages (71 in first year, 191 in second year, 245 in third year, 100 in fourth year, 113 in fifth year, 38 in sixth year, and 34 intercalating). The mean age of the participants was 22.5 years. The participants were categorized into 2 cohorts for the purposes of analysis: younger than the mean age (503 students) and at or older than the mean age (346 students). A significant difference ($P<.001$) can be seen between participants younger and older than their average age and their self-reported familiarity with PFTPs. A greater proportion of participants younger than the average age expressed lower familiarity (1 or 2) with the training pathway compared to those aged above average (<22.5 years=42.5% vs ≥ 22.5 years=23.7%), with older respondents reporting higher familiarity (4 or 5) with the training pathway (<22.5 years=23.1% vs ≥ 22.5 years=41.3%; Figure 4-A in [Multimedia Appendix 2](#); [Table 1](#)).

Results also showed a significant difference between age and PFAP ($P<.001$), where participants younger than the average age reported being less familiar (1 or 2) with PFAP (<22.5 years=72% vs ≥ 22.5 years=43.7%). In parallel, fewer participants with a younger age than average expressed higher familiarity (4 or 5) than those who aged above average (<22.5 years=8.9% vs ≥ 22.5 years=23.7%; Figure 4-B in [Multimedia Appendix 2](#); [Table 2](#)). There was no significant difference ($P=.76$) between training pathway selection and age groups (Figure 4-C in [Multimedia Appendix 2](#) and [Table 3](#)).

Future Resources

Participants were also asked about their preferred method of further guidance on the application processes, where 72.9% (612/850) chose a website explaining all the training pathways and the application processes, 44.5% (378/850) selected mentorship schemes, 45.1% (383/850) chose short videos, and a third (281/850, 33.1%) chose lectures.

Discussion

Overview

Female students reported lower familiarity with the application process than male students. Numerous studies have demonstrated the lower number of women in academic medicine [6], surgical specialties [7], and leadership roles [8] in health care. This is despite a higher proportion (54% in 2019) of female doctors registering with the General Medical Council each year [9].

However, this high proportion of female medical students currently does not translate into a high proportion of female consultants, who only make up 36% of the consultant population [10]. Although this number has improved (30% in 2009), the rate of improvement has been very slow. Moreover, this number is much lower in historically male-dominated specialties such as surgery (14.7% in 2022) [11].

The lower self-reported familiarity with the training pathways and the application process could contribute to this lower rate of progression, especially in training pathways such as CST, where there is a strong emphasis on portfolio building in the

years leading to the application. One of the factors contributing to this is the lack of senior female role models and mentors who would be able to advise the students throughout their medical school [12]. Implicit bias by seniors could also lead to an uneven distribution of portfolio-building opportunities [13].

The BAME medical students reported being less familiar with the PFAP than students from a White ethnic background. The proportion of UK graduates from a BAME background registering with the General Medical Council was 23% in 2019 [9]. A great amount of work has been done to increase the number of successful applications to medical schools for students from non-White ethnic backgrounds. The Medical School Council reported an increase of 58% in students of Black heritage in 2019 [14].

Many widening participation schemes have been designed to provide opportunities such as voluntary work, shadowing placement, and interview practice, among others, for pupils from diverse ethnic and socioeconomic backgrounds. However, most support programs stop after entry into medical school. This could be a contributing factor to the lower self-reported familiarity of students from BAME. Similar to gender, the lower representation of BAME doctors in senior roles translates into a lower number of role models, which could be affecting the students' overall familiarity with PFAP.

Almost a third (255/850, 30%) of the students reported being from a medical background, and the majority of those (217/255, 85%) believed that this had a positive impact on their self-reported familiarity with PFTP and PFAP. This was reflected in the familiarity responses, where students from medical backgrounds reported higher familiarity with PFAP. These results show that being from a medical background could have an impact even after entry into medical school. Medical students would be able to learn about the requirements of PFAP early on through their medical contacts, enabling them to get involved in extracurricular activities such as teaching, research, and presentations earlier than their peers. The subject of the heritability of medicine is a concept that has been introduced previously. A study on 3 generations of Swedish physicians found that the proportion of physicians with one parent from a medical background rose from 6% in the 1950s to 20% in 1980 [15]. They hypothesized factors such as financial background as important contributors to this rise in medical students from medical backgrounds. However, this study suggests that the role of nonfinancial advantages cannot be ignored, as it was demonstrated that a medical background is correlated with significantly higher self-reported familiarity with PFAP.

Lastly, we analyzed the impact of age on the students' self-reported familiarity. The different lengths of medical degree

courses (4-year, 5-year, and 6-year courses) as well as the possibility of intercalating at different stages throughout the medical school do not allow direct comparison between training years. As expected, the self-reported familiarity with PFTP and PFAP is different between age groups. As the students spend more time in the clinical setting by completing their clinical years, they are more likely to become familiar with PFTPs and PFAP. Furthermore, they are also more likely to come across mentors who can guide them through the process.

There are clear differences between gender, ethnic background, and medical background, and medical students' self-reported familiarity with PFTPs and PFAP. It is unclear how early self-reported familiarity with the PFTP and PFAP impacts career progression and success in postgraduate training. However, assuming early self-reported familiarity correlates to actual familiarity and, in turn, an advantage, this may be a predisposing factor to some of the discrepancies observed in the demographic composition of the general population and the senior doctor community.

Traditionally, medical schools are thought to be places that prepare students for the early years after graduation. However, certain aspects of postgraduate training applications, such as leadership, teaching, and research, take time to develop. The earlier the students know about these requirements, the more likely they are to be able to seek opportunities to develop those skills in time for postgraduate applications. Addressing this gap in the undergraduate curriculum requires national collaboration from medical schools and Royal Colleges to develop resources and signpost students to them. As suggested by the students, this could take the form of one website with all the required information, a series of short videos explaining the PFAP, as well as mentoring schemes.

This study had several limitations. First, low numbers in smaller specialties such as radiology and neurosurgery make it difficult to draw any conclusions about these specialties. Similarly, low numbers of nonbinary, nonconforming students mean no statistically significant conclusions can be drawn. Lastly, we used candidates self-reported familiarity. Future studies should consider using objective measures of familiarity by evaluating knowledge through questionnaires.

Conclusions

Self-reported familiarity with PFTPs and PFAP differs significantly based on gender, ethnicity, medical background, and age. It is unclear whether early familiarity with PFTPs and PFAP offers an advantage in the subsequent recruitment process, and further studies are required to explore this. Free, easily accessible national resources need to be developed to allow early student access and eliminate uneven access to information.

Acknowledgments

We are grateful to all the local collaborators (Adanna Collins, Carola Bigogno, Aditya Gaur, Carolina Valensise, Joyce Ira Go, Rumitha Rubaratnam, Harshita Bagul, Lyuben Truykov, Laura Chan, Muhammed Hamza Shah, Ray Chong, Wei Ying Chua, Nidhi Vivek, Olivia Meeke, Nicole De Sousa, Nikita Chauhan, and Yvonne Sum) for their contribution to the recruitment of participants. No funding was received to perform this study; therefore, the authors acknowledge that there are no financial disclosures for this study.

Data Availability

The data sets used and analyzed during this study are available from the corresponding author upon a reasonable request.

Authors' Contributions

All authors were responsible for the designing and conducting the study. KD wrote the main manuscript. KD, TR, ACC, RI, KCNK, and ERBK performed a literature review around the topic and contributed to the writing of the manuscript. LH performed the statistical analysis. All authors reviewed the final draft and contributed edits before submission.

Abstract

Background: Scoring and awarding credit are more complex for multiple-select items than for single-choice items. Forty-one different scoring methods were retrospectively applied to 2 multiple-select multiple-choice item types (Pick-N and Multiple-True-False [MTF]) from existing examination data.

Objective: This study aimed to calculate and compare the mean scores for both item types by applying different scoring methods, and to investigate the effect of item quality on mean raw scores and the likelihood of resulting scores at or above the pass level (≥ 0.6).

Methods: Items and responses from examinees (ie, marking events) were retrieved from previous examinations. Different scoring methods were retrospectively applied to the existing examination data to calculate corresponding examination scores. In addition, item quality was assessed using a validated checklist. Statistical analysis was performed using the Kruskal-Wallis test, Wilcoxon rank-sum test, and multiple logistic regression analysis ($P < .05$).

Results: We analyzed 1931 marking events of 48 Pick-N items and 828 marking events of 18 MTF items. For both item types, scoring results widely differed between scoring methods (minimum: 0.02, maximum: 0.98; $P < .001$). Both the use of an inappropriate item type (34 items) and the presence of cues (30 items) impacted the scoring results. Inappropriately used Pick-N items resulted in lower mean raw scores (0.88 vs 0.93; $P < .001$), while inappropriately used MTF items resulted in higher mean raw scores (0.88 vs 0.85; $P = .001$). Mean raw scores were higher for MTF items with cues than for those without cues (0.91 vs 0.8; $P < .001$), while mean raw scores for Pick-N items with and without cues did not differ (0.89 vs 0.90; $P = .09$). Item quality also impacted the likelihood of resulting scores at or above the pass level (odds ratio ≤ 6.977).

Conclusions: Educators should pay attention when using multiple-select multiple-choice items and select the most appropriate item type. Different item types, different scoring methods, and presence of cues are likely to impact examinees' scores and overall examination results.

Introduction

In dentistry, multiple-choice items are often used to test theoretical knowledge in written examinations [1]. Multiple-choice items can be divided into single-choice items (eg, Type A) and multiple-select items. In multiple-select items, examinees are required to judge multiple answer options/statements independently within a single item. The correctness of an answer option/statement does not affect the other answer options/statements within the same item. Therefore, a more active knowledge reproduction takes place as examinees cannot identify the correct answer option at the first glance and must not ignore the remaining answer options. In contrast to single-choice items, scoring of multiple-select items is more complex. While examinees' responses on single-choice items might be either correct (1 full credit point is awarded) or incorrect (no credit points are awarded or a penalty score is given), multiple-select items might result in partially correct responses (ie, some answer options/statements are marked correctly while others are marked incorrectly).

Within electronic written examinations of dental undergraduate students at the University Medical Center Göttingen, Type A single-choice items and 2 kinds of multiple-select multiple-choice items, known as Pick-N [2,3] and Multiple-True-False (MTF) [4], are used. Examples of the item types are shown in Figure 1. Since the first mention of these item types, various scoring methods for scoring multiple-select items have been described in the literature. A summary of different scoring methods and their corresponding mathematical scoring algorithms as identified by 2 recent systematic reviews [5,6] is shown in Multimedia Appendix 1.

Pick-N items consist of a variable number of answer options (with the number $[n]$ ranging from 5 to 26 [7-9]), and examinees are asked to select all true answer options. The total number of true answer options (t) within each item is disclosed to examinees and might vary between 2 and $n-1$ [3,7,9-11]. In recent years, Pick-N items were described to typically consist of 1 circumscribed question and a number of very short answer options (ie, a single word or very short phrases) [7,10]. This item type has also been named *k from n* and *n out of many* in the literature [8,9].

MTF items consist of a question stem and a variable number of statements (ie, complex statements as opposed to very short answer options used in Pick-N items), which need to be labeled independently as true or false by examinees. Any number of statements (including zero and n) might be correct, and the number of true statements is not disclosed. This item type has also been named *true-false format*, *cluster-true-false*, *cluster (multiple true-false) variety*, *cluster-type true-false*, *Kprim*, *Kprime*, *K'*, and *Type X* in the literature [12-16]. Based on the above-mentioned definitions of Pick-N and MTF items, the example shown in Figure 1 should be employed as a Pick-N item instead of an MTF item.

Although indications for the use of multiple-select multiple-choice items and corresponding instructions for examinees vary between both item types [7,10], it is unknown whether educators employ Pick-N and MTF items according to the above-mentioned recommendations. Moreover, the relation between examinees' true ability (ie, *true knowledge*) and expected scoring results differs between both item types [5,6]. In case of examinations consisting of single-choice items with 5 answer options only (ie, with a guessing probability amounting to 20%), a pass mark of 60% tests examinees for a level of 50% *true knowledge*, as examinees with 50% *true knowledge* achieve 60% of the possible total score on average due to the possibility of guessing (using an all-or-nothing scoring method without applying a penalty for incorrect responses). Depending on the employed multiple-select item type, the number of answer options/statements per item, and the used scoring method, examinees might require either more or less *true knowledge* to gain 60% of the possible total score on average.

Therefore, this study aimed to (1) retrospectively apply different scoring methods to existing examination data from multiple-select multiple-choice items and analyze the obtained results from examinees (ie, scores) and (2) investigate the impact of item characteristics (ie, selection of appropriate item type and presence of cues) on scoring results (ie, mean raw scores and the likelihood of resulting scores at or above pass level when using different scoring methods).

The null hypotheses were as follows: (1) scoring results for Pick-N and MTF items do not differ between different scoring methods and (2) item characteristics do not impact scoring results.

Figure 1. Examples of matched Pick-N (top) and Multiple-True-False (bottom) items with 5 answer options/statements.

Dental erosion is the chemical loss of mineralized tooth substance caused by exposure to acid. Which of the following causes of erosion are most likely to be classified as exogenous?
(Please select 2 answers!)

- ☐ Gastroesophageal reflux
- ☐ Bulimia
- ☒ Occupational exposure
- ☐ Anorexia nervosa
- ☒ Alcohol abuse

Dental erosion is the chemical loss of mineralized tooth substance caused by exposure to acid. Please rate if the following causes of erosion are exogenous!
(Please make a decision for each answer!)

	True	False
Gastroesophageal reflux	<input type="radio"/>	<input checked="" type="radio"/>
Bulimia	<input type="radio"/>	<input checked="" type="radio"/>
Occupational exposure	<input checked="" type="radio"/>	<input type="radio"/>
Anorexia nervosa	<input type="radio"/>	<input checked="" type="radio"/>
Alcohol abuse	<input checked="" type="radio"/>	<input type="radio"/>

Methods

Ethical Considerations

Owing to the retrospective design of the study and the fact that only anonymized item scores at the level of previous examinations (ie, not at the level of identifiable students) were available from the examination software, no ethical approval was required.

Multiple-Select Multiple-Choice Items

At the University Medical Center Göttingen, both Pick-N and MTF multiple-select multiple-choice items are used. While Pick-N items might contain a variable number of answer options (up to 26), local examination guidelines recommend 5, 6, 7, or 8 answer options. According to local examination guidelines, MTF items might contain 4, 5, or 6 statements.

For Pick-N items, a total of 24 different scoring methods have been described in the literature [6]. Moreover, for MTF items, a large variety of scoring methods exist, and a total of 27 scoring methods have been described in the literature [5]. By removing duplicate scoring algorithms, 41 scoring algorithms were identified and were retrospectively applied to examinees' markings of both multiple-select multiple-choice item types.

Electronic Examinations

Prior to their use, all items were subjected to a review process at the department responsible for the respective examination. During electronic examinations, answer options/statements were displayed and permuted for each examinee using UCAN's CAMPUS Examination software [17]. Until the end of the examination, examinees were able to modify their markings. Total examination time was calculated based on 90 seconds per item.

For Pick-N items, examinees had to mark only the true answer options (t). For each item, the number of true answer options was displayed to the examinees. Marking more answer options as true than the given number of t was technically impossible. If examinees marked fewer answer options than t as true, a

warning message was shown indicating that they were intended to select t answer options. Despite the warning message, examinees were allowed to continue without selecting t answer options. Within the context of MTF items, examinees were required to mark each statement as either true or false, and there was no possibility to omit individual statements.

For all examinations (usually consisting of 20 to 30 items), a uniform pass mark of 60% (ie, 0.6 credit points) was used irrespective of the included item types according to local examination guidelines.

Examination Data

Written examinations of the Department of Preventive Dentistry, Periodontology and Cariology and the Department of Prosthodontics of the undergraduate dental curriculum (1st to 10th semester) at the University Medical Center Göttingen were retrospectively screened for multiple-select multiple-choice items. Due to the overall lower number of Pick-N items, Pick-N items and examination data were retrieved from all examinations with at least five participants between 2016 and 2020. In case of Pick-N items used in multiple examinations, only the version and marking events from the examination with the most examinees or the first examination (in cases of the same number of examinees) were assessed. MTF items and corresponding examination data were retrieved from a previous publication [18] containing items from examinations with at least five participants during winter term 2016/2017 only. If MTF items were used in multiple eligible examinations, marking events from all examinations were combined. To allow for comparison, MTF items from the previous publication were limited to the fields of Operative Dentistry and Prosthodontics.

Quality Criteria of Items

Judgement regarding the use of an appropriate item type was based on the definition by Krebs [10]. In order to further evaluate the quality of identified items, a validated checklist regarding formal quality criteria, presence of cues, and content correctness was used (Table 1) [18]. Formal quality and presence of cues were jointly assessed by 3 authors (PK, MH, and TR)

to classify items for the subsequent analyses. Content validity was assessed by 2 expert clinicians (AW for items within the field of Operative Dentistry; TW for items regarding Prosthodontics).

Table 1. Checklist for the quality assessment of items as described previously [18].

Quality parameter	Items fulfilling the criteria	
	Pick-N (N=48), n (%)	Multiple-True-False (N=18), n (%)
Formal		
Is the item linguistically correct?	25 (52)	12 (67)
Are the answer options homogeneous (eg, no double negatives, approximately equal length of statements)?	40 (83)	11 (61)
Are students of the subject able to understand the question?	46 (96)	15 (83)
Is the correct item type used?	18 (38)	14 (78)
Cues		
Have cues (eg, grammar hints, correct statement is the longest option, diametrical statements, statements which mutually exclude/condition each other, verbal association between question and statements, absolute formulations such as never or always) been avoided?	27 (56)	9 (50)
Content		
Is the content correct?	44 (92)	18 (100)
Are answer options homogeneous regarding their content?	47 (98)	13 (72)

Statistical Analysis

Scoring results for all marking events (ie, individual student entries on a single item) of identified Pick-N and MTF items were calculated according to the identified scoring algorithms shown in [Multimedia Appendix 1](#), using Excel for Mac (version 16.39; Microsoft Corp). Based on these results, a mean score across all examinees and items was calculated for each scoring algorithm and item type. Separately for Pick-N and MTF items, differences between the mean scores of all scoring methods were assessed by the Kruskal-Wallis test.

The effect of item quality (use of an appropriate item type [yes vs no] and absence of cues [yes vs no]) on mean raw scores was assessed by the Wilcoxon rank-sum test. Raw scores were derived from method 10 (Partial Scoring $1/n$, $PS_{1/n}$), which awards partial credit equally for each correctly marked answer option/statement.

Separately for each scoring method, the likelihood of achieving a score of ≥ 0.6 was assessed by multiple logistic regression analyses. The use of an inappropriate item type (yes vs no) and presence of cues (yes vs no) were simultaneously entered as predictor variables. A dichotomous outcome was defined as a score at or above pass mark (≥ 0.6 credit points) versus below pass mark (< 0.6 credit points).

All calculations were performed using the software R [19] (version 4.0.4) and the package “PMCMR” (version 4.3). The level of significance was set at $\alpha=.05$.

Results

Marking Events

A total of 48 Pick-N and 18 MTF items were included. Items presented 5, 6, or 7 answer options (Pick-N), or 5 or 6 statements

(MTF). A total of 1931 (Pick-N) and 828 (MTF) marking events were investigated. On average, for Pick-N and MTF items, each item was answered by 40.2 (SD 5.7) and 46.0 (SD 30.7) examinees.

Scoring Results

Except for method 9 (Monash Medical School Scheme), which has only been described for cases of $n=4$, all identified scoring methods were applied on all included items.

For both item types, mean scores differed significantly between scoring methods ($P<.001$). For Pick-N items, mean scores per item varied between 0.5, when applying method 16 (Guessing Penalty), and 0.98, when applying method 2 (Dichotomized MTF) or method 32 (Formula 3 by Blasberg et al [8]). Overall, mean scores of ≥ 0.90 per item were achieved when using method 2 (Dichotomized MTF), method 32 (Formula 3 by Blasberg et al [8]), method 15 (Guessing Fair Penalty), or method 29 (Formula 6 by Duncan and Milton [20]). For MTF items, mean scores per item varied between 0.02, when applying method 16 (Guessing Penalty), and 0.96, when applying method 2 (Dichotomized MTF). Only 2 scoring methods resulted in mean scores of ≥ 0.90 (method 2 [Dichotomized MTF] and method 15 [Guessing Fair Penalty]). The results of further scoring methods are shown in [Table 2](#).

For Pick-N and MTF item types, histograms showing the distribution of scoring results from different scoring methods are presented in [Figures 2](#) and [3](#), respectively. As depicted, different scoring methods allow for different levels of partial credit.

Table 2. Mean scoring results across all examinees per item for different scoring methods.

Method number	Scoring method	Scoring result, mean (SD)	
		Pick-N	Multiple-True-False (MTF)
1	Dichotomous Scoring	0.752 (0.432)	0.512 (0.500)
2	Dichotomized MTF	0.982 (0.133)	0.963 (0.190)
3	Half-point Scoring	0.752 (0.431)	0.675 (0.371)
4	Partial Scoring 50% (PS ₅₀ , MTF) ^a	0.867 (0.241)	0.737 (0.285)
5	Blasberg-Method (Formula 4 by Blasberg et al [8])	0.807 (0.340)	0.734 (0.312)

^aWithin the context of Pick-N and Multiple-True-False items, the scoring method named Partial Scoring 50% (PS₅₀) is related to different scoring methods.

^bOnly used in case of 4 answer options/statements per item.

^cN/A: not applicable.

Figure 2. Distribution of scoring results per item among all 1931 marking events of Pick-N items. The ranges of scoring results are shown on the x-axis in intervals of 0.2 with a scale ranging from -2 or -1 to +1 credit points per item. MTF: Multiple-True-False.

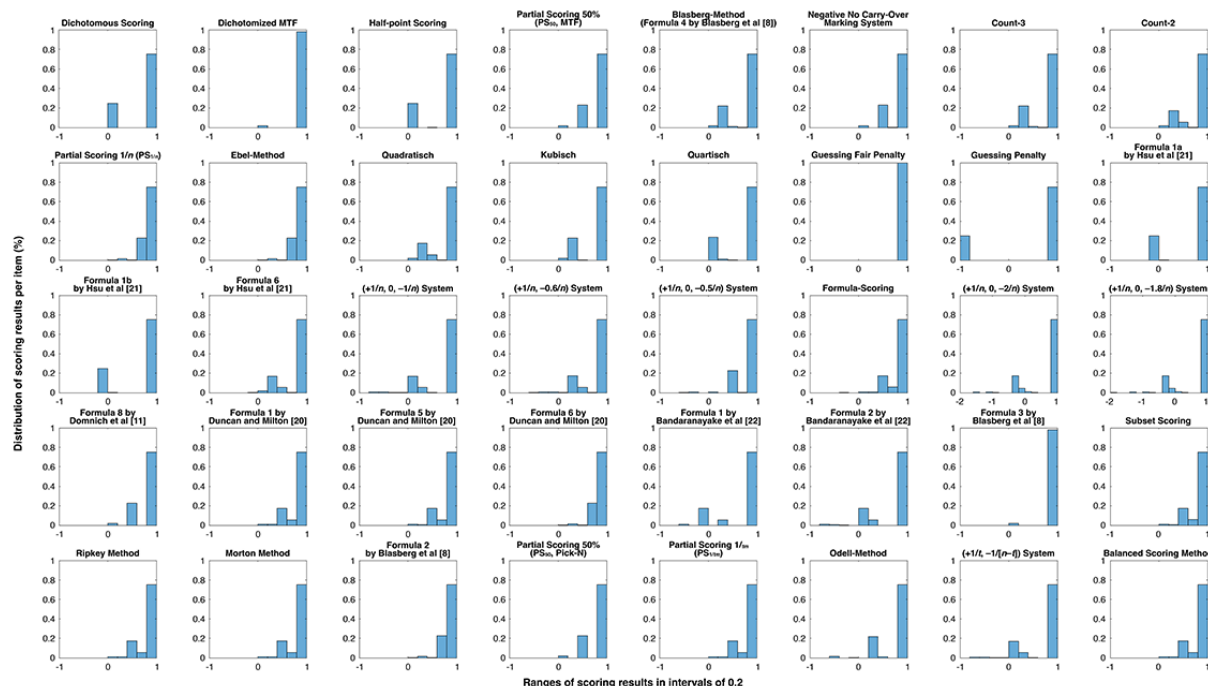

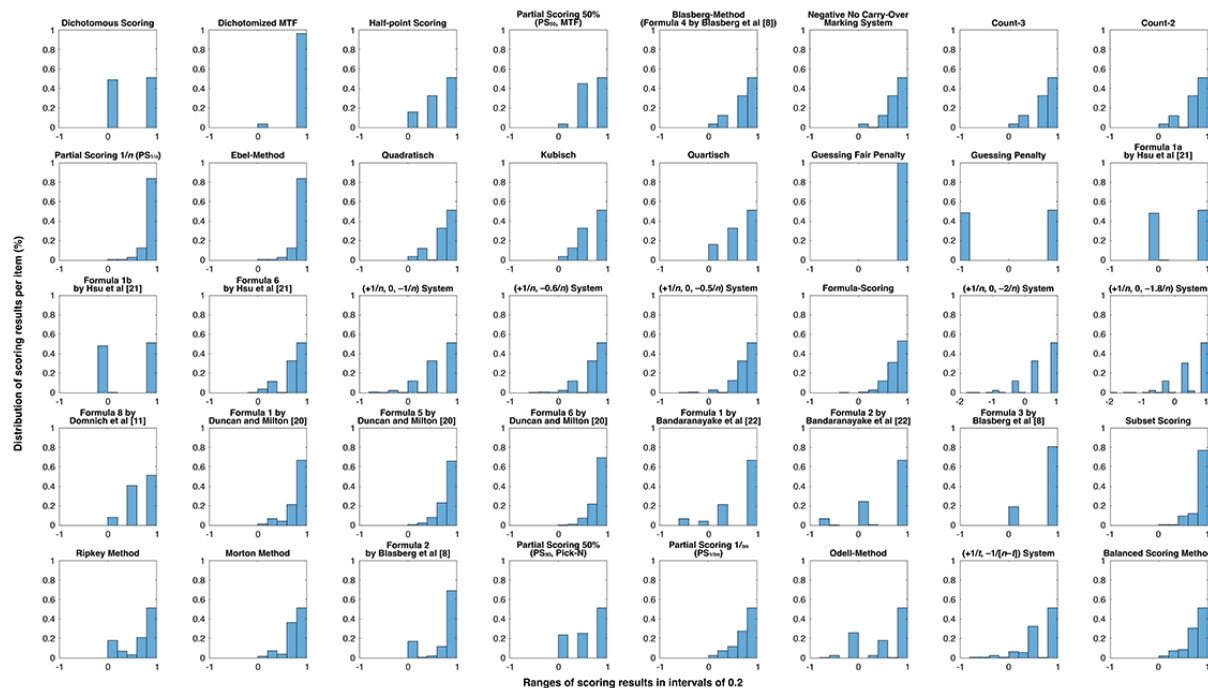

Figure 3. Distribution of scoring results per item among all 828 marking events of Multiple-True-False (MTF) items. The ranges of scoring results are shown on the x-axis in intervals of 0.2 with a scale ranging from -2 or -1 to +1 credit points per item.

Impact of Item Quality on Scoring Results

A total of 30 (63%) Pick-N items should have been used as MTF items, while 4 (22%) MTF items should have been used as Pick-N items instead. Presence of at least one cue was found in 21 out of 48 (44%) Pick-N items, while at least one cue was identified in 9 out of 18 (50%) MTF items. However, the content of items was formally correct in 44 out of 48 (92%) Pick-N items and all (100%) MTF items.

Inappropriately used Pick-N items (ie, these items should have been written as MTF items instead) resulted in lower mean raw scores (mean 0.88, SD 0.20 vs mean 0.93, SD 0.16; $P<.001$), while inappropriately used MTF items resulted in higher mean raw scores (mean 0.88, SD 0.19 vs mean 0.85, SD 0.17; $P=.001$). Mean raw scores from items with and without cues differed for MTF items (mean 0.91, SD 0.15 vs mean 0.84, SD 0.18; $P<.001$), but not for Pick-N items (mean 0.89, SD 0.18 vs mean 0.90, SD 0.18; $P=.09$).

For Pick-N items used inappropriately, most scoring methods showed a lower likelihood of achieving a score of ≥ 0.6 compared to credit from proper Pick-N items (odds ratio [OR] ≤ 0.559 ; Table 3). For items written up inappropriately in MTF style, most scoring methods showed a greater likelihood of

achieving a score of ≥ 0.6 compared to items that were designed appropriately (Table 3). The highest effect was found for method 38 (Partial Scoring $1/t_m$, $PS_{1/tm}$; OR 5.724) and method 27 (Formula 1 by Duncan and Milton [20]; OR 4.776). Only 2 scoring methods showed a lower proportion of scores ≥ 0.6 when an inappropriate item type was used (method 32 and method 36 [Formula 2 and 3 by Blasberg et al [8]], both OR 0.625).

Within Pick-N items, the presence of cues was associated with a greater likelihood of achieving a score of ≥ 0.6 (equaling scores at or above the pass mark that is $\geq 60\%$ of the total score) for a minority of scoring methods only (Table 3). Differences in the likelihood of scores ≥ 0.6 between items with and without cues were most pronounced when using methods 27, 34, 35, 38, and 41 (all OR 1.394). No scoring method resulted in a lower proportion of scores ≥ 0.6 in case of cues being present. Different results were found for MTF items. For most scoring methods, the presence of cues was associated with a greater likelihood of achieving a score of ≥ 0.6 (Table 3). Scoring methods 30 and 31 (Formula 1 and 2 by Bandaranayake et al. [22]) showed the highest susceptibility to cues (both OR 6.977). Only 2 scoring methods showed a lower proportion of scores ≥ 0.6 in the presence of cues (methods 32 and 36 [Formula 2 and 3 by Blasberg et al [8]], both OR 0.451).

Table 3. Results of multiple logistic regression analyses regarding the effect of item quality on scoring results (≥ 0.6 vs < 0.6 credit points).

Discussion

Principal Findings

When retrospectively applying the described scoring methods on examination items, the applied scoring method, presence of cues, and use of an inappropriate item type impacted the credit assignment. Therefore, both null hypotheses must be rejected.

Averaged scores differed significantly between different scoring methods for both item types. For Pick-N items, mean scores ranged from 0.50 (method 16) to 0.98 (method 2) credit points for the same markings, while MTF items showed an even bigger range of 0.02 (method 16) to 0.96 (method 2) credit points. Both the use of an inappropriate item type and presence of cues significantly impacted the scoring results. Inappropriately used Pick-N items resulted in lower mean raw scores (mean 0.88, SD 0.20 vs mean 0.93, SD 0.16), while inappropriately used MTF items resulted in higher mean raw scores (mean 0.88, SD 0.19 vs mean 0.85, SD 0.17). The mean raw score from MTF items with cues was 0.91 (SD 0.15), while items without cues resulted in a lower mean raw score of 0.84 (SD 0.18). These differences emphasize the effects of different scoring methods, presence of cues, and inappropriately used item types, as examinees might either pass or fail the examination based on an assumed fixed pass mark of 60% (ie, 0.6 credit points on average). For most scoring methods, item quality impacted the likelihood of scores ≥ 0.6 . Inappropriately used Pick-N items showed a lower likelihood of scores ≥ 0.6 , while inappropriately used MTF items showed a higher likelihood of scores ≥ 0.6 . MTF items containing at least one cue showed a higher likelihood of scores ≥ 0.6 than items without cues.

Two different types of multiple-select multiple-choice items were used in this study. Between Pick-N and MTF items, examinees' decision-making and response behaviors are fundamentally different. In Pick-N items, the number of true answer options to be selected is disclosed to examinees. Therefore, marking answer options within Pick-N items is dependent on the marking of all other answer options within the same item [6]. The metric *expected chance score* [23] from

random guessing amounts to $\frac{1}{n}$. In contrast, every statement within an MTF item might be either true or false (including zero or even all statements). Thereby, examinees are forced to independently assess each statement as true or false, and the expected chance score amounts to 0.5^n [5]. Based on these

theoretical implications, lower mean scores can be expected if examinees are not aware of the total number of correct answer options/statements (such as in MTF items). To address these differences regarding the relative item difficulty between both item types, local examination guidelines might suggest different scoring methods or pass marks for both item types. This study found scores resulting from both Pick-N and MTF items to vary based on the selected scoring methods. Therefore, examination results should only be interpreted in light of the employed scoring method or methods.

Within this study, items were extracted from different examinations covering a broad range of topics and learning objectives. Therefore, no direct comparison of the item difficulty between MTF and Pick-N items was made. Instead, the effect of item quality was assessed. Inappropriately used MTF items resulted in higher mean raw scores, while inappropriately used Pick-N items resulted in lower mean raw scores. This observation might be attributed to the definitions regarding the correct use of Pick-N and MTF items. MTF items require more complex statements than Pick-N items [7,10]. As a result, MTF items are likely to be overall more complex, requiring higher cognitive skills from examinees. If local examination guidelines suggest different scoring methods or pass marks for both item types to overcome the above-mentioned differences between both item types, the use of an inappropriate item type might result in either an inflation (in case of inappropriately used MTF items) or deduction (in case of inappropriately used Pick-N items) of scores at or above the pass mark.

Besides item types used inappropriately, cues were found to impact scoring results. While the mean raw scores of Pick-N items with and without cues did not differ, the presence of cues in MTF items resulted in a higher proportion of correctly marked statements. Thus, MTF showed a higher susceptibility to cues. As examinees are likely to consider cues during their decision-making process, educators should carefully evaluate each item using a checklist for quality assessment and cues (eg, grammar hints, diametrical statements, or absolute formulations) to eliminate cues prior to its use in an examination.

Besides selecting an appropriate item type, educators need to select an adequate scoring method. In contrast to single-choice items, scoring of multiple-select items is complicated as examinees might give partially correct responses. In recent systematic reviews, a total of 41 scoring methods for MTF and Pick-N items were described [5,6]. Scoring methods focusing

on the number of correct responses instead of the number of true answer options/statements marked as true (t_m) and accurately discriminating between different levels of knowledge are most frequently recommended [5]. Scoring methods yielding negative scores should not be used because of jurisdictional reasons [5,18,24]. However, available item types and scoring methods are often set by local examination guidelines.

Overall, the results of this retrospective assessment of real examination data confirm the assumption that credit assignment on MTF and Pick-N items differs between varying scoring methods. Furthermore, it was shown that item quality characteristics like selection of an appropriate item type and avoidance of cues have a significant effect on scoring results in the case of most scoring methods.

Strengths and Limitations

The strengths of this assessment include the use of up to 41 scoring methods and a high number of marking events (Pick-N items: 1931; MTF items: 828). Previous studies on this topic were based on theoretical calculations only [5,6] or used a smaller number of different scoring methods/item types [18]. For each item, quality was assessed based on a validated checklist. However, a number of limitations are present. First, items were derived from previous examinations, which resulted in an unequal distribution of both item types. While 48 Pick-N items were included, only 18 MTF items were assessed. Second, all items were extracted from different examinations covering

a broad range of topics. Therefore, no direct comparison of the item difficulty between MTF and Pick-N items was possible. Third, no further predictor variables (eg, student-related variables such as age and gender) were available due to the retrospective and anonymous design.

Future Directions

To address these limitations, further prospective studies should evaluate different scoring methods and item types by employing matched items on the same learning objectives. Moreover, further predictor variables (eg, student-related variables such as age and gender) should be considered.

Conclusion

Educators should pay attention when using multiple-select multiple-choice items. Scoring and awarding credit are more complex for multiple-select multiple-choice items than for single-choice items. This manuscript may guide educators to make informed decisions regarding the use of multiple-select multiple-choice items.

Different item types, different scoring methods, and presence of cues are likely to impact examinees' scores and overall examination results. Therefore, educators should carefully select the most appropriate item type. Moreover, cues should be avoided as far as possible. Finally, examination results should be interpreted in light of the used item type and applied scoring method.

Acknowledgments

This study was funded by the Kurt Kaltenbach Stiftung, Germany. The authors acknowledge support by the Open Access Publication Funds of Göttingen University. The funder had no role in the study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Data Availability

The data sets generated during or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

PK, AW, and TR contributed to the study's conception and design. PK, MH, AW, and TR assessed the examination items. PK and DS performed statistical analyses. PK, DS, AW, and TR drafted the manuscript. All authors critically revised the manuscript and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Digital surgical simulation and telecommunication provides an attractive option for improving surgical skills, widening access to training, and improving patient outcomes; however, it is unclear whether sufficient simulations and telecommunications are accessible, effective, or feasible in low- and middle-income countries (LMICs).

Objective: This study aims to determine which types of surgical simulation tools have been most widely used in LMICs, how surgical simulation technology is being implemented, and what the outcomes of these efforts have been. We also offer recommendations for the future development of digital surgical simulation implementation in LMICs.

Methods: We searched PubMed, MEDLINE, Embase, Web of Science, Cochrane Database of Systematic Reviews, and the Central Register of Controlled Trials to look for qualitative studies in published literature discussing implementation and outcomes of surgical simulation training in LMICs. Eligible papers involved surgical trainees or practitioners who were based in LMICs. Papers that include allied health care professionals involved in task sharing were excluded. We focused specifically on digital surgical innovations and excluded flipped classroom models and 3D models. Implementation outcome had to be reported according to Proctor's taxonomy.

Results: This scoping review examined the outcomes of digital surgical simulation implementation in LMICs for 7 papers. The majority of participants were medical students and residents who were identified as male. Participants rated surgical simulators and telecommunications devices highly for acceptability and usefulness, and they believed that the simulators increased their anatomical and procedural knowledge. However, limitations such as image distortion, excessive light exposure, and video stream latency were frequently reported. Depending on the product, the implementation cost varied between US \$25 and US \$6990. Penetration and sustainability are understudied implementation outcomes, as all papers lacked long-term monitoring of the digital surgical simulations. Most authors are from high-income countries, suggesting that innovations are being proposed without a clear understanding of how they can be incorporated into surgeons' practical training. Overall, the study indicates that digital surgical simulation is a promising tool for medical education in LMICs; however, additional research is required to address some of the limitations in order to achieve successful implementation, unless scaling efforts prove futile.

Conclusions: This study indicates that digital surgical simulation is a promising tool for medical education in LMICs, but further research is necessary to address some of the limitations and ensure successful implementation. We urge more consistent reporting and understanding of implementation of science approaches in the development of digital surgical tools, as this is the critical factor that will determine whether we are able to meet the 2030 goals for surgical training in LMICs. Sustainability of implemented digital surgical tools is a pain point that must be focused on if we are to deliver digital surgical simulation tools to the populations that demand them the most.

Introduction

Background

Safe surgical care is an often-neglected component of health systems, with an estimated 5 billion people lacking access [1]. According to The Lancet Commission for Global Surgery, only 6% of surgeries are performed in the poorest countries, despite the fact that they contain one-third of the world's population. Education and training of the workforce was identified as a crucial issue, with massive shortages of certified surgeons constituting a significant barrier to care in low- and middle-income countries (LMICs). To address the care shortage, it was suggested that the surgical, anesthetic, and obstetric workforce in LMICs be increased to 40 per 100,000 population by 2030 [1]. Despite the fact that traditional models of surgical training adopted in high-income countries (HICs) include a system of graded autonomy that spans up to 7 years of training, up to 30% of these trainees do not feel confident operating independently after residency [2,3]. Given the constraints imposed on surgical education in many LMICs, this failure to cope with a large surgical disease burden is directly responsible for worse patient outcomes [4].

These factors have effects that extend beyond the operating room and have led to a large brain drain of skilled trainees to other countries in search of more material resources to pursue robust surgical training [5]. This is exacerbated by the difficulty trainees face in accessing relevant literature translated into their language that is context specific to the unique and complex disease presentation in LMICs [6]. Existing solutions to combat this have been proposed, such as development of surgical simulation suites, but these require a significant amount of resources; increasing access to cadaveric and animal model simulations, but this requires additional training and specialized staff; and low-fidelity simulation, but this lacks the sophistication of the advanced techniques used in this field that evolve into more refined approaches of care [7-10]. Innovative simulation-based tools, such as virtual reality (VR), augmented reality (AR), and tele-simulation applications, are best suited for trainees who want to improve their skills in light of the aforementioned obstacles [11,12]. We use the digital domains of digital surgery, previously defined in detail within the HIC literature, to define the scope of this study and the investigated term, *digital surgical simulation*, including smartphone apps, sensors, VR, AR, artificial intelligence, and robotics [13]. In HICs, these technologies have been used to improve surgical performance and patient safety; however, the impact of these technologies in LMICs is unknown.

Despite the shift in surgical training methodology, studies qualifying the efficacy of digital surgical training in LMIC settings are lacking. Although it has been demonstrated that surgical simulation is a highly effective way to scale up training in HICs, the implementation barriers within LMICs are unknown [9,11,12]. Understanding clinical outcome and benefit is essential, but if the outcomes cannot be implemented in practice,

the technology remains ineffective and only useful in theory. Therefore, it is crucial to study the implementation of these technologies. With the urgent need to scale up training in LMICs, our global innovation efforts may be ineffective if we do not assess implementation in this context.

In light of this, we intend to investigate the implementation outcomes of digital surgical simulation tools in LMICs by conducting a scoping review. Given the heterogeneous literature examining a variety of tools, surgical procedures, and LMICs with distinct and context-specific problems, a scoping review is the most appropriate method for answering this question.

Objectives

In this study, we will conduct a scoping review of all the current surgical trainees and practitioners in LMICs who use digital surgical simulation tools, and we will conceptualize these findings using the implementation outcome framework. Our objectives will be to determine which types of surgical simulation tools have been most widely used in LMICs, how surgical simulation technology is being implemented, and what the outcomes of these efforts have been. We also offer recommendations for the future development of digital surgical simulation implementation in LMICs.

Methods

Overview

This scoping review was conducted in accordance with the Joanna Briggs Institute (JBI) methodology [14]. Full search results were reported and displayed in a Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Review (PRISMA-ScR) flowchart [15]. In addition, we have completed a PRISMA-ScR checklist ([Multimedia Appendix 1](#) [15]). A preliminary search of MEDLINE, Cochrane, PubMed, and PROSPERO did not reveal any active or forthcoming reviews on this subject.

Search Strategy

For this study, PubMed, MEDLINE, CINAHL, Web of Science, Embase, and the Central Register of Controlled Trials were searched. Before title screening, abstract screening, and full text review in Rayyan, the results were exported to EndNote (version X8; Clarivate) to remove duplicates. No limitations were placed on the original publication language or date (last search was completed on March 12, 2022). Any papers that were not written in English were translated using Google Translate (Alphabet Inc) to account for the literature published specifically for LMICs that was written in a specific language. The search string was generated by searching sources and developing pertinent search terms that were tested for sensitivity in advance of this review by a previous analysis of PROSPERO study protocols and key term analysis of the literature. For this search, we used the World Bank's definitions of LMICs, Atallah's [13] framework for defining the scope of digital surgery and near-terms, and Proctor et al's [16] classification of implementation outcomes. We chose to remain rigid to these

terms as the scope of this paper is to examine how well these tools have been implemented, not whether the tools exist or not, as the implementation of these tools is arguably a more important factor in determining their success and reproducibility (Textbox 1).

Guidelines for reporting conformed to PRISMA Scoping Review requirements. These terms have been modified to search the specifics of each database and are accessible ([Multimedia Appendix 2](#)).

Textbox 1. Eligibility criteria.

Study types

Given the nature of this paper to study implementation outcomes, for a study to be eligible for inclusion the paper must describe and report outcomes on the specific effectiveness of a given intervention through explicit testing of implementation strategy. As such, they must fall within the “effectiveness-implementation” hybrid model first described by Curran et al [17]. Excluded papers were secondary studies such as systematic reviews and nonempirical studies such as books, protocol, viewpoints, and commentaries.

Participants or population

Study participants from LMICs were included, according to the World Bank definition, who were surgical trainees or practitioners at any level of their training. Surgical obstetric care was included as a part of this review. Excluded participants were those who were not medical degree holders but are allied health care professionals that engage in task-sharing—a novel practice being introduced into LMICs to address the human resource gap [18].

Intervention or exposure

This review will focus on studies that have implemented or evaluated a digital surgical simulation tool. We have defined digital surgical simulators as innovations that allow trainees to develop surgical skills through use of digital technology by a hands-on approach based on previously published literature [13]. These may include virtual reality, augmented reality, serious games, tele-simulations, tele-proctoring. Patient-specific anatomy that has been rendered into a virtual reality model utilizing 3D modeling was included. Studies were excluded if the digital surgical simulator described was a web-based or flipped classroom model. Similarly, studies that used 3D-printed models as simulators were excluded as these are not digital simulations.

Control

Eligible studies will compare implementation interventions (digital surgical simulators) in terms of effectiveness by looking at surgical competency before and after use of the simulator. Studies may also compare participants' baseline confidence in conducting the surgery. Studies that compared control intervention (conventional simulation, animal and cadaveric simulation, or lecture-based education models) were also included.

Outcome

As a part of this study, implementation and quantitative evaluation of the digital surgical simulators for surgical trainees must be included. At least one outcome measure must be reported to be included as a study. We use Proctor et al's [16] study to describe the specific 8 sub-classifications of implementation success of digital surgical simulators of acceptability, adoption, appropriateness, feasibility, fidelity, implementation cost, penetration, and sustainability. This model has historically been used in a Wellcome study protocol [19] to explore low-technology simulation for training in LMICs for surgical intervention of gastroschisis and as such is relevant for this study as well.

Data Synthesis and Extraction

Following the search, all citations were compiled and uploaded to EndNote X8 for duplicate removal. Two reviewers carried out a title and abstract screening (AM and AH). The references of included articles were examined to determine whether additional literature should be included. Using the inclusion criteria, the full texts of selected papers were carefully evaluated. In the scoping review flowchart, the reasons for excluding full-text evidence sources that did not meet the inclusion criteria were recorded and reported.

Using a data extraction tool adapted from the JBI methodological template and supplemented with framework items from Proctor et al [16], we extracted data from the papers included in the scoping review [14]. The extracted data will include specific information regarding the study's location, objectives, study design, type of digital surgical simulation, number of individuals trained, acceptability, adoption, adequacy, feasibility, fidelity, implementation cost, penetration, and sustainability, as well as key findings pertinent to the review questions. This approach to data extraction is comparable to previously published methods [20]. Described study characteristics were followed by a summary of results based on

Proctor et al's [16] subclassification. If there is insufficient information on a particular subclassification, these taxonomy components were removed from qualitative analysis and an appropriate explanation was provided. Due to the heterogeneity of this paper's scope, quantitative analysis between papers was omitted in favor of qualitative and narrative descriptions of included papers in order to answer the research question and achieve the objectives. The extraction sheet with specifics is available in [Multimedia Appendix 2](#).

We determined the suitability of instruments using Proctor et al's [16] concept of implementation outcomes, despite the fact that the constructs did not always fit neatly within the established objectives. Where the description of such constructs fit more than one of Proctor et al's [16] outcomes, the instrument was categorized according to the outcome that predominated, as determined by a comprehensive study and count of every instrument item. In the absence of a clear distinction, taxonomy components were thematically grouped and analyzed qualitatively. If tools evaluated additional components outside of the taxonomy, we did not include them in our extraction of the articles; however, we did analyze thematic parallels between the reporting in this paper. Any disagreements that arise between the reviewers are resolved through discussion, if applicable.

Given the heterogeneity of indications and outcomes of digital surgical simulation for trainees in LMICs, no meta-analysis was conducted. Instead, a mixed-methods analysis of the extracted literature was conducted in consideration of our implementation outcome model. The individual sources of evidence were not evaluated in accordance with JBI protocol.

Our search method restricted the discovered publications to the implementation of Proctor et al's [16] taxonomy results. This may result in the removal of pertinent publications that examined digital surgical instruments in LMICs. However, given that researchers have previously relied on Proctor et al's [16] framework due to the pragmatic nature of its content in the broader surgical simulation literature, we determined that

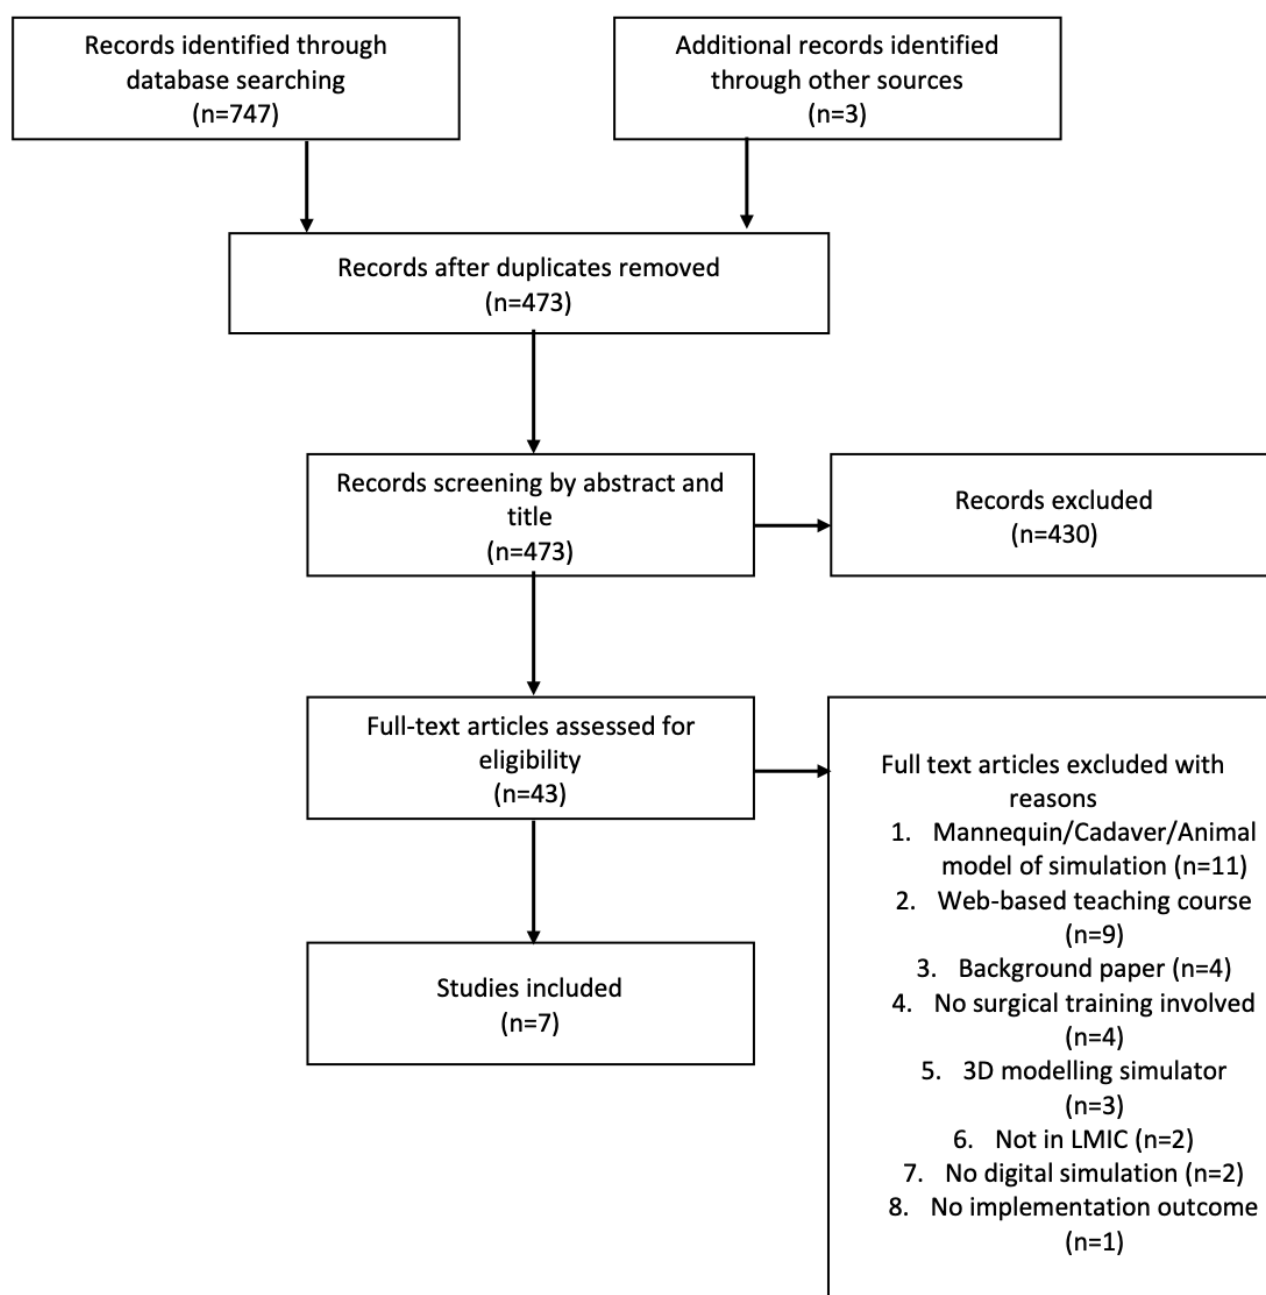

Proctor et al's [16] framework is the most relevant context- and intervention-specific framework to evaluate digital surgical tools in LMICs [19].

Results

Included Studies

The database search revealed 747 papers with an additional 3 added from other sources through scanning of bibliographies of papers. After sorting of duplicate papers, 473 papers were included. These were subsequently screened and searched according to title and abstract screening and 43 papers were left. Seven papers remained after excluding other papers by full text. Reasons are listed in Figure 1.

Figure 1. Preferred Reporting Items for Systematic reviews and Meta-Analyses Extension for Scoping Review (PRISMA-ScR) checklist. LMIC: low- and middle-income country.

Study Characteristics

Among a total of 7 studies, there were 3 cross-sectional observational studies, 2 case studies, and 2 randomized controlled trials [20-26]. In 74% (81/110) cases, medical students and residents were the intervention group. A total of 72% (79/110) of the participants in the studied cohorts were men, compared to 28% (31/110) women. The included studies were conducted in 9 different nations. The majority of authors were from the United States, with 6 of the 7 first authors hailing from HICs. Participants number ranged from 2 to 30. The most used digital surgical tool was a VR-based model, used in 4 studies, which was considered to be cost-effective and of low fidelity, or cost-prohibitive with higher fidelity. This was followed by tele-proctoring tools in 2 studies and app-based training tools in 1 study. Indications for design varied with tools being developed across the spectrum of surgical burden including orthopedic, vascular, obstetric, and minimally invasive surgeries. The evaluation of the evidence was not performed in accordance with the JBI's recommendations.

Synthesis of Proctor's Classification

Acceptability and Adoption

A review of 4 studies highlighted the acceptability and implementation outcomes of surgical simulators and telecommunications devices in LMICs [21-24]. All participants rated the acceptability of the 3D VR gesture-mediated simulator as attractive. One hundred percent of those polled believed that the prototype could be a solution for ubiquitous learning in minimally invasive surgery [21]. In addition, in the VR simulator of an open radical abdominal hysterectomy, participants reported that the simulation they experienced was similar to their university hospital's operating room as a digital replica of the theater's equipment, instruments, supplies, and lighting [22]. Surgical students who used VR as a learning and practice tool for lower limb amputation reported significantly higher levels of engagement in their course. The same students who used VR to study reported higher levels of perceived learning [23]. Students who used a virtual surgery app to prepare for tendon repair simulation rated it as a useful or very useful training and assessment tool 92% of the time, and as a useful or very useful rehearsal tool 85% of the time. Note that 62% of these students indicated that it would be a good or very good curriculum requirement [24].

Appropriateness, Feasibility, and Fidelity

Six reviewed studies addressed the appropriateness, feasibility, and fidelity of surgical simulator and telecommunication device implementation outcomes in LMICs [21-26]. On a Likert scale, 94% of students who used a 3D VR gesture-mediated simulator for training rated the tool highly for appropriateness. A total of 93% of participants rated the ability to realistically represent and test hand-eye coordination, and 87% rated the ability to realistically represent depth perception. All of the participants highly rated the device's usability; however, they commented on how physical forces represented in the virtual environment were less than ideal. There was no significant difference between the expert (practicing surgeon) and referent (surgical residents) groups in any of these fidelity scores [21]. The participants

interviewed who used the VR simulator for an open hysterectomy reported that the simulator increased their anatomical and procedural knowledge. In addition, they believed that the skills acquired in the simulator could be applied to other aspects of medical care and practice. The simulator, according to students and surgeons who used it, bolstered their anatomical knowledge and helped them manage complications in the operating room [22]. Surgical residents who received VR instructions on lower limb amputations earned higher scores on average, but the SD overlapped [23]. Surgical residents whose operative skills in a tendon repair simulation were graded by raters demonstrated a disparity between how they prepared for the test and how their skills were evaluated. Touch Surgery, the virtual phone app, resulted in a mean rubric score of 89.71% for students, while textbook learning resulted in a mean score of 63.4% ($P<.001$) [24]. The 2 surgeons who used Google Glass to coordinate field operations in Mozambique reported that the technology was extremely useful as an intraoperative and perioperative training tool. Nevertheless, both participants reported moderate visual impairment due to image distortion and excessive light exposure. Additionally, video stream latency and connection interruptions were cited as limitations [25,26]. Surgeons in Ecuador who were tele-mentored by a Yale University surgeon found their mobile-based, low-bandwidth telemedicine app to be effective in supporting remote health care delivery [26].

Implementation Cost

A total of 4 studies reported the cost to implement their unit [21,22,25,27], while the remaining studies [23,24,26] listed their equipment so that the reader can infer the cost to implement. The creators of the 3D VR gesture-mediated simulator for learning fundamental psychomotor skills in minimally invasive surgery spent a total of US \$200, excluding software costs, to build their device [21]. Without software licenses, the low-cost VR open hysterectomy simulation setup using an Oculus Rift (Meta Platforms) headset and hand controllers was estimated to cost slightly less than US \$1500 [22,27]. The Google Glass device telecollaboration setup used by the 2 surgeons in Mozambique and the United States cost US \$999 for the Google Glass device and a yearly subscription fee of US \$6990 for the required AMA XpertEye software (Tracxn Technologies). In addition, one required 2 computers or laptops and a Wi-Fi connection [25]. The remaining studies listed required products without associated costs. The Lower Limb Surgical Amputation Virtual Reality Tutorial Study used an unspecified Oculus VR headset [23]. According to the tendon repair study, the Touch Surgery smartphone app costs US \$25 [24]. The only requirements for the design of the telecommunications study conducted in Ecuador were an internet connection, 2 laptops with a single camera, and telemedicine and video conferencing software [26].

Penetration and Sustainability

Penetration and sustainability of digital surgical simulation were heavily underreported outcomes. Both refer to project implementation over a longer scale; penetration refers to the degree to which a new technology has been adopted and used, and sustainability refers to the long-term viability of a

technology within their specific contexts. No paper provided results on either of these outcomes, however reference was made to hypotheses from authors of how participants could be willing to incorporate digital surgical simulation into regular training regimens. Additionally, sustainability was neglected in reporting with no reference made to sustainability in terms of cost, upkeep, widespread adoption among all trainees, and implementation on a wider scale.

Discussion

Overview

The scoping review examined the outcomes of digital surgical simulation implementation in LMICs. The majority of participants were medical students and residents who were identified as male. Participants rated surgical simulators and telecommunications devices highly for acceptability and usefulness, and they believed the simulators increased their anatomical and procedural knowledge. However, limitations such as image distortion, excessive light exposure, and video stream latency were frequently reported. Depending on the product, the implementation cost varied between US \$25 and US \$6,990. Penetration and sustainability are understudied implementation outcomes, as all papers lacked long-term monitoring of the digital surgical simulations. The fact that the majority of authors are from HICs suggests that innovations are being proposed without a clear understanding of how they can be incorporated into surgeons' practical training. Overall, the study indicates that digital surgical simulation is a promising tool for medical education in LMICs; however, additional research is required to address some of the limitations in order to achieve successful implementation, unless scaling efforts prove futile.

Results in Context

Our findings must be contextualized within the larger body of literature. Although our findings indicate that training using digital surgical simulation may be effective, the Lancet Commission reports that all digital surgical tools should be used as a supplementary resource and not as a primary resource, which would drain hospital resources and compromise patient safety [1]. Several factors are implicated in the context of Proctor et al's [16] taxonomy. To begin with, it appears that little emphasis is placed on understanding what the implementation costs are. Rather, many authors hope that the tool's novelty will be sufficient to ensure its successful implementation. If we are to scale technologies across the regions that have the greatest demand for them, implementation must be incorporated with greater consideration. One strategy revealed that participants placed a great deal of emphasis on mentoring, suggesting that mentor-champions must be assigned to medical students and surgical trainees to encourage implementation of these technologies in order to scale use in their respective environments [22]. Moreover, while technically all of these tools may be feasible, the implementation of these tools in contexts that none of the HIC lead authors may be aware of is of greater importance [26]. This was countered by a single study that attempted to replicate the exact visual field of the operating room [22]. However, more thoughtful integration of

LMIC authors and incorporation of specific implementation strategies is urgently required.

Cost of development is an important factor to consider when evaluating the eventual uptake of digital surgical simulators in LMICs. When learning how to use a 3D, VR-generated simulator for psychomotor skills in surgeons, one such device costs US \$200. However, this did not include software costs or the possibility of recurring fees for subscription-based models. It is crucial to recognize that in the delivery of educational content, the requirement to register for software is a direct barrier to long-term content access. It has been made abundantly clear the significance of developing technology that is easily consumable offline and relevant to local clinical practice [28]. The ideal situation would be one that does not require continuous mobile phone data as well, since limitations of continuous and reliable internet access are still prevalent despite the increasing use of smartphones in professional settings. Using Oculus Rift headsets, a commercial brand with a proven track record of quality and dependability, the costs are approximately US \$1500, with software licensing not being recognized in the literature as a recurring cost that could negatively impact the future sustainability of many of these surgical simulators. Although these may appear to be high costs, it is important to note that they are significantly less than those of many surgical mission trips. In addition, some innovations only required a camera and an internet connection, which eliminates travel expenses entirely [26]. Extremely low-cost VR and AR technology is being developed for use with smartphone apps and low-cost headsets, such as Google Cardboard, to use immersive technologies—with the clear recognition that wearable immersive technologies have contributed to a sustainable model of training in low-resource settings [29].

Acceptability was frequently rated quite highly across the majority of studies and was reported by the vast majority of reviewed studies. Responses indicated that the reality of the surgery and the virtual simulation were consistent. This is often in stark contrast to traditional methods of simulation, which lack an understanding of unique and complex 3D structures and fail to improve our understanding of how instruments are handled in the operating room [30]. In orthopedic settings in countries with a high standard of living, the development of curricula with training modules for digital surgical systems demonstrates encouraging results [31]. Novel alternatives, such as printing low-cost 3D silicone models for perineal repair and simulating cricothyroidotomy, have been demonstrated in the literature [32,33]. Depending on the indication, however, these models may be of high fidelity or low fidelity. In silicone models, the lack of simulated fascia, fat, and tissue reduces the responsiveness of the absence of haptic and tactile feedback observed in digital surgical simulations. In addition, although these models may be less expensive, they may not function as intended, with some requiring frequent updates and modifications to a multitude of models that already take up to 11 hours to print [32]. In a study published with the help of the College of Surgeons of East, Central, and Southern Africa (COSECSA), 3D models were cited as the most preferred tool for surgical simulation (45%), with slightly more than 30% of participants seeking VR-based simulations [34]. Approximately

35% of participants found low-cost training models to be the least preferred option. The path forward for surgical trainees in LMICs appears to be paved with innovation and unique simulation techniques. Traditional methods such as animal and cadaver dissection are being phased out of medical school education, despite their undeniable utility. By acknowledging these structural obstacles, acceptance and adoption of novel technologies are increasing. It is essential for trainees in LMICs to be able to engage in simulation without leaving the workplace, as this would ultimately increase the surgical simulator's acceptance and usage.

When evaluating the success of the implementation of a novel technology, sustainability is a crucial factor to consider. It has been demonstrated that for 67% of all COSECSA trainees, learning surgical techniques with new technology was the most beneficial method of education [34]. However, 85% of the time, a lack of suitable tools and models was cited as a barrier to successful implementation, and 49% of the time, maintenance of facilities for residents was cited as a barrier. Interestingly, since the majority of trainees experienced simulation teaching as a short crash-course model of instruction with little long-term follow up and poor engagement that they could continuously act upon in their own time, this may be the preferred model of instruction for many. In one of the studies we observed, participants assigned to the intervention group continued to use it throughout the duration of the study, demonstrating that the authors recognized the benefit it provided the participants and gave them the opportunity to use such a novel technology [22]. In the broader literature, long-term studies of implementation have been demonstrated with collaborations lasting up to 30 years. Taking into account the challenges of educating and training skilled surgeons, it is possible to study how sustainable these new training models will be in practice [29]. To add to this point about sustainability, fidelity of the instruments and their adaptability to an ever-evolving world of surgical advancement are required. Through their inherent ability to update and modify over time, digital surgical simulators may be able to circumvent this obstacle and reduce implementation costs while extending the device's sustainability. It is interesting to note, however, that although the fidelity of each simulator may seem important at first glance, it has been demonstrated that the use of high-fidelity simulation models is not significantly superior to the use of low fidelity simulation models. Consequently, in areas with limited resources, low fidelity simulation models may be used [35].

Limitations

The limitations of this paper are as follows. First, as previously discussed in the methods section, our search strategy may have screened out papers based on our search string criterion; however, we chose to adhere to this as it has been previously outlined in extant global digital surgical literature that examines implementation outcomes in LMICs that such an approach is appropriate. Second, there was a high degree of inconsistency and vagueness in the reporting of implementation outcomes. Although the purpose of this study was to examine the implementation of tools, whether these tools had been developed, determining the most appropriate approaches to implementation required author discussion and may have been

subject to bias. Third, the small sample size we discovered during our scoping review carries a high risk of bias. Future reviews may need to have a greater focus on the gray literature to examine tools that have failed to be implemented in order to obtain a more cohesive picture of the state of digital surgical implementation in LMICs. This is because there may be a positive reporting bias with the already small number of published papers, as only successfully developed and implemented tools are being reported.

Future Implications

Traditional methods of increasing surgical capacity in LMICs through mission trips have been criticized for lacking sustainability and for inadequate follow-up. As an alternative solution, systems that prioritize and conduct research on local sustainability and health system capacity have been proposed. Ideally, these systems would incorporate health care worker education and surgical training; therefore, it is the responsibility of the global surgeon to envision a new model that provides long-term educational support and knowledge [36]. Teaching must be a central and fundamental strategy in this regard; otherwise, the model of medical "voluntourism" will be implemented at the level of HIC institutions and forego involvement of LMIC institutions [36]. We advocate the use of digital surgical simulation for trainee education so that large foreign institutions can avoid this while continuing to play an important role in the education of surgeons from LMICs. AR and VR technologies are useful in the world of digital surgical simulation, but adaptation to the novel and long-term disruptions caused by the pandemic is required, and digital surgical simulations may play a crucial role in the training of surgeons in LMICs to increase surgical capacity [37]. The pandemic has unquestionably impacted the quality of access to traditional models of education through participation in or observation of surgical procedures. Lack of access to external training opportunities has exacerbated this problem, but digital surgical simulations provide a straightforward solution. We exercise caution when generalizing the effects of each implementation, as each region is unique and each innovation may require a different strategy in each community. Understanding the economic impacts of digital surgical simulation has been a crucial aspect of our paper, as this is one of the primary factors that may be considered crucial in the discussion of LMIC surgical trainees. Our findings demonstrate that despite the fact that many authors have made significant efforts to generate low-cost models, this often comes at the expense of fidelity, appropriateness, and sustainability of the tools—all of which COSECSA trainees rank as the most important aspects of their training [34]. This suggests that although authors may assume financial burdens are the most important factor, we propose that in fact the combination of all of these implementation factors is more than the sum of its parts, and we should avoid approaching aspects of development as the "most essential" components; rather we should develop a cohesive plan for implementation success. We urge innovators to work more closely with authors from LMICs to develop tools that can be built on top of existing technologies, as opposed to parachuting in novelties. Notwithstanding, we view these examples of innovation in LMICs as opportunities for reverse innovation,

given that LMICs frequently have surgical populations presenting with more complex illness and provide a unique surgical approach that trainees in HICs may never encounter in their careers. Opportunities to engage in open radical hysterectomy, an approach largely replaced by laparoscopic approaches in HICs, is an illustration of this surgical approach [22]. However, the development of the VR toolkit for trainees in Zambia has created an intriguing opportunity to scale the learnings from LMICs to HICs [22].

Conclusions

The scoping review on the implementation outcomes of digital surgical simulation implementation in LMICs revealed that participants, primarily medical students, and male residents rated surgical simulators and telecommunications devices highly for acceptability and usefulness, as they gained anatomical and procedural knowledge. However, image distortion, excessive light exposure, and video stream latency were commonly cited as shortcomings. The implementation cost varied by product, with the cost of development being a significant factor to consider. The study indicates that digital surgical simulation is a promising tool for medical education in LMICs, but further research is necessary to address some of the limitations and ensure successful implementation. In order to scale the use of these technologies in their respective environments, it is necessary to assign mentor-champions to promote their implementation. Acceptability and fidelity were rated quite

highly in the majority of studies, and the reality of surgery and the virtual simulation were comparable; however, these are all technically feasible and there is a dearth of reporting on successful implementation. In addition, the use of low-cost 3D silicone models has been demonstrated, though they may not function as intended and require frequent updates and modifications. Therefore, it would be ideal to develop technology that is easily usable offline and pertinent to regional clinical practice. We urge more consistent reporting and understanding of implementation of science approaches in the development of digital surgical tools, as this is the critical factor that will determine whether we are able to meet the 2030 goals for surgical training in LMICs. Sustainability of implemented digital surgical tools are a pain point that must be focused on if we are to deliver digital surgical simulation tools to the populations that demand them the most. The limitations of the paper are that there was a high degree of inconsistency and vagueness in the reporting of implementation outcomes, a small sample size of papers, and a lack of inclusion of the gray literature. The suggested implication of our paper is to develop systems that prioritize local sustainability and health system capacity as opposed to traditional models of increasing surgical capacity in LMICs. We believe that digital surgical simulation can play a crucial role in training surgeons from these regions while allowing large foreign institutions to avoid implementation of unsustainable medical “voluntourism.”

Abstract

Background: Remote and virtual simulations have gained prevalence during the COVID-19 pandemic as institutions maintain social distancing measures. Because of the challenges of cost, flexibility, and feasibility in traditional mannequin simulation, many health care educators have used videos as a remote simulation modality; however, videos provide minimal interactivity.

Objective: In this study, we aimed to evaluate the role of interactivity in students' simulation experiences. We analyzed students' perceptions of technology acceptance and authenticity in interactive and noninteractive simulations.

Methods: Undergraduate nursing students participated in interactive and noninteractive simulations. The interactive simulation was conducted using interactive video simulation software that we developed, and the noninteractive simulation consisted of passively playing a video of the simulation. After each simulation, the students completed a 10-item technology acceptance questionnaire and 6-item authenticity questionnaire. The data were analyzed using the Wilcoxon signed-rank test. In addition, we performed an exploratory analysis to compare technology acceptance and authenticity in interactive local and remote simulations using the Mann-Whitney *U* test.

Results: Data from 29 students were included in this study. Statistically significant differences were found between interactive and noninteractive simulations for overall technology acceptance ($P < .001$) and authenticity ($P < .001$). Analysis of the individual questionnaire items showed statistical significance for 3 out of the 10 technology acceptance items ($P = .002$, $P = .002$, and $P = .004$) and 5 out of the 6 authenticity items ($P < .001$, $P < .001$, $P = .001$, $P = .003$, and $P = .005$). The interactive simulation scored higher than the noninteractive simulation in all the statistically significant comparisons. Our exploratory analysis revealed that local simulation may promote greater perceptions of technology acceptance ($P = .007$) and authenticity ($P = .027$) than remote simulation.

Conclusions: Students' perceptions of technology acceptance and authenticity were greater in interactive simulation than in noninteractive simulation. These results support the importance of interactivity in students' simulation experiences, especially in remote or virtual simulations in which students' involvement may be less active.

Introduction

Background

The COVID-19 pandemic has prompted many health care providers to transition to remote or virtual simulations to comply with physical distancing guidelines. Many instructors opted to use commercial simulation software such as vSim for Nursing [1], Shadow Health [2], and Lippincott Clinical Experiences [3]. These software products have been valuable resources for health care instructors during the pandemic [4] and were appreciated by students [5]; however, flexibility is limited as these products are typically predeveloped and offer few options for customization. This creates challenges for instructors when the predeveloped scenarios do not meet the institution's learning objectives. Some companies offer to modify their existing content or develop new scenarios according to requested specifications; however, these services often come at a high cost and are time-consuming. Many instructors who sought a more flexible and cost-effective modality used tele-simulation [6]. In tele-simulation, the instructor uses a videoconferencing platform to demonstrate a mannequin-based simulation to students remotely [7]. Tele-simulation has been shown to be beneficial for learning and well received by students [8], but the logistics of conducting a tele-simulation are difficult to orchestrate, especially during the pandemic [9]. Instructors often host the tele-simulation from a simulation facility and may need to assemble additional computer equipment to connect with students via the videoconferencing platform. As an alternative to tele-simulation, many instructors have found that simply recording their simulation videos was more feasible and cost-effective during the pandemic [10,11]. Similar to tele-simulation, simulation videos may require instructors to access simulation facilities; however, the recorded videos can be used to conduct numerous simulations without returning to the facility. A disadvantage of simulation videos is that interactivity is reduced compared with modalities such as tele-simulation. While watching videos, students' engagement is passive, and they have minimal opportunity to collaborate or play an active role in the scenario.

Objective

In response to the need for a virtual simulation technology that is flexible, cost-effective, and interactive, we developed a software that transforms multimedia content (eg, video, images, and text) into an interactive simulation that can be conducted remotely or locally. In a previous study, we found that our interactive video simulation (IVS) software promoted higher-order learning and authenticity to a greater extent than noninteractive simulation videos when used remotely over a videoconferencing application [12]. The IVS software can also be used in the classroom as a modality that reduces physical contact and engages students in an interactive and team-oriented experience. As a continuation of our prior work, this study investigated the role of interactivity in local simulations. We asked two research questions and two exploratory questions as follows:

1. Question 1: Is technology acceptance greater for interactive simulation than that for noninteractive simulation?

2. Question 2: Is interactive simulation perceived as more authentic than noninteractive simulation?
3. Exploratory question 3: Is technology acceptance of interactive simulation greater when the content is delivered remotely over internet than when it is delivered locally without internet?
4. Exploratory question 4: Is authenticity of interactive simulation greater when the content is delivered remotely over internet than when it is delivered locally without internet?

Methods

We conducted an interactive video condition (INT) simulation and a video condition (VID) simulation to evaluate the role of interactivity in health care simulations. The INT simulation was conducted using a software that we developed. The methods used in this study are further discussed in this section.

Development

IVS Software

We developed the IVS software in Unity 3D using the C# programming language [13]. The IVS software requires 2 monitors to be connected to the computer. One monitor displays a dashboard of buttons that are used by the facilitator to control the simulation content displayed on the second monitor. The dashboard is viewed only by the facilitator, and the second monitor displaying the content is viewed by the students. Each button on the dashboard corresponds to one piece of multimedia content, such as a video clip, image, or text. When a button is clicked on the dashboard, the corresponding content is displayed on the students' monitor. The dashboard enables content to be displayed on the students' monitor seamlessly and in any order. The multimedia content is imported into the software before the simulation. The software stores the content information and button data (eg, labels, colors, and order) in csv files. These files can be modified to assign content to buttons and to change the layout and design of the dashboard. During the simulation, the facilitator provides students with a Scenario, Background, Assessment, and Recommendation (SBAR) and asks them to describe the steps of the patient care. As the students describe their patient care, the facilitator displays the associated multimedia content on the students' screen. For example, if students explain that they want to administer nitroglycerin medication, the facilitator will play the video clip of a nurse administering the medication. If students want to review the patient's electrocardiogram, the facilitator will display an image of the electrocardiogram. When a button is clicked, the data are written to a log that the facilitator can later review to evaluate students' performance.

The IVS software can be used to conduct a simulation locally or remotely. In a remote simulation, the facilitator connects with students via a videoconferencing application. The facilitator then uses the screen sharing feature to allow students to view the monitor displaying the simulation content, whereas the other monitor displaying the dashboard remains visible only to the facilitator. In this study, the simulation was controlled locally without the use of a videoconferencing application or the

internet. In a previous study, we used the IVS software to conduct a remote simulation over Zoom [12,14]. We found that streaming videos over Zoom caused a reduction in the frame rate, and the videos lagged on the students' screens. Many students reported that the lagging videos were distracting to their learning experiences [12]. In this study, the simulation was conducted locally without the internet to eliminate this factor, allowing us to focus exclusively on interactivity.

Educational Component

Simulation scenarios were developed to complement didactic or classroom content. The scenarios addressed stroke and chest pain management, which are challenging topics referred to as high risk and low volume in clinical practice. Simulation-based experiences are used to reinforce important concepts. In both interactive and noninteractive simulations, students were evaluated against Quality and Safety Education for Nurses competencies. The Quality and Safety Education for Nurses competencies include assessment, intervention medication, intervention communication, evaluation, and safety [15]. These competencies comprise the knowledge, skills, and attitudes that each prelicensure learner must develop to be competent. The scenarios incorporated the elements of these competencies. The interactive simulation enabled students to be more actively engaged in these competencies compared with the noninteractive simulation.

Scenarios

Overview

We used 2 scenarios from the nursing curriculum at the University of Central Florida (UCF), designed by nursing educators at UCF. The scenarios described a patient exhibiting stroke symptoms and a patient with chest pain. In these scenarios, the students were required to consider safety precautions for the patient, assess the patient's condition, and administer medications according to the protocol.

Stroke Scenario

In the stroke scenario, a patient named Vera Real presented with a cerebral vascular accident or stroke. Students began their interventions by ensuring the safety of the patient, and then they conducted a thorough neurological assessment to identify a hypertensive crisis. The patient's signs of a stroke should alert students to administer the appropriate prescribed medications according to physician orders and then report the patient's status to the physician. Laboratory results, radiological scans, and physician orders were provided to guide the students' patient care decisions.

Chest Pain Scenario

In the chest pain scenario, a patient named Anne Marie complained of chest pain and anxiety. This scenario encouraged students to think critically, as they must determine whether the chest pain is the result of anxiety or a serious cardiac event. At the start of their patient care, students ensured that the patient was safe, and then they administered oxygen and appropriate prescribed medications for cardiac irregularities and anxiety. Students should then provide a report to the physician.

Laboratory results, electrocardiogram images, and physician orders were provided to students for review.

Simulation Content

The video content used in this study was recorded at the UCF College of Nursing simulation laboratory. The videos showed a nurse performing the scenarios with a mannequin patient. A total of 40 video clips were recorded, with 18 (45%) video clips for the stroke scenario and 22 (55%) video clips for the chest pain scenario. Each video clip showed the nurse performing 1 step in the scenario, such as washing hands, administering medication, or calling the provider. The videos were recorded as clips so that they could be used in the IVS software. We created exemplar videos by concatenating these video clips in the order of the correct sequence of steps. The exemplar video for the stroke scenario played for 15 minutes, 10 seconds, and the exemplar video for the chest pain scenario ran for 16 minutes, 8 seconds. All the videos were in the MP4 format and had a frame rate of 30 frames per second and resolution of 1920×1080. The INT and VID simulations included the same video content in the form of both unordered video clips and an exemplar video. In the INT simulation, the video clips were incorporated into the IVS software, and in the VID simulation, the video clips were used to guide the debriefing. The exemplar videos were used in both the INT and VID simulations. Therefore, the students were exposed to the same video content twice in each simulation. In addition to the video content, we captured images of the provider orders, laboratory results, and scans reviewed by the nurse in the videos. These images were provided for students to view via the IVS software in the INT simulation and were used during the debriefing in the VID simulation. The INT simulation also included text content to display the patient's vital signs during the simulation.

Recruitment

The participants of this study were 32 third-semester undergraduate nursing students at the UCF College of Nursing. Participants were recruited through a course required in the nursing curriculum. Student participation in the simulation scenarios was mandatory as part of the course, but completion of the surveys for the study was voluntary. The incomplete data of 9% (3/32) of participants were excluded, resulting in the inclusion of data from 91% (29/32) of participants. Of the 29 participants, 24 (83%) participants were identified as female and 5 (17%) as male. Racially and ethnically, 38% (11/29) of participants were identified as Hispanic, 34% (10/29) as White, 24% (7/29) as Asian, and 3% (1/29) as West Indian. All (100%) the participants reported previous experience with simulation: 24 (83%) participants had experience with mannequins, and 26 (90%) participants had experience with virtual simulation.

Procedure

Overview

The study procedure was approved by the Institutional Review Board before the study was conducted. The design of this study was within-participants. The INT and VID simulations were conducted locally on the UCF campus. Students participated in the INT and VID simulations, and each simulation included either the chest pain or the stroke scenario. Students who viewed

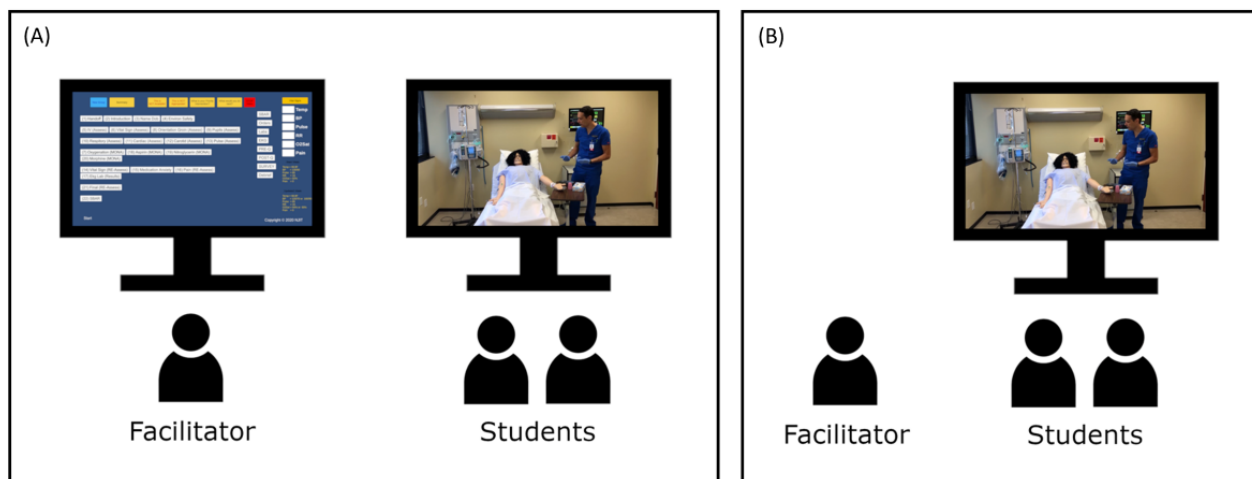

the chest pain scenario in the INT simulation viewed the stroke scenario in the VID simulation, whereas those who viewed the stroke scenario in the INT simulation viewed the chest pain scenario in the VID simulation. Students were randomly allocated to eight 3-member teams and four 2-member teams for a total of 12 teams. Students remained in their teams for the duration of the simulations. The teams' order of participation was counterbalanced to prevent order effects: 6 teams participated in the INT simulation first and 6 teams participated in the VID simulation first. Before engaging in the simulation, students were shown the SBAR for 3 minutes.

INT Simulation

Setup

The INT simulation was conducted using the IVS software that we developed. The facilitator ran the software on a computer that was connected to 2 monitors. The dashboard was displayed on 1 monitor and remained visible only to the facilitator, whereas the students viewed the simulation content on another monitor. The INT simulation setup is shown in Figure 1A.

Figure 1. Setup for the (A) interactive video condition and (B) video condition simulations.

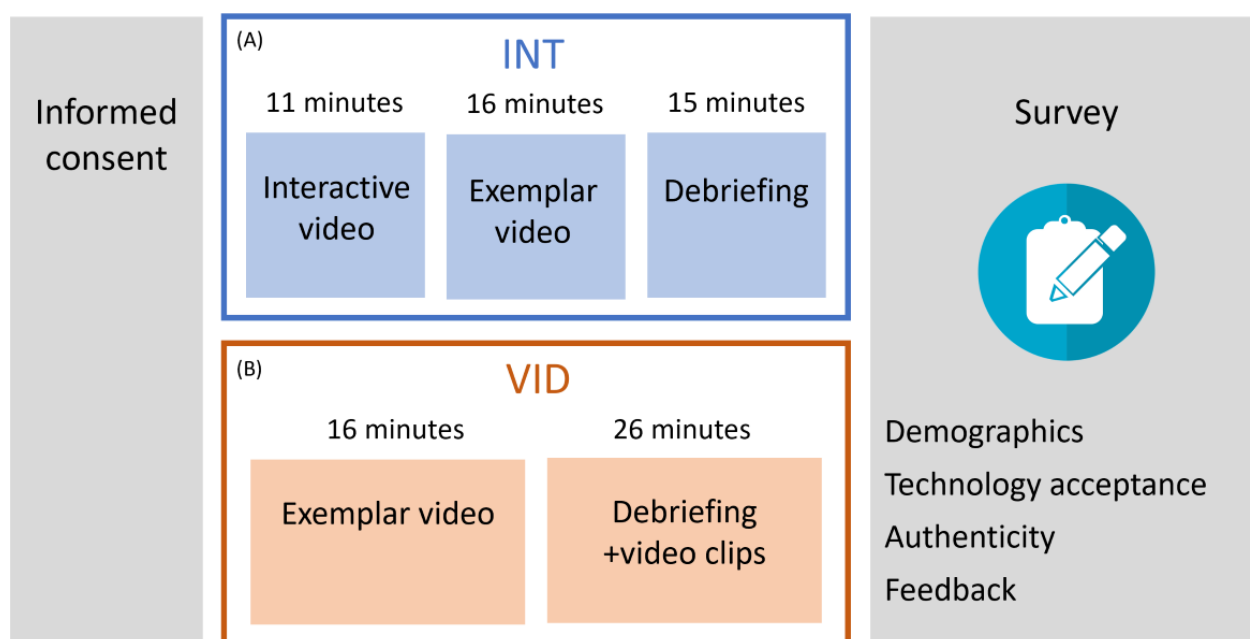

Procedure

The students participated in the interactive video via the IVS software for 11 minutes. During the interactive video, the facilitator asked the students to collaboratively describe the steps of their patient care. Students needed to unanimously agree on each step they would perform, and the facilitator then displayed the corresponding simulation content (ie, video clips, images, or vital signs) on the students' monitor. If the students described a step not included in the simulation content, the facilitator acknowledged the students' attempt and asked them to continue to the next step. Students could review the SBAR, provider orders, laboratory images, scans, or vital signs at any

point during the simulation to inform their decisions. After completing the interactive video, the students watched the exemplar video for the scenario, which portrayed all the video clips in the correct sequence. The exemplar video was approximately 16 minutes long. The students were then debriefed by the facilitator for 15 minutes. In the debriefing, the facilitator discussed the students' patient care decisions, recognized correct interventions, and clarified any areas of confusion or misunderstanding. After the debriefing, students were provided with a QR code to access a survey on their cell phones. The students completed the survey in 5 minutes. The procedure of the INT simulation is shown in Figure 2A.

Figure 2. Procedures for the (A) interactive video condition (INT) and (B) video condition (VID) simulations. Informed consent was obtained at the start of each simulation, and students completed a survey at the end of each simulation.

Simulation

Setup

In the VID simulation, the students watched the exemplar video uninterrupted with no interactive components. Students viewed the correct sequence of steps that were performed by a nurse and did not provide their own input. The facilitator's role in the VID simulation was to play the video for the students and conduct the debriefing. The setup of the VID simulation is shown in Figure 1B.

Procedure

Students watched the noninteractive exemplar video for approximately 16 minutes. After watching the video, the students were debriefed by the facilitator for 26 minutes. During the debriefing, the facilitator elaborated on the decisions made by the nurse in the exemplar video and responded to any of the students' questions. Discussions during the debriefing were guided by video clips and images. After the debriefing, the students used a QR code to access a survey on their cellphones and completed the survey in 5 minutes. The procedure of the VID simulation is shown in Figure 2B.

Measures

The measures evaluated in this study were technology acceptance and perceived authenticity of the simulations. Technology acceptance refers to the students' willingness to use and adapt to a simulation technology, and authenticity refers to the extent to which a real-life encounter is accurately represented in a simulation. The survey used in this study

included questionnaires derived from the Technology Acceptance Model (TAM) [16] and Virtual Patient Evaluation (VPE) [17] to measure technology acceptance and authenticity, respectively. The original TAM and VPE questionnaires are validated [16,17]; however, to make the questionnaires more suitable for this study, we modified or excluded some items. The TAM and VPE questionnaires were not validated after our modifications. The TAM questionnaire included 10 items scored on a Likert scale from *lower level* (1) to *higher level* (10). The TAM scores ranged from 10 to 100. The TAM questionnaire is presented in Textbox 1. The VPE questionnaire included 6 items scored on a Likert scale ranging from *strongly disagree* (1) to *strongly agree* (5). The VPE scores ranged from 6 to 30. Textbox 2 presents the VPE questionnaire. After the TAM and VPE questionnaires were completed, the survey included 3 open-response items to collect student feedback. The first item asked the students, "Which simulation technology did you prefer (video vs interactive video) and why?" The last 2 items asked the students, "Any comments about the simulation technology you just used?" and "Any other comments?" These data were used to quantify students' preferences of the INT or VID simulations and to understand the factors that contributed to their preferences. All items of the survey were marked as required, except for the last 2 items, which permitted students to leave additional comments. The TAM questionnaire, VPE questionnaire, and student feedback questions were presented on different pages of the same survey. The survey was administered to participants via a QR code on Google Forms (Google LLC) [18]. The usability and technical functionality of the survey were tested before the study was conducted.

Textbox 1. Technology Acceptance Model (TAM) questionnaire that was included in a survey given to students after completing the interactive video condition and video condition simulations.

TAM1: learn

- The use of the simulation software could help me to learn about nursing interventions more rapidly.

TAM2: use

- I think that I could easily learn how to use the simulation software.

TAM3: time

- The simulation software could help me get the most out of my time to learn about patients.

TAM4: clarity

- I believe that the learning carried out by the simulation software would be clear and easy to understand.

TAM5: performance

- The simulation software can improve my performance in patient care.

TAM6: flexibility

- I think that the simulation software is a flexible technology to interact with.

TAM7: interesting

- I find it interesting to use the simulation software for the learning about patients.

TAM8: intention

- I have the intention to use the simulation software when necessary to learn about patients.

TAM9: clinical practice

- The use of the simulation software may promote good clinical practice.

TAM10: benefit

- The use of the simulation software is beneficial for the care of my patients.

Textbox 2. Virtual Patient Evaluation (VPE) questionnaire that was included in a survey given to students after completing the interactive video condition and video condition simulations.

VPE1: decisions

- While working on this case, I felt I had to make the same decisions a nurse would make in real life.

VPE2: nursing care

- While working on this case, I felt as if I were the nurse caring for this patient.

VPE3: gathering info

- While working on this case, I was actively engaged in gathering the information (eg, history questions, physical exams, lab tests) I needed to characterize the patient's problem.

VPE4: revising image

- While working on this case, I was actively engaged in revising my initial image of the patient's problem as new information became available.

VPE5: summarizing problem

- While working on this case, I was actively engaged in creating a short summary of the patient's problem using medical terms.

VPE6: nursing priorities

- While working on this case, I was actively engaged in thinking about which findings supported or refuted my nursing priorities.

Statistical Analysis

Overview

The participants' scores for technology acceptance and authenticity were compared between the INT and VID simulations. Statistical analyses were performed using the Wilcoxon signed-rank test, which is a nonparametric test equivalent to the 2-tailed paired samples *t* test. We performed the statistical analysis of students' total questionnaire scores to evaluate the overall perceptions of technology acceptance and authenticity. We also performed statistical tests on each questionnaire item to focus on the concept of each item separately. To prevent the occurrence of type I error in multiple comparisons, we applied the Bonferroni correction to adjust the error rate. An α value of .05 was assigned to the statistical tests. For the analysis of the TAM questionnaire results, the error rate was adjusted to .005 to account for 10 comparisons. To analyze the VPE questionnaire results, the error rate was adjusted to .008 to account for 6 comparisons. We also compared the participants' technology acceptance and authenticity scores for the INT simulation from our previous study and this study. This analysis was performed using the Mann-Whitney *U* test, which is a nonparametric test equivalent to the 2-tailed independent samples *t* test. We used nonparametric tests because the data were not normally distributed; therefore, a parametric test is not recommended [19,20].

Data Exclusion

Missing and incomplete data from 3 participants were excluded. One participant did not submit the survey for either of the 2 simulations; 2 participants submitted the survey for only 1 of

the 2 simulations. The Wilcoxon signed-rank test evaluates repeated measures; therefore, incomplete data could not be included.

Ethics Approval

Ethics approval was granted by the UCF Institutional Review Board (ID: STUDY00002297). This study was approved with an exemption determination because it involved no or minimal risk to participants. Informed consent was obtained before students' participation in the study. Students were informed that their deidentified survey data would be stored on a protected computer.

Results

Technology Acceptance

The students' TAM scores ranged from 50 to 100 for the INT simulation and from 35 to 100 for the VID simulation. The mean TAM scores were 89.72 (SD 11.76) for the INT simulation and 83.38 (SD 14.89) for the VID simulation. The results were statistically significant for TAM scores of the INT and VID simulations ($P<.001$). The results for the TAM scores are shown in Figure 3A and Table 1. Comparisons between students' INT and VID scores of individual TAM questionnaire items revealed statistical significance for TAM1 ($P=.002$), TAM3 ($P=.002$), and TAM9 ($P=.004$); these items pertained to learning, time, and clinical practice, respectively. Students' mean TAM scores were higher for the INT simulation than for the VID simulation for all statistically significant TAM questionnaire items. The results for individual items of the TAM questionnaire are shown in Table 2.

Figure 3. Students' (A) Technology Acceptance Model (TAM) and (B) Virtual Patient Evaluation (VPE) scores for the interactive video condition (INT) and video condition (VID) simulations. The statistical data are shown in Table 1.

Authenticity

The students' VPE scores ranged from 19 to 30 for the INT simulation and from 8 to 30 for the VID simulation. The mean VPE scores were 27.97 (SD 3.04) for the INT simulation and 23.07 (SD 6.18) for the VID simulation. The results were statistically significant for the VPE scores of the INT and VID simulations ($P < .001$). The results for the VPE scores are shown in [Figure 3B](#) and [Table 1](#). Comparisons between students' INT and VID scores for individual VPE questionnaire items revealed

statistical significance for VPE1 ($P = .001$), VPE2 ($P < .001$), VPE3 ($P < .001$), VPE4 ($P = .003$), and VPE6 ($P = .005$); these items pertained to decision-making, nursing care, gathering information, revising the image of the patient's problem, and defining nursing priorities, respectively. The students' mean VPE scores were higher for the INT simulation than for the VID simulation for all statistically significant VPE questionnaire items. The results for individual items of the VPE questionnaire are shown in [Table 3](#).

Table 3. Results of the Wilcoxon signed-rank test evaluating students' Virtual Patient Evaluation (VPE) scores for the interactive video condition (INT) and video condition (VID) simulations.

Student Feedback

Of the 29 students who participated in this study, 28 (97%) preferred INT simulation and 1 (3%) preferred VID simulation. The student who preferred the VID simulation did not specify a reason but mentioned that although they preferred the VID simulation, they felt that they learned more in the INT

simulation. Some of the students' comments were given in the [Textbox 3](#).

Students' feedback indicated that they preferred the INT simulation over the VID simulation, primarily for reasons pertaining to critical thinking, knowledge retention, engagement, and enjoyment.

Textbox 3. Students' comments regarding the simulations.

Comments regarding interactive video simulation

- "[I] really liked the interactive video, a lot more than any other kind of simulation. Made me think critically and got to ask plenty of questions with instructor."
- "Interactive video allowed me to make mistakes and learn from them, which I feel helps to solidify the knowledge."
- "It felt live, even though it was on video."
- "I loved the 'choose-your-own-adventure' style."
- "It helped me learn how to prioritize nursing care. It felt more involved."
- "I really like it for learning."

Comments regarding noninteractive video simulation

- "It felt counterintuitive to watch a scenario unfold without me having a say in what happens."
- "I found myself losing concentration while watching the video. The interactive video kept me engaged."

Exploratory Results

The exploratory analysis evaluated students’ TAM and VPE scores of the INT simulation from the first and second studies. Study 1 refers to our previous study [12] and study 2 refers to this paper. Students’ TAM scores ranged from 15 to 100 in study 1 and from 50 to 100 in study 2. The mean TAM scores were 76.06 (SD 23.60) for study 1 and 89.72 (SD 11.76) for study 2. The results were statistically significant for the TAM

scores from studies 1 and 2 ($P=.007$). The TAM scores from the studies are shown in Figure 4A and Table 4. Students’ VPE scores ranged from 6 to 30 in study 1 and from 19 to 30 in study 2. The mean VPE scores were 25.43 (SD 5.51) for study 1 and 27.97 (SD 3.04) for study 2. The results were statistically significant for the VPE scores from studies 1 and 2 ($P=.027$). The results of the VPE scores from the studies are shown in Figure 4B and Table 4.

Figure 4. Students’ (A) Technology Acceptance Model (TAM) and (B) Virtual Patient Evaluation (VPE) scores between studies 1 and 2 for the interactive video condition simulation. The statistical data are shown in Table 4.

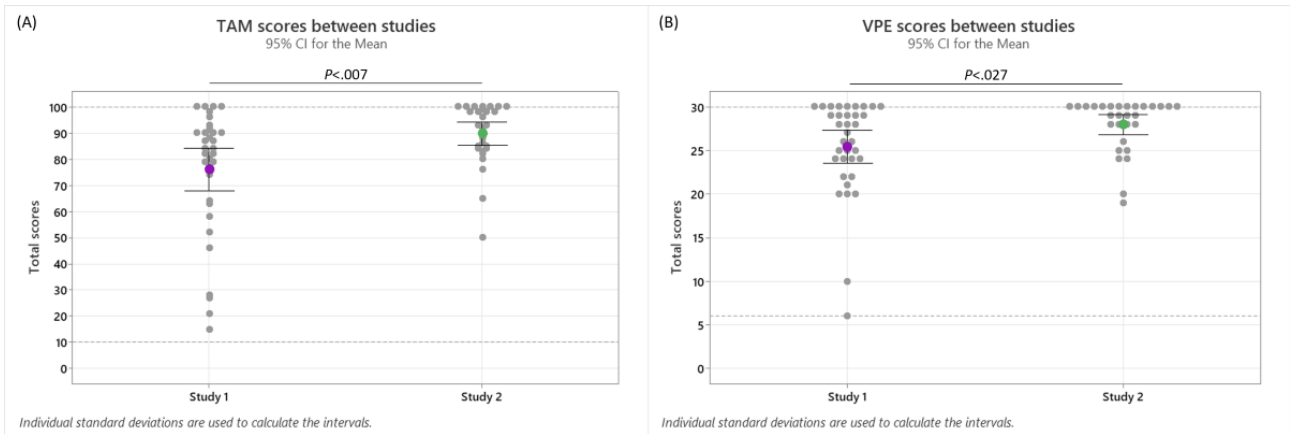

Table 4. Results of the Mann-Whitney *U* test evaluating students’ Technology Acceptance Model (TAM) and Virtual Patient Evaluation (VPE) scores between studies 1 and 2 for the interactive video condition simulation^a.

Discussion

Principal Results

Our results indicate that interactivity in health care simulation promotes students’ technology acceptance and perceived authenticity. Students also exhibited a strong preference for interactive simulation over noninteractive simulation.

Technology Acceptance

TAM predicts users’ acceptance of a technology by evaluating ease of use and perceived usefulness [21]. In the context of health care simulation, this implies that students are more likely to accept simulation technology if it is perceived to be uncomplicated and beneficial to their future learning. In this study, the students exhibited greater technology acceptance of interactive simulation than that of noninteractive simulation; that is, the interactive simulation technology was perceived by students to advance their learning (TAM1), be a valuable use

of time (TAM3), and promote good clinical practice (TAM9). These results answer our first research question.

Authenticity

In the interactive simulation, the students were actively involved in the progression of the patient’s care and watched the case evolve based on their decisions. The interactive component of the simulation promoted a sense of agency in the scenario and reflected the role of a nurse more accurately. As a result, the students perceived the interactive simulation to be more authentic than the noninteractive simulation. The students felt responsible for the decision-making (VPE1) and care (VPE2) of the patient and were engaged in gathering information (VPE3), identifying the problem (VPE4), and determining priorities (VPE6). These results answer our second research question.

Student Feedback

Students largely preferred the interactive simulation over noninteractive simulation. Students reported that the interactive simulation increased their engagement, critical thinking, and knowledge acquisition and was overall more enjoyable. Interactivity was perceived to have broadly impacted many aspects of learning and was associated with positive outcomes.

Exploratory Results

The exploratory analysis evaluated whether remote and local simulation modalities could impact students' technology acceptance and perceptions of authenticity. The results indicate that local simulation may increase technology acceptance and authenticity compared with remote simulation. In our analysis, data for remote simulation were collected in our previous study, which was conducted over the internet via a videoconferencing application [12], and data for local simulation were collected in this paper. In both the studies, we measured technology acceptance and authenticity using TAM and VPE questionnaires. Our previous study was limited by poor internet connection, which caused the videos to lag over the videoconferencing application. The technology acceptance results in that study were not statistically significant and therefore not reported in our previous publication [12]. Students had mentioned that the lagging videos negatively impacted their simulation experiences [12], and we suspected that the poor internet connection contributed to the insignificant results. We decided to conduct this study to re-evaluate students' perceptions of the simulations and eliminate any factors caused by poor internet connection. This allowed us to focus on the effects of interactivity on technology acceptance and authenticity more exclusively, without the results being obscured by uncontrolled variables. Our first study supported that interactive remote simulation promotes higher-order learning and increases authenticity compared with noninteractive remote simulation. This study demonstrated that interactive local simulation may further increase technology acceptance and authenticity compared with interactive remote simulation. While remote simulation has advantages, internet connection may introduce limitations that inhibit students' experiences, in which case local simulation conducted without internet or with a more stable internet connection may be more advisable. These results answer our exploratory research questions.

These results are reported as exploratory and not definitive because there were minor discrepancies in the study procedures. In the first study, students in the INT simulation did not watch the exemplar video and students in the VID simulation did not view the video clips. Therefore, the students' exposure to the multimedia content was unequal between the simulations. In this study, the students' exposure to the content was equal in the INT and VID simulations. Our motivation for modifying the procedure was to improve the experimental design; however, this modification may have influenced the results of our analysis. A separate study focusing on evaluating remote and local simulations is required to provide definitive results. Nonetheless, this exploratory analysis provides further insight into remote and local simulation technologies.

Limitations

Our study was limited by 2 factors. First, interactivity in multimedia education is formally defined as direct learner-computer interaction [22]; however, participants' interaction with the IVS software in the INT simulation was indirect. In our study, students determined the system input (selection of the button representative of the patient care step) and were the recipients of the output (display of simulation content). Ultimately, it was the facilitator that directly interacted with the system by pressing buttons on the dashboard to prompt the display of content. The facilitator acted as a mediator between the students and the simulation system, resulting in indirect learner-computer interaction. However, despite the students' indirect interaction, the INT simulation promoted a level of interactivity far greater than the VID simulation did. In the VID simulation, the students only passively watched the simulation video and provided no input. As a result, we believe that our comparison between interactive and noninteractive simulations remains valid. Direct learner-computer interaction in the INT simulation may have strengthened our results, but many of our comparisons between the INT and VID simulations remained statistically significant despite this limitation. We are currently developing the IVS software to permit direct learner-computer interaction, and we plan to conduct future studies to further investigate the role of interactivity in health care simulation. Second, our exploratory analysis compared the results for the INT simulation from this study and our first study published in [12], although the procedures of the studies were not the same. We modified the procedure of this study to equalize students' exposure to the multimedia content between the INT and VID simulations because it was not equal in the first study. In the first study, the INT simulation did not include the exemplar video, whereas in this study, it did. Consequently, students had greater exposure to the content in this study than in the first study. Students' higher TAM and VPE scores in this study may have been attributed not only to the local facilitation but also to the greater exposure to content. We included the analysis in this paper because it still has value, but we call it an "exploratory" analysis owing to this limitation. To confirm the validity of these results, we would need to conduct a future study in which the local and remote simulations incorporate the same procedure.

Comparison With Prior Work

The role of interactivity in health care simulations has been addressed in previous studies. Medical education research often differentiates between passive learning and active learning. Passive learning implies a direct transfer of knowledge from the educator to the learner with minimal involvement from the learner, whereas active learning emphasizes engagement, observation, and reflection, and knowledge is constructed by the learner rather than transferred to them in active learning [23]. The advantages of active learning in students' cognition have been supported by ample literature [24]. One meta-analysis of 225 studies found that active learning resulted in a 6% increase in students' exam scores and failure rates were 55% higher in traditional lectures than in active learning classes [25]. Active learning has also been shown to promote long-term knowledge retention [26] and cultivate engagement [27]. After

the onset of the COVID-19 pandemic, educators have used web-based infrastructure that can further facilitate active learning, promote knowledge acquisition, and improve learner satisfaction [28].

Despite the overwhelming endorsement of active learning, some educators are reluctant to implement these methods without more evidence-based research [29]. The results of active learning studies are often generalized without thorough evaluation of significant variables, such as the intensity of active learning, teacher and student characteristics, and outcome measures [30]. One study found that active participation did not improve students' performance in simulation compared with passive observation and suggested that the debriefing structure may be the more influential factor [31]. Despite limited knowledge of the variables affecting active learning outcomes, the multiplicity of studies advocating active learning suggests that there must be some value in these methods. Active learning research is continuing to develop, and more critical analyses will enhance our understanding of active learning and its contribution to students' experiences.

As we increased interactivity in our study, we observed a shift toward a nontraditional simulation structure. In traditional simulation, the debriefing is conducted after the simulation. Postsimulation debriefing involves providing minimal feedback during the simulation and discussing students' performance after the simulation has been completed. In an alternative approach called Rapid Cycle Deliberate Practice (RCDP), the debriefing is a continuous process that occurs throughout the course of the simulation. The RCDP simulation is paused at various points to allow students to reflect on their decisions, discuss their subsequent tasks, and receive feedback from the facilitator. These reflective pauses are commonly referred to as microdebriefs. Previous research has demonstrated that microdebriefing reduces the cognitive load of the simulation by breaking it into segments that are more manageable for students to comprehend [32]. Learners have also reported that reflective pauses add greater value to their simulation experience than postsimulation debriefing [33]. In this study, the INT simulation incorporated a debriefing method resembling RCDP, whereas the VID simulation incorporated the traditional postsimulation debriefing. The use of segmented and itemized multimedia content in the INT simulation permitted the students

to pause, reflect, and discuss at each step of the scenario. During these pauses, students collaborated among their groups to decide their next action, and the facilitator was present to guide their discussion. However, in a typical RCDP simulation, the facilitator immediately acknowledges students' mistakes and allows them to rethink their actions. The INT simulation differed from the RCDP simulation in that the facilitator did not provide immediate corrections unless students described actions that were inappropriate for the scenario (eg, administering contraindicated medications). In these cases, the facilitator would address the mistake and let the students reconsider their decisions. However, if students missed or incorrectly ordered some steps, the facilitator proceeded with the simulation and discussed these mistakes after completion of the simulation. Productive failure pedagogy recognizes that there is value in allowing students to commit mistakes in simulations [34]. In this pedagogy, explicit instruction is avoided to allow students to execute their mistakes in a safe environment. Students' mistakes are then discussed between the students and facilitators in a postsimulation debriefing. Productive failure has been shown to benefit students' learning to a greater extent than explicit instruction [34]. The IVS software generates a simulation that combines the elements of both RCDP and productive failure. Reflective discussion is guided by the facilitator after each step of the scenario; however, students are not prevented from committing and learning from their mistakes.

Conclusions

As the use of remote and virtual simulation technologies becomes more prevalent, the role of interactivity in students' simulation experiences should be considered. This study demonstrated that interactivity in simulations may have advantages in terms of technology acceptance and authenticity. The interactive simulation in this study was met with greater technology acceptance and was perceived to be more authentic than the noninteractive simulation. Our exploratory analysis revealed that interactive simulation conducted locally without an internet connection may promote greater technology acceptance and perceptions of authenticity compared with remote delivery over an internet connection. Students also indicated a strong preference for interactive simulation over noninteractive simulation.

Acknowledgments

We thank Talaar Rastguelenian for contributing to the development of the interactive video simulation software and Syretta Spears, Dana McKay, and Niki Hutchinson for assisting with conducting the study.

Abstract

Background: Telemedicine use increased as a response to health care delivery changes necessitated by the COVID-19 pandemic. However, lack of standardized curricular content creates gaps and inconsistencies in effectively integrating telemedicine training at both the undergraduate medical education and graduate medical education levels.

Objective: This study evaluated the feasibility and acceptability of a web-based national telemedicine curriculum developed by the Society of Teachers of Family Medicine for medical students and family medicine (FM) residents. Based on the Association of American Medical Colleges telehealth competencies, the asynchronous curriculum featured 5 self-paced modules; covered topics include evidence-based telehealth uses, best practices in communication and remote physical examinations, technology requirements and documentation, access and equity in telehealth delivery, and the promise and potential perils of emerging technologies.

Methods: A total of 17 medical schools and 17 FM residency programs implemented the curriculum between September 1 and December 31, 2021. Participating sites represented 25 states in all 4 US census regions with balanced urban, suburban, and rural settings. A total of 1203 learners, including 844 (70%) medical students and 359 (30%) FM residents, participated. Outcomes were measured through self-reported 5-point Likert scale responses.

Results: A total of 92% (1101/1203) of learners completed the entire curriculum. Across the modules, 78% (SD 3%) of participants agreed or strongly agreed that they gained new knowledge, skills, or attitudes that will help them in their training or career; 87% (SD 4%) reported that the information presented was at the right level for them; 80% (SD 2%) reported that the structure of the modules was effective; and 78% (SD 3%) agreed or strongly agreed that they were satisfied. Overall experience using the national telemedicine curriculum did not differ significantly between medical students and FM residents on binary analysis. No consistent statistically significant relationships were found between participants' responses and their institution's geographic region, setting, or previous experience with a telemedicine curriculum.

Conclusions: Both undergraduate medical education and graduate medical education learners, represented by diverse geographic regions and institutions, indicated that the curriculum was broadly acceptable and effective.

Introduction

Telemedicine—the delivery of health care remotely using telecommunication technology [1]—emerged at the forefront of clinical care during the COVID-19 pandemic. Over the last 20 years, known benefits include increased patient access (especially in underserved and rural areas), decreased health care costs, and high patient and physician satisfaction [2,3]. Although the pandemic unexpectedly accelerated the adoption of telemedicine [4], many academic medical centers are now purposefully developing strategies for the long-term integration of telemedicine and digital health tools into clinical care and medical education [5,6]. Furthermore, with the emergence of technologies such as remote patient monitoring, there is an urgency to train future physicians in the meaningful use of telemedicine in the context of a rapidly evolving health care landscape.

Recognizing a need for telemedicine education, the Association of American Medical Colleges (AAMC), the Liaison Committee on Medical Education, and the American Academy of Family Physicians (AAFP) recommended adoption of telemedicine into medical school and residency training before the pandemic [7]. Between 2018 and 2021, the number of US medical schools offering telemedicine education in a required or elective course dramatically increased from 58% to 90% [8]. Similarly, telemedicine use in residencies rapidly expanded once the Centers for Medicare and Medicaid Services extended reimbursement for telemedicine outside of rural areas and allowed remote precepting [9]. Proposed changes to the Accreditation Council for Graduate Medical Education family medicine program requirements state, for the first time, that resident patient encounters should include telemedicine visits [10].

Despite the expansion of telemedicine education at medical schools and residency programs, there are still significant telemedicine curricular gaps [11,12]. For example, while medical students express a desire to learn telemedicine best practices in undergraduate training [11], a 2020 survey of 156 internal medicine postgraduate year 1 (PGY-1) residents demonstrated that 74% of them did not receive dedicated telemedicine training during medical school, and only 12% of them felt “at least moderately” prepared to conduct telemedicine visits at the start of residency [12]. A 2021 survey of 213 residents (PGY-1 to PGY-7) representing 51 different specialties showed 72% felt that specific training in telemedicine was important for their careers [13].

Medical schools frequently cite a lack of faculty experience in telemedicine as a significant barrier to developing telemedicine education [14]. An additional barrier is the lack of a recognized

gold standard for telemedicine training [15-18]. In response to this, the Society of Teachers of Family Medicine (STFM) formed a task force to create a national telemedicine curriculum for medical students and family medicine (FM) residents [19], using an expanded version of AAMC’s cross-continuum telemedicine competencies [20]. This study describes the feasibility and acceptability of this national telemedicine curriculum, covering 20 telemedicine competencies over 5 web-based modules, across a diverse group of undergraduate medical education and graduate medical education (GME) settings.

Methods

Curriculum Development

The STFM Telemedicine Task Force convened in June 2020 to develop a national curriculum for medical schools and FM residencies, covering foundational topics and best practices in telemedicine. Task force members included multidisciplinary medical educators and telehealth experts from diverse organizations, including the AAFP, AAMC, the US Department of Veterans Affairs, academic medical centers, and large health delivery systems across the country [19].

Task force members developed the telemedicine curriculum between September 2020 and August 2021. Curriculum development used Kern’s 6-step framework [21], including a targeted needs assessment, learning objectives mapped to AAMC competencies, incorporation of effective web-based educational strategies, and implementation as a multi-institutional pilot for evaluation. The needs assessment was conducted through a comprehensive literature review of existing telemedicine curricula. Learning objectives were mapped to AAMC’s telehealth competencies [20], and additional competencies were added by consensus decision-making [22]. Developed with the use of evidence-based principles in multimedia instruction [23,24], the modules incorporated instructional videos, animations, and interactive exercises to foster effective learning; modular content was organized into visually engaging screens for easy, self-paced scrolling on a laptop or mobile device. The modules prompted learners to apply, analyze, and synthesize learning concepts (hierarchical elements of Bloom’s taxonomy [25]) through interactive click-and-point exercises, reflective questions, and case-based medical decision-making.

Table 1 details the content of the 5-module curriculum. Module 1 (Intro to Telehealth) provides evidence-based telehealth uses. Module 2 (The Telehealth Encounter) reviews best practices in setting up a confidential, therapeutic environment, as well as “webside” manner, remote physical examinations, and medical decision-making. Module 3 (Requirements of Telehealth) covers

technology requirements and documentation. Module 4 (Access and Equity in Telehealth) focuses on access and equity to mitigate bias, promote cultural competence, and address potential technology barriers. Module 5 (Future of Telehealth)

addresses the promise and potential perils of emerging technologies. [Figures 1](#) and [2](#) are representative screenshots of the modules; a short overview video of the curriculum can be found in the [Multimedia Appendix 1](#).

Table 1. Overview of the Society of Teachers of Family Medicine national telemedicine curriculum, 2021: five comprehensive modules.

Module	AAMC ^a competency domain	ACGME ^b core competency and sub-competencies	Learning objectives	Teaching method in module
Introduction to telehealth	Patient safety and appropriate uses	<ul style="list-style-type: none"> Practice-based learning and improvement: investigate and evaluate patient care practices, appraise and assimilate scientific evidence Systems-based practice: coordinate patient care within the health system, incorporate considerations of cost awareness and risk/benefit analysis 	<ul style="list-style-type: none"> Describe the appropriate uses of telehealth Discuss the benefits and limitations of telehealth Identify factors that impact patient and practice barriers to incorporating telehealth Explain the roles and responsibilities of team members in telehealth encounters 	<ul style="list-style-type: none"> Evidence-based research on current telemedicine uses, risk and benefits Review of telemedicine barriers including patient readiness and access to technology Interactive point-and-click graphics and multiple-choice question
The telehealth encounter	Communication; data collection, and assessment	<ul style="list-style-type: none"> Interpersonal and communication skills: create and sustain a therapeutic relationship with patients and families Patient care and procedural skills: gather essential and accurate information, counsel patients and family members, make informed diagnostic and therapeutic decisions Medical knowledge: demonstrate an investigative and analytical approach to clinical problem solving and knowledge acquisition, apply medical knowledge to clinical situations 	<ul style="list-style-type: none"> Establish a therapeutic environment and develop effective rapport with patients Obtain a history and conduct an appropriate physical examination through telehealth Incorporate information from the patient's surroundings into the clinical assessment Apply appropriate medical decision-making in the context of providing care at a distance, including escalating care when necessary Complete documentation for telehealth encounters 	<ul style="list-style-type: none"> Case-based teaching with standardized patient videos: learners assess therapeutic environment, clinical symptoms, and respond to multiple-choice and free response questions Interactive exercises to navigate communication challenges (including sample scripts) and identification of health risks in environmental Tutorial videos on best practices for webside manner, physical examination, medical decision-making
Requirements for telehealth	Technology for telehealth; ethical practices and legal requirements (privacy regulations, informed consent, professional requirements)	<ul style="list-style-type: none"> Systems-based practice: advocate for quality patient care and optimal patient care systems, work in interprofessional teams to enhance patient safety and improve patient care quality 	<ul style="list-style-type: none"> Describe the technology requirements for a telehealth encounter Resolve common telehealth technical issues List the documentation requirements Identify the key elements of an effective telehealth work environment 	<ul style="list-style-type: none"> Point-and-click interactive exercises for technology troubleshooting Review of Health Insurance Portability and Accountability Act (HIPAA) compliance, documentation requirements including sample language and resources
Access and equity in telehealth	Access and equity (mitigate bias, promote health equity, address potential barriers to use)	<ul style="list-style-type: none"> Professionalism: demonstrate professional conduct and accountability, humanism, and cultural proficiency Interpersonal and communication skills: create and sustain a therapeutic relationship with patients and families 	<ul style="list-style-type: none"> Describe how telehealth may mitigate or amplify socioeconomic gaps in health care access Assess and accommodate patients' needs, preferences, and potential cultural, social, physical, cognitive, and linguistic/communication barriers to technology use Use telehealth to effectively deliver care for special populations (child/adolescent, geriatric patients with dementia or in a nursing home, patients at risk for intimate partner violence, LGBTQI patients, incarcerated patients, mental health care) 	<ul style="list-style-type: none"> Interactive, case-based scenarios for telemedicine visits with pediatric and adolescent patients; dementia and nursing home patients; lesbian, gay, bisexual, transgender, queer, and intersex (LGBTQI); mental health patients; visits with interpreters Reflective questions on cultural competence, barriers to care, maintaining confidentiality

Module	AAMC ^a competency domain	ACGME ^b core competency and sub-competencies	Learning objectives	Teaching method in module
Future of telehealth	Technology for telehealth (Emerging technologies)	<ul style="list-style-type: none"> Practice-based learning and improvement: investigate and evaluate patient care practices, appraise and assimilate scientific evidence Systems-based practice: incorporate considerations of risk/benefit analysis, advocate for quality patient care and optimal patient care systems, participate in identifying system errors 	<ul style="list-style-type: none"> Describe the current trends in telemedicine delivery models and new technologies Describe the types of technological innovations that may impact telemedicine in the future, including artificial intelligence Discuss methods of data acquisition Describe methods of interpreting healthcare data and subsequent utilization of this data 	<ul style="list-style-type: none"> Review of emerging innovations (remote patient monitoring and artificial intelligence), for chronic care management and population health Evaluation of emerging technology with consideration to impact on physician-patient relationship, safety/quality, and ethical, equitable care

^aAAMC is the Academic Association of Medical Colleges [26].

^bACGME is the Accreditation Council for Graduate Medicine Education [27].

Figure 1. Screenshot of “The Telehealth Encounter” in Module 2.

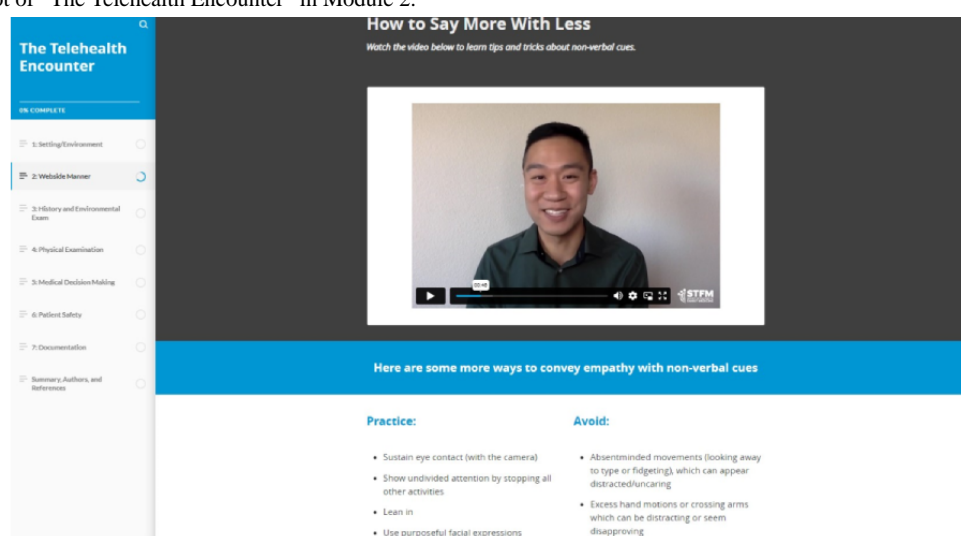

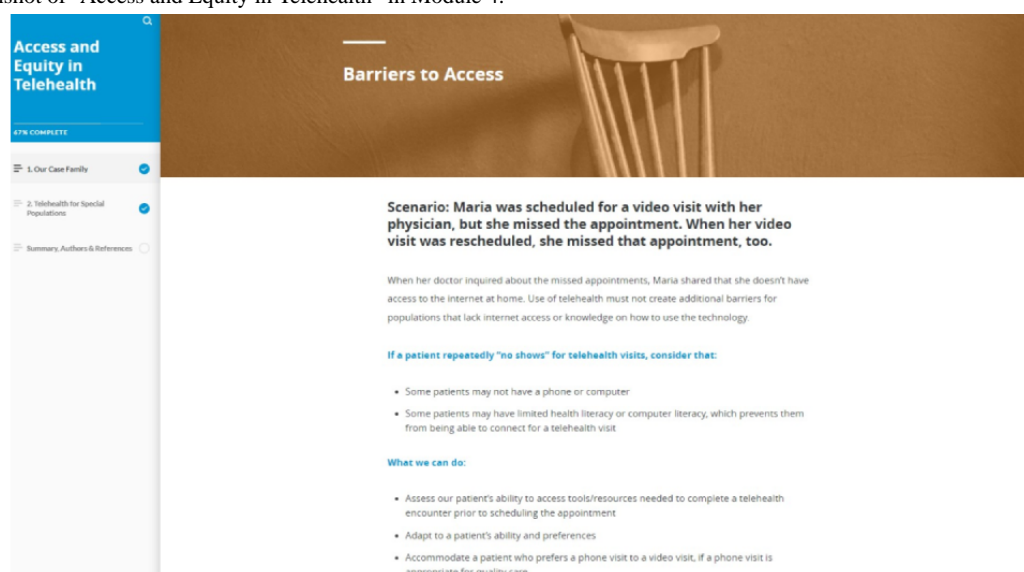

Figure 2. Screenshot of “Access and Equity in Telehealth” in Module 4.

Multi-institutional Evaluation of Curriculum

A total of 17 medical schools and 17 FM residencies implemented the STFM national telemedicine curriculum between September 1 and December 31, 2021. Selected from

75 applicants that responded to an open call, applications were reviewed with attention to diverse characteristics including geography, private or public institution, practice setting, and previous exposure to telemedicine education. Selected institutions represented all 4 US census regions and 8 of 9

divisions (except for East South Central due to a lack of applicants from that area). The 25 represented states comprised 5 Western states, 8 Midwestern states, 8 Southern states, and 4 Northeastern states; 8 of the sites were in rural locations, 10 sites were urban, and 12 were suburban.

Upon completion of site selection, task force members conducted an informational meeting for site leads through Zoom to ensure an understanding of the study requirements. As part of the application process, each institution completed a prepilot survey and designated a site lead. The site leads completed the following tasks: (1) collated learner names to track curriculum completion, (2) implemented the modules as a required activity, (3) initiated follow-up with learners with incomplete work, and (4) submitted a postpilot survey on curricular implementation. Each institution distributed study information to learners, describing the use of deidentified and aggregated survey responses. A poststudy meeting was held in January 2022 with site leads to debrief on their experiences.

Learners completed a survey immediately after completing each of the 5 web-based modules, assessing their reaction and changes in knowledge, skills, and attitudes. Faculty site leads completed postpilot surveys that assessed faculty perception of the curriculum, including quality of each module, usefulness in developing telehealth skills, and overall satisfaction. All surveys used can be found in the [Multimedia Appendices 2-4](#).

Data Analyses

Statistical analysis was conducted using R statistical software (version 4.1.2; The R Foundation). Ordinal logistic regression analyses were performed for learner responses to 4 questions. Response variables ranged from either “strongly disagree” to “strongly agree” or from “way too basic” to “way too advanced.” Explanatory variables included institutions’ US census region,

setting, and prior exposure to telemedicine curriculum. Chi-square tests were used to determine whether learners’ training level (eg, medical student or resident) was related to selecting “strongly agree” for gaining new knowledge, skills, or attitudes, the effectiveness of module structure, and overall satisfaction. We also tested whether learners’ training level was related to selecting “way too basic,” and, separately, “way too advanced” for appropriateness for the level of medical training. Results are presented for tests run with and without Yates’ correction.

Ethics Approval

The AAFP Institutional Review Board approved this study (protocol #21-420, approved August 5, 2021).

Results

Results of Overall Curriculum

A total of 1203 learners, including 844 (70%) medical students and 359 (30%) FM residents, participated in the study ([Table 2](#)). Learners in all years were represented; third-year medical students represented the largest learner group, accounting for 36% (433/1203) of participants. 92% (1101/1203) of learners completed the entire curriculum (ie, all 5 modules). Most participants completed each module in 15-30 minutes (62%, SD 8%).

Across the modules overall, 78% (SD 3%) of participants agreed or strongly agreed that they gained new knowledge, skills, or attitudes that will help them in their training or career; 87% (SD 4%) reported that the information presented was at the right level for them; 80% (SD 2%) reported that the structure (eg, layout and organization) of the modules was effective; and 78% (SD 3%) agreed or strongly agreed that they were satisfied ([Figures 3-6](#)).

Table 2. Demographics of participants in the national telemedicine curriculum evaluation, 2021.

	Medical students (N=844), n (%)	Family medicine residents (N=359), n (%)
Level of training

^aNot available.**Figure 3.** Responses to the statement, "By completing this module, I gained new knowledge, skills, and attitudes that will help me in my training or career."**Figure 4.** Responses to the statement, "Overall, for my level of medical training, the information in this module was."

Figure 5. Responses to the statement, "Overall, the structure (layout, organization, etc) of this module was effective."**Figure 6.** Responses to the statement, "Overall, I was satisfied with this module."

Results for Individual Modules

Using the completion of module 1 as baseline (1203/1203), the completion rate for modules 2 to 5, respectively, was 95% (1144/1203), 94% (1132/1203), 93% (1115/1203), and 92% (1101/1203). For modules 1 to 5, respectively, the proportion of participants who agreed or strongly agreed that they gained new knowledge, skills, or attitudes that will help them in their training or career was 77% (921/1203), 82% (942/1144), 73% (832/1132), 81% (898/1115), and 78% (855/1101); the proportion who reported that the information presented was at the right level for them was 83% (1003/1203), 89% (1,023/1144), 81% (913/1132), 90% (1009/1115), and 90% (994/1101); the proportion who reported that the structure of the module was effective was 82% (983/1203), 82% (935/1144), 76% (858/1132), 80% (888/1115), and 78% (862/1101); the proportion who agreed or strongly agreed that they were satisfied was 80% (965/1203), 82% (940/1144), 73% (822/1132), 80% (893/1115), and 77% (850/1101).

Experience of Medical Students Versus FM Residents

The Overall experience did not differ significantly between medical students and FM residents on binary analysis (ie, agree or strongly agree vs disagree or strongly disagree). Medical students were significantly more likely than FM residents to strongly agree that they gained new knowledge, skills, or attitudes that will help them in their training or career for most of the modules (Modules 2 [$P=.009$], 3 [$P=.003$], 4 [$P=.04$], and 5 [$P=.01$]). FM residents were significantly more likely than medical students to report that the information presented

was "way too basic" in modules 2 ($P=.02$), 4 ($P=.007$), and 5 ($P=.007$); but not 1 or 3. Medical students were significantly more likely than FM residents to strongly agree that the structure of the module was effective in modules 1 ($P=.009$), 2 ($P=.02$), 3 ($P<.001$), and 4 ($P=.008$); but not 5. Medical students were significantly more likely than FM residents to strongly agree that they were satisfied with modules 1 ($P=.01$), 2 ($P=.01$), 3 ($P=.002$), 4 ($P<.001$), and 5 ($P<.001$).

Experience Versus Institutional Characteristics

No consistent statistically significant relationships were found between participants' responses and their institution's geographic region, setting (ie, urban, suburban, and rural), or previous experience with a telemedicine curriculum. When asked whether they were overall satisfied, as compared to those in rural settings, participants in urban settings were significantly less likely to agree or strongly agree for module 1 (OR 0.696, 95% CI 0.5-0.96; $P=.03$) and 2 (OR 0.718, 95% CI 0.52-0.99; $P=.04$), but not 3, 4, or 5. Compared to those at sites without a preexisting telemedicine curriculum, participants at sites with a telemedicine curriculum were significantly less likely to agree or strongly agree that they were satisfied for module 3 (OR 0.661, 95% CI 0.49-0.88; $P=.005$), but not 1, 2, 4, or 5.

Faculty Evaluation

Faculty survey responses were received for 16 of 17 (94%) medical schools and 15 of 17 (88%) residencies. The faculty rated each module on a scale of 1-5 with 1 being poor and 5 being excellent. The overall mean rating for the entire curriculum was 4.2 ($n=31$); the range was 3.9-4.7. Both the

medical school and residency faculty rated module 2 (The Telehealth Encounter) the highest at 4.7 and 4.4, respectively. The majority of faculty at medical schools (13/16, 81%) and residency programs (11/15, 73%) reported that the information presented was at the right level; 19% (3/16) of medical school faculty assessed the curriculum as a little too advanced, and 27% of residency faculty (4/15) assessed the curriculum as a little too basic. All medical school faculty were satisfied (3/16 very satisfied, 13/16 satisfied) with the curriculum and would recommend it to other medical schools (16/16, 100%). All residency faculty were satisfied (8/15 very satisfied, 5/15 satisfied, 2/15 somewhat satisfied) and the vast majority (14/15, 93%) would recommend it to other programs.

Discussion

Principal Findings

The STFM telemedicine curriculum was broadly accepted and well-received by learners at different stages of training and from multiple geographic regions and institutions, both with and without preexisting curricula. Most learners and faculty felt the curriculum was appropriate for their current needs—a surprising finding given the wide range of learners from early medical school to graduating residents—indicating that the curriculum can be tailored across the training continuum. For example, some faculty for preclerkship medical students implemented the curriculum in first- or second-year doctoring courses, highlighting history-taking and communication skills, while some clerkship-level faculty used the curriculum to develop clinical reasoning skills before clinical experiences or observed structured clinical examinations. Curricular implementation in GME includes use in intern orientation or group didactics, supplemented with case discussions to include more advanced applications, such as remote physical examination techniques and medical decision-making. In this manner, the curriculum functioned as a building block for a competency-based curriculum [28-30] in various ways, from acting as the entire telemedicine curriculum to being used as part of a flipped classroom, or grafted onto the existing curriculum to enhance content. The flexible, asynchronous nature, and feasible time frame for completion of the modules further optimized integration within crowded undergraduate medical education and GME training spaces.

Comparison to Prior Work

While medical educators recognize the urgency to develop competency-based telemedicine curricula [28,29], the burden of creating curricula falls heavily on individual institutions, which may be particularly challenging for programs with limited resources. Prior studies indicate barriers to creating curricula include lack of faculty experience in this rapidly evolving field [14]. Furthermore, lack of standardized curricular content across institutions creates inconsistencies and gaps in telemedicine education [11,12]. Given potential limitations related to faculty resources, STFM's "off-the-shelf" curricula offers a readily implementable tool for equitable access to telemedicine education with standardized, competency-based content.

Strengths and Limitations

To our knowledge, our study is the largest multi-institutional evaluation of a telemedicine curriculum to date. Participating sites represented 25 states in all 4 US census regions with urban, suburban, and rural settings. In addition to geographic diversity, participants included both private and public institutions, as well as institutions with varying degrees of exposure to telemedicine education before our curriculum, from institutions with no previous exposure to those with preexisting curricula. In this diverse context, we found that both medical students and FM residents indicated that the STFM national telemedicine curriculum was effective and broadly acceptable.

We acknowledge several limitations to our study—first, our study primarily focused on evaluating learner experiences; however, some mitigation of potential bias has been made with faculty evaluations. Second, resident participants in our study were all from FM residencies. Although this curriculum does not address discipline-specific telemedicine applications, alignment with broader AAMC telemedicine competencies suggests that its value should extend well beyond the study group. Finally, while the asynchronous, self-paced format enabled flexibility to readily implement it across multiple institutions, we acknowledge that this learning format has limitations. Specifically, we were unable to assess higher level learning outcomes, such as whether learners changed behaviors, as this was not feasible at the scale of the study. Future research is needed to evaluate the curriculum's impact on learner performance and outcomes. For example, this curriculum's comprehensive learning objectives, mapped to AAMC's telemedicine competencies, can serve as a springboard to develop standardized assessment checklists for observed structured clinical examinations or "live" clinical assessments.

Future Directions

As medical educators innovate around telemedicine curricula, teaching future clinicians to consider ethical and societal implications of emerging technologies should not be overlooked. More than ever, learners require skills to critically assess new technologies, such as remote patient monitoring—with thoughtful consideration of their benefits and potential pitfalls. Given a widening "digital divide" between populations with and without access to these technologies [31,32], cultivating awareness and promoting equitable access cannot be overstated. The current STFM curriculum devotes 2 modules to inclusion of vulnerable populations and evaluating emerging technologies; future iterations of telemedicine curricula should continue to explore telemedicine's role in mitigating—rather than exacerbating—existing health disparities, as more research in this area emerges.

The STFM national telemedicine curriculum was designed for medical students and residents. Inviting interprofessional colleagues to participate in the development and use of future iterations could facilitate interprofessional care. Telemedicine affords the opportunity for learners from various disciplines to participate in clinical care and enables the participation of learners who might otherwise be excluded from in-person learning. In this manner, when optimally and thoughtfully leveraged, telemedicine training can serve as a multifaceted

opportunity for teachers and learners to explore equitable and learner- and patient-centered health systems that purposefully integrate telemedicine and digital health tools into clinical care and medical education.

Conclusions

The STFM telemedicine curriculum was broadly accepted and well-received by learners at different stages of training and from multiple geographic regions and institutions in this large national study. It has the potential to serve as a foundation for a

competency-based telemedicine curriculum for medical learners. Further research is warranted to evaluate the curriculum's impact on learner performance and outcomes.

Prior Presentations

Parts of this study were presented at the Society of Teachers of Family Medicine Conference on Medical Student Education (January 27-30, 2022) and the Society of Teachers of Family Medicine Annual Spring Conference (April 30-May 4, 2022).

Acknowledgments

The authors would like to thank the members of the Society of Teachers of Family Medicine Telemedicine Curriculum Task Force, including Tom Banning (Texas Academy of Family Physicians), Lance Fuchs, MD (Kaiser Permanente San Diego Family Medicine Residency), Kevin Galpin, MD (Office of Connected Care, Veterans Health Administration), Brett Johnson, MD (Methodist Health System Family Practice Residency Program), Bonnie Jortberg, PhD, RD, CDE (University of Colorado School of Medicine), John Moore, DO (Pacific Northwest University College of Osteopathic Medicine), Mahesh Patel, MD (University of Illinois), Kerry Palakanis, DNP, PRN (Connect Care Options), David Rakel, MD (University of New Mexico School of Medicine), Scott Shipman, MD (Association of American Medical Colleges), Duane Teerink, DO (Pacific Northwest University College of Osteopathic Medicine), and Steve Waldren, MD (American Academy of Family Physicians).

The work of the Society of Teachers of Family Medicine Telemedicine Curriculum Task Force, including the development of the curriculum, was supported by the Society of Teachers of Family Medicine and the Pacific Northwest University College of Osteopathic Medicine.

The authors also wish to thank Brian Hischier and Emily Walters (Society of Teachers of Family Medicine) for their contributions to the development of the curriculum's web-based modules; William Cayley Jr, MD, MDiv (Prevea Family Medicine Residency Program), Sandra Stover, MD (University of Minnesota Medical School), and Jyothi Patri, MD, MHA (Adventist Health Hanford Family Medicine Residency Program) for their review and feedback of the manuscript; and Grace Hong, BA and Anna Devon-Sand, MPH (Stanford University School of Medicine) for their statistical data analysis.

Data Availability

The data sets generated and analyzed during the current study are available from the corresponding author on reasonable request.

Conflicts of Interest

RB and SL served as unpaid volunteers on the Society of Teachers of Family Medicine Telemedicine Curriculum Task Force, which developed the curriculum. WF, LG, KJ, and AR are unpaid volunteers, not affiliated with the Society of Teachers of Family Medicine Telemedicine Curriculum Task Force. MT was a paid employee of the Society of Teachers of Family Medicine at the time of this work, now a paid contractor.

Abstract

Background: The COVID-19 pandemic presented significant challenges to both clinical practice and the delivery of medical education. Educators and learners implemented novel techniques, including distance learning and web-based rounds, while trying to stay updated with the surge of information regarding COVID-19 epidemiology, pathogenesis, and treatment. Hence, we designed and implemented a technologically enhanced course called “COVID-19 Rounds” to educate students about the rapidly evolving pandemic.

Objective: The objectives of this study are to describe a technologically enhanced course called “COVID-19 Rounds” and evaluate the following: (1) student satisfaction and program usefulness in achieving preset objectives, (2) perceived improvement in literacy regarding the pandemic, and (3) the impact of student engagement by designing infographics and initiating COVID-19-related research projects.

Methods: This is a cross-sectional study measuring the impact of the implementation of the web-based “COVID-19 Rounds” course. This program included web-based clinical experiences with physicians on actual rounds in COVID-19 wards in the hospital, weekly updates on evolving data and new research, and engagement in student-led projects. The study population included 47 fourth-year medical students at the Mohamed Bin Rashid University of Medicine and Health Sciences in Dubai, the United Arab Emirates, who attended the course. We designed and administered a 47-item survey to assess student satisfaction, program usefulness, impact on knowledge, and student engagement. Data were collected at the end of program delivery via Microsoft Forms.

Results: In total, 38 (81%) out of 47 fourth-year medical students participated in this study. The final course evaluation revealed an overall high satisfaction rate, with a mean rating of 3.9 (SD 0.94) on the 5-point Likert scale. Most students were satisfied with the course format (27/38, 71%), organization (31/38, 82%), and the learning experience (28/38, 74%) that the course offered. The course was particularly appreciated for offering evidence-based talks about aspects of the pandemic (34/38, 90%), providing weekly updates regarding emerging evidence (32/38, 84%), and enhancing understanding of the challenges of the pandemic (34/38, 90%). Satisfaction with distance learning was moderate (23/37, 62%), and a minority of students would have preferred an in-person version of the course (10/37, 27%). Student engagement in the course was high. All students participated in small group presentations of infographics of pandemic-related topics. Perceived advantages included conciseness and visual appeal, and disadvantages included the lack of detail and the time-consuming nature of infographic design, especially for students with no prior design experience. After the course ended, 27 (57%) students began research projects. This resulted in 6 abstracts presented at local meetings and 8 scientific papers published or submitted for publication.

Conclusions: This inquiry-based adaptive approach to educating medical students about updates on COVID-19 via web-based learning was successful in achieving objectives and encouraging engagement in research. However, shortcomings of the course related to the lack of in-person teaching and clinical activities were also highlighted.

KEYWORDS

medical education; COVID-19; technology-enhanced learning; distance learning; student engagement; 5E instructional model

Introduction

A key component of a competent physician's practice is staying up to date with emerging data in their field of expertise and applying that knowledge to clinical practice for the benefit of patients [1]. COVID-19 has highlighted the significance of adapting medical education to ensure that students and physicians can keep up with emerging data and guidelines amid such turbulent times. The surge of data has caused an "infodemic" for health care providers at the front lines [2]. It has also posed a challenge to medical schools, especially for students in their clinical years, with most sites halting their clinical rotations and some experimenting with web-based alternatives [3-5]. The need to continue training physicians in a safe and impactful manner is greater now than ever before [6].

Medical schools have responded to the challenges posed by the COVID-19 pandemic in transformative and innovative ways [7-10]. The Mohammed Bin Rashid University of Medicine and Health Sciences (MBRU) is a newly established medical school in Dubai, located in the health care hub of the United Arab Emirates. The undergraduate medical program at MBRU is based on a competency-based educational model and takes 6 years to complete. The curriculum is divided into 3 phases, with each phase building on the preceding one, resulting in a spiral-like approach. Phase 1 takes place over 1 academic year and covers basic sciences. Phase 2 spans 2 academic years and covers organ systems. Phase 3 spreads over the final 3 academic years and covers clinical sciences. The longitudinal themes curriculum spans the duration of phase 3 and integrates topics such as quality improvement, safe prescribing, and procedural skills.

In response to COVID-19, the MBRU phase 3 clinical sciences faculty introduced "COVID-19 Rounds" as part of the longitudinal themes curriculum to provide physicians and patients with web-based clinical experiences in hospital COVID-19 wards. The goal of the course was to actively engage students with the unfolding challenges of a new pandemic. Learning theories were incorporated including the biopsychosocial model of illness and the 5E (Engage, Explore, Explain, Elaborate, and Evaluate) model framework for learning, initially described by the Biological Sciences Curriculum Study for science teaching and adapted to medical education [11,12].

Based on this model, essential components of the course included web-based clinical experiences with COVID-19, weekly updates on local and global epidemiological statistics, information about microbiology and transmission, and emerging evidence about diagnosis and treatment. Students presented COVID-19-related infographics and research projects, with the aim of contributing to medical knowledge by participating in scientific conferences and publishing in peer-reviewed journals. Our goal for this study is to report on the experience with this

inquiry-based web learning course for medical students in their clinical years during the pandemic.

This study aims to (1) describe a technology-enhanced course named "COVID-19 Rounds" to educate medical students regarding a rapidly developing pandemic and (2) evaluate the course in terms of student satisfaction and program usefulness in meeting preset objectives, perceived improvement in literacy regarding the COVID-19 pandemic, and the impact of student engagement (by designing infographics and initiating research projects).

Methods

Study Participants

We conducted a cross-sectional study and collected data via a survey at 1 time point at the end of program delivery. The study participants included 38 (out of 47 who enrolled in the course) fourth-year (out of 6 years) Bachelor of Medicine and Bachelor of Surgery medical students at MBRU. All students in the fourth-year class were part of our sample, as this "COVID-19 Rounds" course was delivered under the longitudinal theme's curriculum at MBRU. This was an optional pass/fail course with the requirements of a student assignment. There was a 100% pass rate observed. The course ran from March 29, 2020, to September 1, 2020, with a total of 22 sessions delivered via Microsoft Teams (Microsoft Corp). This course was delivered while student clinical rotations were converted to web-based learning and continued through the summer.

Curriculum Development

The "COVID-19 Rounds" curriculum was designed by the university's clinical faculty, taking into consideration the rapidly evolving nature of information about Sars-CoV-2 and the COVID-19 pandemic. The Engel biopsychosocial model of instruction [13,14] and inquiry-based learning via the 5E learning framework [15] were utilized to inform and enhance the curriculum. The biopsychosocial model is strongly applicable to the COVID-19 pandemic due to the complex interaction of biological mechanisms of disease; population factors related to disease control; and the social, political, and psychological elements related to vaccinations and group dynamics [14]. Students were encouraged to reflect on the pandemic's evolution from a wider lens and consider the various biological, psychological, and social aspects at play. The 5E learning framework is a type of inquiry-based learning approach to allow students to construct learning experientially. This was implemented by engaging students through the stages of engagement, exploration, explanation, elaboration, and evaluation [15]. The development was also informed by carrying out interactive activities and discussions and incorporating different levels of instruction ascending the Bloom taxonomy of learning from basic didactic instruction to self-directed group tasks [16].

Data Collection

Quantitative and qualitative data were collected by open survey method utilizing Microsoft Forms and created based on the objectives of the study ([Multimedia Appendix 1](#)). Data collection was open for 10 weeks, starting at the end of program delivery to allow for maximum response rates and accounting for factors that could influence response rates, such as coinciding exams. Convenience sampling was used based on the context of the study and was made available to the 47 fourth-year medical students who took the course. The survey was sent via email, along with a description of the study ([Multimedia Appendix 1](#)) and a link to input responses into Microsoft Forms.

The survey consisted of 4 sections and 47 questions spanning 9 pages. It required 7 minutes to complete on average. The sections were entitled “Satisfaction with COVID-19 Rounds,” “COVID-19 Rounds Effectiveness,” “Impact of “COVID-19 Rounds on Knowledge and Level of Understanding,” and “Added Value of the Web-Based Program and Use of Infographics.” The initial survey draft was pilot-tested to establish face validity, correct poorly-worded questions and unambiguity, and shorten it to reduce respondent fatigue. Most of the data were measured via a 5-point Likert scale [17] ranging from strongly disagree to strongly agree. The course rating was via a 5-star rating scale. In total, 6 open-ended questions were included to assess expectations, perceived advantages and disadvantages associated with web-based course delivery, and infographic design. Responses to open-ended questions were analyzed by quantifying the responses, and they were given descriptively. Different answers that were variations of the same meaning were grouped by mutual agreement of the investigators.

Ethics Approval

This study was approved by the MBRU Institutional Review Board (MBRU-IRB-2020-26). Participation was completely voluntary. The participants were provided with a written consent document and were asked to agree to the study; if so, they were automatically sent the link to the survey. Participant data remained anonymous and completely deidentified, and privacy and confidentiality protections were guaranteed. Participants could discontinue at any time during the process of data collection and skip any sensitive questions as needed. No compensation was provided for participation in this study. Moreover, participants were able to review and change their answers if needed and request a summary of their responses at the end of the survey. There was no automated way to prevent multiple entries, but there were no known or apparent incentives for this to occur. Data were stored in an encrypted file on a secure computer.

Statistical Analysis

Stata 16 software (StataCorp) and Microsoft Excel were used for statistical analyses. All 47 fourth-year medical students were eligible to participate in the study. Power calculations, based on a CI of 95%, yielded a target sample size of 42 medical students. Frequencies with proportions were reported for

categorical variables, including the questions graded via the Likert scale. Additionally, means with SDs were reported for continuous variables.

Results

Course Description

The “COVID-19 Rounds” course consisted of a guided inquiry-based approach to web-based learning based on the 5E instructional model of 5 phases to engage, explore, explain, elaborate, and evaluate [11]. The program was presented online via the Microsoft Teams platform for 1 hour twice weekly to the whole fourth-year class. The presentations were divided into several sections. First, the students were engaged by physicians who were videotaped in actual rounds in COVID-19 wards, presenting patients along with laboratory and radiologic data. This enabled students to experience the events unfolding in hospitals in real time despite the remoteness of the lockdown. Second, the program promoted exploration by providing frequent updates on the status of the pandemic in terms of the epidemiology of the infection in various countries. Following the Engel biopsychosocial model of disease, the updates included information both on scientific developments related to the virology of COVID-19 and the societal and economic effects of the pandemic. Third, students were engaged in explaining by being divided into groups and tasked to design and present infographics about COVID-19, spanning topics such as epidemiology, microbiology, diagnosis, treatment, immunology, and the psychosocial/ economic impact of the COVID-19 pandemic ([Multimedia Appendix 2](#)). Next, the students were encouraged to elaborate by building on these topics and emergent knowledge by working in groups to develop novel research questions and lead research projects in collaboration with faculty and clinicians. Finally, the students were able to evaluate their knowledge via a postcourse questionnaire, as well as in the revision and review processes inherent in the publication experience. This model has been shown to be effective in enhancing student progress in science-related instruction [11].

Student Satisfaction and Program Usefulness

A total of 38 (81%) fourth-year medical students participated in this study, out of the 47 students who participated in the course. Overall, student satisfaction was high, with a mean rating of 3.9 (SD 0.94) on a Likert scale from 1 (low satisfaction) to 5 (high satisfaction). Overall, most students agreed that the course format and delivery were satisfactory (27/38, 71%), effective (28/38, 74%), and well-organized (31/38, 82%). In addition, 62% (23/37) of the students agreed that the distance learning component of the course was beneficial, while 27% (10/37) would have preferred a face-to-face version of the course. Almost half of the students (18/37, 49%) indicated that the web-based format stimulated interest in participating. [Figure 1](#) provides further details about the student satisfaction rates measured via the survey.

Figure 1. Survey responses: student satisfaction and program effectiveness.

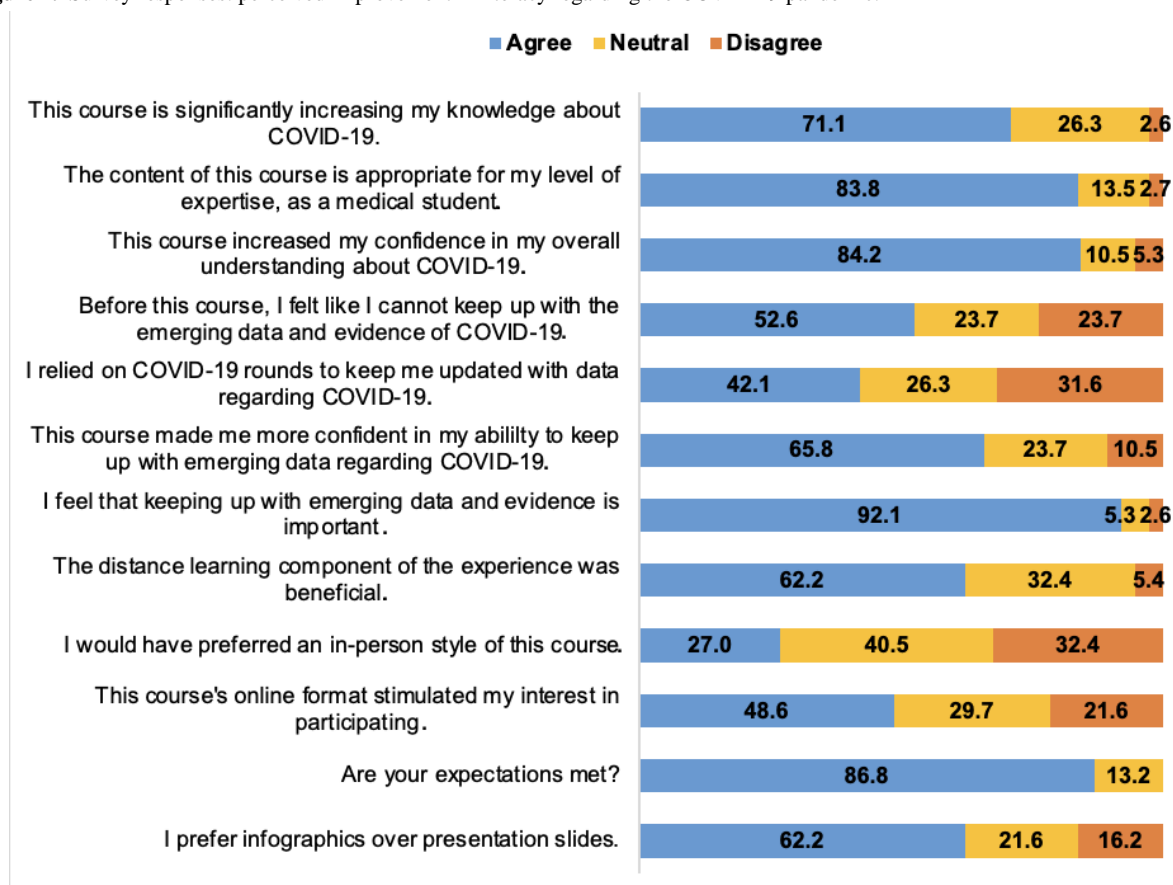

The preset objectives included providing weekly evidenced-based talks, enhancing understanding of the status and challenges of the pandemic, providing web-based clinical experiences with patients, and encouraging student-led research. The course was successful in meeting the preset objectives. Overall, 90% (34/38) of the students agreed that the course offered an evidence-based series of talks regarding different aspects of the COVID-19 pandemic. However, the value of the web-based clinical experience was not uniformly agreed upon. Only 63% (24/38) of students agreed that the course provided a satisfactory web-based clinical experience with patients in hospitals and COVID-19 wards. Further data regarding meeting preset objectives can be found in [Figure 1](#).

Perceived Improvement in Literacy About the COVID-19 Pandemic

We investigated students' improvement regarding the pandemic literacy or knowledge base. Our data indicate that the course increased most of the students' knowledge about COVID-19 (27/38, 72%) and was appropriate for the students' level of understanding (31/37, 84%). Importantly, the course increased the large majority (32/38, 84%) of the students' confidence in understanding COVID-19 data.

Additionally, 92% (35/38) of the students agreed that keeping up with emerging data is important. Despite this belief, more than half (20/38, 53%) of the students admitted to facing challenges with keeping up to date with emerging evidence regarding COVID-19 prior to the course. It is important to highlight the students' engagement with other information resources outside of this curriculum as well. Before the course, only 53% (20/38) of the students reported not being able to keep up with emerging data and evidence. Moreover, despite finding the course helpful, less than half (16/38, 42%) relied solely on the COVID-19 rounds to keep up to date.

Furthermore, the course enhanced students' confidence in teaching others about various aspects of COVID-19, such as local and international guidelines (28/38, 74%), immunology and vaccination development (26/38, 68%), and the psychosocial and economic impact of the pandemic (26/38, 68%). The course allowed 58% (22/38) of the students to feel confident in understanding statistics after COVID-19 rounds. Questions related to student literacy and the development of the infographics can be found in [Figure 2](#). These data show that students agreed that the course increased knowledge, expertise, knowledge, and confidence and met expectations.

Figure 2. Survey responses: perceived improvement in literacy regarding the COVID-19 pandemic.

Impact of Designing Infographics and Initiating Research

We sought to investigate the course's impact on student engagement through the process of creating infographics and initiating research projects. Overall, 74% (28/38) of the students had designed infographics before taking this course. Many students liked using infographics to present data (28/37, 76%) and appreciate that infographics are becoming more popular in the medical literature (28/37, 6%). Students

also felt that infographics are a valuable tool for presenting and summarizing information (32/37, 86%). In total, 62% (22/37) preferred infographics over presentation slides.

Furthermore, one of the long-term goals of the course was to promote student research. As illustrated in Table 1, during the course, 27 (57%) students developed and worked on 10 research projects. Most have been published in peer-reviewed journals to date and have contributed to the development of important student skills.

Expectations, Advantages, and Disadvantages of COVID-19 Rounds

At the end of the questionnaire, we included a component consisting of open-ended questions to provide students with the opportunity to express their thoughts and expand on the reasoning behind their choice of questionnaire options. These questions pertained to expectations of COVID-19 rounds; perceived advantages and disadvantages of the course; and advantages, disadvantages, and challenges of and feedback on designing infographics. The classification of students’ responses can be found in [Table 2](#).

As indicated in [Table 2](#), part of assessing the preset objectives included asking students about their expectations of the course and providing an opportunity for feedback in cases where their expectations were not met (5/38, 13%). In general, most respondents were expecting updates on the COVID-19 pandemic, spanning domains such as statistics, management, treatment, and research. Regarding unmet expectations, some students felt the course was “repetitive” and “more like a journal club.”

Most respondents agreed that an advantage of the course was providing regular updates on the status of the pandemic and being easily accessible over the internet ([Table 2](#)). The

disadvantages voiced pertained to the timing of the course in relation to exams/other courses, being didactic in nature, decreased interaction due to the course delivery format, and technical difficulties during patient rounds. Students expressed that the web-based nature of the course was disadvantageous in some ways due to decreased interaction and challenges with communication. Some students indicated that attending the talks could be time-consuming prior to exams or that the talks were occasionally “more didactic than true rounds.”

The perceived advantages and disadvantages of infographics were explored ([Table 2](#)). The stated advantages commonly revolved around the course’s simplicity, conciseness, and visual appeal ([Multimedia Appendix 2](#)). On the other hand, the common perceived disadvantages of infographics include a lack of detail, course information becoming outdated quickly, the time-consuming design, and the fact that it required design experience rather than traditional PowerPoint skills. Additionally, 1 student spoke about the disadvantage of the inability to incorporate multimedia into infographics.

The common challenges experienced by students include issues with teamwork over the internet, formatting, challenges with condensing information into small spaces, and meeting course deadlines.

Table 2. Classification of the students' responses.

Expectations of COVID-19 rounds	Occurrences of the theme, n (%)
Category	
Updates ^a	34 (89)
Scientific knowledge	1 (3)
Personal protective equipment	1 (3)
Management of COVID-19	1 (3)
Feedback for unmet expectations	
Information not useful	2 (5)

Advantages	
Updates	16 (42)
Accessibility	5 (13)
Social Distancing	2 (5)
Disadvantages	
Difficulty with web-based communication	4 (11)
Timing (scheduling issues, class schedules)	4 (11)
Less patient interaction	4 (11)
Technical difficulties	1 (3)
Didactic	1 (3)
Infographics: advantages, disadvantages, and challenges faced	
Advantages	
Concise and easy to understand	16 (42)
Visually appealing	8 (21)
Accessible	4 (11)
Teamwork	3 (8)
Disadvantages	
Lack of detail	7 (18)
Time-consuming to design	4 (11)
Require design experience	4 (11)
Condensed information is hard to understand	2 (5)
Quickly outdated	1 (3)
Difficult to present online	1 (3)
Inability to incorporate multimedia	1 (3)
Challenges	
Requires design experience	9 (24)
Lack of teamwork	6 (16)
Summarizing	5 (13)
Time management and meeting deadlines	5 (13)
Formatting	4 (11)
Literature search	2 (5)

Expectations of COVID-19 rounds	Occurrences of the theme, n (%)
Lack of objectives	1 (3)
Difficulty with web-based team communication	1 (3)

^aSome students indicated that they were expecting updates about management (n=6, 6%), statistics (n=5, 13%), research (n=2, 5%), local implications (n=1, 3%), and global implications (n=1, 3%).

Discussion

Principal Results

This inquiry-based learning approach to educating medical students about COVID-19 was successful in achieving high student satisfaction rates, educating students about the pandemic during lockdown, and promoting active student engagement in research. The format of this course resulted in high levels of student engagement in explaining through designing infographics and elaborating and evaluating by engaging in original research. In addition, students expressed appreciation for the rising importance of infographics in medical literature, but they also recognized the limitations of this format. The shortcomings of the course related to challenges with the lack of in-person teaching and actual clinical activities with COVID-19 patients. Overall, we hope that this initial experience can help bridge the literature gap regarding adaptive and inquiry-based educational strategies implemented amid the COVID-19 pandemic.

Due to the limitations of an almost universal lockdown, classroom teaching and clinical rotations in the hospital were limited to web-based instructional strategies. Similar to all medical schools worldwide, we adopted a new web-based teaching experience that had not been specifically described before the onset of the pandemic. We used known software and tools such as Microsoft Teams, in addition to videotaping physicians who were working on COVID-19 care wards, coupled with presenting emerging new data by field experts. Students were engaged using an inquiry approach that involved both explanation and exploration, with new emerging data involving the assignment of creating infographics to explain new information to other students, followed by exploration through new research ideas. We found similar challenges to what has been described [10], including challenges related to technological failures faced by both faculty clinicians and students during the web-based rounds on the COVID-19 wards and trying to maintain proper infection control measures while using video-calling technology. Additional challenges included engaging students in new forms of design and difficulties modifying these formats with continually changing data. We have previously documented the major challenges faced by the faculty during this time, specifically in dealing with uncertainties, unfamiliar web-based teaching and meeting programs, and blurring of work-life balance [8,10]. These findings informed subsequent web-based learning efforts at our institution.

Students expanded on their expectations, perceived advantages, and disadvantages of the course. Our results indicated that students appreciated regular updates on the pandemic due course's ease of access via the internet; however, they expressed

that some components of the course were more didactic in nature and that they experienced scheduling conflicts and technical difficulties with web-based ward rounds. The feedback indicated that more active engagement in learning rather than didactics was appreciated, as emphasized by the students' enthusiasm about infographic presentations and their widespread involvement in research. Overall, students appreciated the conciseness and visual appeal of the course, but they expressed difficulties related to the lack of detail, the design experience requirements, and the fact that this format may not be suitable for rapidly emerging data, which are prone to becoming outdated quickly.

The feedback from this experience shed light on potential improvements for the clinical distance learning climate at our institution. Going forward, we will acknowledge the importance of providing updates balanced with student engagement and participation to avoid didactic instructional styles. Moreover, we will focus on improving the technology used in wards to avoid any difficulties. Finally, we will implement the use of infographics for topics less prone to continuous changes and provide short tutorials on infographic design prior to student assignments.

Comparison With Prior Work

The learning challenges experienced with COVID-19 have been recently summarized. Systematic reviews have detailed the numerous distance learning strategies that medical schools developed during COVID-19, including technology-enhanced learning and technology-based clinical education, such as web-based rounds, bedside teaching, and clinic visits [7,27]. A recent systematic review of 51 publications related to remote learning in response to the COVID-19 pandemic described multiple remote learning strategies, including moving classrooms to synchronous activities with various web-based engagement techniques. They found that evaluations were generally positive regarding attitudes and increasing knowledge and skills [10].

In addition, the challenges faced by medical school faculty and educators in dealing with uncertainty, rapid decisions, and lack of experiential learning have been outlined [8]. Student attitudes included higher satisfaction rates with distance learning if they had prior experience with it and when instructors actively participated in their sessions using multimedia and active engagement [28]. They also appreciated the flexibility of web-based learning [29]. A student survey in the United Kingdom found that students greatly increased their online learning during COVID-19 with a perceived advantage of flexibility but struggled with family distractions and internet connectivity issues [29].

After our experience, several other academic centers published their experience specifically related to clinical online teaching.

Hofmann et al [30] reported a similar adaptational experience by implementing web-based rounds via Zoom [31]. In total, 92% of the students in that study strongly agreed that this experience improved their literacy about the pandemic, which is similar to our study's results. Overall, they had a favorable student response but faced similar challenges with audio and network issues.

Additionally, medical schools worldwide have reported on their experiences with web-based rounds spanning many subspecialty clerkships [32-34]. Muhammad et al [35] conducted a systematic review of 201 studies reporting on the effectiveness of web-based medical teaching during the COVID-19 pandemic. Overall, many studies reported positives of web-based teaching, including flexibility, convenience, engagement, effectiveness as an alternative to in-class teaching, and increased networking with worldwide specialists. In our study, students preferred the convenience of web-based learning and the ability to keep up with emerging data. Common disadvantages of web-based teaching observed by Mohammad et al [35] included the loss of face-to-face interaction and decreased engagement [36-41]. Sud et al [42] and Michael et al [43] postulate that the loss of direct student-teacher interaction could be a factor for decreased student engagement. Khamees et al [10] reported similar challenges, including a lack of hands-on learning and social interaction and frustrations with technology. These disadvantages are similar to those in our study, despite the overall course being rated as useful.

While many universities have had to redesign clinical curricula during the lockdown, our study aims to highlight a key cornerstone of future physicians rising through this pandemic and becoming actively engaged at multiple levels using an inquiry-based approach. A cornerstone of the "COVID-19 Rounds" course is its engagement of students in their learning process. This was accomplished by the inquiry-based format and active learning by generating infographics and engaging in student-led research projects with clinicians and faculty. Students were instructed to use infographics as the mode of presentation rather than traditional PowerPoint presentations. Most of our students were familiar with infographics and appreciated their aesthetically pleasing, concise nature and rising importance in medical literature. A frequently voiced opinion was the challenge of condensing the breadth of information into a summarized format, as well as the technical and design skills required to design them compared to the traditional presentation. From the British Medical Journal to the Journal of the American Medical Association, infographics have served as a concise, yet eye-catching way to visually present information. Infographics allow readers to receive a message more quickly and effectively than a paragraph with the same content [44,45].

Engaging students in the learning process involved giving them opportunities to design and lead original research with faculty members. The majority of students actively participated in a

total of 8 research projects, resulting in 6 abstract presentations at local scientific research conferences. To date, all 8 research projects have been published in peer-reviewed and indexed journals. This was facilitated by the engagement of senior clinician-researchers with these student-led projects. The students were able to leverage the cancellation of clinical placements and spend that time doing research. Studies on the impact of adapting to distance learning during clinical training should consider opportunities for new types of learning, such as those highlighted in this paper.

Additionally, MBRU adopted similar strategies to this course's models in their online teaching, including learning principles and the ability to motivate students to initiate research projects. This focus on research projects as an application has been applied to other courses in the College of Medicine at MBRU, including a 2-year longitudinal course on quality improvement and health systems.

Limitations

Our study has its limitations. First, the small sample size limits its generalizability. This could be mitigated by administering the course to more student years (1-6) or other medical schools. Second, technical challenges in course delivery due to confidentiality limited student interaction with patients and clinical education. This could be mitigated in the future by using a secure encrypted portal for student education to allow for more interaction with patients over the internet. Third, we did not have precourse data to compare pre- and postcourse knowledge improvement, resulting in a descriptive study. In the future, pre-versus postcourse literacy could be better calculated via *t* tests and regression models to help elucidate gaps in the course, as well as its effectiveness. However, the salient strengths of our study include that this was one of the first in the literature reporting on the implementation of a web-based learning platform with an inquiry-based focus on educating medical students about COVID-19. It also served as a platform for discussions and participation to gather high-quality evidence and engage in research presentations and publications. Our study provides insight into the advantages of providing students with a structured method for weekly updates on emerging evidence and their receptiveness to engagement and participation in learning.

Conclusions

Our inquiry-based and active learning approach with online technology via the "COVID-19 Rounds" course has helped foster lifelong learners in the age of the "infodemic." Our weekly web-based course, which provided medical students with updates about COVID-19, increased pandemic knowledge and literacy and encouraged peer-to-peer education and engagement in research. However, shortcomings of the course related to the lack of in-person teaching and clinical opportunities were also highlighted.

Acknowledgments

We gratefully acknowledge the students of the Mohammed Bin Rashid University of Medicine and Health Sciences (MBRU) for their participation in this study.

Abstract

Background: Supporting patients to live well by optimizing behavior is a core tenet of primary health care. General practitioners and practice nurses experience barriers in providing behavior change interventions to patients for lifestyle behaviors, including low self-efficacy in their ability to enact change. Web-based learning technologies are readily available for general practitioners and practice nurses; however, opportunities to upskill in behavior change are still limited. Understanding what influences general practitioners' and practice nurses' adoption of web-based learning is crucial to enhancing the quality and impact of behavior change interventions in primary health care.

Objective: This study aimed to explore general practitioners' and practice nurses' perceptions regarding web-based learning to support patients with behavior change.

Methods: A qualitative, cross-sectional design was used involving web-based, semistructured interviews with general practitioners and practice nurses in Queensland, Australia. The interviews were recorded and transcribed using the built-in Microsoft Teams transcription software. Inductive coding was used to generate codes from the interview data for thematic analysis.

Results: In total, there were 11 participants in this study, including general practitioners (n=4) and practice nurses (n=7). Three themes emerged from the data analysis: (1) reflecting on the provider of the Healthy Lifestyles suite; (2) valuing the web-based learning content and presentation; and (3) experiencing barriers and facilitators to using the Healthy Lifestyles suite.

Conclusions: Provider reputation, awareness of availability, resources, content quality, usability, cost, and time influence adoption of web-based learning. Perceived quality is associated with culturally tailored information, resources, a balance of information and interactivity, plain language, user-friendly navigation, appealing visual presentation, communication examples, and simple models. Free web-based learning that features progress saving and module lengths of less than 2 hours alleviate perceived time and cost barriers. Learning providers may benefit by including these features in their future behavior change web-based learning for general practitioners and practice nurses.

Introduction

Web-based technologies are a rapidly growing tool for learning in continuing professional development. Continued learning improves the knowledge, skills, and performance of general practitioners (GPs) and practice nurses (PNs), enhancing clinical competency and quality of care [1]. Opportunities for continued learning have expanded considerably in recent years, with a 42% increase in clinicians (including GPs) opting for web-based offerings in 2018 (prepandemic) [2]. Web-based learning is regarded as effective as traditional modalities for improving professional competence and skill development [3,4]. Unfortunately, GPs and PNs experience many barriers to web-based learning [5-11]. Given the rise of more technologically inclined clinicians and the effects of the pandemic, web-based modalities can be predicted to increase and should be given further consideration by learning providers.

Behavior change is a complex practice area in primary health care and comprises any activities used by health professionals to elicit changes in patient behaviors [12]. While GPs and PNs are encouraged through practice guidance to advocate for healthy lifestyles [13], only 8% of all interactions involve behavior change [14]. Behavior change interventions in Australian primary health care are insufficient in frequency [14], as GPs and PNs experience many barriers to providing behavior change interventions to their patients, including inadequate skills and knowledge [15-18], lack of time [15-19], and insufficient resources [5,15,18,20]. While learning programs for behavior change have been shown to reduce these barriers and improve behavior change skills [21,22], GPs and PNs lack the opportunities to upskill in areas such as behavior change [15]. Thus, GPs and PNs need support to develop the skills required to facilitate behavior change in partnership with their patients, which may assist in addressing the trajectory of chronic disease.

Despite the rise of web-based offerings, no studies have exclusively explored the views of GPs and PNs regarding web-based learning to support patients with behavior change. Particularly with the increasing prevalence of chronic disease [23], it is vital to understand the factors influencing Australian GPs' and PNs' selection of web-based learning to ensure the delivery of impactful behavior change interventions. Queensland Health recognizes the importance of primary health care and has developed a web-based Healthy Lifestyles suite, hosted by Insight, to facilitate learning and assist health professionals in motivating patients to make healthier choices [24]. However, the acceptability and feasibility of the Healthy Lifestyles suite has yet to be established. The aim of this study was to explore GPs' and PNs' perceptions regarding web-based learning to support patients in improving their lifestyle behaviors through behavior change. This information is essential to inform future web-based learning design and improve the adoption and implementation of behavior change interventions in primary health care.

Methods

Overview and Aim

A descriptive, cross-sectional design was used involving semistructured interviews, as contextualized in qualitative research [25]. This study aimed to explore GPs' and PNs' perceptions regarding web-based learning to support patients with behavior change. The study comprised two objectives: (1) to explore GPs' and PNs' perceived needs for web-based learning for behavior change related to lifestyle behaviors; and (2) to explore GPs' and PNs' perceptions of the acceptability and feasibility of the Healthy Lifestyles suite.

The Healthy Lifestyles suite is a web-based learning toolkit for providing brief behavior change interventions and includes an introductory module and 8 topic modules covering nutrition and physical activity, smoking, healthy pregnancy, oral health and alcohol and other drugs [24].

Interview Protocol Development and Pilot Testing

The interview protocol (Multimedia Appendix 1) was developed based on research conducted in the literature review and questions put forward by the research team [26]. The questions were designed to elicit responses pertaining to the study's aims and objectives. All questions were reviewed by the research team. Three pilot interviews were conducted to determine the validity and effectiveness of the interview questions [26].

Recruitment

Eligible participants were GPs and PNs employed within Queensland primary health care settings. For context, approximately 7500 GPs and approximately 3000 PNs were registered in Queensland during 2022 [27-29]. Purposive and snowball sampling methods were used to recruit prospective participants. The study was advertised through (1) a practice-based research network, (2) GP and PN social media groups, (3) primary health networks (PHN) newsletters, and (4) the Royal Australian College of General Practitioners (RACGP) research notice board. Participants were asked to contact the lead researcher via email with a preferred time and day for interviews. The lead researcher responded to the participants with all required information, hyperlinks to the Microsoft Teams website and the Healthy Lifestyles suite [24,30], and confirmation of interview date and time. The lead researcher scheduled the interviews and sent invitations to the participants on Microsoft Teams [30].

Data Collection

Data were collected through semistructured interviews via Microsoft Teams [26,30]. Participants were asked to respond to questions from the interview protocol and use the "think aloud" method while completing the Brief Interventions: Nutrition and Physical Activity web-based module of the Healthy Lifestyles suite [31]. The think-aloud method was used to capture perceptions outside of questions included in the interview protocol [31]. The interviews were audio and video recorded.

All interviews were transcribed using the Microsoft Teams built-in transcription software [30,32]. The transcripts were then

compared against the recorded interviews, with any identified errors corrected. The lead researcher emailed the transcript to each participant for verification of responses.

Data Analysis

The verified transcripts were analyzed according to the Braun and Clark [33] 6-step framework for thematic analysis: (1) familiarity with the data, (2) generating initial codes, (3) searching for themes, (4) reviewing themes, (5) defining and naming themes, and (6) producing the report. An inductive approach was used, whereby themes were generated from the interview data [33]. All data analysis was completed by hand using Microsoft Excel. Data saturation was achieved after 9 interviews when no new themes could be derived from the transcriptional data [34]. Two additional interviews were performed to ensure thorough exploration and data quality [35].

Triangulation

Researcher triangulation was used to verify the generated themes and subthemes [36]. Correspondence between the lead researcher and the research team continued until consensus was achieved upon themes and subthemes.

Ethics Approval

Study approval was granted by the Griffith University Human Research Ethics Committee (2022/120) before the

commencement of data collection and was conducted in accordance with the Australian National Statement on Ethical Conduct in Human Research. Prospective participants were offered AU \$100 (approximately US \$70) gift cards as reimbursement for their time. All participants were provided with an overview of the interview process, information sheet, and consent form via email correspondence prior to interview scheduling. Additionally, at the beginning of each interview, a verbal overview of the study was provided, and participant consent for the interview and analysis of recorded materials was obtained. Each recorded transcript was deidentified by assigning an identification number to ensure participant confidentiality. All interview recordings were deleted once transcript accuracy was established.

Results

Overview of Participants

In total, 11 participants completed a semistructured interview. The demographic characteristics of participants are described in Table 1. The sample predominantly comprised women (n=10). Of the 11 participants, 7 were employed as PNs and 4 as GPs. Their practice experience ranged from 2 to 35 years, with a mean of 15 years.

Table 1. Demographic characteristics of participants (n=11).

Characteristic	Participants, n
Gender	
Male	1
Female	10
Other	0
Occupation	
Practice nurse	7
General practitioner	4
Years in practice	
<5	2
5-9	3
10-14	3
>30	3

Overall Themes

Overview of Themes

Three themes were identified from the data: (1) reflecting on the provider of the Healthy Lifestyles suite; (2) valuing the web-based learning content and presentation; and (3) experiencing barriers and facilitators to using the Healthy Lifestyles suite.

Theme 1: Reflecting on the Provider of the Healthy Lifestyles Suite

Many participants perceived Queensland Health as a reliable source of accurate information. Some participants appeared to

trust the web-based module, given that it was created by a government institution.

I have a baseline sense of trust, given that this is an official module from Queensland Health. You know the information is correct. [P05, GP]

Notably, 1 highly experienced GP voiced a contrasting view regarding Queensland Health’s reputation and the trust placed in the learning material.

Anything to do with Queensland Health sort of turns me off. I have...[a] little bit of a lack of trust with anything to do with Queensland Health.... I did

wonder about what the motivation was for Queensland Health to have these modules. [P10, GP]

A few PNs assumed there was an access barrier to web-based learning opportunities provided by Queensland Health. Although the Healthy Lifestyles suite is publicly available, some participants believed that they needed to be a staff member to access the learning materials, which prevented them from attempting to access learning opportunities through Queensland Health. As GPs and PNs must complete learning each year, this steered participants to pursue learning opportunities from other sources.

No, not unless you're a member of Queensland Health...once you're sort of locked out of that Queensland Health system...you sort of have to hunt and gather for your own CPD over multiple different, smaller websites. [P07, PN]

Some participants expressed being aware of or already having an account with the Insight web-based learning platform. However, no GPs or PNs in the study seemed to be aware that the Healthy Lifestyles suite was available, despite being readily accessible.

I know I already had an account.... No, I was not [aware of the Healthy Lifestyles suite]. [P02, PN]

GPs and PNs suggested strategies they thought would improve awareness of the Healthy Lifestyles suite while thinking aloud. Many participants recommended advertising through the PHNs, the Australian Health Practitioner Regulation Agency, the RACGP, and other professional organizations, which appeared well known for promoting learning opportunities. Other suggestions included advertising through social media and primary health care practices.

Whether it's [advertising] through the PHNs, they would be great in terms of putting these [web-based modules] up. The RACGP, having it [the Healthy Lifestyles suite] on their platform as well because I think a lot of people do their CPD through those sort of things as well. [P06, GP]

I do get a lot of emails weekly from the PHNs and they'll often have newsletters and updates.... A bulk email to practices.... Or perhaps something on Facebook? [P07, PN]

Theme 2: Valuing the Web-Based Learning Content and Presentation

Participants highly valued information regarding Aboriginal and Torres Strait Islander populations. While thinking aloud, GPs and PNs drew upon their moral perspectives, as emphasis was placed on the importance of understanding diverse cultures and priority populations, which is relevant to culturally safe practice.

I didn't know though, there was an Aboriginal Torres Strait Islander version of that [Australian Guide to Healthy Eating], which I really liked, so that was some new information for me. [P06, GP]

I do find this thing about cultural identity interesting like, I think that is a gap missing sometimes. [P09, PN]

The participants seemed to appreciate the resources such as pamphlets, brochures, and hyperlinks to reputable websites available within the web-based module, particularly for patient education purposes. Participants expressed that resources are generally challenging to find but are considered a powerful adjunct to consultations by facilitating conversations with patients.

It's [the web-based module] got lots of resources that I can use to talk with my clients about for sure. Not just clients, but family and friends as well. [P02, PN]

The amount of resources [is good value].... I find with a lot of things, when you're informing patients, it's hard to find resources. [P04, PN]

One GP expressed while thinking aloud, the importance of Queensland-based resources. State-based resources were thought to increase GPs' awareness of local programs available, which would be more relatable to their patients.

One of the best things about this whole resource is it's all Queensland relatable. So you know that these things are within the state. [P06, GP]

When asked about the tone of language within the web-based module, words such as *easy*, *basic* and *everyday English* were used. Participants seemed to believe that plain language was more engaging and applicable to many different learning styles. Plain language was described as more transferable across professions, particularly given the broad range of health professions requiring learning.

You're better off using plain language that people can relate to. Keeps people's attention more, but it's still got the really healthy balance of keeping you on the edge of kind of always learning a bit more. [P01, PN]

[The information is] easy to read...it's quite broad in that it can reach many health care individuals from various backgrounds so.... I think it appeals to many different learning styles. [P08, PN]

One participant expanded on language further, recalling a previous web-based learning experience containing many acronyms.

I did one [web-based learning] that had a key for all their acronyms in a separate appendix right down the bottom, but all throughout they were using all sorts of different acronyms. It just didn't read well and it was confusing. [P07, PN]

Web-based learning that consisted of predominantly text, interactive activities, or long videos was described as uninteresting and appeared to reduce GPs' and PNs' engagement. In contrast, a balance of information and interactivity seemed to increase engagement with the web-based module and facilitate greater learning. Many participants voiced their opinions that the web-based module contained an acceptable combination of information and interactivity that

was conducive to learning, which is crucial given the nature of health professions.

I just like how it breaks it [the web-based module] up.... I don't mind reading lots of text, but I found it just keeps my interest going for a bit longer and for me it's almost like a little bit of a break. Something different to sort of switch my brain to. [P06, GP]

It's [the web-based module] not too thick and fast, and it's not just a boring, barren, stream of words without anything in there to break them up. I think it's a pretty good mix. [P07, PN]

Responses implied that information accuracy is crucial for learning, which is pertinent to evidence-based practice. Many GPs and PNs perceived the use of statistics and references as an indicator of information accuracy. Additionally, some participants appeared to use their prior knowledge or experiences to determine the accuracy of the information.

I've just finished a public health masters, so all this [information] is pretty fresh, but it's always nice to be reminded of it all. [P02, PN]

Well, I guess it's [the information] based on some sort of statistics and research. I believe it should be accurate. [P05, GP]

I feel as if the content is very in tune with what sort of conversations actually happen behind closed doors in a treatment room. [P08, PN]

When queried about the quality of the web-based module, participants referred to the use of pictures, colors, fonts, headers, and spacing. Referencing throughout the web-based module also seemed to increase the participants' perception of quality.

I think its [the web-based module] of really good quality. A lot of good links...the color and presentation and information provided. [P04, PN]

It's [the web-based module] got nice big font [emphasis on big font], lots of headers, good spacing between each line. Lots of pictures. [P07, PN]

Spacing and font size in the web-based module was perceived to increase usability, particularly for those with visual impairments or who spend substantial time on computers.

It's [the web-based module] pretty well spaced out. Good for people with any visual impairments or difficulty with glasses or spending a lot of time on the computer. [P01, PN]

Prior experience with technology appeared to increase the ability to navigate the web-based module with ease, particularly with the burgeoning use of telehealth since the start of the COVID-19 pandemic. Participants noted that including a side menu, scrolling, and clicking were easy to use, increasing the web-based module's usability. Some participants stated that having a similar format to the Queensland Health COVID-19 web-based module increased familiarity and efficiency in navigating the Healthy Lifestyles web-based module.

All the nurses are familiar with the COVID vaccination training module that we've all had to do

to give out COVID vaccines. It's [the web-based module] very much the same format. [P03, PN]

To me it [the web-based module] feels very intuitive to know, click, read, click, read. Like it does feel intuitive to scroll down, and then there's the continue button. Alright, I've reached the end of that bit. Move on to the next bit. [P09, PN]

PNs seemed to highly value the learning within the web-based module. Both PNs and some GPs believed that the learning would assist them in performing better patient assessments and reminded them of the importance of discussions around healthy lifestyle behaviors, which is vital given the prevalence of chronic disease.

It [the web-based module] raises for me the importance of the discussions around nutrition and physical activity and to not skim over them but spend some time doing that. [P09, PN]

Other GPs perceived they already knew all the information presented in the web-based module and that it was not pitched appropriately for their profession. Two GPs felt that the web-based module would be more suitable for PNs and GP registrars due to the nature of the content.

All doctors more or less know all of that [information in the web-based module], so it would be interesting more for doctors in training, graduates, maybe. [P05, GP]

It's [the web-based module] pitched low for a GP really or pitched inappropriately for a GP. It's not really understanding what happens in a consultation...perhaps for the practice nurses. [P10, GP]

While thinking aloud, some participants said they experienced difficulties with wording questions related to lifestyle behaviors, highlighting the complexity of behavior change interventions. Participants perceived the simplified 5A's model and examples of engaging in behavior change discussions would facilitate difficult conversations with their patients, particularly in initiating behavior change interventions.

I really like the questions to ask part here because I think one of the things I find challenging sometimes is how to word certain questions.... I actually noted a couple down so that way I can just remind myself to use them in my consults as a conversation starter. [P06, GP]

It's good that they give you a three-step model to help you apply the brief interventions instead of giving a whole bunch of information and no guidance for how to administer it. [P07, PN]

Many participants expressed that the web-based module allowed them to upskill and reinforce their prior knowledge, which is essential to all health care professions.

The intensities of exercise and the subjective measures example.... I really like that because I get patients all the time who ask me OK, the guidelines say do moderately intense exercise.... I think we kind of

always say, vigorous or moderately intensive and patients, the lay person doesn't really know what that means...this sort of gives you a really good example of what that's trying to say. [P06, GP]

I think this is important and updating my clinical information, things like the waist measurement.... I thought it was 90 centimeters for women but it's 80. [P09, PN]

I suppose it's [the web-based module] going to encourage me at actually to do waist circumferences a bit more. [P10, GP]

Theme 3: Experiencing Barriers and Facilitators to Using the Healthy Lifestyles Suite

Participants appeared surprised and impressed that the Healthy Lifestyles suite was free of charge, given their recall that learning opportunities were usually expensive. The importance of free learning was highly emphasized by many participants and would directly alleviate the cost barrier.

Having a free service is pretty huge because most people have gone from uni [sic] to then having a job and they don't really want to go to then spending more money out of their pocket on education. So I think free education is really important. [P01, PN]

Participants voiced that the progress saving functionality offered them the opportunity to step away from the web-based module and return to it at their convenience, which appeared to alleviate time constraints. Progress saving reportedly provides flexibility, allowing for learning to be completed within shorter available time blocks during the working day.

The progress being saved, that's good because I can jump out and come back to it [the web-based module], especially whilst I'm working...it's good and not frustrating that you have to come back every time to the beginning. It's nice that it's saved. [P02, PN]

GPs and PNs had opposing views regarding the time frame to complete the web-based module. Some participants believed they could complete the web-based module within the estimated time frame of 60 minutes. In contrast, others stated the web-based module would take longer than an hour but were comfortable spending more time on it due to its simplicity and richness of information. Participants expressed that lengthier web-based modules were overwhelming and brought up the perceived issue of time constraints associated with primary health care.

I like the module length for this one. It's not too long, not too short, as in there are not too many components to complete to be able to finish it. I think sometimes when you've got more than 10 components for each part, you feel it can be a bit overwhelming. [P06, GP]

I don't know that I would complete it [the web-based module] in an hour only because there's so much good information in it that I just want to take my time and read and digest and sort of consider how I might use that in a clinical setting. [P08, PN]

Discussion

Principal Findings

This study explored GPs' and PNs' perceptions regarding web-based learning to support patients with behavior change. Qualitative inquiry explored the factors influencing GPs' and PNs' participation in web-based learning, including provider reputation, awareness of availability, resources, content quality, usability, cost, and time. Perceptions of quality web-based learning appears to be associated with culturally tailored information, resources, a balance of information and interactivity, plain language, user-friendly navigation, appealing visual presentation, communication examples, and simple models. Whereas free web-based learning that features progress saving and module lengths of less than 2 hours alleviate perceived cost and time barriers. These findings were generally consistent across the participants, except for some GPs' comments.

Learning providers' reputation and awareness of availability appear to impact GPs' and PNs' adoption of web-based learning. Several studies indicate GPs' and PNs' perceive that professional organizations have a lower reputation for learning [5,10]. Therefore, provider reputation may have a more significant impact on GPs' and PNs' perceptions than initially expected. Two studies found less than a third of GPs and PNs perceived awareness of learning opportunities as a barrier [2,5]. The Healthy Lifestyles suite is not currently advertised to GPs and PNs, which may explain the participants' lack of awareness. GPs and PNs discover more learning opportunities through professional associations (58.6%) than health care organizations (33%) [5], which coincides with participants' advertising suggestions. Advertising may play a crucial role in increasing GPs' and PNs' awareness of web-based learning opportunities. Queensland Health may benefit by advertising through the suggested professional organizations to communicate the availability of the Healthy Lifestyles suite to GPs and PNs.

Culturally tailored information and resources seemed to be appreciated by participants and increased perceptions of quality. Including Aboriginal and Torres Strait Islander information was described as beneficial to practice, highlighting the need to support learning for cultural competence in primary health care. Previous studies indicate that clinicians, including GPs and GP registrars value, but lack learning opportunities around Aboriginal and Torres Strait Islander populations [37,38], which is congruent with this study. However, these studies were not specific to web-based learning or behavior change. Many participants emphasized the resources in the web-based learning to facilitate behavior change interventions. Similarly, GPs' work-related internet usage was higher for obtaining information for patients (93.5%), compared to learning (80.4%) [6]. This suggests information that is accurate, suitable, and culturally appropriate may be challenging to find, which was mentioned by a participant in this study. The Healthy Lifestyles suite contains Aboriginal and Torres Strait Islander information and resources, which may help to address the barrier of insufficient resources [5,15,18,20].

Perceptions of quality content in web-based learning appear to be associated with using plain language, a balance of information and interactivity and information accuracy. A study of GPs (n=12) evaluating a web-based module on vitamin D found that most participants strongly agreed that the plain language was easy to understand [39], which is reflective of this study. Many participants reported that the web-based module contained an appropriate balance of information and interactivity to facilitate learning. Several studies demonstrated greater satisfaction and comprehension from incorporating interactive elements in learning [11,40]. Another study indicated that GPs and PNs desire more interactivity and visual aids [5]. These studies did not examine web-based learning exclusively. The participants perceived the presented information as accurate, which appears to be related to statistics, references, prior knowledge, and experience. Australian GP registrars value referencing in web-based learning [41], which is reflective of this study and evidence-based practice. Furthermore, nurses use their knowledge and experience when evaluating information relevance and trustworthiness in web-based learning [42]. This is congruent with participant statements, suggesting that GPs and PNs critically evaluate information in learning. No data could be found for GPs' and PNs' perceptions of information accuracy relative to statistics. Therefore, plain language, the proportion of information and interactivity, and information accuracy may affect GPs' and PNs' perceptions of quality and engagement in web-based learning. The Healthy Lifestyles suite uses plain language, references, and reportedly has an acceptable balance of information and interactivity.

Visual presentation and usability were also reported indicators of quality web-based learning. Headers, fonts, spacing, colors, and pictures appeared to influence the perception of quality and facilitate engagement with the web-based module. Previous research indicates that visual presentation influences nurses' perceived usefulness, ease of use, and enjoyment of web-based learning, which impacts intention to use [7]. These preferences are subjective and may be influenced on an individual level. Participants perceived the user-friendly navigation as a facilitator of web-based learning. A feasibility study of a web-based module with similar navigation to the Healthy Lifestyles suite was considered user-friendly by GPs [39]. A good structure and explicit instructions increase perceived functionality, facilitating more effective content navigation, producing a more enjoyable experience [7]. The Healthy Lifestyles suite appears to have an acceptable visual presentation and user-friendly navigation.

Many participants believed that the web-based module allowed them to upskill and reinforce their prior knowledge. A systematic review found that web-based learning modalities improved nurses' knowledge, skills, attitudes, and self-efficacy, leading to improved performance [43]. These results are comparable with this study but are not based on web-based learning for behavior change. Many participants perceived that the web-based module's communication examples and simple model facilitated their learning for behavior change interventions. Similarly, a behavior change learning program using the 5A's model and motivational interviewing significantly increased GPs' and PNs' behavior change skill use [22]. Statistical analysis demonstrated improvements from baseline

to clinical practice [22]. Qualitative exploration found a reduction in perceived barriers to behavior change interventions, including time constraints, patient resistance, and improved clinician-patient relationships [21]. Furthermore, web-based learning containing motivational interviewing examples improved nurses' (n=31) perceived skill and self-reported skill use [4]. The Healthy Lifestyles contains communication examples and a simple model, which may help to facilitate professional knowledge and skill development for delivering behavior change interventions to patients.

Factors including cost and time were emphasized by participants as impacting learning. GPs and PNs want cost-effective learning options [20], but report many as expensive [9]. Similarly, participants in this study expressed cost as a significant barrier to learning. Perceived time constraints seemed to impact GPs' and PNs' ability to complete learning [8]. GPs and PNs want greater availability, backtracking, and to learn at their own pace [5], which is congruent with this study. The progress saving feature was reported to alleviate time constraints and facilitate web-based learning, particularly during work hours. Participants reported opposing views regarding their ability to complete the web-based module within the estimated time frame. A study of a vitamin D web-based module reported an average completion time of 124 minutes by GPs [39]. Feedback from participants (n=12) indicated that most (n=10) perceived the completion time as reasonable [39]. In contrast, web-based modules that required 6 hours to complete were too lengthy, even with progress saving [44]. The Healthy Lifestyles suite is free of charge, uses the progress saving feature and estimates an hour to complete, thereby appearing to be acceptable and feasible by participants.

Recommendations for Future Research

Further research should be conducted to increase understanding of the effects of culturally tailored information, plain language, information accuracy, and communication examples for web-based learning. This study would benefit from further analysis to compare the cost and benefits to Queensland Health and the broader health system through GPs' and PNs' use of the Healthy Lifestyles suite, including changes to practice and patient health outcomes.

Limitations

All interviews were conducted by a single researcher, which produced consistency in interviewing but increased the potential for researcher bias. The development of the interview protocol and 3 pilot interviews were done to reduce bias and reinforce the research methods. The overwhelming majority of the participants were female. While this was anticipated for PNs, it was not for GPs. Male GPs and PNs were underrepresented in the study, thereby possibly affecting the generalizability of the results. The lead researcher was unable to observe some participants using the web-based module due to an inability to share their screens. This impacted the researcher's ability to view participants' interactions with the web-based module and the timing of questions.

Conclusions

This study highlights the factors and features influencing GPs' and PNs' adoption of web-based learning to support patients with behavior change. Influential factors include provider reputation, awareness of availability, resources, content quality, usability, cost, and time. GPs and PNs desire quality web-based learning that contains culturally tailored information, resources, a balance of interactivity and information, plain language,

user-friendly navigation, appealing visual presentation, communication examples, and simple models. Free web-based learning that features progress saving and module lengths of less than 2 hours alleviate perceived cost and time barriers. The Healthy Lifestyles suite contains many of these features and appears highly acceptable and feasible by participants. While further research is required, learning providers may benefit by including these features in their future behavior change web-based learning for GPs and PNs.

Abstract

Background: Graduate students in medical fields must learn about epidemiology and data analysis to conduct their research. R is a software environment used to develop and run packages for statistical analysis; it can be challenging for students to learn because of compatibility with their computers and problems with package installations. Jupyter Notebook was used to run R, which enhanced the graduate students' ability to learn epidemiological data analysis by providing an interactive and collaborative environment that allows for more efficient and effective learning.

Objective: This study collected class reflections from students and their lecturer in the class "Longitudinal Data Analysis Using R," identified problems that occurred, and illustrated how Jupyter Notebook can solve those problems.

Methods: The researcher analyzed issues encountered in the previous class and devised solutions using Jupyter Notebook. These solutions were then implemented and applied to a new group of students. Reflections from the students were regularly collected and documented in an electronic form. The comments were then thematically analyzed and compared to those of the prior cohort.

Results: Improvements that were identified included the ease of using Jupyter R for data analysis without needing to install packages, increased student questioning due to curiosity, and students having the ability to immediately use all code functions. After using Jupyter Notebook, the lecturer could stimulate interest more effectively and challenge students. Furthermore, they highlighted that students responded to questions. The student feedback shows that learning R with Jupyter Notebook was effective in stimulating their interest. Based on the feedback received, it can be inferred that using Jupyter Notebook to learn R is an effective approach for equipping students with an all-encompassing comprehension of longitudinal data analysis.

Conclusions: The use of Jupyter Notebook can improve graduate students' learning experience for epidemiological data analysis by providing an interactive and collaborative environment that is not affected by compatibility issues with different operating systems and computers.

KEYWORDS

learning; Jupyter; R; epidemiology; data analysis; medical education; graduate student; longitudinal data analysis; graduate education; implementation

Introduction

All graduate students in medical fields must eventually learn about epidemiology. Graduate students also study essential

subjects, such as research methodology and data analysis, to conduct and complete the research projects that are part of their degree requirements [1]. Studying R in an epidemiology course can help students develop important skills for data analysis,

reproducibility, and collaboration, which are essential for conducting rigorous and impactful research in their field [2]. There are collections of functions that use R, known as R packages, which enhance the ability to conduct data analysis in diverse fields, such as medicine [3]. However, R packages may not be compatible with all computers or operating systems (OSs); this is often evident in the classroom environment [4].

R is a programming language-based software environment that beginners learn by studying numerous examples of command usage [5]. Teaching advanced R analysis within scheduled lecture times is not possible if compatibility issues prevent students from following along with their instructors [4]. These compatibility issues may emerge from discrepancies among various versions of R, its packages, and the OS that the student is using. These issues can lead to errors, unpredictable program behavior, or challenges in code maintenance. To minimize compatibility problems during the practicum, it is crucial that the instructor and all students use the same version of R and the packages [4]. This process must also be executed differently for Windows and Mac OSs, and there may be a diverse use of OSs among the students, including different versions of the two OSs [6]. Students may also have trouble installing packages, which requires time to fix [4]. Owing to the aforementioned difficulties, the students may be less enthusiastic about learning R [1].

Jupyter Notebook is an integrated development environment for R and Python that can function either on- or offline and allows for the blending of narrative text, mathematics, and executable code [7]. Jupyter Notebook is an open-source platform that provides an excellent learning environment for students and a better graphics interface than the original R platform [8]. Jupyter Notebook can improve the ability of graduate students in medical fields to learn epidemiological data analysis by providing an interactive and collaborative environment that allows for more efficient and effective learning [9]. By using Jupyter Notebook, students can perform interactive data analysis in R through integrated step-by-step instruction that allows them to learn data analysis easily. It also allows students to document their data analysis steps in a clear and reproducible way [10]. This can be especially important for assignments, as it allows others to follow along and understand their analysis process. Using Jupyter Notebook online can also facilitate collaboration between students and their instructors. Instructors can create and share Jupyter Notebook instances with students, and students can share their work with friends for peer review and feedback [9]. Hence, instructors can flexibly use an online Jupyter server to create interactive tutorials, assignments, and quizzes.

In our classroom, teaching R in the original version for longitudinal data analysis has often been delayed due to compatibility problems, leading to learning issues. The students were disappointed in their learning experience as computing errors and crashes during package installation prevented them from following the instructions. In this study, we collected class reflections from the students, then determined possible solutions using Jupyter Notebook. Jupyter Notebook was implemented in our classroom for the next cohort of students. This study also

compared the satisfaction of the students in the original R class with the satisfaction of the students who used Jupyter Notebook.

Methods

Study Design

This study used action research to conduct a thematic summary of issues that were raised by the lecturer and students in the class. Action research is a form of systematic inquiry that involves educators engaging in a cyclical process of problem-solving about their practices. It is often used to improve teaching by identifying and addressing specific issues or challenges within a specific educational setting [11]. In this approach, the teacher is both the researcher and the participant, and the ultimate goal is to improve the teacher's own practice and their students' learning experiences. The original R version for longitudinal data analysis was used to accomplish this task. Subsequently, a detailed illustration of the solutions to the problems created through teaching the original version of R was presented using Jupyter Notebook. The solutions were implemented with a new cohort of students, and the students' average satisfaction scores were compared with those of the previous cohort to validate the solutions' effectiveness. This analysis identified areas for potential improvement, which can be useful in enhancing the sustainability of this approach.

Setting and Data Source

This study was based on the longitudinal data analysis class using the tidyverse package [12]. All students had background knowledge in using Basic R and the epiDisplay package [13]. The class instruction and learning materials were shared through a circulated email system. The Department of Epidemiology, Faculty of Medicine, Prince of Songkla University (PSU) routinely collected satisfaction information from students using a web-based questionnaire (shown in [Multimedia Appendix 1](#)). The questionnaire used a five-point Likert scale and was distributed to students after class. It assessed satisfaction across five dimensions: appropriate duration, media suitability, communication skills, discussion encouragement, and critical thinking promotion. These dimensions evaluate various aspects of course satisfaction: duration pertains to time allocation for topics; media suitability measures the effectiveness of instructional materials; communication skills rate the instructor's clarity, organization, and engagement; discussion encouragement gauges the fostering of interaction and dialogue; and critical thinking promotion examines the support for in-depth analysis and problem-solving. Higher scores in each dimension signify a more satisfactory learning experience for students.

The questionnaire was created for internal use in an arbitrary manner due to the limited number of students per annum. Consequently, no reliability study was undertaken. Routine requests were made to the students to complete the questionnaire and include their reflections on a web-based sheet after class. All data reported by the students were anonymously recorded in a secured database. This mitigated the possibility of social desirability.

Jupyter Server Setup

In accordance with the JupyterHub guidelines [14], we established a self-hosted Jupyter server on a dedicated machine (US \$8700) procured from the Division of Digital Innovation and Data Analytics (DIDA), Faculty of Medicine, at PSU. The server is equipped with a 64-core CPU and 256 GB of RAM. For the default configuration, each student was allocated a server with 1 CPU core and 500 MB of RAM. This allocation sufficed for storing their notebook and any requisite data files for the course. However, it should be noted that individual access settings can be adjusted within the server's capacity constraints.

To initiate the server, we created a virtual machine on the DIDA server and preinstalled all necessary packages. The cost of operating this instance amounted to approximately US \$20 per month, as per the university's established rates. The management of a JupyterHub server for users necessitated that the authentication be implemented via the PSU passport service, which is provided by the Computer Center of PSU, and that resources be allocated for each user. This ensured that every student had access to essential resources without overwhelming the server's capacity.

Participants

With the participation of students and author PK as the teacher, the classroom action research was a collaborative learning method that changed specific actions. Participants in this study included PK and all graduate students in medical fields who were taking the longitudinal data analysis class run by PK. All students had already passed a basic epidemiology exam, so it could be inferred that they possessed a foundational understanding of epidemiological concepts and were familiar with relevant basic statistical techniques, including the R base and EpiDisplay packages. All students needed to independently analyze epidemiological data to finish their research and complete their PhD or MSc in epidemiology. The first class (class 1) was taught the original R version in October 2020, and the second class (class 2) was conducted using Jupyter Notebook in July 2022. Each class took 6 hours and comprised different students. After class finished, students from both class 1 and 2 were asked to answer the same web-based satisfaction questionnaire given by the educational assisting staff.

The intended learning outcome of both class 1 and 2 was for students to exhibit competence in using R programming for the analysis of longitudinal data. PK normally observed the action of students during each class. To facilitate individualized learning within the small class setting, students were required to independently interpret results or address parallel questions after completing exercise segments on a section-by-section basis. To further promote understanding, PK presented each student with a spontaneously devised distinct problem (improvised question) that used the same technique. For example:

- The exercise question (use "airquality" data set):
 - Calculate the differences between the square root of the ozone levels on the adjacent days.
- The improvised question (use "airquality" data set):

- Calculate the differences between the cube root (change function) of the sulfur dioxide levels (change variable) for 2 consecutive days with a lag of 2 (day lag=2).

This approach ensures that students do not merely replicate the code provided in instructions but rather gain a comprehensive grasp of the material.

Problem Identification and Solution

PK noted the problems that occurred and retrieved the comments reported by the students in class 1 from the database. The notes and comments were thematically analyzed to create the problem list. The problems were reviewed and used to develop the R Jupyter for the instruction of longitudinal data analysis. The R Jupyter content was developed incrementally to solve the problems, and subsequently, a flipped class [15] assignment was included as a preclass assignment as group work. The flipped class assignment may introduce bias due to the confusing effects of using Jupyter R Notebooks. However, it is impossible to avoid since it was mandated by the university in 2022. This enabled the students to exchange ideas through the web-based platform and collaboratively prepare for the longitudinal data analysis class.

Implementation and Evaluation

PK created a mitigation plan for class 2, which included the development of the Jupyter Notebook (see our GitHub [16]) and PDF instruction file (see [Multimedia Appendix 2](#)). These materials were distributed to students 2 weeks prior to the commencement of the class. The students were allowed to use the Jupyter server using their PSU passport account [17]. The problems detected during class 2 were noted by PK. The anonymized satisfaction scores and comments from students were sent to PK a week later. Additional details of the average age and sex distribution of the students were attached; however, those were not linked with the scores to protect personal data.

Analysis

This study used a thematic analysis to examine the notes and comments made by PK, which were provided by students in class 2, and compare them with thematic issues in class 1. In addition, descriptive statistics were used to compare satisfaction scores between class 1 and class 2 by ignoring parametric assumptions due to the small sample size. Opportunities for improvement were identified based on the observations made in the notes and comments gathered by PK, which were not previously observed in class 1.

Ethics Approval

This study was approved by the Human Research Ethics Committee, PSU (REC 66-104-18-1), which authorized a waiver of consent.

Results

Differences Between Class 1 and 2

Table 1 summarizes the characteristics of students in two different classes. Class 1 had 9 students with a mean age of 32.9 years, while class 2 had 8 students with a mean age of 30.9

years. Both classes had a similar number of male and female students. Before starting, class 2 was given a link to access a Jupyter server and a password for internet access, and students were allowed to use any device to connect to the classroom’s wireless internet. All students chose to use their laptop.

Table 1. Differences between class 1 and 2.

Demographics	Class 1	Class 2
Students’ characteristics		
Students, n	9	8
Age (years), mean (SD)	32.9 (7.2)	30.9 (6.3)
Sex, n		
Male	5	5
Female	4	3
Requirement before starting the class		
Basic knowledge	R base and EpiDisplay	R base and EpiDisplay
Material provided	R script file	Jupyter Notebook file and PDF file for instructions to access and use the Jupyter server
Internet	Not required	Required
Computational tool	Laptop computer without internet connection	Any device that can connect to the wireless internet in the classroom
Preclass assignment	None	Flipped classroom assignment
Intended learning outcome		
Outcome	Demonstrating proficiency in applying R programming for longitudinal data	Demonstrating proficiency in applying R programming for longitudinal data
Evaluation	Active engagement in class discussions and independent problem-solving	Active engagement in class discussions and independent problem-solving; flipped classroom assignment

Problem Identification in Class 1 and Mitigation Plan

Table 2 presents a list of thematic issues that arose during class 1, along with their corresponding mitigation plans. It also

outlines particular feedback provided by students in class 1 that had to be addressed before commencing class 2.

Table 2. Problem identification and solution.

Thematic issue from class 1	Mitigation plan
Author PK’s note	
Experiencing difficulty in installing packages	All packages would be installed in the Jupyter R server before class starts.
Delays in class due to unexpected errors	All codes for instruction should be tested in the Jupyter R server. All errors should be fixed before sending the material to the students.
Insufficient student participation	A mini-quiz will be actively assigned to students after each instruction and its example.
Reflections from the students	
Being unable to keep up with the pace of instruction due to the fast-paced environment	A Jupyter R file will be provided to the students with step-by-step instructions in a PDF file. Students could try all codes in the instruction by themselves before the class.
Difficulty in comprehending the analysis	A preclassroom assignment should be assigned to students as group work, so they could help each other to prepare for the class.
Lack of resources to support advanced materials	The GitHub link [18] of PK’s work should be provided to students after finishing class to ensure continuous learning through real-world data.

Comparison Between Class 1 and 2

Table 3 presents feedback on the use of Jupyter R for instruction and improvement in class 2 problems, as well as comments from the students regarding their feelings about the changes in the class.

Figure 1 shows the satisfaction ratings of the two classes (class 1 and class 2) across different dimensions of satisfaction related to their learning experience. Overall, the findings suggest that class 2 (using Jupyter R) was more effective when compared to class 1, as clearly shown by the higher mean ratings and lower

variability in the ratings for class 2. The explicit suitability of media in class 2 was found to be higher than that in class 1.

Table 3. Improvement after the use of Jupyter R for instruction.

Class 1 problems	Notes/comments supporting improvement in class 2
Experiencing difficulty in installing packages	<ul style="list-style-type: none"> Without needing to install packages, all students were able to immediately use the Jupyter R server for their data analysis. (author PK's note)
Delays in class due to unexpected errors	<ul style="list-style-type: none"> The students were able to run all the example codes provided in the instructions without errors. However, when they attempted to code their own solutions, they encountered errors. (PK's note)
Infrequent student questioning	
PK's note	<ul style="list-style-type: none"> All students asked questions frequently because they were curious about the solution for the preclass assignment and mini-quizzes.
Comments from students	<ul style="list-style-type: none"> "My interest in the course was stimulated by the lecturer." "The lecturer challenged students to do their best work and answer questions in class." "The lecturer stimulated discussions and responded to questions."
Being unable to follow due to the fast-paced environment	<ul style="list-style-type: none"> All students could try all functions of the codes through the instruction material on their own without any delay from computer-compatibility errors. (PK's note)
Difficulty in understanding the analysis	<ul style="list-style-type: none"> "This subject equipped me with a comprehensive understanding of advanced statistical techniques, which will be beneficial in analyzing and interpreting the results of my research project." "The practical exercises and case studies in this subject allowed me to apply the concepts and techniques taught in class, enhancing my data analysis skills and increasing my confidence in working with large and complex data sets." "This subject emphasized the importance of integrating statistical analysis into research projects and providing a framework for approaching data analysis in a scientifically rigorous manner. The lessons and exercises in this subject have prepared me to effectively apply my statistical knowledge and skills to my own research project, leading to robust and reliable results." (comments from students)
No source for the continuation of advanced practicing	<ul style="list-style-type: none"> "The lecturer diversified the learning level. I can learn more through Jupyter Notebook in the GitHub repository." "I also learned to design my own research and built my analysis plan based on the example in GitHub." (comments from students)

Figure 1. The six-dimensional satisfaction scores.

Opportunities for Improvement

Table 4 presents the opportunities for improvement in class 2 and notes/comments from both the instructor and students. PK noted that there was uncertainty regarding the long-term effectiveness of the course, as there was no standard procedure in place to monitor whether students continued to engage with coding in R after class was completed. Furthermore, there is also a lack of knowledge regarding their proficiency in solving coding challenges independently. Despite PK’s emphasis that students are able to use Jupyter Notebook when they face compatibility issues related to traditional R (we also provided a Jupyter server for the alumni), it is unclear whether students would remember this or if they would use another program

altogether to conduct their data analysis. Hence, a plan was developed to devise a system that could effectively monitor the adherence of students to the practice of coding in R, such as the R Skill Challenge Activity, through the Jupyter server. The student reflections highlight the need for a teaching assistant during class, as some practice sessions run slower when students require specific help. Even though the lecturer was able to cover all the necessary material with the students within the scheduled time by using Jupyter Notebook and teaching at a new pace, the students appeared to be unwilling to wait for assistance in resolving an error while the lecturer was assisting another student. Therefore, a few statisticians will be assigned as teaching assistants in upcoming classes.

Table 4. Opportunities for improvement.

Opportunities for improvement in class 2	Notes/comments from class 2
Uncertainty regarding the long-term effectiveness	<ul style="list-style-type: none">Currently, we do not have a standard procedure in place to monitor the extent to which students continue to engage in R coding after class. Additionally, we lack knowledge regarding their proficiency in independently solving coding challenges in advance. (author PK note)
Teaching assistantship	<ul style="list-style-type: none">“We have no teaching assistant during the class, and it made some practice sessions run slower because some of us encountered specific problems during the practice.”“It would be nice if teaching assistants can join these courses to help us during the practice session.” (comments from students)

Discussion

Principal Findings

This study focused on the challenges faced in teaching R programming in epidemiology classes and proposed the use of Jupyter Notebook as a potential solution. The study aimed to evaluate the effectiveness of Jupyter Notebook in a longitudinal data analysis class and collected reflections from students in a previous class regarding the problems they encountered in learning R programming. The findings of the study indicated that Jupyter Notebook could provide an interactive and collaborative environment that improves the effectiveness and efficiency of the learning process.

Reflections on the action research process revealed that compatibility issues and package installation crashes were the most common challenges faced when teaching R programming. These challenges were resolved by using Jupyter R Notebook, which also facilitated group work and collaborative learning. This study is innovative in its use of Jupyter Notebook as a pedagogical tool for the instruction of epidemiology and, to the best of the author’s knowledge, is the first study to do so. However, previous studies in other fields [9,19-22] have revealed that Jupyter Notebook is an effective tool for teaching data analysis.

The primary strength of this study was its collaboration with students, allowing their problems to be identified so that solutions could be found to address those issues. Moreover, the use of Jupyter Notebook as a tool to enhance learning is an innovative approach to teaching epidemiology. The use of this tool was a pragmatic remedy to the obstacles encountered when instructing students in R programming within epidemiology

courses. Jupyter Notebook provided an effective and efficient learning environment, enabling students to explore data and document their analysis steps in a clear and reproducible way. Moreover, Jupyter Notebook facilitates collaboration between students and instructors, allowing instructors to create interactive tutorials, assignments, and quizzes.

Limitations

Unfortunately, this study’s focus on a particular class and context constrains its generalizability. Additionally, the long-term efficacy of the Jupyter Notebook method in enhancing student learning outcomes remains unreported. Future research should assess the long-term effectiveness of the Jupyter Notebook strategy in augmenting student learning outcomes. Moreover, to adhere to ethical standards during student data collection, it is crucial to establish a research protocol that delineates the process for securing informed consent prior to further evaluation. The use of a flipped classroom assignment in class 2 may have influenced the overall feedback, complicating whether the observed outcomes could be exclusively attributed to the Jupyter Notebook approach.

Considering these constraints, we propose that subsequent research should examine the long-term effectiveness of the Jupyter Notebook approach in fostering student learning outcomes while accounting for confounding factors, such as flipped classroom assignments. This will facilitate a clearer understanding of the primary effect and aid in discerning the distinct contributions of the Jupyter R notebook method to student learning.

Conclusion

Jupyter Notebook can enhance the learning of epidemiological data analysis for graduate students by providing an interactive

and collaborative environment that allows for more efficient and effective learning. The findings of this study demonstrate that Jupyter Notebook can help address the challenges of teaching R programming in epidemiology classes, which are caused by compatibility issues with different OSs and computers.

Acknowledgments

The appreciation of the author is extended to the Division of Digital Innovation and Data Analytics, Faculty of Medicine, Prince of Songkla University for their development of the Jupyter server. The author would also like to thank the Office of International Affairs, Faculty of Medicine, Prince of Songkla University for their English editing support services.

Data Availability

The pedagogical resources pertinent to this research are publicly accessible via the GitHub repository [16]. The data sets substantiating the outcomes of this investigation can be available from the corresponding author, contingent upon a reasonable request.

Abstract

Background: Older adult care organizations face challenges today due to high personnel turnover and pandemic-related obstacles in conducting training and competence development programs in a time-sensitive and fit-for-purpose manner. Digital microlearning is a method that attempts to meet these challenges by more quickly adapting to the educational needs of organizations and individual employees in terms of time, place, urgency, and retention capacity more than the traditional competency development methods.

Objective: This study aimed to determine if and how an app-based digital microlearning intervention can meet older adult care organizations' personnel competency development needs in terms of knowledge retention and work performance.

Methods: This study assessed the use of a digital microlearning app, which was at the testing stage in the design thinking model among managerial (n=4) and operational (n=22) employees within 3 older adult care organizations. The app was used to conduct predetermined competency development courses for the staff. Baseline measurements included participants' previous training and competency development methods and participation, as well as perceived needs in terms of time, design, and channel. They then were introduced to and used a digital microlearning app to conduct 2 courses on one or more digital devices, schedules, and locations of their own choice during a period of ~1 month. The digital app and course content, perceived knowledge retention, and work performance and satisfaction were individually assessed via survey upon completion. The survey was complemented with 4 semistructured focus group interviews, which allowed participants (in total 16 individuals: 6 managerial-administrative employees and 10 operational employees) to describe their experiences with the app and its potential usefulness within their organizations.

Results: The proposed advantages of the digital microlearning app were largely confirmed by the participants' perceptions, particularly regarding the ease of use and accessibility, and efficiency and timeliness of knowledge delivery. Assessments were more positive among younger or less experienced employees with more diverse backgrounds. Participants expressed a positive inclination toward using the app, and suggestions provided regarding its potential development and broader use suggested a positive view of digitalization in general.

Conclusions: Our results show that app-based digital microlearning appears to be an appropriate new method for providing personnel competency development within the older adult care setting. Its implementation in a larger sample can potentially provide more detailed insights regarding its intended effects.

KEYWORDS

digital microlearning; elderly care; older adult care; competency development; implementation research; dementia; COVID-19

Introduction

Adequate training and competence development among personnel in older adult care organizations are not only vital for their health, well-being, safety, and self-confidence but also for the outcomes of care receivers. Such development minimizes ill-health and related leave of absences and enhances staff continuity [1]. Older adult care in Sweden is faced with several concurrent challenges to this kind of training and development. These include high staff turnover, staff with shorter education, inadequate skills, and limited Swedish language proficiency. For this group, standard training and competence development programs are less prioritized due to heavy workload, more difficult to conduct, and when conducted are less likely to give expected benefits [2].

Regulations regarding infectious disease control as a response to the COVID-19 pandemic also created a dramatic change in work methods, affecting both skills and competency requirements. Fit-for-purpose training and development initiatives need to be provided in a safe and effective manner despite changes in work routines and limitations on physical gathering and contact. The pandemic also complicated the “feedback loop” between employees and management regarding knowledge and competency gaps, making them more difficult to identify or remedy in time and scope. These developments made many work environments less adaptable in considering the personnel’s health, safety, and development and led to adverse work-related outcomes and increased absence due to illness [3].

Digital training and competency development tools have the potential to ameliorate some of these challenges. One such tool, digital microlearning, is a less formal competency development tool that aims to fill knowledge gaps identified by the staff themselves through self-assessment, known as personalized learning. To achieve this, digital microlearning provides brief learning modules (seconds to minutes to conduct) on demand via digital means (eg, computers, mobile telephones, or tablets) that are highly specific to the individual’s learning context and environment. The method often includes an assessment that is provided in close proximity to the learning modules in terms of timeframe and delivery channel. Digital microlearning aims to increase flexibility in organizations’ competency development compared to standard and more formal methods, which are often delivered broadly through written course literature and lectures

with a longer time lag between current needs and delivery. Organizations undergoing change may benefit from shorter, more focused, and directed training efforts that can be delivered on short notice to specific roles and individuals [4,5]. A recent review of microlearning in health professions training concluded that, as a competence development strategy, it contributed to positive effects in actual knowledge retention as well as self-confidence in work performance compared to standard training methods [6]. This may be due to a reduction in the information load associated with the broader scope and time allotment of standard formal training [7]. Furthermore, many digital microlearning tools reduce the administrative burden on managers in documenting and following employees’ learning progress toward set goals.

The use of digital microlearning among health and social care settings and professionals is not well documented in the research literature, although its use in some thematic materials relevant to these professions, such as dealing with violent behavior and mental health issues, have been attempted [6].

This study focused on health and social care organizations providing home and institutional care to older persons, to answer the following research questions:

1. What are the competency development needs of employees and managers in older adult care organizations in terms of subject matter, time, method of provision, and channels?
2. Can digital microlearning meet the identified needs of employees and managers in older adult care organizations), and if so, how can the efficiency of delivery and effectiveness of retention and app be improved?
3. Are professionals’ own assessments of confidence in their knowledge and work performance affected by digital microlearning, and if so, how?

To answer research questions 2 and 3, the study used a digital microlearning app (The Minnity Learning Platform) that was in the later iterative stages of test mode according to the design thinking model [8]. This study evaluated the effects of a digital microlearning app at the testing stage (stage 4) in the design thinking model (Figure 1). Stages 1-3 in the model had already been conducted in other populations, although some steps in these stages were repeated in this study. A codevelopment process for the app was used involving the developer, municipal caregiving organizations, and the academic research sector.

Figure 1. The stages of the Design Thinking Model [8]. The digital microlearning app in this study was in stage 4 at the time of the study and had undergone previous iterative rounds of the other stages.

Methods

Recruitment and Participants

Recruitment of participants for the study was conducted between January and May 2021. Targeted offers to participate in the study were sent to 6 health and social care organizations providing home- and institution-based older adult care. The offers specified that a small reimbursement (~US \$1200) would be given for their time. Three organizations volunteered to participate in the study, each located in different Swedish municipalities with comparatively diverse demographic characteristics. Managerial or administrative employees (n=4) and operational caregiving employees (n=22) without previous experience with microlearning methods were internally recruited

within the organizations to voluntarily participate in the study (26 in total). Participants then received both verbal and written information about the aims of the study, their expected contributions, potential benefits and risks, and how data and personal information gathered during the study would be used in line with recommendations on good research practice from the Swedish Research Council [9] and the EU General Data Protection Regulation. All participating organizations and employees then provided informed consent verbally and in writing to participate in the study. Background data regarding the organizations and the employee participants were collected from the respective organizations' official administrative data. The three participating organizations and the recruited participants from these organizations are described in Table 1.

Table 1. Characteristics of the participating organizations and employees.

	Location	Turnover (2020); number of employees	Care receivers, n	Study participants
Organization 1: unit within municipal caregiving company	Small municipality (<30,000 inhabitants)	~US \$40 million; 20-25 employees	50-75; with addition of several hundred home emergency alarm users	Nine nursing assistants and 1 manager; average age 49 years (between 35 and 60 years); average employment experience 13 years (between 0 and 35 years)
Organization 2: unit within the caregiving foundation	Large municipality (~1,000,000 inhabitants)	~US \$6.5 million; 60-65 permanent contract employees	65-70	Four nursing assistants, 2 operational team managers, and 2 administrative managers; average age 51 years (between 35 and 65 years); average employment experience 6 years (between 0 and 15)
Organization 3: municipal caregiving unit	Small municipality (<35,000 inhabitants)	US \$2.5 million; 30-35 permanent contract employees	30-35	Six nursing assistants, 1 operational team manager, and 1 administrative manager; average age 48 years (35-65 years); average employment experience 13 years (0-25)

Intervention

Overview

The study intervention was conducted between April and November 2021. It consisted of three stages: (1) characterization and assessment of previous competence development and identification of current or future needs, (2) implementation

and evaluation of a market-ready digital microlearning app and courses, and (3) assessment of the app's potential usefulness in meeting future competence development needs.

Characterization and Assessment of Previous Competence Development and Identification of Current or Future Needs

A web-based survey of all participants was then conducted to obtain individual responses regarding competence development initiatives conducted during the previous 2 years of employment, including themes or subject matter, time allotted to, channels and evaluation methods used, and experiences and satisfaction with such initiatives. For the experiences and satisfaction dimensions, the survey posed statements that the respondent should then choose an appropriate response to from a 5-point Likert scale, with the response alternatives “completely agree,” “mostly agree,” “both agree and disagree,” “mostly disagree,” and “completely disagree” (see [Multimedia Appendix 1](#)). The survey also addressed desired support, needs, and pandemic-related aspects regarding current and future competence development. All participants were given approximately 1 month to complete the survey.

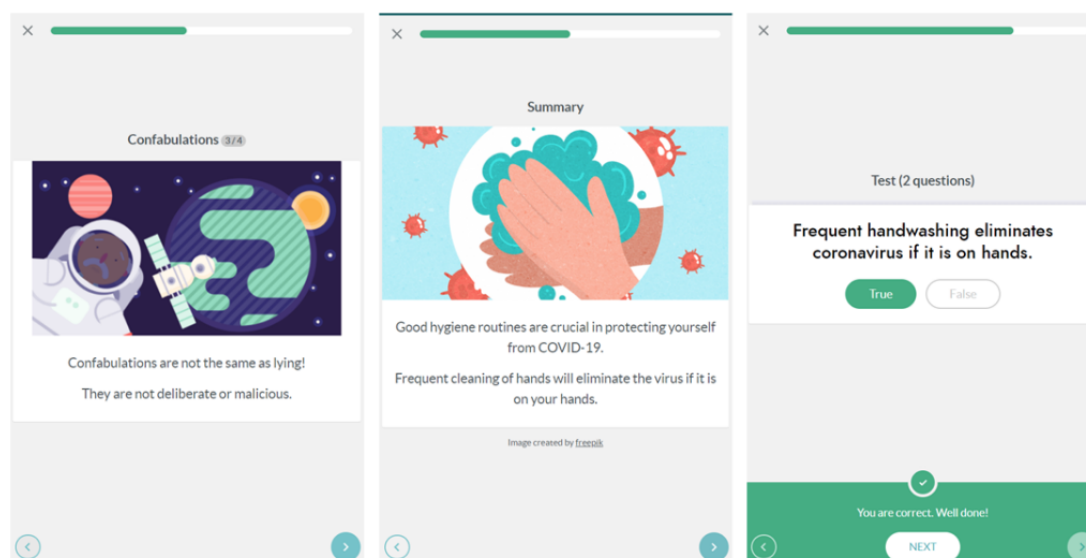

Implementation and Evaluation of the Digital Microlearning App and Courses

Participants were then introduced to The Minnity Learning Platform digital microlearning app that was to be implemented

as part of the study. The internet-based app could be used on mobile (smartphone and tablet) or computer platforms. All participants received 30 minutes of instructive group training on how to use the app, as well as unlimited access to web-based manuals and support afterward. Managers received additional training on how to monitor employees' progress through the microlearning modules via the administrative view in the app.

Two full microlearning courses were conducted via the app: (1) COVID-19 and hygiene when providing home care and (2) care approaches for people with dementia. (A trial of the COVID-19 module is available publicly [10] in English, French, and Swedish languages.) The courses consisted of several small modules, each of which was expected to take 2-3 minutes to complete, with a repeatable self-assessment test to be completed at the end of each module ([Figure 2](#)). The entire course therefore was expected to take approximately 15-20 minutes to complete but could be started and stopped after each module, and modules could be repeated as desired. Participants were given 1 month to complete the modules, during which time they could freely choose to conduct the modules as they wished. The progress of individuals through the modules could be seen by themselves as well as by the manager involved in the project from their organization.

Figure 2. Screenshots from the mobile version of the digital microlearning app. From left to right: the dementia course, the hygiene course, and the self-assessment test for the hygiene course.

Upon completing the course, individuals were then directed to a short (approximately 3 minutes) web-based survey conducted via a link from the app to evaluate their perceptions about the course content, its usefulness and applicability, and different user experience dimensions regarding the digital microlearning app itself ([Multimedia Appendix 2](#)). The surveys posed the same statements and used the same 5-point Likert scale as in the initial survey (characterization of previous competence development and identification of current or future needs section).

Assessment of the App's Potential in Meeting Future Competence Development Needs

After all participants in an organization had completed the modules, 2 semistructured group interviews were conducted with the managerial-administrative participants and the operational participants, respectively. The approximately 1-hour interviews were conducted either physically or via web-based meeting as chosen by the participant organization (which had different restrictions on receiving external visitors during the COVID-19 pandemic), recorded, and transcribed. The interviews initially focused on three main themes: (1) the participants' conduct of the digital microlearning courses, such as time, place, amount, and strategy, and their discussions with colleagues regarding the courses' content; (2) their own assessment of the

app's and courses contents' effects on their comprehension and retention of the courses' content, as well as their confidence in and ability to apply the content material in their daily work; and (3) their own assessment of if and how the app could be used in the future within their organizations, how the current course content could be developed, and what other courses that would be useful to conduct. The interviewers assisted participants in identifying subthemes and additional themes during the interviews using the constant-comparison method [11]. Participants spoke freely both individually and among themselves during the interview. The interview guide used can be found in [Multimedia Appendix 3](#).

Statistical Analysis

For quantitative data, descriptive univariate analysis was applied across organizations, and results were presented as sums or averages (with range or SD where applicable). Within-groups and between-groups analyses were conducted for the organization (3 participating) and role within the organization (2 participating) variables.

Transcribed qualitative interview data were descriptively coded by 2 researchers (first level) to formulate a primary list of themes and associated citations, followed by second-level coding to expand or amalgamate themes. The themes and their content were summarized and designated as facilitating, hindering, or neutral by 2 researchers independently conducting the analysis.

Ethical Considerations

Head administrators of the participating organizations, as well as the individual employees recruited within them, signed written informed consent forms to participate in the study after receiving oral and written information about the aims of the study, their expected contributions, potential benefits, and risks, and how data and personal information gathered during the study would be used. A nonconditional reimbursement of ~US \$1200 was offered to organizations at the time of recruitment. Individual participants' data were coded after data collection and remained anonymous to both researchers and others from that point onward. Participation was voluntary and could be ended at any point without explanation, at either the individual or the organizational level. Ethics approval by the Swedish Ethics Review Board was not sought as it was deemed, after following internal Mälardalen University process, that the study did not meet the requirements for mandatory national ethics

review. The study did follow recommendations on good research practice from the Swedish Research Council [11] as well as adhering to the EU General Data Protection Regulation.

Results

Overview

Organizations 2 and 3 (n=16) completed all 3 stages of the study. Organization 1 (n=10) completed the first 2 stages of the study but not the third stage due to logistical difficulties (both directly and indirectly influenced by the ongoing pandemic) in participating in the interview.

Characterization and Assessment of Previous Competence Development and Identification of Current or Future Needs (N=26)

For all organizations, 15 employees confirmed that they had participated in educational or competence development initiatives within the organization during the 2 years prior to the study. Of those confirmed, 6 had participated for 1-2 days per year, 3 had participated for 3-5 days per year, 1 had participated for 6-10 days, 3 had participated for 11-20 days per year, and 1 had participated for more than 20 days per year. There was no difference between organizations for these measures, although managerial and administrative employees on average participated in more initiatives (mean 12.5, SD 9.6 days) than operational employees (mean 1.6, SD 4.2 days). Web-based educational modules consisting of mixed methods (video and text lectures, quizzes, and assignments) were the most common form of competence development received (5 participants), followed by lectures (digital or in person; 4 participants). Workshops, internships or mentoring, and structured reading, study circles, written assignments, or other methods were also used. For conducting educational and competence development initiatives, the workplace was the most common site (65.2% of all initiatives), while educational institutions (8.7%), own residence, or other sites (13% each) were less used. Educators outside of the organization were most used for conducting the initiatives (35.7% of all initiatives), followed by web-based content (25%), internal educators (21.4%), paper literature (14.3%), and other resources (3.5%). The individual assessments of previously conducted education or competence development initiatives are shown in [Figure 3](#).

Figure 3. Participants' (N=26) assessment of previous competency development and educational initiatives conducted within their respective organizations. The statements under the bars that participants stated their level of agreement about are shortened for space purposes; the full statements can be found in [Multimedia Appendix 1](#).

Evaluation of the Digital Microlearning Courses and App (N=26)

The survey assessments of the digital microlearning courses showed that a majority of participants were entirely or mostly in agreement regarding the content in both the COVID-19 and dementia courses. The participants found the courses to be valuable and beneficial, with a high probability of retaining the acquired knowledge. They were able to apply this knowledge to enhance their work performance and to improve their work environment and workflows. Additionally, they expressed satisfaction and enjoyment in attending the course (Figures 4 and 5). However, the majority mostly disagreed or disagreed

regarding satisfaction with work following attending the COVID-19 module, and new knowledge gained from the dementia module. No differences were found between operational and managerial-administrative participants' responses regarding the courses.

A majority of the participants were also entirely or mostly in agreement that the digital microlearning app was simple to use and well integrated, and that they could quickly learn to use it, felt comfortable in using it, and wanted to use it regularly (Figure 6). There were no differences between the operational and managerial-administrative participants' responses regarding the app.

Figure 4. Participants' (N=26) assessment of the COVID-19 hygiene digital microlearning course. The statements under the bars that participants stated their level of agreement about are shortened for space purposes; the full statements can be found in [Multimedia Appendix 1](#).

Figure 5. Participants' (N=26) assessment of the dementia care digital microlearning course. The statements under the bars that participants stated their level of agreement about are shortened for space purposes; the full statements can be found in [Multimedia Appendix 1](#).

Figure 6. Participants' (N=16) assessment of the digital microlearning app. The statements under the bars that participants stated their level of agreement about are shortened for space purposes; the full statements can be found in [Multimedia Appendix 2](#).

Assessment of the Digital Microlearning App's Potential in Meeting Future Competence Development Needs (n=16)

Several future course topics were suggested as appropriate for the digital microlearning app in comparison to traditional planned educational initiatives, due to its more time-sensitive and on-demand nature, including:

- Protective and restrictive interventions for aggressive or violent care receivers, as well as management and prevention of other behavioral problems such as problematic anxiety and restlessness. These were seen as more acute in time and expedient access to knowledge would be particularly useful delivered through the app.
- Mealtime layout planning and related cultural knowledge in holiday meal settings. These events were often time specific and in some cases needed adjustment on a very short time scale, and the knowledge level of employees with non-Swedish ethnic and geographic backgrounds on this topic required additional support.
- Digital signing and transfer of responsibilities regarding, for example, care provision or medication, as well as documentation of, for example, adverse events or deviating procedures. These have strict local, regional, and national regulations that newer employees felt a need for support in adhering to.
- Purely methods-related knowledge, such as wound and sore management and how to apply insulin or eye drops in various care receiving groups.
- Areas of knowledge that changed quickly due to, for example, regulation development, societal or organizational changes, or research-based findings. The changing knowledge status during the COVID-19 pandemic was according to some a particularly relevant example of how

needs could be more easily solved in a digital microlearning setting.

A key advantage of having these topics provided via a digital microlearning app was that several employees felt that knowledge retention would be greater with the ability to repeat the same educational modules. Previously offered educational initiatives were often single sessions and significant amounts of the material were quickly forgotten according to some. For example, 1 nurse summarized, "(The course material) is fresh in your mind while you're there, but the forgetfulness sets in fast." Another stated that with the application, "...you can have the material close to you all the time... and use it to quickly freshen up your memory."

Other potential topics were seen as appropriate for the digital microlearning app, but in tandem or complementary to previously used planned educational initiatives as they could not provide the in-depth material, discussion of it with colleagues and instructors, or collegial guidance that the previously used methods enabled. As 1 nursing assistant stated:

Some education needs to be about ethics and dilemmas... and then it's better to be in the same place with others and have a forum for discussion.

Examples of such topics included the following:

- Support to relatives and informal caregivers when the professional caregivers were not available or involved, regarding, for example, the management or transfer of certain care responsibilities requiring a higher level of knowledge or proficiency. The app was seen as useful in providing a similarly accessible and summary format to informal caregivers "on the spot."
- End-of-life and palliative care routines, where certain recurring situations or events required expedient access to standard knowledge. The ethical and personal reflection

regarding such situations was, however, not seen as appropriate for the app and required other educational approaches.

Other User Groups' Interaction With the Digital Microlearning App

Study participants also commented that the app would be useful for other user groups that had a stake in their own work activities, specifically managers within the organization, informal caregivers or relatives, and other relevant professional groups such as doctors and nurses within primary or secondary care, physiotherapists, and work therapists.

Managerial participants had access to a function that allowed them to see operational participants' time and level of completion of the modules, and this function was considered useful so that reminders could be provided. This function was used during the study to remind operational participants who had not completed the courses that they were nearing the end of the designated period within the study.

For informal caregivers and relatives, a similar supportive function in obtaining new knowledge as for professional caregivers was seen as potentially useful by the study participants. This would potentially allow less confusion and a higher level of informal care when both professional and nonprofessional caregivers were helping the same individuals. It was suggested that the course content would be adjusted to the user group, but that similar themes or topics of relevance to the organization would be available on the informal caregivers' own devices, and that new content could be delivered as seen fit.

For other professional caregiving groups such as doctors, nurses, and therapists, it was seen by several study participants as beneficial that these groups *"could see the same material"* as the study participants, primarily to reduce confusion when transferring care duties, as these groups were often seen as having a lower level of knowledge regarding older adult care in their professions. Through the use of the app, these groups could gain and adhere to the same knowledge base. Some study participants expected that these other professions could, for various reasons, not prioritize the same educational initiatives as the older adult care professionals, and thus the digital microlearning app was more likely to be used due to its added advantage regarding time and availability.

Some disadvantages were also noted in using the digital microlearning app regarding meeting future competence development needs. These included some local routines that did not permit the use of personal mobile devices while interacting with care receivers, the inability to install, or overall inaccessibility of organization-provided mobile devices or internet connection. Hygiene aspects related to digital devices were also raised as a concern; *"yet another time I need to think about washing my hands"* was 1 response when deciding whether to take up their mobile to do part of a course. These were seen as general digitalization challenges that some organizations had not yet overcome. One team manager stated regarding this issue:

We say all the time that (the mobile phones) they should not be in our pockets when we're on the floor, but in our bags instead... but at the same time we need to be more digital. We give very mixed signals to our employees about this.

For those organizations that had come further in their digitalization, the app's lack of integration with existing digital administrative platforms, or within existing workflows, was also seen by some as an inconvenience to using it. "Not another self-standing application" with its own login requirements, device of installation, and so forth was a comment fielded by a few employees. Some employees with a lower level of Swedish language competency, dyslexia, or other learning difficulties also felt that the textual content itself was "too academic" or advanced, and thus difficult to understand.

Some employees were slightly dismayed at the inability to use the app as a type of knowledge base that could be used more like a guidebook or encyclopedia, for already attained knowledge or to replace existing local knowledge documentation currently in paper form. While the app was not presented as such a solution, some employees felt that it would have been at least as useful in this role as in providing new knowledge content.

The ability to both read and listen to the content was seen as a potential development of the app, which currently only provides content visually (via text, images, and video). Other audio contents such as podcasts within the application were also suggested as complementary material to the course content. Varying the course content for different professional roles using it was also seen as a potentially useful development.

Discussion

Principal Results

Our results show that app-based digital microlearning appears to be an appropriate new, person-centered method for providing continuing educational development within the older adult care setting. The proposed advantages of the digital microlearning app were largely confirmed by the participants' perceptions, particularly regarding ease of use and accessibility, and efficiency and timeliness of knowledge delivery.

While some knowledge areas were deemed appropriate for delivery through the app, others requiring more discussion or reflection were viewed as less appropriate. In these cases, the microlearning method was thought to be more appropriate as a complement or addition to previously used competence development methods. This suggests a combined tailored approach to course theme, and content is advisable when using digital microlearning for complex themes, and that standalone courses conducted via such an app should be appropriately limited in terms of scope, interpretability, and dimensional complexity.

The majority of the participants partially or entirely disagreed that new knowledge had been attained following the dementia course may be explained by the initial knowledge level of the participating organizations. The employees of 1 participating organization appear to have accounted for most of the

disagreement, and this organization's employees had the longest operational careers within older adult care of all participants. Since the themes for the 2 courses conducted within the study were predetermined without direct input from the participating organizations, the material may have been perceived as repetitive or less necessary about current knowledge needs. Similarly, the majority that disagreed that workplace satisfaction had increased following the COVID-19 course were also characterized by longer employment histories. This might suggest that the microlearning courses used in the study provided greater benefits for younger or newer employees in organizations that had more apparent knowledge needs within the course themes. Microlearning courses are, outside of this study, designed and provided in accordance with user organizations' needs and wishes, which would likely lead to more positive ratings of the app's perceived usefulness. Our results therefore advise carefully considering organization-specific aspects and context both when implementing and assessing the effects of digital microlearning in health and social care organizations.

Participants perceived an increase in confidence in knowledge and work performance benefits following their use of the app. Ideally, the use of digital microlearning would then lead to better health outcomes and improved safety and quality of life for care receivers. This would create both organizational improvements sooner and increase the return on investment for competency development initiatives. Although this study did not measure such health, safety, and quality of life outcomes among care receivers, the obtained results suggest that such outcomes could logically be achieved. Further research that measures such outcomes would be justified in future studies of digital microlearning.

The app development suggestions from the study participants, including audio-based functions, searchable reference-type functions, and adaptable text content for user groups, suggest an interest in using the capabilities of digital platforms even more than at present. Combined with the overall positive assessment of the app, this can be interpreted as a willingness to digitalize, including the more traditional aspects of health

and social care workplaces such as education and training. These results also support upscaled testing within the codevelopment process for the digital microlearning app.

Considering the challenges regarding staff composition and recruitment within the older adult care sector, research regarding competency development via digital methods might help identify ways of increasing the attractiveness of the caregiving professions. The assessed digital microlearning app demonstrated good potential to assist organizational transformation through tailored employee development with little perceived resistance. The benefits of this may be more pronounced among younger or less experienced employees with more diverse backgrounds, which would fit well with currently dominating demographic trends in health and social care personnel management.

Limitations

The research was conducted in Swedish municipal care settings and used largely user-assessed outcomes. Future research should focus on objective evaluation of health-related outcomes, quality of care, and employee health outcomes following digital microlearning interventions.

Comparison With Prior Work

Our results are in line with a recent systematic review [6] of 17 studies that demonstrated a positive effect of microlearning on the knowledge and confidence of health profession students in performing procedures, retaining knowledge, studying, and engaging in collaborative learning.

Conclusions

This study contributes to the currently limited empirical evidence related to digital microlearning [12]. The digital microlearning app demonstrated positive effects at the testing stage in the design thinking model and appears mature for implementation in wider but more tailored use. Competence development strategies should consider digital microlearning as a potential intervention in health and social care organizations.

Acknowledgments

The study was funded by FORTE (Forskningsrådet för hälsa, arbetsliv och välfärd), the Swedish Research Council for Health, Working Life and Welfare (project 2020-01578). The funding was provided for projects involving multisectorial codevelopment within health and social care themes.

Authors' Contributions

MXR and OA conducted the data collection and the data analyses. KH-W provided the digital microlearning app and support for users during the data collection. MXR, OA, and SW-A authored the manuscript, and all authors have read it upon submission. All authors contributed to the study idea and methodology.

Conflicts of Interest

MXR, OA, and SW-A declare they have no financial or otherwise competing interests in the study. KH-W is the CEO and cofounder of Minnity AB, the developer of the digital microlearning app used in the intervention.

Abstract

Background: Despite guidelines recommending the use of glucagon-like peptide-1 receptor agonists (GLP-1 RAs) in certain patients with type 2 diabetes (T2D), they are not being prescribed for many of these patients. Web-based continuing medical education (CME) patient simulations have been used to identify clinicians' practice gaps and improve clinical decision-making as measured within a simulation, but the impact of this format on real-world treatment has not been researched.

Objective: This study aimed to evaluate the effect of a simulation-based CME intervention on real-world use of GLP-1 RAs by endocrinologists and primary care physicians.

Methods: Two evaluation phases of the CME simulation were conducted: phase I, the CME simulation phase, was a paired, pre-post study of 435 physician learners in the United States; and phase II, the real-world phase, was a retrospective, matched case-control study of 157 of the 435 physicians who had claims data available for the study period.

Results: Phase I CME results showed a 29 percentage point increase in correct decisions from pre- to postfeedback (178/435, 40.9% to 304/435, 69.9%; $P < .001$) in selecting treatment that addresses both glycemic control and cardiovascular event protection. Phase II results showed that 39 of 157 (24.8%) physicians in the intervention group increased use of GLP-1 RAs, compared to 20 of 157 (12.7%) in the comparison group. Being in the intervention group predicted GLP-1 RA use after education (odds ratio 4.49; 95% CI 1.45-13.97; $P = .001$).

Conclusions: A web-based CME simulation focused on secondary prevention of cardiovascular events in a patient with T2D was associated with increased use of evidence-based treatment selection in the real world.

Introduction

The leading cause of morbidity and mortality in people with type 2 diabetes (T2D) is cardiovascular disease (CVD) [1-7]. Cardioprotective benefits of glucagon-like peptide-1 receptor

agonists (GLP-1 RAs) have been confirmed when used in patients with T2D. However, despite current guidelines that strongly recommend the use of GLP-1 RAs in patients with T2D who already have or are at high risk for CVD [8-10], most patients who are eligible for these treatments are not receiving

them. Multiple studies indicate that less than 8% of patients with T2D and CVD are receiving a GLP-1 RA [11-17]. Moreover, an analysis of the National Health and Nutrition Examination Survey (NHANES) from 2017 to 2018 found that although one-third of sampled patients with diabetes mellitus were eligible for GLP-1 RAs, in 2018 the use of these agents was limited to only 1 in 100 eligible patients [18].

Therapeutic inertia in diabetes care, generally defined as the failure to initiate or advance therapy when a patient's glycated hemoglobin A_{1c} (HbA_{1c}) is too high (typically >7%), significantly increases the risk of myocardial infarction, heart failure, stroke, and the composite of these 3 cardiovascular (CV) events [19]. Epidemiologic data indicate that for every 20 people with T2D with an HbA_{1c} value 1% above a target of 7%, 1 will experience a microvascular complication within 5 years [20]. Physician factors that contribute to therapeutic inertia may include underestimating the number of patients who are not at target HbA_{1c}, lack of knowledge of the efficacy and safety of therapeutic agents, resistance to prescribing new medication, and difficulty in keeping up to date with changing guideline recommendations [20,21].

Importantly, it is suspected that primary care physicians (PCPs) are not fully aware of the benefits of GLP-1 RAs shown in CV outcome trials, because these physicians have fewer

opportunities for education on CVD and diabetes than specialists [22]. However, therapeutic inertia is reported to be significant even among specialists [23]. Consequently, there is a clear need for education on CV complications of diabetes and the use of new guideline-based treatment approaches to prevent and treat adverse CV outcomes in patients with type 2 diabetes [24].

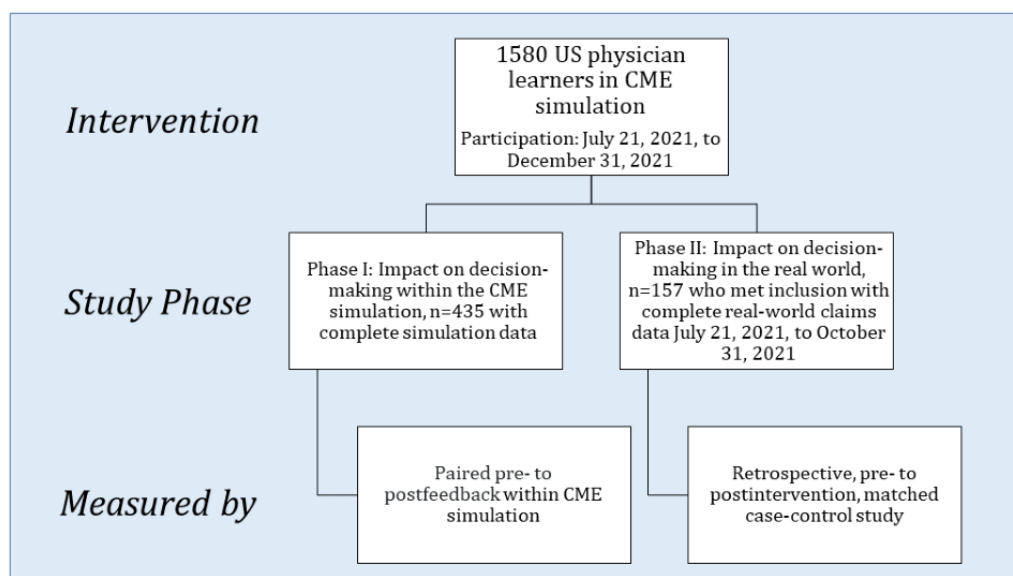

Continuing medical education (CME) is an effective tool to close physician practice gaps related to T2D among PCPs and can potentially help improve patient outcomes [25-27]. Patient simulation has been used to identify clinicians' knowledge gaps and prescribing patterns and improve clinical decision-making [24,28-32], but the impact of web-based, simulation-based CME on real-world treatment selection among clinicians who treat patients with T2D has not been researched. The aim of this study was to investigate the effect of web-based CME simulation on the physician selection of cardioprotective antihyperglycemic treatments in real-world clinical practice.

Methods

Study Design

Two study phases were conducted. Phase I focused on decision-making within the MedSims patient simulation, and phase II focused on treatment decisions in the real world (Figure 1).

Figure 1. Study design. CME: continuing medical education.

Phase I: CME Simulation

A paired, pre-post study was conducted from July 21, 2021, to December 31, 2021. PCPs and endocrinologists who made at least one decision in the simulation and were shown feedback were included.

Phase II: Real World

A retrospective, matched case-control study was conducted from April 21, 2021, to January 31, 2022. The participation period was July 21, 2021, to October 31, 2021. The participation date upon which the 3 months prior to and after are calculated is herein referred to as the index date. Physicians were included

if they had *International Statistical Classification of Diseases and Related Health Problems, Tenth Revision (ICD-10)* claims for T2D and prescription data available. Patients were required to have had at least one visit with either a patient simulation CME intervention (intervention group) clinician or a matched control group (comparison group) clinician. In addition, during those visits T2D was coded, and in the 3 months prior to or after the index date an oral T2D treatment was prescribed. Clinician- and patient-level data were obtained through licensed claims data that contains data from over 320 million US patients. A data specialist provided aggregated deidentified clinician-level data to the study lead author (KSL), who analyzed the data.

Intervention for Phase I and Phase II

The intervention was a web-based MedSims CME simulation activity: Beyond Glycemic Control...Comprehensive Management of T2D [33].

This MedSims patient simulation, which allows learners to order lab tests, make diagnoses, and prescribe treatments in a manner matching the scope and depth of actual practice, contains 2 cases—one focused on primary prevention of CV events in a patient with T2D and one focused on secondary prevention of CV events in a patient with T2D. MedSims simulation provides a customized learning experience with point-of-decision (formative) feedback. Decision-making is open-ended, and opportunities to review decisions allow learners to make real-time changes based on formative feedback. Learners also go through a full review at the end of each case to make adjustments when considering the patient visit as a whole. The intervention addressed the following learning objectives: improve performance associated with ordering appropriate tests to assess glycemic control and CV risk in patients with T2D and improve performance associated with selecting appropriate treatments for primary and secondary prevention of CV events in patients with T2D and CVD.

For the purposes of this study, we limited our investigation to the case that focused on secondary prevention, for which the learners were expected to choose the GLP-1 RA as the most appropriate treatment because GLP-1 RAs are indicated for T2D and secondary CV risk reduction.

Sample

Phase I: CME Simulation

A total of 1580 US physicians (190/1580, 12.03% endocrinologists, 1011/1580 63.99% PCPs) were learners between July 21, 2021, and December 31, 2021. Of those, 435 (74/435, 17% endocrinologists, 287/435, 66% PCPs) made at least one decision, were shown feedback in the secondary prevention case, and were included in this phase of the study.

Phase II: Real World

A total of 579 US physicians were learners in the intervention between July 21, 2021, and October 31, 2021. This time frame was chosen because data at the time of pull were available for 3 months of follow-up. Of those physicians, 424 had prescription claims for patients who were on treatment for T2D and had a T2D diagnostic code from July 2020 through January 2022. The 424 physicians who met the inclusion criteria were case-matched with nonparticipant physicians on the following parameters using propensity score matching through Syniti Match [34]: total volume of T2D prescriptions and top 10 prescriptions for patients with T2D (see [Multimedia Appendix 1](#) for prescription codes), profession, specialty, and geographic location (first 2 digits of zip code) using claims data. Of the 424 physicians, 157 intervention-group physicians and their matches had the complete 3 months of preintervention data and 3 months of postintervention data available in licensed claims data. The 157 intervention-group physicians represented 17,004 patients with T2D; 19 of 157 (12.1%) of the physicians were endocrinologists and 108 of 157 (68.8%) were PCPs. The 157

comparison-group physicians represented 16,049 patients with T2D; 16 of 157 (10.2%) of the physicians were endocrinologists and 91 of 157 (58%) were PCPs ([Multimedia Appendix 2](#)).

Measures

Phase I and Phase II

Participation

For the purposes of this study, learners are defined as those who made a decision and were shown feedback in the intervention.

Demographics

Medscape member registration provided country of residence, profession, and specialty.

Phase I: CME Simulation

Ordering Appropriate Tests to Assess Glycemic Control and CV Risk

Within the CME simulation, learners could order any tests to evaluate the patient with T2D. If they ordered tests that assessed glycemic control and CV risk, they met this learning objective. Appropriate tests to assess glycemic control included HbA_{1c}; appropriate tests for CV risk included fasting lipid profile. Learners had the opportunity to choose tests both before and after feedback was given, allowing for revision or reinforcement of their choices.

Selection of Appropriate Treatments for Secondary Prevention of CV Events In Patients With T2D

Within the CME simulation, learners could select any available pharmacologic and nonpharmacologic treatment for the simulated patient (or continue the treatment), such as oral glycemic control agents, treatments that are effective for blood glucose management and CV event prevention, weight management therapies, and exercise. If they selected treatments that are effective for CV event prevention and glycemic control, they met this learning objective. Decisions were collected before and after clinical feedback was given.

Phase II: Real World

Treatment Selection in the Real World

Insurance claims (private, commercial, government) in the United States that indicated a prescription fill were utilized to understand GLP-1 RA use at the clinician and patient levels. GLP-1 RAs included in the analysis were injectable liraglutide, dulaglutide, and semaglutide. Treatments had to have been prescribed for patients with T2D via *ICD-10* codes for T2D and drug names ([Multimedia Appendix 1](#)).

Statistical Analysis

Phase I: CME Simulation

Decisions were coded as correct or incorrect pre- and postfeedback. McNemar tests using the Rserve analytics extension for Tableau 2022 were conducted to examine the effect of the CME simulation's clinical feedback on decision-making to determine whether change in best decisions was statistically significant [35].

Phase II: Real World

Logistic regression using SAS (version 9.4; SAS Institute) was conducted to examine the intervention’s impact on clinician GLP-1 RA use for patients with T2D. The dependent variable was GLP-1 RA use postintervention (dummy coded; GLP-1 RA use=0). The independent variable of interest was intervention participation (dummy coded; intervention=1). Controls were chosen because of their association with use of GLP-1 RAs: being a diabetes specialist (dummy coded; endocrinologist=1), prior use of GLP-1 RAs (dummy coded; prior GLP-1 RA use=1), and number of patients with T2D in the 6-month period of the study (discrete).

Ethical Considerations

According to the US Department of Health and Human Services, this study was exempt from institutional review board approval because it was compliant with the Code of Federal Regulations (CFR) and Medscape privacy policy and leveraged study of existing data that were deidentified to the investigator under 45 CFR 46.104(d)(4); this study qualified for educational research exemption under 45 CFR 46.104(d)(1) [36].

Results

Phase I: CME Simulation

Across physicians, there was a 10 percentage point increase in correct responses from pre- to postfeedback (313/435, 71% to 352/435, 80.9%; $P<.001$) for assessing glycemic control and CV risk. There was a 29 percentage point increase in correct responses from pre- to postfeedback (178/435, 40.9% to 304/435, 69.9%; $P<.001$) for selecting treatment that addresses both glycemic control and CV event protection.

Phase II: Real World

Descriptive results showed that after participation, 69 of 157 (44%) intervention-group clinicians used GLP-1 RAs with their patients with T2D compared with 51 of 157 (32.5%) comparison-group clinicians (Multimedia Appendix 2). Overall, 39 of 157 (24.8%) intervention-group clinicians increased their use of GLP-1 RAs with their patients with T2D compared with 20 of 157 (12.7%) comparison-group clinicians.

Logistic regression results showed that being in the intervention group predicted GLP-1 RA use (odds ratio [OR] 4.49, 95% CI 1.45-13.97; $P=.001$). The intervention group was 4.2 times more likely to use GLP-1 RAs for patients with T2D than the comparison group, controlling for the number of total patients with T2D, being an endocrinologist, and prior use of GLP-1 RAs (Table 1).

Table 1. Logistic regression results for use of glucagon-like peptide-1 receptor agonists.

	Estimate	SE	P value	Odds ratio (95% CI)
Intercept	−3.89	0.57	<.001	N/A ^a
Total patients with type 2 diabetes	0.005	0.003	.06	1.01 (1.000-1.010)
Intervention	1.50	0.58	.001	4.49 (1.445-13.969)
Glucagon-like peptide-1 receptor agonist use in the preintervention period	5.42	0.65	<.001	225.53 (62.928-808.282)
Endocrinologist	1.09	1.005	.28	2.98 (0.416-21.384)

^aN/A: not applicable.

Discussion

Principal Findings

Results from decisions made within the CME simulation show an improvement in assessment of CV risk and glycemic control and selection of GLP-1 RAs within the simulation, and the matched case-control study shows that participation in the CME simulation was associated with significant increases in use of GLP-1 RAs.

Previous research has shown that short, case-based, web-based CME activities improved knowledge, competence, and self-reported performance in T2D management among health care professionals (HCPs) [37]. The results of this study go beyond the limitation of HCPs’ self-reported performance to suggest that patient simulation CME is reflective of real-world practice behavior, as there was concordance (within the same phase I time frame) in decision-making between the percentage of clinicians who selected GLP-1 RAs in the CME simulation prior to feedback (178/435, 41%) and the entire population of

clinicians using GLP-1 RAs for patients with T2D in the real world (394,133/947,437, 40.6%) prior to the intervention. However, there was not concordance between the percentage of clinicians who selected GLP-1 RAs in the CME simulation after feedback (304/435, 69.9%) and the percentage of clinicians using GLP-1 RAs in patients with T2D in the real world who also participated in the CME simulation (69/157, 44%). This difference is likely due to barriers faced in the real world that may limit prescribing (such as insurance coverage and patient readiness for injectables), as well as the limitation inherent in presenting only 1 patient type in the simulation, whereas many different patient types and possible care scenarios exist in the real world. For example, real-world patients may refuse certain treatments, but this possibility was not a factor in the CME simulation; thus, clinicians who participated in the simulation may need additional education that presents them with several patient types.

To provide context for physicians’ use of GLP-1 RAs postintervention, it is helpful to note the reasons they offered

within the CME simulation for selecting a treatment for secondary prevention of CV events. The top 6 reasons given by endocrinologists were drug efficacy (25/53, 47%), clinical trials supporting drug use (23/53, 43%), patient profile (20/53, 38%), guideline recommendation (17/52, 33%), familiarity with use (17/52, 33%), and indication for primary and secondary prevention (3/55, 5%). The top 6 reasons given by PCPs were guideline recommendation (80/195, 41%), clinical trials supporting drug use (76/195, 39%), patient profile (72/190, 37.8%), indication for primary and secondary prevention (70/195, 35.9%), efficacy (61/190, 32.1%), and familiarity with use (10/195, 5.1%).

Notably, drug efficacy held nearly inverse positions for endocrinologists and PCPs as a reason for treatment selection. This may indicate that endocrinologists take a more granular view of drug-specific factors described in guidelines [38], which show high efficacy for GLP-1 RAs but only intermediate efficacy for sodium-glucose cotransporter-2 (SGLT2) inhibitors. As nonspecialists, PCPs may be more reliant on guideline decision trees [38], which present the selection of GLP-1 RAs and SGLT2 inhibitors as an “either/or” treatment choice for patients with or at high risk for atherosclerotic CVD (ASCVD). Indeed, only 10 of 195 (5.1%) PCPs who participated in the CME simulation chose familiarity with use as a reason for treatment selection.

The most common reasons offered by endocrinologists for not selecting a treatment for secondary prevention of CV events were being unfamiliar with use (9/20, 45%), the drug being unavailable on the formulary (8/22, 36%), the patient not needing secondary prevention (4/23, 18%), and drug cost (4/23, 18%). The most common reasons given by PCPs were cost (36/92, 39%), being unfamiliar with use (36/92, 36%), the patient being uncomfortable with injection (21/90, 23%), and the drug being unavailable on the formulary (18/91, 20%).

Although in the real world physicians were using GLP-1 RAs with patients with T2D, the majority of their patients with CV event risk factors were still not receiving treatment; only 205/4372 (4.68%) of patients with T2D and ASCVD received GLP-1 RAs in the CME group after the intervention. More education is needed to address barriers to use of this class of drugs with patients who would benefit. Our results suggest that education for endocrinologists should emphasize familiarity with the use of GLP-1 RAs and recognition of patients who would benefit; for PCPs, education should aim to improve familiarity with use and comfort with injection.

Limitations

Possible limitations of our study are the inability to determine clinicians’ rationale for selecting GLP-1 RAs in practice, lack of randomization, small sample size for non-PCP participants, inability to determine if increased real-world use of GLP-1 RAs could be associated with all patient simulation CME interventions (ie, our results are localized to this intervention), and a follow-up limited to a 3-month period. The 3-month follow-up limits our ability to evaluate whether increased and new prescribing were a durable result associated with the intervention. However, durability of results for this type of study typically wanes the further out from the intervention period the results are measured. Unmeasured confounders such as motivation to take the intervention for the intervention group versus not take it for the control group were not considered. Simply the motivation to undertake the CME simulation could contribute to the effect found. Finally, the study design helped minimize the sampling bias, but there still may be unmeasured confounders. These may include consumption of other content, such as other CME activities, published studies, and collegial conversations, as well as level of motivation to adjust treatment selection.

Conclusions

A strength of this study is that claims data indicated that before the intervention, the percentage of physicians in the intervention group who treat patients with T2D with GLP-1 RAs (59/157, 37.6%) and the percentage of the total population of US physicians who treat patients with T2D with GLP-1 RAs were comparable (394,133/947,437, 40.6%). In addition, claims data showed that before the intervention, the percentage of patients treated with GLP-1 RAs by the intervention-group physicians (1056/17,004, 6.21%) and the percentage of patients treated with GLP-1 RAs in the US population were also comparable (848,607/13,731,508, 6.18%). These similarities between groups indicate that our study has direct implications for impact on public health. Ultimately, the results are generalizable for clinicians who treat patients with T2D, are members of clinical news and medical education platforms, and engage in web-based, simulation-based CME on the topic of newer T2D treatments that have potential benefits for glycemic control and CV protection.

A case-based virtual patient simulation CME intervention focused on secondary prevention of CV events in a patient with T2D was associated with increased selection of cardioprotective antihyperglycemic treatments in clinical practice among both endocrinologists and PCPs.

Acknowledgments

Abstract

Background: Innovation and entrepreneurship training are increasingly recognized as being important in medical education. However, the lack of faculty comfort with the instruction of these concepts as well as limited scholarly recognition for this work has limited the implementation of curricula focused on these skills. Furthermore, this lack of familiarity limits the inclusion of practicing physicians in health care innovation, where their experience is valuable. Hackathons are intense innovation competitions that use gamification principles to increase comfort with creative thinking, problem-solving, and interpersonal collaboration, but they require further exploration in medical innovation.

Objective: To address this, we aimed to design, implement, and evaluate a health care hackathon with 2 main goals: to improve emergency physician familiarity with the principles of health care innovation and entrepreneurship and to develop innovative solutions to 3 discrete problems facing emergency medicine physicians and patients.

Methods: We used previously described practices for conducting hackathons to develop and implement our hackathon (HackED!). We partnered with the American College of Emergency Physicians, the Stanford School of Biodesign, and the Institute of Design at Stanford (d.school) to lend institutional support and expertise in health care innovation to our event. We determined a location, time frame, and logistics for the competition and settled on 3 use cases for teams to work on. We planned to explore the learning experience of participants within a pragmatic paradigm and complete an abductive thematic analysis using data from a variety of sources.

Results: HackED! took place from October 1-3, 2022. In all, 3 teams developed novel solutions to each of the use cases. Our investigation into the educational experience of participants suggested that the event was valuable and uncovered themes suggesting that the learning experience could be understood within a framework from entrepreneurship education not previously described in relation to hackathons.

Conclusions: Health care hackathons appear to be a viable method of increasing physician experience with innovation and entrepreneurship principles and addressing complex problems in health care. Hackathons should be considered as part of educational programs that focus on these concepts.

Introduction

Given the rapid pace of societal and technological changes and the growing complexity of the health care sector, medical education is increasingly focused on skills that will improve the provision of high-value, quality patient care [1]. Innovation, interprofessional collaboration, and entrepreneurship are recognized as critical skills for training physicians to address the challenges of health care in the 21st century. These skills have been incorporated into medical education at the undergraduate and graduate levels [2,3]. The importance of teaching health-systems science is often described as the “third pillar of medical education” [4].

Medical education did not traditionally teach principles of quality improvement, interprofessional collaboration, and health care innovation [5]. Education in this area has improved with the incorporation of health-systems science content into the Association of American Medical College's Entrustable Professional Activities and Accreditation Council for Graduate Medical Education Milestones [2,3]. However, current curricula may not equip physicians with the innovative strategies needed to address larger and more complex health care problems [6-8]. Several medical schools now include innovation and entrepreneurship curricula that draw on techniques from business and design to develop approaches to solving challenging health care problems [8]. It should be noted that entrepreneurship in this context refers to considering the commercial viability of a solution and is strongly connected to evaluating the feasibility of an innovation [7]. The lack of faculty comfort with the principles of health care innovation and entrepreneurship is an identified barrier to the expansion of these programs [7]. Furthermore, the lack of exposure to these curricula among postgraduate physicians may limit their potential to address systems-level problems uncovered in practice. Despite this need, few programs exist that address continuing professional development in this area, and there is a need for an educational intervention to address this gap [5,8].

A hackathon, a portmanteau of the terms “hack” and “marathon,” is an intense competition where individuals or teams seek to develop novel solutions to challenging problems over a short time period [9]. Hackathons have their origins in the fields of computer science and engineering but more recently have been described as a method of innovation in health care that provides an educational opportunity for all participants [10]. Hackathons are based on the principles of gamification, which refers to the use of game elements (teams, time limits, and prizes) in nongame contexts [11]. Gamification is growing in popularity in medical education, but a complete understanding of the learning experience in gamified activities is still being described [11]. To our knowledge, the use of a hackathon as a method of increasing emergency physician knowledge of the principles of health care innovation and entrepreneurship has not been described.

We aimed to design, implement, and evaluate a health care hackathon with two main goals:

1. To improve emergency physician familiarity with the principles of health care innovation and entrepreneurship

2. To develop innovative solutions to 3 discrete problems facing emergency medicine (EM) physicians and patients

Methods

Development of the Hackathon

We, a team of innovation-focused physicians from Stanford's Department of Emergency Medicine, used the best practices for health care hackathons described by Silver et al [10] in 2016 to guide the development and implementation of our hackathon. Our first task was to identify internal and external stakeholders, explain our vision, and recruit needed support. The American College of Emergency Physicians (ACEP) had previously hosted innovation events at their annual Scientific Assembly, and they had expressed interest in hosting a similar event in the future. We partnered with them to conduct the event during the ACEP Scientific Assembly in San Francisco, California (October 1-3, 2022). We decided on 2 and a half days for the duration of the event, as we did not have access to a space continuously and wanted to allow those in our event the opportunity to be involved with other aspects of the assembly.

Several of the team members previously worked on the Stanford Emergency Medicine Innovations Symposium (StEMI X) [12] and are fellows in the Stanford Emergency Medicine Innovation and Design Fellowship. These members paired their clinical knowledge as practicing emergency providers with previous experience developing innovation competitions to help design this event. We recognized the need for further expertise in design thinking and the business side of innovation, so we partnered with faculty from the Stanford Byers Center for Biodesign [13], a training program designed for health technology innovators. This completed the assembly of our team, all aligned in the development of a successful event, but with unique perspectives: ACEP as a large professional organization representing an interest in developing innovation within the field of EM; Stanford's Biodesign School contributing academic and industry experience; and the Stanford Emergency Medicine Innovation and Design Fellows integrating the perspectives of these 2 organizations.

Through collaboration using weekly videoconference meetings and asynchronous Slack (Slack Technologies) discussions, we drew on professional experience in EM and health care innovation and arrived at 3 use cases for the teams to work on. These were as follows:

1. Deciding how to use data from personal wearable technology (heart-rate monitors, step-counters, etc) in the emergency or acute care setting
2. Determining how EM can integrate “hospital at home,” where patients receive inpatient-level care through remote monitoring in their home, into our practice
3. Addressing how health care surveillance tools can be used to identify patterns of disease and improve care for patients in the emergency department

These cases were purposefully nonspecific, selected to be relevant to emergency physicians, and included emerging topics without clearly defined solutions. We wished to encourage and motivate individuals to participate by allowing teams to select

their own specific problem and making these problems relevant to EM. We focused on the ideation part of the process. Teams were expected to develop an appealing pitch deck for a concept that could be prototyped in the future. We did not want to limit participants to those who had technical skills to develop a working model of their solution.

As a group, we settled on rules and developed a web-based registration form so that participants could select which use case they would like to work on. Advertisements were sent with registration materials 2 weeks before the ACEP Scientific Assembly ([Multimedia Appendix 1](#)). Since our target audience was physicians, we paired teams with coaches who had previous experience in health care innovation or biodesign. To further equip participants with the skills necessary to address their designated problems, we recruited a diverse group of speakers to give short presentations on health care innovation topics over the course of the hackathon. These talks were largely informed by content from the Institute of Design at Stanford, also known as the d.school [14], and School of Biodesign [13]. We planned a pitch competition during the final day of the event and recruited a group of judges in leadership positions in EM and health care innovation. The winning prize was free consultation with the Stanford Emergency Medicine Partnership Program [15], an organization of Stanford health care providers who provide consulting services for entrepreneurs in the health care innovation space.

Study Design

Previous research on health care hackathons has called for additional scholarship that focuses on the use of these events for medical education. Therefore, we designed a study to explore the educational experience of participants [9,10,16]. Our aim in this analysis was to create useful knowledge for the development of future hackathons in this space. With this goal in mind, we elected to conduct this research in a pragmatic paradigm with an abductive methodology. Unlike inductive research, aimed at building theory from interpretive methods, or deductive research, which often aims to objectively test theory, abductive research aims to find a middle ground, with equal engagement with empirical data and existing theory [17]. Rooted in the philosophy of pragmatism, abductive research aims to find the most logical solution and useful explanation for phenomena.

Data Collection

We planned to gather study data from a variety of sources: direct observation with field notes, informal interviews, web-based documents and communications, and a qualitative questionnaire. We adapted our questionnaire from content previously used by one of the authors to evaluate hackathons as a pedagogical tool for medical students studying population health [18]. A qualitative survey was used in that investigation, and we elected to do the same to allow for a more comprehensive description than a quantitative survey can provide. As others have described, web-based qualitative surveys are usually less burdensome for participants than face-to-face methods, and we anticipated that the considerable time commitment to the hackathon would be a barrier to recruiting participants for interviews [19]. Our survey adaptation was guided by web-based qualitative survey

methodology: questions were designed to be open, concise, and unambiguous, and we aimed to keep the survey short to minimize participant fatigue [19]. To optimize content and internal structure evidence, we adapted this survey using an iterative editing approach. The instrument was extensively tested by all the authors for survey functionality, matching of item content to construct, optimal phrasing, and quality control. The survey was piloted within the author group and pilot results were cross-checked for consistency, providing some evidence of response process validity. The survey was distributed to participants by email using the Qualtrics Survey Tool (Qualtrics, Inc) as well as the hackathon team Slack channels. Consent information documenting risks and benefits of participation in the research was distributed with the survey, and completion implied voluntary, informed consent.

Direct observation and informal interviews were performed in the field by one researcher (CP), and detailed field notes, memos, and a reflexivity journal were kept. The researcher's presence and purpose of conducting observations was made known to all participants. The participants were informed that no identifying information would be documented. Informal interviews were conducted during the hackathon by CP, and the researcher received assent from participants before questions were asked.

Ethical Considerations

The Stanford University Institutional Review Board deemed this research exempt (IRB 67403).

Reflexivity

All the authors are EM physicians. CP is a medical education scholarship fellow currently pursuing a master's degree in medical education, which includes formal training in qualitative research methods. JRD and GB are innovation fellows. MBT is a professor of EM, and RK is a chief EM resident. CP, RK, and JRD identify as male. MBT and GB identify as female. CP, JRD, GB, and MBT delivered educational lectures at the hackathon. JRD, GB, and RK were involved in the development and implementation of the Stanford Emergency Medicine Innovations Symposium and the hackathon.

Data Analysis

One researcher (CP) evaluated our data using an abductive thematic analysis based on Thompson's [17] approach. This method draws from the tradition of Braun and Clarke's [20] reflexive thematic analysis, which centers on the researchers' role in knowledge production, rather than "coding reliability" approaches, which often use multiple coders and aim for "reliable" or "accurate" coding. Based on our pragmatic paradigm, the subjective nature of a single researcher's analysis was acceptable to achieve our goal of a logical and useful explanation of the learning experience.

This process was aided by NVivo software (version 1.7; QSR International, Inc). The researcher familiarized himself with the collected study data and generated initial codes. He then reviewed the codes to develop themes. The next step was theorizing, the process of explaining the relationships between themes and data. In keeping with an abductive thematic analysis,

“clustering and explanation of themes [was] guided, but not determined by existing theoretical understanding” [17]. CP reviewed the themes in the context of theoretical knowledge and frameworks described in the medical education literature; however, a suitable model was not uncovered. Given that this was an exercise in innovation and entrepreneurship, the search was expanded to include educational literature in these fields. A framework for practice-based entrepreneurship education described by Neck et al [21] was uncovered that provided insight into the developed themes, and a reanalysis of the data sensitized by this framework was completed [21].

Results

Implementation

HackED! took place between October 1-3, 2022. Based on registration preferences, individuals were assigned to teams for each use case (3 total). At the start of the event, our preassigned teams were reorganized to accommodate the difference between participants who registered and those who showed up. Each team ended up with 4 core team members who completed the event from start to finish. During the conference, participants met at a dedicated space of the exhibition hall equipped with 4 long tables situated with 2 on each side of a small stage. Each team received a whiteboard, pens, and erasers, and participants were instructed to bring their own laptop or smart device. Each team was provided a dedicated Slack channel to facilitate communication within teams when they were not all gathered in the hackathon space.

The first day ran from 11:00 AM to 3:30 PM with a 1-hour lunch break and four 15-minute lectures. Lecture topics from the first day included innovation in health, needs assessment, design thinking, and considerations for advising or investing in health care start-ups ([Multimedia Appendix 1](#)). The second day ran from 9:00 AM to 3:30 PM again with a 1-hour lunch break and included lectures on securing funding and valuation, missing data, application testing, and artificial intelligence. During the second day, several registrants that had been delayed for the first day joined teams. The final day ran from 9:00 AM to 12:30 PM, and the pitch competition occurred between 1:30 and 3:30 PM. Lectures before the pitch competition were on applying the EM mindset to product management and innovation through experience.

Each of the teams delivered pitches to the panel of judges, who were physician leaders, accomplished innovators, informaticists, and technical experts. A final winner was selected based on feasibility and viability, impact, and progress on a solution.

Description of the Study Sample

In all, 12 participants completed the hackathon from start to finish. Participants identified as physicians (n=9), engineers (n=2), entrepreneurs (n=2), and user-experience designers (n=1). Some identified as multiple roles: 1 engineer/entrepreneur and 1 physician/entrepreneur. For physicians, their clinical experience ranged from 3-31 years in a variety of different clinical settings.

Learning Experience of the Participants

Framework

Neck et al's [21] formulation of entrepreneurship education requires “a practice-based approach as a model of learning to support entrepreneurial action.” This framework is based in Billet's [22] conception of practice theory, which postulates that learning activities can “generate richer understanding about practice, but from and through practice, not on behalf of it.” Neck et al [21] describe 5 specific practices in entrepreneurship education: practice of play, practice of empathy, practice of creation, practice of experimentation, and practice of reflection.

Practice of Play

This practice focuses on imaginative thinking, games, and competition to develop innovative ways of being entrepreneurial. Hackathons in general are gamified. They are competitions with prizes and time limits and are often team based. Several participants commented on their enjoyment of the competitive nature of the event and indicated that this led to greater enthusiasm for participation.

Practice of Empathy

This practice is characterized by the development of skill in feeling and understanding the perspectives of others. Participants were observed to consider needs from a variety of different perspectives: patients, financiers, physicians, and insurance companies. As one participant remarked, “there's a lot to consider...and what might be good for the patient might not be good business.” Participants also appreciated the difference in perspective others from the group shared: “I never had the opportunity to sit down with an engineer and a businessman, I always approach problems from the physician side.” “I reacted to your experience as an ED [emergency department] doc...it helped me understand the physician and patient experience more clearly.” Participants were seen to consider a variety of different perspectives, which was central to the practice of empathy.

Practice of Creation

This practice is informed by effectuation theory, which focuses on producing something of value with the resources at hand, even if other resources may be more desirable [23]. Several teams initially were challenged with the limited resources available, and they approached this difficulty in a variety of different ways. The hospital-at-home team felt they had a lack of expertise in this area, so they were able to use their professional contacts to identify someone at the conference with experience in this field to briefly consult with them. The wearable device team initially was working on a glucose-monitoring app, but they felt that they did not have enough collective knowledge to completely develop their idea, so they pivoted to developing a physician wellness app, which they had more experience with. The health care surveillance team recruited other EM physicians to join when they needed additional expertise. All of these activities demonstrate taking action with what is available rather than waiting for the perfect opportunity, a core idea in the practice of creation.

Practice of Experimentation

This practice in the tradition of entrepreneurship education draws from problem-based learning, evidence-based learning, and sense making [24]. It is the combination of these theories that encourage students to “act, learn from that action, and build the learning into the next iteration” [22]. This practice can also be seen as similar Kolb’s [25] experiential learning cycle, which describes concrete experience, reflective observation, abstract conceptualization, and active experimentation. The open-ended use cases developed for this event required experimentation with a number of potential problems and solutions, observed in the brainstorming process of all groups. Groups developed an idea, experimented with it in a variety of ways, and then either refined their idea or moved to a new concept. Here, interaction with group facilitators appeared to be a valuable method of experimentation. The wearable group was developing a glucose-monitoring idea and they explored the source of funding for this product with the group facilitator, which identified some problems with marketability. Others noted that discussion with the group identified “knowledge gaps” in their development process that led to refinement.

Practice of Reflection

This final practice is a metacognitive process to promote deep learning as a result of the other action practices. In entrepreneurial education, this is often facilitated, and although this was not our *a priori* intention, our qualitative survey encouraged reflection by several participants. When asked about learning experiences from the event, several participants commented on the team dynamics: “[I learned] how to interact with others when I’m not the formal leader,” and “[we] learned to come together to quickly listen to each other [and] generate ideas.” They also highlighted the event was “incredible for networking,” and as one person said, “[I] met incredible people that I never would have met otherwise.” Lecture content was also reflected on as being “valuable,” showing “the process of working through real problems,” and illustrating “design thinking tactics,” as well as, “the mental models one might use to evaluate medical business ideas.”

Others noted that the event would have an effect on future career plans: “I walked away with more clarity on the role I would like to play when working in healthcare innovation,” and, “[it] showed me some avenues to get more involved as a physician.” Overall, participants’ emotional response to the event was positive, commenting, “loved it,” “100% would repeat,” and “it was a joy...deeply satisfying to direct energy to something that could truly make the world a better place.” These data suggest that participants underwent reflective practice on their experience and learning.

Solutions Developed

The hackathon teams developed a pitch deck describing an idea for an innovative solution to each of the 3 use cases. The wearable health care data team developed “Happiness Rx,” a lifestyle-tracking app designed to combat physician burnout. The app would provide recommendations for ideal shift scheduling, sleep, and nutrition to optimize physician performance and improve mental health. The hospital-at-home

team developed “Dorothy.ai,” an app-based measure using validated clinical decision-making tools to screen patients to both determine the safety of discharge as well as the coordination of their expected resources needed at home. The surveillance team developed “ForecastER,” a subscription-based service for hospitals to get real-time maps of disease patterns to help emergency departments and hospitals prepare their staff and resources for potential patient surges. Based on the evaluation of the teams’ pitch, the panel of judges declared “Dorothy.ai” the winner. This solution had the greatest potential to translate into a viable product through continued development.

Discussion

Principal Findings

Here, we report on our experience with HackED!, a health care hackathon designed to improve EM physician experience with health care innovation by addressing 3 use cases relevant to EM. In terms of generating solutions to the use cases, the event was a success. We arrived at 3 innovative solutions that addressed the problems laid out for the competition.

Our data also support that the event was meaningful in terms of not only improving participant familiarity with health care innovation but in teaching entrepreneurship within a practice-based model. Health care education has generally focused on medical knowledge and practice, and the methodology used to inform those educational practices may not be effective in a different field. It is telling that we had difficulty capturing the learning experience of this event using educational theory commonly referenced in medical education literature. Health care innovation is more closely related to entrepreneurship as a practice, and thus, it makes sense that our results fit better in a framework from education in that field.

Considering *innovation and entrepreneurship* curricula are of growing interest at both the undergraduate and graduate levels of medical education, the lack of faculty comfort with these concepts as well as the methods of teaching them are of importance [7]. Similarly, in designing future events to teach health care innovation, organizers should be aware of the different educational approaches that may be of relevance to make these events of maximum benefit to participants.

Neck et al’s [21] practice-based approach, including practice of play, practice of empathy, practice of creation, practice of experimentation, and practice of reflection, provides a framework for considering the learning experiences of hackathons. Future organizers of hackathons or other innovation curricula may find this to be a useful framework in considering how participants engage with the event and might include aspects that encourage the development of the described practices.

Our experience demonstrates that a relatively short, competition-based event can have educational value in teaching entrepreneurship and innovation principles. Holding a hackathon may be a way to add to an innovation curriculum or incorporate some innovation experience into medical education at all levels. Through the adaptation of the problem and scope of the event, hackathons could be developed for problems unique to other

medical specialties or be used to develop more cross-specialty collaboration.

We plan to repeat this event in 2023 in partnership with ACEP and will draw upon our experience from this endeavor, as well as our new understanding of entrepreneurship education theories, to design our next hackathon in a way that encourages the 5 practices we describe in this paper. We also are exploring ways of continued involvement with teams to develop ideas into viable products and follow-up evaluations to determine the longer-term value of the knowledge gained. Finally, we are considering broader recruitment strategies to further diversify our participants and ways to optimize the timing of this event with the ACEP Scientific Assembly. The optimal size of teams for a hackathon of this type, the advantages of having multiple use cases versus a single use case, and the effects of the diversity of participants on learning are questions we hope to answer in the future.

Limitations

This report has several limitations. We describe one event with a limited number of participants, and it is likely that this sample only reflects the most enthusiastic participants. Our study was not designed or conducted in a way that objectively evaluates

learning experiences, and our inferences regarding learning based on self-reported information and observation were not designed to provide definitive answers about the knowledge gained by participants. Our study also does not provide information about the implementation or durability of this new knowledge. The outcomes seen in this study are not generalizable to a larger group of EM physicians, but we hope that our data inspire further investigation into hackathons as a viable learning modality for health care innovation.

Conclusion

Skills in health care innovation, interprofessional communication, and entrepreneurship are increasingly recognized as fundamental to tackling the complex health care challenges of the 21st century. These skills can empower health care professionals to lead from within. However, the lack of training in the development of these skills remains a barrier for such engagement and the resulting impact. Although a number of medical institutions are now offering such curricula, their broader adoption is limited by the lack of faculty training in this area. Health care hackathons appear to be one viable method of achieving this aim and could be offered within a continuing professional development program on health care innovation.

Acknowledgments

Finally, the authors would like to thank the American College of Emergency Physicians (ACEP), Stanford's Department of Emergency Medicine, and Stanford's Byers Center for Biodesign for supporting the event. We are appreciative to the ACEP HackED! team, and particularly to Dhruv Sharma, Michele Byers, Pawan Goyal, Joseph Kennedy, and Jodi Talia. We are also grateful to Drs Daniel Imler, Jason Lower, Matthew Strehlow, and Ryan Ribeira from Stanford's Department of Emergency Medicine. We would also like to thank Gordon Saul, Josh Makower, and James Wall from the Byers School of Biodesign.

Data Availability

The data sets generated during this study are available from the corresponding author upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: The COVID-19 pandemic has imposed unprecedented hurdles on health care systems and medical faculties alike. Lecturers of practical courses at medical schools have been confronted with the challenge of transferring knowledge remotely.

Objective: We sought to evaluate the effects of a web-based medical microbiology course on learning outcomes and student perceptions.

Methods: During the summer term of 2020, medical students at Saarland University, Germany, participated in a web-based medical microbiology course. Teaching content comprised clinical scenarios, theoretical knowledge, and instructive videos on microbiological techniques. Test performance, failure rate, and student evaluations, which included open-response items, for the web-based course were compared to those of the on-site course from the summer term of 2019.

Results: Student performance was comparable between both the online-only group and the on-site comparator for both the written exam (n=100 and n=131, respectively; average grade: mean 7.6, SD 1.7 vs mean 7.3, SD 1.8; $P=.20$) and the oral exam (n=86 and n=139, respectively; average grade: mean 33.6, SD 4.9 vs mean 33.4, SD 4.8; $P=.78$). Failure rate did not significantly differ between the online-only group and the comparator group (2/84, 2.4% vs 4/120, 3.3%). While lecturer expertise was rated similarly as high by students in both groups (mean 1.47, SD 0.62 vs mean 1.27, SD 0.55; $P=.08$), students who took the web-based course provided lower scores for interdisciplinarity (mean 1.7, SD 0.73 vs mean 2.53, SD 1.19; $P<.001$), opportunities for interaction (mean 1.46, SD 0.67 vs mean 2.91, SD 1.03; $P<.001$), and the extent to which the educational objectives were defined (mean 1.61, SD 0.76 vs mean 3.41, SD 0.95; $P<.001$). Main critiques formulated within the open-response items concerned organizational deficits.

Conclusions: Web-based courses in medical microbiology are a feasible teaching option, especially in the setting of a pandemic, leading to similar test performances in comparison to on-site courses. The lack of interaction and the sustainability of acquired manual skills warrant further research.

Introduction

The COVID-19 pandemic, caused by the SARS-CoV-2 virus, is arguably one of the biggest crises of modern times, with a multitude of repercussions on societal, economic, and medical systems [1-4]. A considerable fallout has affected school and university education alike [5]. In many countries, primary and secondary schools were closed during the first pandemic wave in spring 2020 [6-8], and the majority of universities were equally overwhelmed by this inciting incident [9]. Without a ready-made alternative plan, medical faculties suspended on-site education and were forced to hastily provide provisional materials via web-based platforms [10]. While the theoretical content of preclinical courses can be regarded as more easily adaptable to an online format, lecturers of practical courses, such as dissection or microscopy courses, struggle substantially to remotely present knowledge and manual skills [11-13]. As such, medical (or clinical) microbiology is a subject containing both theoretical knowledge and practical skills. Moreover, it is a subject that is not only critical for diagnostic purposes but is also important for understanding diseases caused by emerging pathogens such as bacteria, fungi, or viruses. Thus, it carries an inherent importance for medical students and, hence, future physicians, especially in the face of future potential pandemics and the already prevalent shortage in microbiologists and infectious disease specialists [14,15].

Although some literature on adapted medical education has cumulated since the beginning of the pandemic [16-20], data on the specific hurdles to implementing online or distant learning in medical microbiology during the COVID-19 pandemic are scarce. Particular challenges that could threaten the quality of online learning include technical difficulties, reduced social interactions, “video-conferencing fatigue,” and lack of focus among learners [21]. Some of these challenges touch upon “transactional distance,” which occurs between a student and a faculty member when interacting through a technological platform [22]. According to the Theory of Transactional Distance by Moore [23], learners in an online format experience particular interactions that not only include the faculty, other learners, and the subject matter, but also the delivery platform itself and external resources. However, with an adequate design and delivery strategy, online learning tools can overcome these hurdles [24]. Previously, additional online learning for medical microbiology had been shown to be beneficial for student performance in a before-and-after study from Dublin in the pre-pandemic era [25]. Here, we sought to evaluate the effectiveness of a web-based microbiology course compared with an on-site course format by measuring exam results and student perceptions at a single center in Germany during the first wave of the COVID-19 pandemic in 2020. We hypothesized that student performance and satisfaction would be comparable between the web-based and on-site course formats.

Methods

Study Design

During the summer term of 2020 (April to July 2020), medical students at Saarland University, Germany, participated in a

novel, web-based course in medical microbiology, delivered via a modular object-oriented dynamic learning environment (Moodle). Teaching content comprised lectures with audio recordings; clinical scenarios, including high-resolution imaging of agar plates and Gram stains; and instructive videos on microbiological techniques (see Figures S1-S4 in [Multimedia Appendix 1](#)). Techniques that were video-captured included a Gram staining; catalase, coagulase, and oxidase tests; and streak and spread plating. Photographs and videos were captured with a Panasonic Lumix DMC GH4 (Panasonic Corporation) and a Sigma 18-35 mm f/1.8 lens (Sigma Corporation), adapted with an MFT T Speed Booster XL (Metabones). Videos were edited with iMovie (Apple Inc).

Students' test performance, failure rate, and perceptions and satisfaction pertaining to the web-based course were compared to those of the students who took the on-site course in the 2019 summer term. Both cohorts were at the same time point in terms of the progression of their studies when starting their respective course.

Examinations

The written exam was performed on paper and in person. It consisted of 10 multiple-choice or open-item questions, covering the topics of medical microbiology, infectious diseases, infection prevention and control, and vaccinations (maximum of 10 points). The in-person oral exam included questions on 5 thematic complexes from the domains described above (maximum of 40 points). In addition, a written exam on virology had to be taken as well (maximum of 10 points). In total, the pass/fail score was $\geq 60\%$ (36 out of 60 points). Students can choose to postpone either the written or oral exam to a later time point or term. To assess the failure rate, only students who took both the written and oral exams were taken into account.

Student Evaluation

Course evaluation by the students was assessed using a 5-point Likert scale and open-text questions via a web-based platform. Invitations were distributed via email. The open-text answers from the students of the web-based course were analyzed in terms of their predominant value, either positive or negative, and simultaneously grouped into the following domains: interaction between students and faculty, practical content of the course, organizational aspects, and quality of content.

Statistics

Statistical analyses were performed with GraphPad Prism (version 8.0; GraphPad Software Inc), using a 2-sided *t* test for continuous variables and the Fisher exact test for categorical data. Using the Bonferroni correction in light of multiple testing needed for the 9 items obtained in the course evaluation, we calculated and set the statistical significance level at .0056 (.05/9).

Ethical Considerations

All data were obtained during the provision of student education. All data analyses were carried out in accordance with relevant regulations. No administrative permissions were required to access the raw data used in this study. Course evaluation by students was conducted anonymously and voluntarily. All data

used in this study were completely anonymized. In addition, quantitative data were obtained as an aggregated data set. Since no individual, identifiable student data, including biomedical, clinical, and biometric data, were used, neither ethical committee approval nor informed consent was necessary.

Results

Exam Results

In the web-based course, 100 students took the written exam, 86 took the oral exam, and 84 took both exams. Of the students in the on-site course, 139 took the oral exam, 131 took the

written exam, and 120 took both exams. The mean score for the written exam was 7.6 (SD 1.7; median 8, 95% CI 6-9) for the web-based course and 7.3 (SD 1.8; median 7, 95% CI 6-9) for the on-site course ($P=.20$) (Figure 1). The mean score of the oral exam was 33.6 (SD 4.9; median 35, 95% CI 30-38) for the web-based course and 33.3 (SD 4.8; median 34, 95% CI 30-37) for the on-site course ($P=.73$) (Figure 1).

There was no significant difference in the failure rate between students in both years. In the online-only group, 2 out of 84 students failed the exam (failure rate of 2.4%), compared to 4 out of 120 students in the on-site course (failure rate of 3.3%) ($P\geq.99$).

Figure 1. Whisker plots of the (A) written and (B) oral exam results for students who took the on-site course (2019) and the web-based course (2020).

Evaluation Results

The evaluation was completed by 96 and 32 students for the on-site and web-based courses, respectively. While lecturer expertise was rated similarly as high by students in both groups, students from the online-only group provided lower scores for the course's relevance for the exam, its level of interdisciplinarity, the motivation of the lecturer, and the knowledge they gained from the course (Table 1; Figures 2 and 3).

Differences were more distinct for the following aspects: quality of the course material and content, opportunities to ask questions and for discussion, intelligibility and clarity, and the extent to which the educational objectives were defined (Table 1; Figures 2 and 3). We asked for the level of challenge posed by the course as perceived by the students; while a similar proportion of students in both the web-based course and the on-site course regarded the educational challenge of their respective course as

adequate (18/31, 58% vs 56/94, 60%; $P\geq.99$), 19 out of 31 (61%) students from the online-only group stated that they would recommend the course compared to 73 out of 90 (81%) students in the on-site course ($P=.049$).

The main critique concerned organizational aspects (32 negative mentions vs 1 positive mention), including the overlap of exam dates with other subjects, delivery of information and content on short notice, and time constraints with regard to the exam preparation period. Furthermore, the lack of practice was criticized (2 negative mentions), although it was acknowledged that this was due to the special circumstances. Of note, the opportunities for interaction were rated predominantly positively (2 negative vs 5 positive mentions) in the open-text answers. Similarly, the quality of the content received 10 negative and 22 positive remarks. We specifically analyzed mentions of the unique multimedia content, identifying 16 additional positive mentions.

Table 1. Mean (SD) scores (1=very good, 2=good, 3=moderate, 4=weak, 5=very weak) for different items of the evaluation completed by students in the on-site course (2019) and the web-based course (2020).

Item	On-site course (n=96), mean (SD)	Web-based course (n=32), mean (SD)	P value
Grade the expertise of the lecturer.	1.27 (0.55)	1.47 (0.62)	.08
To what extent do you regard the course as relevant to the exam?	1.33 (0.52)	1.78 (0.70)	<.001
Grade the level of interdisciplinarity.	1.7 (0.73)	2.53 (1.19)	<.001
Grade the motivation of the lecturer.	1.43 (0.61)	2.59 (1.13)	<.001
Grade the knowledge gained from the course.	1.66 (0.77)	2.61 (1.05)	<.001
Grade the quality of the course material and content.	1.71 (0.8)	2.91 (1.28)	<.001
Grade the opportunities provided to ask questions and for discussion.	1.46 (0.67)	2.91 (1.03)	<.001
To what extent was the course intelligible and clear?	1.7 (0.77)	3.13 (1.29)	<.001
How well were the educational objectives defined?	1.61 (0.76)	3.41 (0.95)	<.001

Figure 2. Distribution of the online-only students' rating of the different aspects of the course on a 5-point Likert scale, from "very bad" (dark orange) to "very good" (dark blue).**Figure 3.** Distribution of the on-site course students' rating of the different aspects of the course on a 5-point Likert scale, from "very bad" (dark orange) to "very good" (dark blue).

Discussion

Principal Findings

The undisputed challenges posed by the COVID-19 pandemic demanded quick and feasible solutions for students of all levels and subjects on a global scale. In this before-and-after study performed in real-life pandemic circumstances, we showed that a web-based medical microbiology course for undergraduates led to similar learning outcomes, as measured by exam results, to a conventional, on-site course, even though several aspects of the web-based course were evaluated with significantly lower scores by the students. In addition, the web-based course was met with discontent owing to mainly organizational drawbacks.

Similarly, in a survey study from California by Shahrvini and colleagues [26], medical undergraduates, despite appreciating this more flexible way of learning, still perceived preclinical remote learning as disadvantageous due to the lack of opportunities for participation. Of note, this study revealed that the quality of instruction is a recurrent issue, as observed in our study, that merits further attention in order to improve distant learning experiences.

Depending on the geographical background of students, other challenges may also be prevalent, such as technical, infrastructural, or financial issues [27]. As shown previously [25], online elements can be beneficial for student performance in fields outside of medical microbiology; however, students have reported being in favor of a blended approach that combines the advantages of both self-paced online learning and in-person instruction in a lab environment [28].

Strengths and Limitations

Our study has several strengths. To the best of our knowledge, this is the first study to assess the hurdles faced by a medical microbiology faculty during the COVID-19 pandemic and the feasibility of a web-based teaching alternative while simultaneously monitoring the transition from in-person to online teaching formats. Furthermore, our approach contained an in-depth qualitative analysis of students' perceptions, which may help to deliver improved undergraduate education in the terms to come. This is especially true since further restrictions on on-site teaching are to be expected due to the presence and increasing predominance of SARS-CoV-2 variants of concern with increased transmissibility [29] and the somewhat slow rollout of mass vaccinations [30].

Our study also has limitations. First, this is a single-center experience from one country, which may limit its generalizability. Second, the noninferior exam results during the pandemic term may have been influenced by a more generous approach taken by the examiners than in the previous

year, owing to an inherent understanding of the difficult situation. Third, we analyzed the summer term of 2020, which already dates back several terms, while modes and methods of online learning have rapidly evolved since the beginning of the pandemic. Hence, even more modern technologies are available and used in both undergraduate and postgraduate teaching [31-35]. Furthermore, course evaluation by the students was voluntary, leading to a smaller number of respondents than students taking the respective exams. Another limitation is the fact that students could postpone the exam, which may have biased the results of the online-only cohort as some students may have been struggling with the new format. Last, but not least, it has to be acknowledged that the course duration and hence the content had to be reduced, and although the multimedia content was appreciated, manual skills cannot be completely substituted by web-based learning alone.

The acceptance of or resistance to online learning, in general, may partly be subject to generational influences as well. Students in 2020 and 2021 could presumably be more open, acquainted, and comfortable with (social) media as a platform for knowledge transfer and dissemination than students from previous decades [33,36-38].

The findings of our study are relevant for faculties and decision makers in medical education, primarily in, but not limited to, medical microbiology, as shown previously for other subjects as well (eg, virtual microscopy courses in histology [39]). Despite its largely devastating effects, the pandemic can be seen as a "catalyst of change" that also incited innovation, especially pertaining to (digital) education [40]. Novel technologies will continue to be introduced into medical education and ideally will facilitate the delivery of practical course content in online formats [41-45].

Conclusions

We showed that web-based undergraduate teaching in medical microbiology is partly feasible with the right tools, but efforts must be made to circumvent subpar organization, lack of face-to-face interaction, and limited opportunities for participation. Additionally, the lack of skills training is an undeniable issue that needs further focus, especially for subjects with practical content. With the unpredictable nature of the pandemic, it is highly conceivable that adaptations to medical curricula will be required both in the short and medium terms. Future studies should therefore focus on identifying the correct balance between online and on-site training, as well as evaluating the utility of novel tools and formats such as mobile phone apps, while also avoiding a lack of constructive alignment that can accrue due to the differences between the mode of teaching and the mode of assessment.

Acknowledgments

We thank all students and faculty members for their patience and endurance during these times. We are grateful to Thomas Volk, Barbara C Gärtner, and Norbert Graf for their thoughtful guidance prior to data analysis and to Dominik Monz and Silke Mahler for their assistance in data curation. This project was conducted as part of the Teach the Teacher Course for habilitation candidates at Saarland University Hospital.

Abstract

Background: The COVID-19 pandemic caused a major disruption in the health care sector with increased workload and the need for new staff to assist with screening and vaccination tasks. Within this context, teaching medical students to perform intramuscular injections and nasal swabs could help address workforce needs. Although several recent studies discuss medical students' role and integration in clinical activities during the pandemic, knowledge gaps exist concerning their role and potential benefit in designing and leading teaching activities during this period.

Objective: The aim of our study was to prospectively assess the impact in terms of confidence, cognitive knowledge, and perceived satisfaction of a student-teacher–designed educational activity consisting of nasopharyngeal swabs and intramuscular injections for the training of second-year medical students in the Faculty of Medicine, University of Geneva, Switzerland.

Methods: This was a mixed methods pre-post surveys and satisfaction survey study. Activities were designed using evidence-based teaching methodologies based on the SMART (specific, measurable, achievable, realistic, and timely) criteria. All second-year medical students who did not participate in the activity's old format were recruited unless they explicitly stated that they wanted to opt out. Pre-post activity surveys were designed to assess perception of confidence and cognitive knowledge. An additional survey was designed to assess satisfaction in the mentioned activities. Instructional design was blended with a presession e-learning activity and a 2-hour practice session with simulators.

Results: Between December 13, 2021, and January 25, 2022, a total of 108 second-year medical students were recruited; 82 (75.9%) students participated in the preactivity survey and 73 (67.6%) in the postactivity survey. Students' confidence in performing intramuscular injections and nasal swabs significantly increased on a 5-point Likert scale for both procedures—from 3.31 (SD 1.23) and 3.59 (SD 1.13) before the activity to 4.45 (SD 0.62) and 4.32 (SD 0.76) after the activity ($P<.001$), respectively. Perceptions of cognitive knowledge acquisition also significantly increased for both activities. For the nasopharyngeal swab, knowledge acquisition concerning indications increased from 2.7 (SD 1.24) to 4.15 (SD 0.83), and for the intramuscular injection, knowledge acquisition concerning indications increased from 2.64 (SD 1.1) to 4.34 (SD 0.65) ($P<.001$). Knowledge of

contraindications for both activities increased from 2.43 (SD 1.1) to 3.71 (SD 1.12) and from 2.49 (SD 1.13) to 4.19 (SD 0.63), respectively ($P<.001$). High satisfaction rates were reported for both activities.

Conclusions: Student-teacher-based blended activities for training novice medical students in commonly performed procedural skills seem effective for increasing their confidence and cognitive knowledge and should be further integrated within a medical school curriculum. Blended learning instructional design increases students' satisfaction about clinical competency activities. Future research should elucidate the impact of student-teacher-designed and student-teacher-led educational activities.

Introduction

The COVID-19 pandemic had a significant impact on health care delivery and caused important disruptions to medical education and training. These disruptions led to the realization of the major importance of clinical competency training at the pregraduate level, which is commonly based on in-person teaching activities and practical practice with peers on standardized and real patients. Access to all of these activities was restricted during most of the waves of the pandemic [1]. This forced medical schools and educators to reinvent teaching activities and use alternative and innovative ways for delivering education to ensure adequate training [2,3]. The methods typically used were videoconferences, e-learning modules, and other technology-based learning activities, which all proved to be efficient and beneficial during the pandemic [4-9].

However, clinical competencies require in-person teaching activities and practice, as mastering these skills is important for increasing students' confidence to perform procedural skills and ensure patients' safety [8]. In our institution, these activities are usually designed by senior physicians and led by student-teachers in the form of small group activities based on theoretical knowledge repetitions and low fidelity simulations. Student-teachers in our institution are medical students in their fourth to sixth year of medical school (in a 6-year curriculum).

The COVID-19 pandemic has put health systems worldwide under exceptional pressure and worsened an already existing shortage in medical staff [4,5,9-11] due to an overwhelming number of inpatient consultations, increased workload, as well as infected and quarantined health professionals [12,13]. Switzerland, for example, experienced a rapid deployment of national screening and vaccination programs, with more than 5700 vaccine doses administered daily [14] and more than 26,000 patients screened with nasal swabs [15]. This required additional workforce who could be rapidly trained to perform these procedures.

Within this context, teaching medical students to perform intramuscular injections and nasal swabs was a way to address this urgent need. However, as clinical medical educators were tied up in clinical activities related to the pandemic [4,9,16], the use of advanced medical students as student-teachers both for the design and as leaders of these activities might represent

an interesting, viable, and valuable opportunity for the teaching of the abovementioned procedural skills and could eventually be extended to other similar activities within the medical school curriculum. Indeed, there is an increasing body of evidence claiming the pedagogical benefits of student-teacher-based activities in terms of improved critical thinking, learning autonomy, motivation, collaboration, and communication skills [17]. These benefits seem to apply not only to novice students but also to the student-teachers leading the activity [18-20].

Although several recent studies discuss medical students' role and integration in clinical activities during the pandemic, knowledge gaps exist concerning their role and potential benefit in designing and leading teaching activities during this period [4,5,9]. Moreover, only a paucity of evidence exists concerning medical students' perceptions and satisfaction from peer-designed and peer-led activities during the pandemic. The aim of our study was to prospectively assess the impact in terms of confidence, cognitive knowledge, and perceived satisfaction of a student-teacher-designed educational activity consisting of nasopharyngeal swabs and intramuscular injections for the training of second-year medical students (6-year medical school) in the Faculty of Medicine, University of Geneva, Switzerland. Our main hypotheses were that these activities would increase the perception of confidence and cognitive knowledge about these procedures among novice medical students and that students would be satisfied by the activity and its related instructional design.

Methods

Ethical Considerations

Ethics exemption was received by the Geneva Canton's ethics committee as the project is outside the field of Human Research as described in the Federal Act on Research involving Human Beings. The exemption ID was REQ-2022-00453.

Medical Curriculum and Local Health Care System

The medical school of the University of Geneva provides a 6-year medical curriculum. The first 3 years are considered preclinical with the main concentration on basic sciences, anatomy, physiology, and pathology. Teaching activities are for the most part conveyed in a problem-based learning instructional design. Nevertheless, the clinical competencies

education starts from the second year with more than 80 educational activities and 5 formative assessments with standardized patients, with the goal of connecting scientific elements to clinical practice and preparing students for their clinical practice.

The medical school is affiliated with the Geneva University hospitals, which is the largest hospital in Switzerland and serves a regional population of more than 500,000 people. During the first 4 waves of the COVID-19 pandemic, the hospital handled more than 90% of the regional urgent and inpatient COVID cases. Medical students, as a regional policy, took active part in COVID-19-related care in different medical wards. Within this context, the mission of training novice medical students for nasopharyngeal swabs and intramuscular injections was given to the clinical competencies program team by the medical directors of the hospital and faculty with the purpose of increasing the potential workforce and alleviating pressure from the system.

Study Population

This study included second-year medical students from the Faculty of Medicine in the University of Geneva, Switzerland. We excluded those who had already participated in the activity's old instructional design and those who had explicitly stated they wanted to opt out of the study. The educational activities were mandatory, as it is a part of the regular medical school's curriculum, and all eligible students were requested to participate. However, the participation in this study was on a voluntary basis and any student had the ability to opt out at any given moment. With regard to the transfer of knowledge to clinical practice, the participation in the screening and vaccination activities was on a voluntary basis, coordinated by the medical directorate of the hospital, and there were no sanctions imposed on the students.

Student-Teachers

Fifteen medical students in their fourth, fifth, or sixth year of medical school are recruited each year to conduct 2 hours of practical training sessions for second-year and third-year medical students in the medical faculty of the University of Geneva.

Student-teachers are recruited through a yearly call for applications. The selection process for student-teachers is done by the clinical competencies program's faculty members and is based on academic achievements, teaching experience, and motivation. Each training session concerns the clinical competencies of a specific body system or a procedural skill. Before each session, including this study's activities, student-teachers are trained by a senior specialist concerning the seminar's specific theme.

Role of Senior Experts

The clinical competencies program in our institution is run by a group of senior experts in different clinical domains. Each expert is responsible for all the training materials and activities concerning his/her domain of expertise (eg, Cardiology, Respiratory Medicine, Neurology). All the activities in our study were coordinated by IZ. Each expert will conduct a 2-hour yearly training session targeted at student-teachers to prepare them for their own teaching activities with novice students. Within the context of this study's activity and due to time restrictions, 2 senior experts provided a 1-hour training for student-teachers and were present as backup during the activity. The activity's material and support were designed and drafted by the student-teachers themselves with the supervision of the program's coordinator IZ.

Activity Design and Timing Considerations

Instructional design was blended with presession e-learning and video-based self-directed learning tasks followed by a 2-hour in-person practice session in small groups of 4-6 students using simulators. The time for the completion of presession tasks was estimated to be 60 minutes. During the practice session, 1 hour was dedicated to nasopharyngeal swab collection and 1 hour was focused on intramuscular injection. This study, including the training session and pre-post surveys, was conducted between December 13, 2021, and January 25, 2022. The learning objectives for the activity were drafted based on the SMART (specific, measurable, achievable, realistic, and timely) criteria [21], and all verbs mapped to Bloom's taxonomy [22] for cognitive and psychomotor objectives (Table 1 and Table 2).

Table 1. Learning objectives of the nasopharyngeal swab activity.

Number	Learning objectives
1	Cite the most frequent clinical situations indicating the performance of a nasopharyngeal swab.
2	List the main indications to perform a nasopharyngeal swab.
3	List the main contraindications to perform a nasopharyngeal swab.
4	Identify the anatomical landmarks on the dedicated model.
5	Cite the standardized sequence for performing a nasopharyngeal swab.
6	Prepare the personal protective equipment necessary to perform a nasopharyngeal swab.
7	Perform a nasopharyngeal swab on the mannequin or on a patient: install the patient, name the tube with the patient's label, introduce the flexible swab into the nasal duct until it reaches the nasopharynx and make 3 rotations, close the tube, and send it to the laboratory.

Table 2. Learning objectives of the intramuscular injection activity.

Number	Learning objectives
1	Cite the two most frequent clinical situations indicating the performance of an intramuscular injection (drug administration, vaccine).
2	List the main indications to perform an intramuscular injection.
3	List the main contraindications to perform an intramuscular injection.
4	Name the 3 main complications of an intramuscular injection (local hematoma, allergic reaction, injection site infection).
5	Identify the different injection sites (deltoid muscle, large gluteal muscle, vast external muscle) on the mannequin or on a peer student.
6	Prepare the material to perform an intramuscular injection.
7	Perform an intramuscular injection: install the patient, maintain asepsis during the procedure, prick the deltoid/gluteus maximus muscle ensuring no reflux before injecting, apply a protective dressing, and monitor.

Technology and Media Use

The e-learning module for the nasal swab was created using Rise Articulate 360 (Articulate Global Inc) [23] and

multiple-choice questions, text explanations, images, videos, and self-evaluation questions (Figures 1 and 2).

Question

05/10

Dans quel ordre devez-vous réaliser les opérations suivantes pour réaliser un test diagnostic?

Reliez (drag and drop) le nom de l'action au numéro de l'étape

Préparer le matériel de prélèvement	Première étape
Préparer la zone de test	Deuxième étape

Practical Session/Activity

Random groups of 4-6 students were formed and led by student-teachers. The first 15 minutes were dedicated to discussing indications, contraindications, and hygiene measures for performing nasal swabs and intramuscular injections. This was followed by 10 minutes for demonstration of the procedural skill by the student-teacher, followed by dedicated time to perform the procedures on simulators under the supervision of the student-teacher.

Activity Assessment

No formal assessment was done. Participation in the activity qualified as a passing grade.

Pre-Post Activity Evaluation

To assess students' perceptions of confidence in performing nasopharyngeal swabs and intramuscular injections as well as cognitive knowledge concerning indications and contraindications for both procedures, faculty members designed and validated presurveys and postsurveys. Answers to all

surveys were based on a 5-point Likert scale (1=not at all, 2=rather not, 3=I don't know, 4=rather yes, 5=perfectly) with the last question being an open-ended question for general comments. The preactivity survey was sent a few days before the activity and the postactivity survey was sent on the following day after the activity with several reminders to ensure an acceptable participation rate. An additional survey was created to assess students' satisfaction in the designed activities.

Postsession Satisfaction Survey

All students were given the opportunity to complete a 13-question web-based survey (Table 3) on their satisfaction based on a validated tool [24] to assess the perceived satisfaction and quality of the activity's instructional design. The survey was created and disseminated using the LimeSurvey platform [25]. Answers to all questions were based on a 5-point Likert scale (1=I strongly disagree, 2=I disagree, 3=neither one nor the other, 4=I agree, 5=I completely agree) with the last question being an open-ended question for general comments. A score of ≥ 4 for each question was considered an acceptable rating of the activity's quality.

Table 3. Satisfaction survey questions.

Number	Questions
1	I believe I acquired the learning objectives related to the nasopharyngeal swab and intramuscular injection.
2	The e-learning and simulation on the nasopharyngeal swab were effective and useful.
3	The e-learning on the nasopharyngeal swab was motivating and helped me to learn.
4	The e-learning combined with the simulation provided me with a variety of teaching methods allowing me to acquire the technical skills related to nasopharyngeal smear and intramuscular injection.
5	The practical training sessions on the nasopharyngeal smear and the intramuscular injection allowed me to acquire the knowledge and skills necessary for my immersion in the clinical environment.
6	These practical training sessions on the nasopharyngeal swab and the intramuscular injection are relevant during my learning curriculum.
7	I know how to use this simulation to remember the important elements of both technical procedures in case I have to perform them in the future.
8	I will know where to find the necessary references if I have any doubts about my skills in performing a nasopharyngeal swab or an intramuscular injection.
9	The student-teacher provided me with appropriate resources and references when needed.
10	The way the student-teacher taught the simulation was adapted to my way of learning.
11	The student-teacher's responsibility is to give me constructive feedback on the technical gestures of the nasopharyngeal swab and the intramuscular injection.
12	The e-learning and simulation on the nasopharyngeal swab were effective and useful.
13	The e-learning on the nasopharyngeal swab was motivating and helped me to learn.

Statistical Analysis

A mixed methods analysis was performed. Quantitative data were presented as mean (SD). We compared data between the 2 student groups by using the 2-sided *t* test for means. Stata version 16 (StataCorp LLC) was used for all statistical analyses [26]. A *P* value <.05 was used to indicate significance. Qualitative data were analyzed using a thematic analysis approach.

Results

Preactivity and Postactivity Survey Results

There were 192 eligible students. Out of them, 84 were excluded as they had participated in the activities in their old format. A total of 108 second-year medical students who met the inclusion criteria participated in both activities and were invited to answer

the survey. Among them, 82 (75.9%) responded fully to the preactivity survey and 73 (67.6%) to the postactivity survey.

Students' perception of knowing the indications for performing both procedures significantly increased from 2.7 (SD 1.24) to 4.15 (SD 0.83) for the nasopharyngeal swab ($P<.001$, Table 4) and from 2.64 (SD 1.1) to 4.34 (SD 0.65) for the intramuscular injection ($P<.001$, Table 5). We observed a similar increase in the contraindications, with the average score increasing from 2.43 (SD 1.1) to 3.71 (SD 1.12) and from 2.49 (SD 1.13) to 4.19 (SD 0.63), respectively. Novice students' confidence in their ability to perform a nasal swab significantly increased from 3.59 (SD 1.13) before the activity to 4.32 (SD 0.76) after the activity ($P<.001$, Table 4, Figure S1 in Multimedia Appendix 1). Regarding intramuscular injection, confidence increased from 3.31 (SD 1.23) to 4.45 (SD 0.62) after the activity ($P<.001$, Table 5, Figure S2 in Multimedia Appendix 1).

Table 4. Survey questions and responses on nasopharyngeal swab.

Question	Preactivity survey (n=82), mean (SD)	Postactivity survey (n=73), mean (SD)	<i>P</i> value
I think I know all the indications for a nasopharyngeal swab.	2.7 (1.24)	4.15 (0.83)	<.001
I think I know all the contraindications for a nasopharyngeal swab.	2.43 (1.1)	3.71 (1.12)	<.001
I am confident in my ability to realize a nasopharyngeal swab.	3.59 (1.13)	4.32 (0.76)	<.001

Table 5. Survey questions and responses on intramuscular injection.

Question	Preactivity survey (n=85), mean (SD)	Postactivity survey (n=74), mean (SD)	P value
I think I know all the indications for an intramuscular injection.	2.64 (1.1)	4.34 (0.65)	<.001
I think I know all the contraindications for an intramuscular injection.	2.49 (1.13)	4.19 (0.63)	<.001
I am confident in my ability to realize an intramuscular injection.	3.31 (1.23)	4.45 (0.62)	<.001

Satisfaction Survey Results

A total of 56 (51.2%) novice students responded to the satisfaction survey sent after the activity. Attainment of activity's learning objectives was rated at 4.38 (SD 0.62) (Figure S3 in [Multimedia Appendix 1](#)) on a 5-point Likert scale. The ability of the blended learning design to help acquire competencies was rated at 4.11 (SD 0.71). The e-learning on the nasopharyngeal swab was considered effective and useful with an average of 4.3 (SD 0.69). Students perceived it as a motivating tool to learn, with a mean of 4.2 (SD 0.72) and found the practical activity relevant to their medical curriculum, with a rate of 4.54 (SD 0.76) on the 5-point Likert scale. Student's ability to use the simulations to remember the important elements of both technical procedures in case of need to perform them in the future was rated at 4.27 (SD 0.67) and their ability to find the right information in case of doubt received a score of 4.29 (SD 0.82). Novice students considered the practical training sessions useful to acquire the knowledge and skills necessary for their immersion in the clinical environment with a mean of 4.34 (SD 0.67).

Regarding peer-to-peer teaching, providing constructive feedback on the procedural skills was considered a part of instructor's roles, with a rate of 4.55 (SD 0.66) on a 5-point Likert scale. The student-teacher provided novice students appropriate resources and references when needed, with a mean of 3.75 (SD 0.98), and global appreciation of the student's teaching was rated with a mean of 4.64 (SD 0.59). Novice medical students considered the instructional design of the activity to fit their study methods, with a rating of 4.57 (SD 0.68).

Open-ended Answers

The topics raised in the open-ended answers could be summarized into 4 main themes ([Table 6](#)). Novice students seemed to have seized the relevance of the activity in the public health crisis and were happy to acquire competencies, which could help them participate in the collective effort. One student said, "Very relevant teaching in the context of the current pandemic. It was very interesting to receive this training to participate in the common effort in the vaccination and screening centers." Moreover, students found the blended design useful to prepare for the practical activity. Further, students would have liked to have additional time to practice the procedures.

Table 6. Medical students' open-ended answers (translated from French).

Theme	Illustrative quotes
Activity relevance	<p>...The module was really interesting and well explained, useful for my future career.</p> <p>...Very relevant teaching in the context of the current pandemic. It was very interesting to receive this training in order to participate in the common effort in the vaccination and screening centers.</p> <p>...Useful learning for the current health situation.</p> <p>...Useful and necessary session in times of pandemic.</p> <p>...Very good module. I work in a testing center and it was very helpful.</p>
Instructional design	<p>...E-learning is very useful to review the knowledge.</p> <p>...The practical part was a good summary of the e-learning main points, allowing a relevant synthesis of the information.</p>
Activity content	<p>...Regarding the content of the course's written guide, more details would have been beneficial.</p>
Activity context	<p>...It should have been stated more specifically whether this was considered as training or as a formation to participate in the vaccination or screening campaign. The nasopharyngeal teaching was a bit quick (not much information in terms of indications and contraindications were recalled).</p> <p>...In general terms, it's relevant to have integrated this in our curriculum, thanks!</p> <p>...The intramuscular injection was very well presented and conducted. ...However, the nasopharyngeal smear was very quick, with few explanations. Considering the actual conditions, I understand the lack of time, but I would have liked more explanations and precisions on this invasive practice.</p> <p>...Very good and useful course. I would have appreciated a little more detail on indications and contraindications in some groups.</p> <p>...Take the time to explain how to prepare the vaccines (we only saw how to inject them) and how the SARS-CoV-2 antigen test works.</p> <p>...It was a very quick session, as well as all the technical procedure lessons we had. I don't know if I'll feel comfortable practicing it on my own.</p>

Discussion

Principal Findings

Our study aimed to examine the impact, in terms of confidence, cognitive knowledge, and satisfaction, of a student-teacher-designed and student-teacher-led activity to train second-year medical students at the University of Geneva, Switzerland, for nasopharyngeal swab collection and intramuscular injections during the COVID-19 pandemic. We provide several important insights in this study. First, the activity that was both designed and led by advanced students significantly increased the perception of confidence as well as cognitive knowledge among novice peers. Second, high scores in the satisfaction survey seem to indicate students' acceptability for student-teacher-led activities for the teaching of basic clinical competencies. Third, the blended instructional design seemed to be effective for attaining learning objectives, increasing motivation, and providing callback references.

Comparison to Prior Work

Recent studies have focused on the role and integration of medical students in clinical activities during the COVID-19 pandemic. However, there is a paucity of evidence concerning their potential role as teachers and instructional designers during and outside the context of the COVID-19 pandemic [4,5,9,27]. This role might be of interest during a pandemic period and could provide several benefits both to novice students (student-teachers) as well as the academic system [17]. In fact, many medical educators were overloaded with clinical activity, creating a shortage of workforce in academic settings. Advanced medical students with adequate supervision could help address this manpower gap in certain areas. In fact, in our study, the activities designed and led by students were effective in increasing novice peers' confidence and cognitive knowledge for basic clinical competencies and were rated with high student satisfaction. Moreover, providing medical students with the role of a teacher and instructional designer might increase their motivation [18,19], promote continuous education, and develop the scholarship of teaching, as it will help them take control of their own curriculum and provide more value for the role of a teacher [8].

In addition, current body of evidence shows that student-teacher-led activities are beneficial not only to the learners by increasing their academic performance [28,29] but also to the student-teachers. In their systematic review, Yu et al [30] showed that peer teaching achieved similar short-term learners' outcomes as the outcomes in activities run by the senior faculty. Moreover, systematic reviews showed a beneficial effect, both academically and professionally for student-teachers [29,30]. Similar results were reported by Benè and Bergus [29] in the context of problem-based learning and clinical skill activities, showing comparable performance in students trained by student-teachers versus those trained by faculty members. Their study [29] showed a positive impact of peer teaching on student-teachers themselves by enhancing their learning in relation to the content being taught. Our study reinforces these findings and provides more evidence to the beneficial effects of student-teachers. The integration of students as faculty

support for clinical competencies teaching within and outside of crisis periods could be of value, and widespread implementation throughout the clinical medical curriculum should be considered.

Potential Benefits of Blended Learning for Clinical Competencies Education

Blended learning is defined as a combination of traditional face-to-face learning and asynchronous or synchronous e-learning [31]. It was increasingly used as an instructional design during and outside the context of the pandemic [2] and was shown to be effective in terms of improving communication skills [32] and increasing students' satisfaction [17,33,34] and confidence through the teaching activities [31,35,36]. Recent studies have shown the benefit of a blended design as well for the teaching of clinical skills [8,17,31,36]. Our study provides more evidence to support the usefulness of blended learning in this context. In fact, the use of the e-learning in our study in addition to the practice sessions was perceived as motivating and useful and provided a variety of teaching methods to stimulate learning. Indeed, a blended design for the teaching of clinical competencies can have several advantages. First, presession e-learning activities and providing interactive cognitive knowledge teaching can generate better preparation for the practice sessions, thus freeing up more time for the actual practice on simulators or with peers. Second, the designed material can be used as callback references and promote the use of high-quality and validated references by medical students in their curriculum. Finally, the designed material can be used by more advanced learners for training and callback and can potentially be translated to other disciplines such as nursing to enhance the training opportunities [17]. Therefore, the use of a blended learning design for clinical competencies teaching seems to be of value and should be further integrated within the medical school's curriculum.

Strengths and Limitations

Our study has several limitations. First, the sample size was small but did represent all the potential exposed students to the activity. In fact, all second-year medical students who did not already participate in the activities in their old format were eligible to participate in both activities. Second, the observational nature of the study could decrease the confidence in our results. Third, we did not have a control group of learners who were taught the same competencies with a different instructional design; however, as to the novelty of the activity's design and the specific context of the pandemic, such control might not have been possible to establish. Future comparisons of students' perceptions for the same activities run by senior experts versus those run by student-teachers would be of value to further assess the impact of student-teachers' integration in teaching. Finally, we did not correlate our results of confidence, cognitive knowledge, and satisfaction to a measurement of performance. The measurement of performance as with the use of standardized scores in the form of Objective Structured Clinical Examinations could indeed be of value to attest the impact of student-teacher-led activities on clinically relevant outcomes and students' preparedness for clinical practice. The latter will provide quantitative and standardized data, which

could increase the confidence in our results. Due to the logistical constraints in the pandemic context, this was outside of the scope of our study; however, this will be the subject of our future work. The strengths of our study include the fact that the activities and related surveys were based on validated evidence-based tools and instructional design. In addition, the prospective recruitment of participants as well as the high participation rate in all the surveys represent important strengths of our work.

Conclusions and Future Directions

The COVID-19 outbreak caused a major disruption within the health profession education and forced many institutions to reinvent teaching activities in a reality where the educational workforce was limited. Teaching of clinical competencies within

this context represented an additional and unique challenge, as it required in-person teaching and introduction of new competencies to the curriculum. The use of student-teachers to lead and design such activities seemed to be effective to increase confidence and cognitive knowledge among medical students and resulted in high satisfaction ratings among learners. Blended learning design has the potential to increase learners' satisfaction in clinical competency activities and provide more time for in-session practice. Designed teaching material could be introduced in postgraduate medical education and other medical disciplines. Further research should be performed to better understand the impact of student-teacher-led and designed activities on the quality of learners' clinical competencies and their performance.

Acknowledgments

We would like to thank the Johns Hopkins University's Master of Education in the Health Professions program's staff for their guidance and availability. IZ received financial support from the Hubert-Tuor Foundation to attend the Master of Education in the Health Professions program at Johns Hopkins University.

Data Availability

The data sets generated during or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

JB wrote the manuscript, designed the activity, and performed literature review and statistical analysis. CT wrote the manuscript, designed the activity, and performed literature review and statistical analysis. IZ was the main investigator who wrote the manuscript, designed the activity and evaluation, and performed the literature review and the statistical analysis. ES critically revised the manuscript, assured clinical quality, and took part in activity and evaluation design and approval. MN critically revised the manuscript and took part in activity design and approval. GLS critically revised the manuscript and took part in activity design and approval. KB critically revised the manuscript and took part in activity design and approval.

Conflicts of Interest

None declared.

Abstract

Background: Field notes, a form for resident-preceptor clinical encounter feedback, are widely adopted across Canadian medical residency training programs for documenting residents' performance. This process generates a sizeable cumulative collection of feedback text, which is difficult for medical education faculty to navigate. As sentiment analysis is a subfield of text mining that can efficiently synthesize the polarity of a text collection, sentiment analysis may serve as an innovative solution.

Objective: This study aimed to examine the feasibility and utility of sentiment analysis using 3 popular sentiment lexicons on medical resident field notes.

Methods: We used a retrospective cohort design, curating text data from University of Toronto medical resident field notes gathered over 2 years (from July 2019 to June 2021). Lexicon-based sentiment analysis was applied using 3 standardized dictionaries, modified by removing ambiguous words as determined by a medical subject matter expert. Our modified lexicons assigned words from the text data a sentiment score, and we aggregated the word-level scores to a document-level polarity score. Agreement between dictionaries was assessed, and the document-level polarity was correlated with the overall preceptor rating of the clinical encounter under assessment.

Results: Across the 3 original dictionaries, approximately a third of labeled words in our field note corpus were deemed ambiguous and were removed to create modified dictionaries. Across the 3 modified dictionaries, the mean sentiment for the "Strengths" section of the field notes was mildly positive, while it was slightly less positive in the "Areas of Improvement" section. We observed reasonable agreement between dictionaries for sentiment scores in both field note sections. Overall, the proportion of positively labeled documents increased with the overall preceptor rating, and the proportion of negatively labeled documents decreased with the overall preceptor rating.

Conclusions: Applying sentiment analysis to systematically analyze field notes is feasible. However, the applicability of existing lexicons is limited in the medical setting, even after the removal of ambiguous words. Limited applicability warrants the need to generate new dictionaries specific to the medical education context. Additionally, aspect-based sentiment analysis may be applied to navigate the more nuanced structure of texts when identifying sentiments. Ultimately, this will allow for more robust inferences to discover opportunities for improving resident teaching curriculums.

Introduction

Competency-based medical education emphasizes skills development and educational outcome measures (eg, entrustable professional activities) designed within an individualized timeline of progression [1]. One increasingly adopted tool used in competency-based medical education across Canadian medical training programs is field notes. Preceptors fill out these structured feedback forms for residents, evaluating their “Strengths” and “Areas of Improvement” in a clinical encounter. They are a qualitative way to track learner progress and improve feedback documentation [2]. Residents believe that using field notes increases feedback volume [3], focuses the feedback, and makes the feedback more useful overall [4].

Methods that computationally summarize the growing amounts of text data from field notes are needed. In their raw form, extensive text collections from field notes are difficult for faculty program leaders to navigate. Efficient strategies to synthesize and compare the sentiment in field notes are valuable for evaluating information to help improve the teaching curriculum.

Sentiment analysis is a subfield of text mining or natural language processing [5]. It is the process of computationally detecting whether a piece of text is inherently positive, neutral, or negative. In health care, sentiment analysis has been used to monitor public health care concerns on social media [6] and to synthesize patient reviews of health care services in England [7]. Despite rising interest in machine learning tools, sentiment analysis has been applied sparingly to medical education and resident performance evaluation [8].

In this study, we assess the feasibility and utility of using sentiment analysis to synthesize a large corpus of medical education field notes. We apply 3 commonly employed sentiment lexicons (ie, BING, AFINN, and NRC) [9]. In health care, the 3 lexicons have been comparatively evaluated on tweets from nurses during the COVID-19 pandemic [10] and electronic health records for suicide risk assessments [11]. We will be the first to use these lexicons to analyze feedback generated in resident-preceptor field note performance evaluations. Quantitatively summarizing sentiment information from field notes will allow for subsequent analysis that may reveal valuable insights for medical education program design. For example, predicted sentiment scores can be correlated with learning parameters such as teaching locations or type of patient encounter. Predicted sentiment scores can also be correlated with resident and preceptor characteristics to preemptively identify residents falling behind and preceptors who might apply systematically different evaluation standards from others. All these results inform essential decision-making regarding improving a training program.

Methods

Study Design and Setting

The study used a retrospective cohort design. We used clinical encounter-based field notes written between July 1, 2019, and June 30, 2021, by preceptors for family medicine residents from

14 training sites affiliated with the University of Toronto's Department of Family and Community Medicine.

In field notes, preceptors write comments on their perception of the strengths and areas of improvement of the resident's performance during a clinical encounter. Preceptors also provide an overall performance rating for the clinical encounter on a 5-point Likert scale, with 1 indicating the poorest and 5 indicating the best performance. The categories that preceptors fill out in the field note template used at the University of Toronto's Department of Family and Community Medicine are as follows: assessee, date of encounter, state of residency, assessment tool (CanMEDs roles), rotation service, site, area(s) of observation, level of performance or competency (5 levels), strengths, and actions (areas of improvement).

Sentiment Lexicons

We applied lexicon-based sentiment analysis using 3 well-established sentiment dictionaries: BING, AFINN, and NRC. The BING dictionary was first designed around the domain of e-commerce customer reviews [12]; AFINN was created for synthesizing Twitter microblogs [13]; and NRC was a large, crowdsourced lexicon geared toward a more generalized domain [14]. We reported the number of unique words in each lexicon and the number of unique words labeled by each lexicon within our text data. From this subset, a single subject matter expert (KL) then labeled and removed words deemed ambiguous in the context of medical resident clinical teaching; another study team member (CM) reviewed and adjudicated decisions regarding ambiguous words identified by KL.

Statistical Analysis

Text was extracted from preceptor-resident field notes from the “Strengths” and “Areas of Improvement” sections, and word-level sentiment analysis was applied to these sections, respectively. On the word level, we identified the most prevalent words of each sentiment in each section and calculated their frequencies. On a document level, a sentiment score output was generated by computing the mean polarity of all words labeled. Documents were further classified as positive, neutral, or negative based on their sentiment score.

Agreement between the 3 sentiment dictionaries was evaluated by calculating Cohen weighted kappa statistics.

To assess the concurrent validity of the sentiment scores, we measured the association between our derived document-level sentiment scores and overall preceptor ratings (measured on a 5-point Likert scale).

Ethics Approval

Approval for this study was obtained from the University of Toronto research ethics board (protocol 41745).

Results

Overview

Between July 1, 2019, and June 30, 2021, a total of 20,455 field notes written across 14 resident training sites affiliated with the University of Toronto Department of Family and Community Medicine were included in the analysis. Of them, 20,452 field

notes contained a “Strengths” text entry, and 20,411 field notes had an “Areas for Improvement” entry. The median number of words for the strengths text was 28 (IQR 16-44), whereas the median length of the areas for improvement text was 14 (IQR 4-29) words. The study sample included 662 unique residents and 500 unique preceptors. The median number of field notes per resident was 27 (IQR 13-44), whereas the median number of field notes per preceptor was 22 (IQR 5-59). Completion of a field note was not mandatory after clinical encounters.

Word-Level Sentiment Analysis: Restricted Applicability of Established Sentiment Lexicons in Field Note Feedback

The following 3 lexicon dictionaries were individually used to assess the sentiment of field note text: AFINN, BING, and NRC. The degree of applicability was assessed for each dictionary by evaluating the proportion of ambiguous words out of the total number of unique words labeled by our corpus ([Table 1](#)).

Table 1. Proportion of ambiguous words labeled in field note text data by three standard lexicon dictionaries.

Dictionary	Unique words in dictionary, n	Unique words labelled, n	Ambiguous words labelled, n	Proportion of ambiguity
AFINN	2477	1081	305	0.282
BING	6780	1885	550	0.291
NRC	5464	2039	720	0.353

The 3 dictionaries showed a similarly restricted level of applicability when applied to our medical education field note corpus. About a third of all uniquely labeled words across all 3 dictionaries were labeled as ambiguous, with the NRC lexicon having a slightly higher ambiguity rate than the others.
