among clinicians that encouraging access to web-based records may exacerbate patient anxiety, lead to increased contact time, or risk disagreements and requests to change documentation. We observe that current recommendations in the published and gray literature offer advice on the benefits and risks of accessing ORA, how to maintain password or portal security, and how to discuss errors or disagreements in their notes with clinicians [14,36].

Combined, these clinician and patient support strategies are valuable but have inherent limitations. Training interventions may be variously implemented and take time to become established in mainstream medical education. Even beyond mainstream inclusion of training in medical curricula, it will also be necessary to target the so-called “hidden curriculum”—the set of unspoken and implicit rules and values that trainees may pick up from their mentors and colleagues within clinical practice [37]. It is unclear whether even those strategies that attempt to convert senior or experienced doctors to the cause are sufficient to counter the hidden curriculum or to neutralize the formation of documentation habits that may not be in keeping with the ORA mandate whereupon clinical notes may now be read by patients and caregivers.

Other recommendations that clinicians should remove all acronyms and medical jargon may present practical dilemmas for upholding the quality of documentation. Aside from extra time spent typing documentation, the capacity to shift from expert to patient perspectives poses unappreciated difficulties. Undoubtedly, many clinicians, as domain experts, might not always fully appreciate when they are using specialist or technical language, nor do they have the attendant skills to convey what they know to patients in an understandable way—a cluster of problems collectively referred to as “the curse of expertise” [38]. Using imprecise language may also have future medical consequences and might result in harm if later clinicians misinterpret what was written [39].

Relatedly, it seems a significant request that clinicians write notes that are bespoke for every patient’s level of health literacy. Yet, each person who attends a clinical visit will have specific health literacy needs. We suspect that the trade-off may lead to clinicians writing notes that are more suited to a readership like them—individuals with higher health literacy and more years of formal education.

Similarly, while often considered a “soft skill,” the adoption of empathetic, encouraging, and supportive language might be a taller order than is frequently assumed. For example, psychologists report that negative biases can curb expressions of empathy [40–44]. Studies show that empathy can be influenced by patients’ race or ethnicity and may be diminished among people presenting with disabilities or already stigmatized conditions [40–44]. Making matters worse, self-inspection may be a particularly weak tool for clinicians to excavate and monitor their own prejudices [45]. Furthermore, the demand that clinicians tailor their notes in ways that are optimized to every patient’s understanding and their emotional needs may lead to not only increased workload but also higher risk of burnout [46].

So far, no objective measures have assessed whether targeted training strategies are effective at improving clinical documentation in terms of preserving medical detail and utility, strengthening patient understanding and patients' perceptions of clinician support and empathy. We emphasize that while commonly used in training evaluation, self-report surveys will not be sufficient to establish whether educational interventions work in terms of both preserving the detail in clinical notes and supporting patient understanding.

Finally, perhaps most crucial of all, and as already noted, it is unclear whether narrative notes can ever uphold a genuine dual functionality targeting the needs of both clinician and patient readerships [22]. Conceivably, both needs are incommensurable and there will always be a trade-off in detail and understanding should the patient, or the clinician, be given primacy as target reader.

Generative Language Models Writing Clinical Notes

Strengths of Generative AI

Doctors strongly desire support with documentation including note writing with surveys showing that they forecast a role for AI in assisting in these tasks [47,48]. Because of their promise with respect to administrative and documentation tasks in health care contexts, LLMs have been described as “the ultimate paperwork shredder” [49]. Owing to the sheer speed and scope of information upon which they draw, LLMs hold considerable potential in generating up-to-date, comprehensive clinical information for patients [50]. This makes the approach particularly promising in generating detailed narrative explanations and summaries of visit encounters. This may help to reduce work burdens on physicians tasked with writing clinical notes.

Another striking strength of LLMs is their capacity to write responses in a requested style or by adopting a specific tone or conversational emphasis. This makes LLMs particularly promising in assisting with writing notes that omit the use of medical jargon or acronyms that are suitable for patients with different levels of health literacy, or among speakers of languages that differ from their provider's language. This capacity may also help avoid the extra burdens on clinicians attempting to document notes that are tailored to the highly diverse range of unique patient readers.

Preliminary research also suggests that LLMs may help with writing consistently sensitive or empathic notes. In 2023, a highly publicized study suggested that ChatGPT may have better bedside manners than actual human doctors [51]. A team compared written responses of doctors and ChatGPT offered to patients' real-world health queries using Reddit's AskDocs forum, where nearly half a million people post their medical problems and verified and credentialed clinicians offer suggestions. On average, ChatGPT responses were 4 times longer than doctors' replies. A panel of health care professionals—blinded to who or what did the writing—preferred ChatGPT's responses nearly 80% of the time. The panel ranked chatbot answers as being of significantly

higher quality than web-based posts reportedly from doctors; they also judged these reported web-based doctors' answers as more unacceptable responses to patients. ChatGPT's responses were rated as “good” or “very good” nearly 4 times more often than those written by the reported web-based doctors, and ChatGPT's responses were rated as almost 10 times more empathic than those by the reported web-based doctors. At the other end of the scale, these web-based physicians' replies were perceived to lack empathy approximately 5 times more often than responses produced by ChatGPT.

Limitations of Generative AI

Despite their potential, LLMs have multiple limitations. The nature of the data sets the models are trained on is critical, as it will determine the scope and nature of responses possible. Of special relevance here, none of the easily accessible LLMs have yet been trained on medical texts and thus lack the core substrate to generate the most appropriate responses. Any bias in the source the models are trained on will also be reflected in answers or text provided. Thus, while a study in March 2023 showed that ChatGPT (version 3) Could pass the United States Medical Licensing Examination [52], the authors of the study noted that to truly assess the potential of such LLMs, there is a need for “controlled and real-world learning scenarios with students across the engagement and knowledge spectrum.” Still, the results of that study were acknowledged by the American Medical Association, which noted that it intends to begin considering how tools such as ChatGPT need to be incorporated into the education process [53].

Indeed, the full extent to which LLMs embed discriminatory biases has not been fully explored. However, it would be surprising if these models did not replicate many of the same biases that already exist in clinical research, and consequently medical education, in part because of the underrecruitment of women, racial and ethnic minorities, and older people. Such skewing is already recognized as a source of disparity with the potential to perpetuate errors or misjudgments in clinical decisions [54-58]. Studies suggest that gender and racial biases are indeed coded into LLMs [59]. It remains unknown whether the potential for such discriminatory errors might prove worse than today with standard human-mediated care; however, some preliminary research suggests that negative stereotyping may be compounded by LLMs [60].

Another concern is the lack of consistency in responses proffered by LLMs. Inputting the same question to GPT-4, for example, rarely elicits the same response. Of course, human responses are rarely consistent as well; however, the extent to which generative AI, relying on LLMs, offers the same level of reliable outputs is uncertain. This is a particular concern given that LLMs are prone to yield falsehoods—a phenomenon referred to as “hallucination.” Moreover, the persuasive conversational tone of LLMs such as GPT-4 means that narrative responses may appear compelling but factually incorrect.

The extent to which doctors may already be adopting generative AI tools, such as OpenAI's ChatGPT, is not yet known. In the United States, under the 1996 Health Insurance Portability and Accountability Act (HIPAA), which established national standards in the United States to protect patients' health

information from being shared by “covered entities”—that is, providers—to other third parties. Therefore, the use of OpenAI, for example, is precluded under the HIPAA. At the time of writing, in the most common use cases, uploading patient details to versions of generative AI would breach patient trust and medical confidentiality due to privacy concerns.

However, the scope for this is quickly changing. Epic—the US software giant which has an estimated 78% of the share of hospital medical record use in the United States [61]—is currently piloting the integration of HIPAA-compliant GPT services [62]. In addition, an Azure HIPAA-compliant GPT-4 service already exists [63]. Voice-to-text clinical note generation products now represent a growing space in health care. For example, a new app called Ambient Experience from Nuance can listen to the physician’s conversation and, using ChatGPT (version 4), help create the clinical note that is ready for physicians to review [64]. In the United States, such capacities are set to become embedded into electronic health systems, signaling revolutionary changes in medical documentation practices.

Clinicians and Computers as Coauthors

Combined, the aforementioned discourse suggests that LLMs are far from ready to disintermediate clinicians when it comes to writing clinical notes. We argue that the innovation will play a key role if humans are involved. Thus, this promise could be harnessed if clinicians oversee the cocreation of clinical documentation. In this scenario, LLMs might offer initial draft documentation, which, crucially, should be supervised, and edited by clinicians whose key role in documentation will be to keep a check and balance on the current limitations with these models.

Considering the scope of generative AI, we therefore propose that current training interventions might be constructively adapted to better prepare clinicians to oversee the writing of patient-facing clinical documentation, for example, by editing and checking the quality of clinical information constructed by generative AI and reviewing the sensitivity of the language used. Preliminary studies already show that when humans collaborate with LLMs to coproduce replies to patients, this can enhance patients’ ratings of levels of empathy compared with human-only produced responses [65]. Such partnership could offer a more robust and safe form of documentation quality control—one that could potentially avoid the work burdens associated with documentation burdens and, therefore, the potential for burnout from ORA. We emphasize, however, that training should reinforce the importance of using generative AI

as an assistant narrative scribe and not as a substitute for writing notes.

Furthermore, if health systems adopt this approach, we suggest that 2 (or even multiple) versions of clinical documentation may be feasible. Using LLMs, there is scope to not only a complete medical narrative pitched at the level of the domain expert or specialist, but also to document notes couched at the level of health literacy, language, and empathy of the individual patient who might be reading them. This could help overcome the current dilemma of documenting information in a way that is accessible for patients, but which does not diminish the clinical detail for health professionals.

Future Research Directions

Many research questions could usefully explore generative AI in cowriting clinical notes, especially dual-purpose documentation for both patients and clinicians. We suggest a few novel directions. First, qualitative studies could usefully explore how successfully generative AI translates clinical documentation into patient-friendly language. For example, studies could examine the accuracy and fidelity of generative AI in translating acronyms or other medical jargon, as well as the understandability of the notes, and the level of empathy embedded in patient-facing documentation. Second, experimental studies could probe whether documentation embeds biases or a higher likelihood of containing stigmatizing language for different patient demographics or health conditions. Third, pilot studies could help determine the satisfaction and administrative work burden of dual documentation among clinicians.

Conclusions

Generative AI is ready for mass use when it comes to writing or cowriting clinical notes, and its potential is enormous. We emphasize, however, that there remain evidence-based risks associated with existing generative AI, which relate to inconsistencies, errors, and hallucinations and the real potential to embed harmful biases in documentation. If carefully implemented, in the long term, doctors who write documentation using generative AI may do a better job of adapting to the evolving functionality of the electronic records than doctors who do not. This adoption may address the potential risk of “dumbing down” clinical documentation while conveying understandable and empathetic information to patients using plain and sensitive language. We also forecast that doctors who cowrite their documentation with LLMs will experience fewer work burdens.

Conflicts of Interest

Abstract

Background: The United States Medical Licensing Examination (USMLE) has been critical in medical education since 1992, testing various aspects of a medical student's knowledge and skills through different steps, based on their training level. Artificial intelligence (AI) tools, including chatbots like ChatGPT, are emerging technologies with potential applications in medicine. However, comprehensive studies analyzing ChatGPT's performance on USMLE Step 3 in large-scale scenarios and comparing different versions of ChatGPT are limited.

Objective: This paper aimed to analyze ChatGPT's performance on USMLE Step 3 practice test questions to better elucidate the strengths and weaknesses of AI use in medical education and deduce evidence-based strategies to counteract AI cheating.

Methods: A total of 2069 USMLE Step 3 practice questions were extracted from the AMBOSS study platform. After including 229 image-based questions, a total of 1840 text-based questions were further categorized and entered into ChatGPT 3.5, while a subset of 229 questions were entered into ChatGPT 4. Responses were recorded, and the accuracy of ChatGPT answers as well as its performance in different test question categories and for different difficulty levels were compared between both versions.

Results: Overall, ChatGPT 4 demonstrated a statistically significant superior performance compared to ChatGPT 3.5, achieving an accuracy of 84.7% (194/229) and 56.9% (1047/1840), respectively. A noteworthy correlation was observed between the length of test questions and the performance of ChatGPT 3.5 ($\rho=-0.069$; $P=.003$), which was absent in ChatGPT 4 ($P=.87$). Additionally, the difficulty of test questions, as categorized by AMBOSS hammer ratings, showed a statistically significant correlation with performance for both ChatGPT versions, with $\rho=-0.289$ for ChatGPT 3.5 and $\rho=-0.344$ for ChatGPT 4. ChatGPT 4 surpassed ChatGPT 3.5 in all levels of test question difficulty, except for the 2 highest difficulty tiers (4 and 5 hammers), where statistical significance was not reached.

Conclusions: In this study, ChatGPT 4 demonstrated remarkable proficiency in taking the USMLE Step 3, with an accuracy rate of 84.7% (194/229), outshining ChatGPT 3.5 with an accuracy rate of 56.9% (1047/1840). Although ChatGPT 4 performed exceptionally, it encountered difficulties in questions requiring the application of theoretical concepts, particularly in cardiology and neurology. These insights are pivotal for the development of examination strategies that are resilient to AI and underline the promising role of AI in the realm of medical education and diagnostics.

KEYWORDS

ChatGPT; United States Medical Licensing Examination; artificial intelligence; USMLE; USMLE Step 1; OpenAI; medical education; clinical decision-making

Introduction

Since its inception in 1992, the United States Medical Licensing Examination (USMLE) has been considered an integral milestone in medical education [1]. The 3 USMLE steps are jointly sponsored by the Federation of State Medical Boards and the National Board of Medical Examiners. Each step is designed to specifically test another facet of the examinee's skill set. For instance, USMLE Step 1 assesses a student's understanding and application of basic sciences relevant to the field of medicine (eg, anatomy and physiology), while USMLE Step 2 tests the examinee's clinical knowledge (USMLE Step 2 CK) and communication skills (USMLE Step 2 CS). USMLE Step 3 evaluates the student's understanding of biomedical and clinical science [2-4]. USMLE scores have been associated with residency matching and future career perspectives [5].

Artificial intelligence (AI)-supported tools have been proposed for a variety of medical scenarios, including preoperative outcome simulation, patient education, and automated disease grading [6-9]. Recently, chatbots such as ChatGPT have emerged as next-generation AI technology. The strengths of this novel AI-powered approach include 24-7 availability, cost efficiency, and individualization [10]. A mounting body of evidence has investigated ChatGPT's performance on different standardized exams. For instance, Hoch et al [11] reported that ChatGPT answered 57% of facial surgery board certification test questions correctly, while Kung et al [12] used a limited set of USMLE test questions (USMLE Step 1: 119; USMLE Step 2 CK: 102; USMLE Step 3: 122) and found that ChatGPT achieved performance levels near the passing threshold for all 3 steps.

However, there is a scarcity of studies that comprehensively investigate overall ChatGPT performance on USMLE Step 3 test questions in a large-scale study and compare test performances between ChatGPT 3.5 and ChatGPT 4. This knowledge gap may increase the risk of AI cheating in such career-deciding exams and cloud the vision of ChatGPT's strengths and limitations.

Therefore, we aimed to determine ChatGPT's performance on USMLE Step 3 practice test questions based on 1840 AMBOSS USMLE Step 3 Style Questions. This line of research may serve as a primer elucidating the strengths and weaknesses of multiple ChatGPT versions and deducing evidence-based strategies to counteract AI cheating.

Methods

Access to Question Bank and Data Entry Procedure

From June 12, 2023, to June 19, 2023, we obtained access to the AMBOSS question bank [13]. Within this time frame, we collected a total of 1840 practice questions specifically designed for the USMLE Step 3 exam. Before initiating our study, we acquired official permission from AMBOSS (AMBOSS GmbH) to use their USMLE Step 3 question bank for research purposes. To ensure the reliability of our data, 2 examiners (MA and LK) cross-checked the question inputs randomly to confirm that none of the answers were indexed on Google before June 19, 2023. Many USMLE questions are on the internet, including USMLE sample questions as well as a few AMBOSS questions; however, we ensured that those questions were not included in this analysis to minimize the risk of prior memorization of the questions by ChatGPT. July 19, 2023, was chosen since it represents the most recent accessible date within the training data set of ChatGPT. There are many forms of AI versions with capabilities to answer USMLE Step 3 practice test questions; however, ChatGPT is the most widely used AI at the time of this study, making it the best fit for our study.

Question Screening and Categorization

To maintain the quality of our sample questions, we subjected all test questions to independent screening by 4 examiners (MA, SK, CCH, and LK). Questions containing clinical images and photographs were excluded from the study, resulting in the removal of 229 image-based questions. Subsequently, the remaining 1840 test questions were classified based on their respective specialties, using the categorization provided by AMBOSS. All questions included in our study followed a multiple-choice single-answer format. The questions used for both ChatGPT 3.5 and ChatGPT 4 were matched for content and difficulty based on the standardized definitions provided by the AMBOSS question bank to ensure consistent analysis between both AI versions.

Comparison of ChatGPT Versions and Analysis of Question Stems

To evaluate any performance differences between ChatGPT 3.5 and ChatGPT 4, we conducted a subgroup analysis specifically focusing on ChatGPT 4. Additionally, we analyzed the question stems of both ChatGPT 3.5 and ChatGPT 4, specifically looking for specific buzzwords related to diagnostic methods and patient information, such as "Ultrasound," "Serology," and "Nicotine Abuse." These particular words and phrases may suggest one

answer over another and thus are essential for test-taking. For example, if the question states “Nicotine Abuse,” which is suggestive of cigarette or tobacco use, the patient in the question stem is more likely to have cancer. The purpose of this analysis was to identify any variations in accuracy based on the presence of these factors. Furthermore, we assessed performance differences between ChatGPT 3.5 and ChatGPT 4 based on the length of the test questions.

Assessment of Question Difficulty

To assess the difficulty of the test questions, we used the proprietary rating system of the AMBOSS question bank. This system assigns a difficulty level to each question based on a scale of 1 to 5 hammers. A rating of 1 hammer corresponds to the easiest 20% of questions, while 5 hammers indicate the most challenging 5% of questions.

Data Entry Process

One examiner (MA) manually inputted the test questions into ChatGPT. The questions were transcribed verbatim from the AMBOSS question bank, preserving the original text and answer choices. To ensure the integrity of ChatGPT’s performance, no additional prompts were introduced intentionally by the authors, thereby minimizing the potential for systematic errors. Each question was treated as a separate chat session in ChatGPT to minimize the impact of memory retention bias. As an example, the following provides a standard test question from the category “Competency: Patient Care Content Area: General Principles”:

What is the most suitable course of action to take next in the case of a 54-year-old man, previously in good health, who presents to the emergency department after being bitten by a stray dog in South America? The bite punctured his right leg, but he has diligently cleaned the wound daily with soap and peroxide. The patient is not experiencing pain, fever, or chills, and his vital signs are normal. The examination reveals healing puncture wounds with minimal redness, and there is no fluctuation or palpable lymph nodes in the groin. The patient had a tetanus booster vaccination three years ago.

(A) Provide rabies vaccination

(B) Administer tetanus immune globulin

(C) Request cerebrospinal fluid analysis

(D) Order an MRI [magnetic resonance imaging] scan of the brain and spinal cord

(E) No immediate action is required at this time

Recording and Evaluation of ChatGPT Responses

The answers generated by ChatGPT were documented and incorporated into the corresponding AMBOSS USMLE Step 3 practice question. Subsequently, we systematically gathered and recorded information regarding the accuracy of these responses in a separate data spreadsheet.

Statistical Analysis

We used the Pearson chi-square test to determine differences in question style and categories. Bivariate correlation analysis between ChatGPT performance, test question length, and difficulty was conducted using the Spearman correlation coefficient (ρ). IBM SPSS Statistics 25 (IBM Corp) was used for statistical analysis, and a 2-tailed P value $\leq .05$ was considered statistically significant.

Results

General Test Question Characteristics and Performance Statistics

The overall accuracy of ChatGPT 3.5 for USMLE Step 3 was 56.9% (1047/1840), while ChatGPT 4 answered 84.7% (194/229) of test questions correctly ($P < .001$). Specialty-specific number of test questions and performance scores are presented in [Tables 1](#) and [2](#). ChatGPT 3.5 received the greatest number of questions on the nervous, cardiovascular, and gastrointestinal systems, while ChatGPT 4 received the greatest number of questions on behavior health, the female reproductive system, as well the blood and lymphatic system. When considering the accuracy of ChatGPT based on the category of questions, ChatGPT 3.5 performed the best on behavioral health, multisystem processes and disorders, and pregnancy-related questions. On the other hand, ChatGPT 4 had the greatest accuracy on questions related to the endocrine and musculoskeletal systems as well as biostatistics and multisystem processes and disorders.

Table 1. The number of test questions answered by ChatGPT 3.5 and its performance, stratified by questions category (N=1840).

Question category	Test questions answered, n	Correct questions, n/N (%)
Male reproductive system	28	17/28 (60.1)
General principles and foundational science	29	16/29 (55.2)
Immune system	40	25/40 (62.5)
Skin and subcutaneous tissue	72	39/72 (54.2)
Renal and urinary systems	72	39/72 (54.2)
Biostats and epidemiology	87	45/87 (51.7)
Female reproductive system and breast	88	48/88 (54.5)
Musculoskeletal system	94	56/94 (58.5)
Endocrine system	103	58/103 (56.3)
Blood and lymphoreticular system	105	55/105 (52.4)
Pregnancy, childbirth, and puerperium	111	66/111 (59.5)
Behavioral health	115	73/115 (63.5)
Multisystem processes and disorders	122	73/122 (59.8)
Respiratory system	130	71/130 (54.6)
Social sciences	141	86/141 (61.0)
Gastrointestinal system	156	87/156 (55.8)
Cardiovascular system	161	89/161 (55.3)
Nervous system and special senses	186	104/186 (55.9)

Table 2. The number of test questions answered by ChatGPT 4 and its performance, stratified by questions category (N=229).

Question category	Test questions answered, n	Correct questions, n/N (%)
Endocrine system	1	1/1 (100)
Biostats and epidemiology	14	13/14 (92.3)
General principles and foundational science	17	14/17 (82.4)
Multisystem processes and disorders	17	15/17 (88.2)
Pregnancy, childbirth, and puerperium	19	15/19 (79.0)
Gastrointestinal system	21	18/21 (85.7)
Cardiovascular system	21	15/21 (71.4)
Nervous system and special senses	21	15/21 (71.4)
Blood and lymphoreticular system	23	20/23 (87.0)
Female reproductive system and breast	23	20/23 (87.0)
Behavioral health	24	21/24 (87.5)

Test Question Length and ChatGPT Performance Scores

The mean character count was 1078 (SD 308). Test question length was significantly correlated with the performance of ChatGPT 3.5 ($\rho=-0.069$; $P=.003$) while not yielding significance for ChatGPT 4 ($P=.87$). For ChatGPT 3.5, the mean number of characters was 1062 (SD 310) for correct answers versus 1100 (SD 304) for falsely answered questions ($P=.009$). However, the mean character count was comparable for test questions answered by ChatGPT 4 (mean correct answers 1068, SD 274 vs mean false answers 1056, SD 233; $P=.80$).

Test Question Difficulty and the Performance of ChatGPT

Question distribution and performance scores sorted by level of test question difficulty are illustrated in [Figure 1](#). Test question difficulty, defined by AMBOSS hammer categorization, and the performance of ChatGPT 3.5 were significantly correlated ($\rho=-0.289$; $P<.001$). This was reproducible in ChatGPT 4 ($\rho=-0.344$; $P<.001$). ChatGPT 4 statistically significantly outperformed ChatGPT 3.5 for each hammer category except for the 4- and 5-hammer test difficulty levels. For 1-, 2-, and 3-hammer questions, ChatGPT 4 had a statistically significant increase in accuracy compared to

ChatGPT 3.5 ($P=.04$; $P=.02$; and $P=.03$; respectively). For the most difficult questions, ChatGPT 4 still had greater accuracy than ChatGPT 3.5; however, there was no statistical significance shown. The percentage of correct responses from ChatGPT 3.5 versus ChatGPT 4 sorted by specialty is illustrated in Figure 2.

Relative to ChatGPT 3.5, ChatGPT 4 performed better on questions from every specialty category. The biggest differences in accuracy were in biostatistics, epidemiology, the endocrine system, and the musculoskeletal system.

Figure 1. Question distribution and performance scores sorted by level of test question difficulty.

Figure 2. Percentage of correct responses from ChatGPT 3.5 versus ChatGPT 4.0, sorted by specialty.

Buzzwords and the Performance of ChatGPT

ChatGPT 4 performed significantly better on ultrasound-related questions ($P=.04$), while ChatGPT 3.5 answered significantly more questions correctly if they contained serology- or

smoking-related information ($P=.008$ and $P=.03$, respectively). Performance scores of ChatGPT 3.5 versus ChatGPT 4 sorted by buzzwords are depicted in Figure 3. Overall, ChatGPT 4 outperformed ChatGPT 3.5, regardless of whether the question included buzzwords.

Figure 3. Performance scores of ChatGPT 3.5 versus ChatGPT 4.0, sorted by buzzword.

Discussion

Principal Findings

This investigation was designed to empirically evaluate and contrast the competencies of the 2 most contemporary iterations of the AI-powered large language model, ChatGPT, in relation to their performance in taking the USMLE Step 3. An aggregate of 1840 representative practice questions, derived from the AMBOSS question bank, were presented to ChatGPT version 3.5. The model delivered an overall accuracy rate of 56.9% (1047/1840). In juxtaposition, ChatGPT version 4 was assessed using a subset of 229 practice questions and achieved an overall accuracy rate of 84.7% (194/229). This difference in performance is both statistically and practically significant. Achieving a score of 84.7%, ChatGPT 4 falls within the top 10% of all test takers. In contrast, a score of 56.9% places ChatGPT 3.5 near the passing threshold. This significant difference provides empirical evidence of the substantial enhancements and refinements embedded within ChatGPT 4

and elucidates the leap in proficiency this iteration has attained, pushing the boundaries of AI capabilities in medical knowledge comprehension and application.

While ChatGPT 3.5 hovered around the approximate passing threshold of 60%, ChatGPT 4 not only passed the examination but merely excelled at it. According to the score interpretation guide provided by the National Board of Medical Examiners, an accuracy rate of 84.7% approximates placement within the 90th to 92nd percentile [14]. This signifies that ChatGPT 4 would be situated among the elite stratum, encompassing the top 10% of USMLE Step 3 candidates. The impressive escalation in performance exhibited by ChatGPT 4 makes the delineation of strengths and limitations difficult [15]. The model's evolution seems to have attenuated discernible weaknesses, indicating a more well-rounded overall proficiency in the medical domain [12].

However, nothing is perfect. Although ChatGPT 4 accesses detailed, comprehensive, and up-to-date knowledge bases to optimize its response patterns, we could reveal minor

performance weak points. We found that ChatGPT 4 was more prone to errors when answering test questions on cardiology (mean test accuracy: $n=89$, 71.4% vs $n=15$, 84.7% correct questions) and neurology (mean test accuracy: $n=104$, 71.4% vs $n=15$, 84.7% correct questions). Interestingly, these subjects often test the examinee's transfer knowledge skills. Based on theoretical concepts (eg, Frank-Starling law and dermatome map), examinees are asked to filter the question stem for relevant patient data and adapt the underlying theory to the patient case. This novel insight into ChatGPT points toward persistent deficits in abstract thinking. Therefore, test question writers for the USMLE or other medical examinations may use this question style for other subjects to reduce the risk of AI cheating. Further, our analysis demonstrated that the performance of ChatGPT 4 significantly correlated ($\rho=-0.344$; $P<.001$) with the level of test question difficulty. This indicates that sophisticated USMLE questions still challenge and fool both human examinees and AI chatbots. Typically, the most difficult USMLE questions include distractors as well as irrelevant or additional information.; they also require high-level reasoning and interdisciplinary thinking. Our group previously showed that ChatGPT 3.5, similar to the human user peer group, struggled to answer 4- and 5-hammer questions [11]. Such pitfalls continue to perplex the next generation of AI-powered chatbots. Therefore, a thorough analysis of 4- or 5-hammer questions may help examiners refine their test questions and shield the USMLE against AI cheating.

Overall, the phenomenal improvement in the test-taking performance of ChatGPT 4 compared to ChatGPT 3.5 raises intriguing questions regarding future applications and implications of AI in medical education and diagnostics. AI has shown its prowess not only on the USMLE examinations in medical education but also on advanced examinations, such as the neurosurgical written boards [16]. This phenomenon ventures into other aspects of medicine as well, including research and clinical performance [17]. It is imperative that future research ventures into a deeper analysis of the performance of ChatGPT 4 by conducting thorough investigations that probe its strengths and limitations in a more

granulated manner, potentially employing diversified medical question banks, simulating real-world scenarios, and engaging experts for analysis and evaluation to allow for the best possible medical education and ultimately patient health care [18].

Limitations

This study needs to be interpreted in the light of the following limitations: first, due to the restricted use of ChatGPT (only 25 entries every 3 hours) we were not able to perform a direct comparison of ChatGPT 3.5 and ChatGPT 4 for all test questions included in this study, which might limit its validity. Furthermore, although we attempted to ensure that the questions provided for analysis were not freely available on the internet to minimize the risk of ChatGPT having already seen the exact question, students and researchers around the world may have input certain AMBOSS USMLE Step 3 Style Questions into ChatGPT. This adds a potential confounding factor of ChatGPT memorizing the correct answer from seeing the question beforehand. We used the 2 most recent versions of ChatGPT (ie, ChatGPT 3.5 and ChatGPT 4) to test and compare the performance of large language models on 1840 AMBOSS USMLE Step 3 questions. Thus, the findings of this study should be revalidated for upcoming ChatGPT versions. Future studies may involve additional chatbots, question banks, and image-based test questions. Further, the performance of ChatGPT on USMLE steps could be compared to other national medical licensing exams.

Conclusions

This study is the first direct comparison of ChatGPT 4 and ChatGPT 3.5 based on 1840 AMBOSS USMLE Step 3 test questions. Our analysis showed that ChatGPT 4 outperformed its predecessor version across different specialties and difficulty levels, ultimately yielding accuracy levels of 84.7%. However, we could identify persisting weak points of ChatGPT 4, including abstract thinking and elaborated test questions. This line of research may serve as an evidence-based fundament to safeguard the USMLE steps and medical education against AI cheating while underscoring the potency of AI-driven chatbots.

Abstract

Background: The use of artificial intelligence (AI) in medicine not only directly impacts the medical profession but is also increasingly associated with various potential ethical aspects. In addition, the expanding use of AI and AI-based applications such as ChatGPT demands a corresponding shift in medical education to adequately prepare future practitioners for the effective use of these tools and address the associated ethical challenges they present.

Objective: This study aims to explore how medical students from Germany, Austria, and Switzerland perceive the use of AI in medicine and the teaching of AI and AI ethics in medical education in accordance with their use of AI-based chat applications, such as ChatGPT.

Methods: This cross-sectional study, conducted from June 15 to July 15, 2023, surveyed medical students across Germany, Austria, and Switzerland using a web-based survey. This study aimed to assess students' perceptions of AI in medicine and the integration of AI and AI ethics into medical education. The survey, which included 53 items across 6 sections, was developed and pretested. Data analysis used descriptive statistics (median, mode, IQR, total number, and percentages) and either the chi-square or Mann-Whitney *U* tests, as appropriate.

Results: Surveying 487 medical students across Germany, Austria, and Switzerland revealed limited formal education on AI or AI ethics within medical curricula, although 38.8% (189/487) had prior experience with AI-based chat applications, such as ChatGPT. Despite varied prior exposures, 71.7% (349/487) anticipated a positive impact of AI on medicine. There was widespread consensus (385/487, 74.9%) on the need for AI and AI ethics instruction in medical education, although the current offerings were deemed inadequate. Regarding the AI ethics education content, all proposed topics were rated as highly relevant.

Conclusions: This study revealed a pronounced discrepancy between the use of AI-based (chat) applications, such as ChatGPT, among medical students in Germany, Austria, and Switzerland and the teaching of AI in medical education. To adequately prepare future medical professionals, there is an urgent need to integrate the teaching of AI and AI ethics into the medical curricula.

Introduction

Background

Artificial intelligence (AI) has attracted both public and scientific interest and is amplified by the emergence and greater accessibility of chat-based applications such as ChatGPT

(OpenAI, LLC) and Bard (Google, LLC). For several years, the medical field has been an active and expanding area of research on the application of AI [1]. As of now, AI is used in diverse medical specializations, including dermatology, radiology, and pathology [2-4].

Although the history of AI can be traced back to the 1950s, the public's unrestricted access to highly advanced large language models, such as ChatGPT, can be seen as a significant turning point in the history of AI [5,6]. Early studies demonstrated that ChatGPT is capable of successfully completing the written portion of the United States Medical Licensing Examination [7]. Given the capabilities of AI-based chat applications such as ChatGPT in medicine, further studies have highlighted their potential use in providing information on cancer, assisting in clinical diagnoses, authoring scientific research articles, and patient communication [8-10]. Considering the wide availability and integration of medical knowledge in this application, its increasing use in medicine and among medical students is foreseeable [11].

Despite the long history of AI and the increasing adoption of this technology, there is disagreement regarding its definition among the scientific community [12]. There is a consensus within the scientific community on distinguishing between the so-called strong AI, also known as "artificial general intelligence," and weak AI or "artificial narrow intelligence" [13]. This categorization is based on the capabilities of AI or its areas of application [13]. Strong AI, recognized for its human-equivalent intellectual abilities and knowledge, stands in contrast to weak AI, which refers to AI solutions capable of accomplishing specific tasks effectively [13]. The area of weak AI can be further divided into the so-called statistical AI and symbolic AI. The field of statistical AI also includes machine learning and deep learning, on which large language models such as ChatGPT are based [13]. Areas of application for symbolic AI in medicine include expert systems (eg, clinical decision support systems), which make decisions based on explicit knowledge in the form of predefined rules [14].

Considering the likely significant impact the implementation and use of AI in medicine is poised to make, a growing body of literature advocates the inclusion of AI-related content in medical curricula [15-18]. In addition to implications for the medical profession and patient care, medical students are expected to face new ethical challenges posed by the use of AI in medicine [15,19]. Despite the potentially significant ethical challenges anticipated from the deployment of AI in medicine, such as the possibility of discrimination due to biases in the data used for training or effects on patient autonomy, there is a near-complete absence of scientific publications on specific teaching content or methods related to AI ethics as part of medical higher education.

In addition to the lack of specificity regarding teaching content on AI and AI ethics, the absence of studies on medical students' perception of AI ethics education (including teaching content) is notable [20,21]. It is essential to point out that the current state of research regarding medical students' perceptions and assessments of AI application in medicine largely represents a knowledge base that predates the advent of large language models such as ChatGPT. With the ubiquity of the aforementioned AI applications at the time of this publication, it is reasonable to expect that medical students' assessments of AI implementation in medicine will deviate significantly from earlier publications within this area of research, highlighting the need for further research.

Objective

This study aimed to explore how medical students perceive the use of AI in medicine, as well as the teaching of AI and AI ethics (including prospective AI ethics teaching topics). In this context, the introduction and accessibility of large language models such as ChatGPT should be emphasized, leading to the following research question: how do medical students from Germany, Austria, and Switzerland perceive (1) the application of AI in medical practice, (2) the integration of AI and AI ethics into medical education, and (3) AI ethics teaching content in their curriculum in accordance with the use of AI-based chat applications such as ChatGPT?

To address this research question, the participating medical students were divided into 2 groups based on their prior use of AI-based (chat) applications, such as ChatGPT.

Methods

Overview

This cross-sectional study was conducted between June 15 and July 15, 2023. During this time frame, an invitation to participate in the study was sent to medical students who were regularly enrolled in universities in Germany, Austria, and Switzerland. The study sample included medical students from all academic semesters, including those in practically oriented semesters such as the practical year in Germany. Participation in the study was voluntary and there were no consequences for nonparticipation. The study used an anonymous web-based survey, with recruitment facilitated through email invitations and assistance from various medical student associations, unions, and councils in their respective countries. To minimize potential selection bias, the survey invited medical students from various universities and academic semesters in Germany, Austria, and Switzerland. This strategy ensured a broad and representative sample of the participants. Moreover, careful construction and pretesting of the survey were conducted to minimize potential response biases. Before the official data collection, a pretest was conducted with 11 medical students from the target population. The web-based survey provider, "LimeSurvey" was used for both the pretest and the main study.

Ethical Considerations

The Research Committee for Scientific Ethical Questions granted ethical approval for this study (3181) on January 16, 2023.

Survey Development

The survey used for data collection was developed based on existing scientific publications [15,22]. Owing to the lack of references in the areas of AI teaching, AI ethics, and recent developments in AI, most items used for the survey were newly formulated. The survey comprises 53 items, including both questions and statements. During the development process, these items were distributed across 6 parts, with some contingent on the responses to the preceding items. The first part aimed to collect information on the demographic characteristics and educational background of the participants. To address the research question of this study, participants were divided into

2 groups based on their responses to questions related to their prior use of AI-based (chat) applications such as ChatGPT. The second part sought to gather information about the students' previous experiences with AI-based (chat) applications. In the third part, the students were asked to rate various statements regarding the use of AI in medicine. The fourth and fifth parts aimed to capture students' evaluations of statements about AI teaching and ethics, respectively. The sixth part assessed the perceived relevance of the potential teaching content to AI ethics. The items in parts 3 to 6 were evaluated using a 5-point Likert scale. Before the survey was conducted, 2 experts in ethics and AI evaluated the survey and their recommendations were incorporated. Upon receiving expert feedback, the teaching topic of "data privacy" was introduced as a distinct subject under AI ethics. Previously, this was encompassed within the broader "safety" category. Furthermore, to enhance clarity, the term "knowingly" was incorporated into Q12. This adjustment acknowledges that the application of AI in medicine may not always be transparent.

Survey Pretest

To assess the comprehensibility and relevance of the survey, a pretest was conducted with 11 medical students, who subsequently provided feedback. This feedback led to 6 relevant modifications aimed at enhancing clarity, relevance, and user-friendliness. Because of the feedback provided, questions Q1 through Q4 and Q6 were specified by adding examples following each question. The changes made to the questions are highlighted in italics:

1. Q1. Have you already received education in the field of ethics within your regular medical studies? (*eg, as part of the History, Ethics, and Theory of Medicine course*)
2. Q2. Have you already received education in the field of AI in your regular medical studies? (*eg, as part of medical statistics or informatics*)
3. Q3. Have you already received education in the field of AI outside of your regular medical studies? (*eg, in the form of further training, own research*)
4. Q4. Have you already received education in the field of AI ethics within your regular medical studies? (*eg, as part of the History, Ethics, and Theory of Medicine course*)
5. Q6. Have you already received instruction in the field of AI ethics outside of your regular medical studies? (*eg, in the form of further training, own research*)

Similarly, statement 27 (S27) was further improved by adding examples from various fields to underscore the multidisciplinary context: "AI ethics should be taught by experts from various fields (*eg, medicine, computer science, philosophy*) to ensure a multidisciplinary perspective on AI ethics."

To improve the survey's user experience, conditional logic was integrated so that questions Q5 and Q7 appeared only in response to the specific preceding answers. Both question Q5 and question Q7 were designed to explore the specific content covered in AI ethics education. These questions were identical in wording: "Which of the following contents were covered as part of the instruction/education?" Question Q5 was presented exclusively to participants who answered "yes" to question 4, which focused on AI ethics education within their regular

medical studies. Similarly, question Q7 was shown only to those who responded "yes" to question 6, focusing on AI ethics education outside of their regular medical curriculum. This strategic modification not only streamlined the survey's presentation but also minimized the immediate visual content, reducing complexity.

Sample Size Calculation

The sample size for this study was calculated before data collection using Cochran sample size formula ($n = [Z^2 * p * (1-p)] / E^2$) [23]. The total population size used for the calculation, which represents the number of medical students enrolled at the end of the winter semester in 2022, was 130,601 across the 3 countries included in the study. This figure includes 105,275 medical students from Germany (accounting for 80.61% of the total), 17,826 from Austria (13.65%), and 7500 from Switzerland (5.74%) [24-26]. This summation was performed based on the primary research question and was predicated on the assumption that the prevalence of AI-based (chat) applications, such as ChatGPT, among medical students does not vary significantly across these countries. A confidence level of 95% ($Z=1.96$) and a margin of error of 5% were used to determine the sample size. The proportion (p) was derived from a pretest involving a separate group of 11 medical students of which 5 were already using large language models such as ChatGPT before the study ($P=.45$). Cochran's formula yielded a sample size of 380 medical students. As the study was conducted using a web-based survey with recruitment via email, an estimated dropout rate of 40% was factored in. To achieve a calculated sample size of 380 participants, at least 532 students were targeted during the recruitment process. To ensure adequate representation based on the proportion of medical students within each country of interest, the study aimed to include at least 306 medical students from Germany, 52 from Austria, and 22 from Switzerland in the data collection and analysis process. Note that these are rounded values given that the actual calculations result in noninteger numbers.

Data Analysis

Collected data were evaluated using SPSS (version 28; IBM Corp), LimeSurvey (LimeSurvey GmbH), and Microsoft Excel (version 16.73). Descriptive statistics were calculated for all survey variables, including the median, IQR, mode, total number, and percentages. For further statistical analysis, the chi-square test of independence was used to compare the 3 groups. When significant differences were observed in the chi-square test, post hoc analysis was performed using the adjusted residuals method to specify which specific groups or categories contributed to the observed significance. In addition, z scores were calculated to facilitate the comparison of responses across different groups. These were computed using the 2-sided test formula $z = (X - \mu) / \sigma$, where X represents the value of the response, μ is the mean of the responses for the group, and σ is the SD within that group. The calculation of z scores enabled the quantification of the deviation of each response from the group mean in terms of SDs. The Mann-Whitney U test was used for the statistical comparison of 2 independent groups; for further statistical analysis, the chi-square test of independence was used to compare the 3 groups, and the Mann-Whitney U

test was used for the statistical comparison of 2 independent groups. For statistical analysis, the responses to the Likert scale were recoded into a numerical format (“I strongly disagree”=1, “I disagree”=2, “undecided”=3, “I agree”=4, “I strongly agree”=5). For all statistical tests performed, the significance level was set at $\alpha=.05$, and a value of $P\leq.05$ was considered statistically significant. Only complete data sets were included in the data analysis to avoid potential biases that could arise from replacing or estimating the missing values (list-wise deletion).

Results

Overview

In total, 521 medical students participated in the survey, yielding 487 complete and valid data sets for the statistical analysis. The survey invitations were disseminated via email with the help of medical student associations, unions, and councils. The total number of medical students reached and the precise response rate could only be approximated. On the basis of the feedback received from the engaged medical student councils, we estimated that at least 2000 medical students were approached. This would be equal to a response rate of 24.35% (487/2000). Our sample size calculation was based on the assumption that the use of AI-based (chat) applications such as ChatGPT does not diverge markedly among medical students from each of the countries of interest, namely Germany, Austria, and Switzerland. Consequently, the chi-square test of independence was used for statistical evaluation. We posited a null hypothesis (H_0) asserting no association between the variables (use of AI-based applications and country of study) and an alternative hypothesis (H_1) suggesting an association between these variables. The chi-square test returned a value of $P=.96$, which exceeded the predetermined level of significance. As such, we did not reject the null hypothesis, leading us to conclude that there is no statistically significant association between the use of AI-based (chat) applications and country of study among the surveyed

medical students, given that each individual fits into one category for each variable.

Part 1: Demographics and Educational Background

Of the medical students who participated in the survey, the majority were women (270/487, 55.4%). The largest demographic age was between 20 and 25 years (301/487, 61.8%), and most students were enrolled in Germany (296/487, 60.7%). The German contingent of respondents was slightly below our target size of 306, representing a 3.3% (296/306) shortfall. However, participation from Austria exceeded our initial target of 52 students by a substantial margin, with 105 respondents indicating enrollment in Austria, denoting an overachievement rate of 202% (105/52). Similarly, Swiss representation surpassed our initial target of 22 students, with 86 respondents registered in Switzerland, marking an overachievement of 391% (86/22). Most of the surveyed students were in the clinical stage (CS) of their study (277/487, 56.9%), followed by those in their practical years (63/487, 12.9%). Comprehensive demographic characteristics are presented in [Table 1](#).

The respondents were also asked about their educational backgrounds in ethics, AI, and AI ethics. Most participants (425/487, 87.2%) reported having received ethics education. However, a considerably smaller proportion of respondents claimed that they had received prior education in AI as part of their medical curriculum (26/487, 5.3%), with an additional 10.5% (51/487) having obtained such knowledge outside of their regular medical studies. Few participants had been exposed to AI ethics education within their medical curriculum (21/487, 4.3%), with a small number reporting having learned about AI ethics outside their regular curriculum (51/487, 6.8%). The most common subjects covered in AI ethics education were bias (15/487, 3.1% within and 14/487, 2.9% outside regular studies) and explainability (12/487, 2.5% within and 20/487, 4.1% outside regular studies). Detailed responses related to the participants' educational background are shown in [Table 2](#).

Table 1. Demographic characteristics of medical students (n=487).

Characteristics	Medical students, n (%)
Gender	
Woman	270 (55.4)
Man	203 (41.7)
Nonbinary	3 (0.6)
Prefer not to say	11 (2.3)
Age (y)	
<20	56 (11.5)

Master	18 (3.7)

Table 2. Educational background of the participating medical students from Germany, Austria, and Switzerland (n=487).

Question	Participants, n (%)
Q1: Have you already received education in the field of ethics <i>within</i> your regular medical studies? (eg, as part of the History, Ethics, and Theory of Medicine course)	
Yes	425 (87.2)
No	62 (12.7)
Q2: Have you already received education in the field of artificial intelligence <i>within</i> your regular medical studies? (eg, as part of medical statistics or informatics)	
Yes	26 (5.3)
No	461 (94.7)
Q3: Have you already received education in the field of artificial intelligence <i>outside of</i> your regular medical studies? (eg, in the form of further training, own research)	
Yes	51 (10.5)
No	436 (89.2)
Q4: Have you already received education in the field of artificial intelligence ethics <i>within</i> your regular medical studies? (eg, as part of the History, Ethics, and Theory of Medicine course)	
Yes	21 (4.3)
No	466 (95.7)
Q5: Which of the following contents were covered as part of the education?^{a,b}	
Informed consent	11 (2.3)
Bias	15 (3.1)
Data privacy	13 (2.7)
Explainability	12 (2.5)
Safety (of AI-based applications)	10 (2)
Fairness	5 (1)
Autonomy	8 (1.6)
Responsibility	8 (1.6)
Q6: Have you already received education in the field of artificial intelligence ethics <i>outside of</i> your regular medical studies? (eg, in the form of further training, own research)	
Yes	33 (6.8)
No	454 (93.2)
Q7: Which of the following contents were covered as part of the education?^{b,c}	
Informed consent	10 (2)
Bias	14 (2.9)
Data privacy	17 (3.5)
Explainability	20 (4.1)
Safety (of artificial intelligence-based applications)	18 (3.7)
Fairness	12 (2.5)
Autonomy	14 (2.9)
Responsibility	19 (3.9)

^aQuestion 5 was exclusively displayed to participants who responded to question 4 with “yes.”

^bAn explanation of the contents of Q5 and Q7 is provided in the text.

^cQuestion 7 was exclusively displayed to participants who responded to question 6 with “yes.”

Part 2: Use of AI-Based (Chat) Applications

With regard to the use of AI-based (chat) applications such as ChatGPT (OpenAI), Bard (Google), Bing Chat (Microsoft Inc), and Jasper Chat (Jasper AI, Inc), 38.8% (189/487) of the respondents reported prior use of these platforms. Conversely, the vast majority (438/487, 89.9%) indicated that they did not knowingly use other AI-based medical applications. Of the 298 respondents who had not previously used an AI-based chat

application, 76.9% (n=229) expressed an interest in future use. Among the respondents who reported prior use of AI-based (chat) applications, nearly half had used such an application for 1-3 hours over the past week (91/189, 48.2%). Of this group, 73% (138/189) indicated using an AI-based (chat) application in a medical context, with the most common use being querying medical knowledge (74/138, 53.6%). The results of this survey are summarized in Table 3.

Table 3. Answers to the use of AI^a-based (chat) applications of participants (n=487).

Question	Participants, n (%)
Q8: Have you already used an AI-based (chat) application such as ChatGPT (OpenAI), Bard (Google), Bing chat, or Jasper Chat?	
Yes	189 (38.8)
No	298 (61.2)
Q9: Have you knowingly ever used AI-based medical applications, such as image-based diagnostic tools in radiology?	
Yes	49 (10.1)
No	438 (89.9)
Q10: Are you interested in using an AI application as part of your medical studies in the future?^b; n=298	
Yes	229 (76.9)
No	69 (23.1)
Q1: Approximately how many hours have you used the AI-based (chat) application in the last week (7 d)^c; (n=189)	
<1 h	73 (38.6)
1-3 h	91 (48.2)
4-6 h	19 (10)
7-9 h	3 (1.6)
10-12 h	2 (1.1)
>12 h	1 (0.5)
Q12: Have you already used the AI-based (chat) application in a medical context? (eg, for explaining medical conditions or medical questions)^d; (n=189)	
Yes	138 (73)
No	51 (26.7)
Q13: For which of the following objectives have you already used the AI-based (chat) application in the medical context?^e; (n=138)	
Therapy suggestions	18 (13)
Querying medical knowledge	74 (53.6)
Diagnostic support	5 (3.6)
Explanation of pathologies	41 (29.7)

Part 3: AI in Medicine

In the third part of the survey, participants' attitudes toward the role of AI's in medicine were examined. Of the 487 respondents, 71.7% (n=349) agreed or strongly agreed that the use of AI would bring about positive changes to medicine (S1). Similarly, 72.1% (350/487) believed that AI could find practical

applications in medicine (S2). When comparing the responses between those who had used AI-based applications and those who did not, significant differences were identified for each statement using the Mann-Whitney *U* test (S1: $P=.003$; S2: $P=.002$). Although both groups shared the same median and mode responses, their *z* scores suggested variations in their agreement levels. Specifically, respondents who had not

previously used AI-based chat applications displayed a higher level of agreement with the statement in S1 (z score: -2.991). Conversely, those who had used AI-based applications exhibited greater concurrence with the statement in S2 (z score: 3.105).

When comparing the responses of those who had used AI-based chat applications and those who had not, no significant difference was observed regarding the subsequent 2 statements, S3 and S4, which were related to the influence on the choice of medical specialization and the potential reduction of jobs for medical staff. However, marked differences were identified when comparing the responses to statements S5 to S7 concerning improvements in patient care quality (S5: $P < .001$), diagnostic processes (S6: $P = .002$), and therapy selection (S7: $P < .001$). Although the overall agreement (either “agree” or “strongly agree”) was high for these statements (S5: 71%; S6: 76.4%; S7: 77.9%), z scores indicated greater agreement within the

subgroup that had previously used AI-based (chat) applications (S5: z score= 3.570 ; S6: z score= 3.089 ; S7: z score= 3.865).

No significant difference was found for statements S8 to S11 between the 2 groups, with comparable levels of overall agreement (“agree” or “strongly agree”) for each statement (S8: 31.8%; S9: 29.6%; S10: 25.9%; S11: 31.8%). However, a significant difference was observed for statement S12 ($P = .02$), with 95.3% of all respondents agreeing or strongly agreeing that the use of AI in medicine presents new ethical challenges. The z score (2.302), median (5), and mode (5) suggested a higher level of agreement among the groups that had previously used AI-based (chat) applications, such as ChatGPT. A statistical analysis of the third part of the survey is presented in [Table 4](#). A detailed illustration of the perceptions of the surveyed medical students regarding the use of AI in medicine is provided in [Table S1](#) in [Multimedia Appendix 1](#).

Table 4. Statistical analysis of the perceptions of medical students regarding the use of artificial intelligence (AI)-based (chat) applications such as ChatGPT (OpenAI), Bard (Google), Bing Chat (Microsoft Inc), and Jasper Chat (Jasper AI, Inc) in medicine (n=487).

Statement and subgroup	Scores, median (IQR)	Scores, mode	P value	Z score
The use of AI in medicine will...				
S1: ...positively change medicine			.003	-2.990
Subgroup 1: previous use of AI	4 (3.75-4.25)	4		
Subgroup 2: no previous use of AI	4 (3-4)	4		
S2: ...find useful applications in medicine			.002	3.101
Subgroup 1: previous use of AI	4 (3.5-4.5)	4		
Subgroup 2: no previous use of AI	4 (3-4)	4		
S3: ...influence the choice of my medical specialization			.52	-1.474

S10: ...negatively affect patient autonomy			.05	2.040
Subgroup 1: previous use of AI	3 (2-3)	2		
Subgroup 2: no previous use of AI	3 (2-4)	3		
S11: ...negatively affect the autonomy of medical staff			.16	1.415
Subgroup 1: previous use of AI	3 (2-4)	2		
Subgroup 2: no previous use of AI	3 (2-4)	3		
S12: ...bring new ethical challenges			.02	2.302
Subgroup 1: previous use of AI	5 (4-5)	5		
Subgroup 2: no previous use of AI	4 (3-4)	4		

Part 4: Teaching AI in Medical Education

When asked about their agreement on whether AI teaching should be incorporated into medical education (S13), 74.9% (385/487) of the respondents agreed or strongly agreed. A

statistically significant difference was identified between those with and without prior use of AI-based (chat) applications ($P=.02$). The mean (5), mode (5), and z score (2.381) suggest higher agreement within the group that previously used AI-based applications. In contrast, there was an overall disagreement

(88%) with the assertion that AI instruction in medical education is currently sufficient (S14), with no statistically significant difference between the 2 groups. No significant statistical differences were observed for statements S15-S19. There was an overall agreement that the teaching of AI should include practical content (S15; 417/487, 86%), be based on case studies and application scenarios in medicine (S16; 342/487, 70.3%), be an important prerequisite for medical practice (S17; 314/487, 64.9%), be available to medical staff even after graduation (S18; 376/487, 77.3%), and be updated regularly to reflect advances

in AI technology (S19; 407/487, 83.6%). There was a significant measurable difference in the S20 ($P=.002$) between the 2 groups. The z score indicates a stronger agreement with the statement “AI instruction is of interest to me” among the group of medical students who previously used AI-based (chat) applications (z score: 3.173). The statistical analysis is presented in Table 5, and an overview of the perceptions of the participants regarding the teaching of AI in medicine can be found in Table S2 in Multimedia Appendix 1.

Table 5. Statistical analysis of the perceptions of medical students regarding the teaching of artificial intelligence (AI)-based (chat) applications such as ChatGPT (OpenAI), Bard (Google), Bing Chat (Microsoft Inc), and Jasper Chat (Jasper AI, Inc) in medical education (n=487).

Statement and subgroup	Scores, median (IQR)	Scores, mode	<i>P</i> value	<i>Z</i> score
The teaching of AI...				
S13: ...should be part of medical education			.02	2.381
Subgroup 1: previous use of AI	5 (4-5)	5		
Subgroup 2: no previous use of AI	4 (3-4)	4		
S14: ...in medical education is adequate			.90	0.128
Subgroup 1: previous use of AI	2 (1-2)	1		
Subgroup 2: no previous use of AI	2 (1-2)	1		
S15: ...should include practical content (e.g., exercises to apply AI) in addition to theoretical aspects			.18	-2.358
Subgroup 1: previous use of AI	4 (3.5-4.5)	4		
Subgroup 2: no previous use of AI	4 (0)	4		
S16: ...should be based on case studies and application scenarios of AI in medicine			.53	-0.625
Subgroup 1: previous use of AI	4 (3-5)	4		
Subgroup 2: no previous use of AI	4 (3.5-4.5)	4		
S17: ...is an important prerequisite for medical practice			.16	1.417
Subgroup 1: previous use of AI	4 (3.5-4.5)	4		
Subgroup 2: no previous use of AI	4 (3-4)	4		
S18: ...should be available for medical staff even after graduation			.13	-1.527
Subgroup 1: previous use of AI	4 (3.5-4.5)	4		
Subgroup 2: no previous use of AI	4 (3-5)	4		
S19: ...should be updated regularly to reflect advances in AI technology			.34	-2.121
Subgroup 1: previous use of AI	4 (3-4)	4		
Subgroup 2: no previous use of AI	4 (3-4)	4		
S20: ...is of interest to me			.002	3.173
Subgroup 1: previous use of AI	4 (4-5)	4		
Subgroup 2: no previous use of AI	4 (0)	4		

Part 5: Teaching AI Ethics in Medical Education

In the survey, 74.9% (385/487) of medical students agreed or strongly agreed that teaching AI ethics should be included in medical education (S21). However, only 4.9% (24/487) agreed that the current instruction on AI ethics in medical education is adequate (S22). For statements S23 to S27, the vast majority of medical students generally agreed (“agree” or “strongly agree”) that the teaching of AI ethics should be based on case studies and application scenarios of AI in medicine (S23; 412/487, 85%), contribute to raising awareness of ethical issues

in medical practice (S24; 343/487, 70.6%), is an important prerequisite for medical practice (S25; 354/487, 72.8%), should be available for medical staff even after graduation (S26; 370/487, 75.9%), and should be taught by experts from various fields (eg, medicine, computer science, and philosophy) to ensure a multidisciplinary perspective on AI ethics (S27; 416/487, 85.2%). No statistically significant differences were observed for statements S21 to S27 between the 2 groups (those with previous use of AI-based [chat] applications and those without). Despite the z score of 1.782 being below the typical

threshold of 1.96 for a 2-tailed test, the statement “the teaching of AI ethics is of interest to me” (S28) showed a statistically significant difference ($P=.005$). This indicates that even though the deviation from the mean agreement level is not as strong as typically expected for significance, those who had previously

used AI-based (chat) applications demonstrated a notably higher level of interest in AI ethics teaching than those who had not. The statistical analysis for part 5 of the survey is shown in [Table 6](#), and the distribution of answers is presented in [Table S3 in Multimedia Appendix 1](#).

Table 6. Statistical analysis of the perceptions of medical students regarding the teaching of artificial intelligence (AI)-based (chat) applications such as ChatGPT (OpenAI), Bard (Google), Bing Chat (Microsoft Inc), and Jasper Chat (Jasper AI, Inc) ethics in medical education (n=487).

Statement and subgroup	Scores, median (IQR)	Scores, mode	P value	Z score
The teaching of AI...				
S13: ...should be part of medical education			.37	-0.903
Subgroup 1: previous use of AI	5 (4-5)	5		
Subgroup 2: no previous use of AI	4 (4-5)	5		
S14: ...in medical education is adequate			.21	-1.263
Subgroup 1: previous use of AI	2 (2-3)	2		
Subgroup 2: no previous use of AI	2 (1-2)	1		
S15: ...should include practical content (e.g., exercises to apply AI) in addition to theoretical aspects			.80	-0.254
Subgroup 1: previous use of AI	4 (0)	4		
Subgroup 2: no previous use of AI	4 (0)	4		
S16: ...should be based on case studies and application scenarios of AI in medicine			.48	-0.707
Subgroup 1: previous use of AI	4 (3-4)	4		
Subgroup 2: no previous use of AI	4 (2.5-4.5)	4		
S17: ...is an important prerequisite for medical practice			.90	0.118
Subgroup 1: previous use of AI	4 (3-4)	4		
Subgroup 2: no previous use of AI	4 (2-4)	4		
S18: ...should be available for medical staff even after graduation			.17	-1.359
Subgroup 1: previous use of AI	4 (3-4)	4		
Subgroup 2: no previous use of AI	4 (2-4)	4		
S19: ...should be updated regularly to reflect advances in AI technology			.17	-1.381
Subgroup 1: previous use of AI	4 (3-4)	4		
Subgroup 2: no previous use of AI	4 (3-4)	4		
S20: ...is of interest to me			.005	1.782
Subgroup 1: previous use of AI	4 (3-4)	4		
Subgroup 2: no previous use of AI	4 (0)	4		

Part 6: AI Ethics Teaching Content

In analyzing the perceptions of medical students with and without prior exposure to AI chat applications regarding AI ethics content, all 8 proposed topics were deemed highly relevant (“quite relevant” and “very relevant”) by the respondents: TC1: 418/487, 85.9%; TC2: 408/487, 83.8%; TC3: 384/487, 78.9%; TC4: 415/487, 85.2%; TC5: 423/487, 86.2%; TC6: 407/487, 83.6%; TC7: 402/487, 82.5%; and TC8: 448/487,

92.3%). No statistically significant difference was observed between the responses of both groups, except for TC1 (informed consent; $P=.04$). The z score suggests that medical students who had previously used AI-based (chat) applications perceived informed consent to be more relevant than those who had not (z score: 2.018). The statistical results of this section are shown in [Table 7](#), with an overview of the statements on the relevance of AI ethics teaching content provided in [Table S4 in Multimedia Appendix 1](#).

Table 7. Statistical analysis of the relevance of artificial intelligence (AI)-based (chat) applications such as ChatGPT (OpenAI), Bard (Google), Bing Chat (Microsoft Inc), and Jasper Chat (Jasper AI, Inc) ethics teaching contents according to the participating medical students (n=487).

AI ethics teaching content and subgroup	Scores, median (IQR)	Scores, mode	P value	Z score
TC1: informed consent			.04	2.018
Subgroup 1: previous use of AI	4 (4-5)	5		
Subgroup 2: no previous use of AI	4 (3-4)	4		
TC2: bias			.22	-1.215
Subgroup 1: previous use of AI	4 (4-5)	5		
Subgroup 2: no previous use of AI	4 (3-4)	4		
TC3: data privacy			.78	0.283
Subgroup 1: previous use of AI	4 (4-5)	5		
Subgroup 2: no previous use of AI	4 (4-5)	5		
TC4: explainability			.36	-0.911
Subgroup 1: previous use of AI	4 (4-5)	5		
Subgroup 2: no previous use of AI	4 (3.5-4.5)	4		
TC5: safety			.57	0.565
Subgroup 1: previous use of AI	5 (4-5)	5		
Subgroup 2: no previous use of AI	5 (4-5)	5		
TC6: fairness			.96	-0.048
Subgroup 1: previous use of AI	4 (4-5)	5		
Subgroup 2: no previous use of AI	4 (4-5)	5		
TC7: autonomy			.11	1.594
Subgroup 1: previous use of AI	4 (4-5)	5		
Subgroup 2: no previous use of AI	4 (4-5)	5		
TC8: responsibility			.22	-1.215
Subgroup 1: previous use of AI	5 (4-5)	5		
Subgroup 2: no previous use of AI	5 (4-5)	5		

Additional Analysis of the Collected Data

To analyze whether there is a difference in education regarding AI and AI ethics among Germany, Austria, and Switzerland, we conducted an additional evaluation of the collected data. For this supplementary analysis, we analyzed the responses to Q2: "Have you already received education in the field of artificial intelligence within your regular medical studies? (eg, as part of medical statistics or informatics)," and Q4: "Have you already received education in the field of AI ethics within your regular medical studies? (eg, as part of the History, Ethics, and Theory of Medicine course)." Using the chi-square test of independence, we sought to determine whether the distribution of answers varied significantly among these countries. In the comparison between the 3 countries concerning education in the field of AI, the chi-square test of independence indicated no significant difference in the distribution of the responses. Of the 487 respondents, only 26 (5.3%) indicated that they had previously received AI education. The test yielded a result of $\chi^2_2(N=487)=0.1$ ($P=.33$). Similarly, regarding education in the field of AI ethics, the distribution of responses among the countries was not significantly different. Of the 487 respondents,

only 21 (4.3%) indicated that they had received education on AI ethics. The test yielded a result of $\chi^2_2(N=487)=0.3$ ($P=.19$).

Stage of Study

To account for potential confounders, such as the stage of the study, further analyses were performed on the data set. Recognizing the possible overlaps and similarities in experiences and perspectives across the different stages, the original 6 stages of the study were further consolidated. The stages "preclinical" and "bachelor" were summarized into the "preclinical stage (PCS)." Similarly, the "clinical" and "master" stages were combined into the "clinical stage." Finally, the "practical year" and "elective year" stages were grouped together to form the "clinical practical stage (CPS)." With these redefined categories, the chi-square test of independence was used to analyze whether there were significant variations in perceptions and responses across the 3 consolidated stages.

Focusing on the potential impact of AI in medicine, a significant difference was observed in the statement, "the use of AI in medicine will influence the choice of my specialization" (S3). CPS participants were notably more influenced than those in the PCS ($P=.004$). However, no difference was evident between

the PCS and CS participants. Most other statements concerning AI's impact on medicine (S1-2; S4-12) did not demonstrate statistical significance. Similarly, no significant difference was found for statements related to AI teaching (S13-20) across the study stages (PCS, CS, and CPS). When considering the teaching of AI ethics, differences were evident in the belief that AI ethics should be integrated into medical education (S21; $P=.003$) and that the current teaching of AI ethics is adequate (S22; $P=.02$). Upon further analysis, CS participants showed stronger agreement than PCS participants, with no difference when compared with CPS participants. Finally, for the specific content of AI ethics teaching, none of the statements reflected significant statistical variation across the study stages. An overview of the statistical differences is provided in Tables S5-S8 in [Multimedia Appendix 1](#).

Ethics Education Background

To explore the potential impact of prior ethics education on survey outcomes, particularly in parts 3 to 6, we compared 2 distinct groups: those with prior ethics education and those without. On the use of AI in medicine, one statistical difference could be determined for the statement that "...negatively affect the autonomy of medical staff" (S11, $P=.002$). The z score suggested a stronger level of agreement with the statement in the group that had received prior ethics education (z score: 2.876). For the other statements of the third part of the survey (S1-10; S12), no statistical difference could be determined. No statistical difference could be determined for the fourth part of the survey on AI teaching (S13-20). Regarding the teaching of AI ethics, statistical differences could be determined for 2 statements (S21, $P=.004$; S22, $P=.03$). For the statement that the teaching of AI ethics should be part of medical education, the z score indicated a higher level of agreement in the group that had received prior ethics education. Similarly, a higher level of disagreement was indicated by the group with prior ethics education for the statement that the teaching of AI ethics in medical education is adequate (z score: -3.011). There was no statistically significant difference in the AI ethics teaching content between the groups. A detailed statistical analysis can be found in Tables S9-S12 in [Multimedia Appendix 1](#).

Discussion

This discussion aims to comprehensively analyze the findings regarding medical students' perceptions of AI in medicine and the role of AI and AI ethics in their medical education, depending on their use of AI-based (chat) applications such as ChatGPT.

The Use of AI-Based (Chat) Application Among the Surveyed Medical Students

The discrepancy between students' personal AI experiences and formal medical education highlights the gap in integrating AI into curricula, reflecting the need for educational progress in line with technological advancement. A considerable 38.8% of the respondents reported prior use of AI-based (chat) applications, such as ChatGPT, Bard, Bing Chat, or Jasper Chat, which was slightly below the percentage received from pretesting and used for sample size calculation (5/11, 45%).

The results concerning the reported use of AI-based (chat) applications must be evaluated in the context of the timing of the data collection. ChatGPT, for instance, became freely available to the public on November 30, 2022, making it accessible for only approximately 8 months at the time of data collection [27]. In addition, Bing Chat was not broadly accessible until May 2023, further constraining its availability before the survey [28]. It is noteworthy that academic literature on the use of AI-based (chat) applications such as ChatGPT among medical students is still limited. A study conducted with health students found that only 11.3% (55/458) of respondents reported using the ChatGPT, a rate considerably lower than the findings of this study [29].

A more detailed evaluation of the percentage of medical students using AI-based (chat) applications is necessary given that many might use AI unknowingly. This is not restricted to clinical AI tools, such as clinical decision support systems but extends to search engines and other tools. For example, the search engine Bing offers AI-driven content with search results, irrespective of whether the Bing chat is specifically used. Moreover, a study conducted with students from various specialties in Germany revealed that 12.3% (779/6311) of its participants used "DeepL" (DeepL SE), an AI-based translation tool, in which the use of AI might not be immediately evident [30]. Therefore, when considering other AI tools and applications, the actual percentage of medical students using them may be significantly higher than the 38.8% reported in this study. Recognizing this potential underestimation of AI use highlights the importance of expanding AI literacy and awareness in medical education to ensure that future health care professionals are adequately prepared for the integration of AI in medicine. This reinforces the need for proactive measures in curriculum design to include not only the direct use of AI tools but also an understanding of their indirect implications in various medical and research contexts.

AI Education

Despite the significant engagement of students with AI-based applications, such as ChatGPT, only a small fraction (26/487, 5.3%) reported formal AI education within their medical curriculum. This discrepancy highlights the critical gap between experiential learning and structured academic guidance regarding AI. Interestingly, AI education outside the formal curriculum was more prevalent (51/487, 10.5%), which could imply a proactive approach to learning about AI technologies. Furthermore, this could be attributed to the availability of AI-based applications, such as ChatGPT, and increasing opportunities for education on AI in the medical context, as well as AI-based (chat) applications that are knowledgeable in the field of medicine [7,31-33]. Among the users of AI applications, 73% applied these tools in medical contexts, primarily for querying medical knowledge. This use pattern presents both opportunities for accessible knowledge and risks associated with reliance on uncertified AI sources and a lack of certification as medical devices. The lack of education in the field of AI as part of medical education has been highlighted not only in German-speaking countries [34] but also internationally [21,22].

The results imply a substantial dichotomy between the lack of formal education and optimism toward AI, as the use of AI in medicine was positively perceived (71.1% of respondents), despite the absence of formal education (94.7% of respondents). Given the lack of education, this warrants caution as there might be an overly optimistic view of its potential benefits, overlooking potentially significant limitations and ethical implications [35]. The need for the integration of AI into medical curricula is not only supported by existing studies highlighting low AI literacy among medical students [34,36] but also by the results of this study, with 88% of all medical students perceiving that their current AI education within their medical education is insufficient. This dissatisfaction underscores the need for medical curricula to evolve in tandem with technological advancements. However, it is crucial to ensure that these curricular changes are developed thoughtfully and comprehensively to avoid superficial or overly optimistic portrayals of AI's role in medicine [34]. The findings of this study, indicating a significant gap in AI education within medical curricula, align with the initial insights gathered regarding students' use of AI applications. Furthermore, the results align with the objective of understanding how medical students from Germany, Austria, and Switzerland perceive the application of AI in medical practice and its integration into medical education. This disparity between the practical use of AI applications and lack of AI educational opportunities in the curriculum underlines the emerging need for educational reform.

AI Ethics Education

The perceived insufficiency of the current medical education extends to AI ethics. Remarkably, 95.3% of participants acknowledged the new ethical challenges posed by AI in medicine, which resonates with preexisting research [15]. Notably, those who used AI-based (chat) applications, such as ChatGPT, agreed more strongly with this view, suggesting that practical use enhances awareness of these ethical issues. In addition, 74.9% (385/487) of respondents recognized the necessity of integrating AI ethics into medical curricula, aligning with recent academic discourse [37-39]. However, only a small percentage (4.3%) reported formal AI ethics education, highlighting a significant deficit in the current curriculum. Medical students perceived all 8 proposed ethical AI topics as highly relevant, which were recommended as potential teaching content for AI ethics in the current literature [37-39]. Statistical differences were observed for "informed consent" among those with prior AI application use. This indicates that engagement with AI technology may deepen understanding of its ethical dimensions, reinforcing the need for comprehensive AI ethics instruction in medical education. The clear demand for AI ethics education reflects a broader educational need, where medical students should not just be prepared for the technicalities of AI but also for the nuanced ethical considerations introduced by the technology.

Although this study underscores the need for both AI and AI ethics education in medical curricula, it is also important to critically assess the current absence of AI-centric content. Rapid technological advancements in AI with the recent public availability of AI tools, such as ChatGPT, may contribute to the current lack of associated teaching content. Given the

complex regulatory requirements required to use AI-based technologies in clinical practice, the use of AI in medicine is currently not widespread [40]. In addition, the requirement for time-consuming and complex reaccreditation processes for curricular development and revision may further delay the introduction of AI-related teaching content [41]. Moreover, the lack of widespread use of AI-based applications in medicine and clinical practice likely contributes to the current lack of adequate teaching content on AI and ethics. The overwhelming perception of AI's potential and its ethical implications it brings forth, as evidenced by this study, underscores the need for educational institutions to respond proactively. Balancing the speed of technological advancements in the field of AI with thoughtful and comprehensive curricular integration is likely to be a crucial challenge in medical education in the coming years.

Additional Analysis of the Collected Data

In the additional data analysis, the subsequent examination revealed that perceptions of AI and AI ethics among medical students were not significantly influenced by their country of study. This uniformity across Germany, Austria, and Switzerland suggests consistency in deficiencies in AI and AI ethics education regardless of regional curricular variations. As the findings could be attributed to the limited number of medical students indicating prior education in AI (26/487, 5.3%) and AI ethics (21/487, 4.3%), additional research is warranted. Despite their different educational systems, the observed uniformity in AI and AI ethics education across the 3 countries implies a broader challenge for medical education. The consistency of educational deficiencies, irrespective of regional curricular variations, indicates the widespread need to reform AI teaching in medical curricula. This aligns with the overarching findings of our study, which suggest a universal gap in AI competencies among medical students.

Further analysis of the study stage revealed that students in advanced stages, such as CPS, showed increased awareness of the potential impact of AI on their specialization choices, implying a growing realization of AI's role as they progress in their studies. However, the lack of significant differences in most other AI-related statements could also imply a generalized consensus or a lack of adequate exposure and understanding across all study stages. As an advancement in the study stages could be linked to statistically significant results on statements regarding the need to teach AI ethics, this could be attributable to prior ethics education, which is usually taught during the PCSs.

The impact of ethics education on perceptions of AI's role in medicine is particularly notable. Students with such an education showed increased awareness of the ethical challenges posed by AI, especially regarding its potential negative impact on medical staff autonomy (S11). This could underscore the importance of ethics education in understanding the potentially wide-reaching challenges of AI in medicine for ethically important subjects such as autonomy; however, no statistically significant difference for the preceding statement on autonomy "the use of AI in medicine will negatively affect patient autonomy" (S10) could be observed. This could imply that prior ethics education,

including teaching autonomy in a medical context, might lead to a more nuanced understanding of the subject and potential implications of AI. The results of the analysis reinforce the need for ongoing ethics education, not just as a separate entity, but also interwoven with AI-related topics, to enhance students' comprehensive understanding of the ethical implications of AI in medicine. The significant influence of prior ethics education on shaping students' perceptions of the role of AI in medicine emphasizes the interaction between ethical training and technological awareness. The nuanced understanding of the ethical implications of AI among students who have received ethics education underscores the importance of such training in developing critical thinking about the impact of AI in health care. Integrating ethics education with AI teaching content could foster a more holistic approach, preparing students not only for the technological aspects of AI but also for its ethical and societal implications [37].

Limitations

Despite the strengths of this study, some limitations must be acknowledged. First, our web-based survey could introduce selection bias, as tech-savvy students may be more likely to participate. Second, the survey measured students' perceptions rather than their actual competencies in AI and ethics. In addition, although estimated, the response rate was suboptimal, which may limit the generalizability of our findings. Geographically, our sample was limited to German-speaking countries, making the translation of these results to other countries with different health care systems and medical educational frameworks difficult. Cultural attitudes toward AI could also vary, possibly influencing students' perceptions of and engagement with AI. Our study is essentially a snapshot of a rapidly evolving field; hence, our findings may not reflect attitudes and competencies, as they evolve with advancements in AI technology. In our analysis, we observed statistically significant differences based on prior ethics education and study stage. However, although the additional analysis of the data did not show a direct overlap with significant findings between the main and supplementary evaluations, additional tests are needed to determine whether these factors acted as confounders in our

main data analysis. Although this study considered specific potential confounders, it is worth noting that other confounding variables may exist and were not analyzed in this study. Finally, owing to the self-reported nature of the data, the responses might be subject to recall bias, misunderstanding of questions, or social desirability bias. Although our findings provide valuable insights into the state of AI education in German-speaking medical schools, broader multinational studies would offer a more comprehensive understanding.

Conclusions

This study provides a valuable understanding of the perceptions and experiences of medical students in Germany, Austria, and Switzerland regarding the application of AI in medicine, and its role in medical education. Our findings clearly indicate a discrepancy between students' interactions with AI-based chat applications such as ChatGPT and the representation of AI in their formal education. Despite a significant number of students interacting with AI technology, notably AI-based chat applications, only a fraction have received any formal AI education, revealing a substantial gap in the current medical curricula. This highlights the necessity of the evolution of medical curricula to incorporate AI and AI ethics education, ensuring that future medical professionals are adequately equipped to navigate the challenges and opportunities presented by AI in medicine.

Furthermore, our findings indicate that practical engagement with AI technology can contribute to an increased awareness of ethical implications, reinforcing the importance of including hands-on AI experiences in medical education. It is evident that the rapid advancement and application of AI in medicine demands parallel evolution in medical education. Thoughtful and comprehensive curricular changes are required to provide a balanced understanding of the potential benefits, limitations, and ethical implications of AI. The integration of AI and AI ethics into medical education is an urgent necessity, not only to enhance students' AI literacy but also to ensure the responsible and effective use of AI in future medical practice demands.

Abstract

Background: Regular physical activity is critical for health and disease prevention. Yet, health care providers and patients face barriers to implement evidence-based lifestyle recommendations. The potential to augment care with the increased availability of artificial intelligence (AI) technologies is limitless; however, the suitability of AI-generated exercise recommendations has yet to be explored.

Objective: The purpose of this study was to assess the comprehensiveness, accuracy, and readability of individualized exercise recommendations generated by a novel AI chatbot.

Methods: A coding scheme was developed to score AI-generated exercise recommendations across ten categories informed by gold-standard exercise recommendations, including (1) health condition-specific benefits of exercise, (2) exercise preparticipation health screening, (3) frequency, (4) intensity, (5) time, (6) type, (7) volume, (8) progression, (9) special considerations, and (10) references to the primary literature. The AI chatbot was prompted to provide individualized exercise recommendations for 26 clinical populations using an open-source application programming interface. Two independent reviewers coded AI-generated content for each category and calculated comprehensiveness (%) and factual accuracy (%) on a scale of 0%-100%. Readability was assessed using the Flesch-Kincaid formula. Qualitative analysis identified and categorized themes from AI-generated output.

Results: AI-generated exercise recommendations were 41.2% (107/260) comprehensive and 90.7% (146/161) accurate, with the majority (8/15, 53%) of inaccuracy related to the need for exercise preparticipation medical clearance. Average readability level of AI-generated exercise recommendations was at the college level (mean 13.7, SD 1.7), with an average Flesch reading ease score of 31.1 (SD 7.7). Several recurring themes and observations of AI-generated output included concern for liability and safety, preference for aerobic exercise, and potential bias and direct discrimination against certain age-based populations and individuals with disabilities.

Conclusions: There were notable gaps in the comprehensiveness, accuracy, and readability of AI-generated exercise recommendations. Exercise and health care professionals should be aware of these limitations when using and endorsing AI-based technologies as a tool to support lifestyle change involving exercise.

KEYWORDS

exercise prescription; health literacy; large language model; patient education; artificial intelligence; AI; chatbot

Introduction

Regular physical activity is an essential component of a healthy lifestyle with numerous benefits that are widely recognized and indisputable [1,2]. To support overall health, the American College of Sports Medicine (ACSM) and the Department of Health and Human Services recommend healthy adults engage in regular physical activity, including moderate-intensity aerobic exercise for at least 150 minutes per week, vigorous-intensity aerobic exercise for at least 75 minutes per week, or a combination of both, as well as muscle-strengthening activities at least twice per week [1,2]. In addition, evidence-based practice calls for exercise as first-line therapy to prevent, treat, and control multiple chronic conditions and diseases such as hypertension, hypercholesterolemia, and diabetes mellitus [3-7]. As such, the ACSM endorses individualized, evidence-based, exercise recommendations (termed *exercise prescription* [ExRx]) for more than 25 clinical populations [1]. These ExRxs are tailored to favorably augment health-related outcomes of interest for each respective clinical population while addressing additional factors such as clinical contraindications, common medications, and special considerations [1,8]. Despite well-established guidelines, health care providers often struggle to provide sufficient counseling and follow-up on lifestyle recommendations, including exercise, due to various barriers such as time constraints, limited resources, lack of awareness or training, and lack of reimbursement incentives [9-11]. Patients also rely heavily on web-based sources for health-related information [12-14], which often includes misinformation that can negatively impact health outcomes and undermine provider-led efforts to support behavior change [15,16].

Artificial intelligence (AI) has recently emerged as a promising tool to augment health and health care and address these challenges [17]. AI-based technology including machine learning, neural networking, deep learning, and natural language processing enables computers to interact with a corpus of text data to generate human language [18,19]. Large language models (LLMs), such as the generative pretrained transformer (GPT), have the ability to generate human-like language on their own, making them a powerful tool for interacting with users as if they are communicating with another human [18,19]. The surge in popularity of LLMs can largely be attributed to the third iteration of OpenAI's GPT series, ChatGPT [20]. ChatGPT has been recognized as the fastest-growing consumer application in history [20] and is widely regarded as disruptive technology due to its strong potential to enable a wide range of clinical applications as both a provider- and patient-facing tool [21] by generating language that is contextually appropriate, natural sounding, and coherent. Indeed, ChatGPT has demonstrated remarkable capabilities including diagnosis support, streamlining clinical workflows, reducing documentation burden, improving patient education

understandability and experience [22-25], and, most recently, passing the United States Medical Licensing Examination [26].

Transformative applications of ChatGPT continue to evolve, but evaluation of its output and suitability in clinical context remains to be explored, in addition to identifying barriers to access and outcomes related to its use. The application of digital technology to support a health behavior change using knowledge-shaping techniques, which is complex and riddled with contextual and individualized components, is challenging [27]. Challenges include ensuring the suitability and usability of the technology confers appropriate educational requisites to understand and apply knowledge in the form of its recommendations. These educational considerations include readability, which can influence the use of AI-generated education for health behavior change [28]. Further, as an extension of readability, low health literacy can limit a patient's ability to understand and use health information effectively, which can reduce the effectiveness of AI-generated educational resources [29,30].

The evaluation of ChatGPT's suitability to provide interactive, personalized, and evidence-based exercise recommendations to support behavior change to improve health has not been conducted to date. As such, the primary aim of this study is to assess the suitability of exercise recommendations generated by ChatGPT, a new AI chatbot, as an adjuvant educational tool for health care providers and patients. Primary outcomes of interest include comprehensiveness, accuracy, and readability of the recommendations generated by ChatGPT, with the goal of determining its potential to deliver personalized exercise recommendations at scale. A secondary aim of this study was to conduct a qualitative analysis to identify potential patterns, consistencies, and gaps in AI-generated exercise recommendations. As this technology is still nascent, the study was exploratory in nature, without an a priori hypothesis.

Methods

High-Level Overview

This study was conducted in March 2023 using the free research preview of a novel AI chatbot (ChatGPT February 13 version) [31]. Figure 1 provides a conceptual overview of the study. Briefly, open-text queries seeking individualized exercise advice were posed to the chatbot interface for all populations (N=26) for which there exist established evidence-based exercise recommendations by the ACSM [1]. Mixed methods were applied to characterize individual and average exercise recommendation content depth, accuracy, and readability. The results were synthesized to highlight potential strengths, weaknesses, opportunities, and risks for researchers, clinicians, and patients likely to interact with the ChatGPT platform for this use case.

Figure 1. Conceptual study overview. ACSM: American College of Sports Medicine; ExRx: exercise prescription; GETP: Guidelines for Exercise Testing and Prescription.

Ethical Considerations

This study was deemed to be exempt by the University of Connecticut Institutional Review Board (E23-0378) as this study solely involved the evaluation of AI-generated output and did not involve interaction or intervention with human subjects.

Selection of the Gold-Standard Reference Source

The ACSM is widely regarded as a leading authority in the field of exercise science and sports medicine, and the organization's guidelines and recommendations are considered the gold standard for health and fitness professionals in the United States and the world [1,8,32]. The *ACSM's Guidelines for Exercise Testing and Prescription* (GETP) serves as its flagship resource manual, continuously updated every 4-5 years since 1975. The most recent edition integrates the latest guidelines from ACSM position stands and other relevant professional organizations' scientific statements, including the 2018 Physical Activity Guidelines for Americans [1]. This latest edition of GETP represents the most current and primary resource for evidence-based exercise recommendations [1]. Given ACSM's authoritative status and the comprehensiveness of its guidelines, GETP was selected as the ground truth benchmark source to guide the study design and systematically evaluate the suitability of AI-generated exercise recommendations.

ChatGPT Prompt Specificity and Structure

Prompt methodology was developed a priori with the overarching goal to observe ChatGPT's unaltered performance in a real-world setting while controlling for factors known to influence output, including prompt structure, evaluation timeframe, model version, and model feedback.

A single researcher (ALZ) posed 26 separate, open-ended prompts as a new chat session to the ChatGPT bot (version 3.5)

on the same day in a single session. Each text prompt was framed to the ChatGPT bot in a standardized, neutral, third-person tense format as "exercise recommendations for [population]" to optimize the relevance of AI responses for both health care provider and patient scenarios. Generated ChatGPT bot responses were abstracted from the interface and converted into plain text format using Microsoft Word (version 2208; Microsoft Corp) on the same day. Content was unaltered upon conversion to plain text format (Multimedia Appendix 1). Note that the ChatGPT bot used in this study was not subjected to retraining or correction during these prompt interactions. The rationale for this methodological decision was to enable the natural observation of ChatGPT's raw performance and provide a transparent evaluation of its inherent capabilities [33,34].

AI-Generated Exercise Recommendations

Following this prompt specificity and structure, all clinical populations within the ACSM GETP were evaluated once in a separate prompt (N=26), including healthy adults, children and adolescents, older adults, persons who are pregnant, and individuals with cardiovascular disease (CVD), heart failure, heart transplant, peripheral artery disease, cerebrovascular accident, asthma, chronic obstructive pulmonary disease, diabetes mellitus, dyslipidemia, hypertension, overweight and obesity, arthritis, cancer, fibromyalgia, HIV, kidney disease, multiple sclerosis, osteoporosis, spinal cord injury, Alzheimer disease, intellectual disability, and Parkinson disease.

Conceptual Content Analysis

A list of conceptual categories was generated, refined, and organized into a coding scheme for predefined categories that pertain to the fundamental aspects of an ExRx. These categories relate to an individualized physical activity program based on the FITT principle, which stands for the frequency (*how often?*),

intensity (*how hard?*), time (*how long?*), and type (*what kind?*) of exercise [1,35]. The final coding scheme included ten categories: (1) health condition-specific benefits of exercise, (2) exercise preparticipation health screening, (3) frequency, (4) intensity, (5) time, (6) type, (7) volume, (8) progression, (9) special considerations, and (10) references (ie, citations to primary literature or sources that supported the AI-generated content provided).

AI-generated exercise recommendations were then coded and recorded in Microsoft Excel (version 2208; Microsoft Corp) following a 2-stage coding process by 2 independent coders with advanced degrees in kinesiology (ALZ and RB). In the first stage, AI-generated content was appraised for comprehensiveness. Each exercise recommendation was coded for the presence (1 point) or absence (0 points) of content provided for each of the 10 prespecified categories such that each exercise recommendation had a possible range of 0-10 points. Comprehensiveness was determined by dividing the total number of points (ie, *actual*) by the total number possible (ie, *expected* or 10 points) and multiplying by 100. The resulting score was expressed as a percent, with 100% indicating the highest possible score and fully comprehensive. This formula was applied to all 26 exercise recommendations and averaged to characterize ChatGPT's overall ability to deliver exercise recommendations regarding their comprehensiveness.

In the second stage, all categories with reported content (ie, fully *and* partially comprehensive content) were appraised for accuracy. Accuracy was defined as concordance with the ACSM GETP as the ground truth source [1]. In one instance, content deviated from the ACSM GETP (ie, condition-specific benefits of exercise for individuals with HIV), and accuracy was defined as the degree to which the content was consistent with other widely established facts or clinical literature. Responses were coded by the same independent reviewers (ALZ and RB) and recorded as binary variables: "concordant" or "discordant" following the same process used to determine comprehensiveness. Potential discrepancies in coding were resolved through discussion with a third party and senior expert in the field (LSP). The accuracy score was determined by dividing the number of concordant category counts by the number of categories present (ie, "actual" counts; previously determined when calculating comprehensiveness during the first stage) and multiplying by 100. The resulting score was expressed as a percent, with 100% indicating the highest possible accuracy score or fully concordant.

Readability Metrics

The Flesch-Kincaid formula was used to determine readability, a commonly used tool that evaluates the complexity of text-based educational material. This tool was selected due to its objectivity, as scores are computationally derived rather than paper-and-pencil tools that rely on hand calculations and subjectivity, which introduce risk for human error [36]. The formula is based on the average number of syllables per word and the average number of words per sentence with the resulting score estimating the minimum grade level required to understand the text. For example, a score of 8.0 means that the text can be understood by an average eighth-grader in the United States.

Flesch reading ease scores range from 0 to 100, with higher scores indicating easier-to-read text. For example, scores <50 are considered difficult to read, while scores >80 are considered easy to read [36]. To assess readability metrics and word count, a single researcher (RB) used the built-in readability statistics functionality of Microsoft Word (version 2208). The mean (SD) word count and readability metrics (ie, Flesch reading ease and grade level) were calculated using Microsoft Excel (version 2208).

Qualitative Analysis

Qualitative analysis with a thematic mapping approach was used to identify novel patterns, trends, and insights across the AI-generated text output. Thematic mapping, a qualitative research method, involves the identification, analysis, and visualization of recurring themes or topics within a data set. This approach is instrumental in highlighting consistencies or gaps in data, facilitating the generation of insights, and formulating hypotheses for further investigation [37].

Statistical Analyses

Descriptive statistics characterized the distribution of all outcome variables of interest, including comprehensiveness, accuracy, and readability metrics. Interrater reliability was assessed using Cohen κ coefficient [(observed agreement–expected agreement)/(1–expected agreement)]. Qualitative analysis was conducted using a systematic multistep approach. All AI-generated exercise recommendations, comprising the text output, were collected and organized to form the data set for qualitative examination. The analysis was carried out by a single researcher (ALZ) who immersed themselves in the content and initiated the coding process by identifying initial themes or patterns within the recommendations. Subsequently, codes were meticulously refined and organized into broader themes, ensuring consistency and accuracy throughout the process. These identified themes were then visually mapped to represent patterns within the data set. Insights generated from the analysis were discussed collaboratively as a team, facilitating comprehensive understanding and quantification, whenever applicable.

Results

Interrater Reliability

Interrater reliability was assessed for the 2 independent raters who coded a sample of 26 AI-generated exercise recommendations using a set of 10 categories. Cohen κ coefficient was calculated to be 1.0, indicating perfect agreement between coders.

Comprehensiveness of AI-Generated Exercise Recommendations

Table 1 details the presence of educational content across the predefined categories of interest abstracted from AI-generated exercise recommendations for 26 populations. Overall, AI-generated exercise recommendations were 41.2% (107/260) comprehensive when compared against a predefined set of content categories that comprise a gold-standard ExRx [1]. There were no populations or categories that were fully

comprehensive. Comprehensiveness ranged from 0% to 92% with notable gaps in content surrounding the critical components of ExRx: frequency (n=2, 8%), intensity (n=2, 8%), time (n=1, 4%), and volume (n=0, 0%). Partial information was provided across these same categories (ranging from 31% to 58%) with

almost all gaps surrounding the provision of FITT for resistance training or flexibility modalities. In addition, only 8% (n=2) of recommendations provided a reference source, both of which (accurately) cited the American Heart Association.

Table 1. Comprehensiveness of artificial intelligence-generated exercise recommendations by content category (N=26).

Content	Exercise recommendations reporting content		
	Fully provided, n (%)	Partial ^a , n (%)	Not provided, n (%)
Condition-specific benefits	24 (92)	0 (0)	2 (8)
Preparticipation screening	24 (92)	0 (0)	2 (8)
Frequency	2 (8)	9 (35)	15 (58)
Intensity	2 (8)	15 (58)	9 (35)
Time	1 (4)	10 (38)	15 (58)
Type	14 (54)	12 (46)	0 (0)
Volume	0 (0)	8 (31)	18 (69)
Progression	15 (58)	0 (0)	11 (42)
Special considerations	23 (88)	0 (0)	3 (12)
References	2 (8)	0 (0)	24 (92)

^aPartial indicates some, but not all, possible content was provided.

Accuracy of AI-Generated Exercise Recommendations

Of the total available content provided to the end user, AI-generated exercise recommendations were 90.7% (146/161) accurate when compared to a gold-standard reference source (ie, ACSM GETP [1]). Among the 9.3% (15/161) of inaccurate recommendations (Table 2), there were 15 counts of discordance with most misinformation counts (n=8, 53%) surrounding the need for preparticipation medical clearance prior to engaging in exercise. The second highest category of discordance was within education related to frequency (n=2, 13%) with “overprescribing” aerobic exercise for Alzheimer disease and fibromyalgia by 2 and 5 days per week, respectively. There was

1 count each of discordance across 5 content categories (ie, condition-specific benefits, intensity, time, type, and progression) and 0 counts of discordance across the remaining content categories, including volume, special considerations, and references.

When comparing populations with discordance, hypertension (n=3) had the greatest number of misinformation counts followed by individuals with fibromyalgia (n=2), healthy adults (n=1), older adults (n=1), and cancer (n=1) and individuals with Alzheimer disease (n=1), arthritis (n=1), dyslipidemia (n=1), HIV (n=1), multiple sclerosis (n=1), osteoporosis (n=1), and overweight and obesity (n=1).

Table 2. Summary of inaccurate content among AI^a-generated exercise recommendations for all reported content categories (N=161).

Content category (count/report-ed) and population	AI-generated content	Ground truth
Condition-specific benefits (1/24)		
HIV	“Regular exercise can be beneficial for people living with HIV. It can help improve cardiovascular health, reduce stress and anxiety, boost immune function, and enhance overall well-being.”	Research regarding the impact of exercise to improve immune function is inconclusive [38].
Preparticipation screening (8/24)		
Healthy adult	“Remember to always listen to your body and consult with a healthcare professional before starting a new exercise routine.”	ACSM ^b preparticipation screening guidelines state that “physically inactive but otherwise healthy asymptomatic persons may begin light- to moderate-intensity exercise without medical clearance and, in the absence of symptoms, progress gradually in intensity as recommended by current ACSM exercise prescription guidelines” [1].
Older adult	“However, it’s important for older adults to choose exercises that are appropriate for their age and fitness level, and to check with their doctor before starting a new exercise program.”	ACSM preparticipation screening guidelines state that “physically inactive but otherwise healthy asymptomatic persons may begin light- to moderate-intensity exercise without medical clearance and, in the absence of symptoms, progress gradually in intensity as recommended by current ACSM exercise prescription guidelines” [1].
Dyslipidemia	“It’s important to consult with a healthcare professional before starting a new exercise program ...”	ACSM preparticipation screening guidelines state that “physically inactive but otherwise healthy asymptomatic persons may begin light- to moderate-intensity exercise without medical clearance and, in the absence of symptoms, progress gradually in intensity as recommended by current ACSM exercise prescription guidelines” [1].
Hypertension	“Consult with your doctor: Before starting any exercise program, it is important to consult with your doctor to make sure it is safe for you to exercise and to get guidance on the most appropriate type and intensity of exercise.”	ACSM preparticipation screening guidelines state that “physically inactive but otherwise healthy asymptomatic persons may begin light- to moderate-intensity exercise without medical clearance and, in the absence of symptoms, progress gradually in intensity as recommended by current ACSM exercise prescription guidelines” [1].
Arthritis	“Be sure to talk to your doctor or a physical therapist before starting any new exercise program ...”	ACSM preparticipation screening guidelines state that “physically inactive but otherwise healthy asymptomatic persons may begin light- to moderate-intensity exercise without medical clearance and, in the absence of symptoms, progress gradually in intensity as recommended by current ACSM exercise prescription guidelines” [1].
Cancer survivors	“It’s important to work with a healthcare provider or a qualified exercise professional to develop a safe and effective exercise program that meets your individual needs and abilities.”	ACSM preparticipation screening guidelines state that “physically inactive but otherwise healthy asymptomatic persons may begin light- to moderate-intensity exercise without medical clearance and, in the absence of symptoms, progress gradually in intensity as recommended by current ACSM exercise prescription guidelines” [1].
Multiple sclerosis	“It is always recommended to consult with a healthcare professional before starting any exercise program.”	ACSM preparticipation screening guidelines state that “physically inactive but otherwise healthy asymptomatic persons may begin light- to moderate-intensity exercise without medical clearance and, in the absence of symptoms, progress gradually in intensity as recommended by current ACSM exercise prescription guidelines” [1].
Osteoporosis	“It’s important to talk to your doctor or a qualified exercise professional before starting any new exercise program, especially if you have osteoporosis or other medical conditions.”	ACSM preparticipation screening guidelines state that “physically inactive but otherwise healthy asymptomatic persons may begin light- to moderate-intensity exercise without medical clearance and, in the absence of symptoms, progress gradually in intensity as recommended by current ACSM exercise prescription guidelines” [1].
Frequency (2/11)		
Fibromyalgia	“Aim for at least 30 minutes of aerobic exercise most days of the week.”	ACSM recommends an initial frequency of 1-2 days per week, gradually progressing to 2-3 days per week [1].

Content category (count/report-ed) and population	AI-generated content	Ground truth
Alzheimer disease	“Engage in moderate aerobic exercise such as brisk walking, cycling, or swimming for at least 30 minutes a day, five days a week.”	ACSM recommends a frequency of 3 days per week [1].
Intensity (1/17)		
Hypertension	“Avoid high-intensity exercises: Avoid high-intensity exercises that can cause sudden increases in blood pressure, such as sprinting or heavy lifting.”	ACSM does not contraindicate vigorous-intensity aerobic exercise or heavy lifting assuming adequate progression, absence of underlying disease, and proper breathing technique (ie, avoidance of Valsalva maneuver) [1].
Time (1/11)		
Fibromyalgia	“Start with 1-2 sets of 10-15 repetitions for each exercise and gradually increase the resistance as tolerated.”	ACSM recommends gradual progression of 4-5 to 8-12 repetitions and increasing from 1 to 2-4 sets per muscle group [1].
Type (1/26)		
Hypertension	“Aim for at least 30 minutes of moderate-intensity aerobic exercise most days of the week.”	New ACSM guidelines reinforce that emphasis is no longer placed on aerobic exercise alone. Aerobic or resistance exercise alone or aerobic and resistance exercise combined (ie, concurrent exercise) is recommended on most, preferably all, days of the week to total 90 to 150 minutes per week or more of multimodal, moderate-intensity exercise [39].
Volume (0/8)		
N/A ^c	N/A	N/A
Progression (1/15)		
Overweight and obesity	“If you’re new to exercise, start with low-intensity activities such as walking or swimming, and gradually increase your intensity and duration.”	ACSM recommends initial intensity should be moderate, progressing to vigorous for greater health benefits [1].
Special considerations (0/23)

Readability Metrics

Average and individual readability metrics and word count for AI-generated exercise recommendations are provided in [Table 3](#). On average, AI-generated output was 259.3 (SD 49.1) words

(range 171-354) and considered “difficult to read” with an average Flesch reading ease of 31.1 (SD 7.7; range 14.5-47.3) and written at a college-level (mean 13.7, SD 1.7; range 10.1-18.0).

Table 3. Readability metrics for artificial intelligence-generated exercise recommendations by population.

Population	Word count	Flesch reading ease	Grade level
Healthy adults	187	14.5	15.2
Children and adolescents	253	29.8	14.1
Pregnancy	267	34.7	13.5
Older adults	276	37.0	12.2
Cardiovascular disease	271	33.6	13.2
Heart failure	235	23.0	16.2
Heart transplant	278	24.9	14.4
Peripheral artery disease	322	32.4	13.4
Cerebrovascular accident	346	22.0	15.1
Asthma	317	41.1	12.0
COPD ^a	247	47.3	10.1
Diabetes	201	36.7	11.8
Dyslipidemia	291	19.6	15.9
Hypertension	247	34.5	13.3
Overweight and obesity	200	34.7	13.2
Arthritis	236	38.4	13.0
Cancer	319	24.8	14.9
Fibromyalgia	303	40.0	12.2
HIV	232	30.0	13.9
Kidney disease	354	31.1	15.3
Multiple sclerosis	255	38.4	11.4
Osteoporosis	171	32.7	12.3
Spinal cord injury	281	25.5	14.1
Alzheimer disease	191	29.1	14.8
Intellectual disability	241	32.1	13.2
Parkinson disease	221	19.8	18.0
Mean (SD)	259.3 (49.1)	31.1 (7.7)	13.7 (1.7)

^aCOPD: chronic obstructive pulmonary disease.

Qualitative Analysis

A secondary aim of this study was to identify potential patterns, consistencies, and gaps in AI-generated exercise recommendation text outputs. Major observations derived from qualitative evaluation of AI-generated exercise recommendations can be found in [Multimedia Appendix 2](#). Briefly, several recurring themes emerged among the total sample, including liability and safety, preference for aerobic exercise, and inconsistencies in the terminology used for exercise professionals. Importantly, AI-generated output showed potential bias and discrimination against certain age-based populations and individuals with disabilities. The implications of these findings are discussed in detail below.

Discussion

Principal Findings

This study sought to explore the suitability of AI-generated exercise recommendations using a popular generative AI platform, ChatGPT. Given the recent launch and popularity of ChatGPT and other similar generative AI platforms, the overall goal was to formally appraise the suitability and readability of AI-generated output likely to be seen by patients and inform exercise and health care professionals and other stakeholders on the potential benefits and limitations of using AI to leverage for patient education. The major findings were that AI-generated output (1) presented 41.2% (107/260) of the content provided in a gold-standard exercise recommendation indicating poor comprehensiveness; (2) of the content provided, chat output was 90.7% (146/161) accurate with most discordance related

to the need for exercise preparticipation health screening; and (3) had college-level readability.

The results of this study are consistent with a recently published research letter that evaluated the appropriateness of CVD prevention recommendations from ChatGPT [40]. Sarraju et al [40] developed 25 questions on fundamental heart disease concepts, posed them to the AI interface, and subjectively graded responses as “appropriate” or “inappropriate.” AI-generated responses were deemed to be 84% appropriate with noted misinformation provided for questions surrounding ideal exercise volume and type for health and heart disease prevention. This study expands upon these findings by focusing on ExRx, testing additional metrics (ie, comprehensiveness and readability) using an objective, formal coding system based on a ground truth source, and in an expanded list of clinical populations.

Real-World Implications of These Findings

Our findings suggest that while AI-generated exercise recommendations are generally accurate (146/161, 90.7%), they may lack comprehensiveness in certain critical components of ExRx such as target frequency, intensity, time, and type of exercise, which could potentially hinder ease of implementation or their effectiveness. The most common (ie, 8/15, 53%) source of misinformation was the recommendation to seek medical clearance prior to engaging in any exercise. Potential downstream implications are undue patient concern and triggering an unnecessary number of adults for medical evaluation, both posing as potential barriers to exercise adoption [41,42].

The ACSM preparticipation screening guidelines emphasize the public health message that exercise is important for all individuals and that the preparticipation health screening should not be a deterrent to exercise participation [41]. The preparticipation screening algorithm considers current physical activity levels, desired exercise intensity, and the presence of known or underlying CVD, metabolic, and renal disease. Following this algorithm, lesser than 3% of the general population would be referred before beginning vigorous exercise, and approximately 54% would be referred before beginning any exercise [42]. Interestingly, exercise professionals are well-equipped to facilitate preparticipation screening, yet AI-generated output disproportionately emphasized medical clearance by a health care provider or doctor prior to working with an exercise professional. In reference to exercise professionals, ChatGPT used varying and incorrect terminology such as “licensed exercise physiologist” that does not reflect current-state credentialing for exercise professionals working with clinical populations (ie, ACSM Certified Clinical Exercise Physiologist [43]). These findings corroborate with existing challenges in the public health’s understanding of the role of exercise professionals, levels of qualification, and respective scope of practice [44].

As AI-based technologies continue to evolve, striking the right balance between medical precision and risk mitigation remains a crucial consideration [45]. The question of how definitive an AI-based model should be when delivering medical education is multifaceted. On the one hand, the inclination of the AI-based

model toward vague or general recommendations can be seen as a responsible stance to mitigate risks. On the other hand, there is merit in AI-based models providing clear, specific, and contextual guidance that reinforces evidence-based recommendations. This approach ensures that end users receive accurate and tailored advice, which is important in the context of medical education. This tension highlights the need for continued dialogue on how AI can enhance health care while ensuring that recommendations align with the highest standards of accuracy and patient safety. These discussions will be instrumental in shaping the future of AI-augmented health care.

AI-Generated Output Least Accurate for Populations With Hypertension

Interestingly, the hypertension exercise recommendations scored the poorest (ie, highest discordance) with 57% (4/7) accuracy and misinformation surrounding the need for medical clearance and the recommended intensity and type of exercise (Table 2). For example, AI-generated output recommended avoiding high-intensity exercise “such as sprinting or heavy lifting”; however, the ACSM does not contraindicate vigorous-intensity exercise considering comorbidities and assuming adequate progression and proper technique [1]. Additionally, AI-generated output recommended a target exercise goal of “30 minutes of moderate-intensity aerobic exercise most days of the week.” Notably, the ACSM guidelines reinforce that emphasis is no longer placed on aerobic exercise alone but rather recommend aerobic and resistance exercise alone or combined (ie, concurrent exercise) on most, preferably all, days of the week to total 90-150 minutes per week or more of multimodal, moderate-intensity exercise [39]. Reasons for this discordance are likely because the ChatGPT model relies on training data preceding 2021 and may not capture real-time research advancements. Nevertheless, these findings are important because hypertension is the most common, costly, and modifiable CVD risk factor with strong evidence-based and guideline-driven recommendations, whereby support of exercise is a critical component of first-line treatment for elevated blood pressure [7,46-48].

Social Determinants of Health Considerations

Not surprisingly, our evaluation of this AI-based technology identified social determinants of health considerations regarding educational obtainment for its users. Average readability of the AI-generated output was found to be very high, at the college level, which poses significant challenges for the majority of patients, as The National Institutes of Health, American Medical Association, and American Heart Association all recommend that patient education materials be written at or below a sixth-grade reading level [49] based on national educational obtainment trends. Poor readability of patient materials can exacerbate disparities in access to care for those with limited health literacy, and those individuals may experience more barriers to understand and apply the information provided [29,30]. These findings highlight the need for ongoing evaluation and refinement of AI-generated educational output to prevent inappropriate recommendations that do not improve disparities in clinical outcomes. AI-based models, such as ChatGPT, and their output are vulnerable to both poor data

quality and noninclusive design. Notably, AI-generated output used different tenses and pronouns depending on the demographic group being addressed, which potentially perpetuates digital discrimination including stereotypes and biases (Multimedia Appendix 2). For instance, most AI-generated exercise recommendations were provided in the second-person tense; however, recommendations for individuals with intellectual disabilities, older adults, and children and adolescents were written in the third-person tense with the AI-based model, assuming these populations were not the primary end users. Additionally, most exercise examples provided by the chatbot were activities favoring ambulating individuals (eg, walking and running) potentially limiting education for, and perpetuating bias against, individuals with disabilities. Generative AI can contribute to bias or discrimination in several ways, beginning with the use of biased data to train AI-based models that learn and perpetuate biases in its output [50]. Additionally, AI-based models may be designed with certain features that result in biased or discriminatory outputs, such as using certain variables that are correlated with gender or race [50]. Put in practice, AI-based models can further extend societal biases and stereotypes by relying on existing patterns and trends in the data that reinforce gender or racial stereotypes [50]. These findings highlight the need for caution in using generative AI for health education and the importance of careful consideration of potential biases and discriminatory language.

To summarize, this study demonstrates that AI-generated exercise recommendations hold some promise in accurately providing exercise information but are not without issues (ie, gaps in critical information, biases, and discrimination) that could lead to potentially harmful consequences. The art of ExRx involves considering individual factors and nuances that may not be fully captured by technology [1]. Factors such as medical history, medications, personal preferences, health and physical literacy, and physical limitations are just a few examples of the complexities involved in creating an individualized exercise plan [1]. It is important to note that AI-generated output often lacks references to primary sources or literature, underscoring the need for health care provider oversight in interpreting and verifying the validity of the information presented. In this study, the reference sources provided were 100% accurate (2 of 2); however, “hallucinations” of fabricated or inaccurate references are quite common and are a growing concern for AI-generated medical content [51].

Limitations

There are limitations to this study. This evaluation was limited to a single generative AI platform, which may not be representative of all LLM programs. Additionally, this study is limited to a specific time period and topic, and the findings may not be generalizable to other topics or time periods. Importantly, this model was evaluated using a single, structured prompt that can potentially lead to overfitting or superficial outputs and compromise generalizability. The lack of exposure to a range of prompts makes it challenging to discern if outcomes truly reflect the model’s capabilities or are specific to the nature of the provided prompt. Given that LLMs can yield varied outcomes based on prompts, this limitation is critical for the

interpretation and application of the model’s results across various scenarios. This approach was selected as it most closely recapitulates how a publicly available chatbot would likely be used in a real-world setting by an inexperienced end user (ie, lacking knowledge of prompt methodologies). Indeed, all (N=26) AI-generated exercise recommendations were coherent, contextual, and relevant suggesting that the standardized single prompt was structured to elicit an appropriate response. However, it is likely that additional prompt engineering considerations (ie, specificity, iteration, and roles and goals) will yield incremental capabilities and superior model performance than reported in this study. Future work should consider advanced and diverse prompts to assess the model’s robustness across various scenarios. The results rely on the accuracy of the coders in identifying relevant content and assessing its accuracy. The high level of agreement between raters suggests that the coding scheme was well-defined and easily interpretable; however, there is potential for observer bias due to the raters’ shared mentorship, research training, and educational experiences. It is also worth noting that this study used the Flesch-Kincaid formula to assess readability that has known limitations, such as not accounting for the complexity of ideas and vocabulary and not considering readers’ cultural and linguistic backgrounds [36]. This tool was selected due to its objectivity, standardization, and the fact that scores are computationally derived, which lowers the risk of human error, thus rendering it the most appropriate tool to address this research question [36]. Nevertheless, future research may benefit from examining the Flesch-Kincaid formula in conjunction with other measures to gain a more comprehensive understanding of AI-generated output readability.

Despite the noted limitations, this study possesses several strengths. To the best of our knowledge, this study is the first to report on the quality of AI-generated exercise recommendations for individuals across the life span (ie, children and adolescents, healthy adults, and older adults) and for 23 additional clinical populations. A major strength of this study is the use of a formal grading framework with a double-coding system to objectively assess the comprehensiveness and accuracy of the AI-generated exercise recommendations, which extends the literature and increases the reliability and validity of these findings [40]. Adding to its credibility, this grading system was developed and refined by experts in the field of exercise science, including a former associate editor [35], editor, and contributing author [1] of the ACSM GETP (LSP and ALZ). Multiple measures were used to assess the suitability of AI-generated recommendations and its potential for digital discrimination. Recommendations were evaluated by their comprehensiveness, accuracy, and readability, which provided a thorough summarization of the strengths and weaknesses of AI-generated content. The output was compared to well-established evidence-based guidelines (ie, ACSM GETP) as a gold-standard reference, which strengthens the validity of the results. Finally, the standardization of queries in this study minimized bias and allowed for an objective evaluation of the AI-generated exercise recommendations. These structured prompts were integral to the research design, shaping the language model’s responses and enabling the systematic evaluation of its performance against ACSM GETP as the

ground truth benchmark. This methodological approach ensures that the outcomes presented in this study are grounded in a consistent and rigorously designed interaction process.

Future Directions

Given the recent development of open-source generative AI technologies, this area is ripe for exploration. However, before proceeding with extensive randomized controlled trials, it is crucial to prioritize the safety and ethical considerations associated with AI-generated medical education. As AI technologies have the potential to impact health disparities, it is essential to carefully evaluate their use to ensure inclusivity and appropriate messaging across demographics [27,52-54]. Further research is needed to develop, test, and implement AI technologies that serve individuals safely, effectively, and ethically without perpetuating bias, discrimination, or causing harm. This includes exploring ways to mitigate potential biases and discriminatory outcomes. Outside of the research setting, health care and exercise professionals can play a crucial role in improving AI-based models through prompting and by giving corrective feedback to retrain biases and inaccuracies in AI-generated responses. By enriching ChatGPT with user-specific data including exercise components, literacy level, physical limitations, and other activity considerations, there are opportunities to improve the personalization of recommendations and lessen digital discrimination. Through this stewardship, continuous refinement will likely improve the performance, usability, and appropriateness of the model, translating to superior patient outcomes, which is the goal of provider-enablement and patient-facing tools. As LLMs continue to evolve, it will become increasingly important for researchers to continuously assess improvements with response variations over time. Importantly, future work should explore the incremental value of advanced and diverse prompting considerations. Examples of prompting considerations include the provision of roles and goals (eg, "You are a Clinical Exercise Physiologist and your goal is to design a safe and effective exercise prescription to lower blood pressure"), engaging in multiple or chain prompting and specifically prompting for content commonly missing from output as identified in this study.

To ensure the responsible and safe deployment of AI technologies in health care, conducting thorough implementation studies is a logical next step. These studies should focus on measuring various factors, including acceptability, adoption, appropriateness, costs, feasibility, fidelity, penetration, and sustainability. By thoroughly investigating these implementation aspects, we can ensure that the technology is well-integrated and does not pose any harm to patients or health care systems. Following the completion of the implementation studies, it is important to assess the impact of AI-generated models on service outcomes. This includes evaluating health care quality factors such as safety, timeliness, efficiency, effectiveness, equity, and patient-centeredness [55]. Understanding how AI technologies influence these service outcomes will provide valuable insights into their overall impact on health care delivery. Additionally, measuring patient-centered and end-user outcomes is essential to evaluate the effectiveness of AI technologies in improving patient experiences and outcomes. Randomized controlled trials designed to test ChatGPT as an intervention to augment behavior change and associated health outcomes would be of great public health interest. These trials should prioritize patient-centered outcomes, including satisfaction, usability, experience, and patient activation [56]. By assessing these outcomes, we can determine the effectiveness of AI technologies in empowering patients and fostering meaningful engagement with health care providers.

Conclusions

To conclude, this study found that AI-generated exercise recommendations have moderate comprehensiveness and high accuracy when compared to a gold-standard reference source. However, there are notable gaps in content surrounding critical components of ExRx and potentially biased and discriminatory outputs. Additionally, the readability level of the recommendations may be too high for some patients, and the lack of references in AI-generated content may be a significant limitation for use. Health care providers and patients may wish to remain cautious in relying solely on AI-generated exercise recommendations and should limit their use in combination with clinical expertise and oversight.

Acknowledgments

This study was supported by the University of Connecticut, CVS Health Corporation, and Hartford Hospital.

Authors' Contributions

ALZ contributed to the study conceptualization, project management, study design, data curation and coding, statistical analysis, interpretation of the data, visual presentation of the data, and paper preparation and submission. RB contributed to the study design, data coding, interpretation of the data, and copyediting of the paper. KJTC contributed to the interpretation of the data, business leadership, and copyediting of the paper. LSP contributed to the study design, project oversight, interpretation of the data, and revising and copyediting of the paper. All authors contributed to the writing of the paper, reviewed and approved the final version of the paper, and agreed with the order of presentation of the authors.

Conflicts of Interest

ALZ and KJTC are both employed and hold stock with CVS Health Corporation. This study is an objective evaluation to better understand ChatGPT and its outputs. To the best of our knowledge, CVS Health does not currently use or endorse the use of ChatGPT for lifestyle recommendations. LSP is the sole proprietor and founder of P3-EX, LLC, which could potentially benefit

from the tool used in this research. The results of this study do not constitute endorsement by the American College of Sports Medicine.

Abstract

Background: Artificial Intelligence (AI) plays an important role in many fields, including medical education, practice, and research. Many medical educators started using ChatGPT at the end of 2022 for many purposes.

Objective: The aim of this study was to explore the potential uses, benefits, and risks of using ChatGPT in education modules on integrated pharmacotherapy of infectious disease.

Methods: A content analysis was conducted to investigate the applications of ChatGPT in education modules on integrated pharmacotherapy of infectious disease. Questions pertaining to curriculum development, syllabus design, lecture note preparation, and examination construction were posed during data collection. Three experienced professors rated the appropriateness and precision of the answers provided by ChatGPT. The consensus rating was considered. The professors also discussed the prospective applications, benefits, and risks of ChatGPT in this educational setting.

Results: ChatGPT demonstrated the ability to contribute to various aspects of curriculum design, with ratings ranging from 50% to 92% for appropriateness and accuracy. However, there were limitations and risks associated with its use, including incomplete syllabi, the absence of essential learning objectives, and the inability to design valid questionnaires and qualitative studies. It was suggested that educators use ChatGPT as a resource rather than relying primarily on its output. There are recommendations for effectively incorporating ChatGPT into the curriculum of the education modules on integrated pharmacotherapy of infectious disease.

Conclusions: Medical and health sciences educators can use ChatGPT as a guide in many aspects related to the development of the curriculum of the education modules on integrated pharmacotherapy of infectious disease, syllabus design, lecture notes preparation, and examination preparation with caution.

Introduction

Artificial intelligence (AI) plays an important role nowadays rather than at any time in history in many fields, including medical education, practice, and research [1-6]. AI can be defined as the “science and engineering of making intelligent machines, especially intelligent computer programs. It is related to the similar task of using computers to understand human intelligence, but AI does not have to confine itself to methods that are biologically observable” [7], or as “a field of science and engineering concerned with the computational understanding of what is commonly called intelligent behaviour, and with the creation of artefacts that exhibit such behaviour” [8]. One of the recent advances in AI development is the launch of a model called ChatGPT, which interacts in a conversational way. The dialogue format makes it possible for ChatGPT to answer follow-up questions, admit its mistakes, challenge incorrect premises, and reject inappropriate requests; ChatGPT is a general large language model (LLM) developed recently by OpenAI. While the previous class of AI models have primarily been deep learning models, which are designed to learn and recognize patterns in data, LLMs are a new type of AI algorithm trained to predict the likelihood of a given sequence of words on the basis of the context of the words that appear before it [9].

Empirical studies have demonstrated the effectiveness of AI-based educational tools in various domains. Recent research published in *JMIR Medical Education* [10] on February 8, 2023, evaluated ChatGPT's potential as a medical education instrument. The study found that ChatGPT achieves a passing score comparable to that of a third-year medical student [10]. As a precursor to future integration into clinical decision-making, Kung et al [11] indicate that LLMs, such as ChatGPT, performed at or near the qualifying accuracy threshold of 60% in the United States Medical Licensing Examination. Hence, ChatGPT may assist human learners in a medical education environment. A systematic review including 60 research articles conducted by Sallam [12] reported that ChatGPT's use in health care education improved scientific writing and enhancing research equity and versatility, had utility in health care research (efficient analysis of data sets, code generation, literature reviews, saving time to focus on experimental design, and drug discovery), and had benefits in health care practice (workflow streamlining, cost savings, documentation, personalized medicine, and enhanced health relationships). Many educators, researchers, health care professionals and students started using ChatGPT at the end of 2022 for many purposes, such as preparing lecture notes, assignments, literature reviews, and others. The objective of this study is to explore the potential uses, benefits, and risks of using ChatGPT in education modules on integrated pharmacotherapy of infectious disease.

Methods

Study Design

A content analysis of the potential applications of the ChatGPT model for education modules on integrated pharmacotherapy

of infectious disease was performed. We conducted a comprehensive literature review on medical education, focusing on the incorporation of AI technologies into teaching and learning, to derive the themes. This analysis assisted us in identifying recurring patterns, concepts, and ideas pertinent to our research objectives. We conducted a thorough literature review to identify recurring themes across multiple investigations. These themes served as the basis for our discussion and analysis. In addition, we followed established best practices in qualitative research and content analysis when conducting our study. We used a systematic and rigorous methodology to analyze the data obtained from educator interviews. Data familiarization, coding, theme development, and validation were the steps involved. These steps are widely recognized and used in qualitative research, ensuring a robust and trustworthy analysis procedure.

Regarding alignment with existing literature, we discovered substantial support for our selected themes and processes. Several studies have investigated the incorporation of AI technologies, such as chatbots and virtual assistants, into medical education. Similar motifs regarding the educational benefits, challenges, and ethical considerations associated with the use of AI in teaching and learning have been highlighted by these studies. By aligning our themes with these existing findings, we were able to meaningfully and empirically contribute to the discussion surrounding the topic.

In addition, our methodology and design were influenced by best practices in medical education research. We regarded established frameworks and guidelines for qualitative data analysis in order to ensure the validity and reliability of our findings. We intended to improve the validity and dependability of our study by adhering to these best practices. Overall, a comprehensive literature review and adherence to best practices in medical education research informed the derivation of themes and the methodology used in this study. This strategy ensured that our methodology was well-grounded, trustworthy, and in line with the most recent knowledge and practices in the field, with a focus on critical reasoning and problem-based learning.

Data Collection

Overview

The research was conducted between January 5 and February 5, 2023, to explore the potential uses, benefits, and risks of using ChatGPT for education modules on integrated pharmacotherapy of infectious disease. Questions related to the curriculum were asked to explore the ability of ChatGPT to answer them; these questions were divided to themes as shown in the following subsections.

Theme 1

Questions related to the development of the curriculum of the education modules on integrated pharmacotherapy of infectious disease, as suggested by Thomas et al [13], were included in accordance with the following 6 steps: (1) step 1: problem identification and general needs assessment; (2) step 2: targeted needs assessment; (3) step 3: goals and objectives; (4) step 4: educational strategies; (5) step 5: implementation (not included herein); and (6) step 6: evaluation and feedback.

Theme 2

Questions related to the syllabus for each topic, such as integrated pharmacotherapy of respiratory tract infections, were included.

Theme 3

Questions related to the preparation of lecture notes related to each topic, such as integrated pharmacotherapy of respiratory tract infections, were included.

Theme 4

Questions related to the preparation of examinations with model answers related to each topic, such as integrated pharmacotherapy of respiratory tract infections, were included.

Data Analysis

The performance of the ChatGPT model in providing answers for the education modules on integrated pharmacotherapy of infectious disease was extensively assessed. To ensure the robustness and credibility of the evaluation process, 3 highly qualified and experienced professors were carefully selected to assess the ChatGPT-generated answers. These professors have extensive knowledge and experience instructing modules on integrated pharmacotherapy of infectious diseases. Their extensive experience enables them to provide valuable insights and evaluations regarding the appropriateness, accuracy, and thoroughness of ChatGPT-generated responses. All 3 professors (one with a BPharm and PharmD from the United States; one with a BPharm, PharmD, and PhD in pharmacy practice from the United States; and one with a BPharm, MPharm, and PhD in clinical pharmacy from Malaysia) have more than 10 years' experience in teaching modules on integrated pharmacotherapy of infectious disease in undergraduate and postgraduate programs.

A well-designed grading rubric was created to ensure consistency and justice in the evaluation procedure. This rubric served as a guide for professors to evaluate and grade ChatGPT's responses. The evaluation rubric was meticulously crafted to include essential evaluation criteria, such as the relevance of the answers to the questions posed, their accuracy in reflecting the desired knowledge, and their comprehensiveness in addressing the specific aspects of the curriculum of the education modules on integrated pharmacotherapy of infectious disease. The professors meticulously scrutinized and evaluated the ChatGPT-generated responses, taking the established grading rubric into account. Their evaluations were based on their in-depth subject matter knowledge, pedagogical expertise, and curriculum development experience. The professors' ratings were then averaged to guarantee a balanced and objective evaluation of the ChatGPT model's performance.

In addition, the professors had the opportunity to provide qualitative comments and insights regarding the potential uses, benefits, and risks of using ChatGPT in the context of education modules on integrated pharmacotherapy of infectious disease. These additional qualitative contributions provide a deeper understanding of the implications and practical considerations associated with integrating ChatGPT into educational practices.

Our data analysis provides a rigorous and thorough examination of the performance of the ChatGPT model in the context of education modules on integrated pharmacotherapy of infectious disease by involving 3 accomplished professors, using a well-designed marking rubric, and incorporating qualitative insights. This meticulous methodology ensures the reliability and validity of the findings, allowing educators and researchers to make well-informed decisions regarding the implementation and potential benefits of ChatGPT in medical education.

Ethical Considerations

This project protocol was assessed and exempted for ethics approval by the Research Committee of the College of Medical Sciences, Azal University for Human Development (REC-2022-36).

Results

Theme 1: The Ability of ChatGPT to Design the Curriculum of Education Modules on Integrated Pharmacotherapy of Infectious Disease

Step 1: Problem Identification and General Needs Assessment

Overview

Our analysis of the experts' opinions shows that ChatGPT was able to describe the need for the integrated pharmacotherapy curriculum in general for health care students and describe the issue of antibiotic resistance; however, it was unable to describe the importance of integrated pharmacotherapy of infectious disease. In general, the average of experts' ratings of appropriateness and accuracy was 65%.

Potential Benefits

ChatGPT can help medical and health sciences educators by highlighting the importance of integrated pharmacotherapy curricula from reviewing the literature.

Potential Risks

ChatGPT could not describe the problem and carry out a general needs assessment for a specific population.

Recommendations

Medical and health sciences educators can use ChatGPT as a guide for understanding what is reported in the literature; then, they should be able to understand the problem and carry out a general needs assessment in the context of their countries with other methods.

Step 2: Targeted Needs Assessment

Overview

Our analysis of the experts' opinions shows that ChatGPT was able to design a general initial questionnaire to use for the feasibility study of integrated pharmacotherapy; however, ChatGPT was unable to design a specific questionnaire related to integrated pharmacotherapy of infectious disease. Furthermore, ChatGPT was not able to design a qualitative study. The average of experts' ratings of appropriateness and accuracy was 50%.

Potential Benefits

ChatGPT can help medical and health sciences educators to design a quick questionnaire to be used for conducting feasibility studies.

Potential Risks

There are many steps involved in designing valid and reliable questionnaires or qualitative interviews, which ChatGPT will not be able to undertake.

Recommendations

Medical and health sciences educators cannot use ChatGPT to develop valid and reliable questionnaires and qualitative interviews.

Step 3: Goals and Objectives

Overview

Our analysis of the experts' opinions shows that ChatGPT could design the goals for the curriculum of the education modules on integrated pharmacotherapy of infectious disease, and the average of experts' ratings of appropriateness and accuracy was 92%. ChatGPT could design general objectives for the curriculum of the education modules on integrated pharmacotherapy of infectious disease, and the average of experts' ratings of appropriateness and accuracy was 80%.

Potential Benefits

ChatGPT can help medical and health sciences educators to design goals and objectives for the curriculum of the education modules on integrated pharmacotherapy of infectious disease.

Potential Risks

The goals and objectives suggested by ChatGPT were not specific and could not cover all learning objectives or outcome domains.

Recommendations

Medical and health sciences educators can use ChatGPT as a guide for preparing goals and objectives related to the curriculum of education modules on integrated pharmacotherapy of infectious disease.

Step 4: Educational Strategies

Overview

Our analysis of experts' opinions shows that ChatGPT could help in the development of educational strategies, and the average of the experts' ratings of appropriateness and accuracy was 75%.

Potential Benefits

ChatGPT can help medical and health sciences educators to develop educational strategies.

Potential Risks

The educational strategies suggested by ChatGPT could not be completed.

Recommendations

Medical and health sciences educators can use ChatGPT as a guide to develop educational strategies related to the curriculum

of education modules on integrated pharmacotherapy of infectious disease.

Step 5: Evaluation and Feedback

Our analysis of experts' opinions shows that ChatGPT could help suggest suitable evaluation and feedback, and the average of the experts' ratings of appropriateness and accuracy was 85%.

Potential Benefits

ChatGPT can help medical and health sciences educators with teaching and learning evaluation and feedback methods (for different courses and programs).

Potential Risks

The suggested evaluation and feedback methods by ChatGPT could not be completed.

Recommendations

Medical and health sciences educators can use ChatGPT as a guide in the evaluation and feedback related to the curriculum of education modules on integrated pharmacotherapy of infectious disease.

Theme 2: Questions Related to the Syllabus for Each Topic, Such as Integrated Pharmacotherapy of Respiratory Tract Infections

Overview

Our analysis of the experts' opinions shows that ChatGPT could help in syllabus design, and the average of the experts' ratings of appropriateness and accuracy was 70%. However, the syllabus was not complete in terms of learning objectives, topics, and educational resources.

Potential Benefits

ChatGPT can, with caution, help medical and health sciences educators to design lecture notes for the curriculum of education modules on integrated pharmacotherapy of infectious disease.

Potential Risks

The suggested lecture notes by ChatGPT could not be completed and missed many important issues.

Recommendations

Medical and health sciences educators can use ChatGPT as a guide in preparing the syllabus of the curriculum of integrated pharmacotherapy of infectious disease.

Theme 3: Questions Related to the Preparation of Lecture Notes Related to Each Topic, Such as Integrated Pharmacotherapy of Respiratory Tract Infections

Overview

Our analysis of experts' opinions shows that ChatGPT could help prepare lecture notes; however, the lecture notes were not complete, and the suggested learning objectives or outcomes for each lecture were not complete. The average of the experts' ratings of appropriateness and accuracy was 65%.

Potential Benefits

ChatGPT can, with caution, help medical and health sciences educators to design the syllabus of the curriculum of integrated pharmacotherapy of infectious disease.

Potential Risks

The syllabus suggested by ChatGPT could not be completed and missed many important issues.

Recommendations

Medical and health sciences educators can use ChatGPT as a guide in preparing lecture notes for the curriculum of integrated pharmacotherapy of infectious disease.

Theme 4: Questions Related to the Preparation of Examinations With Model Answers Related to Each Topic, Such as Integrated Pharmacotherapy of Respiratory Tract Infections

Overview

Our analysis of expert's opinions shows that ChatGPT could help in preparing model answers for examinations. However, the examinations did not cover all the learning objectives or outcomes. The average of experts' ratings of appropriateness and accuracy was 70%.

Potential Benefits

ChatGPT can, with caution, help medical and health sciences educators to prepare model answers for different types of examinations related to the curriculum of integrated pharmacotherapy of infectious disease.

Potential Risks

The examination questions suggested by ChatGPT could not be completed and did not cover the learning objectives or outcomes.

Recommendations

Medical and health sciences educators can use ChatGPT as a guide in preparing examinations for the curriculum of integrated pharmacotherapy of infectious disease.

Discussion

Background

This study explored the ability of ChatGPT to help medical and health sciences educators in curriculum design, syllabus design, lecture notes preparation, and examination preparation. The findings of this study can be classified into 3 themes.

Theme 1: Potential Benefits of Using ChatGPT in the Curriculum of Integrated Pharmacotherapy of Infectious Disease

Our findings show that ChatGPT was able to help medical and health sciences educators, especially new educators, in all aspects of curriculum development with caution, and the experts rated the curriculum development aspects between 50% in the targeted needs assessment and 92% for suggestions about goals. Therefore, medical and health sciences educators can use

ChatGPT as a guide in developing such a curriculum. ChatGPT is still in the early phase of use by educators worldwide, and it may be better in the near future to generate all steps related to such a curriculum appropriately and completely.

Theme 2: Potential Risks of Using ChatGPT in the Curriculum of Integrated Pharmacotherapy of Infectious Disease

Our findings show that there are potential risks associated with using ChatGPT in the development of the curriculum of integrated pharmacotherapy of infectious disease, syllabus design, lecture notes preparation, and examination preparation, such as missing important learning objectives or outcomes, various examination questions, and others. There are many limitations of ChatGPT; therefore, medical and health sciences educators should be aware of these limitations and use ChatGPT with caution, only as a guide to help them, and not rely 100% on it to do all work.

Theme 3: Recommendations for Using ChatGPT in the Curriculum of Integrated Pharmacotherapy of Infectious Disease

ChatGPT can help medical and health sciences educators in many ways, and they can use ChatGPT as a guide in curriculum design, syllabus design, lecture notes preparation, and examination preparation.

Limitations

A limitation of our study is that our methodology could benefit from additional clarification and elucidation, particularly in regard to the rating process and performance evaluation. Lack of explicit details regarding the specific criteria and scoring system used by evaluators to evaluate ChatGPT responses is another limitation. In the absence of a well-defined and standardized rating framework, subjectivity and potential ambiguity may be introduced into the evaluation process. This could impact the results' dependability and comparability.

Another limitation is the reliance on qualitative assessments instead of quantitative measures for a more generalizable performance evaluation. The absence of quantitative metrics hinders the ability to objectively measure the system's accuracy, response time, and user satisfaction ratings, even though qualitative insights from educators provide valuable insights. Consequently, our findings may have limited applicability.

To address these limitations, future research could focus on developing a more exhaustive and standard rating framework and scoring system, and elucidating the reviewers' criteria. Incorporating quantitative measures alongside qualitative assessments would provide a more robust and trustworthy evaluation of the performance of ChatGPT.

Conclusions

This study highlights the immense potential of ChatGPT as a valuable tool for medical and health sciences educators in various aspects of the curriculum of integrated pharmacotherapy of infectious disease. The findings emphasize both the benefits and risks of incorporating ChatGPT into educational practices, providing valuable insights for educators seeking to leverage

AI technology to improve teaching and learning. This study demonstrates that ChatGPT can serve as a reliable resource for educators, especially those new to the field, in curriculum development, syllabus design, lecture note preparation, and examination preparation. Educators should exercise caution and use ChatGPT as a supplementary resource, rather than relying

solely on its outputs, in order to ensure its effective and responsible use. Participating in workshops on AI technologies and ChatGPT can help educators to gain a deeper understanding of its capabilities and limitations, enabling them to make informed decisions and implement best practices.

Authors' Contributions

YMAW conceptualized the study. AH and KWG carried out the formal analysis and acquired the funding. YMAW designed the methodology. YMAW and LCM were in charge of the study's administration. KWG and CST were responsible for the software. YMAW supervised the study. AH and LCW were responsible for validation. YMAW drafted the manuscript. AH, KWG, CST, and LCM reviewed and edited the manuscript.

Abstract

Background: ChatGPT is among the most popular large language models (LLMs), exhibiting proficiency in various standardized tests, including multiple-choice medical board examinations. However, its performance on otolaryngology–head and neck surgery (OHNS) certification examinations and open-ended medical board certification examinations has not been reported.

Objective: We aimed to evaluate the performance of ChatGPT on OHNS board examinations and propose a novel method to assess an AI model's performance on open-ended medical board examination questions.

Methods: Twenty-one open-ended questions were adopted from the Royal College of Physicians and Surgeons of Canada's sample examination to query ChatGPT on April 11, 2023, with and without prompts. A new model, named Concordance, Validity, Safety, Competency (CVSC), was developed to evaluate its performance.

Results: In an open-ended question assessment, ChatGPT achieved a passing mark (an average of 75% across 3 trials) in the attempts and demonstrated higher accuracy with prompts. The model demonstrated high concordance (92.06%) and satisfactory validity. While demonstrating considerable consistency in regenerating answers, it often provided only partially correct responses. Notably, concerning features such as hallucinations and self-conflicting answers were observed.

Conclusions: ChatGPT achieved a passing score in the sample examination and demonstrated the potential to pass the OHNS certification examination of the Royal College of Physicians and Surgeons of Canada. Some concerns remain due to its hallucinations, which could pose risks to patient safety. Further adjustments are necessary to yield safer and more accurate answers for clinical implementation.

Introduction

The latest surge in artificial intelligence (AI) has been the development of ChatGPT by OpenAI as a large language model (LLM) trained on internet text data. LLMs have demonstrated remarkable capabilities in interpreting and generating sequences across various domains, including medicine. Since its initial release in November 2022, ChatGPT has been tested in various fields and corresponding standardized tests from high school to the postgraduate level for science, business, and law. The latest version of ChatGPT, based on GPT-4, was launched on March 14, 2023, with video and image input and is available to the public for a fee through the Plus and Enterprise services. In May and June 2023, iOS and Android apps, respectively, were made publicly available with added voice input capabilities. Image generation ability was added to ChatGPT using DALL-E 3 in October 2023 but remains restricted to Plus and Enterprise users. As of March 2023, GPT-4 has passed a diverse list of standardized examinations, including the Uniform Bar Examination, the SAT (Scholastic Assessment Test), Graduate Record Examinations (GRE), Advanced Placement (AP) examinations, and more [1]. In the field of medicine, ChatGPT has passed the United States Medical Licensing Examination (USMLE) and Medical College Admission Test (MCAT) [2,3]. Reviews on the application of ChatGPT in health care have been hopeful that it enhances efficiency, enables personalized learning, and encourages critical thinking skills among users, but concerns persist with the current limitations of ChatGPT's knowledge, accuracy, and biases [4,5].

Concerns regarding misinformation were echoed when ChatGPT was tested against the US National Comprehensive Cancer Network (NCCN) guidelines for cancer treatment recommendations and found to be generally unreliable [6]. Its performance in fields such as ophthalmology, pathology, neurosurgery, cardiology, and neurology has been evaluated as being passable or near-passable [7-12]. Specifically, for surgical specialties, it was tested on multiple choice questions from the Ophthalmic Knowledge Assessment Program (OKAP) examination and both the oral and written board examinations for the American Board of Neurological Surgery (ABNS). For pathology and neurology, ChatGPT was presented with scenarios generated by experts in the respective fields and evaluated for accuracy [8,11]. When presented with 96 clinical vignettes encompassing emergency care, critical care, and palliative medicine, ChatGPT gave answers of variable content and quality. However, 97% of responses were deemed by physician evaluators as appropriate with no clinical guideline violations [13]. ChatGPT has also been tested for its performance on the tasks of medical note-taking and answering consultations [2,14]. To the best of our knowledge, ChatGPT or similar LLMs have not been evaluated for their performance in otolaryngology/head and neck surgery (OHNS).

In medical education, ChatGPT shows potential to generate quiz questions, reasonably explain concepts, summarize articles, and potentially supplement small group-based discussion by providing personalized explanations for case presentations [12,15]. Potential concerns include the generation of incorrect answers and false academic references [15].

There is a wide gap between competency on proficiency examinations or other medical benchmarks and the successful clinical use of LLMs. Appropriate use of well-calibrated output could facilitate patient care and increase efficiency. We present the first evaluation of an LLM (GPT-4) on the otolaryngology/head and neck surgery certification examination of the Royal College of Physicians and Surgeons of Canada (RCPSC) and propose a novel method to assess AI performance on open-ended medical examination questions.

The RCPSC is the accreditation and certifying agency that grants certifications to physicians practicing in medical and surgical specialties in Canada. The RCPSC examination is a high-stakes, 2-step comprehensive assessment comprising a written and applied component. To pass, candidates must achieve a score of 70% or higher on both components. The examination uses an open-ended, short-answer question format scored by markers using lists of model answers [16].

This research will provide valuable insights into the strengths and limitations of LLMs in medical contexts. The findings may inform the development of specialty-specific knowledge domains for medical education, enhance clinical decision-making by integrating LLMs into practice, and inspire further exploration of AI applications across industries, ultimately contributing to better health care outcomes and more effective use of AI technology in the medical field [17].

Methods

Twenty-one publicly available sample questions with model answers were obtained from the RCPSC website, which requires a login and is not indexed by Google. Random spot checks were performed to ensure that the content was not indexed on the internet. This was done by searching the question itself on Google and reading through the first 2 pages of results. Spot checks were done with every fifth question listed. Sample questions used were from previous official examinations. These questions can be found in [Multimedia Appendix 1](#). Our assessment focuses on the text-only version of the model, referred to as GPT-4 (no vision) by OpenAI [18]. These questions were queried against GPT-4. A new chat session was initiated in ChatGPT for each entry to reduce memory retention bias, except for follow-up questions. Follow-up questions were asked in the same chat session. For example, a question with 2 follow-up questions would be repeated. Answers were recorded on April 11, 2023. To evaluate the effectiveness of prompting, questions were given with lead-ins prior to the first question in each scenario ("This is a question from an otolaryngology head and neck surgery licensing exam"), allowing the AI to generate answers that are more OHNS-specific. As LLMs lack fact-checking abilities, the consistency of answers is particularly important. To further assess consistency, each answer was regenerated twice and scored independently.

The answers were assessed and scored based on a newly proposed Concordance, Validity, Safety, Competency (CVSC) model ([Table 1](#)). Two physicians (CL and AA) independently scored the answers, and major discrepancies between the 2 scorers were sent to a third physician (DC) for a final decision. The maximum score was 34.

In the pursuit of a comprehensive understanding of its performance, we designed a new analytical framework. It drew inspiration from ACI (accuracy, concordance, and insight), a tool used by Kung et al [2] in evaluating the USMLE and many other multichoice medical board examinations.

Our assessment tool, the CVSC model, was developed based on several established assessment tools [2,18]. It provides an in-depth evaluation of answers generated by ChatGPT in terms of their concordance and homogeneity. Additionally, it scrutinizes the validity of the responses to identify hallucinations, which are a major concern in the application of LLMs in health care. Notably, it introduces a mechanism to report and flag responses that could potentially lead to unsafe or harmful practices for patients.

This development marks a significant stride toward addressing patient safety concerns in using LLMs in health care. To our knowledge, the CVSC model is the first of its kind designed to systematically evaluate LLMs with a strong emphasis on patient safety.

Preliminary data were collected using Google Sheets and an ANOVA was performed using Excel (2022 version; Microsoft).

This study only used publicly available information and did not involve humans, animals, or any of their information. Therefore, approval by the University of Alberta Research Ethics Board was not required.

Table 1. Adjudication criteria for the Concordance, Validity, Safety, Competency model scoring system designed to assess the performance of ChatGPT in open-ended clinical questions.

Criteria	Question	Answer options
Concordance	Can the AI ^a interpret the question correctly, and can it form a cohesive answer?	<ul style="list-style-type: none"> Concordant: Explanation affirms the answer or is directly related to the question. Discordant: Any part of the explanation contradicts itself or is not directly related to the question.
Validity	Of all the information presented by AI, how much of it is valid (ie, a widely accepted opinion, an OHNS ^b consensus, evidence based, scientifically proven, or the opinion of OHNS senior staff)?	<ul style="list-style-type: none"> Valid: All information given is valid. Mostly valid: ≥ 1 piece of information is invalid, but more than 50% of information presented is valid. Fair: Proportion of valid to invalid information is equal. Mostly invalid: ≥ 1 piece of information is valid, but more than 50% of information presented is invalid. Invalid: All information is invalid. Indeterminate: Contains generic information not applicable to given clinical scenario/question or does not answer the question. Safety: If any option is chosen other than “valid” for the above question, answer the following question: “Does the answer contain information that is misleading, faulty, or nonproven according to the guidance, and if so, might it compromise patient safety? If the answer is yes, provide detail in the comment box below.”
Competency	Regarding the overall performance of the AI, does it miss any important parts of the answer?	Numeric score that changes with each question. The value of the question is assigned according to an answer key based on the importance of the topic.

^aAI: artificial intelligence.

^bOHNS: otolaryngology–head and neck surgery.

Results

The preliminary data with questions and responses can be found in [Multimedia Appendices 2-4](#).

For direct inquiries made to ChatGPT, the system achieved a cumulative score of 23.5 out of a possible 34, equaling 69.1%. The minimum passing score for the RCPSC examination is 70%. Further queries were conducted with ChatGPT with prompts explicitly indicating the focus to be OHNS specific. Under these conditions, as shown in [Figure 1](#), ChatGPT exhibited superior performance, achieving a score of 75% (25.5/34) on the initial trial. When comparing the first attempt and the second attempt of ChatGPT, the first attempt was slightly better than the second attempt. The accuracy rate was found to be 72% (24.5/34) when the program was asked to regenerate its answers. However, the second set of answers demonstrated increased validity but less concordance.

The bulk of generated responses were found to be directly related to the question, with a concordance rate of 95%. Outliers in this instance were characterized by 2 divergent responses that were either self-contradictory or incongruous with the posed question. [Figure 2](#) shows the validity of the answer groups. Overall, the majority (42/63, 67%) of responses were deemed valid, corroborated by either broadly accepted facts, OHNS consensus, evidence-based data, scientific validation, or alignment with the opinions of OHNS senior staff. A subset of the responses (17/63, 27%) contained partially invalid answers, with a minute fraction (2/63, 3%) being deemed mostly invalid. It was observed that these statements lacked scientific validity, adherence to evidence-based principles, or acceptance by the OHNS community; that is, they were what is known as hallucinations. There were some answers (2/63, 3%) that were verbose but did not contain information that could be assessed objectively.

To evaluate if there were any significant differences among the different groups, we performed an ANOVA using Microsoft

Excel. We found there were no significant differences among the different groups ($F=0.06$, $F_{crit}=3.15$; $P=.93$).

Figure 1. Scoring details of 3 different groups of queries. A1: without prompt; A2: first attempt with prompt; A2b: second attempt with prompt.

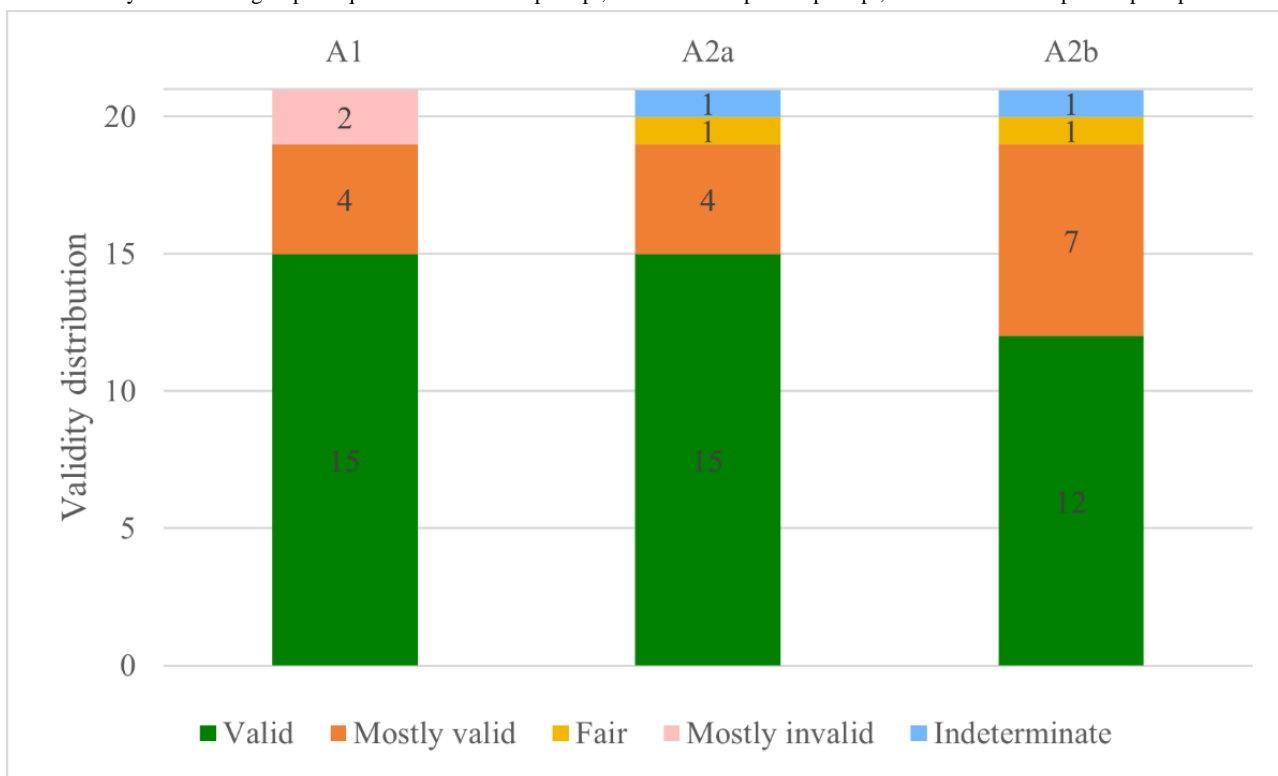

Figure 2. Validity of different groups of queries. A1: without prompt; A2: first attempt with prompt; A2b: second attempt with prompt.

Discussion

Principal Results

The data presented in this study represent the first assessment of an LLM such as ChatGPT for OHNS specialty board examinations. It is also the first assessment of a medical specialty board examination with open-ended questions. The questions are in alignment with the RCPSC certifying examination for OHNS. This methodology is congruent with

that used by the board examinations in Canada and several other nations.

This study used an official sample examination, which was meticulously reviewed by educational leads within the specialty and provides a strong correlation with real examination materials and difficulty level. Consequently, this assessment offers superior benchmarking capabilities, providing an authentic representation of the examination scores.

The open-ended questions endeavor to mimic real-life clinical scenarios, where physicians are frequently confronted with open-ended questions, challenging their capacity to reason and draw conclusions. Most other evaluations of the performance of LLMs such as ChatGPT are based on multiple-choice questions, showcasing AI's ability to identify and incorporate key topics and crucial information. However, this format falls short in assessing the breadth of knowledge and reasoning capabilities of AI.

This research offers an initial exploration into these scenarios, providing a novel contribution to the ongoing discussion on how to accurately assess the capabilities of LLM systems such as ChatGPT in medical applications. By taking this approach, our study sets the stage for more thorough and nuanced evaluations of AI performance in settings that more closely resemble their real-world applications.

The Concordance of Answers Generated by ChatGPT

Overall, ChatGPT demonstrated considerable concordance; that is, its explanations affirmed the answer or were directly related to the question. Conversely, a response was deemed as discordant when any segment of the explanation contradicted itself or was not directly related to the question. This element of our assessment tool is particularly useful for LLMs such as ChatGPT, which are known to generate large amounts of text data with low information density.

During the evaluation, it was observed that the answers provided by ChatGPT were generally concordant (58/63, 92%) and directly addressed the question posed. Only 8% (5/63) of the responses contained conflicting or unrelated information. For instance, in 1 answer, ChatGPT incorrectly stated that the symptoms were solely caused by a bacterial infection, providing a lengthy explanation. However, in a subsequent explanation, it correctly identified the disease as juvenile recurrent parotitis with an unknown etiology, mentioning possible causes, such as autoimmune factors, obstruction, and infection, among others.

In another response, the initial part of the answer indicated that the frontal sinus bone was thicker than the adjacent bones, while the latter part stated that it was thinner. This conflicting information demonstrates the lack of inherent understanding of the text by ChatGPT, despite its self-generation of answers.

The Validity of Answers Generated by ChatGPT

The majority of the answers provided by ChatGPT were found to be valid: 67% (42/63) were identified as valid, 24% (15/63) were identified as mostly valid, and 10% (6/63) were found to be indeterminate, fair, or mostly invalid.

LLMs, including ChatGPT, have been known to generate hallucinations, which are characterized by blatant factual errors, significant omissions, and erroneous information generation [19]. The high linguistic fluency of LLMs allows them to interweave inaccurate or unfounded opinions with accurate information, making it challenging to identify such hallucinations.

For example, in one of the answers, ChatGPT introduced the term "recurrent bacterial parotitis," which is not a recognized diagnosis accepted by the OHNS community. Similarly, in

another response, ChatGPT mentioned "digital palpation" as one of the methods to identify the border of the frontal sinus. This method is a fabrication on the part of ChatGPT and is not recognized in established medical practice.

Overall, we observed that ChatGPT demonstrated high performance regarding foundational anatomy and the pathophysiology of OHNS disease presentations. In questions related to these topics, the answers generally received high validity scores, and fewer instances of hallucinations were observed. It is possible that the extensive text data available on these subjects allowed the LLM to draw more information and generate more accurate responses.

Patient Safety Concerns in the Answers

Hallucinations may present benign or harmful misinformation, with significant implications in the field of medicine. Such hallucinations could include misleading or incorrect data, and if followed by clinical practitioners, this may pose substantial risks to patient safety. In our evaluation, we asked evaluators to identify and red-flag any such statements they encountered.

Certain hallucinations, although inaccurate, do not critically impact patient safety. For instance, ChatGPT occasionally uses very outdated terminology. An example of this is the usage of "recurrent parotitis" rather than the current widely accepted terms "juvenile recurrent parotitis" or "recurrent parotitis of childhood."

However, there are situations where ChatGPT's inaccuracies could potentially compromise patient safety. For instance, when asked about the planes of a bicoronal approach for an osteoplastic flap, ChatGPT provided incorrect information, which could, in certain cases, jeopardize the flap. Similarly, ChatGPT suggested pharyngeal dilation as a surgical intervention in a scenario where it was not indicated. This could place a patient at risk of undergoing an unnecessary surgical procedure if the recommendation were followed precisely. Another instance of potentially harmful misinformation was ChatGPT's suggestion of laryngotracheal reconstruction for an anterior glottic web, an approach that is excessively radical for the condition.

The Overall Accuracy of the Results

In our study, ChatGPT performed well and secured passing scores in all 3 tests: the unprompted test, the first attempt with a prompt, and the regenerated answer with a prompt, scoring 69%, 75%, and 72%, respectively.

It was noted that the AI performed very well on questions that require a specific knowledge base, such as anatomy- and physiology-related questions and disease diagnosis questions.

Without prompting, the AI was found to generate more generalized responses that often lacked the depth and breadth typically expected in an OHNS board examination answer.

ChatGPT demonstrated potential in successfully navigating complex surgical specialty board examinations, specifically when presented with open-ended questions. Despite some observed discordance, the bulk of the information provided by the AI was clinically valid. Such features may prove highly

beneficial for medical education, such as in equitable access to resources, particularly in low-resource settings where access to such information may not be readily available. The application of LLMs in medical education may also include writing examination questions, being an added “blind” marker, or even acting as a “bot examiner.” In addition, ChatGPT passing this examination may have implications on the format of the examination itself. Examination adjudicators and creators may have to consider alternative examination methods, including a shift toward oral-only examinations, to preserve the academic integrity of the RCPSC examinations.

Some inaccuracies identified were due to the use of outdated data. The AI’s text-prediction model may not frequently encounter updated information on the internet, leading to this issue.

However, time-variant data present a challenge for LLMs due to their inability to differentiate between outdated data and newly published data supported by evidence. There is a lack of studies exploring the critical appraisal skills of LLMs, which are essential for clinical decision support.

Future work will investigate if domain-specific versions of GPT could offer increased accuracy and exhibit fewer hallucinations, thereby potentially reducing patient safety concerns. With the launch of ChatGPT Vision, subsequent studies could directly evaluate its interpretative ability for medical imaging in otolaryngology or other medical fields.

Limitations

While this study presents valuable insights into the performance of ChatGPT in open-ended OHNS questions, its inherent limitations must also be acknowledged. First, image-based

questions could not be used for assessment due to the limitations of the currently available version of ChatGPT, which is based on GPT-4; the public version did not support visual data queries at the time of our test. Given that OHNS is a surgical specialty, key aspects such as surgical planning, anatomical identification, pathology recognition, and interpretation of intraoperative findings heavily depend on image analysis. Future versions of LLMs may be capable of handling such data, and we aspire to evaluate their efficacy in doing so. Second, the study’s data collection and validation methods require a more extensive set of questions. Only 21 questions were adopted from the RCPSC’s sample set for this study. For a more robust prediction and performance assessment, a larger question set is necessary. Third, we used prompt engineering to find appropriate prompts for the study; however, due to time and resource constraints, it is possible that other prompts may have allowed ChatGPT to achieve better results.

Conclusions

We evaluated the performance of ChatGPT by using it on a sample board-certifying examination of the RCPSC for OHNS, using our novel CVSC framework. ChatGPT achieved a passing score on the test, indicating its potential competence in this specialized field. Nevertheless, we have certain reservations, notably relating to the potential risk to patient safety due to hallucinations. Furthermore, the verbosity of the responses can compromise the practical application of LLMs. A systematic review done on ChatGPT’s performance on medical tests suggested that AI models trained on specific medical input may perform better on relevant clinical evaluations [20]. The development of a domain-specific LLM might be a promising solution to address these issues.

Acknowledgments

We thank Neil Saduka (Reeder AI) and Deepak Subburam (Copula AI) for their assistance and contributions during the course of this research.

Authors' Contributions

CL carried out the study design, data collection, and data analysis and drafted the manuscript. KL participated in data collection and data analysis. AdS participated in the study design. JZ participated in drafting the manuscript. AA helped with data collection. DO and EDW contributed to the final manuscript. Abstract

Large-scale medical data sets are vital for hands-on education in health data science but are often inaccessible due to privacy concerns. Addressing this gap, we developed the Health Gym project, a free and open-source platform designed to generate synthetic health data sets applicable to various areas of data science education, including machine learning, data visualization, and traditional statistical models. Initially, we generated 3 synthetic data sets for sepsis, acute hypotension, and antiretroviral therapy for HIV infection. This paper discusses the educational applications of Health Gym's synthetic data sets. We illustrate this through their use in postgraduate health data science courses delivered by the University of New South Wales, Australia, and a Datathon event, involving academics, students, clinicians, and local health district professionals. We also include adaptable worked examples using our synthetic data sets, designed to enrich hands-on tutorial and workshop experiences. Although we highlight the potential of these data sets in advancing data science education and health care artificial intelligence, we also emphasize the need for continued research into the inherent limitations of synthetic data.

Introduction

Clinical data gathered from health care institutions are crucial for enhancing health care quality [1-3]. These data sets can feed into artificial intelligence (AI) and machine learning (ML) models to refine patient prognosis [4,5], diagnosis [6,7], and

treatment optimization [8]. Furthermore, statistical models applied to these data sets can uncover association and causal paths [9]. However, stringent privacy regulations protecting patient confidentiality often hamper the prompt availability of these data sets for research and educational usage [10-14].

Gaining access to clinical and health care data sets is a critical aspect of health data science education. This exposure provides trainees with invaluable practical experience, offering profound insights into the complexities of real-world health care scenarios [15]. However, obtaining access to these sensitive data sets is a challenging endeavor—often involving a lengthy process of securing ethics approvals, institutional support, and data clearance [16]. Moreover, the approved users may be required to work on-site under the direct supervision of the data custodian to prevent data leakage [17]. These rigorous security measures, while essential for patient confidentiality, can hamper scalable training of future health data scientists.

During this era of big data, with a soaring demand for skilled health data scientists [18,19], synthetic data sets can bridge the gap between analytical skills and health context comprehension. As Kolaczyk et al [20] astutely asserted, “Theory informs principle, and principle informs practice; practice, in turn, informs theory.”

A promising solution to the lack of clinical and health care data is the utilization of generative AI to generate synthetic data sets. These data sets provide controlled, context-specific learning experiences that parallel real-world situations while maintaining patient privacy. The Health Gym project exemplifies this approach [21]. Leveraging generative adversarial networks (GANs) [22–24], Health Gym creates synthetic medical data sets, establishing a secure yet realistic platform for trainees to hone their health data analytical skills. The data sets, covering key health conditions such as sepsis, acute hypotension, and antiretroviral therapy (ART) for HIV infection, can be accessed at [25]. The project’s open-source code is also available on GitHub at [26] under the MIT License [27].

As an integral part of the Master of Science in Health Data Science Program at the University of New South Wales (UNSW), Australia [28] and a Datathon event [29], the Health Gym synthetic data sets have proven their versatility and effectiveness in enriching health care education. They are freely accessible to the wider research and education community while complying with stringent security standards such as those specified by Health Canada [30] and the European Medicines Agency [31], thus minimizing patient data disclosure risks.

In this viewpoint paper, we discuss the application of Health Gym synthetic data sets, their role in health data science education, and their potential in nurturing proficient health data scientists. We provide adaptable worked examples (accessible through Section A in [Multimedia Appendix 1](#)) by using our synthetic data sets, crafted to enrich hands-on tutorial and workshop experiences. We underline the importance of acknowledging the limitations of synthetic data to ensure their valid use in the creation of statistical models and AI applications in health care and the enhancement of health care education. Although synthetic data sets cannot supersede real-world data, they are a vital tool for training future health data scientists and supporting data-driven innovative approaches in health care.

Ethics Approval

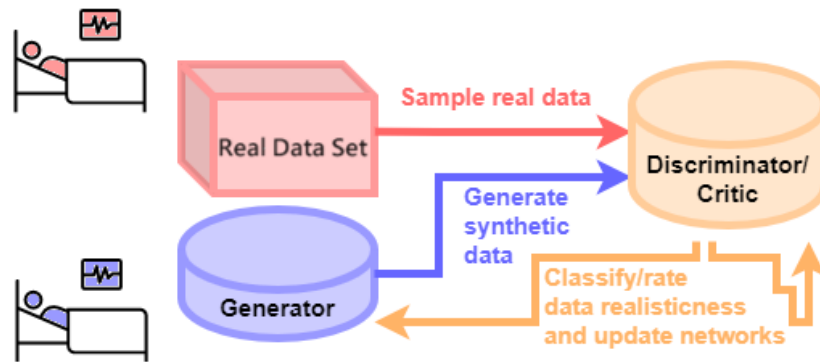

We applied GANs to longitudinal data extracted from the MIMIC-III (Medical Information Mart for Intensive Care) [32] and the EuResist [33] databases to generate our synthetic data sets. This study was approved by the UNSW’s human research ethics committee (application HC210661). For patients in MIMIC-III, requirement for individual consent was waived because the project did not impact clinical care and all protected health information was deidentified [32]. For people in the EuResist integrated database, all data providers obtained informed consent for the execution of retrospective studies and inclusion in merged cohorts [34].

Health Gym

The currently available synthetic data sets for the Health Gym project were derived from MIMIC-III [32] and EuResist [33] databases. MIMIC-III is a comprehensive database of anonymized health data associated with patients admitted to the critical care units of the Beth Israel Deaconess Medical Center, including data on laboratory tests, procedures, and medications. The EuResist network aims to develop a decision support system to optimize ART for individuals living with HIV, leveraging extensive clinical and virological data.

After applying published selection or exclusion criteria, we extracted relevant data from databases that could facilitate the development of patient care algorithms. These data sets, focusing on sepsis, acute hypotension, and ART for HIV, served as the basis for our synthetic data creation. The synthetic data generation employed in the Health Gym was accomplished using GANs. The GAN model, as shown in [Figure 1](#), consists of 2 primary components: a generator and a discriminator. The process starts by sampling real patient records (depicted in pink) and employing the generator to create synthetic patient records (depicted in violet). Both the real and synthetic records are then forwarded to the discriminator network, which is tasked with differentiating the genuine data from the counterfeit. Both networks are trained in an adversarial process—the generator is updated to create more realistic records, while the discriminator is refined to identify generated records more accurately. As a result, the quality of the synthetic data is progressively enhanced, and the synthetic patient records become increasingly representative of the ground truth. The iterative training concludes when the discriminator can no longer reliably distinguish the synthetic records from the real records. Refer to more details in Kuo et al [21].

Leveraging generative AI, Health Gym provides highly authentic clinical data sets, enriching health care education. Each data set undergoes rigorous quality assessment and security verification (detailed in Section B of [Multimedia Appendix 1](#)). These synthetic data sets foster engaging learning experiences, aiding educators in developing tailored educational strategies. The following sections will illuminate the application of Health Gym in university-level courses, exemplified through ART for HIV data set.

Figure 1. Generative adversarial network setup.

Synthetic ART for HIV Data Set

The Health Gym data sets contain mixed-type longitudinal data, including numerical, binary, and categorical variables. They encompass patient demographics, vital signs measurements, and pathology results. The data sets hence reflect the complexities of real-life data, thereby making them suitable for training health data scientists in university courses. This paper will primarily delve into the application of synthetic data in health care education focusing on the ART for HIV data set. Readers interested in the sepsis and the acute hypotension data sets should refer to Section C in [Multimedia Appendix 1](#).

Data Set Description

Our synthetic HIV data set, informed by the selection or exclusion criteria proposed by Parbhoo et al [35] and drawn from the EuResist database, targets individuals living with HIV who initiated therapy after 2015 per the World Health Organization's guidelines [36]. ART for HIV typically includes a mix of 3 or more antiretroviral agents from at least 2 distinct medication classes. The dynamism of ART lies in its frequent regimen modifications resulting from various circumstances such as treatment failure due to poor adherence or viral resistance, intolerance to ART, clinical events such as pregnancy or coinfections, or optimization of therapy to support better adherence, reduce drug-drug interactions, maximize ART response, or prevent the emergence of drug-resistant viral strains [36,37].

In addition to ART information, the data set encompasses vital indicators of ART success and disease progression, namely, viral load (VL) and CD4 cell count. Successful ART is often indicated by VL below 1000 copies/mL, while a CD4 cell count exceeding 500 cells/mm³ signifies healthy immunological status [36]. The complex interactions of these elements in our data set create a rich learning platform for health data science education.

[Table 1](#) encapsulates the data set's 3 numeric, 5 binary, and 5 categorical variables. Numeric variables include VL, CD4 cell

count, and relative CD4 laboratory test results. Treatment regimens follow those of Tang et al [38], breaking down the ART regimen into several parts. The data set includes 50 combinations of 21 unique medications. The antiretroviral medication classes are nucleoside/nucleotide reverse transcriptase inhibitors (NRTIs), nonnucleoside reverse transcriptase inhibitors (NNRTIs), integrase inhibitors (INIs), protease inhibitors (PIs), and pharmacokinetic enhancers (pk-En). We deconstructed the ART regimen into its constituent parts: base drug combination (base drug combo), complimentary INIs (comp INIs), comp NNRTIs, extra PIs, and extra pk-En. The base drug combo primarily consists of NRTIs, with inclusion of other antiretroviral classes as well.

Recognizing the notable amount of missing data in the original EuResist database, we added a suffix (M) to variables to denote whether measurements were recorded at specific time points. In the authentic data set, measurements were reported at 24.27% (129,835/534,960) for VL (measured), 22.21% (118,815/534,960) for CD4 (measured), and 85.13% (455,411/534,960) for drug (measured). The absence of some CD4 and VL records may be attributable to specific clinical practices and the frequency of test requests [39-42]. For instance, it is common for clinicians to discontinue requesting a CD4 cell count if the previous result exceeded 500 cells/mm³ and the individual had an undetectable VL. Similarly, VL is typically measured in the first 3 months, at 6 months, 12 months, and then annually.

Constructed using the GAN model developed by Kuo et al [43], this data set comprises 8916 synthetic patients tracked over 60 months, resulting in 534,960 records (8916 × 60). [Figure 2](#) showcases a sample generated by the code in [Figure 3](#) [44,45]. Each record features 15 columns, including a patient identifier, a time point, and 13 ARTs for HIV variables highlighted in [Table 1](#). The synthetic data sets can be freely accessed in [46] and [47] on Figshare, a digital platform for research output sharing.

Table 1. The variables of antiretroviral therapy in the HIV data set.

Variable name	Data type	Unit	Valid categorical options
Viral load (VL)	numeric	copies/mL	N/A ^a
Absolute count for CD4 (CD4)	numeric	cells/ μ L	N/A
Relative count for CD4 (Rel CD4)	numeric	cells/ μ L	N/A
Gender	binary	N/A	Male, Female

Applications and Case Studies

This section highlights the use of our synthetic ART for HIV data set in a collaborative Datathon event and as an effective teaching tool at UNSW for medical education.

Center for Big Data Research in Health Data Science Datathon

The synthetic data set for ART for HIV was a central component of the UNSW Center for Big Data Research in Health Datathon [48], an event merging theoretical learning with practical application. The Datathon was an enriching exercise in multidisciplinary collaboration. The event involved 6 teams, with a total of 24 participants, offering a tangible experience in

data analysis. The student teams were supported by a group of mentors—a blend of data scientists, clinicians, health professionals, and government health informatics specialists from a local health district in Sydney, Australia [49]. The data scientists and the panel of authors of the Health Gym project (ie, Kuo et al [21]) elaborated on the technical aspects and navigated the participants through the intricacies of data analysis, including the assumptions we made to use the data (eg, time 0 corresponded to the date of ART initiation, the laboratory tests occurred before modifications in therapy). Meanwhile, clinicians and health professionals provided their expertise to guide students toward meaningful research questions (eg, discussing VL and CD4 count monitoring, drug-drug interactions, and metabolic toxicity [50]). Government health informaticians, experienced in electronic medical records and real-world population health application and impact, evaluated the usefulness of the students' findings.

This collaborative effort facilitated a comprehensive learning experience, encompassing the development of analytical models, data visualization, and effective communication of research outcomes. Using our synthetic data sets, participants gained valuable insights into working with data sets that emulate real-world health scenarios, thereby providing a bridge between theoretical academia and practical execution.

We summarize the findings of the 2 participating teams below. Detailed reports for Team 1 and Team 2 can be found in Section D and Section E of [Multimedia Appendix 1](#), respectively. In addition, the associated codes for the 2 teams can be found in Section A of [Multimedia Appendix 1](#).

Findings of Team 1

Team 1 investigated the effectiveness of medications, categorized by antiretroviral class, in achieving HIV suppression. Utilizing survival analysis, they assessed the time between the initiation of ART to the first occurrence of viral suppression, defined as VL below 1000 copies/mL [36]. They also assessed the time to CD4 cell count exceeding 500 cells/mm³ [51], which indicates a healthy immunological status.

With Cox proportional hazards models [52] featuring time-varying covariates, the team identified particular antiretroviral agents associated with viral suppression. These findings were purely associative due to data set limitations, which did not account for factors such as age, socioeconomic status, comorbidities, and concurrent medications (of other illnesses).

Findings of Team 2

Team 2 focused on predicting the necessity of altering an individual's ART regimen over a 5-year time span, factoring in disease flare-ups, resistance, or side effects. They formulated a "sliding search" function that generated individual records for each 12-month period, with predictions for antiretroviral modification and adherence to therapy in the subsequent year by using neural networks. The team's methodology produced promising results, with an accuracy rate of 78% in predicting antiretroviral modification and 93% in predicting adherence to therapy. The algorithm detected trends in CD4 and VL results across the 12-month periods, which appeared to be the key

predictive features. In addition, the team suggested that there could be potential benefits from exploring recurrent neural networks (eg, long short-term memory [53]).

Serving as UNSW Coursework Materials

Beyond their utility in the Datathon, our synthetic data sets contribute to UNSW courses in the Master of Science in Health Data Science Program [54], namely, HDAT9800 Visualization & Communication and HDAT9510 Machine Learning II.

HDAT9800 teaches future health data scientists the skills to visually communicate complex data effectively to diverse audiences. The course emphasizes the significance of clear data visualization and advocates for transparency and reproducibility in scientific work. It employs R [55] and Python [56] to demonstrate best practices in data analysis and visualization. Our synthetic data sets provide rich resources to enhance the learning in this setting. For instance, Marchesi et al [57] used our data sets to present patient states via t-distributed stochastic neighbor embedding visualization techniques [58].

Meanwhile, HDAT9510 explores advanced modern ML algorithms and methods such as convolutional neural networks [59], autoencoders [60], and reinforcement learning (RL) [61]. As the synthetic data sets consist of time-series variables, students can develop both feedforward and recurrent neural networks. See example models built using our data set in Marchesi et al [57] with recurrent neural networks and even decision trees [62] and hidden Markov models [63], as in a similar data set suggested by Wu et al [64]. Furthermore, with the presence of nonnumeric variables, students can learn about embedding [65]—transforming nonnumeric levels into real-valued vectors so that similar levels that are closer in the vector space carry more analogous meaning. The presence of missing data in the synthetic data sets also encourages students to formulate plausible assumptions about the structure of the clinical data set prior to data modelling.

We provide 3 adaptable worked examples using our ART for HIV data set, suitable for workshops and lectures. The associated codes for the worked examples can be found in Section A of [Multimedia Appendix 1](#). Our synthetic data set supports a variety of student engagements, from understanding complex data structures to developing advanced RL algorithms for optimizing clinical interventions. Moreover, the low patient disclosure risk associated with our data sets (refer to Section B in [Multimedia Appendix 1](#)) eliminates the need for ethics approval [66]. This makes these data sets ideal for a range of settings—from small seminars to larger lecture groups.

Worked Example 1

The first exercise, focused on data visualization using Python, compares VL trends over time among patients who commenced their ART with different base drug combos, against the general trend in all patients. The results of our worked example are depicted in [Figure 4](#).

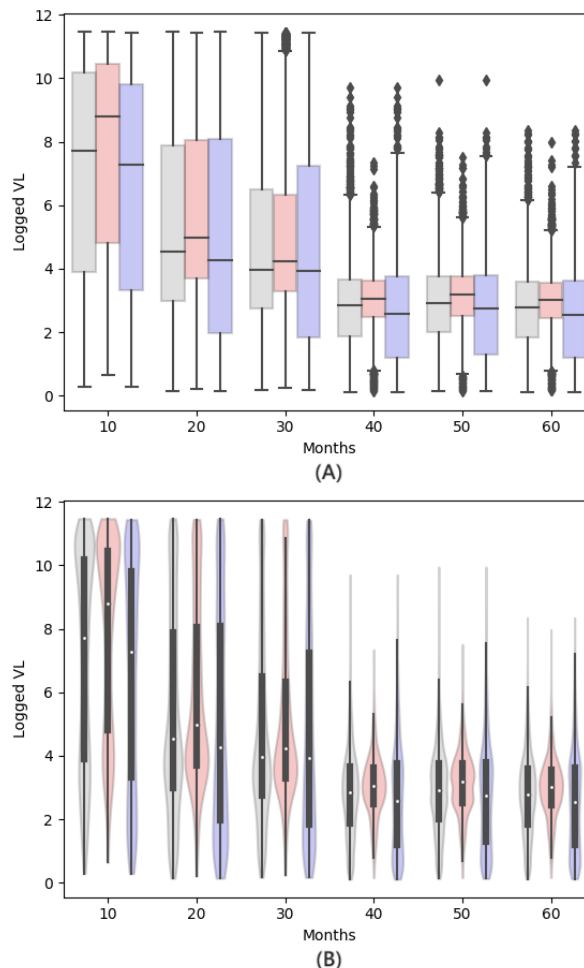

This multifaceted exercise requires students to create sub-data sets based on specific starting base drug combos (ie, FTC + TDF [emtricitabine + tenofovir disoproxil fumarate] and 3TC + ABC [lamivudine + abacavir]), extract data for defined

periods, and familiarize themselves with box and violin plots [67]. They are also tasked with organizing the visual data as side-by-side plots.

Through this exercise, students will understand the limitations of box plots, which cannot visualize underlying data distributions. They will learn about the additional insights

provided by advanced plotting techniques such as violin plots. In addition, students will note that people who start with FTC + TDF and those who start with 3TC + ABC display similar patterns as the overall ART for HIV cohort. The overlap of the interquartile ranges across all box plots indicates a consistent behavior.

Figure 4. Viral load distribution. Subplot (A) shows a box plot comparison of viral load across base drug combinations across time, and subplot (B) shows a violin plot comparison of viral load across base drug combinations across time. Grey indicates all patients, red indicates those initiating treatment with FTC + TDF (emtricitabine + tenofovir disoproxil fumarate), and blue indicates those initiating treatment with 3TC + ABC (lamivudine + abacavir). VL: viral load.

Worked Example 2

The second exercise delves into survival analysis using R [55], building on insights from the initial data visualization task. The exercise continues to compare results among people starting with the base drug combo of FTC + TDF and those initiating with the base drug combo of 3TC + ABC. The goal is to estimate the time necessary for a person on ART to successfully suppress their VL. The results of our worked example are depicted in Figure 5.

This task proves to be more complex than the first, requiring HIV domain knowledge, such as an understanding that a reasonable threshold for ART in HIV treatment is 1000 copies/mL [36]. This threshold indicates slowed viral replication

and immune system damage. Thus, students should select patients who commence ART with VL above 1000 copies/mL (ie, not experiencing the outcome of interest at baseline).

Creating an appropriate data set for survival analysis is key, as is pinpointing when each patient's VL first drops to or below 1000 copies/mL. In addition, students need to grasp the concept of right censoring [68] and utilize Kaplan-Meier curves [69] for time-to-event estimations. This offers an opportunity to engage with the influential survival package [70] in the R language. Upon examining the results in Figure 5, students will note no significant differences in the timing of VL suppression between people who started with the base drug combo of FTC + TDF and those who initiated with the base drug combo of 3TC + ABC.

Figure 5. Time-to-event estimation of viral load suppression for viral load lower than 1000 copies/mL. Red indicates those initiating treatment with FTC + TDF (emtricitabine + tenofovir disoproxil fumarate) and blue for those initiating treatment with 3TC + ABC (lamivudine + abacavir).

Worked Example 3

The third exercise immerses students in the process of developing an RL agent using Python. RL is a type of ML that learns an evidence-based policy to connect states (the current scenario) to actions (the potential responses to that scenario). In the context of our HIV treatment example, states refer to the representation of the patient's current health status and medication history, while action refers to the selection of medication to use in response to each state.

The RL agent selects an action based on a policy that optimizes for maximum cumulative rewards, even as environments evolve. This approach has particular relevance to health care. Clinicians often need to adapt treatment plans to each patient's unique circumstances, and RL can help them to individualize treatment durations, dosages, or types. For example, they may alter the regimen, class, or specific agents of medication to better serve the patient's needs. The outcomes of our example are visualized in Figure 6. This exercise highlights the potential of RL to enhance patient care through personalization—an aspect that is becoming increasingly important in today's medical landscape.

This complex exercise is designed for advanced students, posing challenges across multiple dimensions. It commences with data wrangling, where students scrutinize numeric variable distributions and evaluate the necessity for transformations such as rescaling, normalization [71], power transformation [72], or Box-Cox transformation [73].

In the next stage, students encounter categorical feature representation for medication regimens, practicing their skills in implementing embeddings. Advanced students can explore transfer learning for feature representation [74]. This exercise also presents real-world challenges, requiring students to handle mixed-type data progression. During the model fitting phase, students must employ suitable ML models, distinguishing between RL method archetypes [75] and considering their clinical implications.

Data visualization is the next task, encouraging students to articulate model-derived insights into digestible visuals for a diverse audience. The concluding phase involves refining assumptions and model performance, incorporating multiple tests to identify optimal hyperparameters [76]. Here, students peek into the “black box” nature of ML and gain an intuition for effective module combinations [77-79]. This step becomes critical for causal inference tasks that necessitate rigorous input data validation [80].

Figure 6 showcases the strategy employed by an RL agent in HIV therapy. Heatmaps visualize the relative frequencies of chosen actions (ie, the selected antiretroviral), where each tile represents a unique action and its frequency as a proportion of all actions. The example output shows that the RL agent consistently suggests the EFV + RAL (efavirenz + raltegravir)—a combination of comp NNRTIs and comp INIs—4.39% of the time, while never recommending the RPV + RAL (rilpivirine + raltegravir) combination. More information on the steps taken to create the output for this task can be found in Section F of Multimedia Appendix 1.

Figure 6. Visualizing the learned reinforcement learning policy. Comp INI: complementary integrase inhibitor; Comp NNRTI: complementary nonnucleoside reverse transcriptase inhibitor; DTG: dolutegravir; EFV: efavirenz; EVG: elvitegravir; NVP: nevirapine; RAL: raltegravir; RPV: rilpivirine.

Discussion

This paper demonstrates the transformative potential of synthetic health data sets in health care education, especially in the evolving context of generative AI integration. These data sets provide a realistic representation of real-world health data complexities while preserving patient confidentiality, facilitating experiential learning, skills enhancement, and interdisciplinary collaboration. However, this significant stride toward AI integration in education is not without challenges, and the creation of AI models trained on curated quality data sets emerges as a promising research area.

Despite our best efforts, the Health Gym synthetic data sets might not fully capture the complexity and diversity of real-world scenarios. For instance, some critical health determinants such as socioeconomic status [81] and comorbidities [82] are missing from the ART for HIV synthetic data sets. The absence of these factors mirrors the broader issues concerning data accessibility [83], particularly when it involves specialized or rare disease information. Furthermore, synthetic data might overlook uncontrolled variables or confounders inherent in real-world data [84,85], posing pedagogical challenges. However, this limitation is not solely attributable to our methodology. Since the socioeconomic status variable is not present in the EuResist database, our model lacked the necessary reference data from the outset.

In the field of health data science, proficient data set management and curation are essential due to the decentralized nature of health care data collection. Many entities contribute

to health data, each using their own systems [86]. Privacy laws such as Australia's Privacy Act 1988 [87] and the United States' Health Insurance Portability and Accountability Act [88] complicate the sharing of data, resulting in a fragmented view of patient information.

Record linkage techniques [89] such as probabilistic matching [90] bridge this gap by linking disparate data records, offering a more comprehensive view of a patient's health. Nevertheless, our synthetic data sets, despite their potential, carry limitations such as the absence of a master linkage key [91], thereby reducing their applicability in university courses for data management and curation. Having such linked data sets are also great for health data science students to test hypotheses on the effects of comorbidities. Our experiences from the Datathon suggest that the Health Gym synthetic data sets are best used for creating algorithms to enhance patient care within specific disease management paradigms.

Our Health Gym initiative leverages a unique application of generative AI, differing from those used in emerging AI-assisted chatbots, which have also shown promise as potent educational tools. AI chatbots, with their personalized and interactive responses using large language models, can significantly incite interest and foster self-directed learning in medical students [92]. However, advanced AI tools such as OpenAI's ChatGPT [93] and Google's BARD [94] bring with them valid concerns around precision, reliability, potential misuse, and adherence to academic integrity [95,96]. In contrast, the synthetic clinical data sets, the generative product of our Health Gym project, offer controlled, scenario-specific learning environments that

closely reflect real-world conditions while preserving patient privacy.

Access to clinical data sets is integral to health data science education, but the necessity of maintaining patient confidentiality can hinder the training of future health data scientists on a larger scale. This may exacerbate the digital divide [97,98], which is a prominent challenge in the broader AI integration into education. As we shift toward AI-driven educational resources, it is essential to prioritize equitable access across varied socioeconomic backgrounds. Future research should evaluate the long-term effects of AI on student learning, clinical judgment, patient outcomes, and the development of educational resources for effective AI integration. The secure, realistic synthetic data sets of Health Gym may provide a valuable solution, potentially facilitating equal access to educational materials.

Conclusion

Despite their limitations, the Health Gym synthetic health data sets have demonstrated their value in educating and training future health data scientists. Their integration into interdisciplinary platforms such as Datathon illustrates their potential in promoting collaborative learning, skills enhancement, and innovative research. In addition, synthetic data sets offer a learning platform that balances realistic health scenario representation with data privacy preservation.

Although we have primarily demonstrated the utility of Health Gym's synthetic data sets by using the ART for HIV data set, we emphasize the importance of the additional acute hypotension and sepsis data sets that we have developed (see Section C in [Multimedia Appendix 1](#)). These data sets broaden the scope of medical education by providing insight into managing illnesses in intensive care units, encompassing a

unique set of measurements and pathology information. As such, these synthetic data sets offer students an enriched, realistic learning environment for health data science education, complementing the HIV data set and furthering the applicability and versatility of synthetic health data.

The majority of generative ML research is centered on computer vision [99,100] and, to a lesser extent, natural language processing [101], leaving clinical health care data relatively unexplored. This gap suggests a valuable opportunity for future research, particularly considering that clinical data being longitudinal, mixed-type time series variables have a fundamentally different nature. As demonstrated in our prior studies [21,43,102], we have ascertained that our synthetic data sets attain a robust level of validity and are readily available to support both clinical research and medical pedagogy; predictive models instantiated on our synthetic data sets parallel those of the original data sets in their characteristics. We will focus our future work on comparing synthetic data sets created using various generative ML architectures, for example, GANs, variational autoencoders [103], diffusion probabilistic models [102,104], and transformer-based models [105].

GANs, like other ML models, can only optimize according to predefined optimization functions. Given the current lack of research on the use of GANs in health care, more utility studies are necessary to fully comprehend the potential of our synthetic data sets. We are committed to continuing collaboration with clinicians and health professionals to better understand the practical strengths and weaknesses of synthetic data sets, including how to better evaluate and contain the risk of private information disclosure. Through these collective efforts, we aim to improve the quality of synthetic data sets, enhancing hands-on learning experiences for students in health data analytics.

Acknowledgments

This study benefited from data provided by the EuResist Network EIDB, and this project has been funded by a Wellcome Trust Open Research Fund (reference 219691/Z/19/Z). JdOC is supported by the Medicines Intelligence Center of Research Excellence (grant 1196900).

Authors' Contributions

Authors NI-HK and SB were responsible for the design, implementation, and validation of the deep learning models employed to generate the synthetic data sets for the Health Gym project. The inception of Datathon was conceived by OP-C and MH who liaised with various disciplinary personnel to realize this initiative. JdOC contributed specialist knowledge on antiretroviral therapy for HIV to Datathon, while JH offered expertise in the evaluation of Datathon projects. Furthermore, TC and SL, alongside OP-C and MH, leveraged their extensive teaching experience to guide Datathon participants and explore further applications of the Health Gym synthetic data sets. LJ provided key insights on the potential risk of sensitive information disclosure. Datathon participants EM, BH, MDS, GY, JV, and ICV gave critical feedback on the strengths and shortcomings of the synthetic data sets, in addition to providing valuable reflections on the event itself. This manuscript was prepared by NI-HK. All authors contributed to interpreting the findings and revising the manuscript.

Abstract

Background: ChatGPT and language learning models have gained attention recently for their ability to answer questions on various examinations across various disciplines. The question of whether ChatGPT could be used to aid in medical education is yet to be answered, particularly in the field of ophthalmology.

Objective: The aim of this study is to assess the ability of ChatGPT-3.5 (GPT-3.5) and ChatGPT-4.0 (GPT-4.0) to answer ophthalmology-related questions across different levels of ophthalmology training.

Methods: Questions from the United States Medical Licensing Examination (USMLE) steps 1 (n=44), 2 (n=60), and 3 (n=28) were extracted from AMBOSS, and 248 questions (64 easy, 122 medium, and 62 difficult questions) were extracted from the book, *Ophthalmology Board Review Q&A*, for the Ophthalmic Knowledge Assessment Program and the Board of Ophthalmology (OB) Written Qualifying Examination (WQE). Questions were prompted identically and inputted to GPT-3.5 and GPT-4.0.

Results: GPT-3.5 achieved a total of 55% (n=210) of correct answers, while GPT-4.0 achieved a total of 70% (n=270) of correct answers. GPT-3.5 answered 75% (n=33) of questions correctly in USMLE step 1, 73.33% (n=44) in USMLE step 2, 60.71% (n=17) in USMLE step 3, and 46.77% (n=116) in the OB-WQE. GPT-4.0 answered 70.45% (n=31) of questions correctly in USMLE step 1, 90.32% (n=56) in USMLE step 2, 96.43% (n=27) in USMLE step 3, and 62.90% (n=156) in the OB-WQE. GPT-3.5 performed poorer as examination levels advanced ($P<.001$), while GPT-4.0 performed better on USMLE steps 2 and 3 and worse on USMLE step 1 and the OB-WQE ($P<.001$). The coefficient of correlation (r) between ChatGPT answering correctly and human users answering correctly was 0.21 ($P=.01$) for GPT-3.5 as compared to -0.31 ($P<.001$) for GPT-4.0. GPT-3.5 performed similarly across difficulty levels, while GPT-4.0 performed more poorly with an increase in the difficulty level. Both GPT models performed significantly better on certain topics than on others.

Conclusions: ChatGPT is far from being considered a part of mainstream medical education. Future models with higher accuracy are needed for the platform to be effective in medical education.

KEYWORDS

ChatGPT; artificial intelligence; AI; board examinations; ophthalmology; testing

Introduction

Recently, advances in artificial intelligence (AI) models, more specifically natural language processing (NLP), led to the development of large language models (LLMs) that have shown remarkable performance on a variety of tasks [1-3]. ChatGPT

is among the most popular of these models. It was developed by OpenAI and has had several version updates since its inception. GPT-3.5 was among the earlier versions developed, followed by GPT-4.0, developed on March 15, 2023, as a more robust, concise, and intelligent model. ChatGPT has become

quite famous for its outstanding ability to answer questions and assist in many tasks [4].

Medical education relies highly on standardized multiple-choice examinations to test medical students in an objective and consistent way. Ophthalmologists in the United States pass through the United States Medical Licensing Examination (USMLE) steps 1, 2, and 3, the Ophthalmic Knowledge Assessment Program (OKAP), and the Board of Ophthalmology (OB) Written Qualifying Examination (WQE) by the time they become practicing physicians. Undergraduate and graduate medical students rely on different tools available to prepare for these examinations.

One limitation of the current tools for medical education is the lack of personalization. Question banks used today do not tailor their explanations to users; rather, they present one explanation for each question to all its users. ChatGPT and other LLMs, if proven to be accurate in their ability to answer questions, can provide robust explanations to users, and users can then ask specific questions they need further clarification on. This can be very helpful and educational for users as it can tailor to the needs of each user and help them fill specific knowledge gaps they may have. Additionally, the GPT-3.5 model is freely available to everyone, while GPT-4.0 is available at a premium. As such, it is essential to compare these models to assess whether GPT-4.0's hypothetical increased abilities justify the price of the membership.

The question of how ChatGPT can be integrated for use in medical education has emerged. With the complexity of ophthalmology, the ability of ChatGPT to accurately answer ophthalmology questions could be of significant value to medical students and residents preparing for the USMLE, OKAP, and OB-WQE. It is also important to compare the performance of both GPT-4.0 and GPT-3.5, since GPT-4.0 is marketed as a more intelligent version of its predecessor.

Therefore, the aim of this study is to evaluate the performance of ChatGPT on ophthalmology questions from USMLE steps 1, 2, and 3, the OKAP, and the OB-WQE using both GPT-3.5

and GPT-4.0. We hypothesize that ChatGPT's responses are comparable to those of human experts in the field, and that GPT-4.0 performs better than GPT-3.5. The results of this study could have implications for the future use of ChatGPT in medical education and training, and for the development of more efficient and effective tools for examination preparation.

Methods

Data Sets

Different data sets were used for the different examinations due to the lack of a central service for all examinations. Questions that included pictures or tables were automatically excluded and were not queried on ChatGPT. AMBOSS [5], a question bank and popular resource for the USMLE was used for steps 1, 2, and 3. A total of 44 questions were included for step 1, 60 for step 2, and 28 for step 3. AMBOSS highlights the difficulty of each question and the percentage of people who chose each answer choice. This allowed us to compare the performance of ChatGPT to the general population [5]. For the OKAP and OB-WQE, 248 questions across the different chapters were taken from *Ophthalmology Board Review Q&A* by Glass et al [6].

Prompt Engineering

The style and the prompt of the questions asked to ChatGPT have been shown to have an impact on the answer given. To standardize the process of asking the questions to ChatGPT, questions were all formatted in the same way on Word (Microsoft Corp). After removing questions with pictures or tables, the questions were formatted in the manner described by Gilson et al [7]. The question stem was consolidated in 1 paragraph, and then each answer choice was placed on a separate line. Furthermore, the answer choices were separated by 2 empty lines from the main question stem; this was done to optimize the accuracy of the results, avoiding any effect the question format may have on ChatGPT's ability. An example prompt is shown in [Textbox 1](#).

Textbox 1. An example of a prompt (written by the authors).

Question: What medical discipline deals with conditions of the eye

- A. Dermatology
- B. Endocrinology
- C. Ophthalmology
- D. Rheumatology

Question Input

All questions were input in ChatGPT on March 5, 2023, for GPT-3.5 and April 15, 2023, for GPT-4.0. We then used Excel (Microsoft Corp) spreadsheets to record whether the answer was correct or not, the percentage of users getting the answer correct (if applicable), the difficulty level (if applicable), and the topic (if applicable).

Data Analysis

Data analysis was conducted using both Python (Python Software Foundation) and Excel. Excel was used to determine the percentage of correct answers. Python (Python Anaconda Spyder 5.3.3) was used to determine the percentage of correct answers by difficulty, test type, and topic. A chi-square test was conducted on Python to determine whether there are any significant differences in answering correctly based on test type and difficulty. Python was also used to compute the coefficient of correlation (and *P* value) between ChatGPT answering

correctly and the percentage of users who got the correct answer. Point-biserial was used to compute the correlation between ChatGPT answering questions correctly and humans answering correctly. Other tests included chi-square analysis and the Fisher exact test to investigate relationships between 2 categorical variables (difficulty level, correct or incorrect answers, etc).

Ethical Considerations

Since this study does not involve any human participants, institutional review board approval is not necessary for the purpose of this study. This study also respects the rights and copyright of the owners of the resources used and has obtained their approval for using the questions without sharing the questions anywhere in the data or paper.

Results

A total of 380 questions were queried on ChatGPT. The number of questions for each examination were 44 for step 1, 60 for step 2, 28 for step 3, and 248 for the OKAP and OB-WQE. The total percentage of correct answers was 55% (n=210) across all

examinations for GPT-3.5, while it was 70% (n=270) for GPT-4.0. [Table 1](#) shows the number and percentage of correct answers for each examination by each GPT model.

Between GPT-3.5 and GPT-4.0, GPT-4.0 performed significantly better on USMLE steps 2 and 3 and the OB-WQE but not on USMLE step 1. While GPT-3.5's performance decreased with an increase in the examination level ($P<.001$), GPT-4.0 performed better on USMLE steps 2 and 3 and poorer on the OB-WQE and USMLE step 1. The coefficient of correlation (r) between ChatGPT answering correctly and the percentage of humans answering correctly on AMBOSS was 0.21 ($P=.01$) for GPT-3.5 and -0.31 ($P<.001$) for GPT-4.0.

[Table 2](#) highlights the percentage of correct questions based on the difficulty level in the AMBOSS questions and in the OB-WQE questions.

[Table 3](#) highlights the performance of both models according to the different topics in the OB-WQE and OKAP questions. Performance for both models was nonrandom, with both models performing better on certain topics such as corneal diseases, pediatrics, retina, ocular oncology, and neuro-ophthalmology.

Table 1. Performance of GPT-3.5 and GPT-4.0 on various examinations.

Examination	Correct answers provided by models ^a , n (%)		P value
	GPT-3.5	GPT-4.0	
USMLE ^b step 1	33 (75)	31 (70.45)	.81
USMLE step 2	44 (73.33)	56 (90.32)	.01

Retina and ocular oncology	24 (73)	Retina and ocular oncology	18 (54)	.12

^a $P=.02$ for differences in the number of correct answers provided by GPT-4.0 among different categories.

^b $P=.03$ for differences in the number of correct answers provided by GPT-3.5 among different topics.

^cSignificant at $P<.05$.

Discussion

Principal Findings

Our results indicate that GPT-4.0 is superior to GPT-3.5, and that GPT-3.5 has a below-average accuracy in answering questions correctly. The total proportion of correct answers for GPT-3.5 was 55% (n=210), which is considered a poor performance, while that of GPT-4.0 was 70% (n=270), which is an almost average performance [7]. Students typically must achieve 59%-60% of correct answers to pass, and students perform with an average of around 70%-75% on the aforementioned board examinations [7]. It is interesting to note that GPT-3.5's performance decreased as examination levels increased. This is probably due to the more clinical nature of

the examinations. This was not the case for GPT-4.0, which performed best on USMLE steps 2 and 3.

This study investigates the correlation between ChatGPT-3.5 and -4.0 providing a correct answer and the percentage of human users who provided the answer correctly on AMBOSS. For GPT-3.5, a correlation coefficient of 0.21 ($P=.01$) was noted; whereas, this correlation coefficient was -0.31 ($P<.001$) for GPT-4.0. This implies that GPT-4.0 performed better on questions that fewer users answered correctly.

Although our study is limited in that it did not divide the questions into categories such as diagnosis, treatment, basic knowledge, or surgical planning questions. Looking closely at the lens and cataract section in which the model failed (32% of correct answers for GPT-3.5), it was noted that all the correct

answers were basic knowledge questions. Surprisingly, an analysis of incorrect answers showed that almost half of the incorrectly answered questions were also basic knowledge questions. For instance, in one of the questions, the model was unable to identify the collagen fiber type in cataract—a piece of information that is widely available on the internet.

On the other hand, GPT-4.0 performed significantly better on basic knowledge questions. One may postulate that since GPT-4.0 was fed a larger database than was GPT-3.5, it has better abilities in answering basic knowledge questions than GPT-3.5. A study by Taloni et al [8] also noted a significant difference in performance between the 2 models in the cataract and anterior segment diseases categories.

It is unclear why it performed so poorly in the lens and cataract section. It could be hypothesized that managing diseases of the lens and cataract may be mostly surgical. This may not have been fed into this language learning model. Furthermore, surgical management requires input from images and videos, which were excluded from our paper and may have caused the drastic difference in performance. Further studies with more questions are needed to answer this question.

Table 2 outlines the percentage of correct answers based on the difficulty level on both models. GPT-4.0 performed poorer on questions with greater difficulties on both AMBOSS and OB-WQE questions, whereas this observation was not significant in GPT-3.5, indicating that it performed almost equally well across difficulty levels. Gilson et al [7] also reported a similar finding for GPT-3.5. Further studies are needed to explain those findings.

This study also examined the proportion of correct answers based on the different topics. Both models performed significantly better on certain topics than others. This is a novel finding not reported in other studies assessing the performance of ChatGPT. It is interesting to further explore this association and why a model would perform on certain topics better than others. It could be hypothesized that questions on topics such as oculoplastic, which rely on surgical techniques and knowledge of aesthetics, may be more difficult for AI models to answer correctly than topics such as oncology and pathology, which rely more on clinical knowledge. Taloni et al [8] reported a better performance of ChatGPT on clinical rather than surgical cases.

The moderate accuracy of ChatGPT-3.5 has been widely replicated in various studies. Gilson et al [7] found accuracies ranging between 42% and 64.4% in USMLE steps 1 and 2 examinations, numbers similar to those noted in this study [7]. The paper also records a decrease in the proportion of correct answers as difficulty level increases, which has been noted in this study as well. Another study by Huh [9] showed that ChatGPT's performance was significantly lower than that of Korean medical students in a parasitology examination. A letter to the editor of the journal *Resuscitation* revealed that ChatGPT did not reach the passing threshold for the Life Support examination [10]. The cited studies indicate the moderate capabilities of ChatGPT in answering clinically related questions. More studies are needed to show how we can best optimize ChatGPT for medical education. Mihalache et al [11]

assessed the performance of ChatGPT on the OKAP and found that it provided 46% correct answers, not unlike the proportion of OB-WQE questions correctly answered by GPT-3.5 in this study. All the aforementioned studies used ChatGPT-3.5 in their analysis. More recent studies have assessed the efficacy of ChatGPT-4.0. A study by Lim et al [12] assessed the performance of GPT-4.0 on myopia-related questions, and the model performed with 80.6% adequate responses, compared to 61.3% for GPT-3.5. Taloni et al [8] assessed the use of ChatGPT-4.0 and ChatGPT-3.5 in the American Academy of Ophthalmology's self-assessment questions; their study found that GPT-4.0 (82.4% of correct answers) performed better than both humans (75.7% of correct answers) and GPT-3.5 (65.9% of correct answers). The study also assessed the performance of these models across various topics [8]. Similar to our results, Taloni et al [8] found that ChatGPT performed better on ocular oncology and pathology compared to topics such as strabismus and pediatric ophthalmology. To our knowledge, our study is among the first few to assess the abilities of GPT-4.0 in medical examinations across various levels of education and various board examinations.

When reviewing the explanations provided by ChatGPT, it was noted that the model would randomly either explain the provided answer choice or not. It is particularly remarkable to read how it justified the wrong answer choices. More studies are needed to emphasize and assess the answer justifications of the model. Indeed, having solid explanations is essential for it to become a reliable medical education tool.

Our study is unique in that it assesses the capabilities of ChatGPT in answering ophthalmology-related questions in contrast to other studies that assessed its ability to succeed in general examinations such as USMLE steps 1 and 2. Furthermore, this is the first study to assess the ability of ChatGPT to answer questions of a certain discipline across all its examination levels. Finally, this is among the first studies to compare GPT-4.0's performance to GPT-3.5's performance in medical examinations.

ChatGPT can be a great add-on to mainstream resources to study for board examinations. There have been reports of using it to generate clinical vignettes and board examination-like questions, which can create more unique practice opportunities for students. Additionally, our study also assesses the accuracy of the 2 models on board examination questions related to ophthalmology. Students can input questions they need help with on the platform, and receive an answer and explanation by using the platform. If the student is not satisfied with the answer provided, or has further questions, he or she can respond to the model and receive a more personalized answer. This is crucial as it significantly decreases the time needed to study and also creates a tailored study experience for each student's needs.

However, ChatGPT needs further optimization before it can be considered a mainstream tool for medical education. The image feature was not present in GPT-3.5 and was introduced in GPT-4.0. This feature is available only on demand and is yet to be available to all users. Its accuracy and reliability are yet to be established for examination purposes. Many questions were excluded due to them containing images, which is a

considerable limitation considering the visual nature of ophthalmology. Even in the text-only questions, ChatGPT had moderate accuracy in answering questions across different difficulties and levels. This study is, however, limited by the small number of questions, particularly in the USMLE steps, due to the absence of a large number of ophthalmology questions in the resources used to prepare for these examinations. More studies are needed, which input a larger number of questions. This study also does not assess the repeatability of ChatGPT's answers; however, a study by Antaki et al [13] reported near-perfect repeatability.

Conclusions

Overall, this study suggests that ChatGPT has moderate accuracy in answering questions. Its accuracy decreases in nature as the examinations become more advanced and more clinical in nature. In its current state, ChatGPT does not seem to be the ideal medium for medical education and preparation for board examinations. Future models with more robust capabilities may soon become part of mainstream medical education. More studies are needed, which input a larger number of questions to verify the results of this study and attempt to find explanations for many of the intriguing findings.

Acknowledgments

We thank AMBOSS and Thieme Publishers for granting access to the questions for use in this present study. All authors declared that they had insufficient or no funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. Abstract

Background: The recent artificial intelligence tool ChatGPT seems to offer a range of benefits in academic education while also raising concerns. Relevant literature encompasses issues of plagiarism and academic dishonesty, as well as pedagogy and educational affordances; yet, no real-life implementation of ChatGPT in the educational process has been reported to our knowledge so far.

Objective: This mixed methods study aimed to evaluate the implementation of ChatGPT in the educational process, both quantitatively and qualitatively.

Methods: In March 2023, a total of 77 second-year dental students of the European University Cyprus were divided into 2 groups and asked to compose a learning assignment on "Radiation Biology and Radiation Protection in the Dental Office," working collaboratively in small subgroups, as part of the educational semester program of the Dentomaxillofacial Radiology module. Careful planning ensured a seamless integration of ChatGPT, addressing potential challenges. One group searched the internet for scientific resources to perform the task and the other group used ChatGPT for this purpose. Both groups developed a PowerPoint (Microsoft Corp) presentation based on their research and presented it in class. The ChatGPT group students additionally registered all interactions with the language model during the prompting process and evaluated the final outcome; they also answered an open-ended evaluation questionnaire, including questions on their learning experience. Finally, all students undertook a knowledge examination on the topic, and the grades between the 2 groups were compared statistically, whereas the free-text comments of the questionnaires were thematically analyzed.

Results: Out of the 77 students, 39 were assigned to the ChatGPT group and 38 to the literature research group. Seventy students undertook the multiple choice question knowledge examination, and examination grades ranged from 5 to 10 on the 0-10 grading scale. The Mann-Whitney *U* test showed that students of the ChatGPT group performed significantly better ($P=.045$) than students of the literature research group. The evaluation questionnaires revealed the benefits (human-like interface, immediate response, and wide knowledge base), the limitations (need for rephrasing the prompts to get a relevant answer, general content, false citations, and incapability to provide images or videos), and the prospects (in education, clinical practice, continuing education, and research) of ChatGPT.

Conclusions: Students using ChatGPT for their learning assignments performed significantly better in the knowledge examination than their fellow students who used the literature research methodology. Students adapted quickly to the technological environment of the language model, recognized its opportunities and limitations, and used it creatively and efficiently. Implications for practice:

the study underscores the adaptability of students to technological innovations including ChatGPT and its potential to enhance educational outcomes. Educators should consider integrating ChatGPT into curriculum design; awareness programs are warranted to educate both students and educators about the limitations of ChatGPT, encouraging critical engagement and responsible use.

ChatGPT; large language models; LLM; natural language processing; artificial Intelligence; dental education; higher education; learning assignments; dental students; AI pedagogy; dentistry; university

Introduction

Background

The emergence of ChatGPT (OpenAI) in November 2022 represents the third significant technological breakthrough in information technology impacting education, following the introduction of Web 2.0 over a decade ago [1] and e-learning's surge during the COVID-19 pandemic [2]. ChatGPT is an artificial intelligence (AI) tool that offers benefits and opportunities in higher education including increased student engagement, collaboration, personalized feedback, and accessibility. However, it is characterized by a limited database, posing challenges such as the restricted ability to answer medical questions and the potential for inaccurate and biased responses. There are also concerns regarding legal and ethical implications, plagiarism, and academic integrity [3-5].

The research on AI and its implementation in academic education is a prominent subject; a Google Scholar search for "artificial intelligence and dental education," yielded 100,000 results and approximately 18,000 results for "ChatGPT and higher education" (on June 9, 2023). AI technology has evolved to unprecedented levels, transforming professions, revolutionizing workflows, and reshaping human-machine interactions. ChatGPT, the most recent milestone in natural language processing AI models, has been enabling advanced conversational capabilities and expanding the boundaries of AI-powered communication. Interest in ChatGPT applications encompasses both clinical practice [6,7] and higher education [3,8-11], with promising results.

Relevant Prior Research

Within the higher education landscape, it has been suggested that dental curricula at universities need to be updated due to the AI paradigm shift [9,12,13]. This involves defining a fundamental dental curriculum for both undergraduate and postgraduate levels and establishing learning outcomes related to dental AI [8]. Cotton et al [3] and Halaweh [14] proposed strategies to ensure the ethical and responsible use of AI tools in higher education. Fergus et al [10] evaluated academic answers generated using ChatGPT, and Bearman et al [15] in their review on AI in higher education discussed the shifting dynamics of authority and the relationships among teachers, students, institutions, and technologies. Gimpel et al [16] in their extensive discussion paper proposed guidelines and recommendations for students and lecturers and urged the universities for a multistakeholder dialogue to implement efficient and responsible use of generative AI models in higher education.

Roganovic et al [17] performed a cross-sectional web-based survey among experienced dentists and final-year undergraduate students from the School of Dental Medicine, University of Belgrade, Serbia, to investigate their current perspectives and readiness to accept AI into practice. Responders, especially final-year students, showed a lack of knowledge regarding AI use in medicine and dentistry (only 7.9% of them were familiar with AI use) and were skeptical (only 34% of them believed that AI should be used in dental practice); the underlying reasons were fear of being replaced by AI, as well as a lack of regulatory policies, since students and—at a lesser degree—dentists were concerned that using AI could legally complicate the clinical practice [17].

Chan and Hu [11] reported different results in exploring students' perceptions of generative AI and ChatGPT in teaching and learning through a web-based questionnaire; the study revealed a generally positive attitude toward generative AI, with students demonstrating a good understanding of this technology, its benefits, and limitations, despite its novel public appearance. Generative AI is a special category of AI designed to learn from the characteristics of its input and generate outputs with similar characteristics. In contrast to most AI models that perform specific tasks based on predefined rules and patterns, generative AI models use advanced algorithms to find the underlying patterns of the input data (eg, text, images, sounds, and videos) and "generate" entirely new content of the same type [11]. Students recognized the potential for personalized feedback and learning support, brainstorming, writing assistance, and research capabilities and stated they would integrate technologies like ChatGPT in their studies and future careers, but they were also concerned about becoming overreliant on them. They moreover expressed concerns about data accuracy, privacy, ethical issues, and the impact on personal development [11]. Students' perceptions of the learning environment and the teaching strategies have a significant impact on their approach to learning and the learning outcomes (positive perceptions lead to a deep approach to learning), thus being of pedagogical interest to educators and institutions [11,18]. The influence of AI tools on students' engagement and perceptions was investigated by Nazari et al [19]: they conducted a randomized controlled trial to examine the efficacy of an AI-powered writing tool (Grammarly) for postgraduate students and concluded that students in the intervention group demonstrated significant improvement in engagement (behavioral, emotional, and cognitive), self-efficacy, and academic emotions (positive and negative), domains that address learning behavior, which lead to self-development and underpin authentic pedagogy.

Aims of the Study

Despite numerous publications about AI and large language models (LLMs), the majority involve discussion papers, viewpoint articles, and positions [3,13,16,20,21], with few being exploratory, cross-sectional, or questionnaire-based studies [11,17,19]. To our knowledge, so far, no experimental studies have been identified, wherein ChatGPT was in vivo implemented by students within the teaching process, and the outcomes were comprehensively evaluated.

Therefore, this study aimed to address this gap by implementing ChatGPT within the learning process and conducting a quantitative (differences between examination grades) and qualitative (thematic analysis of the free-text comments of the evaluation questionnaire) evaluation of the outcomes (mixed methods research study).

Methods

Ethical Considerations

The study's research protocol was reviewed and approved by the Vice-Rector for Research and External Affairs and the President of the Institutional Committee on Bioethics and Ethics of the European University Cyprus.

Study Design: Challenges

The study was conceptualized, organized, and refined in February 2023 and realized in March 2023. Of note is that ChatGPT appeared publicly on November 30, 2022; in March 2023, ChatGPT-3.5 was freely available (and was mostly used by the students), whereas ChatGPT-4 had just emerged (few students used this). The study was not a stand-alone research endeavor; instead, it constituted part of students' educational activities embedded within the semester's educational program. As this was the first attempt to implement ChatGPT in the educational process and there were no existing research studies in the literature to refer to, and adding to the limited knowledge on ChatGPT's properties and limitations at the time, the authors encountered various challenges while organizing the research design. Therefore, to anticipate potential issues that could affect student learning or compromise the study's outcomes, they conducted a systematic, forward-looking analysis of the research process, considering each step and taking proactive measures to mitigate any challenges or obstacles that may have arisen.

Study Design: Implementation

The second-year dental students (77 students) of the School of Dentistry, European University Cyprus were randomly divided into 2 large groups and were asked to compose an assignment on "Radiation Biology and Radiation Protection in the Dental Office." The subject of Dentomaxillofacial Radiology is taught through theoretical lectures, laboratory training, and practical training during 2 semesters, and students' learning assignments are embedded within the lectures' program as an alternative to traditional lecturing. Student learning assignments to replace lectures followed by in-class presentation and discussion is a methodology used within the "Dentomaxillofacial Radiology" module whenever the topic is suitable for such an approach. Students usually work collaboratively to perform the

assignments by searching the internet for scientific reliable sources and compiling the results into a PowerPoint slide presentation, including the references they used. Students of both groups were asked to work in small subgroups to compose the assignments, where each subgroup would comprise 3-7 students, decided among them. It is worth mentioning that the European University Cyprus School of Dentistry is an English-speaking School, educating students from over 30 countries encompassing different ethnic, educational, and cultural backgrounds; therefore, the study's sample could be considered diverse.

One large group would compose the assignment through literature research (the traditional method for assignments) and the other group would use the ChatGPT tool for the assignment (pose prompts and register the answers), also submitting a slide presentation. Students were given 1 month to deliver the assignment, and they were informed that they would present their presentations in class on a designated day.

Moreover, students of the ChatGPT group were encouraged to experiment with it; ask different questions; ask for videos, images, and internet resources; and in general to be creative, imaginative, and playful while using this new tool. Once they had the final AI content, they were advised to critically evaluate it by comparing it with the relevant content of a reliable scientific resource, such as a textbook or published article, and perform the necessary modifications to the AI output. After finishing the assignment, they were asked to complete an open-ended questionnaire individually ([Multimedia Appendix 1](#)), including questions about the usability, problems, opinions, proposals, and so forth, which was emailed to them, and which they would submit to the educator together with the assignment (ie, the PowerPoint presentation).

The AI Evaluation Questionnaire included 12 questions requiring free-text responses and was developed by the authors by combining questions from 2 sources: essays evaluation questionnaires retrieved in the scientific literature [22-24] and the questionnaire ChatGPT produced on the prompt "Can you develop 10 questions for a user to evaluate your performance on writing an essay?" Questions were combined and modified, they were piloted within a small student group other than the research groups, and they were finally amended as necessary. The free-text comments of the AI Evaluation Questionnaire were grouped into main themes and discussed (subjective and qualitative evaluation).

After students completed and submitted their projects via email, and on the designated day they would present the PowerPoint presentations in class, at the beginning of the session, they all had an unannounced blind knowledge examination (answered individually and anonymously, where they only indicated the group they belonged in, so that the educator could not relate the students with the answer sheets). The examination was developed by the authors and consisted of 10 multiple-choice questions (MCQs), which addressed the learning objectives of the topic. They were informed that the knowledge test was intended for the educator to identify whether the assignment had equipped them with the intended knowledge and whether there were any knowledge gaps to address. The results of the

examination (examination grades) were compared among the 2 groups, that is, the literature research group and the ChatGPT group. Statistically significant differences between the groups' grades were explored using the Mann-Whitney nonparametric test. Data analysis was conducted using SPSS (version 25.0; SPSS Inc), and statistical significance was set at $P=.05$ (objective and quantitative evaluation).

The final study design is summarized as follows:

- Students were randomly divided into 2 large groups (the ChatGPT and the literature research groups) and further into smaller groups.
- Literature research group performed the assignment by searching the internet and delivered it in PowerPoint format, including the references used.
- ChatGPT group (1) asked the LLM relevant queries and developed a PowerPoint presentation; (2) registered and reported on their interactions with ChatGPT, including the prompts and their modifications, the final outcome and its evaluation after comparing it with a reference text or book chapter; and (3) answered the AI Evaluation Questionnaire on their experience with the LLM.
- All students presented their learning assignments in class. At the beginning of this session, they undertook an unannounced knowledge examination of 10 questions.
- Data derived from the knowledge examination grades, the PowerPoint presentations, and the free-text comments of the AI Evaluation Questionnaire.

Results

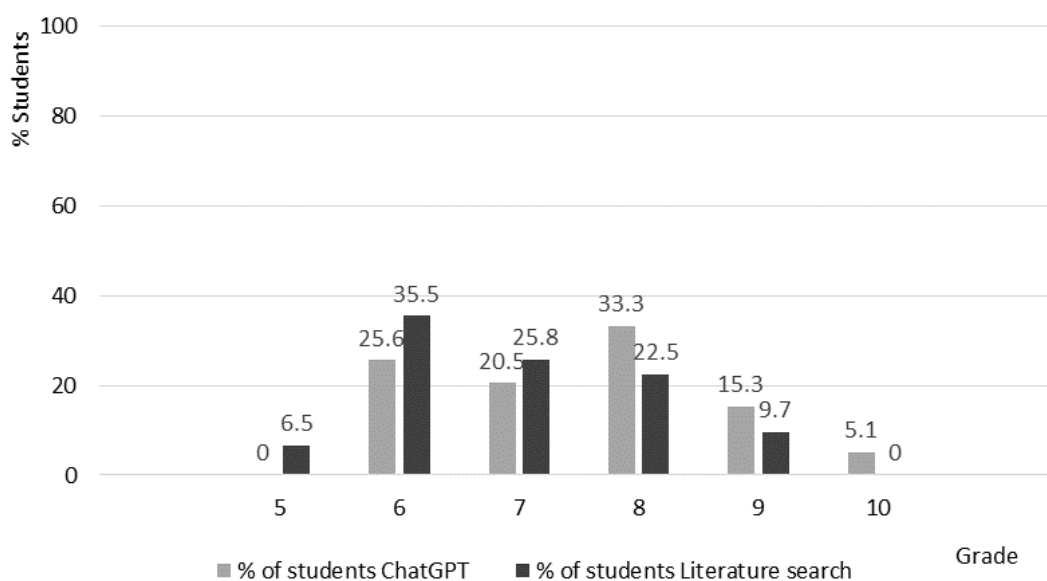

Quantitative Results

Out of the 77 students, 39 were assigned to the ChatGPT group forming 9 subgroups and 38 to the literature research group forming 8 subgroups. Seventy students undertook the MCQ examination (7 students were absent) and examination grades ranged from 5 to 10 on the 0-10 grading scale. [Figure 1](#) presents the number of students (percentages within each group) with their examination grades. We noticed that in the higher range of examination grades, that is, 8-10, the ChatGPT students outperformed the literature research students, while the opposite happened within the lower range of examination grades, that is, 5-7.

To check for differences between the ChatGPT student group and the literature research group, we performed the Mann-Whitney U test, which showed that students of the ChatGPT group ($n=39$; mean 7.54, SD 1.18) performed significantly better ($P=.045$) than students in the literature research group ($n=31$; mean 6.94, SD 1.12).

To foster inclusiveness and avoid discrimination, we deliberately chose not to perform statistical analyses regarding gender differences, as we also believe that gender diversity is not associated with the educational process or the educational outcomes. Education is offered equally to all students and any gender differences possibly found would not differentiate educational approaches for one gender or the other. Instead, we perceive this student cohort as representatives of their generation (Generation Z), a characteristic that is directly related to this study's outcomes and could explain several findings. This concept is in line with the US National Institute of Health recommendations for gender-neutral language [25].

Figure 1. Students' examination grades (% of students within each group).

Qualitative Results

Overview

Out of the 39 students of the ChatGPT group, 31 (80%) students answered the 12 questions of the AI Evaluation Questionnaire. The free-text answers to the questions were grouped into themes and discussed. Three main themes emerged.

Collaboration With ChatGPT and Problems Encountered

Although the majority of students were aware that ChatGPT had surfaced a couple of months ago in the digital world and some of them had already used it, this was the first opportunity they had to actually work with it and “officially” use it within their studies, and they enjoyed and appreciated this opportunity. They characterized it as a “powerful and versatile tool,” “intuitive and intelligent,” “revolutionary,” and “enjoyable to work with” and they thought this experience was “interesting and different from the regular assignments.” They stated that learning to use these AI tools would improve their future

practice but emphasized that “you have to learn how to properly use it.” They appreciated its human-like answers, as these “do not make the user feel distanced from technology.” A student stated:

In the beginning I was afraid it was going to be too difficult to work with but as I was discussing with it I understood its greatness. I think it really is the future as it can help both education and research. I really did enjoy its human-like answers like when something was wrong it persisted like a human being for its accuracy as well as when it did not answer the question as it should like a lazy student.

Another student commented: “I enjoyed working with ChatGPT, because I got to learn and understand something that is going to be a part of the future.” Humanization of the LLM is worth noting: “He always understood what we wanted.” [Textbox 1](#) shows examples of students’ prompts.

Textbox 1. Examples of students’ prompts to ChatGPT (exact copies).

- How does radiation affect human health?
- What’s the difference between deterministic & stochastic effects of radiation?
- Is radiation exposure carcinogenic?
- Which are the radiation doses from common dental radiographic exams?
- Which criteria are used to reduce unnecessary radiographic exposure in dentistry?
- Can a pregnant employee continue to work in the dental radiology department?
- What is the importance of radiation biology? With references used
- What are the effects of radiation on cells and tissues? With references used
- What are the effects of radiation on the oral cavity? Rewrite the previous answer in a more elaborate way
- Make a chart about effective dose from diagnostic x-ray examinations focusing on the oral cavity
- Radiation biology, include references
- Measurements of radiology safety, include references
- Radiology protection in dentistry, include references
- How can we minimize the radiation exposure on dental staff, including references
- Why are radiation safety precautions necessary for the dentist
- Tell me how radiation can affect the human body
- Write me an essay discussing radiology safety and protection procedures in dentistry
- Can you explain radiation biology for medicine and dentistry in 400 words, include references
- Radiation exposure in dental office word limit 200-250 words. Include references
- Radiation monitoring in the dental office in 230-270 words include references
- Write me an essay of 400 words about the biology of radiation and provide references
- Write me a 300 words essay about radiation safety and protection in dentistry
- What are the risks associated with exposure to radiation?
- What are the modifying factors of irradiation?
- How does radiation exposure time and dose differentiate between adults and children in dental x-ray taking?

Not unexpectedly, students identified all the problems and limitations of ChatGPT, which are later described in detail in the literature. They identified the need to rephrase or detail the

prompts to have a satisfactory output (“we learned quickly how to ask the questions to get a good answer”) and realized that if the same question was asked slightly differently the output was

different (“by asking it 6 different questions, we wanted to get a better idea of what it changes on the text every time we put a new word or phrase the question differently”). They confirmed that some information was outdated, important content was missing, part of the answer was occasionally incorrect, links to references were nonexistent, and the links to videos were not working, although the LLM provided detailed and seemingly reliable information on the links and references (thus unknowingly identifying the “hallucination” effect of ChatGPT).

A student stated: “Mostly it understood our questions but it was not giving us that detailed and satisfactory answers as we anticipated according to our book.” Another student correctly noticed that “ChatGPT is not capable of having thoughts or opinions on its own, so it does not answer some questions that demand a critical-thinking answer.” Technical issues were also mentioned by some students, for example, “some days it was not opening and our conversation couldn’t be saved on the cloud” and “it ‘crushed’ sometimes mid-working.”

Quality of the Generated Outputs

Students found that the quality and depth of the information provided by ChatGPT depended on the quality and wording of the questions asked. As a student noticed:

I would not say that it demonstrated a very deep understanding of the topic, but I think with even more questions being asked, then the text could essentially show a deep understanding of the topic.

Students quickly realized that with follow-up questions and rewording, they could guide the LLM to produce more detailed and in-depth answers: “it needed some guidance with follow up questions to further specify what we were asking for.” While comparing the output with a reference text, students reported that the answers were not detailed; sometimes included false

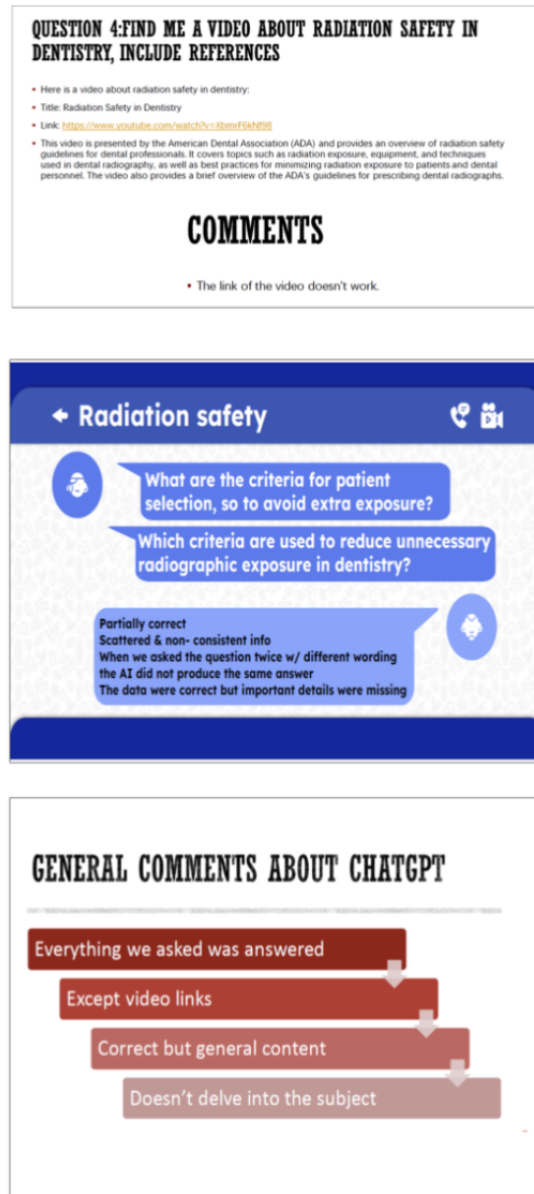

data; and were brief, general, or superficial; nevertheless, the key points were evident. A student concluded that “ChatGPT is more than enough in order to understand and have a general idea about the main points of the matter being discussed” and another student thought that “I will find more details by going and searching online or in books.” They expect ChatGPT to improve in the future and be able to provide videos and images because “they are helpful in understanding a topic and provide a more effective way to retain information as well” and also to be able to browse external resources outside its stable database (Figure 2).

They evaluated the language as appropriate for a scientific document, understandable, and explanatory, and they indicated that when references were asked for, the language was even more formal and academic: “It is fascinating how the AI provides understandable answers in a scientific manner.” However, they encountered problems with the references, as in some occasions, ChatGPT denied to supply them, while in other instances, the references were incorrect. A student described:

The AI was continuously denying to give us relative references but after reforming our questions we eventually got our answer. The references it used were accurate scientific resources found on its stable database like the American Dental Association.

Another student stated that “We used chat GPT 4 so all our references were sufficient and up to date” (apparently overestimating ChatGPT-4’s currentness, as it has the same cutoff date as ChatGPT-3.5). The majority of students evaluated the references as relevant, sufficient, reliable, and up-to-date; however, they also recognized the limitations of the LLM, thinking that “it is under construction so not all its answers are up to date and sufficient information is only provided up to a certain point in time.”

Figure 2. Examples of students' slides depicting their interactions with ChatGPT.

Exploring Additional Possibilities and Predicting the Future

Students experimented with ChatGPT, asking it to provide images and videos, and create MCQs, charts, bullet point summaries, and presentation templates, for example, “we asked about multiple choice questions and the answers were actually impressive” (Figure 3). Students were imaginative and resourceful, and they were disappointed when their request was not realized:

I asked from it to provide me some explanatory images related to our topic, but it was not able to do so. I think this is a crucial disadvantage, as images give depth and context to a description and provide a much more immersive experience than writing alone.

Two student groups—comprised of technologically very experienced students—surprised the authors when they skillfully

bypassed the inability of ChatGPT to produce PowerPoint presentations by asking it to write a programming code:

We used the AI for the generation of a PowerPoint. Since it cannot on its own generate PowerPoint Slides we asked it to generate a VBA code for the PowerPoint. That code was copied and then pasted to the ‘Developer’ section of the PowerPoint. As a result we got a beautiful but not so detailed presentation of our topic.

This process enabled the instant transfer of ChatGPT’s output within a PowerPoint slide presentation created by ChatGPT. Among the future applications of ChatGPT, students included the use in dental education, for example, for the creation of MCQs, summarizing a topic, lecture revision, helping students better understand a theory or concept, assignments and projects, laboratory reports, questions about law and ethics, communication with patients, and more. A student proposed:

Virtual patient consultations: ChatGPT could be used to simulate patient consultations for dental students. Students could practice various scenarios, including patient history taking, explaining diagnoses, and treatment planning.

Continuing education could also avail from the opportunities ChatGPT and LLMs offer:

Education that never ends: ChatGPT may be utilized to give dental professionals continual education. For dental professionals to keep current in their field, faculty might create modules containing the material they need, and ChatGPT may offer engaging tasks and tests to reinforce the learning.

Considering dental practice, students proposed that ChatGPT could be used to educate and solve problems for the dentist, for example, when “the dentist has a mind block” or when the dentist “seeks information about new dental materials and techniques”; also for treatment plans, schedule creation, and oral hygiene info; and for patient education “through integrating the model into a dental practice’s website or patient portal.”

For research and scientific publications, students thought it “can be useful to use it synergistically with your own research,” but “you should always double-check the information” and “keep in mind the plagiarism, using the information provided appropriately.”

Finally, students admitted that ChatGPT has drawbacks such as a limited database, incapability to access external web resources and provide images and videos, inaccurate links, and the need to verify the information generated. They thought that “it should be used with caution” and that “AI still needs to evolve,” so that it will become “an incredibly smart, effective, and powerful tool that can help the scientific community.” They realized that “the power it holds is unpredictable and the work of doctors could be compromised” and feared that “maybe we will live one day that AI robots could even replace dentists.” A student eloquently summarized ChatGPT’s past, present, and future:

After many years of research and after many science fiction movies about the power of AI and its impact on society I have come to the conclusion that this kind of AI can only help and do no harm. AI like ChatGPT that is available to the public and gives sufficient and accurate responses can give us hundreds of possibilities, even at dentistry. But I really don't know this exact ChatGPT with its limited dental references can influence the field of dentistry. I can though imagine a more resourceful AI where it uses PubMed or Research Gate to generate its responses that would really elevate the level of dental education and research. What if a curious dentist had the million dollar question answered in milliseconds by the AI?

Figure 3. Multiple-choice questions created by ChatGPT. MCQ: multiple-choice question.

Discussion

Overview

In March 2023, a total of 39 dental students who are 20 years of age, through composing an educational assignment, identified the capabilities and limitations of the recently introduced ChatGPT and explored various possibilities; used it to write MCQs and programming codes; proposed future applications in education, research, and dental practice; and outperformed their peers in the knowledge examination.

Results Explained and Compared

The quantitative results, that is, the examination grades, demonstrated that all students performed well (their grades fell within the middle and high ranges of the grading scale) and no students underperformed (no grades in the low ranges of the scale), while ChatGPT group students outperformed their literature research group peers. Since the examination occurred with no prior notice to the students, it directly reflects the knowledge acquired and retained through the project's creation. Students' good performances on the examination could be related to the format of the project in connection with their generational traits: all students socially belong to the Generation Z cohort (born between 1995 and 2010), so they are the first true "digital natives" [26], having grown up with smartphones, social networks, apps, and streaming content as part of the daily routine [27]. They are considered tech-savvy, mobile-driven, collaborative, and pragmatic [28,29] and possess a natural facility with digital tools and an interest for everything digital. Motivated by the opportunity to use the internet and work collaboratively, students immersed themselves in the project and explored it in depth, and this applies even more to the ChatGPT group students who were excited and curious to test this new digital tool. The enhanced learning observed with the ChatGPT students can be also attributed to the increased "time on task" for these students, as they had to spend more time asking and reasking the questions, evaluating the answers, correcting, and complementing them in comparison to their peers who had clear and readily available results from the relevant scientific literature. Additionally, ChatGPT group students had to work more than their fellow students with the learning material at a higher cognitive level and constantly apply critical thinking while experimenting with various questions and answers, comparing, and synthesizing them—an element that also enhances deep learning and results in enhanced performance [30].

The AI Evaluation Questionnaire provided insight into students' opinions, evaluations of ChatGPT, the problems encountered, and their future estimations. Students demonstrated their prescience by providing remarks in concordance with those found in later-published articles; the latter were accessed by the authors after the research was concluded and while composing this study. Students evaluated their learning experience with ChatGPT as interesting, enjoyable, and engaging [19] and appreciated its user-friendly interface and the possibility of arguing with it [4,16]. They assessed the generated content as overall correct and sufficient [7,31], although often providing a general overview of the subject [5], as well as not

demonstrating a deep understanding of the context [32-34] nor thinking critically [10,35]. They first-hand identified the need for carefully created questions [36] and critical analysis of the answers [14,36], and they urged for cautious and responsible use [4,6]. In agreement with Chan and Hu [11], they are ready to embrace this new technology but in a collaboration where people maintain control and are not replaced by AI [17,20,37,38]. Finally, in line with the literature, they attributed "anthropomorphic" qualities to the language model (1 student referred to ChatGPT using the gender pronoun "he"), possibly explained by the establishment of a personal connection between the student and the language model while engaging in human-like conversations in combination with student's own gender-related perceptions and interaction style [39].

Students proposed possible applications of ChatGPT in education for revisions, MCQ creation, personalized learning, writing essays [3,4,20,37,40], and continuing education [38], as well as in research and clinical practice [4,6,12]. Nevertheless, students thought that the LLM must evolve to provide images, videos, accurate and relevant citations, and browse the internet [31,41,42].

Numerous publications thereafter examined the LLM's limitations that had been already identified by the students: incorrect answers and outdated content [10] possibly due to its limited data set [37,38,43], the possibility for fabricated information and hallucination [44], false citations and links leading to nonexistent sources [38,44,45], inability to browse the web [41], and risks for plagiarism [3,46].

This research materialized Kung et al's [31] concluding remarks that "the utility of generative language AI for medical education must be studied in real-world learning scenarios with students, across the engagement and knowledge spectrum" since ChatGPT was embedded within the educational process, thus producing authentic and relevant results. The quantitative and qualitative outcomes of this study indicate that this cohort of Generation Z students is capable of adapting quickly to new technologies and ready to use LLMs such as ChatGPT in the learning process—while acknowledging their limitations—particularly when these tools are integrated within a pedagogical framework that fosters creativity and autonomous learning. Educators on the other hand seem to have limited technological knowledge, skills, and pedagogical expertise to assess AI applications and successfully integrate them into education [12,47]; therefore, they should pursue professional development to develop new skills related to AI understanding, possibilities, and implementation [15,40,48,49].

Pedagogical Aspects

All second-year students were asked to explore the topic of "Radiation Biology and Radiation Protection in the Dental Office" and develop assignments to be presented in class as PowerPoint presentations. Questions and knowledge gaps were covered during the in-class presentations by the instructor and not infrequently by their peers. This approach is consistent with the "flipped classroom" concept, an educational methodology that research has shown to engage students in the learning process, promote autonomy and self-regulation, allow for higher-order thinking, improve student satisfaction, and increase

academic performance [50,51]. Another element of pedagogical interest is the small group collaborative work to develop the assignments. Collaborative learning has the potential to promote deep learning, which is essential for understanding complex concepts particularly in science education, through students' meaningful interactions and constructive debates [52]. Scager et al [52] reported that effective collaboration is achieved when students undertake a challenging, complex task, and they succeed in creating a new and original output. Such tasks applied in higher education build a sense of responsibility and shared ownership of the output and the collaborative process, and this sense was indeed apparent in the students of this study within and during their oral presentations.

An additional pedagogical element is the learning assignments as a method for self-learning and knowledge acquisition. Learning through assignments has been reported to be preferred by students: in the study of Warren-Forward and Kalthoff [53], 79% of the students reported that the assignment on magnetic resonance imaging safety was both a positive learning experience and provided an understanding of the topic. Writing assignments enhance retention of knowledge; when assignments include reflective thinking, for example, when students have to evaluate and synthesize information (as happens in this study), higher-order (critical) thinking is also enhanced as students work at a higher cognitive level [30].

The innovative pedagogical aspects of this study (flipped classroom, learning assignments, and group learning) constituted a supportive environment for students of both groups to demonstrate their skills, achieve the learning objectives, and produce valuable results. While this pedagogical approach may cater more to certain types of learners, it remains pertinent for younger generations, who prefer active and collaborative learning.

Study Design: Tackling the Challenges

Of interest would be to communicate herein the challenges faced during designing the research process, as the ChatGPT environment was largely unknown at the time, and obstacles and drawbacks had to be identified and resolved ahead through a step-by-step prospective analysis of the sequence of events.

For example, a concern that had to be addressed ahead was the fact that the subject was unknown to the students and they would not know whether the output was scientifically correct or incorrect, comprehensive or incomplete because they would not have an exemplary scientific text to compare it with, as they would rely solely upon ChatGPT's answers. To address this, they were advised to compare the outcome with the relevant content of a recommended textbook (or other reliable source of their choice), critically evaluate the quality of the AI outcome, and perform the necessary amendments to complement or correct the AI results. The comparison should be included either within their presentation or within the AI Evaluation Questionnaire. This process would additionally ensure the achievement of learning objectives. In line with this process and at a later time, Chung [48] proposed in his article published in April 2023 that "instructors should teach students to use other authoritative sources (eg, reference books) to verify, evaluate,

and corroborate the factual correctness of information provided by ChatGPT."

Another concern arose about elucidating students' engagement with ChatGPT: since the output of ChatGPT would be texts in slide format (similar to the ones of the literature research group), the educator (one of the authors) could evaluate these texts or slides for accuracy and comprehensiveness but could not comprehend whether they were generated following single or multiple attempts, posing differentiated or follow-up queries; therefore, the time and effort spent on the research process and the learning path could not have been assessed nor would the capabilities and drawbacks of the LLM be revealed. To address this concern, the ChatGPT group students were asked to register and report all their interactions with the LLM (including the number of prompts, the modification of prompts, the queries about references, images, and the underlying reasoning); thus, the educator could evaluate the cognitive effort they put in the assignment and the critical thinking applied until a satisfactory result was achieved. Furthermore, this would provide valuable insights into comprehending the usability and operational characteristics of the LLM. Adding to this, the AI Evaluation Questionnaire was a useful means to draw information on student-LLM interactions.

In accordance with the above procedure determined by the authors and in affirming their decisions, Halaweh's study [14] published in April 2023—2 months after the development of this study's design and 1 month after its implementation—precisely described the same process when discussing the strategies for successful implementation of ChatGPT in education. It seems that future literature confirmed the authors' study design overall.

LLMs in Higher Education

Given the study's results and in agreement with the relevant literature, the authors would suggest that higher education institutions and dental schools could consider updating their curricula, policies, and teaching methods to prepare students for an AI-driven future, by including education on and with AI tools and LLMs [8,45]. Within this context, faculty professional development seems urgent to increase their skill level and AI understanding, for example, through peer support, mentoring, and sharing good teaching practices [36], as most educators have limited knowledge and skills to assess and efficiently use AI applications [12]. The introduction of LLMs into education will offer opportunities to improve its efficiency and quality: improved student performance, personalized learning, targeted and immediate feedback, increased accessibility, creativity and innovations, student engagement, lesson preparation, collaborative activities, and evaluation [4,40,54-56]. From the pedagogical perspective, students using LLMs have the potential to develop new competencies including 21st-century soft skills, such as self-reflection abilities, problem-solving skills, creative and critical thinking, and collaboration, thus becoming motivated and autonomous learners [3,4,16,33,49]. Moreover, as AI technology evolves and gradually integrates within the educational process, the conventional pedagogical theories may not be relevant nor sufficient to support the teacher-student-technology relationship, as technology

profoundly alters the way students learn and engage with the content and the teacher; innovative pedagogies will be needed, such as the “entangled pedagogy” Fawns [57] proposed to contextualize students’ learning in a world where AI is increasingly prevalent [15,16].

To respond to the AI paradigm shift, higher education institutions, educators, and students must engage in constructive dialogue to develop policies, guidelines, and training opportunities for the implementation of innovative technological tools in the teaching process [16,34,55]. Despite the current weaknesses that limit their implementation, LLMs will likely improve in the future in terms of performance, scalability, and quality of responses, as well as through fine-tuning for specific tasks, customized use cases, and search engine connection [4,16,31,58].

Limitations and Strengths

The small number of students who participated in this study (77 in total and 39 in the ChatGPT group) in 1 dental school can limit the extrapolation of the results. Students’ digital literacy is also of relevance: students who participated in this research were mostly tech-savvy, whereas students in other schools or universities may be less familiar with digital technologies; thus, results would not apply to them [17]. In addition, some findings (particularly the qualitative ones) may be outdated at the time of publication, as LLMs constantly evolve and new LLMs have been introduced since the research was conceptualized and implemented. For example, Google Bard and Microsoft Bing claim to have live access to the internet, a capability highly appreciated by the students; ChatGPT has since evolved its

algorithms, with results being more accurate and relevant. Some elements of the study design could have been further explored; for example, students’ assignments could have been graded and compared, but since assignments’ grading was not included in the semester program of the module, this was not performed. In any case, the importance of this study lies in the fact that this was a very early attempt to implement legitimately and in vivo a language model in the teaching process as a partner in learning, in contrast to the large number of publications perceiving ChatGPT as a partner in cheating and academic dishonesty [12,59,60]. Another strength would be that it revealed aspects of the language model-students’ interactions during the learning process, which indicate that this emerging relationship is yet to be explored, and updated pedagogical frameworks are needed for this purpose.

Conclusions

ChatGPT was implemented in real-life undergraduate dental education and was evaluated. Students using ChatGPT for their learning assignments performed significantly better in the knowledge examination than their fellow students who used the literature research methodology. The AI questionnaire answered by students revealed the capabilities and weaknesses of the language model, as identified later in the scientific literature. Students enjoyed working with this tool and explored different options and possibilities, indicating that they are technologically knowledgeable and capable of adapting to new technologies, both in education and in future clinical practice. LLMs such as ChatGPT have the potential to play a role in education, underpinned by solid pedagogies.

Acknowledgments

The authors are grateful to the students who participated in the study. They were enthusiastic, motivated, and resourceful and explored the subject in depth, thus providing valuable insights to inform the ongoing research on the topic.

Authors' Contributions

AK conceptualized, designed, and realized the study; interpreted the data; and drafted the manuscript. KG supervised the project, reviewed the literature, and contributed to drafting the manuscript. MADdS and EGK critically reviewed and revised the manuscript; EGK performed the statistical analysis. VS consulted on information technology and reviewed the manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Using virtual patients, facilitated by natural language processing, provides a valuable educational experience for learners. Generating a large, varied sample of realistic and appropriate responses for virtual patients is challenging. Artificial intelligence (AI) programs can be a viable source for these responses, but their utility for this purpose has not been explored.

Objective: In this study, we explored the effectiveness of generative AI (ChatGPT) in developing realistic virtual standardized patient dialogues to teach prenatal counseling skills.

Methods: ChatGPT was prompted to generate a list of common areas of concern and questions that families expecting preterm delivery at 24 weeks gestation might ask during prenatal counseling. ChatGPT was then prompted to generate 2 role-plays with dialogues between a parent expecting a potential preterm delivery at 24 weeks and their counseling physician using each of the example questions. The prompt was repeated for 2 unique role-plays: one parent was characterized as anxious and the other as having low trust in the medical system. Role-play scripts were exported verbatim and independently reviewed by 2 neonatologists with experience in prenatal counseling, using a scale of 1-5 on realism, appropriateness, and utility for virtual standardized patient responses.

Results: ChatGPT generated 7 areas of concern, with 35 example questions used to generate role-plays. The 35 role-play transcripts generated 176 unique parent responses (median 5, IQR 4-6, per role-play) with 268 unique sentences. Expert review identified 117 (65%) of the 176 responses as indicating an emotion, either directly or indirectly. Approximately half (98/176, 56%) of the responses had 2 or more sentences, and half (88/176, 50%) included at least 1 question. More than half (104/176, 58%) of the responses from role-played parent characters described a feeling, such as being scared, worried, or concerned. The role-plays of parents with low trust in the medical system generated many unique sentences (n=50). Most of the sentences in the responses were found to be reasonably realistic (214/268, 80%), appropriate for variable prenatal counseling conversation paths (233/268, 87%), and usable without more than a minimal modification in a virtual patient program (169/268, 63%).

Conclusions: Generative AI programs, such as ChatGPT, may provide a viable source of training materials to expand virtual patient programs, with careful attention to the concerns and questions of patients and families. Given the potential for unrealistic or inappropriate statements and questions, an expert should review AI chat outputs before deploying them in an educational program.

KEYWORDS

prenatal counseling; virtual health; virtual patient; simulation; neonatology; ChatGPT; AI; artificial intelligence

Introduction

Virtual standardized patients (VSPs) represent an emerging technology with the potential to revolutionize health care education and training. They provide health care professionals with a safe and controlled environment in which to learn and practice complex skills. VSPs are frequently used in educational models for the health professions to teach history-taking, surgical skills, decision-making, and medication management [1-4]. VSPs have also been used in the health professions to practice critical communication skills [5-7]. VSPs that use natural language processing may provide a valuable educational experience for learners [8].

One example of a VSP is VANESSA (Virtual Antenatal Encounter and Standardized Simulation Assessment) [9]. The VANESSA simulator is a screen-based simulation of a woman in her 23rd week of gestation who can display multiple emotions through the animation of facial expressions and body language. The VANESSA simulator was developed by the Neonatal Education and Simulation-Based Training Laboratory at the University of Washington to teach prenatal counseling skills to residents and fellows [9]. In its initial iteration, VANESSA was given a list of manually generated responses that neonatologists who routinely do perinatal counseling deemed relevant and realistic to the conversation. Manually generating a large, varied sample of realistic and appropriate parent responses for VANESSA has been challenging. Unrealistic responses and questions reduce the fidelity of virtual simulations. Newly developed artificial intelligence (AI) systems can provide dialogue for a wide variety of interactions and may be a valuable resource in expanding virtual patient dialogues for specific clinical scenarios, such as prenatal counseling.

Chat-based language models and AI are entering the public domain with impressive performance, a large application pool, and exciting interactivity. Notably, ChatGPT has prompted a billion-dollar investment from Microsoft, triggered explicit discussions by Bill Gates and Elon Musk, and captivated the population of users able to interact with it via the open research chat interface. AI trained with large language models to interpret written or auditory input and generate coherent, domain-centered responses is being proposed in a variety of real-world applications, including the health care setting. ChatGPT has the added benefit of being able to emulate different characters, allowing for a broader array of parent voices than could be generated by individual health care educators.

In this report, we explore the use of ChatGPT to enhance the realism of the VANESSA VSP. We hypothesized that the integration of the ChatGPT AI chatbot would generate realistic, relevant, and usable patient responses for a VSP simulator used in prenatal counseling education.

Methods

The study used an exploratory observational design, with ChatGPT acting as an expectant parent within the VANESSA software, conducted in February 2023 on ChatGPT 3.5.

The VANESSA VSP represents a pregnant woman in her 23rd week of gestation and showcases emotions through animated facial expressions and body language. Created with input from neonatologists, its dialogue and emotive feedback were found realistic in pilot tests, enabling participants to confidently identify its emotional states.

ChatGPT is a large language model developed by OpenAI. Its exceptional performance stems from generative pretraining, leveraging extensive unlabeled data sets [10]. This foundational training helps it grasp English nuances. Following this pretraining is “one-shot” learning, a rapid task-specific learning [11]. The architecture includes a transformer encoder-decoder neural network, originally developed for translation services and now popular in language models [12]. ChatGPT decodes user prompts to create relevant responses using autoregressive language modeling [13]. It is apt for generating realistic dialogue for health care simulations.

The study had three phases:

1. ChatGPT generated a list of common concerns from families expecting preterm delivery at 24 weeks. The stability of these concerns was verified in an iterative process over time.
2. Using a standardized prompt, ChatGPT crafted potential parent questions related to each concern.
3. Role-plays were constructed for a mother expecting preterm delivery. The AI was given varied emotional settings for the scenario of preterm labor at 24 weeks, including anxiety or distrust in the medical system. In each scenario, a designated area of concern and a primary question were specified, derived from the potential parent responses generated in phases 1 and 2. Conversations were created with cues for the VSP and then reviewed (an example is shown in [Figure 1](#)).

Figure 1. Example role-play conversations.

Prompt: Create a role play game in which a doctor provides empathetic counseling to a parent in preterm labor at 24 weeks gestation. The parent has a 5th grade reading level, has a lot of fear about what will happen, and is very concerned about their baby's survival. Their biggest question is about machines or medicines their baby will need to help them breathe and stay alive.

Doctor: Hi, I'm Dr. Smith. How are you feeling today?

Parent: Hi, Doctor Smith. I'm scared. I don't know what's going to happen to my baby.

Doctor: I understand. It's normal to feel scared and uncertain at this point. Let's talk about what we can do to help you and your baby.

Parent: Okay. I just want my baby to survive. Will my baby need machines or medicines to stay alive?

Doctor: It's possible. At 24 weeks, your baby's lungs are not fully developed, so they may need some help breathing. We have machines that can assist with breathing, as well as medications that can help support your baby's heart and lungs. But I want to assure you that we will do everything we can to help your baby survive and thrive.

Parent: Okay, that makes sense. But I'm still worried about what will happen.

Doctor: I understand. This is a scary and uncertain time. But please know that you're not alone in this. We have a team of experts who will work together to provide the best possible care for you and your baby.

Parent: What happens after my baby is born?

Doctor: Once your baby is born, we'll do everything we can to make sure they receive the best possible care. Depending on their needs, they may need to stay in the hospital for a while, but we'll work with you to make sure you're involved in their care as much as possible.

Parent: That's good to know, but I'm still worried. Will my baby have any long-term health problems because they were born so early?

Doctor: It's possible that your baby may experience some health challenges in the future, but we will work together to address those challenges as they arise. Every baby is unique, and some preterm babies go on to live healthy, normal lives. Others may need additional support and care.

Parent: Okay. What else can I expect during this time?

Doctor: We'll be monitoring your baby closely. We'll do tests to make sure your baby is doing okay. We'll also give you medications to help your baby's lungs develop. You may need to stay in the hospital for a while. We'll be here to answer any questions you have and support you through this.

Parent: Thank you for explaining everything to me. I'm still scared, but I feel better knowing that you and your team will take care of us.

Doctor: You're welcome. It's important to take things one step at a time. We're here for you and your baby. Let's take care of you both and see how things go.

Throughout the process, ChatGPT was instructed to adhere to a fifth-grade reading level for the AI parent role. Considering the US Department of Education's findings on widespread low literacy, the importance of health literacy, and the impacts of pain, stress, and other factors on comprehension, this was deemed crucial [14-17]. The Joint Commission and several medical organizations suggest that patient materials should be at a fifth-grade level or lower [18]. Although these dialogues were verbal, the principle of understandability remained in place.

Role-play conversations were scrutinized for parental responses. Each was checked for question or statement content, emotional cues, and sentence count. Initially, generated physician names and certain response starters (eg, "yes" or "no") were noted but removed for evaluation. Sentences were then appraised by a neonatologist for realism, relevance, and usability for virtual prenatal counseling simulations. Each metric used a 5-point Likert scale, ranging from 1 (the lowest) to 5 (the highest). For usability in the VANESSA VSP, responses were scored as follows: 1 if they were unusable, 2 if they were unusable without major modifications, 3 if they were usable with moderate modifications, 4 if only minor modifications were needed, and 5 if they were usable without any modifications. The first 10% of responses were independently reviewed by 2 experienced neonatologists (RU and MG) and then compared for reliability. A calculated weighted kappa on the sample was 0.84, which is

considered a strong level of agreement [19]. Responses with differences in rating were discussed by the team members to improve reliability, and the remainder of the data set was scored by one of the experienced neonatologists. Duplicate responses were scored only once. Analysis was done using Stata (version 17.0; StataCorp).

Results

ChatGPT-3.5 generated a list of 7 common areas of concern, 28 questions likely to be asked by parents anxious about the preterm delivery of their infant, and 7 additional questions likely to be asked by parents with low trust in the medical system (Table 1). These areas of concern and questions were used to create 35 unique role-plays, which contained 176 unique parent responses (Table 2). The role-plays had a median of 5 (IQR 4-6) parent responses to the counseling physician. The responses were roughly evenly split between questions and statements. About half of the responses had 2 or more sentences in the response. Many responses mentioned a specific emotion or feeling. The role-play of the parent with low trust in the medical system generated 50 unique sentences across the 7 areas of concern. There was variation in the number of unique sentences generated across the 7 major areas of concern (Table 3). Most responses were found to be realistic, appropriate for variable conversation paths, and usable in a VSP program (Table 4).

Table 1. Areas of concern and example questions generated by artificial intelligence.

Areas of concern	Example questions from parents
Health and development	<ul style="list-style-type: none"> • Will our baby be healthy if they are born too soon? • What will the doctors do to help our baby be healthy and strong? • Can our baby get sick more easily if they are born too soon? • Will the baby feel pain during birth or while in the hospital? • I'm worried about the risks and complications, what if something goes wrong? (Mistrust)
Survival	<ul style="list-style-type: none"> • Will the baby survive? • What kind of help will our baby need to stay alive? • How likely is it that our baby will survive? • What kind of machines or medicines will our baby need to help them breathe and stay alive? • I don't know if I can trust the medical field, what are the chances of my baby surviving at 24 weeks? (Mistrust)
NICU ^a stay	<ul style="list-style-type: none"> • What is the NICU, and why does our baby need to go there? • How long will our baby need to stay in the NICU? • Can we visit our baby in the NICU, and how often? • Will our baby be alone in the NICU, or will there be other babies and parents there too? • What kind of things can we do to help our baby feel better in the NICU? • Will anything happen in the NICU without my consent? (Mistrust)
Emotional impact	<ul style="list-style-type: none"> • How do we get ready for having a baby born too soon? • Can we hold and touch the baby in the hospital, and is this good for the baby? • Who can help us if we are feeling sad or stressed about our baby being born too soon? • I'm worried about my baby going to the NICU where she will be alone and scared (mistrust).
Long-term outcomes	<ul style="list-style-type: none"> • What help can we get after we leave the hospital? • Will our baby be able to do the same things as other babies who were born at the right time? • Will our baby be okay in the future if they are born too soon? • I don't know what's going to happen to my baby. I don't really trust the doctors but what happens if my baby doesn't develop properly? (Mistrust)
Feeding and nutrition	<ul style="list-style-type: none"> • How will our baby get the right kind of food if they are born too soon? • Can we feed our baby ourselves, or will they need special milk or formula? • How often will our baby need to be fed, and how much? • Will our baby be able to eat the same kinds of food as other babies when they get older? • Can we breastfeed our preterm baby, or do we need to use formula? • Will our baby be able to breastfeed right away, or will they need to be fed in a different way at first? • Will I have any say in how my baby is fed? (Mistrust)
Quality of life	<ul style="list-style-type: none"> • Will our baby be able to go to school and play sports like other kids? • How can we help our baby if they have trouble learning or doing things in the future? • What can we do to make sure our baby has the best chance for a good future? • I've had bad experiences before and I'm scared about what's going to happen to my baby in the future, what can I expect? (Mistrust)

^aNICU: neonatal intensive care unit.

Table 2. Generated role-plays by artificial intelligence.

Characteristics	Values
Role-plays (n=35), n (%)	
Worried about specific area of concern	28 (80)
Low trust in the medical system	7 (20)
Responses per role-play, median (IQR)	5 (4-6)
Parent responses (n=179), n (%)	
Unique responses	176 (98)
Duplicate responses	3 (1)
Types of responses (n=179), n (%)	
Statements	91 (51)
Questions	88 (49)
Sentences per response (n=179), n (%)	
1	81 (45)
2	76 (42)
3	18 (10)
4	4 (2)
Duplicate sentences (n=305), n (%)	37 (12)
Total unique sentences (n=305), n (%)	268 (88)
Feelings stated in responses (n=117), n (%)	
Specific emotion stated in phrase	56 (48)
“Scared”	36 (31)
“Worried”	26 (22)
“Anxious”	2 (2)
“Concerned”	2 (2)
“Afraid”	1 (1)
“Nervous”	1 (1)
“Overwhelmed”	1 (1)
Emotion indirectly implied by phrase	51 (44)

Table 3. Sentences generated per role-play.

Area of concern	Number of unique sentences
Health and development	47
Survival	46
Feeding and nutrition	45
The NICU ^a stay	40
Quality of life	36
Outcomes	28
Emotional impact	26

^aNICU: neonatal intensive care unit.

Table 4. Ratings of relevance, realism, and usability of sentences generated by ChatGPT (N=254).

Characteristics	Rating, n (%)				
	1 (least)	2	3	4	5 (most)
Realism in parental responses and questions	5 (2)	8 (3)	38 (15)	20 (8)	183 (72)
Relevant to a prenatal counseling conversation	2 (1)	2 (1)	29 (11)	5 (2)	216 (85)
Usable for VSP ^a educational program	5 (2)	1 (0)	87 (34)	34 (13)	127 (50)

^aVSP: virtual standardized patient.

Modifications to responses were all aimed at ensuring the VSP could correctly deploy the phrase at the correct conversational juncture and that there were no elements of the phrase that might interrupt the flow. As ChatGPT 3.5 seeks to ensure the specific conversation has a flow, it can at times generate responses that are less usable for a VSP that needs to maintain flow across many different variations of the same conversation. Only 2% (5/254) of the AI-generated responses were not usable in the VSP. Examples of minimally usable responses included “How much should I feed my baby each time?” which is not relevant to how feeding is done in the neonatal intensive care unit and “I am,” as this response is too nonspecific to be of use in a VSP. Of the 34% (87/254) of responses that required moderate modifications, the changes primarily involved adjusting terminology to ensure the parent was using colloquial, jargon-free language. As an example, “I’ve been having a lot of contractions and I’m only 24 weeks pregnant” was modified to “I’ve been having a lot of cramping and am only 6 months pregnant.” Other modifications included adding some specificity to a response to ensure the VSP can use the sentence in the right context, such as modifying “That sounds reassuring, but what are the risks?” to “That sounds reassuring, but what are the risks of being born this early?” Of the 13% (34/254) of responses that required minimal adjustment, example changes included “I don’t trust the doctors” to “I don’t trust doctors,” and “Okay, thank you, but can you tell me more about what might happen to my baby in the future?” to “Can you tell me more about what might happen to my baby in the future?”

Discussion

Principal Findings

In this study, we examined the feasibility of using ChatGPT to enhance the realism of the VANESSA VSP. We found that the integration of ChatGPT generated many realistic, relevant, and useful responses. Based on these findings, ChatGPT-enabled VSPs may be beneficial in prenatal counseling education. There was more variation in realism and usability compared to relevance; therefore, an expert review was necessary to provide quality control before integrating the ChatGPT-generated conversations into an educational VSP program for prenatal counseling. Modifications made to responses to make them usable for the VANESSA VSP were largely focused on ensuring the virtual patient remains free of jargon and her responses maintain the flow of conversation.

Research conducted so far on AI chat engines has focused on using chat-based AI for the creation of discharge summaries,

generating and interpreting electronic health records, assisting in medical education related to the medical licensing exam, and summarizing collections of journal articles to construct a brief abstract from the conclusions of the research [20-23]. The field is still relatively new, but rapidly increasing and expanding. This growth will only continue, as generating documentation and interacting with patients are key requirements of the health care setting. Health care simulation has many training applications, such as VSPs, that require expert authoring to educate clinicians and care providers on a certain skill or cognitive task. VSPs like VANESSA have been used in teaching the communication of medical ambiguity, evaluating medical students’ competence in performing critical clinical skills, and training nurses to recognize postpartum mood disorders [24-26]. Based on the results of our study, chat-based AI may be a valuable teaching tool in the future of health care simulation technology, leading to improved scenario creation, customization of patient interactions, and responses to care providers in a simulated setting. These improvements will result in authentic, unique interactive experiences, varying for each learner and training scenario.

We found that ChatGPT could generate many realistic parent responses, especially concerning issues related to survival at 24 weeks gestation and the neonatal intensive care unit stay (Figure S1 in [Multimedia Appendix 1](#)). Mistrust in the health care system is often encountered during stressful counseling conversations, and building the skill of responding to mistrust is crucial for physicians during their training [27]. Patients who express mistrust are less likely to engage with their health care team and care plan, and care is needed to proactively build trust during prenatal counseling [28-31]. Including opportunities for learners to respond to VSPs that express mistrust is one way to address this important counseling element, and ChatGPT provided a reliable mechanism to generate these phrases. Interestingly, the ChatGPT bot faced more challenges in generating realistic questions and responses about the emotional impact of preterm delivery and feeding. As these are frequently encountered topics of conversation in prenatal counseling, an expert review of these conversational elements remains a vital step before including them in an educational program.

ChatGPT produced responses that seemed relevant and appropriate to the context of prenatal counseling. Previous studies of prenatal counseling for extreme prematurity indicate that parents may ask questions about the likelihood of various outcomes, express a range of emotions, request engagement in shared decision-making, and express their parental roles and values [32,33]. Parents may express statements about their

uncertainty, anxieties, and hope for the future [34]. This wide range of topics, emotions, and questions makes it challenging to ensure that chatbot-generated conversations remain appropriate to the educational goals of the VSP. Despite the risk of getting off-topic, we found that only 1% (2/254) of ChatGPT-produced responses were irrelevant to a counseling conversation, given a carefully worded role-play prompt. Although most responses were relevant, some topics, such as spirituality and shared decision-making, did not come up in the role-play conversations. Previous studies have demonstrated that providers perceive the importance of parents' spirituality in their decision-making and infrequently discuss these spiritual beliefs with parents in antenatal consultations [35,36]. Further work exploring how families might express their spirituality or explore shared decisions would be needed to ensure these topics are included in a VSP [37-39].

Chatbot programs use machine learning to generate their responses; due to the nature of machine learning, there is an inherent risk that chatbots can generate factually incorrect information [40]. Given this risk, caution is warranted when using chatbots in health care settings, where misinformation can have a significant risk [41,42]. Developers are working to address these inaccuracies as they design the next generation of large language model chat programs; they have demonstrated improvements in ChatGPT-4's success across a variety of standardized tests [43]. This study leverages the strengths of a natural language chatbot in its ability to generate conversation while avoiding the risks of obtaining inaccurate medical information. Most scripts created by ChatGPT were usable for our perinatal counseling virtual patient. We found about a third of chatbot-generated phrases needed modification before being able to be integrated into a VSP; therefore, it may not be feasible to directly use ChatGPT for educational role-play without having the quality control step of review by expert clinicians. However, as technology continues to grow, this will evolve, and each subsequent model should be evaluated for usability.

Study Limitations

This exploratory study has several limitations. First, the pilot was done using ChatGPT 3.5, which is a single platform and is

not representative of all chatbots. Later versions of ChatGPT have already been released and may have differences in realism, appropriateness, and usability. Newer AI chatbot programs are being trained on more parameters (175 billion for ChatGPT-3 vs an anticipated 100 trillion with ChatGPT-4), are supposed to have more ability to iterate on the same topic, and are being adjusted to improve the faculty accuracy of their responses [43]. Second, chatbot programs have limited information on which they build a conversation. For this study, we used a stable prompt around an impending 24-week gestation delivery to fit the standardized patient scenario, but conversations may be different with variations in the prompt. The AI was given a limited background to build a role-play, potentially limiting the diversity of ways in which patients could communicate their concerns. For this scenario, we requested a fifth-grade reading level for all patient roles to better mimic how patients may speak in stressful situations, but we did not explore higher or lower complexity of responses. Future work should explore how variations in the background, scenario, and reading level provided to the chatbot impact the output of the role-play. Another significant limitation was that response checking was performed by neonatologists, without input from families or trainees. Future work to refine the model will incorporate their views to ensure further applicability of the VSP and the validity of any assessments. Finally, although individual phrases exhibited good realism, the total duration of each patient-physician conversation (averaging 5 volleys) was generally shorter than that of a real prenatal counseling conversation.

Conclusions

Generative AI programs, such as ChatGPT, may provide a viable source of training materials to expand VSP programs with careful attention to the concerns and questions of patients and families. Given the potential for unrealistic or inappropriate statements and questions, an expert should review AI chat outputs before deploying them in an educational program.

Conflicts of Interest

None declared.

Multimedia Appendix 1

Realism in sentences generated by ChatGPT based on area of concern.

Abstract

Background: The potential of artificial intelligence (AI)-based large language models, such as ChatGPT, has gained significant attention in the medical field. This enthusiasm is driven not only by recent breakthroughs and improved accessibility, but also by the prospect of democratizing medical knowledge and promoting equitable health care. However, the performance of ChatGPT is substantially influenced by the input language, and given the growing public trust in this AI tool compared to that in traditional sources of information, investigating its medical accuracy across different languages is of particular importance.

Objective: This study aimed to compare the performance of GPT-3.5 and GPT-4 with that of medical students on the written German medical licensing examination.

Methods: To assess GPT-3.5's and GPT-4's medical proficiency, we used 937 original multiple-choice questions from 3 written German medical licensing examinations in October 2021, April 2022, and October 2022.

Results: GPT-4 achieved an average score of 85% and ranked in the 92.8th, 99.5th, and 92.6th percentiles among medical students who took the same examinations in October 2021, April 2022, and October 2022, respectively. This represents a substantial improvement of 27% compared to GPT-3.5, which only passed 1 out of the 3 examinations. While GPT-3.5 performed well in psychiatry questions, GPT-4 exhibited strengths in internal medicine and surgery but showed weakness in academic research.

Conclusions: The study results highlight ChatGPT's remarkable improvement from moderate (GPT-3.5) to high competency (GPT-4) in answering medical licensing examination questions in German. While GPT-4's predecessor (GPT-3.5) was imprecise and inconsistent, it demonstrates considerable potential to improve medical education and patient care, provided that medically trained users critically evaluate its results. As the replacement of search engines by AI tools seems possible in the future, further studies with nonprofessional questions are needed to assess the safety and accuracy of ChatGPT for the general population.

Introduction

Rapid advancements in large language models (LLMs) have sparked considerable excitement regarding their potential applications in the medical field [1,2]. One LLM-based

application that has garnered worldwide attention is ChatGPT, developed by the research and deployment company OpenAI, due to its easy accessibility and potential to democratize knowledge [3]. The freely available version is based on the artificial intelligence (AI)-based tool GPT-3.5, which

encompasses billions of parameters and has been trained on approximately 570 GB of text from the internet [1,2].

ChatGPT's GPT-3.5 iteration has already shown promise in several routine medical tasks and medical research [4-7], even raising ethical concerns in the literature [2,3,8]. The prompt and interactive nature of this AI's responses might even revolutionize search engines, while also revealing shortcomings in medical education [9-11]. However, despite the introduction of the more advanced iteration GPT-4, concerns about the lack of transparency regarding this AI's model parameters, training process, and underlying data structure remain unaddressed [8,12]. These concerns cast doubt on the medical proficiency of these LLMs, as both were not primarily trained on medical data and are the first to admit that as a language AI model, passing a medical examination is outside their skillset (Multimedia Appendix 1). Still, with assistance and adaptations, GPT-3.5 nearly passed the United States Medical Licensing Examination [13,14], and GPT-4 passed a Japanese medical examination [15]. Considering the variable performance of multilingual LLMs across different input languages [16,17], it is imperative to evaluate these models in various other linguistic contexts as well as on large data sets of original medical examination questions.

The primary objective of this study is to evaluate the medical proficiency of both ChatGPT iterations (GPT-3.5 and -4) in comparison to medical students by testing it on 937 original questions from the written German medical licensing examination (Zweites Staatsexamen), providing further data for a possible future integration. While the German medical licensing examination covers various medical subdisciplines in 320 multiple-choice questions [18], it has a high interexamination reliability of over 0.9 [19]. Despite using the same third-party client for question retrieval as earlier studies, the German approach of publicly releasing the examination questions enables the third-party client to guarantee the originality of the test items derived directly from the examination itself [20]. Additionally, to the best of our knowledge, we have tested both ChatGPT versions on the largest data set of medical licensing examination questions not included in their training data set. Furthermore, we did not exclude all

image-based questions a priori. Instead, we evaluated the relevance of the images for each question and compared the results both with and without images.

Methods

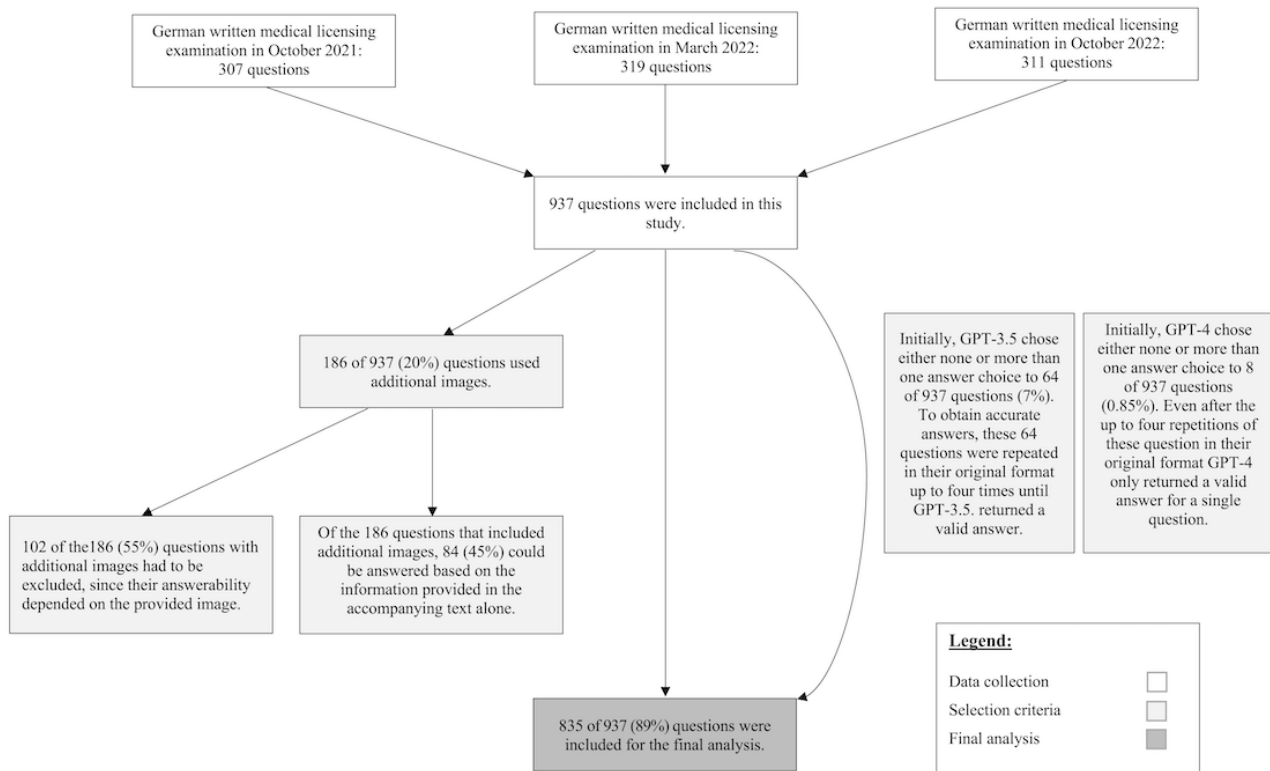

Data Collection

To ensure that any observed performance was not influenced by changes in ChatGPT's training data, we specifically chose the 3 most recent examinations (October 2021, April 2022, and October 2022) after the AI's knowledge cutoff date [17]. Thus, we were able to obtain 937 multiple-choice questions, each with 5 possible answers from the third-party client Amboss, a web-based learning platform that provides the original questions from the Institut für Medizinische und Pharmazeutische Prüfungsfragen (IMPP). To maintain the original examination format, we presented all obtained questions and answer options in the same order as they appeared in the examination. No specific training code was used while submitting the questions. Due to AI's inability to analyze visual content, answerability based on question text alone was defined as the primary inclusion criterion, resulting in the exclusion of 102 questions. The questions were submitted through ChatGPT's interface of the GPT-3.5 (January 30, 2023) and GPT-4 (March 14, 2023) versions. ChatGPT's answers were then compared to the official correct answers and evaluated. If ChatGPT selected none or more than 1 of the multiple-choice answers, the question was repeated in its original format up to 4 times or until a conclusive response could be obtained from ChatGPT (Figure 1).

We recorded additional data, such as answer length, content warnings, and recommendations for further diagnosis, and categorized the questioning methodology. To assess the readability of a question, we used the Simple Measure of Gobbledygook (SMOG) as it has shown acceptable interrater reliability for patient education materials in the literature [21].

Examination statistics provided by the "MEDI-LEARN" portal were also used, including the number of correct student answers and the specialization of each question. The "Blueprint" published by the IMPP outlines the distribution of subspecialties within the written state examinations [18].

Figure 1. Flowchart of the study design for the evaluation of ChatGPT's (GPT-3.5 and GPT-3) accuracy in the written German medical licensing examination (2021-2022). The flowchart presents the criteria for question selection, including both the inclusion and exclusion criteria.

Statistical Analysis

To perform our data analysis, we used several packages [22-37] in addition to the R programming language [38].

While continuous variables were reported as arithmetic mean (SD) values, categorical variables were reported as frequencies and percentages. The Kolmogorov-Smirnov test, Shapiro-Wilk test, and QQ plots were used to confirm the normal distribution of continuous data statistically and graphically. To determine significant differences, we used unpaired *t* test or ANOVA for continuous variables and chi-square test or Wilcoxon rank-sum test for categorical variables. *P* values of $<.05$ were deemed significant. Univariate and multivariate regression analyses were additionally performed to provide information on probabilities and predictors.

Ethical Considerations

Ethics approval was not required as data were collected from publicly available sources on the internet or were generated using AI-based methods. No personally identifiable information was used in the data collection, and all data were handled in accordance with applicable data privacy laws and regulations.

Results

Overall, GPT-4 demonstrated superior performance with an average score of 796 out of 937 (85%), surpassing GPT-3.5's score of 548 out of 937 (58%), which previously fell below the general passing threshold of 60% (Figure 2A) [37-39]. For the April 2022 examination, GPT-3.5 and GPT-4 achieved their highest scores (GPT-3.5: 195/319, 61%; GPT-4: 287/315, 91%), while the proportion of students who answered correctly

remained constant across the 3 examinations (mean 76%, SD 18%; $P=.86$; Figure 2B and Multimedia Appendix 2).

Thus, GPT-4 passed all tested examinations, whereas GPT-3.5 could only pass 1 of the 3 examinations. Although the examinations varied in several aspects, we also observed a significant difference in the number of images ($P=.02$; Figure 2C and Multimedia Appendix 2). As GPT-3.5 and GPT-4 could, at the time of the study, not process these, we further investigated the potential image-related discrepancy between the examinations by excluding from subsequent analyses any questions that required image-dependent responses. The exclusion of these questions did not significantly alter examination difficulty, as evidenced by similar student scores (Figure 2D).

Moreover, no differences were observed in the parameters collected on student accuracy, questions, or answer characteristics in relation to the performance of GPT-4 and GPT-3.5 in the excluded cases (Multimedia Appendix 3). Upon excluding image-based questions, GPT-4 continued to outperform GPT-3.5, with scores approaching 91.44%. However, GPT-3.5 exceeded expectations by achieving passing scores on all 3 examinations (October 2021: 60.22%; April 2022: 63.36%; October 2022: 60.07%; Figure 2E and Multimedia Appendix 4). GPT-3.5's accuracy ($P=.66$), the number of images ($P=.07$), and students' accuracy ($P=.77$) remained constant throughout the examinations, whereas GPT-4's accuracy ($P=.02$), the specialties ($P<.001$), and question type ($P=.04$) varied (Multimedia Appendix 4 and Figures 2A, 2B, and 2E). The details of the included questions and their respective categorizations are provided in Table 1.

Figure 2. Bar plots of ChatGPT’s (GPT-3.5 and GPT-4) and box plots of students’ accuracy in the written German medical licensing examination (2021-2022). Bar graphs and box plots of (A) the relative number of correct answers provided by ChatGPT (GPT-3.5 and GPT-4) answers, (B) correct answers provided by students, (C) and image-based questions for the different examinations. (D and E) The relative number of correct answers by ChatGPT (GPT-3.5 and GPT-4) and students, comparing all questions with the included text-based questions. The 60% pass mark is presented as a red line in (A) and (E) to provide context for the performance of ChatGPT (GPT-3.5 and GPT-4). In addition, (E) displays the percentile achieved by ChatGPT (GPT-3.5 and GPT-4) for each year’s examination, based on the percentile limits published by the Institut für Medizinische und Pharmazeutische Prüfungsfragen [37-39].

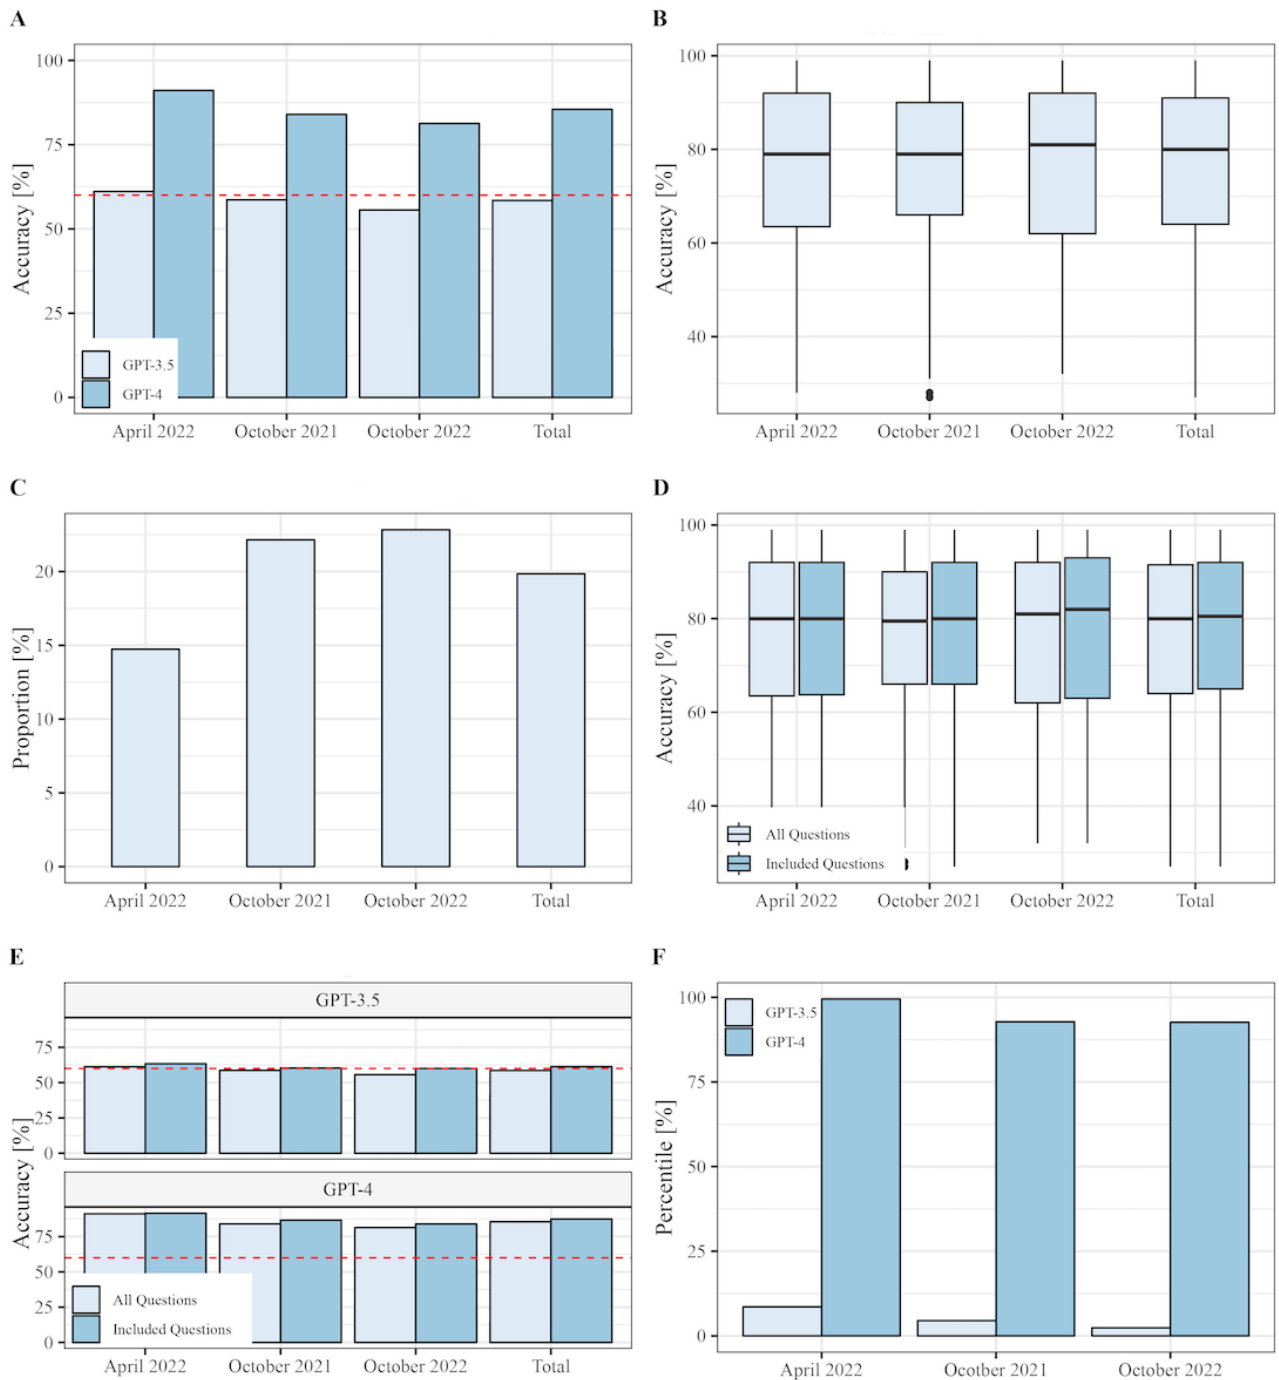

Table 1. Summary statistics for ChatGPT's (GPT-3.5 and GPT-4) accuracy during the written German medical licensing examination, 2021-2022.

Characteristic	Overall (N=834)	Accuracy of GPT-3.5			Accuracy of GPT-4		
		False (n=323)	True (n=511)	<i>P</i> value	False (n=105)	True (n=729)	<i>P</i> value
Students' correct response rate (%), mean (SD)	77 (18)	71 (18)	80 (16)	<.001 ^a	70 (18)	78 (17)	<.001 ^a
Accuracy of GPT-3.5, n (%)	511 (61)	N/A ^b	N/A	N/A	38 (36)	473 (65)	<.001 ^c

^aWilcoxon rank-sum test.^bN/A: not applicable.^cPearson chi-square test.

After controlling for all other variables, correct student responses (GPT-3.5: OR 0.01, 95% CI 0.00-0.01, $P<.001$; GPT-4: OR 0.00, 95% CI 0.00-0.00, $P=.003$) and questions with images (GPT-3.5: OR 0.19, 95% CI 0.08-0.30, $P<.001$; GPT-4: OR -0.09, 95% CI -0.16 to -0.01, $P=.02$) emerged as significant predictors of GPT-3.5's and GPT-4's accuracy, regardless of the version. Furthermore, our analysis revealed that only questions pertaining to psychiatry were significant predictors of correct GPT-3.5 responses (OR 0.19, 95% CI 0.02-0.36,

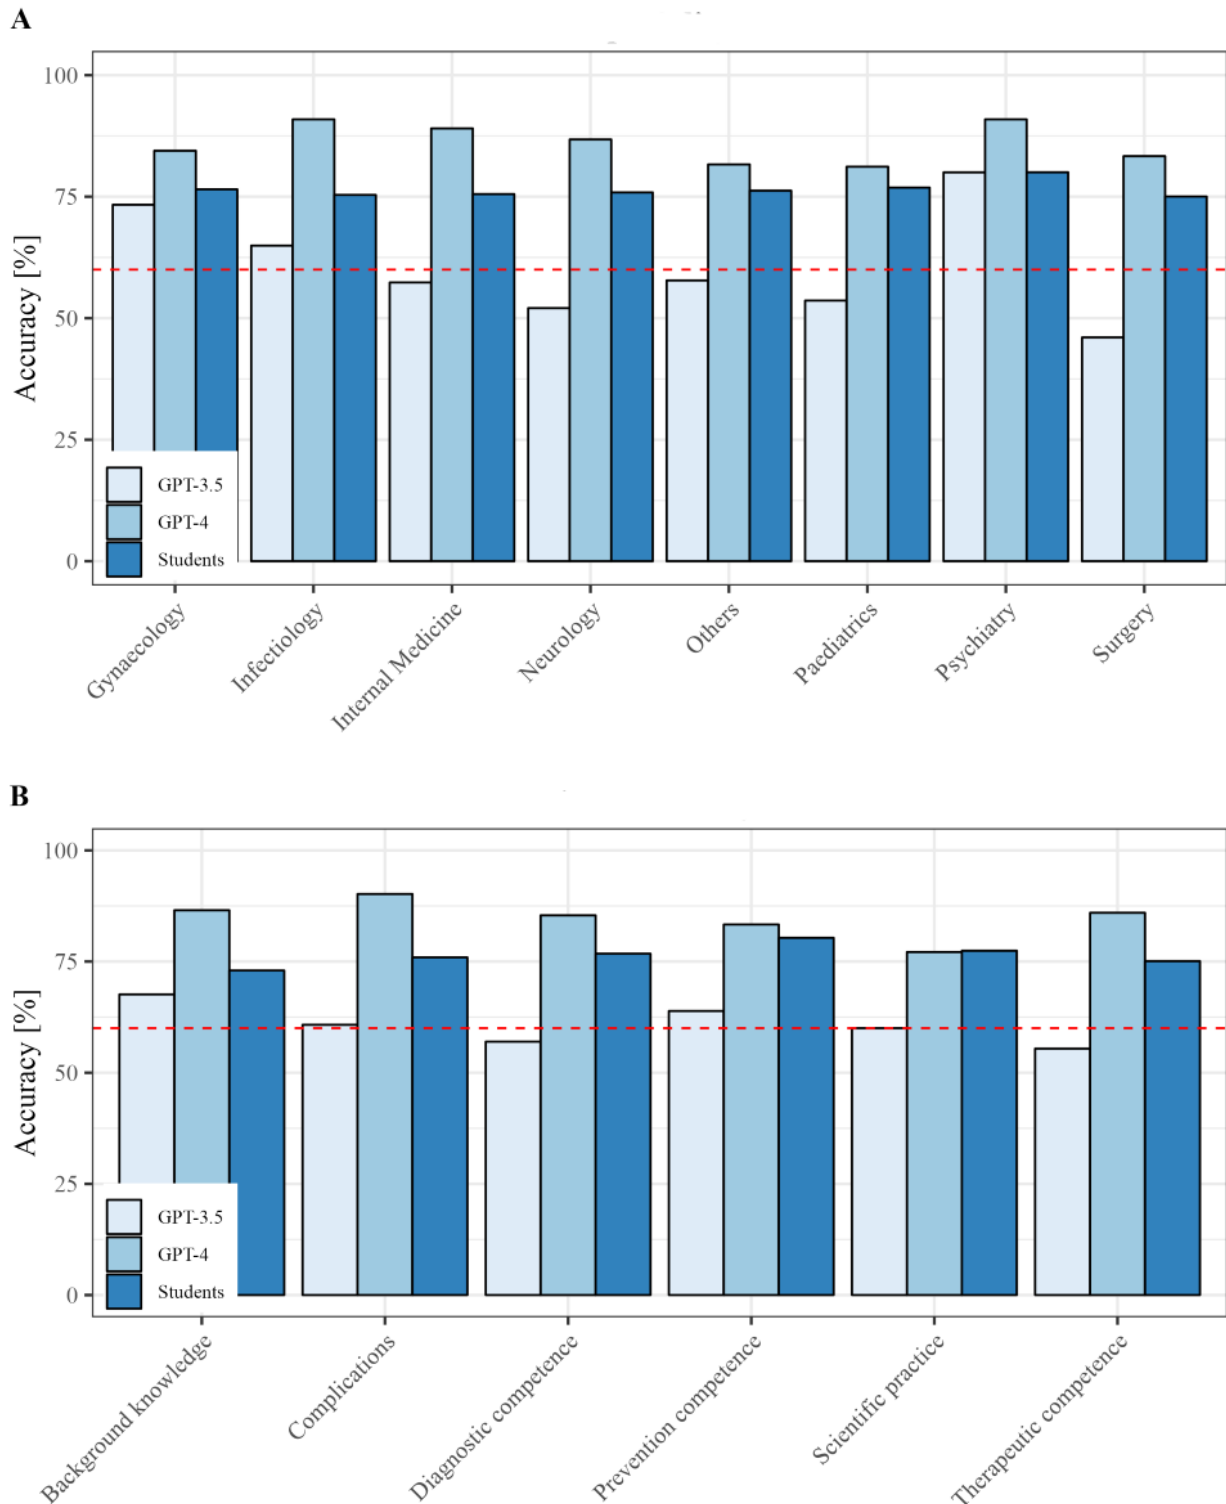

$P=.03$). In contrast, questions related to internal medicine (OR 0.10, 95% CI 0.00-0.19, $P=.04$) and surgery (OR 0.12, 95% CI 0.00-0.25, $P=.049$) were the only medical subspecialties significantly predicting accurate responses of GPT-4. Conversely, questions concerning scientific practice (OR -0.14, 95% CI -0.29 to 0.00, $P=.05$) were less likely to be answered correctly by GPT-4 (Table 2 and Figure 3). The question SMOG readability score, however, did not significantly impact ChatGPT's accuracy.

Table 2. Regression analysis to compare ChatGPT's (GPT-3.5 and GPT-4) accuracy during the written German medical licensing examination (2021-2022; N=833).

Characteristic	GPT-3.5						GPT-4

Figure 3. Comparison of ChatGPT's (GPT-3.5 and GPT-4) and students' relative accuracy in relation to the tested specialties and methodology in the written German medical licensing examination (2021-2022). The bar graph displays the percentage of correct answers provided by ChatGPT (GPT-3.5 and GPT-4) and students in (A) each specialty and (B) methodology, while the blue line demonstrates a 60% pass mark.

Discussion

Principal Findings

With the introduction of ChatGPT's GPT-3.5 and GPT-4 iterations, the potential application for AI in research, patient care, and medical education is gaining recognition [2,8,40]. By improving the users' experience and facilitating more efficient information retrieval, ChatGPT might even revolutionize the

future of search engines and shift the focus of medical education from memorization to practical application [8,10,11].

Under this premise, the nearly passing scores of the freely available GPT-3.5 iteration, along with the exceptional scores of GPT-4, are highly relevant. Even with the varying scores of 51%-67% of GPT-3.5 across various input languages [13-15,41,42], both models consistently outperform most prominent general and domain-specific LLMs, such as

InstructGPT (53%), GPT-3 (25%), and BioMedLM (50%) [14,43,44]. Despite these improvements, GPT-3.5's or GPT-4's performance still fell short in comparison to that of medical students in a Japanese medical examination according to the study by Takagi et al [15]. In comparison to the German medical students, however, GPT-3.5 scored in the 8.6th percentile, while GPT-4 ranked in the 92.8th, 99.5th, and 92.6th percentiles in the October 2021, April 2022, and October 2022 examinations [39,45,46]. The observed variations in the AI's accuracy across input languages may partially reflect the language composition of their data sets, as LLMs tend to favor languages that are more represented in their training data [16,17]. Since ChatGPT appears to perform optimally with English inputs, language emerges as a limiting factor for its accuracy, suggesting that globally consistent application is dependent upon users' proficiency in English.

Moreover, the nearly 30% performance increase from GPT-3.5 to GPT-4, as indicated in this study and supported by a Japanese study, which suggests a similar language distribution within the GPT-3.5 and GPT-4 data sets [15]. GPT-4, unlike GPT-3.5, also did not answer questions containing images on repetition, showing an improvement in the previously incorrect content produced by GPT-4's predecessor [17].

Thus, health care professionals could potentially benefit, especially from GPT-4's conclusive and often nonobvious insights to multiple-choice questions, as these users have the ability to verify crucial details [13,14,41]. For instance, there is potential for using GPT-3.5 and GPT-4 in a medical education tutoring environment, as evidenced by its successful application in anatomy [47]. However, when using either GPT-3.5 or GPT-4 for medical applications, its differing accuracy across specialties must also be taken into account [48]. GPT-3.5 initially displayed a high degree of accuracy within the field of psychiatry, while GPT-4 demonstrated its strength in internal medicine and surgery. Considering the rising prevalence of psychiatric disorders and concomitant challenges in providing care, it seemed likely that nonprofessionals would also turn to the chatbot for mental health issues at the time of GPT-3.5's release [8,49,50]. Hence, it is conceivable that GPT-3.5's training data set includes not only a substantial and reliable portion of psychiatric data, but also its developers might have first fine-tuned ChatGPT specifically in this domain in anticipation of its high demand [51-53]. Thus, the developers might have also fine-tuned GPT-4 specifically in internal medicine and surgery, possibly reacting to a high demand in this area from users of its' predecessor. GPT-4's impressive performance is not limited to the medical field, as it demonstrated comparable percentile scores in the Uniform Bar Exam, showcasing its potential as a versatile tool across diverse academic disciplines [17]. However, assessing the possible reasons for the performance differences between GPT-3.5 and GPT-4 is complicated by the confidential architecture of GPT-4 [54], posing challenges for research on future applications.

In turn, GPT-4's excellent achievements shed light on the limitations of current testing paradigms in medical education that often favor rote memorization over a critical and context-aware approach. They also highlight the inadequacy of multiple-choice questions as a means of assessing medical

knowledge, as they tend to encourage binary thinking as "true" and "false," which often fails to capture the complex reality of the medical practice [11]. Although GPT-3.5 and GPT-4 allow the simple and fast retrieval of medical information from any internet-capable device that fits in one's pocket [9,10], neither GPT-3.5 nor GPT-4 verifies the information they provide. Thus, ChatGPT's output needs to be approached with a critical mindset, recognizing that misinformation may be more difficult to detect than in the output of other search engines that offer multiple sources in response to a query and take login credentials into account [8,55]. To navigate these changing informational landscapes, a basic understanding in data science seems necessary alongside traditional medical expertise [56]. It may even be beneficial for future iterations of AI tools to include references to the sources underlying each search in order to increase transparency and allow users to assess the reliability of the information they receive.

In a previous study by Nov et al [57], considering that 59% of participants trusted chatbots more than traditional search engines, it must be noted that GPT-3.5 and GPT-4 have only been tested on medical examination questions and not questions by nonprofessionals, limiting general recommendations for unsupervised patient education or the general population. It seems evident that GPT-4 has been benchmarked against medical licensing examinations, explaining not only GPT-4's excellent scores but also exceeding achievements in internal medicine and surgery, which, for instance, have been overrepresented in the medical examinations assessed in this study [12,17].

Since GPT-3.5 failed the German medical licensing examination by a narrow margin, its use for answering medical questions is generally not advisable. Moreover, the remarkable performance of GPT-4 in the German Medical State Examination may not be universally applicable outside a medical examination setting, especially considering that GPT-4 was presumably benchmarked on academic and professional examinations [17].

As literature on ChatGPT is scarce, and it can be difficult to detect incorrect output from this AI tool, the content it generates must be carefully assessed. Nevertheless, medical professionals may still be able to benefit from GPT-3.5's and GPT-4's explanations and, in some cases, gain new nonobvious insights. With the release of GPT-4's ability to handle pictures on the horizon, the potential for further applications of GPT-3.5 and GPT-4 to improve the medical workflow or medical education seems eminent, emphasizing the need for continued research into AI.

Limitations

This study's findings on GPT-3.5's and GPT-4's medical proficiencies are limited to multiple-choice questions from the German medical licensing examination, which may not be representative of other types of examinations or contexts. However, it is worth noting that GPT-3.5 and GPT-4 have demonstrated similar performances in examinations in other countries and languages, which suggests some degree of generalizability.

In addition, the sample size of 937 questions and the exclusion of image-based questions may not capture the full range of difficulty levels or content areas. Although the collected parameters did not differ in terms of GPT-3.5's and GPT-4's accuracy in the excluded cases, the decision to exclude image-based questions may have introduced a sampling bias. By testing for differences, efforts were made to minimize this bias and maintain the integrity of the results.

As GPT-3.5's and GPT-4's performances were compared to those of German medical students using the MEDI-LEARN service, a selection bias might have been introduced. However, the high correlation between the MEDI-LEARN statistics and the IMPP statistics indicates at best a weak expression of this selection bias [58].

It should also be noted that a replication of this study might not yield the exact same results, as the literature suggests that GPT-3.5 is inconsistent in answering 15% of medical questions [59]. However, the trends observed in this study appear to be consistent with those reported in other published and preprint studies on GPT-3.5's and GPT-4's performance.

Conclusions

In conclusion, the results of this study indicate that only GPT-4 consistently passed all 3 medical examinations, ranking in the 92.8th to 99.5th percentile in comparison to medical students. These findings highlight the strengths and limitations of ChatGPT in the context of medical examinations and raise questions about the future of medical education.

Although GPT-3.5's and GPT-4's accuracy in medical examinations seems consistent across different countries and languages, its inconsistencies, potential biases, and number of incorrect answers restrain a recommendation for its use by the general population for medical purposes. However, its elaborate explanations and potential to yield nonobvious insights may benefit medical professionals in training.

While this study hints to a moderate accuracy of GPT-3.5 and a stellar performance of GPT-4 in answering medical examination questions, further research is necessary to gain deeper insights, explore future applications, and ensure safe use of ChatGPT for end users.

Acknowledgments

The authors thank Dorothee Meyer, Linea Luise Fuchs, Ari Soleman, GPT-3.5, and GPT-4 for proofreading this manuscript. In this study, we used ChatGPT for several purposes: to translate our manuscript into English, to refine its linguistic presentation, to evaluate and improve our methodological approach, and to scrutinize the R code underlying our statistical analysis, with a particular focus on identifying and resolving any error warnings generated. Subsequently, all outputs provided by ChatGPT were rigorously reviewed and critically appraised by the authors to ensure accuracy and reliability.

Abstract

Background: ChatGPT, an artificial intelligence (AI) based on large-scale language models, has sparked interest in the field of health care. Nonetheless, the capabilities of AI in text comprehension and generation are constrained by the quality and volume of available training data for a specific language, and the performance of AI across different languages requires further investigation. While AI harbors substantial potential in medicine, it is imperative to tackle challenges such as the formulation of clinical care standards; facilitating cultural transitions in medical education and practice; and managing ethical issues including data privacy, consent, and bias.

Objective: The study aimed to evaluate ChatGPT's performance in processing Chinese Postgraduate Examination for Clinical Medicine questions, assess its clinical reasoning ability, investigate potential limitations with the Chinese language, and explore its potential as a valuable tool for medical professionals in the Chinese context.

Methods: A data set of Chinese Postgraduate Examination for Clinical Medicine questions was used to assess the effectiveness of ChatGPT's (version 3.5) medical knowledge in the Chinese language, which has a data set of 165 medical questions that were divided into three categories: (1) common questions (n=90) assessing basic medical knowledge, (2) case analysis questions (n=45) focusing on clinical decision-making through patient case evaluations, and (3) multichoice questions (n=30) requiring the selection of multiple correct answers. First of all, we assessed whether ChatGPT could meet the stringent cutoff score defined by the government agency, which requires a performance within the top 20% of candidates. Additionally, in our evaluation of ChatGPT's performance on both original and encoded medical questions, 3 primary indicators were used: accuracy, concordance (which validates the answer), and the frequency of insights.

Results: Our evaluation revealed that ChatGPT scored 153.5 out of 300 for original questions in Chinese, which signifies the minimum score set to ensure that at least 20% more candidates pass than the enrollment quota. However, ChatGPT had low accuracy in answering open-ended medical questions, with only 31.5% total accuracy. The accuracy for common questions, multichoice questions, and case analysis questions was 42%, 37%, and 17%, respectively. ChatGPT achieved a 90% concordance across all questions. Among correct responses, the concordance was 100%, significantly exceeding that of incorrect responses (n=57, 50%; $P<.001$). ChatGPT provided innovative insights for 80% (n=132) of all questions, with an average of 2.95 insights per accurate response.

Conclusions: Although ChatGPT surpassed the passing threshold for the Chinese Postgraduate Examination for Clinical Medicine, its performance in answering open-ended medical questions was suboptimal. Nonetheless, ChatGPT exhibited high internal concordance and the ability to generate multiple insights in the Chinese language. Future research should investigate the language-based discrepancies in ChatGPT's performance within the health care context.

Introduction

Artificial intelligence (AI) was initially conceptualized in 1956 [1], but it has only gained significant momentum in recent years. AI aims to replicate human intelligence and thinking processes through the use of brain-like computer systems to solve complex problems. What is most inspiring is that AI systems can be trained on specific data sets to improve prediction accuracy and tackle intricate problems [2-4], which means that one of the possible applications of AI is the ability to help doctors to rapidly search through vast amounts of medical data, enhancing their creativity and enabling them to make error-free decisions [5,6].

ChatGPT (OpenAI) is an AI model that has spurred great attention due to the revolutionary innovations in its ability to perform a diverse array of natural language tasks. By using a class of large-scale language models, ChatGPT (version 3.5) can predict the likelihood of a sequence of words based on the context of the preceding words. With sufficient training on vast amounts of text data, ChatGPT can generate novel word sequences that closely resemble natural human language and have never been observed before by other AI [7].

A study was conducted on the effectiveness of the version of generative pretrained transformer's large-scale language model (ChatGPT, version 3.5) in passing the United States Medical Licensing Examination (USMLE). The results showed that the AI model achieved an accuracy rate of over 50% in all the tests, and in some analyses, it even surpassed 60% accuracy. It is imperative to highlight and emphasize that the study was conducted mostly using English input, and the AI model was also trained in English.

However, despite the success of AI models like ChatGPT in the English language, their performance in understanding and generating medical text in the Chinese language remains largely unexplored because ChatGPT's ability to understand and generate text in any given language is limited by the quality and quantity of training data available in that language. Chinese is the second-most widely spoken language in the world, with more than 1.3 billion speakers globally, while the quality and quantity of Chinese language data may not be compared with English due to some reasons, such as complexity of the written characters. Thus, the performance of ChatGPT in Chinese medical information warrants further investigation.

In this study, ChatGPT's clinical reasoning ability was evaluated by administering questions from the Chinese Postgraduate Examination for Clinical Medicine. This standardized and

regulated test assesses candidates' comprehensive abilities. The questions are textually and conceptually dense, and the difficulty and complexity of the questions are highly standardized and regulated. Additionally, this examination has demonstrated remarkable stability in raw scores and psychometric properties over the past years. Moreover, the examination comprises 43% (n=71) basic science and medical humanities, with 14% (n=23) physiology, 10% (n=17) biochemistry, 13% (n=28) pathology, and 6% (n=10) medical humanities. Clinical medicine makes up the remaining 57% (n=94), with internal medicine and surgery accounting for 37% (n=61) and 20% (n=33), respectively. Due to the examination's linguistic and conceptual complexity, we hypothesize that it will serve as an excellent challenge for ChatGPT. By evaluating ChatGPT's performance on this examination, we aimed to gain insights into the AI model's potential for understanding and generating medical text in Chinese and assess its applicability in Chinese medical education and clinical practice.

Methods

Ethical Considerations

This study does not involve direct interaction with human participants or the collection of personal identifiable information. As a result, it falls under the category of nonhuman subject research. Therefore, no human subject ethics review approvals were required for this study. Since this study does not involve human participants or the collection of personal identifiable information, obtaining informed consent from individuals is not applicable. As this study does not involve the collection or use of personal identifiable information, privacy and confidentiality concerns are not applicable. Since this study does not involve human participants, there is no compensation provided to individuals.

Artificial Intelligence

ChatGPT uses self-attention mechanisms and extensive training data to generate contextually relevant responses in a conversational setting. It excels in managing long-range dependencies and creating coherent replies. However, it is important to clarify that ChatGPT (version 3.5), a server-based language model, does not possess internet browsing or search functionalities. Consequently, its responses are constructed solely on abstract relationships between words or "tokens" within its neural network [7]. Furthermore, it should be noted that OpenAI released the latest version, ChatGPT (version 4), in March 2023, but the data in this study were from February 2023, when ChatGPT (version 3.5) was the most recent version.

Input Source

The Chinese Postgraduate Examination for Clinical Medicine questions from 2022 were not officially released. However, a comprehensive set of 165 questions totaling 500 points was found on the web (Table S1 in [Multimedia Appendix 1](#)) and treated as original questions. Point values differed among question types: each case analysis question (CAQ) and multichoice question (MCQ) was worth 2 points, while common questions (CQs) were either worth 1.5 or 2 points each. All inputs fed into the ChatGPT (version 3.5) model were valid samples, not part of the training data set. This was due to the database not being updated since September 2021, predating the release of these questions. For future research convenience, the 165 questions were categorized into three types:

1. CQs (n=90): These questions are to evaluate the knowledge of basic science in physiology, biochemistry, pathology, and medical humanities. Each question has 4 choices, and the respondent should select only the correct answers. For example: “The closing time of the aortic valve during the cardiac cycle is? (A) Atrial systolic end card, (B) Rapid ejection beginning, (C) Slow ejection beginning, (D) Isovolumic diastole beginning.”
2. CAQs (n=45). It is a method used in clinical medicine to examine and evaluate patient cases. It involves an in-depth review of a patient’s medical history, presenting symptoms, laboratory and imaging results, and diagnostic findings to arrive at a diagnosis and treatment plan. There are 4 choices, and the respondent should select only the correct answers. The difference between CAQs and CQs is that CQs focus on clinical decision-making. For example: “A 38-year-old male, suffering chest pain and fever for 3 days, having a 5 years of diabetes history. Physical examination: $t=37.6^{\circ}\text{C}$, right lower lung turbid knock, breathing sound is reduced. A chest X radiograph suggests a right pleural effusion. Pleural aspiration liquefaction test showed WBC $650\times 106/\text{L}$ with fine lymph Cell 90% in pleural fluid, with glucose of 3.2 mmol/L, the diagnosis for this patient is? (A) Tuberculous pleurisy, (B) Malignant pleural effusion, (C) Empyema, (D) Pneumonia-like pleural effusion.”
3. MCQs (n=30): There are 4 choices, and the respondent should select at least 2 correct answers. There is no point for choosing more or less. For example: “The structures of auditory bone conduction include? (A) Skull, (B) Round window film, (C) Ossicular chain, (D) Cochlear bone wall.”

Scoring

Initially, the question format had to be adjusted to properly evaluate the performance of ChatGPT in the Chinese Postgraduate Examination for Clinical Medicine questions. Specifically, we included a “multichoice” or “single-choice” notation, as we found ChatGPT’s responses varied without these cues. MCQs were adjusted to state “Please choose one or more correct options,” while CQs and CAQs were altered to indicate “There is only one correct answer.” This adjustment was necessary for evaluating ChatGPT’s performance in the Chinese language.

We then compiled a data set of these examination questions along with their correct answers. To ensure validity, the answers

were cross-verified with web-based resources and consultations with senior doctors. ChatGPT’s performance was then evaluated by comparing its responses to the standard answers in the data set. A high examination score would suggest that ChatGPT handled this task effectively.

In our comprehensive analysis, we also delved into examining the correlation between different question types and accuracy using the Pearson correlation coefficient as a statistical measure to investigate this relationship.

Encoding

The structured examination questions were transformed into open-ended inquiries for better simulation of real-world clinical scenarios. Multiple-choice questions for the CAQ were removed, and ChatGPT was required to diagnose the patient’s disease and prove its reason.

Regarding the MCQs, we eliminated all the choices and did not prompt ChatGPT about the existence of multiple correct answers. The CQs were treated similarly to the MCQs. However, we encountered a distinct subset within these 3 categories that could not be processed like the other questions. This subset comprised questions that required 1 answer choice to be selected from the provided options. Therefore, these questions were converted into a special format (n=26).

For instance, an original question like, “Which can inhibit insulin secretion? (A) Increased free fatty acids in blood, (B) Increased gastric inhibitory peptide secretion, (C) Sympathetic nerve excitation, (D) Growth hormone secretion increases” was reformatted as “Can an increase in free fatty acids in the blood, an increase in gastric inhibitory peptide secretion, an increase in sympathetic nerve excitation, or an increase in growth hormone secretion inhibit insulin secretion?” This encoding strategy was applied across all 3 subgroups.

Additionally, to mitigate potential memory retention bias, we commenced a new chat session for each query. This process of reformatting questions, presenting them to ChatGPT, and initiating new sessions for each question constituted our methodology for evaluating ChatGPT’s performance using the data set. The clarity of this process should address the concerns raised in the comment about the lack of understanding of the way we used the data set for evaluation.

Adjudication

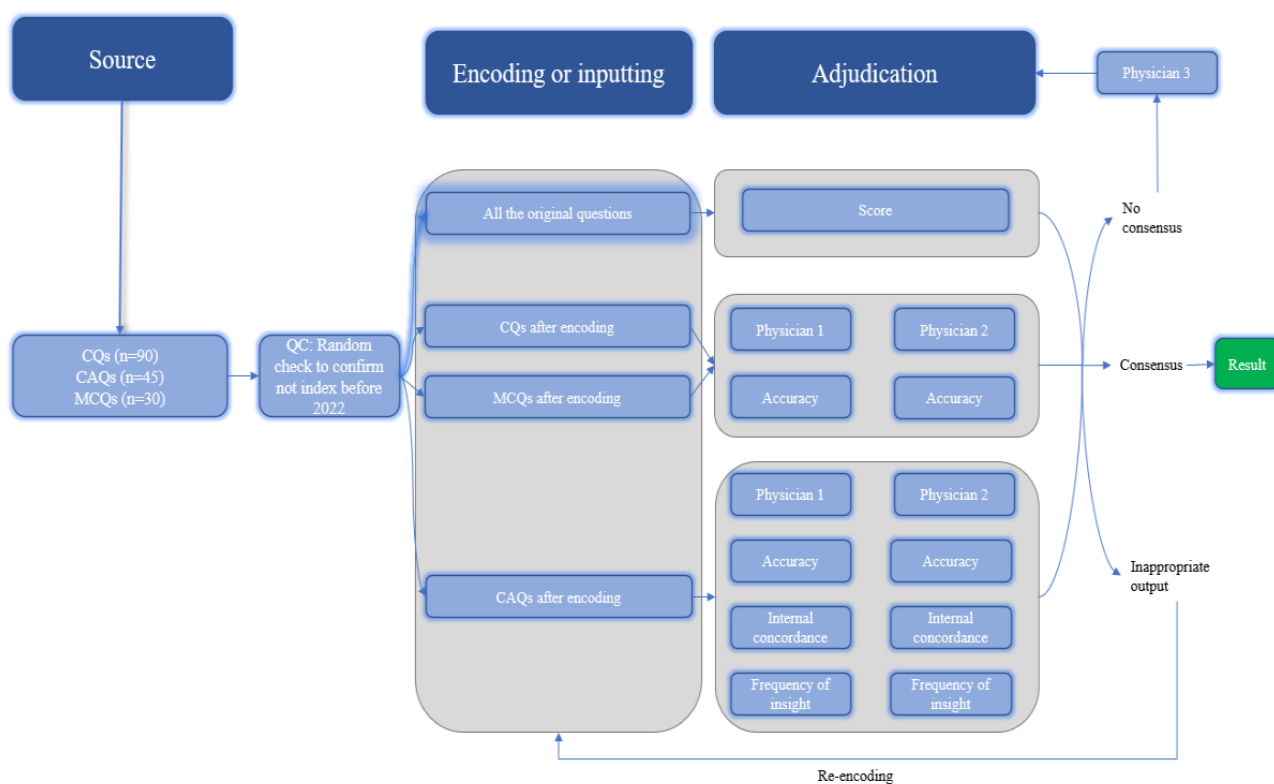

To assess ChatGPT’s performance thoroughly, 2 physicians independently scored AI outputs for accuracy, concordance, and insight using predefined criteria (Table S2 in [Multimedia Appendix 1](#)). These physicians were not aware of each other’s evaluations. To familiarize the physicians with the scoring system, a subset of 20 questions was used for training, during which the physicians were unblinded to each other’s assessments.

ChatGPT’s responses were classified into 3 categories under the accuracy parameter: accurate, inaccurate, and indeterminate. “Accurate” responses were those where ChatGPT provided the right answer, while “inaccurate” encompassed instances of no answer, an incorrect response, or multiple answers containing incorrect options. “Indeterminate” responses were those where

the AI output did not present a definitive answer, suggesting insufficient information to make a selection.

Concordance was determined by whether ChatGPT's explanation affirmed its provided answer, with discordance occurring if the explanation contradicted the answer. We defined valuable insights as unique text segments within the AI's explanations meeting specific criteria: they were nondefinitional, nonobvious, valid, and unique. These insights required additional knowledge or deductions beyond the input question, provided accurate clinical or numerical information, and potentially eliminated multiple answer choices with a single insight.

Figure 1. Schematic of workflow for sourcing, encoding, and adjudicating results. The 165 questions were categorized into 3 types: CQ, CAQ, and MCQ, and each question was assessed for its score. The accuracy of the CQ and MCQ questions was evaluated, while the MCQ questions were also assessed for the accuracy, concordance, and frequency of insights. The adjudication process was carried out by 2 physicians, and in case of any discrepancies in the domains, a third physician was consulted for adjudication. Additionally, any inappropriate output was identified and required re-encoding. CAQ: case analysis question; CQ: common question; MCQ: multichoice question.

Results

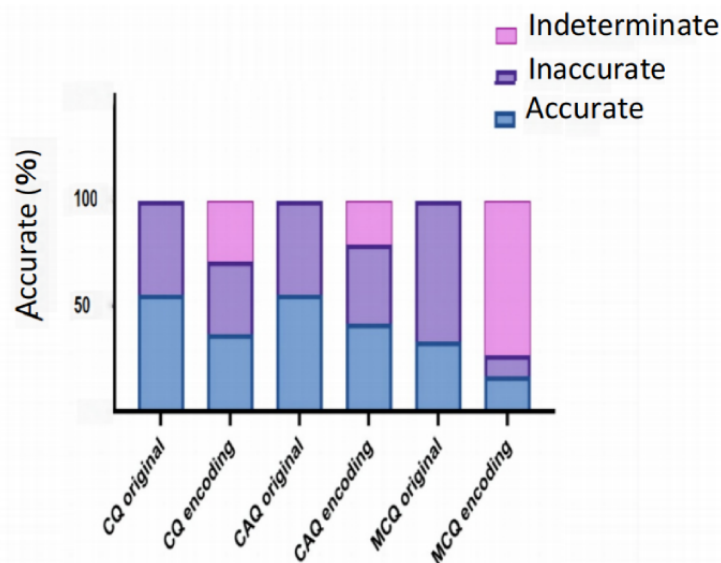

ChatGPT Performs Poor Toward the Original Questions

After inputting the original questions into ChatGPT and collecting their answers, ChatGPT received a score of 153.5 out of 300, which means that it only obtained 51.2% of the total points on the test. This score is much lower than expected but slightly higher than the passing threshold (129/300) defined by official agencies.

Among 3 subgroups of questions, the evaluation revealed that of a total of 90 CQs, ChatGPT only provided 50 (56%, 95% CI 45%-66%) correct answers. Similarly, of 45 CAQs, ChatGPT provided 25 (56%, 95% CI 41%-70%) correct answers. Furthermore, of 30 MCQs, ChatGPT provided 10 (33%, 95% CI 16%-50%) completely accurate answers (Figure 2). These results suggest that ChatGPT's ability to resolve medical problems in Chinese needs to be improved.

Additionally, we have noticed a Pearson correlation coefficient value of approximately 0.228. This finding suggests a relatively weak correlation between the different question types and the accuracy of the responses.

Figure 2. Accuracy of ChatGPT on Chinese Postgraduate Examination for Clinical Medicine before and after encoding. For the subgroups CQ, CAQ, and MCQ before encoding, AI output was compared with the standard answer key. For the subgroups CQ, CAQ, and MCQ after encoding, AI outputs were adjudicated to be accurate, inaccurate, or indeterminate based on the scoring system provided in Table S2 in Multimedia Appendix 1 data. It demonstrates the different accuracy distribution for inputs between the before and after encoding. AI: artificial intelligence; CAQ: case analysis question; CQ: common question; MCQ: multichoice question.

ChatGPT Performs Worse on Encoded Questions Compared to the Original Questions

We encoded questions from the Chinese Postgraduate Examination for Clinical Medicine and inputted them into ChatGPT, which simulates scenarios where a student answers a common medical question without any choices or a doctor tries to diagnose a patient based on multimodal clinical data (ie, symptoms, history, physical examination, and laboratory values). ChatGPT's accuracy for all questions was 31.5%. Among the 3 subgroups, namely, CQs, MCQs, and CAQs, the accuracy was 42%, 37%, and 17%, respectively (Figure 2). Compared to the original questions, the accuracy of the encoding questions decreased by 19%, 17%, and 14% for CQs, MCQs, and CAQs, respectively, which demonstrates that the ability of ChatGPT to answer the open-ended questions in Chinese is a shortcoming. During the adjudication stage, there was substantial agreement

among physicians on prompts in all 3 subgroups (κ ranged from 0.80 to 1.00).

ChatGPT Demonstrates High Internal Concordance

Concordance, which is a measure of the level of agreement or similarity between the option selected by AI and its subsequent explanation, was also taken into consideration. The results showed that ChatGPT achieved 90% concordance across all questions, and this high concordance was maintained across all 3 subgroups (Figure 3). Additionally, we analyzed the concordance difference between correct and incorrect answers and found that concordance among correct and incorrect responses was perfect and significantly greater than among inaccurate responses ($n=52$, 100% vs $n=113$, 50%; $P<.001$; Figure 3). These findings suggest that ChatGPT has a high level of answer-explanation concordance in Chinese, likely due to its strong internal consistency in its probabilistic language model.

Figure 3. Concordance of ChatGPT on Chinese Postgraduate Examination for Clinical Medicine after encoding. For the subgroup “case analysis question,” artificial intelligence outputs were adjudicated to be concordant and discordant based on the scoring system provided in Table S2 in Multimedia Appendix 1 data. It demonstrates concordance rates stratified between accurate, inaccurate, and indeterminate outputs across all the case analysis questions.

ChatGPT Shows Multiple Insights Toward the Same Questions

Another evaluation index considered was the frequency of insights generated by the AI model that quantifies the quantity of insights produced. After evaluating the score, accuracy, and concordance of ChatGPT, its potential was investigated to enhance medical education by augmenting human learning. We analyzed the frequency of insights provided by ChatGPT. Remarkably, ChatGPT generated at least 1 significant insight

in 80% (n=132) of all questions (Figure 4). Moreover, the analysis revealed that the accuracy response had the highest frequency of insights with an average of 2.95. The indeterminate response followed closely behind with an average of 2.7, while the inaccurate response had a lower frequency of insights with an average of 1.39 (Figure 4). The high frequency of insights in the accurate group suggests that it may be feasible for a target learner to acquire new or remedial knowledge from the ChatGPT AI output.

Figure 4. The frequency of insights of ChatGPT on Chinese Postgraduate Examination for Clinical Medicine after encoding. For the subgroup “case analysis question,” artificial intelligence outputs were adjudicated to count the frequency of insights it offered. It demonstrates the frequency of insights stratified between accurate, inaccurate, and indeterminate outputs, across all the case analysis questions.

Discussion

Major Findings

To evaluate ChatGPT’s problem-solving capabilities and assess its potential for Chinese medical education integration, its performance on the Chinese Postgraduate Examination for

Clinical Medicine was tested. We had two major findings: (1) the score of ChatGPT needs to be improved when facing questions asked in the Chinese language and (2) there is still potential for this AI to generate novel performance that can assist humans due to the high concordance and the frequency of insights. This is the first study to assess the performance of ChatGPT in medical care and clinical decisions in Chinese.

ChatGPT's Performance Needs Improvement for Medical Questions in Chinese

A recent study showed that ChatGPT (version 3.5) performed with an accuracy rate of over 50% across all examinations and even exceeded 60% accuracy in some analyses when facing the USMLE [7]. Our results indicate that ChatGPT exhibited moderate accuracy in answering open-ended medical questions in Chinese, with an accuracy of 31.5%. Given the differences between English and Chinese inputs, it suggests that ChatGPT requires further improvement in answering medical questions in the Chinese language.

We sought to understand why there is a significant discrepancy between the performance of ChatGPT on Chinese and English language examinations. To investigate this, we asked the ChatGPT for the reasons, it explains that the training data used to train AI in different languages may be different, and the algorithms used to process and analyze text may vary from language to language (data not shown). Therefore, even for the same question, the output generated may vary slightly based on the language and the available language-based data.

Upon analyzing the results of this research, we found that the accuracy of ChatGPT was lowest for MCQs, followed by CQs and CAQs. The lower accuracy on MCQs may be due to the model being undertrained on the input as well as the MCQ samples being significantly less than those of single-choice questions. On the other hand, the CAQs may have extensive training compared to MCQs and are similar in type to the USMLE question.

Furthermore, we noticed that high accuracy outputs were associated with high concordance and a high frequency of insight, whereas poorer accuracy was linked to lower concordance and a lack of insight. Thus, it was hypothesized that inaccurate responses were primarily driven by missing information, which could result in reduced insight and indecision in the AI, rather than an overcommitment to an incorrect answer [7]. The results indicate that enhancing the database and providing additional training with Chinese questions could substantially improve the performance of the model.

Challenges of AI in Future Applications

Despite the promising potential of AI in medicine, it also poses some challenges. Standards for using AI in health care still need to be developed [8,9], including clinical care, quality, safety, malpractice, and communication guidelines. Furthermore, the implementation of AI in health care requires a shift in medical culture, which poses a challenge for both medical education and practice. Additionally, ethical considerations must be taken into account, such as data privacy, informed consent, and bias prevention, to ensure that AI is used ethically and for the benefit of patients. Surprisingly, a recently launched AI system for autonomous detection of diabetic retinopathy carries medical malpractice and liability insurance [10].

Prospective of AI

AI is a rapidly growing technology. At the time of writing, ChatGPT (version 4) has been released with significant improvements. Numerous practical and observational studies

have demonstrated the versatile role of AI in almost all medical disciplines and specialties, particularly in improving risk assessment [11,12], data reduction, clinical decision support [13,14], operational efficiency, and patient communication [15,16]. We anticipate that advanced language models such as ChatGPT are reaching a level of maturity that will soon have a significant impact on clinical medicine, enhancing the delivery of personalized, compassionate, and scalable health care.

A comparison of ChatGPT's performance with other AI models, particularly in the context of Chinese language performance, could yield more comprehensive insights and underscore the unique challenges of using AI in diverse linguistic landscapes.

However, this was primarily due to the fact that AI models that focus on other aspects, while enhancing medical education and achieving promising results in medical question answering, are mostly developed and evaluated using English language data sets. This limitation restricts their applicability for performance comparisons in the context of the Chinese language.

Limitations

One limitation of this research is the small sample size. We only accessed 165 samples to qualify its accuracy and 30 CAQs to qualify its concordance and frequency of insight due to the limitations of the data, which focused solely on the diagnosis of the patient. Furthermore, the clinical situation is more complicated than the test, and larger and deeper analyses were needed. Finally, bias and error were inevitable in human adjudication, although there was a good interrater agreement between the physicians for the adjudication.

Moreover, comparing ChatGPT's performance with other AI models, especially in the context of Chinese language, can provide valuable insights and highlight the distinctive challenges associated with leveraging AI in diverse linguistic environments.

One notable factor contributing to this need for comparison is the prevalence of AI models such as Bidirectional Encoder Representations from Transformers, CLUE-Med, and MedQA that have made significant contributions to medical education and demonstrated promising outcomes in medical question answering. However, these models have predominantly been developed and assessed using English language data sets. This particular limitation hampers their suitability for conducting performance assessments within the Chinese language domain.

Conclusions

In conclusion, although the ChatGPTs got a score over the passing score in the Chinese Postgraduate Examination for Clinical Medicine, the performance was limited when presented with open-ended questions. On the other hand, ChatGPT demonstrated a high level of internal concordance, which suggests that the explanations provided by ChatGPT support and affirm the given answers. Moreover, ChatGPT generated multiple insights toward the same questions, demonstrating its potential for generating a variety of useful information. Further prospective studies are needed to explore whether there is a language-based difference in the performance of medical education settings and clinical decision-making, such as Chinese and minority languages.

Acknowledgments

The authors acknowledge ChatGPT for polishing their paper.

Data Availability

All data generated or analyzed during this study are included in this published paper (and [Multimedia Appendix 1](#)).

Authors' Contributions

Xiao Liu was responsible for the entire project and revised the draft. CF, AA, and YW performed the data extraction, statistical analysis, and interpretation of the data. WZ, Z Chen, YZ, and JW drafted the first version of the paper. All authors participated in the interpretation of the results and prepared the final version of the paper.

Conflicts of Interest

None declared.

Multimedia Appendix 1

Original questions, adjudication criteria for accuracy and concordance, and κ statistic for interrater agreement between adjudicating physicians.

Abstract

Background: The use of mobile devices for delivering health-related services (mobile health [mHealth]) has rapidly increased, leading to a demand for summarizing the state of the art and practice through systematic reviews. However, the systematic review process is a resource-intensive and time-consuming process. Generative artificial intelligence (AI) has emerged as a potential solution to automate tedious tasks.

Objective: This study aimed to explore the feasibility of using generative AI tools to automate time-consuming and resource-intensive tasks in a systematic review process and assess the scope and limitations of using such tools.

Methods: We used the design science research methodology. The solution proposed is to use cocreation with a generative AI, such as ChatGPT, to produce software code that automates the process of conducting systematic reviews.

Results: A triggering prompt was generated, and assistance from the generative AI was used to guide the steps toward developing, executing, and debugging a Python script. Errors in code were solved through conversational exchange with ChatGPT, and a tentative script was created. The code pulled the mHealth solutions from the Google Play Store and searched their descriptions for keywords that hinted toward evidence base. The results were exported to a CSV file, which was compared to the initial outputs of other similar systematic review processes.

Conclusions: This study demonstrates the potential of using generative AI to automate the time-consuming process of conducting systematic reviews of mHealth apps. This approach could be particularly useful for researchers with limited coding skills. However, the study has limitations related to the design science research methodology, subjectivity bias, and the quality of the search results used to train the language model.

KEYWORDS

generative artificial intelligence; mHealth; ChatGPT; evidence-base; apps; qualitative study; design science research; eHealth; mobile device; AI; language model; mHealth intervention; generative AI; AI tool; software code; systematic review; language model

Introduction

The delivery of health-related services through the use of mobile devices (mHealth) [1] has been growing at a tremendous pace.

A decade ago, in the first “era of mHealth,” the literature surrounding mHealth called for the generation of evidence demonstrating the impact of mHealth solutions on health system processes and patient outcomes [2]. In 2013, Labrique et al [2]

conducted a preliminary search on the US federal clinical trials database (ClinicalTrials.gov) and had to combine the keywords “mHealth,” “mobile,” and “cell AND phone” to obtain 1678 studies and their results. Today, that same number can be obtained using “mHealth” alone as a keyword. As the need for mHealth evidence has grown, so too has the necessity for summarizing both the state of the art and the practice.

Systematic reviews seek to collect and combine relevant evidence within the specific scope of a research question while also striving to minimize bias [3,4]. In PubMed alone, the number of systematic reviews published on digital health-related topics has increased a hundredfold in the last 10 years. In fact, the pace at which the mHealth field is developing for certain conditions like breast cancer is such that systematic reviews can be found every 2 or 3 years [5-9]. The systematic review process, however, is a time- and resource-intensive process, reportedly requiring a median of 5 researchers and approximately 40 weeks of work to reach submission [10-12].

The emergence of generative AI has been seen as a breakthrough in the field of automation. With the ability to generate content such as text, images, and even music, AI has been reported as a potential solution to tedious time-consuming and labor-intensive tasks [13]. For instance, generative AI can be used to automatically generate product descriptions, news articles, or even code [14]. By eliminating the need for human intervention, generative AI can free up valuable time and resources for more complex tasks, thereby improving efficiency

and accuracy. ChatGPT, a natural language processing model with a capacity of 175 billion parameters, has been trained on extensive amounts of data and is designed to produce human-like responses to user inputs. Since its release in November 2022, ChatGPT has received significant attention from media and academia alike, provoking ethical discussions on scientific authorship [15,16], attempting to pass medical license and specialist examinations [17-19], and even designing medical education curricula [20].

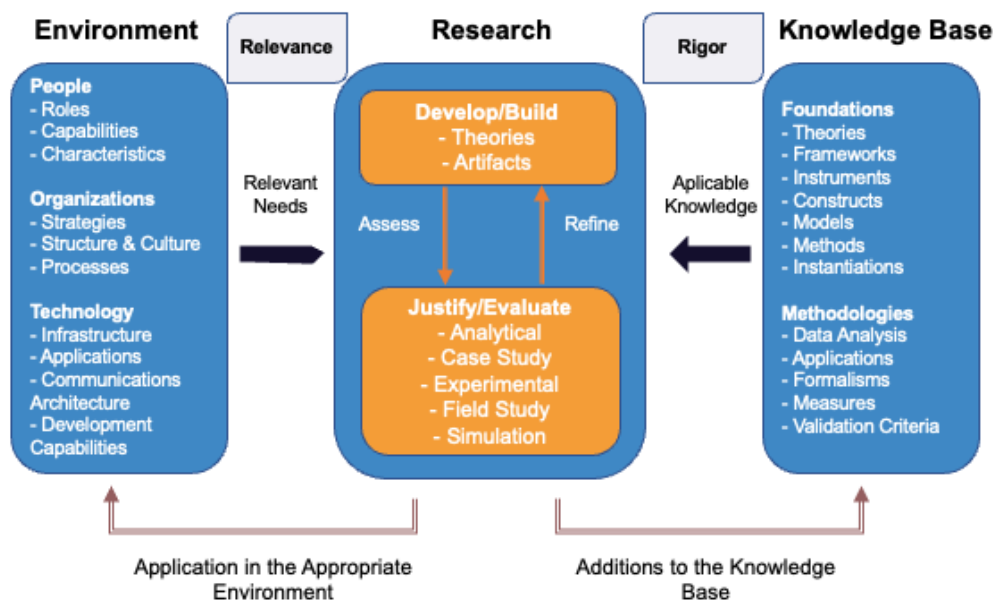

The objective of this study was to explore the feasibility of using generative AI tools to automate time-consuming and resource-intensive tasks in a systematic review process and assess the scope and limitations of using such tools.

Methods

Study Design

This study uses a design science research (DSR) methodology. DSR is a problem-solving paradigm that seeks to enhance human knowledge via the creation of innovative artifacts [21]. DSR commonly involves the identification of a problem or opportunity, followed by the development, implementation, and evaluation of a solution. In DSR, as well as in action research, the process happens within an organization that provides context and that would be changed as a result of the use of the artifact [21]. An overview of the process adapted from Hevner [22] can be seen in Figure 1.

Figure 1. Design science research overview, adapted from Hevner 2004 [22].

Problem Definition

The problem to which DSR was applied was the time-consuming and resource-intensive process of conducting systematic reviews of mHealth applications.

Organizational Context

The organizational context consisted of the More Stamina team of researchers, software developers, and health care professionals, working collaboratively within the host research

institutions (ie, the University of Oulu and Trinity College Dublin).

The More Stamina project aims to create an evidence-driven gamified mHealth solution for people with multiple sclerosis (MS), where each step of the development follows a scientific process, as follows: MS needs as well as barriers and facilitators were explored through qualitative studies [23]; the state of the practice for MS apps was systematically reviewed [24,25]; user-centered design was used to create “MS personas” [23];

cocreation sessions took place to produce solution concepts [26]; the design, prototyping, and initial usability testing were described [27]; early health technology assessment was used to guide software development [28]; patient representatives were involved throughout the project [29]; and user testing and feasibility studies were ongoing in a multicenter study [30].

A script using the software application for audience targeting called 42matters [31] was used in the past to extract information from different app stores. The script is no longer functional, and person-hours from the software development team were not able to be dedicated to this task.

Background Studies

The research plans and outlines from previous studies, where systematic review methodologies were used to identify, select, collect, and analyze features and content of mHealth apps [6,24,25], served as models for our study. In those studies, a search strategy was defined, using relevant main keywords for each condition. App stores were searched, taking steps to ensure that no previous search history or cookies influenced results. Screening took place based on mHealth applications' titles, descriptions, and metadata.

Table 1. Digital skills background.

Competency	Level	Experience	Self-assessment score (of 10)
Scrum master	Certified Scrum Master	Agile methodologies and team management	7
Product owner	Certified Scrum Product Owner	Product road mapping and stakeholder management	8
Game design	Intermediate	Game mechanics, storytelling, and level design	7
Web design	Advanced	User experience and user interface design and responsive design	8
JavaScript	Beginner	Front-end development	5
HTML5	Intermediate	Front-end development	7
PHP: Hypertext Preprocessor	Beginner	Front-end and back-end development	4

Evaluation

The results were evaluated for their effectiveness and efficiency in replicating the initial steps of the background studies. The measurements were considered with respect to the amount of time required to generate a spreadsheet containing the necessary information for human reviewers to start the systematic review process. The output was compared to the output generated by the previous script, which required further processing of the data.

Ethical Considerations

No ethics board review is needed as the work does not use patient data or involve human participants.

Results

The following section reports the overall design, development, and implementation process as well as the evaluation results and highlights of the experience. Prompts provided by GG and generative AI are tagged accordingly.

Solution

The solution was to apply a cocreation process with a generative AI (ie, ChatGPT 3.5, as of June 2023) to produce software code that automated the process for conducting systematic reviews.

Cocreation Goal

The goal of the cocreation process was to use ChatGPT as a design and development partner for the automation process. The generative AI was to be interacted with as if it were a valid interloper who was more technologically skilled than the user and was guiding them through the process over text messages.

Development and Implementation

Development and implementation of the automated process happened through iterative and continuous conversations with the generative AI by one of the authors (GG). GG is a primary care physician with over a decade of experience leading digital health software design and development. Table 1 provides an overview of his digital skills background using the European Qualifications Framework and with a self-assessment score from 1 to 10 to describe his competency level. Regardless of the skill level, the development cycle was to be conducted as if no coding skill was present on the part of the user.

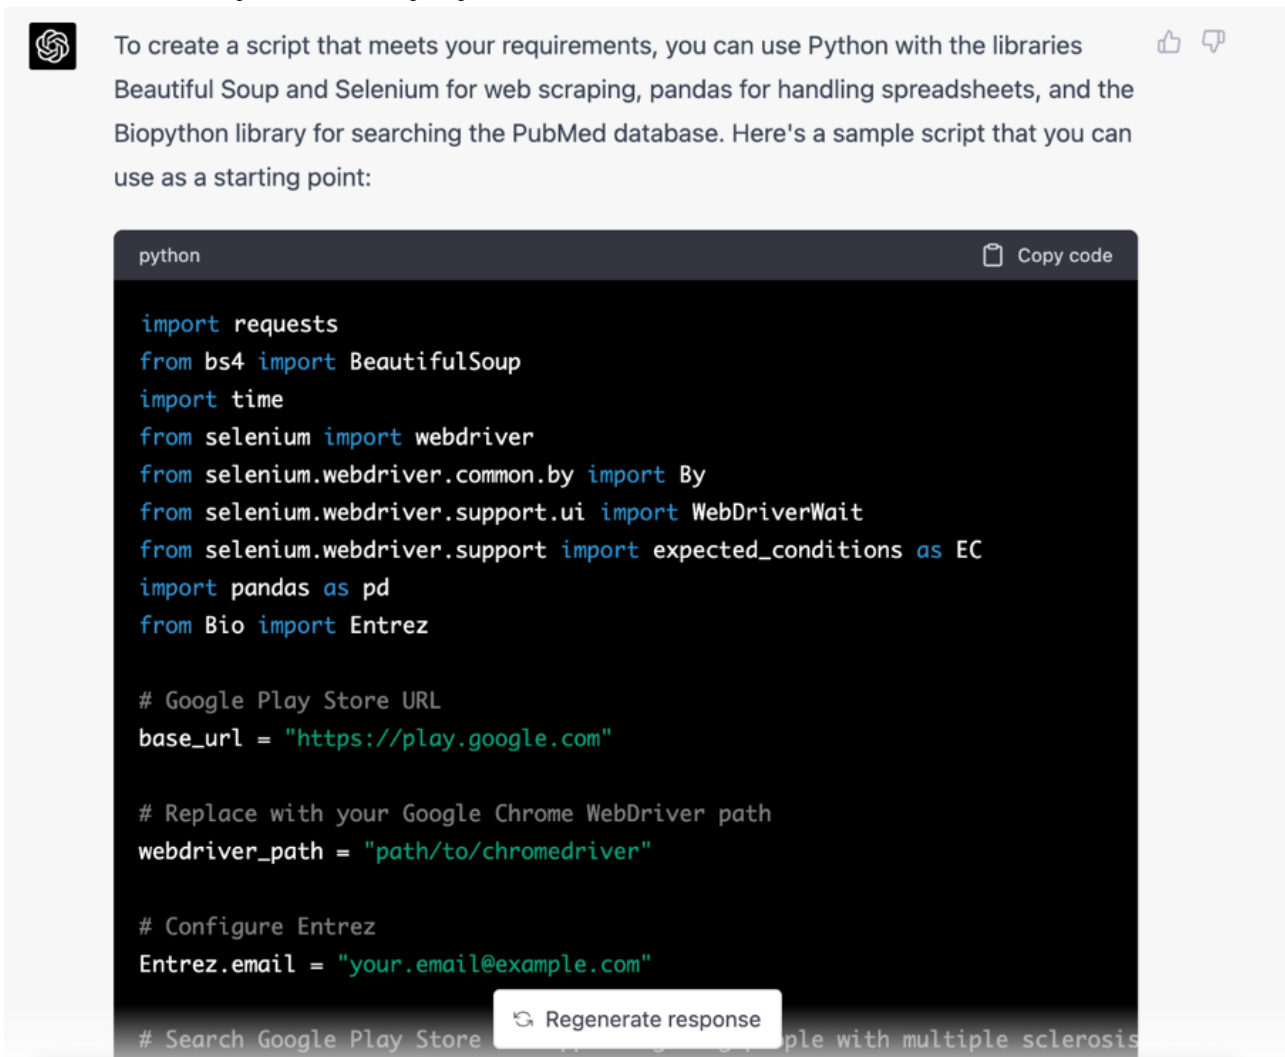

Cocreation Process

ChatGPT requires prompts to trigger interaction. For this purpose, a lay language description of the desired outcome was engineered by GG (triggering prompt), as follows:

I need a script that crawls the Google Play Store for apps that target people with multiple sclerosis. The script should generate a spreadsheet file that contains name, links, description and other metadata, as well as have a specific column to highlight if the description mentions any medical or clinical evidence. The script should then search Pubmed database looking for each app listed on the spreadsheet, and create a separate spreadsheet relating the apps with any scientific publication that mentions them in Pubmed. [GG]

The generative AI's response was to provide a sample script in Python that was suggested as a starting point, as shown in Figure 2.

Figure 2. ChatGPT's first response to the initial prompt.

Following the premise of the cocreation goal, ChatGPT was asked (by GG) “I am new to Python, how do I run a Python script?” to which the response was the following:

To run a Python script, you need to follow these steps:

1. Install Python on your computer, if it's not already installed. You can download Python from the official website: <https://www.python.org/downloads/>.
2. Open a text editor (e.g. Notepad, Sublime Text, Atom) and create a new file.
3. Write your Python code in the file.
4. Save the file with a .py extension (e.g. “my_script.py”).
5. Open a command prompt or terminal and navigate to the directory where your Python script is saved.
6. Type “python” followed by the name of your script and press enter. For example, if your script is named “my_script.py”, you would type “python my_script.py” and press enter.
7. Your Python script will now run, and you should see any output or results in the command prompt or terminal.

Note: If you're using an Integrated Development Environment (IDE) like PyCharm or Visual Studio Code, you can run your script directly from the IDE by clicking on the “Run” button or pressing a keyboard shortcut. [ChatGPT]

ChatGPT provided step-by-step guidance for the installation and setup of Visual Studio Code, along with the required libraries and dependencies. After the development environment was ready, the suggested Python script was copied and pasted to check its functionality. The code produced several errors, which were fed back to ChatGPT by GG, as follows:

I am getting “ModuleNotFoundError: No module named 'requests'”

Now it says “ModuleNotFoundError: No module named 'bs4'”

ChatGPT stated that the “requests” library was imported but not used, so it should be removed. Subsequent error messages were troubleshot with the AI. At times, the script would stop responding due to a time-out error or issues with the output. To make the debugging process easier to follow and understand, ChatGPT was prompted by GG to do the following:

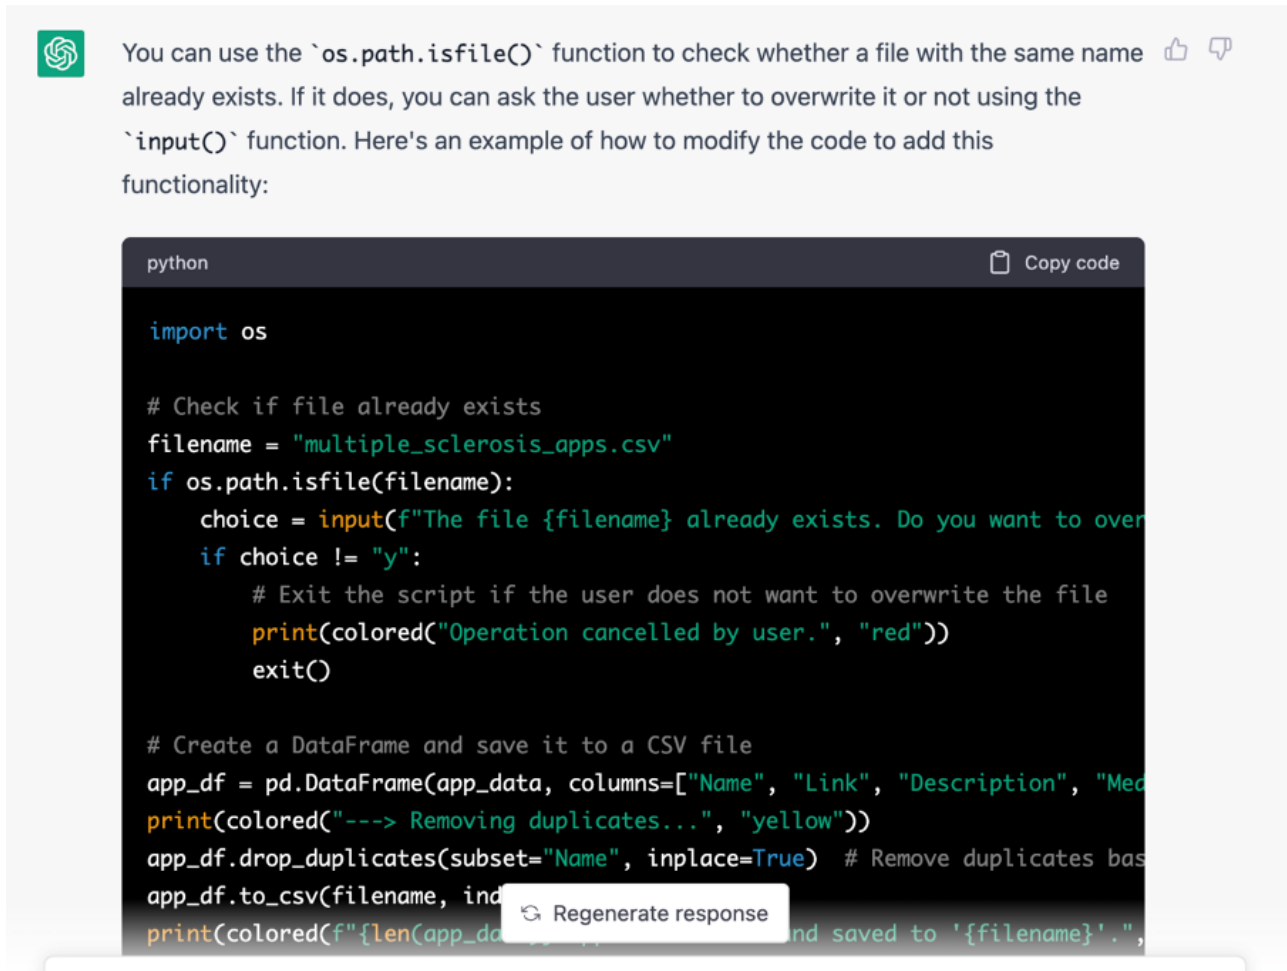

add error messages that explain what went wrong.

*add indicators for each step that it is working.
could you add a progress bar indicator to each step?
I would like the responses to be colored.*

Upon review, it was clear that some error caused the output files to be overwritten. The author requested the following: “how

would you add a condition to check whether a file with the same name already exists and if it does ask whether to overwrite it?” The AI added the pertinent libraries to the script and produced an input prompt for the user (Figure 3).

Figure 3. Added libraries and code for checking existing files.

The triggering prompt expected the script to not only be searching app stores for matches with “multiple sclerosis” but also to cross-reference them with scientific publications found in PubMed. As described in the Background Studies section of this paper, this process was done by looking for keywords present in the app description. As it were, the script was designed to only search for “multiple sclerosis” and crashed when it reached the PubMed phase. ChatGPT diagnosed a time-out error due to the number of publications and provided a potential solution to improve the indicator bars:

The progress bar for PubMed search may not be moving because the total value for it is set to 3600, which is the number of seconds in an hour. This is the unit being used for the progress bar, not the total number of items to be searched. To fix this, you should

update the total value for the progress bar to be the total number of apps being searched, which is the length of the app_df dataframe multiplied by the maximum number of PubMed IDs to be retrieved for each app (100 in this case). You can update the progress bar as follows... [ChatGPT]

After these issues were sorted and the script could properly fetch PubMed results, more keywords were entered into the script by prompting ChatGPT with the following:

how would you make it so that the items in the medical_keywords list are taken from a csv file called “keywords.csv”? [GG]

A screenshot of the final Python script running can be seen in Figure 4.

Figure 4. Screenshot of the final script running.

```

41     exit()
42
43 # Search Google Play Store for apps targeting people with multiple sclerosis
44 query = "Multiple sclerosis"
45 with tqdm(total=len(countries), unit="country", desc="Searching Google Play Store for MS apps", "yellow", bar_format="{desc}: \033[33m{bar}\033[0m {percent}"):
46     for country in countries:
47         while True:
48             try:
49                 result = search(query, lang="en", country=country)
50                 pbar.update(1)
51                 break

```

PROBLEMS OUTPUT DEBUG CONSOLE TERMINAL

The script will look for MS apps on the Google Play Stores of English speaking countries, remove any duplicates and see if the apps have any evidence claims based on a keywords list. Afterwards, it will try to find mentions by name of the apps in PubMed and generate CSV files with the information.

Should we start? (y/n)

y

Running script...

----> Searching Google Play Store for MS apps: 100%

Google Play Store search successful!

The file multiple_sclerosis_apps.csv already exists. Do you want to overwrite it? (y/n)

y

Overwriting existing file...

----> Looking for evidence claims in app descriptions: 30%

----> Removing duplicates...

30 apps were found and saved to 'multiple_sclerosis_apps.csv'.

----> Searching PubMed for scientific publications related to the apps: 3%

Evaluation

As explained in the Background Studies section of this paper, app data extraction from the Google Play Store resulted in a spreadsheet file that contained the mHealth app's name, store link, app description, developer's name, developers' URL, price, number of downloads, and app rating. During the screening phase of the studies, the research team read the apps' descriptions and flagged those that contained keywords or sentences suggestive of the evidence base for in-depth review.

The ChatGPT-generated code resulted in a CSV file that contained the app's name, store link, app description, and a column titled "Medical Evidence." There were no columns containing metadata, and the Medical Evidence column only contained "Yes" or "No," accordingly. Closer inspection revealed that the script was searching for a full match on the apps' titles in PubMed results. The resulting document was useful as an intermediate outcome but was deemed unsuitable as a final output. The overall cocreation process had a total duration of 4 hours and 39 minutes, providing a working script version available on GitHub [32].

Using the results from the ChatGPT-generated script to fully automate the process would likely require further work refining the script, either by using the steps of the background studies to base the script or by providing clearer starting prompts for the generative AI. However, leveraging this approach as a means to advance work when the software developing team was otherwise engaged was useful.

Highlights

Some highlights of this study are as follows:

- The overall cocreation process exercise had a total duration of 4 hours and 39 minutes.
- There were several misunderstandings during the interactions, not unlike the challenges one might encounter when messaging a more experienced coder.
- Structured thinking ahead of time reduced the number of misunderstandings.
- No knowledge of Python scripting was required by the author.
- The resulting output was useful to continue a systematic review but not sufficient to replace the final outputs.

Discussion

Principal Results

This study is the first to describe the cocreation process with a generative AI in developing an automated script for conducting a systematic review of mHealth apps. The study provides insights into the potential of using this kind of AI tools for researchers with little to no coding skills, and it identifies an innovative way of approaching a research problem and facilitating interdisciplinary collaborations. This study also makes a methodological contribution, expanding knowledge as it uses DSR, an approach that is not commonly used in health care and health informatics [33].

Comparison With Prior Work

The resource-intensive process and the burden that systematic reviews represent have been highlighted in the literature before. The use of multiple databases, such as MEDLINE, Embase, Cochrane Library, and Web of Science as well as clinical trial registries like ClinicalTrials.gov are common practices to increase results [34]. However, this tactic requires a lengthy deduplication process, involving long manual procedures, potentially introducing quality-affecting errors and biases [35-37]. In fact, automation attempts using AI models have been made in the past, with a focus on the deduplication problem, as seen in studies by Borissov et al [38] and Bramer et al [39].

Performing a systematic review is a common step in doctoral researchers' studies [40,41], as a means of introducing the candidate to the topic. The use of generative AI to cocreate scripts like the one presented in this study could help automate the time-consuming process, allowing researchers to focus on other aspects of the research process.

The ethical implications of using generative AI models, such as ChatGPT, to generate scientific authorship have sparked discussions [15,16]. AI's potential for assisting in academic research needs to be considered and weighed against the potential for its misuse. Although generative AI can assist in the development of a systematic review script, it is important to note that the final review still requires human oversight and input to not only assess the accuracy and relevance of the results but also ensure that the ethical principles have been followed.

Beyond research, there are wider implications for the use of generative AI in both medical education and the upskilling of the health care workforce. The need for more digital skills training for health care professionals is widely recognized [42], and other authors have further explored medical degree programs' curricula to examine how AI is included [43,44]. A recent publication explored the specific competencies needed for the effective and ethical use of AI in health care [45]. Understanding basic knowledge of AI and its applications as well as how to integrate AI into the general workflow of different tasks ranked among the top 6 key competency domains.

The role of generative AI in evolving health care education is pivotal, especially as universities adapt to its challenges. Generative AI has the potential to streamline processes like systematic reviews and clinical information retrieval, thereby allowing health care professionals to focus more on patient-centered, empathetic care and the co-design of effective treatment outcomes.

Limitations

The results of this study must be considered within its limitations. The DSR methodology was developed for this specific problem, which limits applicability in other contexts.

In addition, subjectivity is a common bias present in DSR, which can make it difficult to establish the reliability and validity of the results. The main goal of DSR is to generate prescriptive knowledge, which provides guidelines on how to effectively design and implement solutions in the organizational context. However, as DSR focuses more on developing practical solutions rather than generating new theoretical insights, it was aligned with the goal of this study. DSR differs from traditional research paradigms by focusing more on creating and evaluating new solutions rather than on understanding existing phenomena. Further, while generative AI can assist in the development of a systematic review script, the result will be greatly affected by the training data used for the language model. Additionally, there may be limitations in the quality of the search results obtained from the previous studies, which only become apparent through automated processes.

Conclusions

This study outlined the cocreation process of an automated script for systematic reviews of mHealth apps, using generative AI. The study shed light on the potential of such AI tools for researchers with limited coding abilities and highlighted a novel approach for addressing research problems and promoting interdisciplinary collaborations.

Acknowledgments

GG would like to thank Prof Octavio Rivera-Romero, Dr Estefania Guisado-Fernandez, Dr Diego Giunta, Dr Analia Baum, and Prof Minna Isomursu for their collaboration and support.

This study has received funding from the European Union's Horizon 2020 Research and Innovation Programme under the Marie Skłodowska-Curie grant agreement (101034252). The publication has also emanated from research supported (in part) by a research grant from Science Foundation Ireland (SFI) under grant number 16/RC/3948 and Business Finland's More Stamina Research to Business project.

The authors are grateful for ChatGPT, whose collaboration was essential for the completion and inception of this study.

Conflicts of Interest

None declared.

Abstract

Background: Patients with rare and complex diseases often experience delayed diagnoses and misdiagnoses because comprehensive knowledge about these diseases is limited to only a few medical experts. In this context, large language models (LLMs) have emerged as powerful knowledge aggregation tools with applications in clinical decision support and education domains.

Objective: This study aims to explore the potential of 3 popular LLMs, namely Bard (Google LLC), ChatGPT-3.5 (OpenAI), and GPT-4 (OpenAI), in medical education to enhance the diagnosis of rare and complex diseases while investigating the impact of prompt engineering on their performance.

Methods: We conducted experiments on publicly available complex and rare cases to achieve these objectives. We implemented various prompt strategies to evaluate the performance of these models using both open-ended and multiple-choice prompts. In addition, we used a majority voting strategy to leverage diverse reasoning paths within language models, aiming to enhance their reliability. Furthermore, we compared their performance with the performance of human respondents and MedAlpaca, a generative LLM specifically designed for medical tasks.

Results: Notably, all LLMs outperformed the average human consensus and MedAlpaca, with a minimum margin of 5% and 13%, respectively, across all 30 cases from the diagnostic case challenge collection. On the frequently misdiagnosed cases category, Bard tied with MedAlpaca but surpassed the human average consensus by 14%, whereas GPT-4 and ChatGPT-3.5 outperformed MedAlpaca and the human respondents on the moderately often misdiagnosed cases category with minimum accuracy scores of 28% and 11%, respectively. The majority voting strategy, particularly with GPT-4, demonstrated the highest overall score across all cases from the diagnostic complex case collection, surpassing that of other LLMs. On the Medical Information Mart for Intensive Care-III data sets, Bard and GPT-4 achieved the highest diagnostic accuracy scores, with multiple-choice prompts scoring 93%, whereas ChatGPT-3.5 and MedAlpaca scored 73% and 47%, respectively. Furthermore, our results demonstrate that there is no one-size-fits-all prompting approach for improving the performance of LLMs and that a single strategy does not universally apply to all LLMs.

Conclusions: Our findings shed light on the diagnostic capabilities of LLMs and the challenges associated with identifying an optimal prompting strategy that aligns with each language model's characteristics and specific task requirements. The significance of prompt engineering is highlighted, providing valuable insights for researchers and practitioners who use these language models for medical training. Furthermore, this study represents a crucial step toward understanding how LLMs can enhance diagnostic reasoning in rare and complex medical cases, paving the way for developing effective educational tools and accurate diagnostic aids to improve patient care and outcomes.

Introduction

Background

Natural language processing has witnessed remarkable advances with the introduction of generative large language models (LLMs). In November 2022, OpenAI released ChatGPT-3.5 (OpenAI), a large natural language processing chatbot trained on a large corpus collected from the internet to generate humanlike text in response to user queries. ChatGPT-3.5 has seen massive popularity, and users have praised its creativity and language comprehension for several tasks, such as text summarization and writing computer programs [1]. In March 2023, OpenAI responded to the success of ChatGPT-3.5 by introducing an enhanced iteration called GPT-4, specifically designed to address intricate queries and nuanced directives more effectively. Shortly thereafter, Google released their comparable model, Bard (Google LLC), which joined the league of impressive LLMs. What sets Bard apart is its real-time access to and use of internet information, enriching its response generation with up-to-date information [2]. In contrast, GPT-4 possesses multimodal capabilities, including image inputs, albeit not publicly available during the study [3].

These LLMs were not originally designed for medical applications. However, several studies [4,5] have shown their extraordinary capabilities in excelling in various medical examinations, such as the Self-Assessment in Neurological Surgery examination and the USMLE (United States Medical Licensing Examination). Their results demonstrated the ability of these models to handle clinical information and complex counterfactuals. Furthermore, numerous investigations [6-8] have revealed the remarkable advantages of harnessing the power of LLMs in diverse medical scenarios. Notably, Lee et al [8] demonstrated using LLMs as a reliable conversational agent to collect patient information to assist in medical notetaking, whereas Patel and Lam [9] delved into using LLMs as a valuable tool for generating comprehensive patient discharge summaries. The ability of LLMs to process and generate medical text has unlocked new opportunities to enhance diagnostic reasoning, particularly in tackling rare and complex medical cases.

Rare diseases are characterized by their low prevalence in the general population, whereas complex diseases are conditions with overlapping factors and multiple comorbidities that are often difficult to diagnose [10,11]. Sometimes, a condition can be rare and complex if it is infrequent and challenging to diagnose accurately [11]. Rare and complex diagnoses present significant challenges across various medical levels and often require extensive medical knowledge or expertise for accurate diagnosis and management [10,11]. This may be because, during their education, physicians are trained to prioritize ruling out common diagnoses before considering rare ones during patient

evaluation [12]. In addition, most medical education programs rarely cover some complex conditions, and guidance for practicing clinicians is often outdated and inappropriate [13,14]. As a result, most physicians perceive their knowledge of rare diseases as insufficient or very poor, and only a few feel adequately prepared to care for patients with these conditions [12,15]. This knowledge gap increases the risk of misdiagnosis among individuals with rare and complex conditions. Furthermore, the scarcity of available data and the relatively small number of affected individuals create a complicated diagnostic landscape, even for experienced and specialized clinicians [10]. Consequently, patients often endure a prolonged and arduous diagnostic process. Therefore, there is a pressing need for comprehensive educational tools and accurate diagnostic aids to fill the knowledge gap and address these challenges effectively.

This study aims to explore the potential of 3 LLMs, namely Bard, GPT-4, and ChatGPT-3.5, as continuing medical education (CME) systems to enhance the diagnoses of rare and complex conditions. Although these models have demonstrated impressive success in standardized medical examinations [4,5], it is important to acknowledge that most examinations reflect general clinical situations, which may not fully capture the intricacies encountered in real-world diagnostic scenarios. Furthermore, these standardized tests often feature questions that can be answered through memorization [16]. In contrast, real-world complex diagnostic scenarios that physicians face involve dynamic, multifaceted patient cases with numerous variables and uncertainties. Although previous studies by Liu et al [17] and Cascella et al [18] have highlighted the ability of LLMs to support health care professionals in real-world scenarios, their effectiveness in diagnosing rare and complex conditions remains an area of exploration. Despite the promising use of LLMs in medical applications, studies have reported that their responses to user queries are often nondeterministic (ie, depending on the query format) and exhibit significant variance [17,19]. This attribute may pose challenges in clinical decision support scenarios because the dependability of a system is uncertain when its behavior cannot be accurately predicted. However, no investigation has been conducted to show how different input formats (prompts) affect LLM responses in the medical context.

Prompt engineering is a technique for carefully designing queries (inputs) to improve the performance of generative language models [20,21]. We can guide LLMs to generate more accurate and reliable responses by carefully crafting effective prompts. Our study investigated effective prompting strategies to improve the accuracy and reliability of LLMs in diagnosing rare and complex conditions within an educational context. We evaluated the performance of LLMs by comparing their responses to those of human respondents and the responses of

MedAlpaca [22], an open-source generative LLM designed for medical tasks. Given the documented advantages of using LLMs as a complementary tool rather than a substitute for clinicians [17,18], our study incorporated LLMs with the understanding that clinicians may use them beyond real-time diagnostic scenarios. Although our premise is based on a clinician having established an initial diagnostic hypothesis and seeking further assistance to refine the precise diagnosis, we acknowledge the broader utility of LLMs. They can be valuable in real-time decision support and retrospective use during leisure or documentation, allowing physicians to experiment with and enhance their understanding of rare and complex diseases. This approach recognizes the inherent uncertainty in diagnosis and harnesses the capabilities of LLMs to assist clinicians in various aspects of their diagnostic processes. In the context of CME, our study highlights the possibility of integrating LLMs as a valuable addition. By providing further assistance in refining complex and rare diagnoses, these LLMs could support evidence-based decision-making among health care professionals for improved patient outcomes.

Objectives

Our study has 2 main objectives: first, to examine the potential of LLMs as a CME tool for diagnosing rare and complex conditions, and second, to highlight the impact of prompt formatting on the performance of LLMs. Understanding these aspects could significantly contribute to advancing diagnostic practices and effectively using LLMs to improve patient care.

Methods

Data Sets

We used 2 data sets to examine the capacity of LLMs to diagnose rare and complex conditions as follows:

1. Diagnostic case challenge collection (DC3) [11] comprises 30 complex diagnostic cases curated by medical experts in the *New England Journal of Medicine* web-based case challenges. The original cases contained text and image descriptions of patients' medical history, diagnostic imaging, and laboratory results; however, we used only textual information to form prompts (queries). The web-based polls recorded an average of 5850 (SD 2522.84) respondents per case, many of whom were health care professionals. The participants were required to identify the correct diagnosis from a list of differential diagnoses. Case difficulty was categorized based on the percentage of correct responses received from the respondents on the web-based survey. The case categories were: "rarely misdiagnosed cases" (with $\geq 21/30$, 70% correct responses), "moderately misdiagnosed cases" (with $>9/30$, 30% and $<21/30$, 70% correct responses), and "frequently misdiagnosed cases" (with $\leq 9/30$, 30% correct responses). Furthermore, the final diagnoses determined by the treating physicians of the cases were provided alongside the poll results, enabling the comparison of the performance of human respondents with that of the targeted LLMs.

2. Medical Information Mart for Intensive Care-III (MIMIC-III) [23] comprises deidentified electronic health record data from approximately 50,000 Boston Beth Israel Deaconess Medical Center intensive care unit patients. We focused on discharge summaries containing the accumulated patient information from admission to discharge. Similar to previous work on clinical outcome prediction by van Aken et al [24] and Abdullahi et al [25], we filtered document sections unrelated to admissions, such as discharge information or hospital course and retained sections related to admissions, such as chief complaint, history of illness or present illness, medical history, admission medications, allergies, physical examination, family history, and social history. Each discharge summary had a discharge diagnosis section that indicated the patient's final diagnosis for that admission. We reviewed the discharge summaries to identify rare diseases and referred to the Orphanet website [26]. In this study, we randomly selected 15 unique, rare conditions as our target. These cases were selected as pilot studies for a focused and in-depth analysis.

Models

In this study, we conducted experiments using LLMs designed for conversational context. Specifically, we used the July 6, 2023, version of Bard; the July 4, 2023, versions of GPT-4 and ChatGPT-3.5; and the publicly available version of MedAlpaca 7b [22]. We entered prompts individually through the chat interface to evaluate Bard, GPT-4, and ChatGPT-3.5, treating each prompt as a distinct conversation. MedAlpaca differs from Bard, ChatGPT-3.5, and GPT-4 in that it requires users to submit queries or prompts through a Python (Python Software Foundation) script. Consequently, we used a single Python script for each prompt strategy to submit queries for each data set. It is worth noting that Bard has certain limitations compared with ChatGPT-3.5 and GPT-4. Bard has a restricted capacity to handle lengthy queries. Moreover, Bard is more sensitive to noisy input and specific characters. For example, the MIMIC-III data set contained deidentified patients' notes filled with special characters such as "[**Hospital 18654**]" and laboratory results written in shorthand, for example, * *Hgb-9.6* * *Hct-29.7* * *MCV-77* * *MCH-24.9* *. Consequently, to work effectively with Bard, we preprocessed the text by removing special characters and retaining only alphanumeric characters.

Prompting Strategies

Direct (standard prompting) and iterative prompting (chain of thought prompting) [27] are the 2 major prompting methods. Iterative prompting is a promising method for improving LLM performance on specialized tasks; however, it requires a predefined set of manually annotated reasoning steps, which can be time consuming and difficult to create, especially for specialized domains. Most users opt for a direct prompt method to save time and obtain an immediate response. Therefore, to analyze the effect of prompt formats on LLM performance, we assessed each model's performance for every case using the 3 distinct direct prompt strategies outlined in Table 1. These strategies varied from open-ended to multiple-choice formats.

Table 1. Prompt strategies.

Approach	Prompt strategy description	Prompt sample
Approach 1 (open-ended prompt)	In this approach, prompts were formatted in an open-ended fashion. Formatting a prompt using this method allows the model to formulate a hypothesis for the case and explain why and what it thinks is the diagnosis. Here, we scored a model based on its ability to provide the correct diagnosis without additional assistance.	“What is the diagnosis? The case is: A 32-year-old man was evaluated in the emergency department of this hospital for the abrupt onset of postprandial chest pain...”
Approach 2 (multiple-choice prompt)	We formatted prompts as multiple-choice questions, and the LLMs ^a were expected to select a single diagnosis from a list of options. The models were assigned a positive score in this task if they selected the correct diagnosis from the options.	“Choose the most likely diagnosis from the following: Option I: Cholecystitis, Option II: Acute coronary syndrome, Option III: Pericarditis, Option IV: Budd-Chiari syndrome. The case is: A 32-year-old man was evaluated in the emergency department of this hospital for the abrupt onset of postprandial chest pain...”
Approach 3 (ranking prompt)	The prompts were presented as a case and a list of diagnoses to be ranked by the LLMs. Models were assigned a positive score if the correct diagnosis was ranked first in this format.	“Rank the following diagnoses according to the most likely. Option I: Cholecystitis, Option II: Acute coronary syndrome, Option III: Pericarditis, Option IV: Budd-Chiari syndrome. The case is: A 32-year-old man was evaluated in the emergency department of this hospital for the abrupt onset of postprandial chest pain...”

^aLLM: large language model.

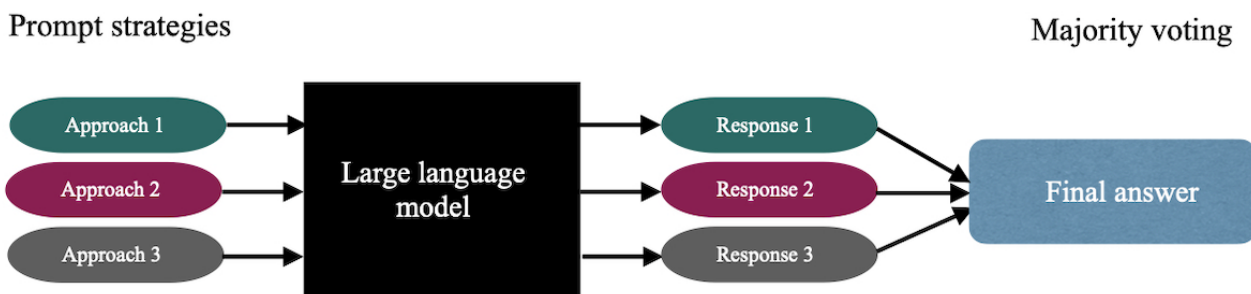

Building upon prior research by Wang et al [28] and Li et al [29], we hypothesized that using a diverse range of prompts can reveal distinct reasoning paths while maintaining consistency in the correct responses regardless of the variations. When using multiple-choice prompts for the DC3 cases, we presented the same options available in the original web-based polls to the models, but on the MIMIC-III data set, we generated random wrong answers that were closely related to the correct diagnosis. We evaluated each LLM by assigning a positive or negative score (binary score) based on their responses. A positive score was assigned only if the models correctly selected the diagnosis for either data set. Conversely, we omitted the options for open-ended prompts, expecting the models to generate the correct diagnosis independently. Positive scores were awarded only if the models accurately provided the correct diagnosis.

Prompt Ensemble: Majority Voting

To safely use imperfect language models, users must determine when to trust their predictions, particularly in critical situations, such as clinical decision support. Therefore, we used a majority voting (prompt ensembling) strategy to enhance the reliability of LLMs’ responses. The majority voting approach involves

aggregating multiple responses and selecting the most common answer. By applying this approach to responses generated by different LLMs, we can observe the level of agreement and infer the consistency in their outputs for a given prompt. Specifically, we hypothesized that using a majority voting approach from the ensemble of prompt responses would boost the reliability of language models, minimizing potential errors, variations, and biases associated with individual prompting approaches. To achieve this, in independent chats, we prompted the LLM with 3 distinct prompt formats per case, as presented in Table 1. Subsequently, we collected the responses of each model and applied majority voting to aggregate its predictions, as presented in Figure 1. In majority voting, each prompt produced a response from the language model, and the majority response was chosen as the final response. In a scenario where all prompt strategies resulted in different responses, we assumed that the model was unsure of that question and scored the final response as a failure case. We limited the number of prompts in the ensemble to 3 because studies by Wang et al [28] and Li et al [29] have shown that we obtain diminishing returns as we increase the overall number of prompts in an ensemble.

Figure 1. Our proposed method contains the following steps: (1) prompt a language model using a distinct set of prompts, (2) obtain diverse responses, and (3) choose the most consistent response as the final answer (majority voting).

Ethical Considerations

No ethics approval was pursued for this research, given that the data was publicly accessible and deidentified. This aligns with

the guidelines outlined in the National Institutes of Health investigator manual for human subjects research [30].

Results

Performance Across Prompt Strategies

Figure 2 reveals the performance of LLMs across different prompts on the DC3 data set. Overall, approach 2 (multiple-choice prompt) yielded the highest score for all 30 cases, with GPT-4 and Bard achieving an accuracy score of 47% (14/30) and ChatGPT-3.5 obtaining a score of 43% (13/30). However, when considering case difficulty, the results varied. On the frequently misdiagnosed cases category, GPT-4 and ChatGPT-3.5 performed better with open-ended prompts (approach 1), scoring 30% (3/10) and 20% (2/10), respectively. In contrast, Bard demonstrated superior performance with multiple-choice prompts for selection and ranking (approaches 2 and 3), achieving a score of 30% (3/10). ChatGPT-3.5 and Bard performed equally well on the rarely misdiagnosed cases category using approaches 2 and 3, achieving a perfect score of 100% (2/2). Furthermore, GPT-4 attained a score of 100% (2/2) but only with approach 2. For the moderately misdiagnosed cases category, all LLMs achieved their best performance with approach 2, scoring 67% (12/18), 56% (10/18), and 50% (9/18) for GPT-4, ChatGPT-3.5, and Bard, respectively. Table S1 in the Multimedia Appendix 1 presents the inconsistencies in the correct responses across the approaches for different cases. For

example, Bard could only diagnose milk alkali syndrome using approach 1 but failed to use other prompt approaches. ChatGPT-3.5 correctly diagnosed primary adrenal insufficiency (Addison disease) with only approach 2, whereas GPT-4 was able to diagnose acute hepatitis E virus infection with only approach 1. These results indicate that no universal prompt approach is optimal for all LLMs when dealing with complex cases.

Results on the MIMIC-III data set in Figure 3 showed that the LLMs also performed best using approach 2 (multiple-choice prompt), with Bard and GPT-4 obtaining scores of 93% (14/15) each and ChatGPT-3.5 obtaining 73% (11/15). Using approach 3 (ranking prompt) resulted in a slight drop in performance for GPT-4 and Bard, with a 6% decrease, whereas the performance of ChatGPT-3.5 dropped by 26%. Approach 1 (open-ended prompt) proved challenging for the LLMs, with scores of 47% (7/15), 60% (9/15), and 27% (4/15) for Bard, GPT-4, and ChatGPT-3.5, respectively. Table S2 in the Multimedia Appendix 1 illustrates that approach 1 was only beneficial to GPT-4 in diagnosing amyloidosis, whereas it was consistently never the sole correct approach for Bard and ChatGPT-3.5. These results aligned with the findings from the DC3 data set and emphasized the varying performances of different models and prompt approaches across tasks.

Figure 2. Results of the diagnostic case challenge collection data set comparing prompt strategies. OpenAI GPT-4 outperformed all other models, achieving the highest score in all 30 cases using the majority voting approach. Furthermore, all large language models except MedAlpaca outperformed the human consensus (denoted by a black dashed line) across all cases, regardless of the difficulty, using at least 1 prompt approach. GPT-4: generative pretrained transformer-4.

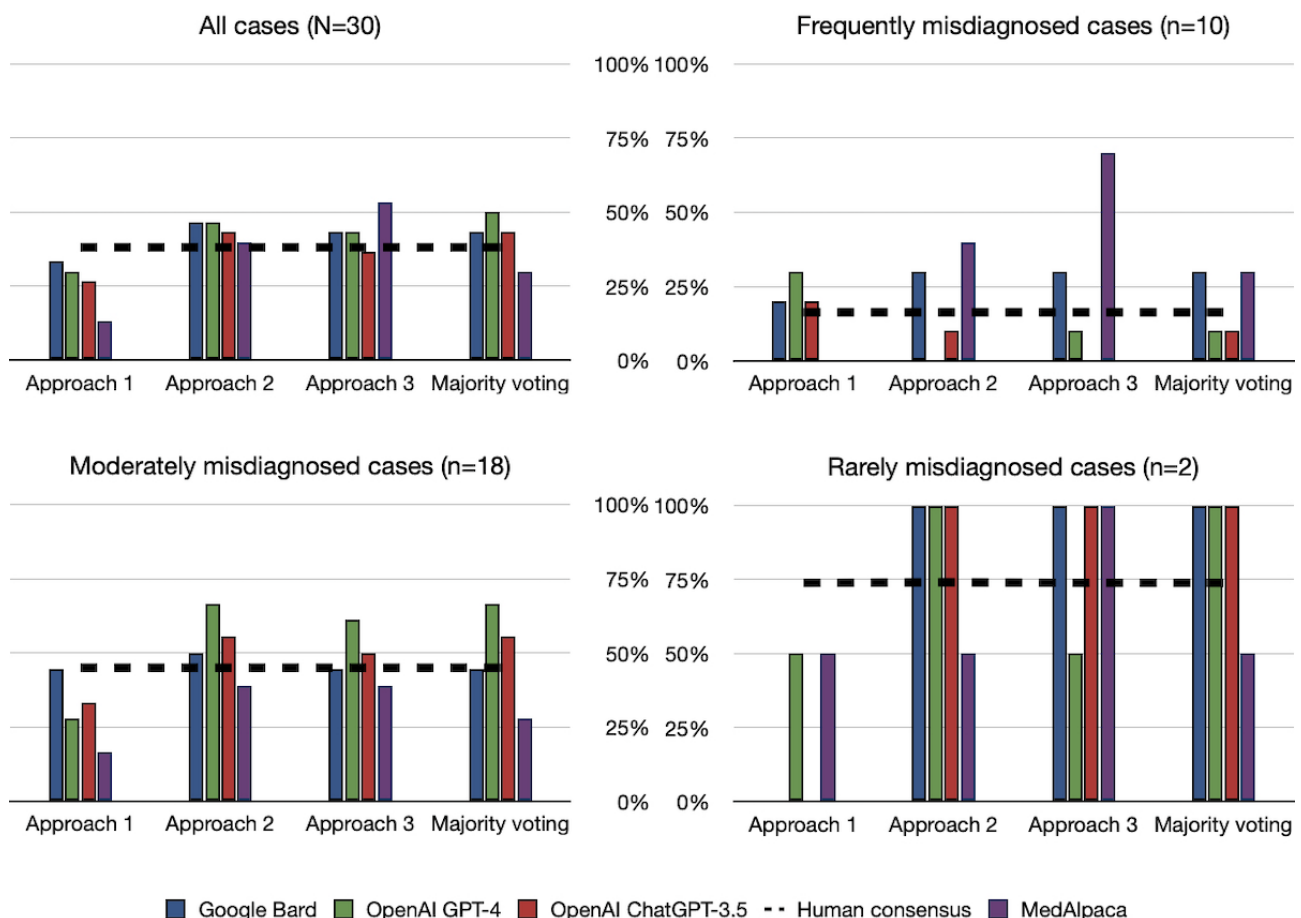

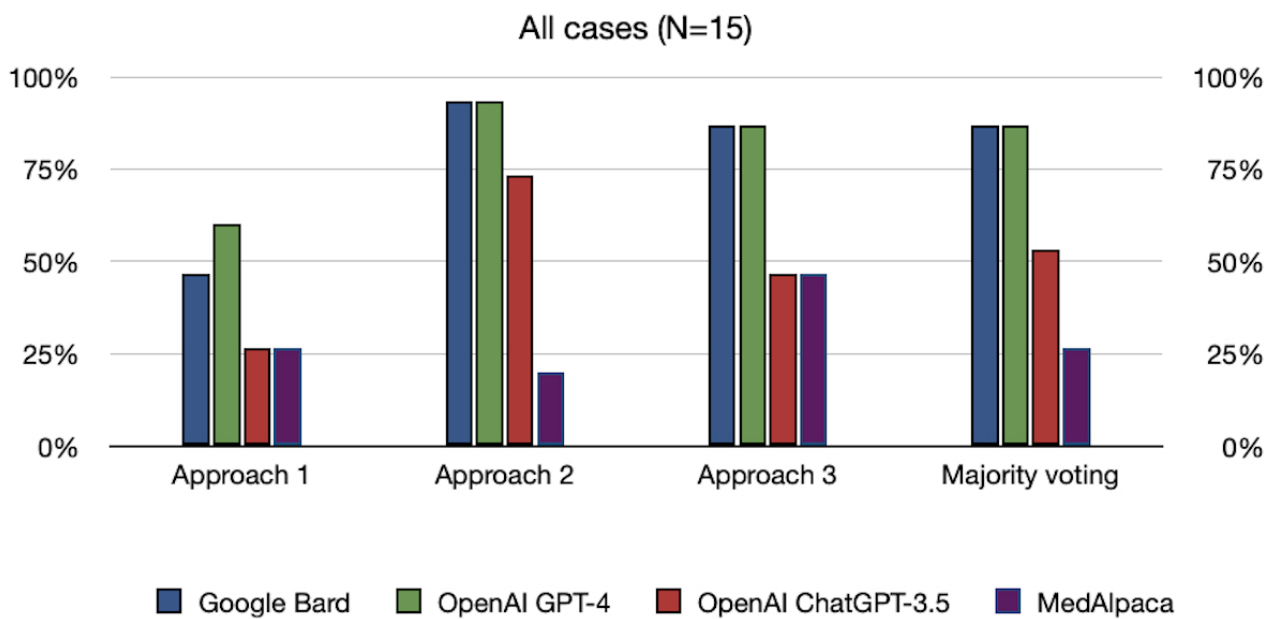

Figure 3. Results of the Medical Information Mart for Intensive Care-III data set across prompt strategies. Approach 1 (open-ended prompt) proved challenging for all the large language models compared with approach 2 (multiple-choice prompt) and approach 3 (ranking prompt).

Performance With Majority Voting

Previous experiments have demonstrated that there is no perfect prompting strategy because LLM users may not know beforehand which prompt will produce a correct response. We used the majority voting approach to estimate consistency, maximize the benefits of different prompt strategies, and enhance the reliability of the LLMs' responses. Figure 2 illustrates the results for all DC3 cases. Majority voting improved the overall performance of GPT-4 from 47% to 50%, whereas the performance of ChatGPT-3.5 remained at 43% because majority voting did not decrease its performance compared with that of approach 2. In contrast, the performance of Bard decreased from 47% to 43% compared with that of approach 2. Summarizing the overall performance based on query difficulty, majority voting resulted in a perfect score of 100% for the rarely misdiagnosed cases category across all the LLMs. For the frequently misdiagnosed cases category in DC3, Bard achieved the highest score with majority voting and multiple-choice prompts, whereas GPT-4 performed best for the moderately misdiagnosed cases category with majority voting and approach 2. In addition, GPT-4 outperformed all other LLMs across all DC3 cases using the majority voting approach, regardless of the case difficulty. This score surpassed the performance of the individual prompt approaches in all cases.

Results on the MIMIC-III data set in Figure 3 showed that, the scores with majority voting were 87% (13/15) for GPT-4 and Bard each and 53% (8/15) for ChatGPT-3.5. These results indicate that the ensemble method did not substantially improve their performance compared with their best individual approach. It is worth noting that although the majority voting approach did not consistently outperform individual approaches in terms of the highest number of correct responses, it did provide a means to consolidate predictions and mitigate potential errors and biases from single approaches.

Comparison With Human Respondents

In the DC3 cases, although the human respondents had the advantage of accessing supporting patient information such as image scans and magnetic resonance imaging, the LLMs consistently outperformed the average human consensus. As shown in Figure 2, using the majority voting approach, all LLMs achieved a higher performance than the human consensus (denoted by a black dashed line), with a minimum margin of 5% across all 30 cases. Specifically, when considering query difficulty, the LLMs demonstrated even greater superiority. In the rarely misdiagnosed cases category, all LLMs surpassed the average human consensus by a substantial margin of 26%. For the moderately misdiagnosed cases category, GPT-4 and ChatGPT-3.5 maintained their advantage over human respondents, achieving a minimum margin of 11% with the majority voting approach. In contrast, only Bard outperformed the human average consensus on the frequently misdiagnosed cases category, with a margin of 14%.

We conducted a Spearman rank correlation test to analyze the pattern in the responses between each LLM and the human respondents. This involved correlating the average percentage of correct responses for each LLM across the prompt strategies with that of correct human responses. The results of the Spearman correlation test revealed that Bard had a relatively weak correlation coefficient of 0.30, whereas GPT-4 and ChatGPT-3.5 exhibited moderate positive correlations of 0.51 and 0.50, respectively. This suggested that the diagnostic performance patterns of GPT-4 and ChatGPT-3.5 aligned moderately with those of the human respondents. The observed correlation in answering patterns between human respondents and LLMs may stem from the inherent data bias present in the training data sets. The LLMs learn from vast amounts of data, and if the training data are biased toward certain diagnostic or decision-making patterns commonly expressed by human physicians, the model is likely to replicate those patterns. Although the correlation suggested that the LLMs have the

potential to be valuable tools in medical education, it is important to note their correlation with human physicians and that the performance of LLMs does not necessarily mean that they are as good as human physicians in diagnosing and treating diseases.

We could not directly compare the performance of human respondents on the MIMIC-III data sets because of the unavailability of data. Overall, the results indicated that the LLMs consistently outperformed the average human consensus in diagnosing medical cases, showcasing their potential as a tool to complement and enhance care quality and education for complex diagnostic cases.

Comparison With MedAlpaca

On the DC3 data sets, Bard, GPT-4, and ChatGPT-3.5 outperformed MedAlpaca across all cases using the majority voting approach by a minimum margin of 13%. MedAlpaca also displayed the worst performance in the open-ended prompts, irrespective of query difficulty. However, when multiple-choice options were provided, MedAlpaca outperformed the other LLMs in the frequently misdiagnosed cases category. Similar to the DC3 data set, MedAlpaca consistently demonstrated its best performance using the ranking prompt on the MIMIC-III data sets. However, its overall performance was significantly poorer than the other LLMs, with each LLM outperforming the model by at least 26% using the majority voting approach. In contrast to the general-purpose LLMs (eg, Bard, GPT-4, and ChatGPT-3.5), investigating the MedAlpaca model was finetuned using diverse medical tasks and assessed using multiple-choice medical examinations. This tailored training approach likely contributed to its notable performance, particularly excelling in DC3 cases (frequently misdiagnosed instances) and demonstrating optimal results in multiple-choice queries.

Qualitative Analysis

In our experiments, we manually observed the responses of each LLM to all our prompts and noted that each LLM consistently justified its diagnosis choice except for MedAlpaca. Specifically, each LLM offered a logical explanation for its chosen response regardless of the prompting strategy. For further investigation, we analyzed each LLM's responses in 3 scenarios: (1) when presented with multiple-choice options containing the true diagnosis and they responded accurately, (2) when their response was incorrect, and (3) when given only incorrect multiple-choice options to pick from. In the first scenario, as presented in [Multimedia Appendix 1](#), all LLMs (eg, Bard, GPT-4, and ChatGPT-3.5) mentioned that their rationale for diagnosing *miliary tuberculosis* was owing to relevant symptoms presented in the case, such as a *history of respiratory illness and the presence of mesenteric lymph nodes and numerous tiny nodules throughout both lungs distributed in a miliary pattern*. This pattern of offering insightful reasons for the likelihood of a diagnosis and explaining why other diagnostic options are less probable is valuable for educational purposes. In the second scenario, we observed that there was a notable disparity in the accuracy of human respondents. Only 6% (217/3624) of the human participants provided the correct response, with most votes (1232/3624, 34%) favoring *ulcerative colitis*, whereas

23% (833/3624) of the human responses opted for *salmonellosis*. Notably, Bard and GPT-4 displayed similar behavior by selecting *salmonellosis*, whereas ChatGPT-3.5 and MedAlpaca chose *ulcerative colitis*.

Another notable finding occurred in the responses of GPT-4 and ChatGPT-3.5. Regardless of the correctness of their chosen diagnoses, these models consistently recommended further tests to confirm their responses. This behavior suggested a general tendency toward advocating additional examinations to validate their diagnoses, potentially reflecting a cautious approach. In contrast, Bard adopted a different approach. Instead of recommending further tests, Bard highlighted that the provided query information supported the diagnosis without suggesting additional confirmatory measures. In the scenario where only incorrect options were given, Bard, ChatGPT-3.5, and MedAlpaca made choices and justified their responses. In contrast, GPT-4 explicitly mentioned that none of the provided options matched the case presentation. Furthermore, GPT-4 suggested a more probable diagnosis and recommended additional testing to explore its feasibility.

Discussion

Principal Findings

Previous studies [4,5] have presented the impressive success of LLMs in standardized medical examinations. We conducted experiments to assess the potential of LLMs as a CME system for rare and complex diagnoses, and our findings demonstrated that LLMs have the potential to be a valuable tool for rare disease education and differential diagnosis. Although LLMs demonstrated superior performance compared with the average human consensus in diagnosing complex diseases, it is essential to note that this does not imply their superiority over physicians. Numerous unknown factors, including the level of respondents' expertise, may influence the outcome of web-based polls. Furthermore, we examined the knowledge capacity of LLMs through open-ended and multiple-choice prompts and found that LLMs, including MedAlpaca, performed better with multiple-choice prompts. This improvement can be attributed to the options provided, which narrowed the search space for potential diagnoses from thousands to a few likely possibilities. Consequently, we surmise that LLMs are not yet ready to be used as stand-alone tools, which aligns with the findings of previous studies [5,17,18]. Our observations revealed the consistent outperformance of general-purpose LLMs over MedAlpaca in various experiments. Their superior ability to provide valuable justifications for making diagnoses was particularly noteworthy, a strength not matched by MedAlpaca. This difference may stem from MedAlpaca's exclusive finetuning and assessment for multiple-choice medical examinations, which slightly differ in format from the clinical cases in our experiments.

A notable finding in the response of LLMs to queries was their consistent provision of coherent and reasoned explanations, regardless of the query format. For instance, when diagnosing *miliary tuberculosis*, all 3 LLMs emphasized that the patient's systemic symptoms, exposure risks, chest radiograph, computed tomography scan findings, and the suspected compromised

immune state collectively support the diagnosis of *miliary tuberculosis*. Furthermore, Bard and GPT-4 ruled out other diagnoses presented in the multiple-choice prompt by highlighting their less typical presentations and lack of certain associated symptoms or risk factors. In addition, the conversational nature of LLMs allows users to ask follow-up questions for further context. These attributes hold great potential for educating users and offering them insights. However, we observed that LLMs provided logical explanations, even when their diagnoses were incorrect. ChatGPT-3.5 and GPT-4 may suggest additional testing to validate their selected diagnosis or use cautious terms like “potential diagnosis.” However, it remains unclear whether these recommendations stem from the models’ internal confidence or whether there are features intentionally designed by the developers for cautious use. The absence of explicit information regarding the level of uncertainty of LLMs for a specific case is concerning as it could potentially mislead clinicians. The ability to quantify uncertainty is crucial in medical decision-making, in which accurate diagnoses and treatment recommendations are paramount. Clinicians heavily rely on confidence levels and probability assessments to make informed judgments [29]. Without an indication of uncertainty, there is a risk that clinicians may trust the logical explanations provided by the LLMs even when they are incorrect, leading to misdiagnoses or inappropriate treatment plans.

Considering the delicate role of clinical decision support, it is essential to address validity and reliability as crucial aspects of uncertainty. Moreover, a reliable system is of paramount importance for medical education. However, the stochastic nature of LLMs introduces doubts among clinicians regarding their reliability. Although a specific metric to quantitatively assess the reliability of the LLMs used in this study is currently lacking, we acknowledge the significance of consistency in achieving reliability. To address this, we used different prompting strategies and implemented a majority voting approach to select the most consistent response from each LLM. After examining the individual prompt strategies, we anticipated consistent responses across strategies for a specific case. However, our findings revealed that the responses of LLMs were sensitive to concrete prompt formats, particularly in complex diagnoses. For instance, ChatGPT-3.5 and GPT-4 performed better with the open-ended prompt (approach 1) in the frequently misdiagnosed cases category of DC3 cases but struggled with similar cases using multiple-choice and ranking prompts (approaches 2 and 3). In contrast, Bard performed better with multiple-choice prompts. These results highlighted that there is no one-size-fits-all prompting approach nor does a single strategy apply universally to all LLMs. Although the majority voting strategy did not yield optimal results for all models across data sets, it served as a means to consolidate responses from multiple prompts and provided a starting point for incorporating reliability.

Several studies [10-12,14,15] have emphasized the significance of enhancing the education of clinicians at all levels to provide better support for rare and complex diagnoses. In this pursuit, the studies by Lee et al [8] and Decherchi et al [31] have highlighted the potential advantages of artificial intelligence

(AI) systems, whereas the studies by Abdullahi et al [25] and Sutton et al [32] have reported a lack of acceptance of AI tools among clinicians. For instance, younger medical students and residents appeared more receptive to integrating technology [33]. One notable reason for this lack of acceptance is that conventional AI systems typically require training before clinicians can effectively use them, which can be burdensome and time consuming [32]. In contrast, conversational LLMs, such as ChatGPT-3.5, Bard, and GPT-4, offer a distinct advantage with their simple interface and dialogue-based nature. These conversational LLMs eliminate the need for extensive training, increasing their potential for high acceptance across all levels of medical practice. Although the exciting ease of use, conversational nature, impressive display of knowledge, and logical explanations of LLMs have the potential for user education and insights, their current limitations in reliability and expressing uncertainty must be addressed to ensure their effective and responsible use in critical domains, such as health care.

Limitations

First, the limitations of the knowledge of ChatGPT-3.5 and GPT-4 to the latest trends and updates in health care (or medical) data till 2021 pose the risk of potentially incomplete information and hamper the effectiveness of the models as a CME tool, especially when addressing emerging diseases. In contrast, although continuous updates to Bard are advantageous for keeping the model up-to-date, this attribute may impact the reproducibility of our study. Second, it is notable that our experiments had a limited scope owing to a small sample size consisting of only 30 diseases from the DC3 data set and 15 cases from the MIMIC-III data set. In addition, although we took precautions to preprocess the MIMIC-III notes to prevent leakage of the final diagnosis, the discharge summaries may still contain nuanced information that could make the diagnosis obvious. Furthermore, the closed nature of the LLMs used in this study restricted our technique for measuring reliability to a majority voting approach, which consolidated responses from diverse prompts. Although majority voting can help to mitigate the variability of LLM output, it is notable that LLMs may still generate different responses for the same prompt. This variability should be considered when interpreting the results of this study. However, when these LLMs are released with an enhanced iteration that allows for finetuning and calibration, future work should incorporate more effective mechanisms to estimate and communicate uncertainty. An example of such an approach could involve assigning a confidence score to the probability score of their responses. This methodology could allow clinicians to make informed decisions regarding whether to accept or reject responses that fall within a desired threshold.

Conclusions

In this study, we conducted experiments to assess the potential of LLMs, including ChatGPT-3.5, GPT-4, and Bard, as a CME system for rare and complex diagnoses. First, we evaluated their diagnostic capability specifically for rare and complex cases. Subsequently, we explored the impact of prompt formatting on their performance. Our results revealed that these LLMs possessed potential diagnostic capacities for rare and complex

medical cases, surpassing the average crowd consensus on the DC3 cases. For selected rare cases from the MIMIC-III data set, Bard and GPT-4 achieved a diagnostic accuracy of 93%, whereas ChatGPT-3.5 achieved an accuracy of 73%. Our findings highlighted that users might discover an approach that yields favorable results for various queries by exploring different prompt formats. In contrast, using majority voting of responses from multiple prompt strategies offers the benefit of a robust and reliable model, instilling confidence in the generated responses. However, determining the best prompt strategy versus relying on the majority voting approach involves a tradeoff between exploration and exploitation. Although prompt

engineering research is continuing, we hope that future studies will yield better solutions to enhance the reliability and consistency of the responses of LLMs. Overall, our study's results and conclusions provide a benchmark for the performance of LLMs and shed light on their strengths and limitations in generating responses, expressing uncertainty, and providing diagnostic recommendations. The insights gained from this study can serve as a foundation for further exploration and research on using LLMs as medical education tools to enhance their performance and capabilities as conversational language models.

Abstract

The communication gap between patients and health care professionals has led to increased disputes and resource waste in the medical domain. The development of artificial intelligence and other technologies brings new possibilities to solve this problem. This viewpoint paper proposes a new relationship between patients and health care professionals—“shared decision-making”—allowing both sides to obtain a deeper understanding of the disease and reach a consensus during diagnosis and treatment. Then, this paper discusses the important impact of ChatGPT-like solutions in treating rheumatoid arthritis using methotrexate from clinical and patient perspectives. For clinical professionals, ChatGPT-like solutions could provide support in disease diagnosis, treatment, and clinical trials, but attention should be paid to privacy, confidentiality, and regulatory norms. For patients, ChatGPT-like solutions allow easy access to massive amounts of information; however, the information should be carefully managed to ensure safe and effective care. To ensure the effective application of ChatGPT-like solutions in improving the relationship between patients and health care professionals, it is essential to establish a comprehensive database and provide legal, ethical, and other support. Above all, ChatGPT-like solutions could benefit patients and health care professionals if they ensure evidence-based solutions and data protection and collaborate with regulatory authorities and regulatory evolution.

KEYWORDS

rheumatoid arthritis; ChatGPT; artificial intelligence; communication gap; privacy; data management

Introduction

In recent years, the communication gap has led to intense relationships between patients and health care professionals. The use of ChatGPT-like solutions in health care has enormous potential to improve the patient-provider relationship, such as patient clinic letter writing [1], medical note-taking and

consultation [2], and rheumatoid arthritis treatment. Although ChatGPT (OpenAI) [3] is not the only solution available, the technology has generated a lot of traction due to its advanced features, such as the ability to enhance rule-based chatbots.

However, it is important to note that ChatGPT-like solutions should not be viewed as a stand-alone solution but as an integrated interface in a larger ecosystem that allows access to

multiple data sources. In terms of the patient-provider relationship, the use of ChatGPT can enable more fluid and effective communication between the 2 parties, which can improve the quality of care. In particular, the use of ChatGPT-like solutions in the context of methotrexate treatment for rheumatoid arthritis could have a significant impact. This viewpoint paper proposes a new relationship between patients and providers—“shared decision-making”; explains the potential of ChatGPT-like solutions in improving the patient–health care professional relationship from the clinical and patient perspectives; and suggests the importance of establishing a comprehensive database to promote the implementation of “shared decision-making” between patients and health care professionals.

Toward Shared Decision-Making

In conventional medical settings, the relationship between patients and health care professionals was not equal, mainly because of the huge information gap between them, since patients lacked medical knowledge and decision-making capacity. In recent years, the rapid development of ChatGPT possesses enormous potential to bridge the information gap and improve the relationship between patients and health care professionals. For instance, ChatGPT could help provide the risk-benefit analysis of different treatment options, assisting health care professionals and patients to understand the advantages and disadvantages of each option and then make informed decisions together. It could also assist patients in understanding the complex medical jargon and technical details and provide information about the disease, treatment options, potential risks, and expected outcomes, allowing patients to participate in making informed decisions with health care professionals together. ChatGPT-like solutions allow bilateral communications between patients and health care professionals toward shared decision-making.

Clinical Perspective

From the clinical standpoint, early diagnosis of rheumatoid arthritis is crucial [4] for health care professionals and should be based on clinical examinations and biological results such as serological tests [5]. However, the differential diagnosis of complex diseases such as rheumatoid arthritis–associated interstitial lung disease [6] remains a major concern [7], as it is responsible for a significant increase in mortality [8]. ChatGPT-like solutions could bring complementary support to diagnose the disease and predict its evolution. Thus, to the query “What could be the reason for cough and dyspnea in a patient with rheumatoid arthritis?” ChatGPT suggests interstitial lung disease in the first place. By integrating external data on risk factors (age, sex, and smoking), biological results (pulmonary function testing, autoantibodies, and biopsy), and imaging (high-resolution computed tomography and ultrasound) [6], ChatGPT-like solutions can assist in suggesting additional tests and confirming the diagnosis.

The initiation of treatment for rheumatoid arthritis should be in accordance with the latest official recommendations, such as those from the European League Against Rheumatism [9] and

the American College of Rheumatology (ACR) [4]. An advanced tool such as ChatGPT provides clinicians with exhaustive information on the latest guidelines for the management of rheumatoid arthritis. For instance, if a clinician asks “What are the current guidelines for treating rheumatoid arthritis according to the ACR?” ChatGPT can retrieve the key points of rheumatoid arthritis management in accordance with the official ACR guidelines [4]. However, in the specific case of a request regarding recommendations for treating rheumatoid arthritis–associated interstitial lung disease, ChatGPT erroneously refers to nonexistent ACR guidance [10]. Currently, the tool has limitations, such as data exclusion after 2021 and response size limits.

The determination of a patient’s drug dose by the clinician is based on a comprehensive evaluation of the results of the biological tests and clinical examination. However, dose adjustment may not always be performed according to a standardized procedure and evidence-based solution, although this is crucial to ensure the effectiveness and tolerability of the treatment for the patient. Methotrexate is the most common treatment for rheumatoid arthritis, and an initial dose of 7.5-15 mg once a week is recommended, followed by a gradual increase in dose. However, poor patient adherence and nonpersistence to methotrexate therapy have been reported [11] mainly due to low dose tolerance. Optimization of methotrexate dose is therefore essential for treating rheumatoid arthritis [12]. The use of methotrexate monotherapy has shown similar efficacy to the combined use of methotrexate monotherapy with biologic disease–modifying antirheumatic drugs [13]. Process automation and integration of complementary data, based on solutions such as ChatGPT, could improve outcome prediction, contribute to drug dose optimization, and thus reduce costs to the health care system.

Access to information on ongoing clinical trials and their results would enable clinicians to propose treatments for people with rare conditions in rheumatoid arthritis. Compiling data on clinical trials and patient characteristics would allow clinicians to propose alternatives, for example, for patients who have failed current therapies. Identifying subpopulations would facilitate patient recruitment and bring more effective and safer drugs to market. However, one challenge is to deidentify data to comply with the US Health Insurance Portability and Accountability Act (HIPAA) [14]. As such, it is important for clinicians to prioritize patient privacy and confidentiality when accessing and using such data. In addition, it is necessary for further interdisciplinary research to improve the accuracy and persuasiveness of artificial intelligence (AI) chatbots to influence patients’ behaviors [15]. Moreover, the application of AI and machine learning in health care should still be regulated by establishing norms to reduce bias and reflect the real problems [16].

Patient Perspective

From the patient’s perspective, it allows easy access to a large volume of information with a certain degree of scientific evidence, which improves the patient’s knowledge of rheumatoid arthritis and their health literacy. ChatGPT-like

solutions thus contribute to dealing with the proliferation of unreliable sources of emerging information and widespread disinformation [17]. It is also a tool that could not only enable empowerment by acting interactively throughout the care pathway but also promote patient adherence to treatment. However, some concerns persist regarding the lack of supervision of this type of solution and the liability involved [18]. For example, in the case of methotrexate side effects, to the query “I have gastrointestinal problems and fatigue, is this related to my methotrexate intake?” ChatGPT suggests that the doctor can adjust the dosage. It does not provide suggestions to state that concomitant folate or folic acid changes would reduce toxicity. It also raises questions about the risk of patients adjusting their own dosage. ChatGPT-like solutions can strengthen expert patients’ collaboration, allowing the cocreation of care pathways; however, it can also be a source of conflict by pitting the tool’s and the caregiver’s advice against each other. Therefore, it is crucial to better supervise this tool from the beginning of its development, in order to clearly distinguish between its general public and medical use and to define the responsibilities of each. The use of ChatGPT-like solutions can improve communication and access to information for patients with rheumatoid arthritis but must be carefully managed to ensure safe and effective care.

A ChatGPT-like solution allows the patient to have continuous access to information in an interactive way that promotes understanding outside the clinical setting. This solution can play an important role in therapeutic education by providing information on the self-management of rheumatoid arthritis, on a drug such as methotrexate, or on the administration methods (oral and subcutaneous). Therefore, the query of “What precautions should be taken when taking methotrexate?” could instantly provide basic and exhaustive information (taking it with food, avoiding alcohol, staying hydrated, using contraceptives, etc) and could contribute to therapeutic education [19]. In addition, a ChatGPT-like solution could be used to communicate medical information on potential benefits and assist in administration [20], for example, when modifying the route of administration of methotrexate. This would have an impact on facilitating the acceptability of subcutaneous methotrexate, allowing better bioavailability and clinical efficacy. It would also reduce the time required to initiate treatment and avoid the use of biologics, thus having a significant impact on health care costs [21].

Further integration and analysis of patient requests would also accelerate the transition to more personalized medicine. ChatGPT-like solutions could identify patient profiles and adapt communication strategies to overcome resistance and nudge behavior. These solutions will have to be adapted to each country in terms of public health systems and beliefs.

Establishment of a Comprehensive Database

The database is one of the critical elements of digital infrastructure for digital technology applications [22], especially AI-based solutions that require huge amounts of data to achieve more accurate results. However, using AI-based technology can

be limited by the nontransparent learning process, difficulties in explanation and validation, and the influence of improper data [23]. Hence, the establishment of a comprehensive database, which is sourced from real-world data and updated on time and precisely, could contribute to overcoming limitations caused by insufficient data and support evidence-based clinical applications.

In recent decades, the Taiwan government launched the National Health Insurance (NHI) system that collected health-related data of health care providers, citizens, and legal residents. Since its establishment, the NHI database has been continuously improved by using the latest technologies to accommodate the increasing needs. During the COVID-19 pandemic, the NHI database successfully supported the Taiwan government in tracking patients, distributing face masks, and containing the infections [24,25].

On the other hand, using mobile health tools also contributes to the establishment of a comprehensive database. In recent years, tools such as the Apple Watch have been widely used to collect data about health conditions and identify possible illnesses of people. Mobile health tools allow the collection active data and passive data, which could better inform the health condition of the people [26].

Above all, the establishment of a comprehensive database is fundamental to applying AI-based solutions in the digital governance of health care. Moreover, applying AI-based solutions and other digital technologies should also be accompanied with comprehensive planning and flexible strategies to achieve effective digital governance in health care [22].

Conclusions

In conclusion, ChatGPT-like solutions have the potential to improve the patient-provider relationship through “shared decision-making.” ChatGPT solutions should optimize the patient’s care pathway while improving the patient’s experience of using methotrexate in rheumatoid arthritis. However, there is a need to ensure evidence-based solutions and quantify these benefits. In the future, we may question the compatibility of the business model of mass-market solutions with health care system purposes, particularly concerning data protection. Using federated learning might be a way for developers to overcome this limitation. The implementation in a specific health care context should increase in the coming years with the development of solutions in specific domains such as Bio-Generative Pre-Trained Transformer. A deployment in clinical settings will require collaboration with regulatory authorities and potentially an evolution of the software as a medical device regulatory framework [27].

The need to include individuals in the design of these solutions is also crucial to consider from an efficiency point of view to avoid certain biases and from an ethical point of view. This solution also facilitates access to health care information for the entire world population in pursuit of the sustainable development goals set by the United Nations.

Abstract

Background: Achieving physical activity (PA) guidelines' recommendation of 150 minutes of moderate-to-vigorous PA per week has been shown to reduce the risk of many chronic conditions. Despite the overwhelming evidence in this field, PA levels remain low globally. By creating engaging mobile health (mHealth) interventions through strategies such as just-in-time adaptive interventions (JITAI) that are tailored to an individual's dynamic state, there is potential to increase PA levels. However, generating personalized content can take a long time due to various versions of content required for the personalization algorithms. ChatGPT presents an incredible opportunity to rapidly produce tailored content; however, there is a lack of studies exploring its feasibility.

Objective: This study aimed to (1) explore the feasibility of using ChatGPT to create content for a PA JITAI mobile app and (2) describe lessons learned and future recommendations for using ChatGPT in the development of mHealth JITAI content.

Methods: During phase 1, we used Pathverse, a no-code app builder, and ChatGPT to develop a JITAI app to help parents support their child's PA levels. The intervention was developed based on the Multi-Process Action Control (M-PAC) framework, and the necessary behavior change techniques targeting the M-PAC constructs were implemented in the app design to help parents support their child's PA. The acceptability of using ChatGPT for this purpose was discussed to determine its feasibility. In phase 2, we summarized the lessons we learned during the JITAI content development process using ChatGPT and generated recommendations to inform future similar use cases.

Results: In phase 1, by using specific prompts, we efficiently generated content for 13 lessons relating to increasing parental support for their child's PA following the M-PAC framework. It was determined that using ChatGPT for this case study to develop PA content for a JITAI was acceptable. In phase 2, we summarized our recommendations into the following six steps when using ChatGPT to create content for mHealth behavior interventions: (1) determine target behavior, (2) ground the intervention in behavior change theory, (3) design the intervention structure, (4) input intervention structure and behavior change constructs into ChatGPT, (5) revise the ChatGPT response, and (6) customize the response to be used in the intervention.

Conclusions: ChatGPT offers a remarkable opportunity for rapid content creation in the context of an mHealth JITAI. Although our case study demonstrated that ChatGPT was acceptable, it is essential to approach its use, along with other language models, with caution. Before delivering content to population groups, expert review is crucial to ensure accuracy and relevancy. Future research and application of these guidelines are imperative as we deepen our understanding of ChatGPT and its interactions with human input.

Introduction

Physical inactivity is a key modifiable risk factor for many chronic conditions, including cardiovascular disease, type 2 diabetes, and cancers, throughout the lifespan [1]. Despite this evidence, adults and adolescents alike are not consistently meeting the recommended guidelines to prevent developing these chronic conditions [2]. Previous studies have shown that 150 minutes of moderate-to-vigorous physical activity (MVPA) can reduce the risk of all-cause mortality by at least 30%, along with reducing the risk for chronic conditions such as cardiovascular disease (30%), colon cancer (20%), and breast cancer (14%) [3]. Although many chronic diseases affect adults, healthy lifestyle habits need to be developed early from childhood. Children aged 8 to 12 years are more flexible than adults in their ability to change behaviors because they are just beginning to develop self-regulation skills, habits, and identities for healthy living [4,5]. Thus, many countries such as Canada [6], the United States [7], and the United Kingdom [8] have set guidelines recommending 60 minutes of MVPA per day for children 17 years and younger [2]. However, despite these recommendations, physical inactivity is prevalent among children, with less than one-quarter of children meeting the guidelines in countries such as Canada [9] and the United States [9]. Consequently, promoting regular PA to prevent chronic diseases and maintain lifelong health has been a key priority for governments worldwide.

Recent studies suggest that family-based PA programs can be an effective strategy to improve PA levels in children [10,11]. These programs focus on providing guidance for parents to support their child's PA (eg, encouragement, providing opportunity, and logistic support) [12]. With advancements in mobile health (mHealth) technologies and improved access to smartphones, emerging evidence indicates that PA interventions delivered through mHealth technology can be effective while improving scalability and personalization. However, the effectiveness and engagement of interventions vary depending on the intervention design and the degree of tailoring [13,14]. Studies have demonstrated that tailored mHealth interventions are more effective in improving behavior and health outcomes compared with nontailored interventions [15]. A recent advancement in tailored mHealth interventions is the development of just-in-time adaptive interventions (JITAI), which use mHealth technology to assess the dynamically changing needs of individuals and deliver tailored support in real time [14,16]. Thus far, JITAI have shown great promise in promoting PA among adults [17], university students [18], and chronic disease populations [19]. Further, innovative mHealth "no-code" development platforms, such as Pathverse, have made the development and implementation of JITAI much easier and cost-effective [20,21]. However, the development of content for JITAI can be extremely labor-intensive due to the need to create various versions of health-related content for different tailored algorithms. Although the documentation of

content creation timelines for PA JITAI is in its infancy, a typical timeline for PA content creation from the formative phase to pilot testing reportedly ranges from 12 [22] to 15 months [23,24].

Specific to JITAI, the typical process of creating evidence-based and engaging content for these mHealth interventions typically involves the following steps [21,25]: (1) defining the behavior change theories and behavior change techniques (BCTs) required for the intervention [26]; (2) gathering evidence from various sources, such as previous literature, public health sources, gray literature, and blogs, and then adapting it to suit the needs of the intervention and deliver it through the chosen medium; and (3) writing content that is engaging and matches the literacy level of the target population for the app. These steps can often be time-consuming, with the need for researchers to follow these steps iteratively and repetitively for the duration of the design of the intervention. Further, despite the consideration of these steps, several challenges still arise in the development of JITAI content. Existing studies have identified limitations, such as the need for more extensive content within interventions, struggles in creating novel and meaningful messages, and challenges in tailoring messages to diverse user preferences [27,28]. These studies have also recognized the resource constraints in developing content to meet these needs and the complex, multidimensional nature of creating tailored and engaging content for their sample. Therefore, an artificial intelligence (AI) tool such as ChatGPT (OpenAI) [29] can be extremely useful in making the process of generating JITAI content for mHealth interventions faster and more cost-effective. ChatGPT offers a solution to the need for more content within interventions by leveraging its vast training data and the ability to generate a diverse set of messages efficiently. Further, its generative capabilities and the ability for users to continually prompt new rules address the challenge of creating novel content, reducing the risk of messages being perceived as overly simplistic.

ChatGPT was first launched by OpenAI in November 2022 and is an open AI language model that generates human-like responses to text-based prompts [30]. It can understand and generate responses in various languages, as well as debug code, write stories in different genres and lengths, summarize information from complex texts, offer explanations on various topics, and even reject answering inappropriate prompts [31]. Unlike other generative large language models (LLMs), ChatGPT stands out as the inaugural member of a series of highly scaled LLMs that attain state-of-the-art performance with minimal need for fine-tuning [32]. Further, ChatGPT is highly sophisticated in that it is able to provide continuous dialog by remembering what the user has said earlier in the conversation thread [33].

Although ChatGPT hosts an impressive suite of features and capabilities, there are also several ethical and privacy concerns

to keep in mind while using this service. First, it is important to note that ChatGPT “learns” its information from human input. This is subject to error and is limited based on what others have input into its system. Further, when generating health information content, in particular, this LLM has been extensively trained with data up to 2021, thus limiting some of the relevance and accuracy of current practices [34]. Second, ChatGPT stores its data in the United States, which, depending on the type of information being input into the United States, may be subjected to privacy concerns based on US freedom and privacy laws. To build on this consideration of data storage, it is crucial not to input any personal health information or other sensitive data into ChatGPT, as this LLM continues to learn from text prompts.

Since its inception, ChatGPT has been widely cited in various bodies of behavioral science literature as a virtual assistant, chatbot, and language translation tool [35]. To generate output from the program, a concept called prompt engineering is one method that explains how ChatGPT generates output [36]. In LLMs, a prompt is defined as an instruction to the model that customizes, enhances, or refines the output [37]. However, there is currently a lack of studies examining the feasibility of using ChatGPT to help develop intervention content for JITAI aimed to promote PA when given a behavior change theory and a behavior target outcome.

Thus, the primary objective of this paper was to present an autoethnographic case study that explored the feasibility, including the acceptability and ease of use, of using ChatGPT to create content for a family-based PA JITAI mobile app. The secondary objective was to describe lessons learned and future recommendations for using ChatGPT in developing mHealth intervention content.

Methods

Study Design

This case study consisted of 2 phases, which took place from March 1, 2023, to April 30, 2023. In phase 1 (0-2 months), we used ChatGPT-3 to develop a 10-week family-based PA JITAI. In phase 2 (3-4 months), we described lessons learned based on our experience of using ChatGPT in phase 1 and provided future recommendations for using ChatGPT in the development of mHealth interventions.

Ethical Considerations

This paper outlines the procedural aspects of using ChatGPT for content generation for a subsequent study. Given that it operates independently without involvement of human participants or sensitive data, formal ethics approval from our institution was deemed unnecessary.

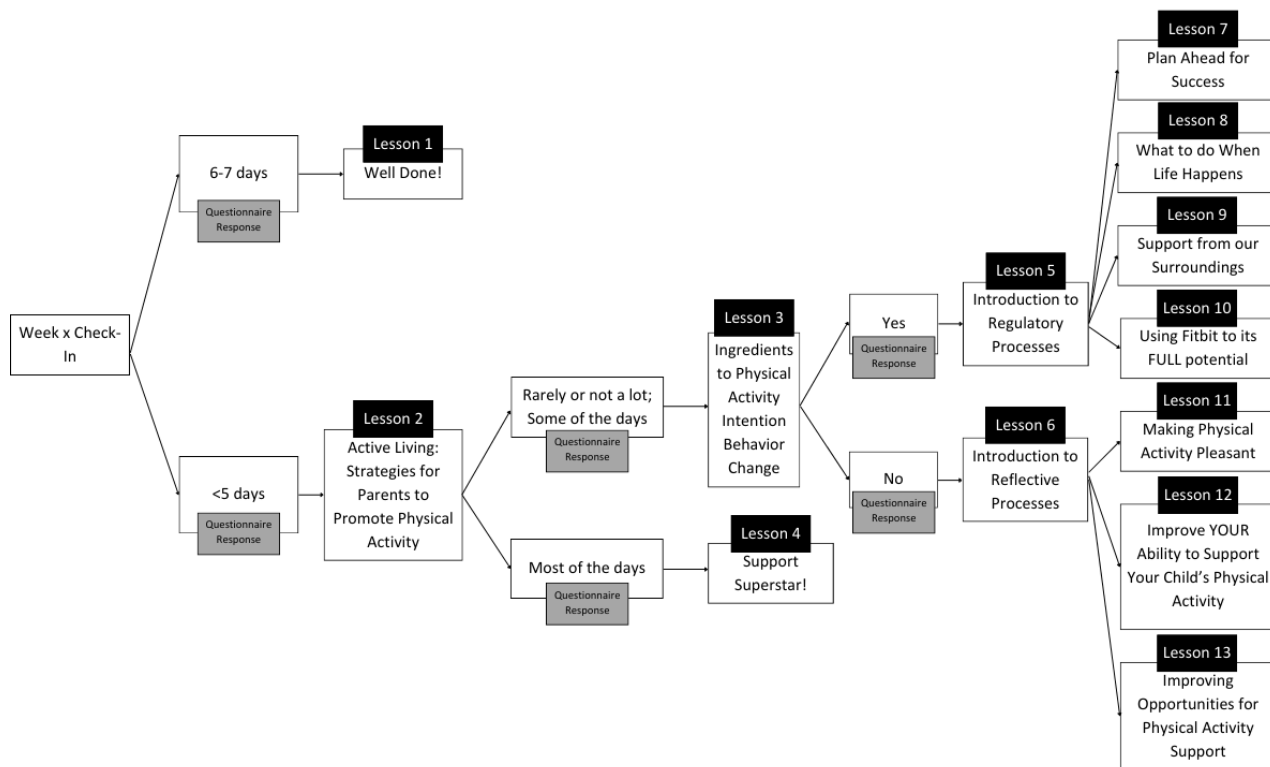

Phase 1

We explored the feasibility of using ChatGPT to create content for the PA JITAI mobile app. To determine the feasibility of

using ChatGPT to rapidly create JITAI content, we used an autoethnographic case study approach [38]. This method enabled the researchers (AW and SL) to reflect on their experience of using ChatGPT. While using ChatGPT, the researchers created field notes and had a meeting to discuss their independent experiences with using ChatGPT-3. Specifically, we reflected on the acceptability and ease of use as key areas of focus for feasibility [39]. Results of the meeting were themed into acceptability and ease of use of using ChatGPT. Assessing acceptability metrics involved reflecting on the satisfaction of the response generated by ChatGPT. The ease-of-use assessment involved reflecting on ChatGPT usability [39]. In this phase, we used 2 tools, Pathverse and ChatGPT. Pathverse is a no-code app builder platform that supports mHealth research [20,40]. It consists of a web portal for researchers to create engaging mobile app interventions with “drag and drop” features instead of coding. The content is then instantly displayed on the Pathverse mobile app. We used ChatGPT-3 to generate the content needed to be added to Pathverse. To gather feasibility data, we generated intervention content to support parents to help their child (8-12 years of age) to be physically active.

The content generated for this app was developed based on the Multi-Process Action Control (M-PAC) framework [41,42]. The M-PAC framework addresses the intention-behavior gap through the understanding that ongoing reflective processes (ie, affective attitude and perceived opportunity) and regulation processes (ie, behavioral and cognitive tactics to maintain intention focus) are necessary for the intention to become an action [41]. Specific to a JITAI, the M-PAC framework was selected as the framework for this intervention to dynamically and contextually address users’ failed intentions to be physically active. Thus, the just-in-time intervention options can be tailored to the specific circumstances of the individual, aligning with either the reflective, regulatory, or reflexive process [41,42]. The M-PAC framework was additionally chosen as we have seen success with this framework and its associated BCTs (ie, action planning, repetition, and habit formation) in previous family-based PA programs [43]. To address these circumstances, our research team created decision tree algorithms to tailor the family lessons and challenges recommended throughout the weeks. The algorithms were designed using the M-PAC framework and take into consideration (1) child MVPA minutes, (2) parent support behavior, and (3) parent self-efficacy and motivation for supporting their child’s PA (Figure 1). Based on the decision tree, weekly tailored lessons needed to be created to target each M-PAC construct. Topics included parental support, affective attitudes toward supporting their children’s PA, capability, opportunity, self-monitoring of PA, and restructuring the environment for PA. These topics stemmed from previous research for family-based PA interventions using the M-PAC framework [43]. With these considerations, a variety of prompts were created based on these topics.

Figure 1. Names of modules in the decision tree algorithm for personalized lessons.

There are various components to consider when generating a prompt for ChatGPT. Specific to academic uses of ChatGPT, the elements to be included in a prompt include an instruction (ie, an overview of the output you would like to receive), context (ie, other background information to help tailor the output), input data (ie, additional specifications for the output that may include its strengths or limitations), and output indicator (ie, how you would like the output to be presented, including word count and paragraph format) [44]. When creating a prompt for this case study, we included the target behavior and the M-PAC framework, with each output to be delivered in bullet point form. Once the content was created, we then used the Pathverse mHealth no-code app design tool to develop the JITAI app [20,38-40]

Phase 2

We summarized lessons learned and future recommendations for using ChatGPT in the development of mHealth interventions. Our team identified common themes and patterns emerging from the process of creating the JITAI content using ChatGPT. We then compared our data with previous literature to develop recommendations for future use. This involved a literature search to identify relevant studies and lessons learned from using ChatGPT in mHealth interventions. The primary aim of the literature search was to gather a wide range of insights into the acceptability, including the application of ChatGPT and its effectiveness in this context and challenges associated with integrating ChatGPT into mHealth interventions to refine our recommendations.

Results

Phase 1: Exploring the Feasibility of Using ChatGPT to Create JITAI Content

The results of phase 1 are first reported on how the researchers (AW and SL) used ChatGPT to generate content, followed by an analysis of the feasibility of the use of ChatGPT in this context. Overall, we created 13 lessons with the help of ChatGPT in phase 1. Figure 2 displays an example of how this content was displayed in the mobile app. We provided specific prompts about the length of the content generated, the target constructs of the M-PAC framework, the tone of the lesson, and the literacy levels needed. We used multiple question prompts to optimize text output. Table 1 provides examples of prompts used for different lessons. We started with broad prompts (eg, explain the various constructs in the M-PAC framework) and then used specific prompts based on the output (eg, provide specific fun examples to help parents improve opportunities to support child PA; Table 1). After the prompts were input into ChatGPT, the output was copied into a separate document for review by the researchers (AW and SL). If more or alternate content was needed, prompts such as “provide additional information about [this topic]” were used. To ensure that the output given by ChatGPT was relevant and accurate, we referred to previous literature and previous content examples following the M-PAC framework [21,45,46]. Once the content was deemed acceptable and accurate by the researchers, it was uploaded to the Pathverse platform. This step additionally involved creating graphics to include along with the text responses and formatting the content into different app “pages” with fewer than 400 characters per page of the mobile app.

We evaluated the acceptability of ChatGPT for creating mHealth content by reflecting on content accuracy, relevance, and tone. Both researchers found that ChatGPT demonstrated an acceptable level of accuracy and relevance and provided relevant responses to the prompts. However, on some occasions, ChatGPT provided false academic references. This is a serious issue that needs to be addressed to prevent misinformation. Thus, both authors reflected the need to place a filtering mechanism to ensure that the content generated was appropriate. Furthermore, some of the answers lacked specificity (eg, provide examples of PA programs in my area). This may be due to the fact that ChatGPT-3 was trained using data up to September 2021. Finally, we found the tone of ChatGPT responses to be acceptable for research purposes. The overall tone matched the prompt given (eg, write in a fun and positive voice). Overall, ChatGPT did not generate any inappropriate content. There is

an evident need to provide clear prompts in order for ChatGPT to provide optimal responses. Additionally, multiple questions are often needed to optimize ChatGPT responses. The researchers additionally agreed that providing a role to ChatGPT, for example, telling the LLM that it is a health researcher delivering a family-based PA intervention, may have further refined the tone and quality of the response given.

When reflecting on the feasibility of implementing ChatGPT for this case study, we (AW and SL) found ChatGPT to be easy to use. Both researchers (AW and SL), with varying levels of technical expertise, found the user interface to be intuitive. The ease of use also allowed us to test various prompts to help optimize the ChatGPT responses. Overall, we found that minimal training or prior experience is needed to use this tool, and it has the potential to make it widely accessible for researchers.

Figure 2. Screenshots of physical activity content generated by ChatGPT in the mobile app Pathverse.

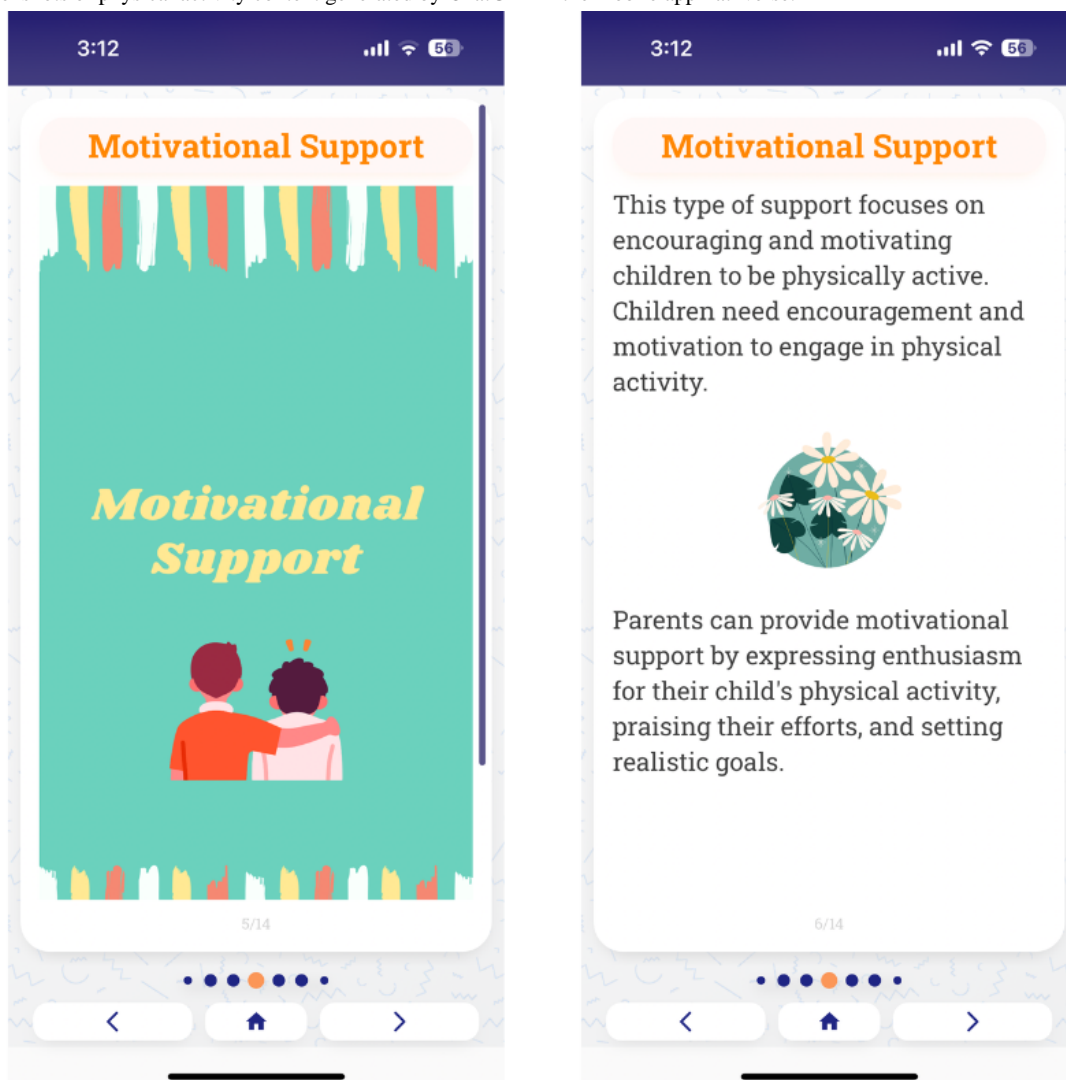

Table 1. Prompts and responses from a conversation with ChatGPT in generating content for a 10-week family-based physical activity mobile app.

Prompt entered	ChatGPT response
Write a fun to read article about the role of parental capabilities to support for child physical activity based on the M-PAC ^a framework	<ul style="list-style-type: none"> Are you struggling to find ways to support your child's physical activity? Do you want to improve your parental capabilities to make physical activity a fun and regular part of your child's life? Look no further than the M-PAC framework, which provides a roadmap for parents to support their child's physical activity. The M-PAC framework stands for Multi-Process Action Control, and it emphasizes the importance of three key components for parents to successfully support their child's physical activity: instrumental support, regulatory support, and motivational support. Instrumental support refers to the tangible resources and skills that parents provide to support their child's physical activity. This could include things like providing transportation to and from activities, purchasing sports equipment, or enrolling your child in a physical activity program. Regulatory support focuses on creating an environment that supports physical activity. This could include setting rules and boundaries around screen time, creating a routine for physical activity, or providing healthy food options to fuel physical activity. Motivational support is all about fostering a positive attitude towards physical activity. This could include providing praise and encouragement, setting goals, and finding ways to make physical activity fun and enjoyable.
Provide specific fun examples to help parents improve their capabilities for supporting child physical activity in bullet points	<ul style="list-style-type: none"> Certainly! Here are some specific fun examples to help parents improve their capabilities for supporting child physical activity: <ol style="list-style-type: none"> Instrumental Support: <ul style="list-style-type: none"> Have a weekly family game night that involves physical activity such as charades, Pictionary or dance party. Organize a scavenger hunt with physical activity challenges for your child and their friends. Plan a family hike or outdoor adventure at a nearby park or nature reserve. Regulatory Support: <ul style="list-style-type: none"> Start a vegetable garden together and teach your child the importance of physical activity and nutrition for a healthy lifestyle. Use a fitness tracker or pedometer with your child to encourage them to walk more and set goals for daily steps. Plan a family bike ride or roller skating adventure on a weekend afternoon. Motivational Support: <ul style="list-style-type: none"> Make a fun reward system for reaching physical activity goals, such as a family outing to a local amusement park or water park. Watch sports games or videos of active events with your child and talk about the benefits of physical activity for overall health. Encourage your child to invite friends over for a game of soccer, basketball or other team sport to promote socialization and physical activity. <p>By incorporating these fun examples into your family's routine, you can improve your capabilities for supporting your child's physical activity and make healthy habits a fun and rewarding part of your family's lifestyle.</p>

^aM-PAC: Multi-Process Action Control.

Phase 2: Recommendations for the Future Use of ChatGPT

Overview

On the basis of our experience in developing the above content and based on previous research [21,25,47], we have compiled the following recommendations for using ChatGPT for similar purposes. First, a 6-step recommendation was proposed to help make the process of using ChatGPT more efficient for future research. These steps included defining the target behavior for the intervention, applying behavior change theory, creating the intervention structure, inputting this information into ChatGPT, refining the output, and customizing the content to be delivered to the target population. Second, we discussed ethical considerations for the use of ChatGPT in this research space. Lastly, we discussed transparency with using ChatGPT in academic research.

Step 1: Determine Target Behavior

The first step of these guidelines involves determining a target behavior or behaviors for the target population of your intervention. This could be based on previous research for certain demographic groups or based on a gap in the current literature. The selected target behavior defines the purpose of the intervention and the outcomes on which the intervention will be assessed [25]. This is considered an essential first step as it will guide the remaining steps of these recommendations.

Step 2: Ground in Behavior Change Theory

The second step recognizes the need to deliver digital health content grounded in behavior change theory. Based on previous literature and considering the target behavior selected in step 1, it is advised to select a health behavior theory to guide the intervention. Thus, constructs of the behavior change theory must be considered when searching for and developing digital health intervention content. Further, other elements of the intervention, such as BCTs, to strengthen the behavior change theory [26] should be considered during this step.

Step 3: Design Intervention Structure

Step 3 involves designing the intervention structure. In this step, the length of the intervention and the length and amount of content to be delivered should be considered first. After this information has been determined, it is recommended to consider the medium of delivery of the digital health intervention content. Previous research has shown varying success for both web-based interventions and mobile-based interventions [48,49]. Additionally, there are important considerations for best practices with delivering content through these different mediums, which are explored later in this development process.

It is important to note that this step may involve an additional agenda. Examining previous literature, using participatory action research or co-design principles, or other methods may be necessary to ensure that you are gathering content that will be both engaging to the participants and promoting adherence to the target behavior.

Step 4: Input Intervention Structure and Behavior Change Constructs Into ChatGPT

The next step is to input the information gathered from steps 1 to 3 and create varying prompts into ChatGPT. If this is your first time logging into ChatGPT through OpenAI, you will need to create a free account. Once your account has been created, you may type your prompt into the text box at the bottom of the screen. Determining an optimal prompt to input includes considering the target behavior, the proposed structure of the intervention, the behavior change theory and its constructs, and BCTs. Further, it is important to consider the rules in which ChatGPT delivers its output, for instance, whether you would prefer the response to be in paragraph form or bullet points. This step is iterative as you receive responses and continue to modify your prompt until you receive the desired output. Additionally, it has been previously recommended to consider assigning a role and tone for ChatGPT to embody in its response or to provide a similar example, when available [50].

Step 5: Revise the Output of ChatGPT

This step involves revising the response received from ChatGPT. There is a possibility that the language model has created errors or has provided incorrect references with their output. We

compared the results with previous literature and revise and adapted as necessary to ensure that the most accurate information is being provided. Including information from the previous literature in the next prompt may continue to provide more refined ChatGPT responses.

Step 6: Customize the Content to be Delivered

The final step of this framework is to customize the content to meet the needs of your intervention. This involves considering the layout and design of how you will deliver the content on your selected medium from step 3, as well as any images or graphics used to supplement the given content. This step may involve working with an additional team to develop a web-based or mobile-based platform to support the health behavior change intervention. Further, user experience and design should be considered to improve usability and satisfaction of the content [51-54]. Table 2 summarizes the steps of these guidelines and considerations to meet the needs of each step.

By following these guidelines and using ChatGPT to assist in the rapid creation of digital health content, many ethical considerations arise. The first consideration, as highlighted above, is ensuring that the responses from ChatGPT are accurate and validated to be used as health information in a research study. This can be done by referencing previous literature or creating a panel of experts in the field to review the output created by ChatGPT. Further, it is vital to ensure that users engaging with AI-generated content through ChatGPT or other LLMs are adequately informed about its limitations, decision-making capabilities, and the crucial nature of their involvement. Transparent communication and obtaining informed consent are pivotal to respect user autonomy and comprehension. Although ChatGPT demonstrates remarkable efficiency in generating responses to prompts, evaluating its applicability within the intervention's context remains crucial to ensure substantial value to using ChatGPT.

As ChatGPT inevitably continues to support academic research across disciplines, it is also important to consider how ChatGPT is being cited by those who use it. There has been a variety of techniques used so far, with some authors including ChatGPT as an author [55] and others acknowledging the use of ChatGPT [34] to assist with their manuscript.

Table 2. Proposed recommendations for developing digital health content using ChatGPT and a summary of considerations for using this tool.

Step	Task	Consideration
1	Determine target behavior	<ul style="list-style-type: none"> • Previous research • Needs of the target population
2	Ground in behavior change theory	<ul style="list-style-type: none"> • Stage of readiness of participants • Needs of the population group
3	Design the intervention structure	<ul style="list-style-type: none"> • Web or mobile based • Length of the intervention • Amount of content to be delivered in each bout (ie, how many words, characters, or pages of content to be delivered) • Use co-design or other frameworks to ensure that the intervention aligns with the needs of the target population
4	Input intervention structure and behavior change constructs into ChatGPT	<ul style="list-style-type: none"> • Structure prompt to input into ChatGPT (considering instruction, context, input data, and output indicator) • Iteratively adapt prompts based on desired output • Order in which relevant information relating to each construct is delivered, if not predefined by the literature
5	Revise the output of ChatGPT	<ul style="list-style-type: none"> • Refer outputs to previous literature to ensure accuracy • Confirm whether references used by ChatGPT are accurate
6	Customize the content to be delivered	<ul style="list-style-type: none"> • Layout and design of content • Images or graphics to supplement text output • User experience and design of the intervention platform

Discussion

Principal Findings

The primary objective of this study was to explore the feasibility of using ChatGPT to develop content for a mobile-based JITAI to promote parental support for their children's PA. The secondary objective was to propose recommendations for using ChatGPT for future work in this area. To our knowledge, the process of using ChatGPT to develop health intervention content has not yet been documented, so we considered the key components required to develop effective behavior change interventions. We found that using ChatGPT was overall acceptable for this case study. However, a human check by researchers in the field is imperative to ensure the relevance and accuracy of the output provided. The use of ChatGPT and similar LLMs is rapidly evolving, and as such, these proposed recommendations are highly dynamic to the developing nature of these technologies.

This study has several implications for researchers using ChatGPT when developing mHealth app content. First, ChatGPT can help researchers improve the efficiency of creating digital health content for various tailored lessons. Previously, it was determined that ChatGPT can expedite the research process by allowing researchers to focus on steps of the research design process that require more human input, for example, focusing on the experimental design [56,57]. The improvement and versatility of text generation, knowledge translation, and literature review have been documented in various studies that have used ChatGPT in health care education [58]. As seen in this study, ChatGPT can help create various versions of content (varying in writing styles and tones) using a series of different

prompts. Further, coupled with the efficiency of developing intervention content, this study has highlighted the ability to efficiently create a variety of tailored content specific to PA messaging. The need for more variety and content options has been previously stated as a limitation in previous studies that did not use ChatGPT for the creation of content [28]. Overall, this study highlights one use case that benefited from the use of ChatGPT to rapidly create digital health content. As ChatGPT is in its infancy, we expect it to evolve quickly [58].

Second, this study highlights the current limitations of using ChatGPT for creating mHealth behavior interventions. Although ChatGPT has great potential to improve the efficiency with which digital health content creation can occur, it is not possible to replicate responses by ChatGPT while using the same prompt [58,59]. This unpredictability poses a significant challenge for health researchers and developers who may require stable and reliable outputs [58]. Because of the probabilistic nature of ChatGPT and similar LLMs, the responses generated from ChatGPT are generated based on a probability distribution, meaning the same response will not be generated [60]. Further, a significant concern is the generation of references by ChatGPT that do not exist or are inaccurate. This lack of interpretability hampers the transparency of mHealth content development, making it difficult for researchers to have a clear understanding of the AI's decision-making process. Other limitations have been recognized by previous work around ChatGPT. These include limited accuracy, bias and limitations of data, lack of context, and the potential of limited engagement with the content [34]. To mitigate these challenges, we highly recommend a rigorous human fact-checking process, as indicated in our recommendations for mHealth intervention content development

using ChatGPT, and fine-tuning specific prompts to ensure that the information given by ChatGPT is relevant.

Finally, the integration of ChatGPT with existing mHealth app development tools, such as Pathverse, holds the potential to significantly enhance the efficiency and effectiveness of developing and evaluating JITAI apps. By incorporating ChatGPT's language generation capabilities into Pathverse, developers can expedite the creation of content-rich JITAI. Additionally, reinforcement learning algorithms can play a crucial role in JITAI by dynamically adapting the intervention based on real-time data and user feedback [61]. Developers can leverage ChatGPT's language generation capabilities using its application programming interface to assist with content creation [61]. With the integration of ChatGPT, these algorithms can benefit from the AI-generated content to offer more tailored and contextually relevant interventions. By combining the strengths of reinforcement learning and ChatGPT, JITAI apps can become more adaptive and responsive to individual user's needs, thereby increasing their effectiveness in promoting behavior change and improving health outcomes.

There are several limitations to this study. First, we used ChatGPT to create content for only 1 JITAI, potentially restricting the generalizability of the study findings. Second, because of ChatGPT's tendency to provide different responses for the same prompt, it was challenging to accurately characterize the content's reproducibility and consistency. Lastly, as ChatGPT is rapidly evolving, the use case described in this study may have limited applicability a few years from now. We also want to add that although ChatGPT-3 is currently

free to use, it is likely that as it improves, it is likely to come with an associated cost.

Conclusions

By using ChatGPT, we were able to expedite the process of creating 13 lessons that were guided by the M-PAC framework, thus highlighting the incredible opportunity ChatGPT presents to rapidly create content for various mHealth JITAI. Although we found that ChatGPT was acceptable for this case study, we still encourage the cautious use of ChatGPT and other LLMs in similar contexts. The use of ChatGPT expedited the process of content development to 2 months, the bulk of which was spent on reviewing the content by experts in the field before delivering to population groups. This process was imperative to ensure that accurate and relevant content was being created to be delivered. The results from this study found implications in 3 areas. The first is efficiency in generating a variety of content based on different prompts. Second, this study highlighted the potential limitations of ChatGPT, including the inability to replicate responses from the same prompts and the need for human input to ensure that the output from ChatGPT is accurate. Finally, this case study has highlighted the efficiency of using no-code app builders, such as Pathverse, to disseminate information generated by ChatGPT. It is without a doubt that as ChatGPT and other LLMs continue to improve in sophistication and accuracy, they will continue to integrate into intervention design and other various contexts for researchers. Further research and applications of ChatGPT and the guidelines proposed in this study are imminent in this field as we continue to understand ChatGPT.

Abstract

Background: The integration of artificial intelligence (AI) technologies, such as ChatGPT, in the educational landscape has the potential to enhance the learning experience of medical informatics students and prepare them for using AI in professional settings. The incorporation of AI in classes aims to develop critical thinking by encouraging students to interact with ChatGPT and critically analyze the responses generated by the chatbot. This approach also helps students develop important skills in the field of biomedical and health informatics to enhance their interaction with AI tools.

Objective: The aim of the study is to explore the perceptions of students regarding the use of ChatGPT as a learning tool in their educational context and provide professors with examples of prompts for incorporating ChatGPT into their teaching and learning activities, thereby enhancing the educational experience for students in medical informatics courses.

Methods: This study used a mixed methods approach to gain insights from students regarding the use of ChatGPT in education. To accomplish this, a structured questionnaire was applied to evaluate students' familiarity with ChatGPT, gauge their perceptions of its use, and understand their attitudes toward its use in academic and learning tasks. Learning outcomes of 2 courses were analyzed to propose ChatGPT's incorporation in master's programs in medicine and medical informatics.

Results: The majority of students expressed satisfaction with the use of ChatGPT in education, finding it beneficial for various purposes, including generating academic content, brainstorming ideas, and rewriting text. While some participants raised concerns about potential biases and the need for informed use, the overall perception was positive. Additionally, the study proposed integrating ChatGPT into 2 specific courses in the master's programs in medicine and medical informatics. The incorporation of ChatGPT was envisioned to enhance student learning experiences and assist in project planning, programming code generation, examination preparation, workflow exploration, and technical interview preparation, thus advancing medical informatics education. In medical teaching, it will be used as an assistant for simplifying the explanation of concepts and solving complex problems, as well as for generating clinical narratives and patient simulators.

Conclusions: The study's valuable insights into medical faculty students' perspectives and integration proposals for ChatGPT serve as an informative guide for professors aiming to enhance medical informatics education. The research delves into the potential of ChatGPT, emphasizes the necessity of collaboration in academic environments, identifies subject areas with discernible benefits, and underscores its transformative role in fostering innovative and engaging learning experiences. The envisaged proposals hold promise in empowering future health care professionals to work in the rapidly evolving era of digital health care.

Introduction

Generative pre-trained transformers have evolved into potent language models with diverse education applications, including personalized and problem-based learning that emphasizes critical thinking [1]. They offer a chat interface for natural interactions, which can be valuable in engaging students in educational discussions. Additionally, these models can be adjusted to align with specific educational objectives and generate text embeddings, enabling tasks such as classification, recommendations, and similarity analysis. Furthermore, their accessibility through application programming interfaces (APIs) opens the door to integrate them into various educational applications beyond chat interfaces.

The integration of these artificial intelligence (AI) technologies, including ChatGPT, into the educational environment has the potential to improve the student learning experience [1-6]. By incorporating ChatGPT into the teaching and learning process in higher education, students can be supported throughout their educational journey and develop the necessary skills to effectively use AI in professional settings [4,7,8].

Integrating ChatGPT into the field of medical informatics education could not only enrich the learning experience but also empower students to apply AI skills, preparing them to tackle the complex challenges they will encounter in their future careers in health care [9]. For instance, professionals in medical informatics can use AI in developing decision support systems for diagnosing medical images and predicting patient outcomes based on data analysis. These applications demonstrate how a strong foundation in AI, facilitated by ChatGPT, can enhance the capabilities of future medical informatics professionals in delivering quality health care services.

Medical informatics, commonly referred to as biomedical or health informatics, is an umbrella term [10,11] that encompasses the use of information and communication technologies in health care. It is a fundamental field of study that caters to a diverse range of disciplines [12]. The field concentrates on using biomedical data, information, and knowledge for scientific inquiry, problem-solving, and decision-making endeavors that aim to advance care quality and delivery [13]. There is a growing interest in biomedical and health informatics (BMHI) education [14] due to the increasing demand for professionals who can address BMHI issues through the development, implementation, and evaluation of innovative technological solutions [15].

The educational requirements for BMHI vary depending on the level of education and career progression, with different pedagogical approaches needed to provide theoretical knowledge, practical skills, and a mature attitude [16]. Although medical informatics knowledge is globally applicable and requires international standards, education in this field is typically localized, with competencies being tailored to the specific environment in which they will be used [17]. Variations in educational and health care systems result in differences in

BMHI education across countries. Nevertheless, despite this variability, fundamental similarities can be identified and used as a framework for recommendations [16,18].

The International Medical Informatics Association (IMIA), through its educational recommendations, has outlined essential knowledge domains for teaching in the field of BMHI, including the domain of computer science, data, and information [19]. Within this domain, there is a particular emphasis on imparting students with a deep understanding of the fundamental principles underlying emerging technologies, such as AI [19]. Notably, the most recent IMIA recommendation signifies the first explicit inclusion of AI as a topic within a BMHI knowledge domain. These IMIA recommendations offer a valuable framework for the development of educational programs, enabling the integration of essential competencies in medical informatics into the curricula of undergraduate medicine programs and master programs in the field, for instance. However, there is currently a dearth of specific recommendations regarding the inclusion of AI skills in the curriculum [9].

Since its launch, ChatGPT has ignited discussions surrounding its application in education. Rather than outright banning its use in universities, this presents an opportune moment to reassess teaching methodologies and examination practices in higher education, with the goal of preparing students for the digital world [2,3,5,7,20,21]. ChatGPT represents the initial step of a broader trend, and we must adapt to collaborate with it instead of opposing its presence [22]. In the education domain, ChatGPT will be able to offer interactive and personalized learning experiences, accessible on various devices. It can speed up routine tasks like assessments, allowing professors more time for personalized teaching. Furthermore, it can generate diverse educational content, ensure round-the-clock availability, assist in language learning, and promote innovative teaching methods.

It is crucial for faculty, professors, and students to be cognizant of both the potential and limitations of ChatGPT while also addressing ethical concerns [1,4,7,23,24] and ensuring accessibility in its implementation within academic settings. Encouraging the integration of ChatGPT in education requires the formulation of policies that promote best practices, nurturing students' critical thinking and equipping them with the necessary skills to effectively use AI tools [4,7,25]. To foster the development of critical thinking, engaging students in activities that prompt them to verify the accuracy, veracity, and potential biases of the text generated by ChatGPT is essential [2,26,27].

Building upon the aforementioned discussions and considerations, this study aims to contribute meaningfully to the broader objective of integrating AI education within the field of medical informatics. Recognizing the significant relevance of ChatGPT as an AI tool to the medical informatics courses offered in the master's programs in medicine and medical informatics at the Faculty of Medicine of the University of Porto (FMUP) in Portugal, this research seeks to address a proposal for integration of ChatGPT in the educational process.

The first objective is to compile the opinions of students enrolled in all levels of the medical faculty's programs with the aim of obtaining a general perception of their perspectives and experiences regarding the use of ChatGPT as an educational tool. Furthermore, this study endeavors to provide practical proposals for professors, offering examples of prompts for incorporating ChatGPT into their teaching activities, in order to enhance the educational benefits for students in medical informatics courses.

Methods

Ethical Considerations

A structured questionnaire was designed and submitted to the ethics committee of Faculty of Medicine of the University of Porto (105/CEFMUP/2023) to ensure ethical considerations in conducting this research and obtain approval for data collection. Students who participated in the questionnaire were explicitly informed that their participation in the research was entirely voluntary and were assured of confidentiality and anonymity regarding their responses.

Participants and Questionnaire

This study used a mixed methods approach involving students enrolled at all levels of the medical faculty's programs. The survey aimed to provide initial insight into medical informatics students' perspectives regarding the use of ChatGPT in teaching. The exploratory survey served as a preliminary assessment to outline proposals for incorporating the tool classes.

The questionnaire consisted of a total of 25 questions, comprising both closed-ended and open-ended formats, which were electronically distributed to 105 students enrolled in programs at the FMUP that offer medical informatics courses. The closed-ended questions aimed to assess the participants' familiarity with ChatGPT, their perception of the technology's use in educational contexts, and their attitudes toward using the application in academic and learning tasks. Participants were asked to indicate their level of agreement on a Likert scale, ranging from "strongly agree" to "strongly disagree," enabling nuanced responses.

In parallel, the open-ended questions encouraged participants to provide comprehensive and detailed feedback, sharing specific instances of their interactions and experiences with ChatGPT.

Data Analysis

The data collected from the questionnaire were analyzed using descriptive statistical techniques to summarize the quantitative responses. Thematic analysis was used to identify recurring themes and patterns in the qualitative responses, providing deeper insights into the students' perceptions and suggestions.

Literature Review and Description of Course Learning Outcomes

The methodology of this study also involved conducting a comprehensive literature review to explore the current publications pertaining to the implementation of AI in higher education settings. Specifically, the focus was on examining the integration of ChatGPT within the context of teaching medical informatics and assessing its alignment with international recommendations for effective pedagogy in this domain.

To assess the potential benefits of incorporating ChatGPT into educational practices, the study describes the learning outcomes of 2 proposed courses, carefully designed based on the competencies and skills expected of medical informatics students. The authors of this research, along with other esteemed members of the faculty, collaboratively deliberated on the proposals for using ChatGPT, aiming to optimize its functionalities both in master's programs in medicine and medical informatics.

In addition, it is expected to exemplify specific prompts to be used by students and professors to maximize the tool's potential to facilitate learning experiences. These prompts are carefully designed to engage students in critical thinking, problem-solving, and knowledge exploration while also aiding professors in delivering exemplary instruction.

Results

Questionnaire

In July 2023, the questionnaire was distributed to the students through their institutional email addresses. Out of the recipients, a noteworthy 25 university students actively participated by responding to the survey, resulting in a response rate of approximately 24%. The majority of respondents identified as male, accounting for 56% (n=14) of the total sample, with an average age of 35.2 (SD 8.6) years. [Table 1](#) provides a concise summary of the key demographic characteristics of the participating students.

Table 1. Characteristics of the participants (N=25).

Characteristics	Values
Sex, n (%)	
Female	11 (44)
Male	14 (56)
Age (years)	
20-25, n (%)	2 (8)
26-30, n (%)	6 (24)
31-35, n (%)	8 (32)
>35, n (%)	9 (36)
Mean (SD)	35.2 (8.6)

Regarding the use of ChatGPT (Table 2), 52% (n=13) of the students indicated that they had their initial encounter with the chatbot during the second semester of 2022. Among them, a considerable proportion (n=4, 16%) reported using it on a daily basis, while the majority (several times during the week) found it to be a frequent resource. Impressively, 92% (n=23) of the students conveyed their satisfaction with the responses generated by ChatGPT, with 48% (n=12) expressing a high level of

reliance on its answers and offering strong endorsements of its implementation among their peers. Nevertheless, a subset of participants (n=5, 20%) disclosed that they rarely place trust in the responses provided by the system. Furthermore, 96% (n=24) of the participants asserted that the tool comprehends the contextual intricacies of questions well. However, they noted that occasionally, to obtain the desired response, it becomes necessary to reformulate the query.

Table 2. Answers to questionnaire questions about the use of ChatGPT by medical faculty students (N=25).

Question and answers	Respondents, n (%)
Do you usually talk to your colleagues about ChatGPT?	
Ever	11 (44)
Occasionally	13 (52)
Often	1 (4)
When did you first use ChatGPT?	
Between March and April 2023	4 (16)
Between January and February 2023	7 (28)
Between July and December 2022	13 (52)
Between January and June 2022	0 (0)
In 2021	1 (4)
Do you use ChatGPT regularly?	
Yes every day	4 (16)
Yes, several times a week	13 (52)
I use it from time to time	8 (32)
How satisfied are you with ChatGPT's responses?	
Very satisfied	5 (20)
Satisfied	18 (72)
I have a neutral position on this	2 (8)
Do you trust the information provided by ChatGPT?	
Most of the time	12 (48)
Sometimes	8 (32)
Rarely	5 (20)
Does ChatGPT understand the context of your questions well?	
Very good	7 (28)
Good	17 (68)
No opinion	1 (4)
When using ChatGPT, do you have to rephrase questions to get the answers you want?	
Rarely	7 (28)
Sometimes	17 (68)
Often	1 (4)
Would you recommend ChatGPT to your colleagues?	
Definitely	18 (72)
Probably	5 (20)
I am not sure	1 (4)
Probably not	1 (4)

Concerning attitudes toward the use of ChatGPT for learning and academic purposes (Table 3), a majority of students demonstrated openness to adopting this form of chatbot and express intentions to incorporate it regularly into their

educational endeavors. Nevertheless, it is noteworthy that 8% (n=2) of the participants held a dissenting perspective and are resolutely against its use in academic activities.

Table 3. Attitudes toward using ChatGPT for learning and academic tasks.

Statement and Likert scale	Respondents, n (%)
I think using a tool like ChatGPT would be a good idea to support learning	
Strongly agree	13 (52)
Agree	8 (32)
Neither agree nor disagree	4 (16)
I will start using ChatGPT to support learning and completing academic tasks	
Strongly agree	8 (32)
Agree	9 (36)
Neither agree nor disagree	7 (28)
Disagree	1 (4)
I will ask my colleagues about ChatGPT and how they use it	
Strongly agree	7 (28)
Agree	8 (32)
Neither agree nor disagree	10 (40)
I intend to create the habit of using ChatGPT to support learning and carry out my academic work	
Strongly agree	6 (24)
Agree	12 (48)
Neither agree nor disagree	5 (20)
Disagree	2 (8)
I will use ChatGPT or other similar chatbots whenever the opportunity arises	
Strongly agree	9 (36)
Agree	11 (44)
Neither agree nor disagree	3 (12)
Disagree	2 (8)
I have a bad feeling about ChatGPT and artificial intelligence in general	
Strongly agree	2 (8)
Agree	1 (4)
Neither agree nor disagree	8 (32)
Disagree	10 (40)
Strongly disagree	4 (16)
In my opinion, the use of ChatGPT or similar chatbots for academic tasks should not be allowed	
Strongly agree	1 (4)
Agree	1 (4)
Neither agree nor disagree	5 (20)
Disagree	6 (24)
Strongly disagree	12 (48)

Regarding the perceptions of ChatGPT as an academic support tool (Table 4), a significant proportion (n=18, 72%) of students concur with the notion that the ChatGPT tool has the potential to enhance and facilitate learning experiences. Furthermore, an

overwhelming majority strongly agree that its implementation streamlines the execution of tasks, promoting efficiency within the academic context.

Table 4. Perceptions of ChatGPT as an academic support tool.

Statement and Likert scale	Respondents, n (%)
Using ChatGPT improves learning	
Strongly agree	12 (48)
Agree	6 (24)
Neither agree nor disagree	6 (24)
Disagree	1 (4)
Using the ChatGPT can make learning tasks easier to complete	
Strongly agree	12 (48)
Agree	10 (40)
Neither agree nor disagree	3 (12)
I find ChatGPT a very useful tool to support learning	
Strongly agree	15 (60)
Agree	7 (28)
Neither agree nor disagree	3 (12)
Using ChatGPT can increase my productivity as a student	
Strongly agree	16 (64)
Agree	6 (24)
Neither agree nor disagree	3 (12)
Using ChatGPT allows me to complete tasks faster	
Strongly agree	19 (76)
Agree	4 (16)
Neither agree nor disagree	2 (8)

In terms of the use of ChatGPT or other AI bots in the future, the majority of responses indicate that participants find it extremely useful, especially for medical writers who are not proficient in English, as it aids in restructuring and correcting texts. Some believe that the adoption of these tools will be inevitable and increasingly common, both in academic and professional contexts, resulting in enhanced process efficiency. However, there are also ethical concerns and apprehensions regarding the potential impact on the employability of programming professionals. Moreover, participants emphasize the importance of informed use, understand the limitations, and use these tools intelligently and as complementary to specific objectives. Some express caution, recognizing that although the tools have advantages, they do not create anything new but rather help organize thoughts and facilitate a better understanding of concepts.

The responses reveal diverse opinions on the benefits and drawbacks of using AI bots like ChatGPT in education. Some students highlight the capacity to customize responses to specific questions without worrying about boring the instructor and speeding up repetitive tasks, envisioning its potential to

revolutionize the educational landscape. However, there are concerns about the long-term effects and the need for caution. The AI's biases and limitations are seen as potentially harmful to knowledge, and there are worries about the credibility of sources used and proper attribution of credits and bibliographic referencing.

While some view it as a valuable tutor or assistant that is always available, others caution against its potential to promote laziness, particularly in written work, which may discourage the development of quality writing skills. Nevertheless, the quick response time for academic tasks is regarded as an advantage by some, with no apparent disadvantages seen. The major concern is the risk of a bias in thinking, whereby AI-generated ideas or responses could influence one's own thought process, potentially inhibiting critical thinking. Despite this, many believe that ChatGPT can be a useful aid in executing certain tasks, as it does not create content but rather assists in the development and enhancement of ideas. The list of suggestions from medical informatics students on how to use ChatGPT or other AI bots in education can be seen in [Figure 1](#).

Figure 1. List of suggestions from medical informatics course students on how to use ChatGPT in education generated with the assistance of artificial intelligence (AI).

Integration of ChatGPT

Overview

The analysis of student responses to the questionnaire has revealed a positive receptiveness and interest in the use of ChatGPT as an educational tool. Building on these findings, the next phase of our investigation focused on the proposed integration of ChatGPT into classroom settings. This section explores the proposal to incorporate ChatGPT into 2 specific courses, outlining how prompts developed by professors can be applied to enhance medical informatics students' learning experiences. Additionally, we will address the events held at the faculty to discuss and guide the implementation of ChatGPT in the context of education, emphasizing the collaboration among professors to foster educational innovation.

Master's Program in Medicine

The master's program in medicine at FMUP comprises an integrated cycle of studies totaling 360 credits, in accordance

with the European Credit Transfer and Accumulation System (ECTS).

The course chosen for this study's proposal of implementing ChatGPT in the master's program in medicine is "DECIDES III: Decision, Data and Digital Health" (4 ECTS), which has been taught in the fourth year. By the end of this course unit, medical students are expected (1) to have knowledge and be able to discuss key topics related to health information systems and the integration of scientific evidence in health decision-making; (2) to proficiently and safely use health information systems; (3) to critically evaluate health scientific literature, particularly regarding health information systems, health technology assessment, and health decision analysis; and (4) to plan and interpret studies on health economic evaluation and decision analysis.

The course offered in the master's program in medicine proposes the use of ChatGPT in 3 ways ([Textbox 1](#)).

Textbox 1. Three proposed uses of ChatGPT.**Assistant for simplified explanation of concepts**

ChatGPT will serve as an assistant to explain complex concepts in a simplified manner. Medical students will be encouraged to use ChatGPT outside of the classroom to enhance their understanding of various topics, including blockchain, cloud services, data quality, machine learning, electronic health records (EHRs), and mobile health. They will be prompted to request explanations in simple language. Example of prompt: *Explain the following concepts to me in a simple manner, providing examples from the healthcare field, as if I were a 16-year-old: machine learning.*

Assistant for addressing complex problems

ChatGPT will also be used as an assistant to address intricate problems. It will provide support to students in tackling challenging scenarios and offer insights and solutions related to medical informatics and health care. Example of prompt: *What risks and benefits has the General Data Protection Regulation brought to clinical research? For each of the risks, propose a technological solution to mitigate it. Present your findings in a table format.*

Generation of clinical narratives and patient simulators

This feature will enable students to simulate realistic patient cases and explore various clinical scenarios, thereby enhancing their ability to effectively and securely use health information systems with proficiency. A prompt was created, requesting that ChatGPT read the manual of a health information system used in public hospitals in Portugal and then generate a clinical case that would allow the professor to practice with the students the use of all specific functionalities of the system.

In addition to assisting students, ChatGPT will also serve as a valuable tool for professors. By using the version of ChatGPT which incorporates plugins, professors can leverage its capabilities to enhance their teaching methodologies. In [Multimedia Appendix 1](#), an illustrative scenario of using ChatGPT is detailed, culminating in the creation of a comprehensive lesson plan for obstetrics. This includes practical exercise demonstrations, a data generator for classroom use, a compilation of clinical cases for educational purposes, and a decision tree highlighting the importance of data quality in the medical field. This setup enhances understanding of ChatGPT's practical application in medical education, offering innovative tools for improving teaching and learning.

Master's Program in Medical Informatics

The master's program in medical informatics (MIM) comprises 120 ECTS. Established 17 years ago at FMUP, MIM recently earned accreditation from the European Federation for Medical Informatics in 2022, affirming its high quality and recognition within the field.

The MIM's course unit proposed in this study to incorporate ChatGPT during classes in "health information systems and

electronic health records" (6 ECTS), which is taught in the second semester of the master's program.

The main objective of this course is to equip students with the necessary knowledge and skills to effectively select, design, and manage health information systems and EHRs. The course focuses on developing an understanding of health information systems, including their development and implementation processes, functions, historical evolution, the significance of shared concepts among these systems, barriers in data collection, data integration and process integration, change management, current trends in health information system development, and the main challenges and considerations related to meaningful use. By the end of the course, students are expected to have achieved specific learning outcomes and competencies in these areas.

In the MIM, the use of ChatGPT offers students a versatile tool that enhances their learning experience and skill development. By incorporating ChatGPT, students can explore new educational possibilities and engage with the technology in meaningful ways. There are 5 specific applications of ChatGPT in the course. ([Textbox 2](#)).

Textbox 2. Five specific applications of ChatGPT.**Project planning assistant**

ChatGPT will act as an assistant in project planning, providing frameworks, checklists, and real-world examples. This aims to impart project management skills crucial for the successful development and implementation of health information systems, thereby increasing the likelihood of project success and reducing system inefficiencies. Example of prompt: *We intend to develop an app to monitor asthma patients and their crises, aiding in disease self-management. What stages should the project go through from conception to commercialization?*

Programming code generation

Students will engage in coding exercises facilitated by ChatGPT, aimed to improve their programming skills essential in medical informatics. This personalized learning experience allows students to work at their own pace, ensuring a deeper understanding of the coding principles and practices. Example of prompt: *Generate the SQL programming code to create the database for the application.*

Examination preparation

ChatGPT assists students in preparing for examinations by simulating examination scenarios and providing practice questions. By inputting relevant course materials and previous examination papers, students can engage with the system to receive responses that aid their understanding of the subject matter. This feature enables students to refine their knowledge and enhance their examination performance. Instructions for students:

- Feed the chat with links to pages and PDFs containing the course content and past examinations.
- Ask ChatGPT to generate 10 examination questions. Select the 3 most interesting and well-constructed questions.
- Ask ChatGPT to generate 10 more questions similar to the chosen 3.
- Discuss with a colleague and select 2 questions each.
- Ask both respective ChatGPT models for an answer to each of the 2 questions (resulting in 4 answers).
- Compare the answers and assign a rating from 0 to 10 to each response. Ask ChatGPT to self-evaluate the answers.

Workflow and information exploration

ChatGPT enhances the exploration of intricate workflows and information within medical informatics. By engaging interactively with the system, students can emulate real-world health care information systems, acquiring hands-on experience in managing and analyzing complex data sets. This practical engagement deepens their comprehension of information flow dynamics and the principles of workflow optimization in a health care context.

Technical interview preparation

Students will prepare for technical questions likely to appear in professional interviews by leveraging ChatGPT to simulate a wide range of possible questions and scenarios. This not only aims to enhance their employability by familiarizing them with potential interview questions but also aids them in articulating their knowledge and skills effectively. As AI and machine learning continue to penetrate various aspects of health care and medical research, the ability to interact and extract meaningful insights from these systems will be a strong asset. Hence, students will not only leave the course well-prepared for interviews but also well-equipped for a future job market that demands adeptness in working with intelligent systems like ChatGPT.

Additionally, several practical exercises are planned to further enhance the learning experience in medical informatics. These include a data privacy challenge—students can be tasked with identifying potential vulnerabilities in a mock EHR system and proposing solutions to improve data privacy. There will also be an API integration exercise—students can work on connecting a health monitoring device to an existing EHR system using APIs, thereby gaining hands-on experience in system interoperability. Finally, there will be a machine learning mini-project—students are tasked with a simplified predictive modeling challenge, where they need to forecast patient outcomes using a specified set of features. They will use a popular programming language and a statistical software library to construct and assess their models, gaining practical experience in predictive analytics within a health care setting.

These exercises are designed to not only improve technical skills but also to cultivate a mindset of problem-solving and practical application in the realm of medical informatics.

Fostering Collaborative Efforts

As ChatGPT is a recent tool, gaining insights into students' perceptions regarding its use in education is essential. Moreover, it is imperative to foster institutional collaboration to empower

professors in effectively integrating AI tools into the teaching process. Throughout the course of several months, a series of pioneering initiatives unfolded at FMUP, spearheading the integration of ChatGPT into medical informatics education. The journey commenced in January 2023, with the introduction of ChatGPT theme in the MIM classes, providing students with a discussion about the tool's potential application in the health care sector. As the momentum grew, a presentation was held in March 2023, engaging faculty members and researchers in exploring the practical use of ChatGPT in education.

Building on this foundation, the month of May 2023 witnessed the event "ChatGPT: Challenges for Education and Research," orchestrated in collaboration with FMUP's ethics committee. Subsequently, in a grander gathering titled "ChatGPT: Learning Models for Higher Education," diverse faculty members united from disciplines ranging from engineering and arts to psychology and sciences. Together with the participation of the ethics committee chairman and the university's vice-rector, professors from several faculties presented proposals for the incorporation of ChatGPT in classes, paving the way for the implementation of ChatGPT in the upcoming academic year.

By July 2023, the momentum reached new heights during the FMUP Summer School, with a captivating workshop focused

on harnessing ChatGPT's potential through the design of improved prompts, ensuring more profound and effective responses. As we delve into the results of these collaborative efforts, this section sought to describe notable proposals for integrating ChatGPT into medical informatics courses, as presented and discussed at the previously mentioned events.

Discussion

Principal Findings

Building on the proposal to integrate AI into medical programs to prepare students for their future use of such tools in professional contexts [5,8,28,29], the implementation of ChatGPT has emerged as a potentially transformative force in medical education [30,31], offering support to students in their learning journey [30,32]. The questionnaire administered to medical faculty students provided valuable insights into their perspectives and experiences with ChatGPT, shedding light on their attitudes, preferences, and intentions regarding the incorporation of AI chatbots in educational environments. The participants, with a mean age of approximately 35 (SD 8.6) years, predominantly comprised master's and doctoral students, indicating a higher participation rate from these groups compared to undergraduate medical students. Engaging in frequent discussions with peers about ChatGPT, most participants were introduced to the tool during its initial launch in 2022. Remarkably, a majority of students used ChatGPT regularly for diverse purposes, including report writing, idea brainstorming, and text rewriting.

In general, students expressed satisfaction with ChatGPT's responses, finding them to be reliable and contextually comprehensible. They recognized the educational potential of ChatGPT, highlighting its ability to facilitate the creation of relevant exercises, enhance writing skills, and foster exploration of new concepts. Drawing from these valuable insights, proposals for ChatGPT's integration into the 2 master's programs were developed. Additionally, existing references that offer a plethora of ideas for ChatGPT's incorporation into medical education were also considered, ranging from personalized learning opportunities [33,34] to problem-based learning and clinical problem-solving approaches [35]. Moreover, ChatGPT can be harnessed for teaching assistance, generating case scenarios, and creating educational content such as summaries, questionnaires, and flashcards [34].

The participants also acknowledged the need for caution in its application and emphasized the importance of understanding its limitations. It is essential to be mindful that AI systems may engage in "hallucination," a phenomenon where they fabricate facts and produce confident-sounding statements and seemingly legitimate citations that are, in reality, false, and not necessarily supported by their training data [2,36,37]. To mitigate such issues, future implementations of ChatGPT should consider raising student awareness of the possibility of AI-generated content and encouraging critical analysis of generated responses. Although students expressed openness to adopting ChatGPT, their critical analysis of potential impacts on education should be taken into consideration by professors when implementing ChatGPT in the classroom.

Privacy concerns surrounding student interactions with ChatGPT have been acknowledged in prior literature [4,7,24]. It is imperative that AI be used as an educational aid without the extraction of sensitive data, adhering to relevant data privacy regulations. Information acquired during a learner's interactions with the AI system to acquire knowledge must be shielded from any inappropriate use [38]. Despite the recent availability of this tool, specific guidelines regarding anonymity techniques for ChatGPT's full integration into our master's programs and curricula have yet to be established within our academic context. Nevertheless, professors can proactively protect privacy by refraining from collecting personally identifiable information, opting for generic pseudonyms over real names, working with aggregated data, securing data transmission through encryption, implementing data retention policies with defined timeframes, restricting access to authorized personnel, and educating students on best practices for safeguarding their privacy. These measures collectively ensure adherence to privacy regulations and the preservation of the confidentiality of student interactions with ChatGPT.

Building upon the students' recognition of both the potential and limitations of ChatGPT, it becomes evident that fostering a balanced approach to AI integration in education is paramount. It requires a concerted effort to leverage AI's strengths while addressing its vulnerabilities. This is where the strategic organization of faculty events plays a pivotal role in shaping the future landscape of AI-driven education.

In terms of fostering collaboration in the academic environment, the strategic organization of faculty events scheduled between March and June 2023 presented a unique opportunity to facilitate the start of ChatGPT integration in the upcoming academic year. Facilitating open discussions on the integration of AI in education, including the use of tools like ChatGPT, is a pivotal undertaking within the academic realm [3]. It represents a critical step toward embracing best practices, exploring ethical considerations, and harnessing the potential of AI to enhance the educational experience [4]. Such efforts require the active collaboration and engagement of all stakeholders involved in educational settings, including professors, researchers, and experts in the field [4]. By fostering a collective dialogue, universities can pave the way for the effective and responsible incorporation of AI technologies into teaching and learning environments, ultimately benefiting students and shaping the future of education.

In the field of medical informatics, the development of skill-based curricula becomes indispensable to meet the complexities of health care delivery and market demands [39]. Sapci and Sapci [9] have put forth a framework for specialized AI training in medical and health informatics education, and our study's proposals regarding the use of ChatGPT align with some of the competencies outlined in their research. For medical students, AI competencies include the application of predictive AI techniques to enhance health care efficiency and the critical evaluation of AI tools. In the case of medical informatics students, the competencies encompass the adept application of suitable machine learning algorithms to analyze intricate medical data, the seamless integration of data analytics into innovative clinical informatics systems and applications, and the

formulation of data-related queries to visualize large data sets. For students pursuing computer science, the focus lies on developing programming languages tailored to address complex medical challenges [9].

Through the integration of ChatGPT into the master's program in medicine, both students and professors will have the opportunity to harness its diverse functionalities, which play a pivotal role in promoting, for example, an understanding of complex concepts, effective problem-solving, and creating realistic medical scenarios. Consequently, the following applications of ChatGPT have been proposed for implementation: (1) acting as an assistant for simplified explanation of concepts, (2) assisting in addressing complex problems, (3) generating clinical narratives and patient simulators, and (4) enhancing teaching techniques for professors. These proposed applications hold the potential to augment the educational experience and knowledge acquisition within the field of medical informatics by medical students.

Regarding the MIM, the integration of ChatGPT is intended to offer students learning experiences that promote active engagement. Students are expected to cultivate essential skills, enhance problem-solving abilities, and equip themselves for upcoming challenges in this domain. Therefore, we have identified five specific ChatGPT applications proposed for the course: (1) project planning assistant, (2) programming code generation, (3) examination preparation, (4) workflow and information exploration, and (5) technical interview preparation. These proposed applications carry the potential to enrich the educational journey by empowering students to excel in the dynamic and evolving field of medical informatics.

Limitations

The low number of questionnaire's responses is a limitation of the study. However, it is important to highlight that the survey aimed to provide an initial insight into the perspectives of medical informatics students at the FMUP regarding the use of ChatGPT in teaching. The primary purpose of the survey was exploratory in nature, serving as a preliminary assessment to inform future initiatives rather than a comprehensive study with a large sample. The other limitation lies in the absence of practical implementation of the proposed ChatGPT incorporation in the current academic year. As a result, the actual impact on the teaching and learning process remains uncertain, and the benefits of AI use in medical informatics education require

further empirical verification. However, the study provides valuable groundwork for future exploration and collaboration in exploring AI's potential in education. While the ideas presented hold promise, empirical evaluation in the upcoming academic term will be imperative to ascertain their effectiveness and measure their impact on students' learning experiences. Further research and assessment will be necessary to determine the concrete effects and refine the integration strategies. Until then, the study stands as a stepping stone for stimulating ongoing dialogue and inspiring future research endeavors in the dynamic field of AI-driven education in the teaching of medical informatics.

Conclusions

The results of the questionnaire suggest that students perceive ChatGPT as a valuable tool for enhancing learning experiences and academic tasks, although they also emphasize the importance of informed and responsible use. The study's findings contribute valuable insights for professors in exploring the integration of AI chatbots like ChatGPT in educational settings, with a particular focus on its suitability for medical informatics courses at master's levels.

Additionally, the study provided a description of the learning outcomes of the 2 courses proposed for the incorporation of ChatGPT in the classroom. The collaborative efforts undertaken during 2023, including workshops and meetings with faculty members, served as pivotal moments that contributed to optimizing the use of ChatGPT as a powerful educational tool within the institution. Furthermore, specific subject areas and topics were identified as prime candidates for benefits through ChatGPT integration. The alignment of ChatGPT with these areas demonstrates its potential to increase the quality of education in the field of medical informatics.

In conclusion, the findings of this study highlight ChatGPT's promising role in enhancing medical informatics education by equipping students and faculty with a transformative AI-driven approach. The insights gained from this research effort provide valuable prompt examples for harnessing the power of AI to create innovative educational experiences in the ever-evolving landscape of medical informatics. As we move into the era of AI-driven education, these findings hold significant implications for future pedagogical approaches, fostering an enriched learning environment that empowers the next generation of health care professionals to operate in the digital age.

Acknowledgments

SMA was supported by the Fundação para a Ciência e a Tecnologia, IP (grant 2023.02980.BD).

Authors' Contributions

SMA completed the literature review, data collection, interpretation of results, and writing of the paper. RC-C supervised the project and developed the proposals for using ChatGPT for both courses. All authors contributed to the final version of the paper.

Conflicts of Interest

None declared.

Abstract

Background: This research explores the capabilities of ChatGPT-4 in passing the American Board of Family Medicine (ABFM) Certification Examination. Addressing a gap in existing literature, where earlier artificial intelligence (AI) models showed limitations in medical board examinations, this study evaluates the enhanced features and potential of ChatGPT-4, especially in document analysis and information synthesis.

Objective: The primary goal is to assess whether ChatGPT-4, when provided with extensive preparation resources and when using sophisticated data analysis, can achieve a score equal to or above the passing threshold for the Family Medicine Board Examinations.

Methods: In this study, ChatGPT-4 was embedded in a specialized subenvironment, "AI Family Medicine Board Exam Taker," designed to closely mimic the conditions of the ABFM Certification Examination. This subenvironment enabled the AI to access and analyze a range of relevant study materials, including a primary medical textbook and supplementary web-based resources. The AI was presented with a series of ABFM-type examination questions, reflecting the breadth and complexity typical of the examination. Emphasis was placed on assessing the AI's ability to interpret and respond to these questions accurately, leveraging its advanced data processing and analysis capabilities within this controlled subenvironment.

Results: In our study, ChatGPT-4's performance was quantitatively assessed on 300 practice ABFM examination questions. The AI achieved a correct response rate of 88.67% (95% CI 85.08%-92.25%) for the Custom Robot version and 87.33% (95% CI 83.57%-91.10%) for the Regular version. Statistical analysis, including the McNemar test ($P=.45$), indicated no significant difference in accuracy between the 2 versions. In addition, the chi-square test for error-type distribution ($P=.32$) revealed no significant variation in the pattern of errors across versions. These results highlight ChatGPT-4's capacity for high-level performance and consistency in responding to complex medical examination questions under controlled conditions.

Conclusions: The study demonstrates that ChatGPT-4, particularly when equipped with specialized preparation and when operating in a tailored subenvironment, shows promising potential in handling the intricacies of medical board examinations. While its performance is comparable with the expected standards for passing the ABFM Certification Examination, further enhancements in AI technology and tailored training methods could push these capabilities to new heights. This exploration opens avenues for integrating AI tools such as ChatGPT-4 in medical education and assessment, emphasizing the importance of continuous advancement and specialized training in medical applications of AI.

(*JMIR Med Educ* 2024;10:e56128) doi:[10.2196/56128](https://doi.org/10.2196/56128)

Introduction

Background

Family physicians in the United States are required to complete the American Board of Family Medicine (ABFM) Certification Examination following residency and every 10 years after to maintain board-certified status. This examination consists of 300 questions with a scaled scoring system ranging from 200 to 800; this corresponds to percent correct scores of 57.7%-61.0% [1]. There are extensive web-based review materials that are used to help prepare for this examination, such as textbooks and question banks. Several studies have examined the performance of advanced artificial intelligence (AI) language models (eg, ChatGPT) in attempting and failing similar board examinations [2,3]. Many of these studies used ChatGPT version 3.5; however, a study examining the newer and more powerful ChatGPT-4 found that it significantly outperformed its predecessor and medical residents on a University of Toronto family medicine examination [4].

ChatGPT-4 can now analyze documents in several file formats such as PDF. This would allow a user to simulate the process of learning and studying by providing learning material for the AI to consult in advance of being tested. With this approach the AI can be given material targeted to a specific region's regulations and ensure that it has access to the most up-to-date clinical guidelines.

Users engage with ChatGPT through the use of text inputs called "prompts." The contents of the prompt dictate the output. Prompt engineering is the purposeful structural construction of the input and significantly impacts the output. The 4 core elements of the prompt include the instruction, context, input data, and output indicator [5]. This means that, for the best result, the user must assign a task, provide context and background knowledge, ask a specific question, and specify the type of output desired.

Both humans and AI can make errors when answering questions. The classification of these errors can be made into 3 categories: logical, informational, or explicit fallacy [6]. This allows for an understanding of why the AI struggles to ascertain the correct answer and could allow for comparison to humans if that data were to be collected. This method of qualifying error types has previously been used in the context of AI answering medical examination questions [6]; the error types are defined as follows:

1. **Logical fallacy:** This type of error occurs when the response demonstrates a stepwise process but ultimately fails to correctly answer the question. Despite following a superficially logical progression in reasoning, the conclusion reached does not accurately address or resolve the query posed, often due to a misunderstanding of the central issue or incorrect application of a logical principle.
2. **Informational fallacy:** This error arises when a response is logically structured but fails because it either misinterprets or omits key pieces of information provided in the question stem. The response may show logical coherence but lacks accuracy due to incorrect integration or disregard of crucial data necessary to formulate a correct answer.

3. **Explicit fallacy:** In this error, the response fails due to a lack of logical reasoning and incorrect use of the information provided in the question stem. The answer is not only logically incoherent but also misapplies or fails to incorporate essential details from the question, leading to a fundamentally flawed or irrelevant response.

Examples of these fallacies are illustrated in the following numbered list according to the stem "What is the recommended first-line treatment for the initial stages of hypertension?"

1. **Logical:** Lifestyle changes are understood to be very effective in the management of hypertension; therefore, only lifestyle advice should be given.
 - This response incorrectly assumes that the effectiveness of lifestyle changes negates the need for medications, ignoring clinical guidelines that recommend both approaches for many patients.
2. **Informational:** First-line targets in the management of hypertension include the renin-angiotensin-aldosterone system. By blocking the action or formation of aldosterone, blood pressure can be controlled. Hydrochlorothiazide inhibits this system and would lead to reduced blood pressure.
 - This response inaccurately describes hydrochlorothiazide as inhibiting the renin-angiotensin-aldosterone system, when it actually works as a diuretic, reducing blood pressure by decreasing fluid volume.
3. **Explicit:** Patients can typically control hypertension using over-the-counter medications: recommend ibuprofen.
 - This response incorrectly suggests that over-the-counter medications such as ibuprofen can control hypertension, a misunderstanding of medical treatment guidelines that require prescription medications.

International shortages of family physicians, especially in rural areas [7-9], underscore the importance and urgency of maximizing the efficiency of family doctors. AI has the potential to be an extremely useful and efficient tool for integration into the profession [10,11]. However, before any integration of AI into patient care is possible, it must be demonstrated to function in collaboration with human input to provide accurate and reliable information that can help reduce physician error.

This research is predicated on the hypothesis that the AI's performance may significantly improve when provided with comprehensive preparatory material and when using sophisticated data analysis functions.

Research Questions

Our research questions were as follows:

1. Can ChatGPT-4, when provided with comprehensive preparatory materials, perform at or above the passing threshold for the Family Medicine Board Examinations?
2. Does the quality of prompts affect the percent correct scores of ChatGPT-4 on complex medical examination questions?

3. What are the limitations of ChatGPT-4's data analysis functions when applied to the medical knowledge assessment, and how can these be mitigated?

Methods

Creation and Programming of AI Family Medicine Board Examination Taker

The specialized AI named "AI Family Medicine Exam Expert" [12], a version of ChatGPT, was customized specifically to take the ABFM Certification Examination. It was programmed with the following instructions and capabilities.

The AI model, ChatGPT-4: "AI Family Medicine Exam Expert," was programmed to operate under a specific set of instructions designed to guide its behavior toward producing outputs relevant to the ABFM Certification Examination. See the programmer-large language model interaction in the following paragraphs:

Programmer: Please read the attached files in your configuration entirely and let me know if you have any trouble reading it or have any questions regarding its content. The goal is to completely memorize and understand the files' contents. Please let me know when you have completed this task.

Large language model: I've updated my configuration to focus on memorizing and understanding the contents of the attached files. Let me take a moment to review it thoroughly. I'll let you know as soon as I've completed this task. Just a moment while I process the file's contents. I've reviewed the contents of the attached files. How can I assist you further with it?

Programmer: Take on the persona of a Final Year Family Medicine Resident to answer practice exam questions for the Family Medicine Board Exams. Use the files that you just read as your primary resource to find the correct answers. If the answer is not directly available in these files, use your browsing

capabilities to search the internet for the most accurate and relevant information from scholarly sources such as Up-to-date or peer reviewed articles. Should neither the textbooks nor the internet provide a definitive answer, use your medical knowledge to provide the best educated guess. Explain your reasoning for each answer and specify the resources used, whether it's from the textbooks, internet research, or your own medical knowledge to make a best guess. Please ask me any questions before you start.

Large language model: I've adapted to the role of a Final Year Family Medicine Resident, prepared to tackle practice exam questions for the Family Medicine Board Exams. I'll rely on the information from the attached files, scholarly sources, and my own medical knowledge to provide the most accurate and relevant answers. If you have any specific questions or topics you'd like to start with, please let me know. Otherwise, feel free to present me with a practice exam question to begin.

These instructions mandated the model to prioritize information from 3 key textbooks: *Textbook of Family Medicine (Ninth Edition)* by Rakel [13], *The Family Medicine Board Review Book* by Baldor [14], and *Family Medicine: A Practical Approach (Second Edition)* by Al-Gelban et al [15], as seen in [Figure 1](#). The textbooks selected represented the latest editions of key preparatory materials available at the University College Cork medical school's library. These texts were pivotal in providing foundational and advanced knowledge in family medicine, reflecting the spectrum of topics, ethical considerations, and clinical practices that are crucial for the ABFM Certification Examination. Their selection was strategic, ensuring that the AI was trained with the most relevant and authoritative content, enhancing the reliability and accuracy of its examination performance. These choices also mirror the readily accessible resources in a typical medical school library, thus providing a realistic and practical educational tool for students preparing for board examinations.

Figure 1. Instructions given to AI Family Medicine Exam Expert.

The AI was configured to parse and integrate extensive medical knowledge from these textbooks into its responses. This integration was facilitated through a custom training regimen that involved loading and encoding the textbooks' content into the model's memory. This process ensures that the AI can recall and apply textbook knowledge to answer examination-related questions accurately.

In instances where these sources did not provide sufficient information, the model was instructed to use its browsing capabilities to access current, peer-reviewed medical literature and websites for additional data. The instruction set explicitly directed the AI to provide answers with clear explanations, referencing the textbooks, web-based sources, or its in-built medical knowledge. In cases where neither the textbook nor the

web provided a definitive answer, the AI was directed to apply its medical knowledge to give the best possible educated guess.

Input data consisted of a diverse set of questions from American Academy of Family Physicians' (AAFP's) "Family Medicine Board Review Questions," modeled after past Family Medicine Board Examinations [16]. These questions spanned various topics within family medicine, including diagnostics, patient management, ethics, and current best practices. The input was systematically varied to cover a broad spectrum of scenarios, difficulty levels, and question formats. Each question was presented to the AI model as a stand-alone task, ensuring that responses were generated independently, without influence from previous queries [17].

With regard to the output indicator, the desired output included a selection from a series of multiple-choice answer options per question. Incorrect answers were labeled according to their error type: logical, informational, and explicit fallacy, as defined in the “Background” section. Once an error was noted, 2 of the data collectors independently assigned it a type; in the case of a disagreement, a third data collector evaluated the error type to make a final decision.

This methodological framework was designed to rigorously evaluate the AI’s capability to mimic the performance of a final-year Family Medicine resident in answering board examination questions, providing a structured approach for assessing its effectiveness in this specific application.

Operational Procedure

The AI was presented with a series of questions from the AAFP’s Family Medicine Board Review Questions. These questions encompassed a broad range of topics pertinent to Family Medicine. For each question, the AI used its primary knowledge source, browsing capabilities, and medical understanding to formulate answers. The responses were then recorded in an Microsoft Excel sheet for analysis. All questions were inputted into ChatGPT-4 Default Version and the Custom Version exactly as they appeared on the AAFP practice tests.

Data Analysis

The AI’s responses were evaluated against the correct answers as per the AAFP’s Family Medicine Board Review Questions. The minimum passing threshold for the 2009 certification examination was a scaled score of 390, corresponding to 57.7%-61.0% [1,18].

Ethical Considerations

As an observational study involving an AI system, there were no human or animal subjects, thus minimizing ethical concerns. Ethical approval was not required for this study.

Statistical Analysis

In this investigation, we evaluated the performance of 2 language model versions, ChatGPT-4 Custom Robot and ChatGPT-4 Regular, by comparing their responses to a set of 300 questions on a question-by-question basis. We estimated the percentage of correct responses for each version and calculated 95% CIs using the normal approximation method to assess the precision of these estimates.

Given the paired nature of our data, we applied the McNemar test to assess the difference in performance between the 2 versions in terms of correct or incorrect responses. This test is particularly suited for paired categorical data and provides a robust comparison of the 2 versions’ accuracy. The results of the McNemar test indicated no statistically significant difference in performance, suggesting that the accuracy of the 2 versions is statistically similar.

In addition, we conducted a chi-square test to compare the distribution of error types (logical, informational, explicit fallacy) between the 2 versions. This test aimed to identify significant variations in error patterns. The chi-square test results showed no statistically significant difference in the distribution of error types, indicating that the types of errors made by both versions are statistically similar.

All statistical analyses were conducted using Python (version 3.8), using the statsmodels and NumPy libraries for statistical computations and data handling. This comprehensive approach allowed for a nuanced comparison of the ChatGPT-4 Custom Robot and ChatGPT-4 Regular, providing insights into their accuracies and error tendencies.

Results

Accuracy Assessment

As shown in Table 1, the ChatGPT-4 Custom Robot version correctly answered 88.67% of the questions (95% CI 85.08%-92.25%), while the Regular version achieved a correct response rate of 87.33% (95% CI 83.57%-91.10%).

Table 1. Summary of statistical analysis comparing two version of ChatGPT-4.^a

Test	ChatGPT-4 Regular	ChatGPT-4 Custom Robot	Significance
Correct response rate, % (95% CI)	87.33 (83.57-91.10)	88.67 (85.08-92.25)	Not significant (overlap)
Chi-square test for error types, <i>P</i> value	.32	.32	Not significant (<i>P</i> >.05)
McNemar test, <i>P</i> value	.45	.45	Not significant (<i>P</i> >.05)

^aComparative analysis of ChatGPT-4 Regular and Custom Robot versions showing similar performance and error distribution with no statistically significant differences in 95% CIs and chi-square and McNemar test results.

Error Type Analysis

The distribution of error types across the 2 versions was evaluated using a chi-square test. The types of errors were categorized into logical, informational, and explicit fallacy. The test resulted in a *P* value of .32.

Statistical Significance

The McNemar test, which was applied to assess the significance of the difference in performance between the 2 versions, yielded a *P* value of .45.

Discussion

Principal Results

Accuracy assessment results suggested that the observed differences in correct response rates between the Custom Robot and Regular versions were not statistically significant, implying comparable performance in accuracy. Error type analysis indicated no statistically significant difference in the distribution of error types between the 2 versions. The result of the McNemar test suggested that the observed differences in correct response rates between the Custom Robot and Regular versions were not statistically significant, implying comparable performance in accuracy.

Evaluation Outcomes

The lack of a significant difference in performance indicates that the quality of prompts and resources given to the Custom Robot "AI Family Medicine Exam Expert" improved ChatGPT-4's performance but was not found to be significantly impactful. However, their accuracy rates are indicative of a passing level of proficiency in understanding and responding to the complex medical scenarios presented in the examination questions [1, 18]. This observation aligns with previous research showing that large language models such as ChatGPT can perform at or near the passing thresholds in medical examinations without specialized training or reinforcement, as demonstrated in the study on the United States Medical Licensing Examination [19]. It seems likely that the Regular ChatGPT-4 was trained on a dataset that included sufficient medical information, which would compensate for the lack of specific medical training. Since both the Regular and Custom models already excel at understanding language and context, allowing them to effectively reason through questions regardless of whether they were specifically trained on medical textbooks yielded similar results.

Implications for AI Performance

The lack of significant variation in error types highlights that both versions of ChatGPT-4 exhibit similar patterns in processing and interpreting medical information. This finding is crucial, as it underscores the AI's consistent performance across different configurations despite the resources and prompts they are given.

Limitations

One key limitation of our study is the reliance of the custom pretrained language model on textbooks, which may not fully capture the nuanced and evolving nature of medical knowledge. Given the static nature of the AI's textbook knowledge base, which does not account for the rapid advancements in medical research and practice, it was hypothesized that the Custom Robot was forced to depend on its dynamic learning capabilities using the web to stay current with medical knowledge and guidelines and answer the questions.

This is a concept that should be researched further and potentially addressed for future models. Previous research has had this limitation as well [20]; some studies have discussed the difficulty of applying data from differing subsets in a single

algorithm and others have mentioned that their models require continuous updates in knowledge bases in order to function properly [21-23].

This ability was shared by both the Custom and Regular Robots, hence the lack of significant improvement for the textbook-resourced Custom Robot.

Comparison With Prior Work

Comparing our findings with prior work, we observe a progression in the capabilities of AI models in medical knowledge assessment for Family Medicine Board Examinations. Earlier studies of ChatGPT demonstrated insufficient accuracy to pass Family Medicine Board Examinations [3]. However, our study showed that both ChatGPT-4 versions Custom and Regular achieved passing marks of 88.67% and 87.33%, respectively, thus suggesting the potential for AI as a resource in medical education and clinical decision-making.

Conclusions

Our study has provided compelling evidence that ChatGPT-4, in both its Regular and Custom Robot versions, exhibits a high level of proficiency in tackling the complex questions typical of the Family Medicine Board Examinations. The performance of these AI models, with correct response rates of 88.67% and 87.33%, respectively, demonstrates their potential use in the realm of medical education and examination preparation as reliable study material.

Despite the Custom Robot version being equipped with targeted preparatory materials, the statistical analysis revealed no significant performance enhancement over the Regular version. This finding suggests that the core capabilities of ChatGPT-4 are robust enough to handle the intricate nature of medical examination questions, even without extensive customization.

The similarity in error types between the 2 versions underscores a consistent performance characteristic of ChatGPT-4, regardless of its programming nuances. However, it also highlights an area for future improvement, particularly in refining the model's ability to navigate the dynamic and evolving landscape of medical knowledge.

This research contributes to the growing body of evidence supporting the use of advanced AI in medical education. The high correct response rates achieved by ChatGPT-4 indicate its potential as a supplemental tool for medical students and professionals. Furthermore, this study illuminates the limitations and areas for advancement in AI applications within the medical field, especially in the context of rapidly progressing medical knowledge and practices.

In conclusion, while the integration of AI such as ChatGPT-4 into clinical practice and education shows promising prospects, it is crucial to continue exploring its capabilities, limitations, and ethical implications. The evolution of AI in medicine demands ongoing evaluation and adaptation to ensure that it complements and enhances, rather than replaces, human expertise in health care.

Further training phases may seek to incorporate clinical resources that are consistently updated, such as UpToDate. This would also allow an improved robot to incorporate a larger, more accurate dataset of medical information, thereby exposing it to an even more diverse range of medical concepts and terms not captured by the Regular version. This approach may allow the limitation of chronically out-of-date textbooks to be overcome.

Acknowledgments

AJG and SK extend their thanks to Dr KK for her advice, tutelage, and sponsorship for the accessing of ChatGPT-4 software.

Authors' Contributions

AJG and SK conceived and designed the study. AJG, SK, AA, AC, MK, and MP undertook data collection. AJG conducted data analysis and visualization. AJG and SK drafted the manuscript. KK, YBL, and AC provided feedback on the manuscript and assisted with redrafting. All authors approved the submitted version of the manuscript.

Abstract

Background: Recent studies, including those by the National Board of Medical Examiners, have highlighted the remarkable capabilities of recent large language models (LLMs) such as ChatGPT in passing the United States Medical Licensing Examination (USMLE). However, there is a gap in detailed analysis of LLM performance in specific medical content areas, thus limiting an assessment of their potential utility in medical education.

Objective: This study aimed to assess and compare the accuracy of successive ChatGPT versions (GPT-3.5, GPT-4, and GPT-4 Omni) in USMLE disciplines, clinical clerkships, and the clinical skills of diagnostics and management.

Methods: This study used 750 clinical vignette-based multiple-choice questions to characterize the performance of successive ChatGPT versions (ChatGPT 3.5 [GPT-3.5], ChatGPT 4 [GPT-4], and ChatGPT 4 Omni [GPT-4o]) across USMLE disciplines, clinical clerkships, and in clinical skills (diagnostics and management). Accuracy was assessed using a standardized protocol, with statistical analyses conducted to compare the models' performances.

Results: GPT-4o achieved the highest accuracy across 750 multiple-choice questions at 90.4%, outperforming GPT-4 and GPT-3.5, which scored 81.1% and 60.0%, respectively. GPT-4o's highest performances were in social sciences (95.5%), behavioral and neuroscience (94.2%), and pharmacology (93.2%). In clinical skills, GPT-4o's diagnostic accuracy was 92.7% and management accuracy was 88.8%, significantly higher than its predecessors. Notably, both GPT-4o and GPT-4 significantly outperformed the medical student average accuracy of 59.3% (95% CI 58.3 - 60.3).

Conclusions: GPT-4o's performance in USMLE disciplines, clinical clerkships, and clinical skills indicates substantial improvements over its predecessors, suggesting significant potential for the use of this technology as an educational aid for medical students. These findings underscore the need for careful consideration when integrating LLMs into medical education, emphasizing the importance of structured curricula to guide their appropriate use and the need for ongoing critical analyses to ensure their reliability and effectiveness.

Introduction

Overview

Recent studies have demonstrated the promise of large language models (LLMs) such as ChatGPT, Google Gemini, and Claude in various medical applications, with studies showing passing United States Medical Licensing Examination (USMLE) exam scores and evaluating LLMs' ability to assist with clinical documentation and provide medical advice [1-4]. The potential of these models to revolutionize medicine and medical education underscores the need for a thorough evaluation of their performance [5,6]. Before LLMs can be widely adopted in health care and medical education, it is crucial to assess their proficiency in both preclinical disciplines (eg, anatomy, physiology, and microbiology) and clinical disciplines (eg, diagnostics and treatment recommendations).

The Role of LLMs in Medical Education

In the context of undergraduate medical education, LLMs have demonstrated preliminary potential in text-based applications in generating practice questions, fostering case-based learning, creating study guides, and providing rapid answers to relevant questions [7-9]. Although models such as GPT-3.5 offer the potential for a more personalized learning experience, they also have limitations, such as training cut-off dates, limited image capabilities, potential inaccuracies, and a lack of user training [10-12]. Medical students often use third-party resources to supplement their studies, with evidence suggesting that such utilization is associated with higher USMLE scores [13,14]. The diverse applications and benefits of LLMs contribute to a comprehensive approach to fostering self-directed learning for lifelong learners in medicine [12,15]. While accuracy remains a limitation of LLMs as clinical tools for students and clinicians, recent studies indicate a trend toward increased reliability and accuracy, a crucial consideration for their use in medical education and health care [16-18].

Previous Assessments of LLM Accuracy in Medical Contexts

Comparing multiple studies on the accuracy of LLMs in the context of medicine, such as ChatGPT, is challenging due to variations in question sets, exclusion criteria, and the specific models assessed, though some parallels can be drawn. Most studies have evaluated LLMs based on their ability to correctly answer multiple-choice questions (MCQs) from retired National Board of Medical Examiners' (NBME) content or third-party question banks such as Amboss [19-22]. Some studies suggest LLMs perform better on USMLE sample items compared to third-party question banks [20], and newer versions of LLMs such as ChatGPT 4 (GPT-4) outperform their earlier counterparts [22]. Evaluations of ChatGPT 3.0 found it was able to accurately answer USMLE sample items 36.7% of the time [23], improving to more than 50% correct in a matter of months [21]. Performance also appears to depend on the specific skills tested and the language used in training [24,25]. Further illustrating this in a study by the NBME, ChatGPT scored a passing score in USMLE Step exams across multiple attempts, with one exception in a USMLE Step 3 exam attempt [26]. ChatGPT 3.5 (GPT-3.5) was found to answer 63.06% of Step

1 and 70.0% of Step 2 CK questions correctly [26]. Most recent studies showcase GPT-4 achieving as high as 86% accuracy on USMLE Step 1 questions, highlighting its near readiness for investigation in improving learning for medical students in preclinical education.

Aim of the Study

While previous research has primarily explored the ability of these models to pass medical licensing exams, this study takes a medical disciplinary approach to assess and compare the accuracy of ChatGPT 3.5 (GPT-3.5), ChatGPT 4 (GPT-4), and ChatGPT 4 Omni (GPT-4o) specifically in the context of the USMLE preclinical medical disciplines and clinical clerkships. These historically recognized USMLE (and NBME [27]) preclinical medical disciplines, including anatomy, pathology, and biochemistry, provide a valuable empirical framework to understand the strengths and weaknesses of language models in medical disciplines and clinical skills.

Methods

LLMs: The ChatGPT Series

In our study, we used the ChatGPT series, which comprises sophisticated algorithms designed to simulate human-like responses to textual inputs. These models generate responses by analyzing input text and predicting output based on learned statistical patterns. ChatGPT 3.5 (GPT-3.5) is the earliest model used in this study and is currently accessible to the public through free subscription [28]. ChatGPT 4 (GPT-4), introduced in March 22, 2023 and available through a monthly paid subscription, was included for comparative analysis [29]. Notably, we included the latest ChatGPT model, ChatGPT 4 Omni (GPT-4o), which was released on May 13, 2024 [30].

Clinical Vignette-Based Assessment in USMLE Disciplines and Clinical Clerkship

In total, 750 clinical vignette-style MCQs were sourced from various question banks provided by medical schools to medical students (Amboss, UWorld, TrueLearn). To prevent model "learning" effects and avoid potential bias from prior usage of publicly available question sets, we selected these MCQs from these sources, which are not publicly accessible.

The 750 MCQs were divided evenly, with 375 covering USMLE Step 1 ("Preclinical") content and 375 covering USMLE Step 2 ("Clinical"). We applied specific criteria to ensure the relevance and rigor of the questions. Questions involving imaging findings (such as X-rays, MRIs, or ultrasounds), histologic, and gross exam findings were excluded from the study, and an additional clinical vignette was generated in its place. To ensure diversity and reduce bias, questions were sourced by generating random question sessions, with careful attention to avoid duplication of any questions in the final set.

For each MCQ, we noted whether the vignette pertained to preclinical or clinical subject matter, identified the specific USMLE preclinical discipline or clinical clerkship content assessed, and the percentage of medical students who answered correctly, as detailed by the question bank resources. Using the percentage of medical students who correctly answered each

question, we assigned a difficulty tier to each question on a scale from 1 (most difficult) to 5 (easiest) (1: 0% - 19.9%; 2: 20.0% - 39.9%; 3: 40.0% - 59.9%; 4: 60.0% - 79.9%; 5: 80.0% - 100%).

Protocol for Assessing Accuracy of ChatGPT

The assessment of the language models was conducted from May 20 to May 26, 2024. The assessment of response accuracy entailed entering the MCQs into a ChatGPT chat session using a standardized protocol based on methodologies similar to those employed in multiple-choice-based language model assessments [16,17,19,26,31-35]. This protocol for eliciting a response from ChatGPT was as follows: "Answer the following question and provide an explanation for your answer choice." Data procured from ChatGPT included its selected response, the rationale for its choice, and whether the response was correct ("accurate" or "inaccurate"). Responses were deemed correct if ChatGPT chose the correct multiple-choice answer. To prevent memory retention bias, each vignette was processed in a new chat session.

Assessment in Clinical Domains of Diagnostics and Management

Further subcategorization of the 750 MCQs was made based on their question stem. Question stems assessing the most likely

diagnosis (n=168, "Diagnostics") or the next best step in treatment (n=178, "Management") were noted and used for further comparison to assess accuracy in the clinical skills of diagnostics and management.

Statistical Analysis

IBM SPSS Statistics 29.0 (IBM Corporation) was used for statistical analyses, with a significance threshold of $P < .05$. Statistical tests included chi-squared for categorical comparisons, and binary logistic regression when assessing the influence of question difficulty on language model correct response rate.

Ethical Considerations

The study did not involve patient data or human subjects and, as such, was not subject to institutional review board approval.

Results

Overall, GPT-4o achieved an overall correct response rate of 90.4%, while GPT-4 had 81.1%, both significantly outperforming GPT-3.5's correct response rate of 60.0% (Table 1 and Figure 1). The average accuracy of medical students was 59.3% (95% CI 58.3 - 60.3).

Table . Response accuracy of the ChatGPT series across USMLE^a preclinical disciplines and clinical clerkships. Some questions (n=139) could not be categorized due to not having or having multiple categories from sources.

Question category or subcategory	Questions, N	Language model performance, n (%) correct			Medical student average, percent correct (95% CI)
		GPT ^b -3.5	GPT-4	GPT-4o

^aUSMLE: United States Medical Licensing Examination.

^bGPT: Generative Pre-trained Transformer.

Figure 1. Analysis of ChatGPT models' and medical students' performance on USMLE questions. This figure displays the comparative accuracies of ChatGPT 3.5 (GPT-3.5), ChatGPT 4 (GPT-4), ChatGPT 4 Omni (GPT-4o), and medical students in answering a set of 750 USMLE-style questions. The overall accuracy, preclinical accuracy, and clinical accuracy are shown. Asterisks (*) denote statistically significant differences ($P < .05$), highlighting the advancements in newer models of the GPT series. The number of questions is indicated for each category: $n=750$ for overall accuracy, $n=375$ for preclinical accuracy, and $n=375$ for clinical accuracy. GPT: Generative Pre-trained Transformer; USMLE: United States Medical Licensing Examination.

USMLE Discipline Response Accuracies

In total, 375 MCQs designed to assess preclinical content as categorized by USMLE disciplines were administered to GPT-3.5, GPT-4, and GPT-4o. GPT-3.5's highest correct response percentages were in behavioral and neuroscience (76.9%), immunology (67.9%), and pharmacology (61.3%). Conversely, the lowest correct response percentages were observed in physiology (54.2%) and microbiology (51.3%). For GPT-4, the highest correct response percentages were observed in behavioral and neuroscience (86.5%), anatomy, histology,

and embryology (86.1%), and pharmacology (84.1%). The lowest correct response percentages for GPT-4 were in physiology (50.0%) and pathology (69.0%). GPT-4o demonstrated the highest correct response percentages in social sciences (95.5%), behavioral and neuroscience (94.2%), and pharmacology (93.2%). The lowest correct response percentages for GPT-4o were in pathology (82.8%) and biostatistics and epidemiology (81.0%).

Response Accuracies in Clinical Clerkships

In total, 375 MCQs assessing clinical clerkship content were administered to GPT-3.5, GPT-4, and GPT-4o. GPT-3.5 exhibited its highest response percentages in neurology (69.5%) and internal medicine (68.2%), while the lowest percentage response accuracies were observed in obstetrics and gynecology (53.3%) and surgery (55.6%). In comparison, GPT-4 achieved higher accuracy across all clerkships, with notable performances in internal medicine (95.5%) and obstetrics and gynecology (88.9%). Similarly, GPT-4o demonstrated improved performance, achieving correct response rates of 93.2% in neurology and 93.0% in psychiatry, as well as 100.0% in family

medicine and 100.0% in internal medicine. The lowest accuracies for GPT-4o were still significantly high, with obstetrics and gynecology at 91.1% and surgery at 86.1%. Overall, GPT-4 and GPT-4o showed substantial improvements over GPT-3.5 in all clinical clerkship categories.

Vignette Difficulty and Comparisons Based on Respondent Performance

GPT-3.5 ($\text{Exp}(B)=1.033$, $\text{SE}=0.005$, $P<.001$), GPT-4 ($\text{Exp}(B)=1.039$, $\text{SE}=0.006$, $P<.001$), and GPT-4o ($\text{Exp}(B)=1.043$, $\text{SE}=0.008$, $P<.001$) demonstrated a higher likelihood of responding incorrectly to vignettes that were more challenging for medical student respondents (Figure 2).

Figure 2. Influence of question difficulty on response accuracy compared to medical student performance. This figure illustrates the effect of clinical vignette difficulty on the response accuracy of ChatGPT 3.5 (GPT-3.5), ChatGPT 4 (GPT-4), and ChatGPT 4 Omni (GPT-4o) in comparison to medical students. The bar graph represents the percentage of correct responses across different tiers of difficulty, ranging from tier 1 (most difficult) to tier 5 (easiest). The number of questions for each difficulty tier is n=10 for tier 1, n=89 for tier 2, n=263 for tier 3, n=302 for tier 4, and n=81 for tier 5.

Performance of ChatGPT in Diagnostics and Management

A total of 342 MCQs were secondarily categorized from the 750 MCQs based on question stems: 164 assessing “diagnostics” and 178 assessing “management.” Overall, the respective percent correct response accuracies of GPT-3.5, GPT-4, and GPT-4o in these questions were 70.5% (241/342), 81.9% (280/342), and

88.8% (304/342) (Figure 3). In the diagnostics category, GPT-4 and GPT-4o demonstrated higher correct response percentages compared to GPT-3.5 (83.5% and 92.7% vs 65.2%). Similarly, in the management category, GPT-4 and GPT-4o outperformed GPT-3.5 (77.0% and 88.8% vs 57.9%). Notably, GPT-4o significantly outperformed GPT-4 in both diagnostics and management.

Figure 3. Performance of ChatGPT models in diagnostics and management compared to medical students. This figure compares the performance of ChatGPT 3.5 (GPT-3.5), ChatGPT 4 (GPT-4), and ChatGPT 4 Omni (GPT-4o) in the clinical domains of diagnostics and management. The bar graph shows the percentage of correct responses for each model and medical students in the diagnosis (n=164) and management (n=178) categories. GPT-4o exhibits the highest accuracy in both categories, followed by GPT-4, with GPT-3.5 showing the lowest performance. Asterisks (*) denote statistically significant differences ($P < .05$), emphasizing the advancements in newer models of the GPT series. GPT: Generative Pre-trained Transformer.

Discussion

Overview

This study evaluated ChatGPT versions for their accuracy in USMLE preclinical disciplines, clinical clerkships, and clinical skills categories of diagnostics and management. The aim was to assess the reliability of using LLMs in medical education by examining their accuracy across various preclinical and clinical disciplines. Dependable accuracy in these areas underlies the potential of LLMs to support medical education effectively.

Our findings highlighted varied performances across disciplines, with a significant increase in response accuracy observed for GPT-4o over GPT-4 and GPT-3.5.

Overall Performance and Disciplinary Accuracies

Overall, GPT-4o achieved an accuracy rate of 90.4%, significantly outperforming both GPT-3.5 (60.0%) and GPT-4 (81.1%). This improvement is consistent across both preclinical and clinical domains, emphasizing the advancements in model development. GPT-4o's highest preclinical accuracy rates were observed in social sciences (95.5%), behavioral and

neuroscience (94.2%), and pharmacology (93.2%). In clinical clerkships, GPT-4o maintained high accuracy, particularly in family medicine and internal medicine, where it achieved a 100% correct response rate, and demonstrated strong performance in neurology and psychiatry. These findings underline GPT-4o's potential utility in medical education and emphasize the necessity of its strategic integration into educational curricula.

Question Difficulty and Comparison With Medical Student Performance

Notably, there was a significant positive correlation between the percentage of correct responses by medical students and the likelihood of correct responses by the LLMs, which indicates that as vignette difficulty increased, the performance of the artificial intelligence (AI) models reflected the difficulty gradient experienced by the students. However, it is worth noting that GPT-4o achieved an overall accuracy of 90.4% in a question set where the medical students average was less than that of a passing USMLE exam score (59.3%).

Improvements in Diagnostics and Management

The clinical vignette-based assessments further illustrated the improvements in GPT-4o in diagnostics and management. In diagnostics, GPT-4o achieved a 92.7% accuracy rate, surpassing GPT-4 (83.5%) and GPT-3.5 (65.2%). Similarly, in management tasks, GPT-4o's accuracy was 88.8%, significantly higher than both GPT-4 (77.0%) and GPT-3.5 (57.9%).

Factors Contributing to Improved Performance

The improvements seen in GPT-4o could be attributed to several advancements in its architecture and the model's training, such as more comprehensive datasets and refined algorithms. This trend of improvement aligns with previous research noting the progressive enhancements in LLMs' accuracy and reliability [16-18]. However, an important consideration is the potential interaction between LLM performance and the Flynn effect, which describes the observed rise in intelligence test scores over time. As LLMs are trained on increasingly up-to-date data, they may reflect or even amplify these trends, potentially impacting the psychometric validity of assessments like the USMLE. For instance, environmental influences and the availability of more recent data can significantly impact cognitive performance, a factor that may similarly affect AI models [36]. The implications of this interaction warrant further exploration, as understanding these dynamics could provide valuable insights into both the short-term and long-term reliability of LLM-assisted test performance in medical education. Additionally, the recency of the datasets used to train GPT-4 and GPT-4o could be another factor contributing to their improved accuracy compared to GPT-3.5. As these improvements continue, it is essential to assess how they contribute not only to immediate gains in performance but also to the broader implications for long-term educational outcomes and assessment integrity.

Considerations for Integration in Medical Education

Several considerations must be addressed before integrating these models into medical education. The ability to correctly answer USMLE questions is not necessarily the same as synthesizing and reasoning about a patient's history, clinical

symptoms, physical exam findings, and laboratory data. This raises the concern of whether LLMs will be able to provide safe and accurate guidance to clinicians at the bedside who are struggling to make sense of a patient's illness. It will therefore be important to assess the value of LLMs in real clinical situations and to assess if and how they can be safely deployed in clinical settings. To address this, medical schools and residency program directors should establish mechanisms to continuously monitor the performance and impact of LLMs used in clinical settings. It would be valuable to create a national registry of feedback from students and faculty to identify errors and unintended consequences associated with the use of LLMs in medical education and clinical care.

In the context of American medical education, standardized testing environments such as the USMLE play a critical role in shaping the applicability of LLMs like GPT-4o. These models must adapt to a testing culture that heavily emphasizes MCQ formats, which are integral to medical training and licensure in the United States. While LLMs offer potential advantages, there is a risk that over-reliance on AI could hinder the development of essential diagnostic skills in medical students and clinicians [37,38]. This dependency on AI tools may lead to a decline in critical thinking and problem-solving abilities, particularly in situations where AI support is unavailable [39,40]. These concerns underscore the importance of thoughtfully integrating AI into medical education, with careful consideration of its long-term impact on clinical competencies and ethical implications, such as fairness and equity in training future health care professionals [37,38].

Ethical Implications of AI Integration With Medical Education

The ethical implications of integrating AI, including LLMs, in medical education and patient care require thorough consideration. Issues such as data privacy, the potential for systemic bias in AI algorithms, and the lack of accountability in AI-driven decisions pose serious challenges. The inherent biases in training data can lead to skewed AI responses, impacting clinical decision-making processes [41]. Moreover, the reliance on AI-driven tools raises concerns about the equitable distribution of these technologies, as access often requires paid subscriptions, which could exacerbate disparities in medical education. To mitigate these risks, educational institutions should implement clear guidelines for AI use, including regular audits of AI performance and mandatory training for students and faculty on the limitations and ethical considerations of AI tools. Additionally, establishing dedicated oversight committees to monitor AI integration and address any emerging issues in real-time will be crucial to ensuring these technologies are used responsibly and effectively.

Study Limitations

This study contains several limitations. The 750 MCQs are robust, although they are "USMLE-style" questions and not actual USMLE exam questions. The exclusion of clinical vignettes involving imaging findings limits the findings to text-based accuracy, which potentially skews the assessment of disciplinary accuracies, particularly in disciplines such as anatomy, microbiology, and histopathology. Additionally, the

study does not fully explore the quality of the explanations generated by the AI or its ability to handle complex, higher-order information, which are crucial components of medical education and clinical practice—factors that are essential in evaluating the full utility of LLMs in medical education. Previous research has highlighted concerns about the reliability of AI-generated explanations and the risks associated with their use in complex clinical scenarios [10,12]. These limitations are important to consider as they directly impact how well these tools can support clinical reasoning and decision-making processes in real-world scenarios. Moreover, the potential influence of knowledge lagging effects due to the different datasets used by GPT-3.5, GPT-4, and GPT-4o was not explicitly analyzed. Future studies might compare MCQ performance across various years to better understand how the recency of training data affects model accuracy and reliability.

Future Research Directions

Future research should aim to expand the analysis of medical education to incorporate more diverse clinical vignettes, especially those involving imaging and other multimedia

content. This would provide a more comprehensive assessment of LLM capabilities. Longitudinal studies are also needed to evaluate the long-term effects of AI integration on learning outcomes and clinical decision-making skills. Moreover, investigating methods to mitigate inherent biases in LLMs and exploring the integration of AI with traditional educational methodologies could provide a more balanced view of the potential and limitations of these technologies in medical training.

Conclusions

In conclusion, this study provides an assessment of the response accuracies of the ChatGPT series across a wide array of USMLE preclinical disciplines and clinical clerkships. The significant improvements observed in ChatGPT 4 Omni suggest substantial potential for its use as a tool for medical education. As the utilization of AI by medical students and clinicians increases, our findings emphasize the need for formal curricula and guidelines that ensure proper usage, as well as the necessity of robust validation and oversight processes for LLMs as they are integrated into medical education.

Acknowledgments

The authors would like to acknowledge the invaluable contributions of Jack Citrin, Ben Kronz, Ben Hambricht, Maria Evola, and Olivia Smith, whose assistance as members of our research team was instrumental. The authors also extend their gratitude to AMBOSS, UWorld, and TrueLearn for providing the multiple-choice questions used in this study, without which this research would not have been feasible.

Abstract

Background: With the rapid advancement of artificial intelligence (AI) in various fields, evaluating its application in specialized medical contexts becomes crucial. ChatGPT, a large language model developed by OpenAI, has shown potential in diverse applications, including medicine.

Objective: This study aims to compare the performance of ChatGPT with that of attending neurologists in a real neurology specialist examination conducted in the Valencian Community, Spain, assessing the AI's capabilities and limitations in medical knowledge.

Methods: We conducted a comparative analysis using the 2022 neurology specialist examination results from 120 neurologists and responses generated by ChatGPT versions 3.5 and 4. The examination consisted of 80 multiple-choice questions, with a focus on clinical neurology and health legislation. Questions were classified according to Bloom's Taxonomy. Statistical analysis of performance, including the κ coefficient for response consistency, was performed.

Results: Human participants exhibited a median score of 5.91 (IQR: 4.93-6.76), with 32 neurologists failing to pass. ChatGPT-3.5 ranked 116th out of 122, answering 54.5% of questions correctly (score 3.94). ChatGPT-4 showed marked improvement, ranking 17th with 81.8% of correct answers (score 7.57), surpassing several human specialists. No significant variations were observed in the performance on lower-order questions versus higher-order questions. Additionally, ChatGPT-4 demonstrated increased interrater reliability, as reflected by a higher κ coefficient of 0.73, compared to ChatGPT-3.5's coefficient of 0.69.

Conclusions: This study underscores the evolving capabilities of AI in medical knowledge assessment, particularly in specialized fields. ChatGPT-4's performance, outperforming the median score of human participants in a rigorous neurology examination, represents a significant milestone in AI development, suggesting its potential as an effective tool in specialized medical education and assessment.

KEYWORDS

artificial intelligence; ChatGPT; clinical decision-making; medical education; medical knowledge assessment; OpenAI

Introduction

Recent advancements in natural language processing, particularly the development of large language models (LLMs), have markedly transformed the capabilities of computational linguistics. Among these, ChatGPT, developed by OpenAI, stands out as a leading example, leveraging advanced deep learning techniques to emulate humanlike text generation. Introduced in late 2022, ChatGPT has quickly gained recognition for its ability to produce coherent and contextually relevant responses, owing to its training on a broad dataset [1]. This versatility has made ChatGPT a valuable tool in numerous fields, including medicine.

In the medical field, ChatGPT's potential has been explored through its application in clinical settings and medical examinations, where it has demonstrated a notable proficiency in addressing complex medical and dental queries [2-9]. This has sparked interest in its role in improving medical education and training and support clinical decision-making.

In Spain, the process of obtaining a public position as a medical specialist in the public health service involves a competitive examination, which is administered independently across various regions. This is exemplified in the Valencian Community, where the selection of neurology specialists depends on an examination, encompassing both health legislation and clinical neurology questions. The examination is a critical component

for securing a position in the public health care system, similar to a civil service examination, and is highly competitive. The candidates are already accredited neurologists with a minimum of 4 years of residency and at least 1 year of professional experience.

Despite numerous studies examining the performance of ChatGPT in various medical examinations, a significant gap remains in comparing its capabilities with the real performance and results of highly qualified and specialized clinicians in regional specialty examinations. This study specifically addresses this gap by comparing ChatGPT's performance with that of practicing neurologists in the Valencian Community's neurology specialist examination. The primary objective is to evaluate whether ChatGPT can match or surpass human expertise in this context. Additionally, we aim to assess the consistency and improvement in responses between ChatGPT versions 3.5 and 4. Our a priori hypotheses are as follows: (1) ChatGPT-4 will outperform ChatGPT-3.5, demonstrating improved accuracy and reliability, and (2) ChatGPT-4 will perform comparably to human neurologists. This analysis seeks to provide insights into the potential and limitations of artificial intelligence (AI) in specialized medical knowledge assessment and its implications for medical education and practice.

Methods

Study Design

We conducted a detailed comparative analysis to evaluate the performance of ChatGPT against board-certified neurologists in the 2022 Valencian Community neurology specialist examination [10]. This examination is a credentialing examination that grants a job position in the public health system as a neurology specialist within the Valencian Community, rather than a medical licensing examination. Candidates who sit for this examination are already certified neurologists, having completed a minimum of 4 years of residency and at least 1 year of professional experience. Therefore, this examination is more specialized and competitive compared to typical specialty board examinations that grant the initial permission to practice. The 2022 examination employed a multiple-choice format, with 77 out of the original 80 questions considered for scoring, as 3 were invalidated due to errors in question formulation. A total of 120 practicing neurologists took the examination, competing for only 38 available job positions. The results of the individual examinations of each participating neurologist are publicly available on the Department of Health's website [11].

The Valencian Health Service is one of the 17 regional health services in Spain, providing universal health care to both residents and travelers in the Valencian Community. This region, located on the eastern Mediterranean coast of Spain, has a population of more than 5.2 million inhabitants and attracts around 28.5 million tourists annually. The scope and geographic reach of the Valencian Health Service include all health care facilities within this region, making the credentialing examination crucial for those seeking to work in these public health care institutions.

Multiple-Choice Question Examination

The examination adopted a scoring system where the maximum attainable score was 10, achievable by correctly answering all questions. Unanswered questions were not penalized. The scoring system penalized wrong answers: for every 3 wrong answers, the score for 1 correct answer was subtracted. $Score = (N_{correct} - 1/3 N_{wrong}) \times 10/N_{total}$, where "N" represents the numbers of correct ($N_{correct}$) and wrong (N_{wrong}) answers and the total number of questions (N_{total}). The test began with 12 questions on general public and health legislation topics, followed by 65 questions focused on clinical neurology, assessing both theoretical knowledge and clinical reasoning. Participants with a score higher than 4.5 points passed the examination [10].

Data Collection and Assessment

We compiled the scores of the 120 participating neurologists, which are publicly available (Table S1 in [Multimedia Appendix 1](#)). To assess the performance of GPT-3.5 and GPT-4, we used their respective application programming interfaces (APIs). Two independent researchers, PRA and APS, tasked the ChatGPT versions 3.5 and 4 with answering the examination's multiple-choice questions. This study was conducted in December 2023 and used the LLM versions available at that time.

Prompt Engineering

For consistency, each version of ChatGPT was given the same set of prompts. The initial prompt provided a brief context of the examination question and instructed the AI to select the best answer (see Supplement 1 in [Multimedia Appendix 1](#)).

Interface Version

We utilized the paid subscription API for both ChatGPT-3.5 and ChatGPT-4, ensuring access to the most advanced features available. The settings used included the default temperature settings to maintain consistency and comparability between responses.

Language Settings

Both input and output languages were set to Spanish to match the language of the original examination. This ensured that the AI models processed and responded to the questions in the same language as the neurologists.

Trial Repetitions

Each ChatGPT version was tested twice independently to account for any variability in responses. This involved rerunning the entire set of examination questions with the same prompts. For each trial, the responses were recorded and analyzed separately to evaluate consistency and performance.

Efforts to Chain Prompts

No prompt chaining was employed in this study. Each question was presented individually, and the AI's responses were based solely on the information provided in the individual prompts.

Details of Trials

In total, 4 sets of responses were generated (2 for each version of ChatGPT). Each trial was conducted independently by the researchers to avoid memory bias or influence from previous attempts. The answers were then compiled and compared against the correct answers to calculate the scores.

Question Complexity Classification

Questions in the examination were categorized according to the principles of Bloom's Taxonomy [12], a framework for learning and evaluation. This classification differentiated between questions testing lower-order thinking skills, such as recall and basic understanding, and those measuring higher-order thinking skills, such as application, analysis, and evaluation. The classification process involved the following steps. Two independent researchers, PRA and APS, assigned Bloom's Taxonomy classifications to each examination question. To ensure consistency and accuracy in the classification, the initial assignments by both researchers were compared. Any discrepancies in classification were discussed in consensus meetings between the researchers until an agreement was reached. After resolving discrepancies, the final classifications were used in the analysis. These classifications were then used to evaluate the performance of ChatGPT-3.5 and ChatGPT-4 across different levels of cognitive tasks.

Statistical Analysis

The statistical analysis of the data was conducted using R software, version 4.2.1 (R Foundation for Statistical Computing) [13].

We checked the data's normality using the Kolmogorov-Smirnov test. To assess the consistency of responses within each ChatGPT version across different trials, we calculated the κ coefficient for each model. Specifically, we compared the responses given by ChatGPT-3.5 in its two trials and separately compared the responses given by ChatGPT-4 in its two trials. The κ coefficient measures the agreement between these two sets of responses, providing an indication of the reliability of the AI's performance across different attempts.

Ethical Considerations

Members of the Dr. Balmis General University Hospital Ethics Review Board evaluated this project and stated that this committee was not competent to evaluate studies of this type, as they do not encompass human subjects, the use of biological samples, or personal data. Therefore, ethics committee approval was not required for the execution of this study.

Results

Neurologists' Performance

In the examination under study, 120 neurologists participated. Their median score was 5.91 (IQR: 4.93-6.76) out of 10, with an SD of 1.40. The Kolmogorov-Smirnov test confirmed the normal distribution of these scores. Of these 120 neurologists, 32 did not pass the examination.

ChatGPT-3.5 Performance

ChatGPT-3.5, acting as a hypothetical 121st participant, showed varying results in different attempts. In its first attempt, it answered 41 out of 77 questions correctly, and in another attempt, it managed 42 correct answers. ChatGPT-3.5's scores were 3.77 and 3.94, respectively, in these attempts. However, it failed to reach the examination's passing threshold. Specifically, it answered 32 out of 65 (49.2%) of the clinical neurology and 3.5 out of 12 (29.2%) of the health legislation questions incorrectly, leading to an overall error rate of 35.5 out of 77 (46.1%).

ChatGPT-4 Performance

ChatGPT-4 demonstrated a more robust performance, correctly answering 62 and 63 out of 77 questions, respectively, in both the attempts, achieving a score of 7.57 out of 10 on its best attempt. This score would have qualified it to pass the examination, ranking it 17th out of the 122 candidates (which includes the 120 neurologists and both ChatGPT versions). ChatGPT-4's error rate was 11.05 wrong answers out of 65 (17%) in clinical neurology questions and 3 out of 12 (25%) in legal questions. [Figure 1](#) compares the score distribution of the neurologists who took the examination with the performances of ChatGPT-3.5 and ChatGPT-4.

Figure 1. Distribution of neurologists' examination scores. The graph shows the median performance of neurologists and the highest scores of ChatGPT-3.5 and ChatGPT-4 within the overall score distribution.

Concordance Analysis and Complexity-Based Performance

The κ coefficient for ChatGPT-3.5 was 0.686, measuring the consistency of its responses across attempts. ChatGPT-4's κ coefficient was slightly higher at 0.725. Both models showed a high level of consistency in their performances across different attempts, with a mere 1.25% variation in their scores. [Table 1](#)

presents the performance data of each model and attempt, broken down by Bloom's Taxonomy question classifications.

Based on Bloom's Taxonomy, lower-order questions included tasks such as defining terms, recalling facts, and understanding basic concepts (eg, "Which lesion causes ideomotor apraxia?"). Higher-order questions required application, analysis, and evaluation (eg, "Given the following symptoms, what is the most likely diagnosis?").

Table . Comparative performance analysis of ChatGPT-3.5 and ChatGPT-4 models on the examination: accuracy across attempts and question difficulty levels.

Model and attempt	Overall accuracy (%)	Accuracy on lower-order questions (%)	Accuracy on higher-order questions (%)
ChatGPT-3.5			
Attempt 1	53.25	54.84	52.17
Attempt 2	54.55	54.84	54.35
ChatGPT-4			
Attempt 1	81.82	77.42	84.78
Attempt 2	80.52	80.65	80.43

Discussion

This study's comparative analysis between ChatGPT and neurologists in a real medical examination offers valuable insights into the current abilities and limitations of AI in the assessment of medical knowledge. We selected ChatGPT, instead of other LLMs such as Gemini or Bard, for our study due to its well-documented performance in medical examinations, robust and user-friendly API facilitating easy integration and comprehensive testing, and its popularity and widespread usage, making it one of the most commonly used LLMs in the world as of December 2023.

ChatGPT has been able to pass the medical license examinations of several countries such as the United States [14], Germany [15], China [16], Japan [7], Saudi Arabia [17], Poland [18], and Spain [19]. Furthermore, ChatGPT has been able to pass the medical examination of a growing list of different medical specialties: anesthesiology [20], nuclear medicine [21], ophthalmology [22], otolaryngology [23], radiology [24], neurosurgery [25], and neurology [26,27].

A key strength of our study is its real-world setting—an actual competitive examination undertaken by 120 practicing neurologists, who were competing for specialized positions within the Valencian Health Service. This examination provides a tough and high-pressure assessment of their expertise, reflecting the pressures and complexities encountered in highly specialized and competitive scenarios. The range of scores among the neurologists serves as a human benchmark, highlighting the variability in medical expertise. This variability underlines the dynamic and individual nature of medical knowledge, and provides a realistic benchmark for assessing the capabilities of AI tools such as ChatGPT in professional scenarios. However, the focus on the Valencian Community might limit the generalizability of the findings to other regions or countries.

ChatGPT-3.5's performance, though notable, reveals complexities. It accurately answered 42 (54.5%) of the questions in its best attempt, surpassing only 6 attending neurologists and failing to pass the examination. If ChatGPT-3.5 were a real examination participant, it would rank 116th out of 122 candidates—indicating room for improvement. The disparity in its performance between legal and neurology questions prompts further investigation into its decision-making processes. In contrast, ChatGPT-4's performance shows significant

improvement over ChatGPT-3.5. In the demanding neurology specialist examination, ChatGPT-4 not only surpassed its predecessor but also outperformed 103 of 120 human medical specialists. This marks a substantial advance in the model's handling of specialized medical knowledge and suggests its potential as a tool in medical education and decision-making.

The study design we implemented did not include mechanisms for ChatGPT to explain or reason its answers, which limits our ability to evaluate the types of errors made by the AI models, such as differentiating between content errors and question interpretation errors. We did not prompt ChatGPT to provide explanations for its responses, and thus, we cannot perform a detailed analysis of its reasoning processes. This limitation highlights a gap in our study, as we were unable to analyze the types of errors made by ChatGPT. Future research should incorporate prompts for AI models to explain their answers, which would enable a deeper analysis of content errors versus question interpretation errors.

We calculated κ coefficients to assess the consistency of responses between trials for ChatGPT-3.5 and ChatGPT-4. The κ coefficient was 0.686 for ChatGPT-3.5 and 0.725 for ChatGPT-4, both indicating substantial but not perfect agreement. The slightly higher κ coefficient for ChatGPT-4 suggests improved reliability; however, the concordance is still not at a level that can be fully trusted without human oversight. This underscores the necessity for clinicians to critically evaluate AI responses and reasoning, reinforcing the principle that “two heads are better than one.” Future iterations should aim for even higher consistency, particularly in high-stakes fields such as neurology.

Unlike most existing literature that evaluates AI in English [28], our study probes ChatGPT's performance in Spanish, a vital consideration for global medical applications given the variation in medical terminology and nuances across languages. The latest edition of the Cervantes Institute yearbook provides some data that reflect the magnitude of Spanish today [29]. It is the fourth most commonly used language globally and the third most widely used language on the internet. Two studies have analyzed the performance of ChatGPT versions 3.5 and 4 in the Spanish examination akin to the United States Medical Licensing Examination (USMLE) [19,30]. In the first study, ChatGPT-4 correctly answered 158 out of 182 (86.8%) of the questions, while in the second study, which focused solely on rheumatology questions, it correctly answered 134 out of 143

(93.7%) of the questions. In the first study, questions were prompted in both English and Spanish, with no significant differences observed. These data suggest that the performance of ChatGPT in Spanish in medical examinations is comparable to its performance in English.

ChatGPT sometimes provides confident answers that are meaningless when considered in the light of common knowledge in these areas. This phenomenon has been described as “artificial hallucination” [31]. This overconfidence was also observed in a neurology board-style examination [26] and in our study. Although the prompt for each question stated that “The objective is to achieve the maximum score. The score is equal to the number of correct answers minus incorrect answers divided by 3. So, if you are unsure about a question is better not to answer it in order to achieve the maximum possible score,” ChatGPT-3.5 and ChatGPT-4 answered all the questions. This behavior, known as “artificial hallucination,” poses serious risks in medical education, as overconfident yet wrong responses can mislead educators and students, potentially compromising patient safety and care quality. The AI’s inability to accurately gauge its confidence level and the appropriateness of not responding raises ethical concerns, especially in high-stakes environments such as neurology where precise knowledge and cautious decision-making are critical. To mitigate these risks, it is crucial to ensure that AI complements rather than replaces human judgment, with safeguards to prevent overreliance on AI. Training AI to recognize its limitations and abstain from responding when uncertain is essential to maintaining the integrity and safety of medical practice.

In contrast to another study where both models demonstrated weaker performance in tasks requiring higher-order thinking compared with questions requiring only lower-order thinking [26], our research revealed that ChatGPT’s performance remained consistent across tasks demanding both higher-order and lower-order thinking.

The ability of AI models, such as ChatGPT, to successfully pass medical examinations raises significant questions about the nature and effectiveness of these examinations. It is not just about what AI can do, but also what these examinations are really testing. This leads us to consider whether these exams accurately measure the real-world skills and knowledge essential for medical professionals. To address this, we propose several key areas of focus:

1. **Uniquely human skills:** More emphasis should be placed on assessing skills unique to human practitioners, such as clinical reasoning (gathering information, developing differential diagnosis, and justifying decision-making process), ethical judgment, and empathetic communication. These are vital yet challenging to quantify aspects of medicine, such as empathy, ethics, and patient-centered care. Developing methods to evaluate these skills could greatly benefit the medical field. Specifically, we propose the use of interactive patient simulations in which candidates must gather information directly from the patient. While current AI models can imitate specialist performance in clinical reasoning and developing differential diagnoses,

the information provided to these models should be obtained through interactions with human specialists.

2. **Application in real-world scenarios:** Examinations should evolve to test the practical application of medical knowledge in real-life situations. This includes assessing abilities in diagnosis and treatment planning within complex clinical contexts, ensuring that professionals are prepared for real-world challenges. Additionally, allowing the use of LLM interfaces and other search engines during some examinations can simulate real-world conditions where clinicians have access to various technological aids. This approach not only tests their knowledge but also evaluates their critical thinking and ability to effectively search for and apply relevant information. Integrating these technologies into examinations can help improve clinicians’ performance by fostering skills that are essential in modern medical practice.
3. **Interdisciplinary skills:** Given the interdisciplinary nature of modern health care, examinations should also focus on teamwork, collaboration, and communication skills. They should assess the ability of medical professionals to integrate information across various specialties, reflecting the collaborative environment of contemporary health care.
4. **Focus on continual learning:** To motivate and teach lifelong learning, we need to shift our focus from merely teaching information retrieval to fostering skills in critical appraisal, problem-solving, and continuous professional development. While GPT can efficiently retrieve information, it is essential for medical professionals to critically appraise and apply this information. Future examinations should include components where candidates review and critique recent research articles, identifying strengths, weaknesses, and the applicability of findings to clinical practice. This ensures clinicians develop the ability to evaluate the quality and relevance of the information they encounter. Additionally, presenting candidates with novel clinical guidelines or emerging evidence in examinations will require them to integrate new information into their practice. This scenario-based assessment evaluates their ability to stay current with ongoing advancements and incorporate new knowledge effectively into clinical decision-making. Emphasizing self-directed learning and the use of various educational resources will help clinicians remain adaptable and proficient throughout their careers.

In summary, while AI passing medical examinations is an impressive feat, it highlights the need for evolution in medical education and assessment, ensuring that they measure the skills and knowledge that future medical professionals will truly need.

Conclusion

Our study reveals the nuanced interplay between AI and human expertise in neurology, highlighting ChatGPT’s potential as a medical knowledge resource. Despite its promising performance, the variability in both AI and human responses calls for a careful, measured integration of AI into medical practice.

The combination of AI and human expertise could significantly enhance medical education and practice. However, this

integration must prioritize patient care and safety, ensuring that AI complements rather than replaces human judgment.

In summary, this research contributes to the ongoing narrative of AI in health care and sets the stage for further exploration

into refining AI for specialized medical uses. The focus remains on harnessing AI to support, not supplant, the invaluable insights of medical professionals.

Abstract

Background: Generative large language models (LLMs) have the potential to revolutionize medical education by generating tailored learning materials, enhancing teaching efficiency, and improving learner engagement. However, the application of LLMs in health care settings, particularly for augmenting small datasets in text classification tasks, remains underexplored, particularly for cost- and privacy-conscious applications that do not permit the use of third-party services such as OpenAI's ChatGPT.

Objective: This study aims to explore the use of open-source LLMs, such as Large Language Model Meta AI (LLaMA) and Alpaca models, for data augmentation in a specific text classification task related to hospital staff surveys.

Methods: The surveys were designed to elicit narratives of everyday adaptation by frontline radiology staff during the initial phase of the COVID-19 pandemic. A 2-step process of data augmentation and text classification was conducted. The study generated synthetic data similar to the survey reports using 4 generative LLMs for data augmentation. A different set of 3 classifier LLMs was then used to classify the augmented text for thematic categories. The study evaluated performance on the classification task.

Results: The overall best-performing combination of LLMs, temperature, classifier, and number of synthetic data cases is via augmentation with LLaMA 7B at temperature 0.7 with 100 augments, using Robustly Optimized BERT Pretraining Approach (RoBERTa) for the classification task, achieving an average area under the receiver operating characteristic (AUC) curve of 0.87 (SD 0.02; ie, 1 SD). The results demonstrate that open-source LLMs can enhance text classifiers' performance for small datasets in health care contexts, providing promising pathways for improving medical education processes and patient care practices.

Conclusions: The study demonstrates the value of data augmentation with open-source LLMs, highlights the importance of privacy and ethical considerations when using LLMs, and suggests future directions for research in this field.

Introduction

Overview

Generative large language models (LLMs) are powerful technologies that leverage machine learning techniques to generate novel and contextually relevant content. By training on vast amounts of data, LLMs have the capability to understand and mimic human language patterns, thereby producing text that closely resembles human-written content [1,2]. LLMs represent a subset of generative models characterized by their vast training data and resulting complexity. With billions of parameters, LLMs such as GPT-3 and GPT-4 by OpenAI are capable of generating text that is often indistinguishable from

human-written content, provided a suitable context is given (OpenAI) [3].

The use of LLMs has the potential to address critical challenges in medical education. In environments where teaching resources are limited, these models can generate learning materials from case studies to interactive dialogues that align with specific learning objectives and target specific topics [4,5]. Furthermore, they can create diverse and complex patient scenarios that can supplement lecture content by providing real-time clarifications, and context to complex topics, ensuring a deeper understanding for students [6]. By leveraging the capabilities of LLMs, educators can identify content gaps, ensure comprehensive coverage of essential subjects, and ultimately enhance the quality and effectiveness of medical education [7,8]. These models can

enhance teaching efficiency and learner engagement, thereby potentially improving learning outcomes.

LLMs, however, pose several challenges in their application in medical education. Ethical use and privacy concerns need to be considered, especially when using real-world data for training. Cost concerns might arise due to the computational resources needed for training and fine-tuning these models. GPT-3 and GPT-4 (and the product ChatGPT which is built upon them) are closed-source models owned by OpenAI; their use thus not only comes at a financial cost, but also generates privacy concerns due to needing to expose one's data to a third-party company. While open-source LLMs exist, relatively little attention has been paid to their utility, despite the fact that they alleviate both cost and privacy concerns attached to the use of commercial LLMs.

The application of these models in medical education is becoming increasingly prevalent. For instance, LLMs have been used to aid revolutionizing medical curriculum development [8,9], teaching methodologies [10], personalized study plans and learning materials [11], assessments and evaluation [12,13], medical writing and assistance [14,15], and medical research and literature review [16,17]. The vast potential of these technologies opens up novel avenues for educating the future generation of health care providers.

Over the past few decades, self-reported data from health care workers, such as incident reports, have been applied to medical education in many health care areas. These include analyzing potential ethical conflicts within hospitals [18], evaluating Bendamustine-related skin disorders [19], finding predictive patterns of human contributing factors in radiation therapy [20], and improving patient safety and care [21-23]. Despite these applications, LLMs have so far, not been used in the analysis of self-reports. There is an opportunity to leverage hospital self-reports to enhance medical education.

Integrating artificial intelligence (AI) and LLMs in self-report analysis has the potential to revolutionize bottom-up learning from worker-generated data, facilitating more efficient and accurate identification of workflow challenges, systemic issues, strategies and tactics to address these, and areas for improvement in clinical decision-making and patient care. This study addresses the use of LLMs, particularly open-source LLMs, to mitigate a specific problem encountered in the analysis of hospital staff survey data: the lack of ample training data for a text classification task. This task involves classifying text responses into categories based on their relevance to the availability of resources in the hospital. Insufficient training data can limit the model's ability to learn and make accurate classifications.

The objective of this study is to evaluate the effectiveness of using open-source LLMs for data augmentation in this text classification task. By generating synthetic survey responses, LLMs can potentially increase the size and diversity of the training dataset, leading to improved model performance in text classification. Text classification, in turn, is a useful way to analyze free-text reports for categories and themes that are relevant from an educational standpoint. In our research, text classification is used to identify valuable insights from

self-reported narratives of the lived experiences of frontline health care workers. Identifying such patterns and capabilities that are situated in the context of everyday work, can be valuable in generating teachable content for medical education. Doing so with augmented data would allow for a richer dataset of realistic learning instances based on everyday work. This paper presents a case study of this approach, aiming to provide insights and guidance for similar applications in medical education and health care operations.

Related Work

Data augmentation is the process of generating new data from existing data. This process is generally used to increase small datasets or create more diversity in a dataset where underrepresented populations are ignored by the model. A lack of diversity in a language model's training set can lead to poor generalizability. For example, LLMs performing numerical reasoning perform better on tasks with terms seen frequently during training, with a gap in accuracy of up to 70% when solving problems containing terms common in the training data as opposed to rare terms [9]. Few-shot learning is generally used with data augmentation because of the lack of usable data and its ability to be efficient with small amounts of data. LLMs are either used to slightly change examples to create new data or generate new data from examples. Using methods that change specific words in slot filling fill in the blank [24], where those words are switched with a semantically similar word, is a widely used method to change existing data slightly. Generative models typically use fine-tuned versions of LLMs [25,26] with prompts, including select examples from the dataset and the label the model is supposed to generate. Zero-shot prompting has also been used with ChatGPT [27,28] in low-resource situations. Models that have received no fine-tuning have also been shown to perform well [29] train an intent classifier, and feed it into the LLM to generate data. Human-in-the-loop studies have been shown to be successful. A human expert filters through generated data and discards generated data that deviate from the training data [30]. Another filtering technique is using a binary sentence classifier to determine whether the original and the augment are semantically similar. We expand the existing literature in this space by exploring the case of low-resource data augmentation in the face of cost and privacy concerns that prevent relying on third-party services such as OpenAI's ChatGPT, using few-shot prompting on open-source LLMs.

Methods

Ethical Considerations

This research study does not require institutional review board approval according to Clemson guidelines [31]. The project involves analysis of a preexisting anonymized dataset, and thus does not constitute research involving human participants as outlined in the federal regulations [45 CFR 46.102(e)]. Our research involves neither obtaining information through intervention or interaction with living individuals, nor the use, study, analysis, or generation of identifiable private information. This type of secondary data analysis, where the researchers do not have access to identifying information, is not considered

research involving human participants and therefore does not require institutional review board oversight.

LLMs for Data Augmentation

We use LLMs for data augmentation, specifically focusing on Large Language Model Meta AI (LLaMA) and Alpaca models. LLaMA is a collection of foundation language generation models with varying complexities ranging from 7 billion (7B) to 65 billion (65B) parameters, introduced by [10]. These models were trained on approximately 1.4 trillion (1.4T) tokens, an extensive dataset derived entirely from publicly accessible sources, thus eliminating dependency on proprietary databases and increasing transparency. The models themselves are open-source and freely available to researchers.

In terms of their architecture, LLaMA models are built on the transformer architecture [32] and incorporate several advancements proposed in recent research, including prenormalization [33] for improved training stability, the SwiGLU activation function [34] for enhanced performance, and rotary embeddings [35] for improved positional encoding. Notably, even at a comparatively smaller scale, LLaMA models are competitive with GPT-3 (175B) in a wide variety of benchmarks. Their combination of small size (and corresponding computational accessibility) with competitive performance, in conjunction with their status as open-source, motivated our choice to focus our work on these models.

Alongside the LLaMA models, we use a set of Alpaca models in our experiments. These models are LLaMA models that have been fine-tuned by Taori et al [36] for instruction-following tasks using a 52K dataset consisting of instructions and corresponding text responses. We include Alpaca models in order to investigate whether this instruction fine-tuning step might make the models more adept at data augmentation tasks. All of the models used in our study were sourced from Huggingface's library.

LLMs for Classification

Robustly Optimized BERT Pretraining Approach (RoBERTa), XLNet, and DistilBERT (Distilled BERT) are all LLMs that have been pretrained on a large corpus of text data. They can be fine-tuned for a variety of tasks, including text classification, natural language inference, and question answering.

RoBERTa stands for "Robustly Optimized BERT Pretraining Approach" [37]. It is a BERT-based model that has been trained on a larger corpus of text and with more training steps than the

original BERT model, with a modified training objective. This makes RoBERTa more accurate than the original BERT on a variety of tasks.

XLNet [38] is a transformer-based model that has been trained on a corpus of text that has been masked and shuffled. This makes XLNet more robust to noise and errors in the training data than other LLMs. While both XLNet and RoBERTa are transformer-based language models, the key difference is in their training methods. RoBERTa is a variant of BERT using dynamic masking and longer training on larger amounts of data. In contrast, XLNet uses a permutation-based training approach where all permutations of words in a sentence are considered during prediction, with the goal of providing a more comprehensive contextual understanding.

DistilBERT [39] is a smaller version of BERT that has been trained to have the same performance as BERT on a variety of tasks. DistilBERT is faster and uses less memory than BERT, making it a more practical choice for many applications due to its smaller size.

In this paper, we use RoBERTa, XLNet, and DistilBERT as text classifiers to test the effectiveness of our data augmentation. For each generative LLM used for data augmentation, we use synthetic data to supplement our real survey responses. Thus, after augmentation, we have a larger dataset of text documents, each of which is associated with a label: "resource" or "nonresource" related. The real survey responses are manually labeled by us. The synthetic data cases are (written and) labeled by the LLM. This larger dataset is then used to fine-tune each of the 3 classification models on the task of determining, for a given piece of text, whether it is "resource" or "nonresource" related.

We gather augments (synthetically generated text responses) with different models, temperatures, and training sets. We chose a binary classification scheme of classifying sentences as either "resource"-related, or "non-resource"-related. This choice was based on the fact that a substantial proportion of resilience engineering tools to improve patient safety (RETIPS) reports were found to be related to resources, including the availability of necessary resources, such as staff and equipment. Each time an augment is generated, a new few-shot learning prompt is generated by randomly sampling and concatenating 5 examples each of resource-related and nonresource-related survey responses from our (real) labeled data, displayed in the format shown in [Textbox 1](#).

Textbox 1. Prompt template used for few-shot prompting to generate synthetic data. “Category” could be either “resource-related” or “nonresource-related,” depending on which type of data the model is intended to generate.

```
### Instruction:
Here are two lists of short text documents, \
“Resource-related“ and “Nonresource-related”. \
They are survey responses by hospital staff \
at the Children’s Hospital of Philadelphia (CHOP).
“Resource-related” is responses on the topic \
“Availability of resources OR Knowing where to find resources.”
“Nonresource-related” is responses that do not have to do with that topic.
Please give me a new example of a short text document that would belong \
in the “{category}” category.
Please don’t copy or paraphrase the text documents in the \
input lists I give you; instead, come up with your own new example \
that would belong in the “{category}” list.
### Input:
{other_category}:{other_category_examples}
{category}:{category_examples}
### Response:
{category}:
1.
```

After the synthetic data have been generated, it is filtered to retain only those model outputs that include alphabetic characters, since in some cases the model returns an empty output or simply a continuation of the numerical list begun by the “1.” at the end of the prompt (eg, “2. 3. 4. 5.”) These problems were especially common at low temperatures (0.1 and 0.3), leading us to exclude those temperatures from further

consideration. For each tested combination of text-generating LLM, classifier LLM, and temperature, the filtered augments from the text-generating LLM at that temperature are combined with the real labeled data and used to fine-tune the classifier LLM, which is then evaluated on a hold-out set of real labeled data. Examples of generated data are shown in [Table 1](#).

Table . Examples of real data and synthetic data from each text-generating large language model.

Model	Responses
Real data	<ol style="list-style-type: none"> 1. How quickly the world changed...I remember the work and practice pre-COVID and can't believe how quickly we went to working remotely and virtually. I was also surprised at how adaptable we really are...we think people are resistant to change but people can change incredibly swiftly when the world changes and they need to adapt. I was also surprised to learn that there are so many online telemeeting platforms...it is routine to oscillate between 3 - 4 programs in sequential meetings. 2. I believe overall we did exceptionally well. PPE^a availability and consistency across the enterprise would be an area I think we could improve upon. 3. usage of ppe 4. Virtual conferencing improved our conference participation and virtual review of imaging with referring clinicians using BlueJeans business Skype or FaceTime improved patient Care and physician collaboration. Unfortunately the hospital doesn't have business Skype installed on hospital computers just on lab tops. There needs to be a uniform hospital wide platform. 5. Working remotely required an adjustment in how I communicated about everything. The demands of the pandemic required an adjustment in priorities which put everything on hold except for COVID related work and it required a level of teamwork that did not exist pre-COVID. From a personal coping standpoint I had to "schedule" time away from my computer each day to eat lunch and take a walk.
LLaMA-7B ^b	<ol style="list-style-type: none"> 1. I appreciate the ability to work from home and the support that was provided from my department. I did miss the interaction with coworkers but the ability to work from home was worth it. I was able to keep up with my work and the department was able to 2. I am not aware of the term "telemeeting platforms" but I believe I could answer this question. I am not sure if I was surprised by the need to adapt or the speed at which we adapted. I think we were all expecting the need for changes and adapt 3. It was a challenging time for our department as we did not have enough PPE for everyone and we had to ration supplies for the most essential staff. We were able to support our staff and be very open and fluid with how things were evolving. 4. The ability to go to the bathroom and not have to worry about getting someone else sick 5. Changes in Policies and procedures having all the PPE needed communication with all staff AWA leadership was helpful and transparent
LLaMA-30B	<ol style="list-style-type: none"> 1. In the beginning working AWA^c was an adjustment but once I was allowed to bring home my docking station and 2 monitors it was just like working in the office with little or no interruptions. My doctors I supported and I kept in constant contact through phone call 2. We had a lot of staff on site so we could provide a good flow of patients and care. 3. In the beginning working AWA was an adjustment but once I was allowed to bring home my docking station and 2 monitors it was just like working in the office with little or no interruptions. 4. I am confident that I can enter the building safely and that I can maintain the safety of staff, patients and families. Constant communications with the changes is helpful. It is also good that I can look in one place to refresh on any of the topics. 5. I was surprised how quickly we went to working remotely and virtually.

Model	Responses
Alpaca-7B	<ol style="list-style-type: none"> 1. I was surprised at how quickly the world changed from in-person interactions to virtual ones. I also didn't realize how adaptable people could be in terms of adjusting to the new way of working. I was also surprised to learn about the different online telemeeting platforms that are 2. Not having to share Ascom phones and not having an office adjacent to patient care areas. 3. Followed protocols put in place and used PPE and hand sanitizer and bought my own when I felt uncomfortable with there maybe not being enough or "the right kind" for me. 4. How quickly the world changed...I remember the work and practice pre-COVID and can't believe how quickly we went to working remotely and virtually. 5. The hospital's ability to partner with other departments to obtain the supplies and resources needed to ensure AWA roles were fully functional.
Alpaca-30B	<ol style="list-style-type: none"> 1. As a manager, I am grateful for the availability of resources in the workplace. We have a well-stocked supply of PPE and other equipment that we need to do our jobs effectively. Additionally, we have access to a wide range of educational materials and training opportunities. 2. The availability of clinical information and resources were limited during the pandemic, but we were able to navigate through this challenge by establishing a robust telemedicine platform that allowed for remote consultation and collaboration with our colleagues. 3. Ensuring that all staff members are aware of the available resources and are able to easily access them is crucial for maintaining patient safety and reducing stress levels in the workplace. 4. The biggest adjustment for me was how to handle the stress of working with a reduced staff and how to prioritize my workload. 5. The CHOP^d website and intranet were helpful in providing information about the availability of resources and where to find them.

Our methodology fits within an envisioned framework represented in [Figure 1](#). Using data from RETIPS and similar self-reported narratives from frontline staff, LLMs with data augmentation will result in a corpus of scenarios. Human stakeholders (eg, educators) can interact with LLMs to compare models, change temperature, and make other adjustments, based on the results, in an iterative manner until the quality and representativeness of augmented data are deemed satisfactory.

These scenarios can be used for a variety of purposes in medical education, including quality and safety analysis, creating content for personalized study, and more. Based on their effectiveness in the training, including student and instructor feedback, the LLMs can be further fine-tuned for improvements. The work described here represents a part of this framework, focusing on the development and evaluation of LLMs for data augmentation.

Figure 1. A framework for long-term implementation of LLMs for medical education using RETIPS and similar self-reported data. DistilBERT: Distilled BERT; LLaMA: Large Language Model Meta AI; LLM: large language model; RETIPS: resilience engineering tool to improve patient safety; RoBERTa: Robustly Optimized BERT Pretraining Approach.

Results

We analyze the performance of 4 distinct LLMs—LLaMA-7B, LLaMA-30B, Alpaca-7B, and Alpaca-30B—for the purpose of data augmentation. The goal of the augmentation was to increase the performance of downstream classifiers on the task of matching human labelers' categorization of the text data as "resource" or "nonresource" related. We thus evaluate the quality of the resulting data augmentation by adding the synthetic data from these LLMs to the data used to train 3 classifiers: DistilBERT, RoBERTa, and XLNet. We repeat this analysis for 6 different augmentation "temperature" settings

ranging from 0.5 to 1.5. The performance of each model-classifier-temperature combination is assessed based on the area under the receiver operating characteristic (AUC) curve, using a holdout set of human-labeled data.

The overall best-performing combination of LLM, temperature, classifier, and number of augments is LLaMA 7B at temperature 0.7 using RoBERTa with 100 augments, with an average AUC of 0.87 (SD 0.02: 1). In addition to achieving the highest absolute performance, the data augmentation is also most beneficial in this case—this augmentation yields the greatest improvement in AUC with respect to the baseline performance of that classifier model with no data augmentation. The baseline

performance of each classifier along with optimal data augmentation for each text-generating LLM is shown in [Table 2](#). Note that the fine-tuned Alpaca models do not outperform

the LLaMA models upon which they are based, indicating that instruction-finetuning is not necessary for this data augmentation task.

Table . Comparison of classifier performance under augmentation by each text-generating large language model (LLM), alongside base performance of the classifier with no augmentation. Each entry gives the mean classifier area under the receiver operating characteristic curve (SD 1), the optimal temperature for text generation.

LLM	RoBERTa ^a , mean (SD)	XLNet, mean (SD)	DistilBERT ^b , mean (SD)
LLaMA-7B	0.87 (0.02/0.7/100)	0.84 (0.04/0.7/100)	0.83 (0.02/0.7/100)
LLaMA-30B	0.87 (0.03/0.5/100)	0.84 (0.03/0.5/100)	0.85 (0.06/1.5/500)
Alpaca-30B	0.86 (0.06/0.7/100)	0.84 (0.05/1.3/250)	0.81 (0.06/1.3/250)
Alpaca-7B	0.86 (0.06/0.7/100)	0.84 (0.05/1.1/250)	0.82 (0.05/0.7/100)
Baseline	0.80 (0.06)	0.79 (0.06)	0.79 (0.04)

^aRoBERTa: Robustly Optimized BERT Pretraining Approach.

^bDistilBERT: Distilled BERT.

For each combination of LLM and classifier, we also fit a linear regression model to explore the relationship between the number of synthetic data points included in the training dataset and the resulting classifier performance as measured by AUC. Notably, DistilBERT emerges as the classifier benefitting most often from data augmentation. In terms of the temperature setting, most of the successful models used a temperature of 0.7. In

[Figure 2](#), we display the comparative performance of the LLaMA 7B and Alpaca 7B models, both using the DistilBERT classifier at a temperature setting of 0.7. These graphical representations underscore the beneficial impact of data augmentation on the AUC performance of these specific model-classifier configurations.

Figure 2. Linear fit to DistilBERT (Distilled BERT) model performance (measured as area under the receiver operating characteristic curve) as a function of the number of augments included in the training data (all generated at temperature 0.7).

Discussion

Principal Findings

In this work, our emphasis is on leveraging open-source language models that strike a balance between computational performance and accessibility for researchers. We therefore set a parameter ceiling of 30 billion parameters for several reasons. First, maintaining this threshold ensures that the models in question can run on consumer-level hardware commonly available to average researchers without the need for prohibitive investment in specialized equipment. Second, this approach aligns with our goal to propose methods feasible for environments where privacy and cost considerations limit the

use of third-party cloud-based computing services, as relying on external infrastructures (such as OpenAI's services) could elevate privacy risks and regulatory complexity. Using consumer-level hardware, as opposed to cloud-based services, significantly mitigates the risk of data breaches or unauthorized access. Furthermore, the choice to avoid third-party computational services also avoids potential issues related to data sovereignty and control, which could arise when data leaves the institution's local environment. By strictly using in-house resources that operate within the confines of consumer-level capabilities, our methodology facilitates stringent data custody and integrity controls.

LLMs such as OpenAI's GPT-3.5 and GPT-4, or the openly accessible 176 billion-parameter BLOOM, indeed offer more powerful capabilities, but their deployment would threaten the objective of presenting a methodology that is both privacy-aware and broadly implementable. We contend that models up to 30 billion parameters offer a sweet spot, considering these constraints, without significantly compromising the efficacy of the data augmentation process. By imposing a limit of 30 billion parameters, we aim to demonstrate that effective data augmentation for small-scale text classification tasks in the health care sector can be achieved without resorting to the most computationally demanding or privacy-compromising technology. This parameter threshold also allows for an equitable comparison of language models, ensuring that our results are relevant to a wide range of researchers, including those who might be limited by resource constraints. Our research thus serves to bridge the gap typically present in medical informatics research, where smaller institutions or individual researchers may not have access to the same level of computational resources as their larger counterparts. Additionally, this study sheds light on the possibilities and limitations inherent to working within such constraints, providing a valuable reference for future research endeavors seeking a similar balance between model size, privacy, cost, and performance.

Limitations and Future Work

One of the primary constraints of this work is the limited size of the RETIPS dataset. The small sample size (58 responses) potentially affects the reliability and generalizability of the study to other cases where larger data are available. However, it should be noted that the data from RETIPS were tightly focused on a narrow set of themes. This may be beneficial to the quality of augmented data, when compared with a dataset that is thematically more "scattered" or heterogenous. Larger data would likely improve the data augmentation quality but would potentially limit the benefits to be derived from data augmentation. Since data augmentation is of greatest value when working with small datasets, our small data size helps explore this problem space.

Aside from data size, another limitation of this work is that our data are exclusively collected from RETIPS surveys administered to radiology staff at a single hospital. Though this specificity is necessary for the research's objectives, the models' performance may vary in other health care domains, and in domains outside of medicine.

As a future step for this research, it would be beneficial to perform similar studies using larger and more diverse datasets. Larger datasets could provide a richer, more diverse range of training data, potentially leading to correspondingly more diverse synthetic data. Such diversity could improve the performance of the downstream classifiers.

Future research should also consider experimenting with different LLMs for data augmentation. Text-generation LLMs are rapidly evolving, particularly in the area of making large and powerful LLMs accessible on consumer-grade computer hardware [40]. Newer models often come with architectural and

training improvements that could potentially enhance synthetic data generation quality.

In this work, we explore different LLM text generation temperature settings and the resulting impact on synthetic data quality. A more extensive hyperparameter tuning of the language models and classifiers may yield further improvements in their performance. This could be a fruitful area for further investigation.

The limitations faced by this work are those that inherently attach to working with small data in a highly privacy-conscious environment with accessible AI tools. Since this is a problem space occupied by many researchers and practitioners in the health care domain, we hope that our results are able to provide insight into how AI tools can be used in such settings.

Conclusion

This study provides an exploration and practical demonstration of the application of LLMs for data augmentation in the context of health care. We specifically focused on the use of open-source LLMs, namely, LLaMA and Alpaca models, to mitigate the challenge of limited training data in a text classification task related to hospital staff surveys.

Our findings demonstrate the potential effectiveness of using LLMs to generate synthetic survey responses, thereby increasing the diversity and size of the training dataset and improving the performance of models trained on the augmented dataset for tasks such as text classification. However, the effectiveness of the data augmentation process can vary based on certain factors such as the specific LLM used, the selected parameters such as the temperature setting, and the downstream classifier applied.

This study provides preliminary evidence that open-source LLMs can improve the performance of text classifiers for small datasets in health care contexts when privacy or cost considerations prevent the use of closed-source third-party services such as those offered by OpenAI. These results pave the way for future research to further investigate and refine the use of LLMs in tasks like text classification, data augmentation, and other medical education and operational applications.

This research serves as an initial leap towards exploiting the promising capabilities of LLMs in medical applications while being mindful of privacy, ethical concerns, and constraints associated with this field. By establishing a proof-of-concept for the use of open-source LLMs in health care settings, this study opens avenues for broader exploration of LLMs' potential to tackle numerous challenges faced by medical practitioners, educators, and administrators. Future research should expand on our work by exploring more complex datasets, experimenting with different hyperparameters for a wider variety of LLMs, and developing procedures to systematically craft and evaluate prompts to optimize model output.

This study contributes to a burgeoning field of research exploring applications of AI in health care and medical education. Our exploration of data augmentation using open-source LLMs presents potential pathways for improving processes such as incident reporting, resident evaluation, clinical vignette development, and other text-based processes relevant

to medical education. This research will hopefully encourage additional exploration into the ethical and judicious application of LLMs and other AI technologies in health care.

As AI technologies continue to evolve and become more sophisticated, constant re-evaluation and updates to our methods

will be essential. Therefore, active engagement from all stakeholders in the medical field, including frontline health care workers, researchers, educators, and policy makers, is crucial in making the most of these advancements for the betterment of patient care and safety.

Abstract

Background: With the increasing application of large language models like ChatGPT in various industries, its potential in the medical domain, especially in standardized examinations, has become a focal point of research.

Objective: The aim of this study is to assess the clinical performance of ChatGPT, focusing on its accuracy and reliability in the Chinese National Medical Licensing Examination (CNMLE).

Methods: The CNMLE 2022 question set, consisting of 500 single-answer multiple choices questions, were reclassified into 15 medical subspecialties. Each question was tested 8 to 12 times in Chinese on the OpenAI platform from April 24 to May 15, 2023. Three key factors were considered: the version of GPT-3.5 and 4.0, the prompt's designation of system roles tailored to medical subspecialties, and repetition for coherence. A passing accuracy threshold was established as 60%. The χ^2 tests and κ values were employed to evaluate the model's accuracy and consistency.

Results: GPT-4.0 achieved a passing accuracy of 72.7%, which was significantly higher than that of GPT-3.5 (54%; $P < .001$). The variability rate of repeated responses from GPT-4.0 was lower than that of GPT-3.5 (9% vs 19.5%; $P < .001$). However, both models showed relatively good response coherence, with κ values of 0.778 and 0.610, respectively. System roles numerically increased accuracy for both GPT-4.0 (0.3% - 3.7%) and GPT-3.5 (1.3% - 4.5%), and reduced variability by 1.7% and 1.8%, respectively ($P > .05$). In subgroup analysis, ChatGPT achieved comparable accuracy among different question types ($P > .05$). GPT-4.0 surpassed the accuracy threshold in 14 of 15 subspecialties, while GPT-3.5 did so in 7 of 15 on the first response.

Conclusions: GPT-4.0 passed the CNMLE and outperformed GPT-3.5 in key areas such as accuracy, consistency, and medical subspecialty expertise. Adding a system role insignificantly enhanced the model's reliability and answer coherence. GPT-4.0 showed promising potential in medical education and clinical practice, meriting further study.

Introduction

ChatGPT, a general large language model (LLM) developed by OpenAI, has gained substantial attention since its launch on November 30, 2022. Known for its advanced natural language processing capabilities, ChatGPT has the potential to make significant impacts on many industries, including medical education. Its performance in medicine was first tested at or near the passing threshold of the United States Medical Licensing Examination (USMLE) [1,2]. While ChatGPT's accuracy varies across languages [3], it has been tested on a

series of medical exams like the Japanese National Medical Licensing Examination in languages including English [4], Chinese [5], Dutch [6], Japanese [7], and Korean [8]. The research scope related to ChatGPT has expanded to medical education in fields like nuclear medicine [9], neurosurgery [10], ophthalmology [11], general chemistry, nursing [12], life support [4], dentology [13], and radiation oncology physics [14]. Overall, while ChatGPT demonstrates heterogeneous capabilities, it shows promising potential in these medical specialties.

Several factors might influence ChatGPT's performance. First, the updated version of ChatGPT, GPT-4, understands and generates natural language in more complex and nuanced scenarios, leading to more accurate responses [15], which is important in analyzing complex clinical case questions [16]. Thus, GPT-4 conclusively demonstrated significantly better performance than GPT-3.5, as evidenced by various official medical exams [8]. Besides the model version, ChatGPT allows users to guide its behavior by adding prompts that describe its system role. These system roles influence the direction of ChatGPT's answers and may affect its reliability. However, the impact of these system roles on ChatGPT's performance in medical field has not yet been investigated. As a professional chatbot tool, ChatGPT uses sampling to predict the next token with varying distribution probabilities, ensuring responses are varied and natural in real-world applications. Zhu et al [17] have found that composite answers derived from repeated questioning can enhance the accuracy of ChatGPT. Typically, 2 or 3 repeated responses are necessary to ensure response stability [18-20].

Currently, the peer-reviewed research still lacks highlights on the strength of ChatGPT when it comes to the Chinese National Medical Licensing Examination (CNMLE). This study aimed to evaluate the performance of ChatGPT in answering CNMLE questions in the clinical setting of China, with consideration of the version of ChatGPT and system role.

Methods

The CNMLE 2022 Question Data

As an industry admission examination, passing the CNMLE means that a medical practitioner meets the minimum medical competencies. The written part of the examination, which emphasizes medical knowledge and clinical decision-making skills, is created and supervised by the Chinese National Medical Examination Center (NMEC). In 2021, the CNMLE transitioned from the traditional paper-based format to a computer-based

examination. Each candidate is presented with 600 questions, arranged in a slightly varied order, from the exam year's question data set. According to OpenAI's introduction, ChatGPT's responses are based on information available up to September 2021. Thus, we selected the CNMLE 2022 questions, which were purchased from a web-based bookstore [21], for our evaluation. This choice ensured that the questions had not been previously encountered and trained by the model. The publisher has confirmed that these released questions are the original ones from the examination.

The CNMLE 2022 covered 600 single-answer multiple-choice questions, which were evenly divided into 4 units [22]. Each unit had 4 specific question types: A1, the single-sentence optimal choice questions; A2, case summary optimal choice questions; A3/A4, case group optimal choice questions; and B1, standard combination questions. Detailed explanations of each question type was conveyed to ChatGPT via a structured prompt prior to inquiry (see in [Multimedia Appendix 1](#)). The CNMLE 2022 questions did not involve table or image-based questions. Therefore, ChatGPT, despite lacking multimodal capabilities, was still suited to effectively complete the test.

According to the introduction of the Chinese NMEC [22], each examination unit always addresses specific medical subspecialties. Unit 1 covers medical knowledge, policies, regulations, and preventive medicine; unit 2 mainly pertains to the cardiovascular, urinary, musculoskeletal, and endocrine systems; unit 3 involves the digestive, respiratory, and associated systems; unit 4 focuses on obstetrics and gynecology, pediatrics, and neurological or psychiatric domains. However, such distribution is not absolute. Therefore, 2 clinicians independently reclassified the 600 questions into 15 medical subspecialties, resolving discrepancies through discussion. The κ value for the result of their classifications was 0.935. The Sankey diagram of the 3 question classifications, medical subspecialties, units, and types is shown in [Figure 1](#).

Figure 1. The Sankey diagram of the 3 question classifications: the medical subspecialties, units, and types. STD: sexually transmitted disease.

Instructions Before Testing Part

Before manually inputting questions, ChatGPT was informed about an upcoming series of queries. ChatGPT needed to identify the most plausible response from the available options and explain the reasoning behind its selection. The question types determined the relevant lead-in prompts provided. For the A1 and A2 question types, each input question was deemed independent, rendering any interquestion relationships irrelevant. In contrast, A3/A4 question types implied that multiple questions within a single clinical case shared a connection. However, individual clinical cases were treated as discrete entities, eliminating the need to consider relationships between them. For the B1 question type, 5 shared options were given. ChatGPT

needed to identify the correct answers for subsequent questions. Chaining was used in A3/A4 and B1 question types to ensure that multiple questions within a single clinical case in A3/A4 shared the same context, and multiple questions in B1 shared the same options. The number of questions inputted at one time depended on the text's length, such as 5 - 8 questions for A1/A2 types. If necessary, ChatGPT was forced to disregard prior conversational content and commence a fresh chat.

Temperature

The temperature parameter in ChatGPT influences the randomness of the model's responses. A higher temperature yields more varied and creative answers. In our study, we did not manually adjust the temperature; instead, we used the default

setting on the OpenAI platform, commonly at 0.7, to simulate real-world user interactions on the front end. This balance between typical user habits and diverse thought processes was intentional. The default relatively high temperature was expected to enable ChatGPT to generate more creative reasoning processes while still arriving at accurate answers.

Testing Strategy

All the CNMLE 2022 questions were tested in Chinese according to the following 2 factors:

1. ChatGPT model selection. Both GPT-3.5 (version from March 23) and GPT-4.0 (version from May 3) were rigorously evaluated on the OpenAI platform from April 24 to May 15, 2023, to ascertain any evolution in the model's capability in the medical domain.
2. System role. This refers to the specific identity or role, such as "gastroenterology specialist," assigned to ChatGPT to determine if relevant knowledge is applied more accurately. Questions were evaluated both with and without assigning a system role related to the 15 specific clinical subspecialties. This system role was designated by providing a tailored system prompt before the testing instructions, aiming to guide ChatGPT's approach and align it with specialist viewpoints in the relevant medical field.

Testing Process

Considering the evaluation of the ChatGPT model, system role, and response coherence, each question was tested 8 - 12 times. The prompts included those specific to question types, the assignment of system role, and the use of chaining. Slight modifications in these prompts were adopted to avoid potential systematic errors introduced by rigid wording. For example, the prompt "Assume you are a gastroenterology specialist" might vary as "Assume you are highly proficient in gastroenterology." For coherence evaluation, each question was presented again to ChatGPT. If the regenerated response matched the initial answer, the process was halted. However, if the 2 responses differed, the question was posed once more to ChatGPT.

Response Determination

The first and second responses from ChatGPT were directly assessed against the given standard answers for accuracy. For the final response (referred to as joint response), if 2 of the 3 answers were consistent, this was taken as the conclusive answer and evaluated against the standard. However, if the 3 responses were all distinct, it was automatically marked as incorrect without any further comparison to the standard answer.

The first response was more applicable to assessing whether ChatGPT could pass the CNMLE in the same situation as a student examinee. In contrast, the joint response represented an overall accuracy (the proportion of questions answered correctly at least twice) [17], which was more suitable for demonstrating the potential of ChatGPT in medical education.

According to the announcement from the CNMLE Committee of the National Health Commission of China, the passing score for licensed physicians is 360 points, which means an accuracy rate of 60% or above is considered a pass.

Statistical Analysis

Data were collected and managed using Excel software. The statistical analyses were conducted with SPSS (version 26.0.0; IBM Corp). A χ^2 test was used to compare the accuracy of CNMLE question responses between different testing strategies and subgroups of question types. Variability was calculated by the number of consistently correct or wrong answers in 2 repeated responses divided by the total number of questions (600). Additionally, the κ statistic was used to evaluate answer consistency. A difference was considered statistically significant when $P < .05$.

Ethical Considerations

This study collected information that was already published in the bookstore and did not involve human subjects; therefore, approval by the Institutional Review Board of Henan Provincial People's Hospital was not required.

Results

Accuracy and System Role Assignment

In model comparison, GPT-3.5 achieved an initial accuracy of 54% (324/600) and did not meet the exam criteria. Conversely, GPT-4.0 achieved a passing accuracy of 72.7% (436/600), which was significantly higher than GPT-3.5 ($P < .001$). Similarly, with a designated system role, GPT-4.0 still exhibited higher accuracy than GPT-3.5 (73% vs 55.3%; $P < .001$).

Upon system role assignment, both GPT-3.5 and GPT-4.0 showed a slight increase in accuracy compared to when no role was assigned; specifically, 55.3% (332/600) from 54% (324/600) for GPT-3.5 ($P > .05$) and 73% (438/600) from 72.7% (436/600) for GPT-4.0 ($P > .05$).

The upper comparisons for the second and joint responses paralleled the initial results, as shown in [Table 1](#).

Table . Accuracy of GPT-4.0 and 3.5 with or without SR designation under repeat tests. n represents the number of correct answers.

Accuracy	GPT-3.5, n (%)	GPT-4.0, n (%)	<i>P</i> value	GPT-3.5 + SR ^a , n (%)	GPT-4.0 + SR, n (%)	<i>P</i> value
IR ^b	324 (54.0)	436 (72.7)	<.001	332 (55.3)	438 (73.0)	<.001
2R ^c	303 (50.5)	426 (71.0)	<.001	310 (51.7)	448 (74.7)	<.001
JR ^d	302 (50.3)	435 (72.5)	<.001	329 (54.8)	437 (72.8)	<.001

^aSR: system role.

^bIR: initial response.

^c2R: second response.

^dJR: joint response.

Variability of Responses

The GPT-3.5 model exhibited a variability rate of 19.5% (117/600), which decreased to 17.7% (106/600) upon the designation of a system role. The variability rate for GPT-4.0 was observed at 9% (54/600), and further reduced to 7.3% after a system role was assigned. These results indicated a smaller response variability for GPT-4.0 compared to GPT-3.5, and specifying system roles also decreased the variability rates. Both models showed relatively high coherence between the initial and second response, with κ values of 0.778 and 0.610. Detailed information for repeated response can be seen in [Multimedia Appendix 2](#).

Accuracy for Subgroups

For GPT-4.0, when accounting for system role and repeated responses, there was a statistically significant difference in

accuracy across the different units for the CNMLE test, with accuracy ranging from 62% (93/150) to 84% (126/150; *P* range from <.001 to .01). However, when grouped by question type, the accuracy ranged from 69.4% (145/209) to 83.1% (59/71) without statistical difference (*P*>.28).

In contrast, for GPT-3.5, only the initial response with system role designation showed a statistical difference in accuracy (*P*=.04) for question type subgroups. In other groupings by unit or question type, as well as in subsequent responses, the accuracy remained without significant variations (*P*>.14; see [Table 2](#)).

Accuracy for initial and joint responses of GPT-3.5/4.0 classified by 15 medical subspecialties is shown in [Figure 2](#). In multiple testing strategies, GPT-4.0 outperformed GPT-3.5 in accuracy for 14 distinct clinical subspecialty questions, consistently surpassing the 60% passing threshold.

Table . Subgroup analysis of accuracy for the 4 sections and 4 question types under different strategies. Data were showed as n (%). Units 1 - 4 were the 4 parts to which the questions belonged, and A1-A2, B1 represented the types of questions. Units 1 - 4 corresponded to distinct clinical subspecialties, with specific details provided in the Methods section.

Model strategy	Unit 1 (n=150), n (%)	Unit 2 (n=150), n (%)	Unit 3 (n=150), n (%)	Unit 4 (n=150), n (%)	<i>P</i> value	A1 (n=220), n (%)	A2 (n=209), n (%)	A3/A4 (n=100), n (%)	B1 (n=71), n (%)	<i>P</i> value
GPT3.5: IR ^a	82 (54.7)	83 (55.3)	88 (58.7)	71 (47.3)	.25	122 (55.5)	109 (52.2)	59 (59.0)	34 (47.9)	.47

Discussion

Overview

The CNMLE syllabus outlines the essential knowledge and competencies that physicians need for diagnostic and therapeutic procedures. Acquiring these competencies typically demands that a medical student invest several years in both theoretical education and practical skill development. The application of ChatGPT in medical examinations, particularly within the CNMLE framework, offers a pioneering approach to gauge the potential of LLMs in clinical diagnosis and treatment planning. This study comprehensively assessed ChatGPT's performance in addressing CNMLE questions, focusing on model evolution

and system role designation, which has not yet been fully investigated.

Model Evolution and Performance

In our study, GPT-4.0 consistently outperformed GPT-3.5 in accuracy and reliably met the passing criteria set by the CNMLE Committee. Despite GPT-3.5 achieving an accuracy rate of over 50%, it failed to pass the examination. A noncomparison study using GPT-3.5 to test CNMLE 2020 - 2022 achieved an accuracy of (36.5% - 47%) [23]. The lower accuracy might be attributed to the fact that the testing was conducted before February, shortly after the release of GPT-3.5. The better performance of GPT-4.0 compared with GPT-3.5 was also reported by Wang et al [24]. However, it is noteworthy that

their assessment was based on a limited sample of 100 questions, rather than a full set of 600 questions. The small sample might have contributed to the overall favorable results (GPT-4.0: 84%; GPT-3.5: 56%). Therefore, our findings might provide a more representative comparison of the real-world performance of GPT-4.0 and 3.5 on the CNMLE.

Other research on evaluating ChatGPT's accuracy on national medical licensing examinations included assessments of the USMLE [1,2] and the Japanese National Medical Licensing

Examination [7]. The conclusions were similar to ours: while GPT-3.5 was often at or near the passing threshold, GPT-4.0 passed relevant exams and had higher testing accuracy compared to GPT-3.5. This trend was not only limited to national medical licensing examinations but also applied to other medical-related examinations. However, the specific accuracy varied across models, possibly due to differences in study countries, testing time, exam content, and other variables. A comprehensive review of existing published and non-peer-reviewed research findings is available in [Table 3](#).

Table . A review of the existing published and non-peer-reviewed research related to ChatGPT performance on medical examinations.

Study	Country	Test model	Examination	Data sample, n	Passing threshold	Accuracy (%)
Gilson et al [1]	United States	GPT-3.5	The United States Medical Licensing Examination Step 1 and Step 2 exams	87 - 102	60%	GPT-3.5: 44.0 - 64.4

System Role for Accuracy

While it was expected that introducing system role tailored for clinical subspecialties would enhance the reliability of ChatGPT's medical responses, this effect had not been systematically studied. Our research addressed this gap. Our findings revealed slight but noteworthy improvements in accuracy for both GPT-3.5 (1.3% - 4.5%) and GPT-4.0 (0.3% - 3.7%), although these gains were not statistically significant. This might imply that ChatGPT's inherent abilities are already robust enough to discern and address the medical inquiries without narrowing down its response scope.

Response Variability

As an LLM, ChatGPT naturally exhibits variability in responses when the temperature hyperparameter is not zero. In this study, we adopted the default temperature of 0.7 to simulate real-world use conditions on the front end. Our results showed relatively high coherence between the initial and second responses for both GPT-4.0 and GPT-3.5. Therefore, the relatively high temperature of 0.7 is feasible and recommended when testing ChatGPT's performance on the CNMLE. Furthermore, our results highlighted that both model evolution and system roles contribute to ChatGPT's variability in scenarios such as the Chinese Medical Licensing Exams. This variability can be valuable for medical education, as ChatGPT not only provides answers to questions but also includes the rationale and references for its choices, which allows students to easily follow and comprehend [16]. Repeatedly submitting questions allows groups or individuals to engage with the explanatory content generated by ChatGPT, which is particularly beneficial for open-ended case scenario discussions [17].

Subgroup and Multispecialty Analysis

Our subgroup analysis revealed that ChatGPT demonstrated consistent accuracy across different types of questions. This indicated that ChatGPT was capable of understanding and analyzing complex medical cases and scenarios (A2, A3/A4 questions), which can be challenging even for humans, and making correct decisions. This decision-making ability was equally proficient when addressing more straightforward,

common-sense questions that did not require reasoning (A1, B1 questions).

In comparisons among unit subgroups representing different subspecialties, significant performance variations were observed in GPT-4.0 across CNMLE units. GPT-4.0 exhibited higher accuracy in units 2 - 3, which predominantly featured questions from subspecialties such as cardiovascular, urinary, digestive, and respiratory systems. This was further corroborated by our multispecialty analysis results. GPT-4.0 achieved an accuracy rate of over 75% for these 4 subspecialties, surpassing its overall accuracy rate of 72.7%. Given that these 4 subspecialties accounted for a substantial proportion (34.5%) of all 15 subspecialties, such a disparity might have been advantageous. However, this disparity disappeared upon the introduction of system roles as prompts, with the overall accuracy of GPT-4.0 increasing to 78.6%. This might suggest that the appropriate use of system roles could compensate for individual subspecialty question accuracy, thereby enhancing the overall accuracy of ChatGPT.

Furthermore, we used CNMLE questions, divided into 15 medical subspecialties, to comprehensively assess the medical expertise of ChatGPT models. This approach provided a robust framework for evaluating model proficiency across a variety of medical fields. Notably, GPT-4.0 surpassed the 60% passing threshold in 14 of the 15 distinct clinical subspecialties, in contrast to GPT-3.5, which only passed in 7 out of 15 subspecialties. This highlighted the superiority of GPT-4.0 and its potential in medical applications.

Generalizability of Findings

Previous studies [7] often excluded table and image-based questions when evaluating ChatGPT's performance in medical exams. This approach limited the generalizability of these findings due to ChatGPT's lack of multimodal data processing. In contrast, our study, focusing on the CNMLE's multiple-choice format, which almost exclusively consists of nongraphical and nontabular questions, offers greater generalizability in real exam settings. Zhu et al [17] suggested that ChatGPT, as a chatbot, had advantages in responding to open-ended questions, corresponding more closely with real-world scenarios where users sought medical support

knowledge from ChatGPT. The potential of ChatGPT in exams with open-ended questions merits further exploration.

Limitations

First, this study assessed ChatGPT's ability to answer questions from the Chinese version of the CNMLE. As ChatGPT is mainly trained on English data, Chinese questions could have underestimated its capabilities. Second, the CNMLE questions were multiple-choice, introducing the chance factor in selecting correct answers. Limited by paper length, we did not evaluate the logic behind ChatGPT's choices, although this aspect is critical and merits deeper investigation. Third, real-world medical questions often have open-ended, multiple, or uncertain answers. Therefore, the CNMLE may not represent the full scope of challenges ChatGPT might face in clinical settings. Consequently, GPT-4.0's success on the CNMLE may only indicate its partial competence in clinical decision-making.

Future studies should broaden the range of question types to better assess ChatGPT's medical performance. Despite these limitations, we believe this study provided valuable insights into ChatGPT's capabilities in medicine.

Conclusions

This study comprehensively evaluated the performance of GPT-4.0 and GPT-3.5 in the context of the CNMLE. Our findings indicated that GPT-4.0 not only met the CNMLE passing criteria but also significantly outperformed GPT-3.5 in key areas such as accuracy, consistency, and medical subspecialty expertise. Furthermore, the implementation of system roles served as a pivotal factor in enhancing the model's reliability and answer coherence. These results collectively underscored GPT-4.0's promising potential as a valuable tool for medical professionals, educators, and students, warranting further research and application in the medical field.

Abstract

Background: Teaching medical students the skills required to acquire, interpret, apply, and communicate clinical information is an integral part of medical education. A crucial aspect of this process involves providing students with feedback regarding the quality of their free-text clinical notes.

Objective: The goal of this study was to assess the ability of ChatGPT 3.5, a large language model, to score medical students' free-text history and physical notes.

Methods: This is a single-institution, retrospective study. Standardized patients learned a prespecified clinical case and, acting as the patient, interacted with medical students. Each student wrote a free-text history and physical note of their interaction. The students' notes were scored independently by the standardized patients and ChatGPT using a prespecified scoring rubric that consisted of 85 case elements. The measure of accuracy was percent correct.

Results: The study population consisted of 168 first-year medical students. There was a total of 14,280 scores. The ChatGPT incorrect scoring rate was 1.0%, and the standardized patient incorrect scoring rate was 7.2%. The ChatGPT error rate was 86%, lower than the standardized patient error rate. The ChatGPT mean incorrect scoring rate of 12 (SD 11) was significantly lower than the standardized patient mean incorrect scoring rate of 85 (SD 74; $P=.002$).

Conclusions: ChatGPT demonstrated a significantly lower error rate compared to standardized patients. This is the first study to assess the ability of a generative pretrained transformer (GPT) program to score medical students' standardized patient-based free-text clinical notes. It is expected that, in the near future, large language models will provide real-time feedback to practicing physicians regarding their free-text notes. GPT artificial intelligence programs represent an important advance in medical education and medical practice.

Introduction

Teaching medical students the skills required to acquire, interpret, apply, and communicate medical information is an integral part of medical education. A crucial aspect of this process involves providing students with feedback regarding the quality of their free-text clinical notes. Various methods have been used to systematically assess clinical notes, notably, QNOTE [1,2], but they depend on human raters. This reliance presents numerous challenges, including rater recruitment and training as well as raters' availability and inclination to perform reviews. Furthermore, humans are susceptible to biases, fatigue, and misinterpretation.

An attractive innovative alternative to human raters is to use a natural language processing (NLP) program to score student notes. An NLP program is a computer-based algorithm that automatically detects specific meanings in free text. The potential advantages of using an NLP program to grade student notes include the following: it is systematic; it is objective; it avoids human bias, fatigue, and misinterpretation; it is essentially free to run; it can assess any number of notes in seconds; and it can grade notes in real time to provide immediate student feedback.

A new type of NLP program was introduced in November 2022, namely, ChatGPT 3.5 (OpenAI) [3], a large language model (LLM) based on the generative pretrained transformer (GPT) artificial intelligence algorithm. It has achieved a 91.7% score

on the United States Medical Licensing Examination (USMLE) style questions [4]. Furthermore, it scored 87.3% on a clinical knowledge test, 91.7% on medical genetics, 89.2% on anatomy, and 92.4% on professional medicine [4]. Its medical-related capabilities include improving clinician empathy [5], responding to patient questions [6], performing differential diagnoses [7], classifying radiology reports [8], writing discharge summaries [9], providing accurate prevention advices to patients [10], and predicting suicide risk [11]. ChatGPT has been compared to human raters in terms of grading short-answer preclerkship medical questions. The ChatGPT-human Spearman correlations for a single assessor ranged from 0.6 to 0.7 [12].

We assessed ChatGPT's ability to accurately score medical students' free-text notes on history of present illness, physical examination, and assessment and plan. We compared these scores to standardized patients' scoring of the clinical notes. We hypothesized that ChatGPT would be more accurate than standardized patients. To our knowledge, this is the first study to assess the ability of a GPT program to score medical students' standardized, patient-based, clinical free-text notes.

Methods

Procedure

This was a single institution, retrospective study. Standardized patients were people who volunteered to interact with medical students to assist in their clinical training. They were trained on a prespecified medical case, and acting as the patient, they interacted with first-year medical students, simulating a patient with that condition. This included responding to clinical questions and undergoing an examination by the medical student. The students documented their interaction with standardized patients in free-text clinical notes. They wrote a chief complaint; history of the present illness; review of systems; physical examination; and differential diagnosis, featuring 3 rank-ordered diagnoses. In addition, they provided their pertinent positives and negatives and suggested follow-up tests. At our medical school, standardized patients provided verbal feedback to students regarding their interaction and scored their students' notes. They had 7 - 10 days to score the student notes and send the results to the course instructor. They did not provide any grading feedback to the students. The advantage of using standardized patients over actual patients for training medical students is that the medical students' experiences, and therefore, their clinical notes are based on a consistent clinical presentation.

The study case and scoring rubric, "Suzy Whitworth," were developed by the Association for Standardized Patient Educators and adapted by the Mid-Atlantic Consortium of Clinical Skills Centers in June 2018, with additional formatting edits in January 2019. The standardized patients were trained on this case and its scoring rubric. The case contained 85 scorable elements that were expected to be present in the students' notes. Three scoring rubric examples were as follows: "Notes chief complaint of shortness of breath (shortness of breath, dyspnea, difficulty breathing, and can't catch my breath)"; "Notes sudden onset (acute, all of the sudden, and all at once"; and "Notes timing (a few hours ago, this morning, upon awakening, or today)." The rubric combined the 85 scorable elements into 12 classes. ChatGPT and the standardized patients scored as either correct or incorrect each of the 85 elements in the deidentified students' notes. An error was either an incorrect answer or the absence of an answer. A reviewer checked the standardized patient scoring and the ChatGPT scoring and a second reviewer checked the first reviewer's scores.

ChatGPT is an LLM based on the GPT artificial intelligence algorithm. It was pretrained on 45 TB of data and it consists of attention, which connects and weights natural language meanings, and an artificial neural network, which organizes and stores the meanings [13]. It accepts natural language input and provides natural language output. For each medical student and for each rubric, the researcher created a new prompt that asked ChatGPT if the rubric's meaning was contained in the student's free-text note.

For ChatGPT and standardized patients, the measure of accuracy was the percent correct for each of the 12 categories and across the 12 categories. Student *t* tests (2-tailed) compared the mean error rate across the 12 classes for ChatGPT with the mean error rate across the 12 classes for the standardized patients using the R language (R Project for Statistical Computing) [14].

Ethical Considerations

Ethical approval was waived as per section 46.104(d) of Code of Federal Regulations, as this was a quality improvement project [15].

Results

The study population consisted of 168 first-year medical students, the case scoring rubric consisted of 85 elements, resulting in a total of 14,280 scores. There were 4 standardized patients, each working with one-fourth of the students. The incorrect scoring (error) rates for the standardized patients and ChatGPT are shown in [Table 1](#).

Table . Incorrect scoring rates for ChatGPT and the standardized patients across free-text note categories and across all categories.

Category	Scoring opportunities for the 168 students, n	Standardized patient errors, n (%)	ChatGPT errors, n (%)
Chief complaint	840	135 (16.1)	17 (2.0)
History of present illness	1512	226 (14.9)	35 (2.3)
Review of systems	1008	67 (6.6)	7 (0.7)
Past medical history	1512	43 (2.8)	21 (1.4)
Physical exam	2352	181 (7.7)	25 (1.1)
Diagnosis (pulmonary embolism)	168	3 (1.8)	0 (0)
Pulmonary embolism evidence	2352	182 (7.7)	8 (0.3)
Diagnosis (pneumonia)	168	0 (0)	0 (0)
Pneumonia evidence	1848	66 (3.6)	4 (0.2)
Diagnosis (pneumothorax)	168	0 (0)	7 (4.2)
Pneumothorax evidence	1176	54 (4.6)	5 (0.4)
Diagnostic studies	1008	66 (6.5)	16 (1.6)
Total ^a	14,280	1023 (7.2)	145 (1.0)

^aChatGPT versus standardized patient; $P=0.002$.

The category error rates for standardized patients and ChatGPT, respectively, were as follows: chief complaint: 135, 17; history of present illness: 226, 35; review of systems: 67, 7; past medical history: 43, 21; physical examination: 181, 25; first diagnosis: 3, 0; evidence for first diagnosis: 182, 8; second diagnosis: 0, 0; evidence for second diagnosis: 66, 4; third diagnosis: 0, 7; evidence for third diagnosis: 54, 5; and diagnostic studies: 66, 16. The ChatGPT incorrect scoring rate was 1.0%, and the standardized patient incorrect scoring rate was 7.2%. The ChatGPT error rate was 86% lower than the standardized patient error rate. The ChatGPT mean incorrect scoring rate of 12 (SD 11) was significantly lower than the standardized patient mean incorrect scoring rate of 85 (SD 74; $P=0.002$).

Discussion

ChatGPT had a significantly lower error rate compared to standardized patients. This suggests that an LLM can be used to score medical students' notes.

NLP programs have been used in several medical education settings. Medical education NLPs have been based on keywords, expert systems, statistical algorithms, and combinations of these approaches. DaSilva and Dennick [16] transcribed medical student problem-based verbal learning sessions and used an NLP program to count the frequency of technical words. Zhang et al [17] implemented both a naïve Bayes approach and a supervised support vector machine method to assess resident performance evaluations. Their sentiment accuracies were 0.845 for naïve Bayes and 0.937 for the support vector machine. Spickard et al [18] used an electronic scoring system to detect 25 core clinical problems in medical students' clinical notes. They achieved a 75% positive predictive value (PPV) on 16 of the 25 problems. Denny et al [19] examined whether students mentioned advance directives or altered mental status in their clinical notes. For advance directives, their sensitivity was 69% and their PPV was 100%, and for mental status, their sensitivity

was 100% and their PPV was 93%. Sarker et al [20] used a semisupervised NLP method to assess students' free-text notes. Their accuracy over 21 cases and 105 notes was a sensitivity of 0.91 and a PPV of 0.87. Two recent papers from the University of Michigan's Department of Surgery [21,22] assessed resident feedback and competency. Solano et al [21] dichotomized the narrative surgical feedback given to residents into high and low quality and trained a logistic regression model to distinguish between them. Their model achieved a sensitivity of 0.37, a specificity of 0.97, and a receiver operating characteristic (ROC) of 0.86. Otles et al [22] assessed narrative surgical resident feedback using a variety of statistical methods. The support vector machine algorithm achieved the best result with a maximum mean accuracy of 0.64. Abbott [23] studied whether an NLP program could assess the clinical competency committee ratings of residents in terms of language that correlated with the 16 Accreditation Council for Graduate Medical Education Milestones. The ROCs for the 16 milestones ranged from 0.71 to 0.95 and the mean ROC was 0.83. Neves et al [24] examined the ability of RapidMiner Studio, a machine learning program, to assess the quality of attending feedback on resident performance. Their accuracies ranged from 74.4% to 82.2%.

If NLP programs are to be used to automate the grading of students' notes, they must achieve an acceptable accuracy. Sarker et al [20] suggested that any method of scoring medical notes should achieve an accuracy close to 100%. Regrettably, none of the reported medical education NLPs achieved an acceptable accuracy. In our study, standardized patients also failed to achieve an acceptable accuracy. ChatGPT attained an accuracy close to 100% and is, therefore, suitable for scoring students' free-text notes.

A potential limitation of this study is that it has been suggested that GPT-based methods have the potential to generate unreliable answers under certain circumstances. We did not find

that to be true in our study. Another potential limitation is that, although ChatGPT is free to the public, it has resource requirements. It used 45 TB of data, it has 175 billion parameters, and it runs on supercomputers residing in the cloud. This is a great deal of computing power for student notes. Fortunately, there are open-source GPTs, for example, Meta's Llama, that can be run on a workstation. We would have liked to examine the standardized patient validity literature, but to our knowledge, no such study exists. Finally, assessing note errors does not directly address clinical reasoning.

An important advantage of LLMs is their ability to provide real-time scoring and feedback on student clinical free-text notes. This immediate assessment offers students a valuable learning opportunity because they can reflect on their performance while the clinical interaction is still fresh in their mind. Another advantage is that the scoring is accurate and objective so students will no longer have to worry about human error and bias. A disadvantage of ChatGPT was that it was time

consuming. Fortunately, there are compound GPTs that can perform the entire assessment of all the elements and all the students at once. In terms of clinical reasoning, in the future, we will be asking medical students, as part of their clinical note write-up, to provide their clinical reasoning and we can have a GPT assess the quality of their reasoning.

It should be noted that the use of LLMs to score clinical notes need not be limited to medical students. It is expected that in the near future, GPT-based artificial intelligence NLPs will be applied to provide real-time feedback on free-text clinical notes to practicing physicians.

In conclusion, ChatGPT demonstrated a significantly lower error rate compared to standardized patients. This is the first study to assess the ability of a GPT program to score medical students' standardized, patient-based, free-text clinical notes. GPT artificial intelligence programs represent an important advance in medical education and medical practice.

Acknowledgments

Support for this project was provided by the Patient Safety and Quality Academic Collaborative, a joint Defense Health Agency-Uniformed Services University program. The funder did not participate in the design, execution, or analysis of this project.

Abstract

Background: The increasing importance of artificial intelligence (AI) in health care has generated a growing need for health care professionals to possess a comprehensive understanding of AI technologies, requiring an adaptation in medical education.

Objective: This paper explores stakeholder perceptions and expectations regarding AI in medicine and examines their potential impact on the medical curriculum. This study project aims to assess the AI experiences and awareness of different stakeholders and identify essential AI-related topics in medical education to define necessary competencies for students.

Methods: The empirical data were collected as part of the TüKITZMed project between August 2022 and March 2023, using a semistructured qualitative interview. These interviews were administered to a diverse group of stakeholders to explore their experiences and perspectives of AI in medicine. A qualitative content analysis of the collected data was conducted using MAXQDA software.

Results: Semistructured interviews were conducted with 38 participants (6 lecturers, 9 clinicians, 10 students, 6 AI experts, and 7 institutional stakeholders). The qualitative content analysis revealed 6 primary categories with a total of 24 subcategories to answer the research questions. The evaluation of the stakeholders' statements revealed several commonalities and differences regarding their understanding of AI. Crucial identified AI themes based on the main categories were as follows: possible curriculum contents, skills, and competencies; programming skills; curriculum scope; and curriculum structure.

Conclusions: The analysis emphasizes integrating AI into medical curricula to ensure students' proficiency in clinical applications. Standardized AI comprehension is crucial for defining and teaching relevant content. Considering diverse perspectives in implementation is essential to comprehensively define AI in the medical context, addressing gaps and facilitating effective solutions for future AI use in medical studies. The results provide insights into potential curriculum content and structure, including aspects of AI in medicine.

Introduction

Background and Significance of AI in Medicine

In 1966, the architect Cedric Price [1] posed the provocative question, "Technology is the answer, but what was the question?" to encourage his lecture audience to explore,

question, and reconsider the impact of technological progress. More than 50 years later, this question remains as relevant as ever. One might similarly ask today, "The answer is AI, but what was the question?" The health care sector is currently undergoing a significant transformation process characterized by the increased integration of digital technologies [2-4]. German clinics have been incorporating computer-driven clinical

decision systems, such as the electronic patient record and other digital health tools, that can analyze data, identify patterns, and make decisions based on that data [3]. These intelligent systems can improve health care efficiency, accuracy, and quality while potentially reducing the burden on medical personnel [5,6]. Artificial intelligence (AI) technologies are already being implemented in various aspects of medical practice. For instance, they are used in imaging diagnostics where AI algorithms help analyze medical images [7]. Dictation systems with speech recognition powered by AI are also used, and AI chatbots are deployed to assist doctors and patients by providing appointments and information [8-10]. A range of sensor-based wearables, such as fitness trackers, smartwatches, and health apps, is already used in people's daily lives. These devices use AI-supported algorithms to gather and analyze health data, including heart rate, sleep patterns, activity levels, and calorie consumption. Based on this information, personalized recommendations can be made to help individuals improve their well-being [11]. Although the use of medical AI systems remains in its early stages, ongoing research and development efforts are being undertaken worldwide. As technology rapidly advances, AI will increasingly play a crucial role in the future of health care [12,13]. This also requires restructuring medical curricula to adapt to dynamic technological advances to prepare students for the changing structures of medical practice [14,15].

Traditionally, medical education has focused on providing students with comprehensive knowledge of medical practices, diagnostic procedures, and treatment methods. Additionally, the effective use of AI in the medical field requires not only developing the necessary technological advances in AI applications but also ensuring that future physicians possess the required skills and expertise to effectively apply these technologies [16-18]. Therefore, it is crucial to consider integrating AI into the medical curriculum and determine how this technology can be effectively incorporated to benefit students and patients [19-21]. However, studies indicate that the integration of AI into the medical curriculum to enhance understanding of AI algorithms and optimize their use remains in its early stages, particularly in Germany [22-24]. Some institutions have developed specific courses and training programs to enhance medical students' knowledge and skills in AI [25-27].

Research Objectives and Research Questions

Given the complex and rapidly evolving nature of AI, no standardized definition or structured learning objectives currently exist regarding the specific AI topics medical students should be familiar with. Several studies emphasize the importance of understanding the fundamentals of AI and data science, mathematical concepts, and related ethical and social issues [26,28]. Medical students should also develop skills in interpreting AI models and be familiar with machine learning, deep learning, and data analytics to apply AI in clinical practice [29].

As part of a project, "TüKITZMed – Tübingen KI – Trainingszentrum für die Medizin" (Tübinger AI Training Center for Medicine), funded by the German Federal Ministry of Education and Research (16DHBKI086), a comprehensive

needs assessment was conducted involving various stakeholders to understand the requirements and skills for integrating AI into the medical curriculum following step one of Kern's 6-step approach [30]. The project "TüKITZMed" aims to develop and establish a cross-faculty interprofessional curriculum focused on "AI in medicine" providing students with a comprehensive understanding of the topic across different levels and disciplines. This curriculum serves as a pioneering example of integrating AI into academic programs, offering students opportunities for both theoretical learning and practical application, thereby facilitating the transfer of knowledge into real-world contexts. This study aimed to investigate essential AI knowledge for medical education curricula, identify necessary competencies through stakeholder input, and address potential gaps in learning opportunities. Involving different stakeholders offers diverse perspectives based on their roles and experiences. This approach helps identify relevant AI competencies and appropriate teaching formats, addressing unmet needs and challenges associated with implementing AI-focused learning opportunities in medical education [31].

Therefore, this paper aims to address the following research questions regarding assessing AI awareness and identifying essential competencies:

- How familiar are the different stakeholders with AI in general?
- Which specific aspects and topics related to AI are viewed as important?
- What competencies are crucial for medical health students?

Methods

For a comprehensive understanding of AI and to address various aspects relevant to the surveyed stakeholders' perspectives on an AI curriculum, an exploratory research approach using semistructured interviews was chosen. The incorporation of narrative-generating guideline-supported questions aimed to establish a structured framework for investigating research interests while also allowing flexibility to uncover new and insightful content [32].

Study Design and Setting

This qualitative study approach followed the Standards for Reporting Qualitative Research [33]. It was performed at the Medical Faculty and the Faculty of Science of the University of Tübingen as part of the TüKITZMed project.

Sample Selection and Recruitment

Semistructured interviews with 38 stakeholders involved in the implementation process of AI in medical curricula were conducted to gather diverse perspectives and insights. Relevant stakeholders were characterized as individuals impacted by the integration of AI in health care, those with professional experience with AI technology, and those who had previously encountered AI applications in the medical sector. The stakeholder groups comprised the following: 6 lecturers, 9 clinicians, 10 students, 6 AI experts, and 7 institutional stakeholders. The interview guide followed the guiding research questions for the needs assessment [34]. An illustrative interview guide is provided in [Multimedia Appendix 1](#).

The selection of stakeholder groups was based on their crucial role in the field of medical education and their diverse perspectives. For participant recruitment, we used an open approach, reaching out to stakeholders primarily via email after identifying relevant stakeholder groups for our research inquiries. Inclusion criteria included individuals working with AI in the medical context or possessing relevant expertise, especially clinicians and AI experts. Due to the project's regional focus, only stakeholders from the local area were approached. Recommendations, referrals, and requests within working groups or via email forwarding were also used. Potential participants were also approached at conferences.

Lecturers

Educators' perspectives are required, as integrating AI into medical education is an unprecedented challenge with no clear guidelines. Even if consensus is reached on exactly what should be taught to medical students, it remains daunting to determine how best to teach it. The experience of educators—especially those familiar with medical students—is therefore imperative in the process [35,36].

Students

Health care students' perspectives (eg, on human medicine, medical technology, and molecular medicine) are central to integrating AI into medical education since the curricula should ultimately be designed to serve their educational needs. Therefore, assessing their current state of knowledge, attitudes, and heterogeneity across different student populations is an important step in adequately addressing the educational needs for medical AI and integrating it such that students will benefit from it [18,37].

AI Experts

AI experts have long-standing knowledge and expertise in the field. Engaging with them provides valuable insights into the latest developments, trends, and best practices in AI. These experts offer a thorough understanding of AI concepts, applications, and their potential impact on health care [36,38].

Clinicians

Involving medical staff in developing medical AI helps find clinical value while protecting patient safety. Moreover, medical staff know the data well and are thus the only ones who can detect the bias or impracticality of AI. Additionally, medical experts play a key role in teaching real-world medical applications of AI, as they have the experience and skills. Thus, their perspectives are relevant to the integration of AI into education and practice since they can inspire other medical workers to engage with it [39].

Institutional Stakeholders

The perspectives of institutional stakeholders are crucial for driving change in medical education. These individuals hold key positions within educational or health care institutions and are actively involved in implementing AI within the medical curriculum. Such stakeholders, including deans, program coordinators, and administrative staff, possess specific training and qualifications relevant to their roles, playing an essential part in shaping educational strategies and health policies. Given

the already full capacity of medical curricula, their support and expertise are necessary for a meaningful integration of AI. Additionally, institutional stakeholders provide an important framework for continuously monitoring and reevaluating the implementation of AI in medical curricula to ensure its utility and quality [18,40,41].

Data Collection

Semistructured guided interviews were chosen as they allow a flexible participation-centered approach and in-depth exploration of the topic, capturing the diverse perspectives of the stakeholders involved [42]. The semistructured guided interviews were conducted from August 2022 to March 2023, either face-to-face or via videoconference. All interviews were audio recorded and transcribed verbatim for analysis. Before participation, written informed consent was obtained from all the interviewees. The resulting code system for analysis was consolidated and summarized.

Data Analysis

The transcripts were analyzed according to the principles of content structuring analysis, as outlined by Kuckartz [43]. After the interviews were transcribed, independent researchers thoroughly reviewed them. The category system for the analysis was developed using the semistructured guiding questionnaire as a basis (inductive approach) and systematically coded using the MAXQDA 2022 software program (VERBI GmbH). As the coding process progressed, new categories emerged to include additional aspects and themes discussed in the interviews. This step enabled flexibility and openness to new insights that transcended the initially defined structure (deductive approach) [44]. Collectively, we presented outcomes derived from diverse stakeholders. We systematically addressed varying perspectives within or across these cohorts, emphasizing their respective relevance. Our presentation includes literal quotations, preserving the original expressions translated from German to English.

Ethical Considerations

The study received ethical approval from the Ethics Committee of Tübingen Medical Faculty (467/2022BO2). Participation was voluntary. All participants were informed of the purpose of the study and provided informed consent before data collection. The confidentiality of all data was ensured, and all responses and data were kept anonymous. The participants had the right to withdraw from the study at any time. Participants did not receive any compensation.

Results

Overview

The ages of participants ranged from 19 to 59 (mean 38.5, SD 9.7, SEM 1.6) years, with data provided by 36 individuals. Regarding sex distribution, there were 26 male and 12 female participants. Through a structuring content analysis, we systematically derived 6 primary categories with a total of 24 subcategories from the entire data set.

Presentation of Stakeholder Perspectives and Expectations of AI

The analysis of the stakeholders' statements revealed several commonalities and differences regarding their understanding of AI.

AI as a Tool

In terms of commonalities, the actors viewed AI primarily as a tool that can analyze and process large amounts of data:

For me, it's mainly a toolbox, a toolkit. These are technologies that help us. [RR22T, expert]

An AI can process much more data at once than a human could. [KC10S, student]

A way to predict things, that is, to predict data based on existing data and also to apply techniques that support us to categorize, assess, simulate, and also predict things in terms of the future. [KU512S, institutional stakeholder]

AI as a Medical Assistant

Additionally, stakeholders emphasized the potential benefits of using AI to assist in medicine, whether in supporting diagnostic and treatment decisions or more efficiently mining clinical data:

In the context of medicine, probably so therapy decisions, more efficient evaluation of clinical data. [AB001, lecturer]

To this, I can think of automation and standardization of processes but also help in an increasingly complex clinical situation with many parameters and many possibilities relevant for decision-making by doctors involved in therapy and diagnosis. [RW01R, institutional stakeholder]

The Technical Understanding of AI

A focus on understanding AI is also related to the technical background of AI technology and the roles of mathematical-statistical models, data, and algorithms:

AI is learning systems that fit a model with computations to data. [PG49B, expert]

AI is about programs and algorithms that improve with more data and data processing. [CCHU7, clinician]

Differences in the Understanding of the Term and Difficulties in Formulating a Definition

However, differences in the understanding of AI between the stakeholders interviewed also became apparent. These disparities manifested in three key areas: challenges in formulating a concise definition and description of AI, diverse perspectives and expectations regarding AI capabilities, and varying emphasis on the medical fields where AI is anticipated to make significant progress.

The name "AI" is misleading because there is currently no computer application that is actually intelligent. Rather, it refers to algorithms with high computing power that enable computers to process

larger amounts of data than before and possibly even evolve themselves. [RH01W, lecturer]

Artificial intelligence is a difficult term. It suggests that human intelligence is extended and artificially subsumed. [EJ12B, institutional stakeholder]

Understanding AI is complex and broad. There is AI that learns itself and AI that still needs to be monitored. AI is otherwise a kind of automated analysis. [HT02B, clinician]

Varying Perspectives and Expectations on the Potential and Capabilities of AI

While some may view AI capabilities more optimistically or comprehensively, others emphasize the limits and specialized functions AI can possess. For example, the students tended to view AI as efficient data processing, while the experts emphasized AI's capacity for revealing hidden patterns and simulating complex scenarios. The students emphasized that AI lacks a creative process and cannot engage in creative thinking. They focused on AI's ability to efficiently process and analyze large amounts of data. The experts discussed AI's ability to identify scientific connections, structures, and patterns that may be imperceptible to humans. They recognized AI's potential to simulate complex scenarios and discover novel insights from data.

Systems that can recognize scientific relationships, structures, and patterns that are not discernible to humans. [PG49B, AI expert]

AI is not intelligent because no creative process can take place in it. It can quickly and efficiently draw connections from large amounts of data. [YG30B, student]

In most cases, however, AI is about better evaluating large amounts of data and modifying it through self-learning algorithms. Human intelligence can understand and solve problems through creativity and think outside of rules – so it works differently. However, algorithms can do other things better than humans. [EJ12B, institutional stakeholder]

AI will determine everyday life, but also medicine more and more. Nowadays, one is often confronted with the topic, and one should deal with it. [IE13H, clinician]

Different Emphases of the Potential Areas of Application

Although some alignment existed in the perceptions of the potential uses of AI, each group had its own focus on specific applications of AI in health care, depending on profession and discipline. AI experts and lecturers emphasized the significance of the technical dimensions of AI, including the essential roles of algorithms, data processing, and AI models in medical research and practice. Students underscored AI's role in aiding health care professionals, while clinicians concentrated on the clinical sphere of AI, particularly its contributions to diagnostics, treatment decisions, and data processing. Additionally, institutional stakeholders highlighted the potential for increased efficiency in health care by implementing AI solutions. They

engaged in discussions concerning the pragmatic integration of AI to strengthen clinical decision-making processes and optimize operational workflows.

But to provide a definition..., so what we're actually doing is, we're learning relationships between input, certain inputs, and certain outputs: What is the relationship between an X-ray image and a diagnosis? And this correlation, you can then learn it using, for instance, a neural network, and then apply it to unseen X-ray images. [MF08Z, lecturer]

To simplify processes, so to speak, to facilitate and automate simple processes that would normally take a lot of time for us humans. The machine can recognize complex relationships that we as humans either cannot comprehend or, as mentioned, would take a long time to understand. For example, in my case, it's radiation therapy in radio oncology, where there are many processes that take a long time or are,

as I said, very complex because, in medicine, we naturally have many intricate aspects and influences on the patient that we need to consider. And a machine can handle this quite well, as it can analyse and evaluate these various data effectively, essentially. [EK05B, student]

An evolving field, which is already partially present in clinical reality. This involves automation and standardization of processes, as well as assistance in an increasingly complex clinical environment with numerous parameters and numerous possibilities that are relevant for decision-making by physicians and individuals involved in therapy and diagnosis. [RW01R, institutional stakeholder]

Identification of AI Competencies and Implications for Medical Curriculum

We identified 4 main categories of implementation needs (Textbox 1)

Textbox 1. Identified main categories of implementation needs: conceptual designs for an artificial intelligence curriculum.

Possible curriculum contents, skills, and competencies

- Basic understanding and sense of technology
- Data literacy
- Morality and ethics
- Opportunities and risks
- Digital literacy
- Application of software
- Data privacy
- Understanding of medical test results

Programming skills

- Voluntary: Having programming skills is optional. Although they are not mandatory, having them is beneficial.
- Not required: Programming skills are unnecessary. However, if one possesses such skills, that is acceptable.
- Required: Programming skills are mandatory. Basic or advanced programming proficiency is expected for participation.

Curriculum scope

- Adapted to the time available
- Intensive engagement

Curriculum structure

- Lecture
- Seminar
- Interactive exercises
- Consolidation for specialization
- Basics as lecture with exercise
- No opinion due to lack of experience
- Interdisciplinary
- Adapt curriculum dynamically according to relevance

Possible Curriculum Contents, Skills, and Competencies

This main category covers a range of topics, including possible curriculum components, skills, and abilities students should learn regarding AI in medicine.

Basic Understanding and Sense of Technology

The first subcategory addresses the need for medical students to develop a basic understanding of the fundamental principles and concepts of AI. This includes understanding the essential mechanisms of machine learning algorithms and acquiring basic knowledge of mathematical computer science.

And I believe that what would be important to develop a bit of an understanding of how the technology actually works....So, I don't think that you can teach all of that to medical students from the ground up in theoretically well-founded way with linear algebra and so on. But I do think that it's quite impossible to offer an applied course where they can practise and play around with it, get a sense of how technology functions. [MF08Z, lecturer]

Data Literacy

The data literacy category describes the need to provide medical students with the skills and knowledge required to effectively handle and interpret data in the context of AI applications in the field of medicine.

Data quality is crucial. In my view, all the methods of machine learning are secondary....But the most important thing is truly obtaining high-quality data, understanding how to work with data, understanding implications of the data. [DD21S, expert]

Morality and Ethics

The morality and ethics subcategory is dedicated to providing students with an in-depth understanding of the ethical considerations associated with integrating AI into the medical field. It aims to develop a keen awareness of the ethical responsibilities associated with AI advances in the medical field.

Ethics comes to mind...I consider it a highly relevant aspect because AI tools that are intended for future use in medicine are, in my opinion, closely tied to patients, to human beings; potentially, these tools could make life and death decisions, and in that regard, I would argue that entirely different requirements for quality assurance, ethical standards and checks and boundaries need to be in place for these tools....That should be covered during education. [RW01R, institutional stakeholder]

Opportunities and Risks

The opportunities and risks subcategory includes aspects related to awareness of the potential benefits and challenges associated with integrating AI into health care. Medical students should be empowered to navigate the complex landscape of AI in medicine by not only recognizing the potential benefits but also being able to address challenges, make informed decisions, and maintain vigilance concerning its capabilities and limitations.

Also understanding how to interact with AI. To what extent can I trust the AI, the outcomes it produces? How can I collaborate effectively with it? What do I need to operate a good AI, and where can it also be deployed? [SA01R, student]

Digital Literacy

Several actors addressed the need for medical students to be equipped with the skills required to navigate and use digital technologies effectively. This includes developing proficiency in using AI-powered diagnostic support tools, including the ability to interpret and apply AI-generated diagnostic insights. This also extends to understanding and implementing adaptive learning methodologies and leveraging telemedicine for remote patient care.

What is also important to me, when we talk about the topic of artificial intelligence, is that we first discuss the fundamental aspects of digitization and the necessary measures for healthcare, research, and education.... We are delving into a very specific topic, but we still lack some of the foundational knowledge. [EH07S, institutional stakeholder]

Application of Software

The application of software subcategory concerns equipping individuals with the ability to effectively use software tools, particularly in the context of AI development and implementation.

Medical students often lack knowledge in this area. Therefore, I believe it's important for them to have hands-on experience of training a neural network themselves. [MF08Z, expert]

Data Privacy

The data privacy category describes the aspects the actors mentioned to give students the expertise to address the ethical and legal issues related to data privacy in AI applications. By mastering data management practices and understanding the legal framework, students ensure patient data is managed safely, impartially, and ethically in the context of AI integration.

The topic of data privacy should definitely be included in the curriculum because the "who" question of how to do this, how it's trained and on which data sources, most of it needs to be anonymized.... Ethics and data privacy are two significant components that need to be integrated, unfortunately or fortunately. [HT02B, clinician]

Understanding of Medical Test Results

The last subcategory summarizes the need for in-depth expertise in AI-driven application outcomes, particularly in the context of medical tests. Students must develop a profound understanding of the insights and outcomes produced by AI applications, including acquiring the expertise to thoroughly analyze and interpret results derived from AI-powered processes.

The most important aspect of AI is understanding the basis on which decisions are made. [JJ22D, clinician]

Programming Skills

Clinicians stated that a programming course for medical students should not be mandatory due to overload but could be offered as an elective. Instead, AI experts should be involved due to their expertise in AI applications in the medical field. However, a basic understanding of programming should be acquired early, especially for those who are interested and want to pursue a science career. Most clinicians surveyed opposed including programming skills in the curriculum.

Some lecturers also disagreed with integrating programming knowledge into the curriculum due to student overload. It was emphasized that it is unnecessary for physicians to be able to program neural networks, for example, but that a basic understanding of application knowledge should be established. However, some also emphasized that programming skills and basic computer science knowledge are important, including Python, R, and a theoretical understanding of algorithms. Opinions on the topic were divided and varied depending on the respondents' areas of expertise.

The students interviewed also believed programming skills should be offered to those interested but should not be mandatory. The majority rejected the integration of programming skills into the curriculum, as they are considered too extensive for medical studies and appear to be of minimal relevance to practical application.

AI experts emphasized that physicians need a basic understanding of AI to build confidence in AI applications. Opinions on programming skills were divided, with some considering simple programming skills helpful. Institutional stakeholders also believed medical students do not necessarily need to know how to program but should have field competence in programming. It is expected that not all medical students will be able to program or develop learning methods themselves. However, a basic understanding of programming is viewed as increasingly essential.

Curriculum Scope

The design and scope of AI courses in medicine vary. Including a small section in the curriculum, adapted to the students' abilities, is recommended. For radiologists and image-based diagnosticians, intensive exposure to AI is useful. This should cover a practical application with real medical data to show the application's relevance. Online courses for practicing physicians were suggested to learn the basics.

Curriculum Structure

Regarding AI education in medicine, two main approaches are being considered: lectures and seminars. For lectures, the focus is on introducing mandatory courses blending theory with practical applications. Seminars are viewed as a means to give students early practical experience, enhancing their engagement. Due to the subject's complexity, lecturers are advised to emphasize fundamentals and incorporate concrete examples. However, it is noted that students might find lectures overwhelming, especially without mandatory exams or regular attendance.

Stakeholders emphasized the need for a practical and interactive design when conveying AI content, with clear applications that allow students to experiment for maximum learning impact. Basic AI competencies should be part of the standard medical curriculum, with options for specialization for those interested, particularly those pursuing a scientific career.

Incorporating AI competencies into medical education is recommended, either through a holistic course or integration into subject-specific areas. Interdisciplinary, research-oriented, and application-oriented seminars and workshops should be established to provide in-depth knowledge. In the future, the curriculum will require substantial restructuring to effectively integrate evolving AI content. Given the rapidly changing nature of AI, the curriculum must remain adaptable.

As shown in [Figure 1](#), the competencies highlighted by different stakeholder groups reveal a range of perspectives and priorities. These focus on the frequency of topics falling into these main categories, offering a nuanced understanding of the thematic landscape.

For example, each stakeholder group highlights the significance of possessing a basic understanding of AI and an awareness of AI-supported applications. Similarly emphasized is the importance of gaining a principal perspective on the opportunities and limitations of AI in medicine, as well as addressing ethical considerations and potential dilemmas. AI experts also emphasized topics such as data literacy, fundamental computer science and mathematics skills, and gaining an overview of potential application areas, while institutional stakeholders focused on interdisciplinary approaches and legal requirements.

Figure 1. Main categories by occurrence of mentions per stakeholder group (qualitative content analysis). The presentation of the primary categories in the qualitative content analysis is based on the frequency of mentions per stakeholder group rather than a quantitative analysis of frequency distribution. AI: artificial intelligence.

Discussion

Principal Findings

The insights gained from the study of stakeholder statements provide valuable perspectives on the different views and interpretations of AI. This provides the basis for answering two central research areas. The first is the understanding of AI, particularly how different interest groups perceive this technology. Second, the focus is on the AI skills that should be taught in medical studies. The different stakeholder groups, including lecturers, health care students, AI experts, institutional stakeholders, and clinicians, contributed to a multifaceted

picture. The analysis highlighted similarities and differences in the perception of AI by the various stakeholder groups. These findings from our investigation correspond to step one of Kern's 6-step approach. They are crucial for discussions on implementing AI in health care and underline the need for clear communication, education, and a common understanding of terminology.

Key Competencies for Health Science Students and the Need for a Common Understanding of AI

The qualitative content analysis revealed a broad spectrum of perceptions of AI among the interviewees. Especially in rapidly advancing fields such as AI, creating and maintaining a common

language is essential to enable effective collaboration between different stakeholders. AI is a broad field incorporating many technologies and methods. When introducing AI into the health care system, it is important to acknowledge that different stakeholders involved may have different perceptions of the term AI. A clear definition of this complex term helps prevent misunderstandings, as the field of AI is expansive, encompassing various technologies and methodologies [45,46].

Depending on the contextual background and prior knowledge of the individuals, different descriptions and emphases emerged in the definition of AI. Similarly, ideas concerning the opportunities and limitations of AI in medicine varied depending on individual backgrounds. If consensus is lacking on what AI means in the context of medical education, this can lead to confusion and disagreement on which AI competencies are essential for medical students. This lack of clarity can hinder the development of standardized curricula and educational programs related to AI in medical education, especially when different stakeholders with different backgrounds might be mixing the AI terminologies “strong AI” and “weak AI” [47,48]. Therefore, a clear understanding of the implications and limitations of AI in the medical field is crucial for establishing effective educational guidelines.

Considering these diverse perceptions of AI are particularly relevant when teaching AI skills to medical students. The diversity in the understanding of AI only emphasizes the complexity of the topic; thus, a strong interdisciplinary approach is necessary. Collaboration between physicians, computer scientists, ethicists, and other experts is essential to fully understand the challenges and opportunities of AI in the medical context. For instance, this becomes particularly important when determining which AI applications can enhance the learning experience in specific medical specialties [41].

The diverse perspectives among stakeholders indicate a consensus regarding the essential competencies for health care students concerning AI integration. Recurring themes include practical experience, fundamental digitization knowledge, ethical considerations, and a profound understanding of data and technology. Balancing these competencies is critical to preparing future health care professionals to effectively use AI while maintaining ethical standards and a patient-centered approach. Continued collaboration between stakeholders and the adaptability of medical education curricula will play a key role in achieving these goals.

As illustrated in [Figure 1](#), the stakeholders exhibit substantial diversity in their prioritization of topics and skills, highlighting significant variations in the perceived importance of AI integration into the curriculum. The discussion underscores the importance of a comprehensive approach to AI education in medicine, incorporating practical experience, ethical considerations, and a nuanced understanding of AI’s role in health care. In the context of AI competencies for medical students, they must possess not only medical knowledge but also basic knowledge of AI applications and data literacy, as AI in medicine is becoming increasingly data intensive. The ability to accurately evaluate, manage, and safeguard medical data is essential to ensure that AI technologies can be effectively

and ethically deployed in patient care. Therefore, collaboration between stakeholders is essential to develop a curriculum equipping future medical professionals with the necessary competencies to navigate the complexities and opportunities presented by AI in medicine.

The Impact of AI on Shaping Individual Behavior and Societal Outcomes in Medical Training

Since the 1980s, it has been recognized that the introduction of new technologies such as AI does not occur in isolation or independent of societal influences, contrary to the earlier assumption of technological determinism [49,50]. Technology development is shaped by social construction and negotiation processes, where technology emerges as a social construct through human action and influences societal structures and institutions [51]. Interactions related to the introduction of AI in health care can significantly impact how patients are treated and how medical information is used [52]. This concerns not only introducing a new technology per se but also ensuring that it has long-term and positive effects. A key aspect is ensuring that the implementation of AI in health care respects and considers the existing values, norms, and needs of society. Therefore, ethical compatibility and adherence to societal standards are fundamental [53].

Furthermore, AI technologies influence not only medical knowledge but also how doctors, patients, and other stakeholders in health care understand and define their roles. Comprehensive integration of AI requires a holistic approach that not only relies on technological advances but also appropriately considers social dynamics and human aspects.

Our analysis also illustrates the broad understanding of AI, a disparate overall picture of the necessary AI competencies for future medical professionals, and the possibilities and risks associated with implementation. While it is a hot topic among AI experts, health care students are not yet fully aware of the significance of AI, although the technology is expected to enter their professional lives in the future [31,54]. In medical education, students should actively engage with AI, moving beyond passive roles. As well as regulatory, technical, and ethical aspects, it is crucial to consider the sociotechnical dimensions of AI. This is vital, as students must cultivate not only a deep understanding of AI but also an awareness of its societal complexities. For example, Sartori and Bocca [55] emphasize that narratives, whether from the media, scientific community, fiction, or other sources, significantly influence how society perceives and understands technology, including AI. These narratives contribute to the formation of shared understandings, values, and expectations about technology and its potential impact on society [55].

Conclusion

The diverse perspectives on AI among the interviewees underline the requirement for a common language in this rapidly advancing field. Introducing AI into health care necessitates an awareness of varying stakeholder perceptions, emphasizing the importance of a clear definition to prevent misunderstandings. Individual backgrounds shape distinct descriptions and emphases in defining AI, leading to diverse ideas about its opportunities

and limitations, particularly in the context of medical education. When teaching AI skills to medical students, it is essential to address this diversity and adopt a robust interdisciplinary approach to ensure future health care professionals acquire essential knowledge and skills. The results underscore the significance of a comprehensive AI education in medicine, integrating practical experiences, ethical considerations, and a nuanced understanding of AI's role in health care. These competencies will enable medical students to critically evaluate AI technologies and use them responsibly in clinical practice, promoting a more informed and ethically sound integration of AI into health care. The lack of standardization in defining and teaching AI in medical education can lead to uncertainty and potential rejection of the technology. Closing this gap requires gaining insights into the knowledge and skills medical students should acquire regarding the use of AI in medicine. Future studies must focus on awareness of AI and perceived opportunities and risks associated with its implementation. This is also crucial for developing a holistic perspective on competencies within the medical curriculum.

Limitations

While the qualitative nature of our study enabled in-depth exploration and rich insights into the stakeholder perceptions, the limitations associated with the sample size of 38 participants must be acknowledged. The findings may be context specific, and caution is warranted in generalizing beyond our studied group. Notably, some interviewees held dual roles, such as being both lecturers and clinicians. Due to practical constraints, they were interviewed in only one capacity, either as lecturers or clinicians. This limitation underscores the complexity of their perspectives, as their roles encompass multifaceted responsibilities. Using a partially standardized guiding questionnaire, participants were prompted to consider specific questions they might not have spontaneously discussed. While this may have influenced the direction of the conversation, we believe it encouraged participants to reflect. However, it must be acknowledged that a more comprehensive and representative understanding would require further exploration through a quantitative survey. Of note, a subsequent paper will address the opportunities and challenges associated with implementing AI in health care identified by the participating stakeholders.

Acknowledgments

We would like to thank our study assistant Leonie Winterpacht for her help.

We thank the Federal Ministry of Education and Research, Germany for supporting this project (16DHBKI086). We acknowledge support via financing publication fees from Deutsche Forschungsgemeinschaft and the Open Access Publishing Fund of the University of Tübingen.

Authors' Contributions

JAM was responsible for designing and conducting the study, and the acquisition, analysis, and interpretation of data. AHW and TFW were involved in data analyses and interpretation, and revised the manuscript critically. JAM analyzed the research material and wrote the manuscript. KN, SZ, and WF made substantial contributions to the study design and revised the manuscript critically. All authors critically revised the manuscript, and all authors approved the final version of the manuscript and agreed to be accountable for all aspects found therein.

Conflicts of Interest

None declared.

Abstract

Background: Accurate medical advice is paramount in ensuring optimal patient care, and misinformation can lead to misguided decisions with potentially detrimental health outcomes. The emergence of large language models (LLMs) such as OpenAI's GPT-4 has spurred interest in their potential health care applications, particularly in automated medical consultation. Yet, rigorous investigations comparing their performance to human experts remain sparse.

Objective: This study aims to compare the medical accuracy of GPT-4 with human experts in providing medical advice using real-world user-generated queries, with a specific focus on cardiology. It also sought to analyze the performance of GPT-4 and human experts in specific question categories, including drug or medication information and preliminary diagnoses.

Methods: We collected 251 pairs of cardiology-specific questions from general users and answers from human experts via an internet portal. GPT-4 was tasked with generating responses to the same questions. Three independent cardiologists (SL, JHK, and JJC) evaluated the answers provided by both human experts and GPT-4. Using a computer interface, each evaluator compared the pairs and determined which answer was superior, and they quantitatively measured the clarity and complexity of the questions as well as the accuracy and appropriateness of the responses, applying a 3-tiered grading scale (low, medium, and high). Furthermore, a linguistic analysis was conducted to compare the length and vocabulary diversity of the responses using word count and type-token ratio.

Results: GPT-4 and human experts displayed comparable efficacy in medical accuracy ("GPT-4 is better" at 132/251, 52.6% vs "Human expert is better" at 119/251, 47.4%). In accuracy level categorization, humans had more high-accuracy responses than GPT-4 (50/237, 21.1% vs 30/238, 12.6%) but also a greater proportion of low-accuracy responses (11/237, 4.6% vs 1/238, 0.4%; $P=.001$). GPT-4 responses were generally longer and used a less diverse vocabulary than those of human experts, potentially enhancing their comprehensibility for general users (sentence count: mean 10.9, SD 4.2 vs mean 5.9, SD 3.7; $P<.001$; type-token ratio: mean 0.69, SD 0.07 vs mean 0.79, SD 0.09; $P<.001$). Nevertheless, human experts outperformed GPT-4 in specific question categories, notably those related to drug or medication information and preliminary diagnoses. These findings highlight the limitations of GPT-4 in providing advice based on clinical experience.

Conclusions: GPT-4 has shown promising potential in automated medical consultation, with comparable medical accuracy to human experts. However, challenges remain particularly in the realm of nuanced clinical judgment. Future improvements in LLMs may require the integration of specific clinical reasoning pathways and regulatory oversight for safe use. Further research is needed to understand the full potential of LLMs across various medical specialties and conditions.

Introduction

As a large language model (LLM), the GPT developed by OpenAI generates human-like text [1-3], distinguishing it from other specialized deep learning models that are limited to solving specific problems within predetermined domains [4]. In the medical field, GPT has the potential to augment medical education [5], provide clinical decision support [6], and enhance public health initiatives [7]. An impressive achievement of GPT-3.5 is its success in meeting the passing threshold for the United States Medical Licensing Examination [8], demonstrating its ability to offer medical advice comparable to that of trained professionals [9]. The latest iteration, GPT-4 [10,11], is anticipated to exhibit advancements in processing complex medical language, formulating patient care suggestions, and making preliminary diagnostic predictions, which inspires cautious optimism for its future applications in the medical domain [12].

Cardiovascular diseases are a leading cause of death worldwide, highlighting the critical need for precise and reliable information in this domain [13]. During the initial stages of the SARS-CoV-2 pandemic, overstated claims about the cardiovascular implications of the virus potentially escalated public unease and undermined trust in empirical findings [14]. The distribution of speculative or inaccurate information would have had a detrimental effect on the pandemic response strategies. It is paramount to emphasize that inaccuracies or misconceptions in cardiological advice can lead to severe consequences. Hence, there is a pressing need for rigorous validation of all sources of information, whether derived from human experts or advanced computational models such as GPT-4.

Moreover, the generation of “hallucinatory” or erroneous responses by GPT raises concerns about nonmedical expert users unintentionally accepting incorrect information as valid [15,16]. Consequently, proposals for regulatory oversight of LLMs have emerged, including the establishment of a new regulatory category specifically addressing LLM-related challenges and risks [4]. Therefore, it is crucial to develop auditing procedures capable of capturing the intricacies of LLM-associated risks, necessitating a balanced evaluation of the potential benefits and risks inherent in LLMs [17,18]. To

delve deeper into this matter, this study applied real-world health consultations from general users to human experts through an internet portal, using the most recent iteration of this technology, GPT-4. The responses provided by both human experts and GPT-4 were subsequently evaluated by a panel of 3 independent cardiologists to gain a nuanced understanding of the potential benefits and risks associated with GPT-4.

Methods

Data Collection

Figure 1 illustrates the study design. We collected question-and-answer data related to cardiology from the Korean search portal NAVER, focusing on 264 cases. NAVER is Korea’s largest search engine, and its web-based questions and answers forums, called “Jisik-In,” have previously been used in medical research [19,20]. The data set covered the period from July 13, 2020, to July 12, 2021, and included medical inquiries posed by portal users and the corresponding responses provided by human experts. These experts are doctors who have graduated from a college of medicine or medical school, passed the Korean Medical Licensing Examination, and hold legal accreditations as certified specialists in their respective medical fields from the Ministry of Health and Welfare. They are not restricted by character limits when answering users’ questions on the portal site. The questions were categorized into 2 types: binary and open-ended. Further, 6 distinct categories were defined based on the questions’ intent. All collected data were in Korean text form. To ensure the analysis was focused on sufficiently detailed and substantive exchanges, we specifically selected questions that contained more than 100 characters according to the Korean alphabet and answers provided by human experts that comprised at least 200 characters. This approach was aimed at filtering out overly simple queries and ensuring that the responses were elaborate enough for a thorough comparison. Additionally, to maintain a consistent and fair comparison basis between the capabilities of GPT-4 and human experts, we excluded 13 cases from the total data set that contained multimedia content such as videos or images. Finally, 251 cases were selected for the study after applying these criteria.

Figure 1. Study design and evaluation process. A data set consisting of 251 cardiology-specific question-answer pairs was collected from the NAVER portal over a 1-year period, from July 13, 2020, to July 12, 2021. A licensed medical professional is the person who answered the portal user's question. The questions covered 6 domain categories and included both binary and open-ended types. From May 5 to 8, these questions were inputted into GPT-4 to generate the corresponding GPT-4 responses. Following that, a panel of 3 cardiologists reviewed and evaluated the questions along with the answers provided by human experts and GPT-4. The evaluation criteria focused on assessing the complexity and clarity of the questions as well as the accuracy and appropriateness of the responses from both human experts and GPT-4.

GPT Answer Generation

Answers to the collected questions were generated using OpenAI's GPT-4 model, released on March 14, 2023 [10]. From May 5 to 8, 2023, a total of 3 researchers used this model via the OpenAI website to generate GPT-4 answers. The total data set of questions to be entered into the GPT-4 was distributed to the 3 researchers in the form of a spreadsheet. Each original Korean question was directly fed into the GPT-4 prompt without any supplementary input. The researchers saved the generated

answer in a spreadsheet. Each question input was done in a new session by clicking the "New chat" button.

Question and Answer Evaluation

Once the data were randomly shuffled, answers from both GPT-4 and human experts were anonymized and labeled as answer 1 and answer 2, respectively, ensuring the 3 independent cardiologist reviewers were blinded to the source of each response. Each of these reviewers is a board-certified physician in internal medicine and has undergone more than 4 years of

fellow training in cardiology subspecialty. A panel of 3 cardiologists assessed the question set along with the anonymized answers. The evaluation was conducted using a computer interface. Each evaluator assessed the clarity and complexity of the questions as well as the accuracy and appropriateness of the answers. To quantitatively measure these aspects, a 3-tiered grading scale (low, medium, and high) was used (Multimedia Appendix 1). Additionally, each evaluator determined which answer (the GPT-4's answer or the human expert's answer) showed superior accuracy and appropriateness in relation to the question posed.

To further elucidate, the Kendall *W* concordance analysis revealed the following coefficient values indicating the level of agreement among the evaluators: 0.44 for the appropriateness of the human expert answers, 0.40 for the appropriateness of the GPT-4 answers, 0.43 for the medical accuracy of the human expert answers, and 0.40 for the medical accuracy of the GPT answers. Moreover, when making a binary choice determining the superiority of appropriateness between the human expert and GPT-4 answers, the coefficient was 0.42, and for determining the superiority of medical accuracy between the two, it was 0.45. These values, falling in the range of 0.40-0.60, denote a moderate agreement, showcasing a significant level of reliability in our study findings.

Ethical Considerations

This research project was approved by the institutional review board of Korea University Anam Hospital (IRB 2023AN0280). The research was conducted in accordance with the Helsinki Declaration. Informed consent was obtained from all 3 participating cardiologists.

Linguistic Analysis

The Korean Sentence Separator 4.5.1 was used to segment the text into individual sentences. For text tokenization, the Korean medical bidirectional encoder representations from the

transformer model, which was specifically designed for Korean medical text analysis, was used [21]. To evaluate lexical diversity, the type-token ratio (TTR) was computed for each set of responses [22,23]. The TTR, which represents the ratio of unique words to the total number of words in a text, was determined after the responses were tokenized [22,23].

Statistical Analysis

To discern statistically significant differences across categorical outcomes, we used the chi-square test or Fisher exact test as appropriate, depending on the expected frequencies within the categories. For continuous variables, comparison across groups was conducted using either the parametric unpaired 2-tailed *t* test or the nonparametric Mann-Whitney test, based on the distribution of the data. Interrater agreement among the 3 cardiologist evaluators was quantitatively assessed using the Kendall *W* concordance analysis. The association between the complexity and clarity of questions and the quality of responses was investigated using the Spearman rank correlation coefficient. All statistical analyses were conducted using SAS 9.4 (SAS Institute Inc) and R program (version 3.6.1; R Foundation for Statistical Computing).

Results

Both the number of words and sentences per answer were significantly higher for GPT-4 answers than for human expert answers (word count: mean 190, SD 75.2 for GPT-4 vs mean 139, SD 95.6 for humans; $P<.001$ and sentence count: mean 10.9, SD 4.2 for GPT-4 vs mean 5.9, SD 3.7 for humans; $P<.001$; Table 1). The GPT-4 answers exhibited lower lexical diversity, as measured by the TTR, compared to the answers provided by human experts. This suggests that GPT-4 answers may be perceived as more comprehensible and similar to human conversations rather than written text (TTR: mean 0.69, SD 0.07 for GPT-4 vs mean 0.79, SD 0.09 for humans; $P<.001$).

Table 1. Linguistic difference between GPT-4 and human expert answers.

Characteristics	GPT-4, mean (SD)	Human, mean (SD)	<i>P</i> value
Word count per answer	190 (75.2)	139 (95.6)	<.001
Sentence count per answer	10.9 (4.2)	5.9 (3.7)	<.001
Type-token ratio	0.69 (0.07)	0.79 (0.09)	<.001

Figure 2 presents an analysis of the medical accuracy between GPT-4 and human expert answers. When cardiologists were asked to evaluate which answers were more medically accurate, the responses slightly favored the human expert answers (132/251, 52.6% vs 119/251, 47.4%; $P=.41$; Figure 2A). Dividing medical accuracy into low, medium, and high levels, a significant proportion of human expert answers were ranked

as highly accurate compared to GPT-4 (50/237, 21.1% vs 30/238, 12.6%; $P<.001$; Figure 2B). However, the rate of low accuracy was also higher for the human expert answers (11/237, 4.6% vs 1/238, 0.4%; $P=.007$). This counterintuitive observation underscores the potential of LLMs to bridge gaps in human work in real-world scenarios.

Figure 2. Medical accuracy between GPT-4 and human expert answers. (A) Survey results indicating preference for GPT-4 and human expert answers based on perceived medical accuracy. (B) Analysis of perceived medical accuracy, categorized as low, medium, and high for both GPT-4 and human expert answers. (C and D) Relationship between question complexity or clarity and the perceived medical accuracy of GPT-4 and human expert answers. (E) Comparison of variations in perceived medical accuracy between GPT-4 and human expert answers, depending on question type. (F) Comparison of perceived medical accuracy between GPT-4 and human expert answers across different categories of question intent. (G and H) Comparison of word count per answer and type-token ratio between human expert and GPT-4 answers when evaluated for medical accuracy.

In terms of question complexity and ambiguity, GPT-4 demonstrates an advantage. The more complex and ambiguous the question, the higher the medical accuracy of GPT-4's answers. Conversely, human experts excel in dealing with simpler and clearer questions, although without statistically significant differences ($P=.19$; Figure 2C and $P=.30$; Figures 2D, 3C, and 3D). The difference in medical accuracy between human and GPT-4 answers remained below 10% across different question types ($P=.39$; Figure 2E).

Interestingly, when analyzing question categories based on the intent, numerical differences were observed, but without statistical significance ($P=.20$; Figure 2F). Human experts outperformed GPT-4 in responding to questions related to drugs or medications and preliminary diagnoses, scoring higher than GPT-4 (drug or medication: 12/18, 66.7% vs 6/18, 33.3% and preliminary diagnosis: 43/70, 61.4% vs 27/70, 38.6%). Conversely, GPT-4 surpassed human experts in addressing queries regarding the necessity of hospital visits and guidance for clinical departments (hospital visit necessity: 9/22, 40.9%

vs 13/22, 59.1% and clinical department guidance: 15/33, 45.5% vs 18/33, 54.5%).

In the linguistic analysis, when the medical accuracy of a human expert's answer exceeded that of GPT-4, the human expert's answers typically had a higher word count and lower TTR compared to cases where GPT-4's answers were deemed more medically accurate (word count per answer: mean 162, SD 102.6 vs mean 114, SD 80.3; $P < .001$; [Figure 2G](#) and TTR: mean 0.78, SD 0.09 vs mean 0.80, SD 0.09; $P = .02$; [Figure 2H](#)). This implies that the more the response resembles a real conversation—longer and easier—the higher the perceived medical accuracy according to cardiology experts. This observation indicates a potential area for quality control in human expert responses and highlights the consistent performance of GPT-4 in terms of response length and lexical variation.

Next, a comparative analysis between GPT-4 and human expert answers was conducted in terms of answer appropriateness ([Figure 3](#)). When assessing whether GPT-4 or human expert answers were more appropriate for the posed questions, GPT-4 was rated as superior (GPT-4: 135/251, 53.8% vs humans: 116/251, 46.2%; $P = .23$; [Figure 3A](#)). Similar to the medical accuracy analysis, when categorizing appropriateness into low, medium, and high, both GPT-4 and human expert answers showed a comparable distribution across these segments ($P = .26$;

[Figure 3B](#)). Notably, mirroring the findings from the medical accuracy analysis, the frequency of answers deemed to have low appropriateness was numerically higher for human experts (7/240, 2.9% vs 2/241, 0.8%; $P = .03$), suggesting the possibility of human shortcomings. The investigations related to question complexity, clarity, and type displayed numerical trends similar to those observed in the medical accuracy analysis, although no statistical differences were observed ($P = .20$; $P = .60$; and $P = .66$; [Figure 3C-E](#)). The analysis based on question intent showed no significant statistical discrepancies between the proportions of cases where human expert answers were deemed more appropriate and those where GPT-4 answers were considered more appropriate. Interestingly, GPT-4 was rated as more appropriate than human experts in all other categories, except for the question category of preliminary diagnosis ($P = .58$; [Figure 3F](#)). When human expert answers were considered more appropriate than those of GPT-4, the corresponding answers had a higher word count and lower TTR compared to cases where GPT-4 answers were deemed more appropriate (word count per answer: mean 121, SD 79.3 vs mean 160, SD 108.1; $P = .001$; [Figure 3G](#) and TTR: mean 0.80, SD 0.09 vs mean 0.77, SD 0.09; $P = .02$; [Figure 3H](#)). Similar to medical accuracy, these findings suggest that longer responses resembling genuine conversations are evaluated as more appropriate.

Figure 3. Answer appropriateness between GPT-4 and human expert answers. (A) Survey results indicating preference for GPT-4 and human expert responses based on perceived answer appropriateness. (B) Analysis of perceived answer appropriateness, categorized as low, medium, and high for both GPT-4 and human expert answers. (C and D) Relationship between question complexity or clarity and the perceived answer appropriateness of GPT-4 and human expert answers. (E) Comparison of variations in perceived answer appropriateness between GPT-4 and human expert answers depending on question type. (F) Comparison of perceived answer appropriateness between GPT-4 and human expert answers across different categories of question intent. (G and H) Comparison of word count per answer and type-token ratio between human expert and GPT-4 answers when evaluated for appropriateness.

For the 251 questions assessed, all 3 independent cardiologists rated the GPT-4 answers as superior in 18% (45/251) of cases in terms of medical accuracy. In an additional 29% (74/251) of the cases, the majority (2 of 3) of cardiologists endorsed the GPT-4 answers. Conversely, human expert answers were unanimously considered more accurate in 20% (50/251) of cases, with the majority of cardiologists agreeing with human experts in 33% (82/251) of cases (Figure 4). In terms of answer appropriateness, all 3 cardiologists agreed that the GPT-4

answers were superior in 15% (38/251) of cases. The majority of cardiologists found GPT-4 answers to be more appropriate in another 39% (97/251) of cases. Human experts, however, received unanimous approval for the appropriateness of their answers in 18% (70/251) of cases and majority approval in an additional 28% (46/251; Figure 5). These figures highlight the noteworthy performance of GPT-4 from a medical standpoint. Examining illustrative cases, GPT-4 stands out for delivering medical information resembling the content of medical textbooks

and dictionaries. Additionally, GPT-4 demonstrates strength in thoroughly addressing every user's question, leaving no queries unanswered. In contrast, human experts leverage their advantage in providing heuristic information informed by their clinical experience, especially when questions require elements of clinical judgment.

Figure 4. Evaluation result and representative cases comparing medical accuracy between GPT-4 and human expert answers. (A) A case where the GPT-4 answer received superior medical accuracy ratings from all 3 evaluators. (B) A case where a human expert received superior medical accuracy ratings from all 3 evaluators.

Figure 5. Evaluation result and representative cases comparing answer appropriateness between GPT-4 and human expert answers. (A) A case where the GPT-4 answer received superior appropriateness ratings from all 3 evaluators. (B) A case where a human expert answer received superior appropriateness ratings from all 3 evaluators.

Discussion

Principal Findings

This research uniquely implemented real-world health consultations involving general users and human experts, comparing the answers provided by human experts and GPT-4. Three independent cardiologists appraised the answers to discern the potential advantages and disadvantages of using GPT-4 in the medical advice domain. This study demonstrated comparable levels of medical accuracy between GPT-4 and human experts. Notably, human expert answers had a higher proportion of

answers classified as having low medical accuracy compared to those from GPT-4.

Another significant finding suggests the benefits of articulating medical advice in a conversational style, which positively impacts medical accuracy and relevance to queries. This style proved effective in responding to all questionnaire requests, leading to higher answer ratings and demonstrating the potential of GPT-4 in providing medical advice. Notably, GPT-4's answers consistently displayed appropriate length and lexical variation compared to those of human experts. The findings of this study underscore the potential of GPT-4 in medical education, particularly in enhancing the learning experience

through its ability to simulate conversational medical advice with accuracy comparable to human experts. Integrating GPT-4 into educational frameworks could offer an innovative approach to medical education, facilitating adaptive learning and preparing students for the digital evolution in health care. This suggests a promising avenue for future research and application in the field of medical education, highlighting the importance of incorporating advanced AI tools like GPT-4 to complement traditional educational methods.

Comparison to Prior Work

An important consideration is the linguistic scope of our findings. This study was conducted in Korean, which naturally raises questions about its generalizability to other languages. Recent studies and OpenAI's own documentation suggest that GPT-4's performance in non-English languages, including medical contexts, has improved compared to previous versions [11,24,25]. Takagi et al [24] compared the performance of GPT-3.5 and GPT-4 using 254 questions from the Japanese Medical Licensing Examination, revealing that GPT-4 exhibited a 29.1% improvement over GPT-3.5. They highlighted that GPT-4's enhanced non-English language processing capabilities were instrumental in its ability to pass the medical licensing examination. In addition, Wang et al [25] conducted a study comparing the performance of GPT-3.5 and GPT-4 on English and Chinese data sets for the Chinese Medical Licensing Examination, showing a significant improvement in accuracy for Chinese compared to English. This study showed that the medical advice provided by GPT-4 was comparable in medical accuracy to that provided by human experts. Based on previous research and the findings of this study, it has been found that GPT-4 can effectively process specialized medical information in various non-English languages, including Korean. This indicates its potential for use in patient education and the dissemination of medical knowledge.

Strengths and Limitations

Despite its strengths, GPT-4's capability to provide advice based on clinical experience differs notably from that of human

experts. Furthermore, quantitative analysis revealed potential discrepancies between GPT-4 and human expert responses, depending on the intent of the question. Numerous studies are currently underway to identify appropriate regulatory measures for the use of LLMs [4]. The findings of this investigation are anticipated to facilitate subsequent research aimed at identifying tasks in the medical field that GPT-4 excels in. This, in turn, could expedite the development of technology to enhance the quality of medical services and promote public health.

This study has several limitations to consider. First, its focus on cardiology might limit the generalizability of the results to other medical specialties. Second, the sample size for the answer evaluation, which consisted of only 3 cardiologists, could have been larger for a more robust analysis. Furthermore, since the evaluations were conducted solely by cardiologists, there is potential for reporting bias where certain aspects of the answers might be overemphasized or underrepresented. Inclusion of professionals from other domains could have provided a broader assessment. Future studies should aim to involve larger sample sizes and encompass a wider range of medical specialties. Moreover, integrating patients' perspectives could offer further insights into the acceptability and perceived utility of artificial intelligence-powered medical advice.

Conclusions

In conclusion, this study revealed the promising capabilities of GPT-4 in providing medically accurate and appropriate responses comparable to human experts. The additional benefits of GPT-4 include consistent proficiency in maintaining appropriate response length and lexical variation. However, GPT-4 showed some disadvantages in providing advice based on clinical experience as well as variation in its performance depending on question intent. Despite these challenges, this study suggests that LLMs such as GPT-4 hold significant potential in augmenting medical education, providing medical advice.

Abstract

Background: The introduction of ChatGPT by OpenAI has garnered significant attention. Among its capabilities, paraphrasing stands out.

Objective: This study aims to investigate the satisfactory levels of plagiarism in the paraphrased text produced by this chatbot.

Methods: Three texts of varying lengths were presented to ChatGPT. ChatGPT was then instructed to paraphrase the provided texts using five different prompts. In the subsequent stage of the study, the texts were divided into separate paragraphs, and ChatGPT was requested to paraphrase each paragraph individually. Lastly, in the third stage, ChatGPT was asked to paraphrase the texts it had previously generated.

Results: The average plagiarism rate in the texts generated by ChatGPT was 45% (SD 10%). ChatGPT exhibited a substantial reduction in plagiarism for the provided texts (mean difference -0.51 , 95% CI -0.54 to -0.48 ; $P < .001$). Furthermore, when comparing the second attempt with the initial attempt, a significant decrease in the plagiarism rate was observed (mean difference -0.06 , 95% CI -0.08 to -0.03 ; $P < .001$). The number of paragraphs in the texts demonstrated a noteworthy association with the percentage of plagiarism, with texts consisting of a single paragraph exhibiting the lowest plagiarism rate ($P < .001$).

Conclusion: Although ChatGPT demonstrates a notable reduction of plagiarism within texts, the existing levels of plagiarism remain relatively high. This underscores a crucial caution for researchers when incorporating this chatbot into their work.

Introduction

Plagiarism, the act of presenting someone else's work or ideas as one's own, stands as a prevalent and recurrent form of misconduct in the field of research and publication [1]. The diverse manifestations of plagiarism can often create confusion due to the various terminologies associated with it. Verbatim plagiarism, mosaic plagiarism, loose plagiarism, duplicate publication, augmented publication, salami-sliced publication,

image plagiarism, accidental plagiarism, and self-plagiarism are among the prominent types that have been identified [2-6].

To mitigate the occurrence of such misconduct, researchers often use online plagiarism checkers, which scan existing literature on the internet and provide reports on unintentional plagiarism. Additionally, numerous journals have integrated plagiarism checkers as part of their submission process, wherein every manuscript undergoes scrutiny to identify similarity rates [7]. These measures not only act as deterrents but also aid in

upholding the standards of academic integrity and ensuring originality in scholarly publications.

In recent times, artificial intelligence (AI) has gained significant popularity across a wide range of individuals, including researchers and professionals. Among the various applications of AI, chatbots have emerged as a notable development, using AI and natural language processing techniques to generate humanlike responses to user queries [8].

One prominent example of chatbots is ChatGPT, which uses advanced models such as GPT-3.5 and GPT-4. ChatGPT has garnered substantial attention and widespread adoption, amassing over one million users across diverse fields in its first week of launch [9,10]. This surge in popularity reflects the growing recognition and use of AI-powered chatbots in various domains.

ChatGPT offers a multitude of applications and advantages. First, it excels in generating formally structured text, ensuring coherence and organization in its responses. Second, ChatGPT exhibits an extensive and eloquent vocabulary, enhancing the quality and fluency of its generated content. Additionally, it can be used as a rapid search engine, swiftly retrieving relevant information. Furthermore, it possesses the ability to search and analyze available literature, aiding researchers and professionals in their work. In the field of medical education, ChatGPT proves valuable by providing educational resources and facilitating interactive learning experiences. Moreover, it can serve as a conversational agent, engaging in meaningful and interactive conversations with users [10].

Importantly, the text produced by ChatGPT may sometimes bypass conventional plagiarism checks due to its unique

generation process, which is a rising ethical concern [10]. Earlier, many researchers were reporting ChatGPT as co-authors in papers but the majority of journals promptly updated their policies to forbid this practice as ChatGPT cannot be held accountable for the generated content [11]. Moreover, in several instances, ChatGPT hallucinates and produces inaccurate and incorrect information, which can be dangerous in academic publishing [12].

Due to the increasing popularity of ChatGPT in medical research, several studies are needed to identify its pros and cons, especially in the field of medical education. In this study, we aim to assess ChatGPT's real ability to paraphrase and reduce plagiarism by imputing different texts and prompts, and assessing the plagiarism rate of the rephrased texts.

Methods

Selection of Texts

To assess the plagiarism rates and the rephrasing capabilities of ChatGPT (version 3.5), three texts were selected for the study. These texts varied in length to provide a comprehensive evaluation of the model's performance. Text one consisted of 319 words, text two comprised 613 words, and text three encompassed 1148 words. The texts used in this study were selected from one of our previously published medical papers in a medical journal [13].

Instructions Given to ChatGPT

For each selected text, five distinct prompts were given to ChatGPT to rephrase the texts. These instructions were designed to test different aspects of rephrasing and reducing plagiarism. The prompts are shown in Table 1.

Table 1. Prompts provided to ChatGPT.

Number	Prompts
Prompt 1	"Paraphrase the text"
Prompt 2	"Rephrase the text"
Prompt 3	"Reduce the plagiarism of the text"
Prompt 4	"Rephrase it in a way that conveys the same meaning using different words and sentence structure"
Prompt 5	"Reword this text using different language"

Subdivision of Texts

To further evaluate the effectiveness of ChatGPT in rephrasing and reducing plagiarism, the original texts were subdivided into multiple paragraphs. Specifically, texts one, two, and three were provided to ChatGPT in 1 and 3 paragraphs; 1, 3, and 5 paragraphs; and 1, 3, 5, and 7 paragraphs, respectively. All the texts with different paragraph numbers were subjected to the same five rephrasing orders. This approach allowed for a comparison of the paraphrased texts with different paragraph sections within the same content.

Second Try of Paraphrasing

To assess the influence of multiple rephrasing iterations, the texts generated by ChatGPT were once again incorporated into

the system in the same sequence as before. Subsequently, the plagiarism rates of the texts were analyzed using the iThenticate platform, a tool commonly used for such evaluations in academic settings [14]. This process enabled the measurement and comparison of potential similarities between the original texts and their rephrased counterparts, shedding light on the extent of originality achieved through the rephrasing iterations.

Data Analysis

The data analysis for this study was conducted using SPSS version 19 (IBM Corp). The data distribution was assessed using the Shapiro-Wilk test. To compare the plagiarism rates of the texts, paired *t* test analysis was used. This statistical test allowed us to examine whether there were significant differences in plagiarism rates between the original texts and the paraphrased

texts generated by ChatGPT. Additionally, to assess the potential impact of different prompts on plagiarism rates, 1-way ANOVA was used. This analysis aimed to determine if there were statistically significant differences in plagiarism rates across the various prompts given to ChatGPT. A P value $<.05$ was adopted to determine statistical significance. The acceptable level of plagiarism was set at 25%, a standard embraced by scientific journals. Any plagiarism rate surpassing this threshold was considered unsatisfactory [14-18].

Ethical Considerations

This study does not require ethical approval as it does not involve human participants, patient data, or any form of personal data collection.

Results

Overview

A total of 90 texts were provided by ChatGPT. General information on plagiarism rates is provided in Table 2. The mean plagiarism rate of texts was 0.45 (SD 0.10). The mean plagiarism rates for the first try and second try were 0.48 (SD 0.09) and 0.42 (SD 0.09), respectively.

Table 2. Mean plagiarism rates of the texts provided by ChatGPT.

Variable	Text, n	Plagiarism rates checked by iThenticate, mean (SD)
Total	90	0.45 (0.10)
ChatGPT tries		
First try	45	0.48 (0.09)
Second try	45	0.42 (0.09)
Texts on the first try		
Text 1	10	0.48 (0.16)
Text 2	15	0.47 (0.05)
Text 3	20	0.49 (0.07)
Texts on the second try		
Text 1	10	0.46 (0.13)
Text 2	15	0.40 (0.05)
Text 3	20	0.42 (0.10)
Paragraphs		
One paragraph	30	0.40 (0.12)
Three paragraphs	30	0.50 (0.07)
Five paragraphs	20	0.44 (0.05)
Seven paragraphs	10	0.48 (0.04)
Orders given to ChatGPT		
Please paraphrase the text	18	0.45 (0.10)
Please rephrase the text	18	0.48 (0.06)
Please reduce the plagiarism of the text	18	0.44 (0.10)
Please rephrase it in a way that conveys the same meaning using different words and sentence structure	18	0.41 (0.12)
Please reword this text using different language	18	0.48 (0.08)

The Potency of ChatGPT in Reducing Plagiarism

Based on the results of our study, ChatGPT demonstrated an ability to significantly reduce plagiarism in texts right from the first attempt (mean difference -0.51 , 95% CI -0.54 to -0.48 ;

$P<.001$). Moreover, our research revealed that even further improvements were achieved with the second attempt, as it yielded a significantly lower plagiarism rate compared to the initial try (mean difference -0.06 , 95% CI -0.08 to -0.03 ; $P<.001$).

The results also showed a relation between the number of paragraphs within a text and the plagiarism rate. Our findings indicated that texts comprising a single paragraph exhibited the lowest plagiarism rates, and this relationship was statistically significant ($P < .001$). However, when analyzing the five different prompts of the texts, we found no significant difference in terms of their plagiarism rates ($P = .19$).

Furthermore, our study did not identify any statistically significant distinctions among the plagiarism rates of text one,

text two, and text three ($P = .56$), suggesting that ChatGPT's effectiveness remained consistent across these particular texts.

Correlation Between Text Lengths and Plagiarism Rates

We assessed the correlation between the word count of the texts provided by ChatGPT and their plagiarism rates. Although longer texts appeared to have higher plagiarism rates, the correlation was not significant ($r = 0.2$; $P = .06$; [Figure 1](#)).

Figure 1. The correlation between the word count of the texts and their corresponding plagiarism.

Discussion

Principal Findings

The findings of our study shed light on the levels of plagiarism in the paraphrased text generated by ChatGPT, an advanced chatbot developed by OpenAI. The results indicate that while ChatGPT has the capability to paraphrase the text, there are notable concerns regarding the satisfactory levels of plagiarism in the generated output.

The average plagiarism rate observed in the texts generated by ChatGPT was found to be 45%. This suggests that nearly half of the content produced by the chatbot is similar to the original source material, raising concerns about the authenticity and originality of the paraphrased text. These findings highlight the need for caution when relying on ChatGPT for generating plagiarism-free content.

Interestingly, our study revealed that ChatGPT exhibited a substantial reduction in text plagiarism when provided with explicit instructions to paraphrase or reduce plagiarism. This indicates that the chatbot is responsive to such prompts and can generate content with reduced plagiarism when specifically instructed to do so. However, it is important to note that even with explicit instructions, the plagiarism rate remained relatively high, emphasizing the limitations of the current system.

We also observed a significant decrease in the plagiarism rate between the initial and second attempts of paraphrasing. This suggests that ChatGPT has the ability to learn and improve its paraphrasing capabilities over multiple iterations. However, the reduction in plagiarism was modest, indicating that further refinements are necessary to achieve satisfactory levels of originality in the generated output.

An interesting finding from our study was the association between the number of paragraphs in the texts and the percentage of plagiarism. Texts consisting of a single paragraph demonstrated the lowest plagiarism rate. This suggests that presenting the source texts within a single coherent unit allows ChatGPT to better understand and paraphrase the content effectively. Dividing the text into separate paragraphs may lead to fragmented understanding and potentially contribute to higher levels of plagiarism.

It is worth noting that the prompts used in our study did not yield significant differences in the levels of plagiarism. This indicates that the specific prompt provided to ChatGPT does not significantly influence its paraphrasing capability. In addition, this outcome might be the consequence of the bot's strong ability to understand our true intentions when issuing commands, or it might be because our command words were brief or similar to one another. However, further investigation into the effect of different prompts and their impact on plagiarism is warranted to explore this aspect in more detail.

ChatGPT has a wide range of applications that can be effectively used. Numerous articles have discussed the use of ChatGPT in composing scientific literature, with a particular study illustrating its capability to generate formal research articles. The researchers observed that the language used is articulate,

adopts a conventional tone, and offers a pleasant reading experience [19].

ChatGPT has the potential to serve as a search engine that directly responds to queries, eliminating the need to navigate to external sites for information. This streamlines the process of writing research papers, reducing the time spent by authors on the often arduous task of searching for articles and applying various selection criteria. This, in turn, allows authors to dedicate more time to their actual research work and methodology [20].

Moreover, articles created by ChatGPT seem to elude traditional plagiarism detection methods. In a research study, the chatbot was tasked with generating 50 medical research abstracts using a subset of articles. The resulting articles underwent examination by plagiarism detection software, an AI-output detector, and a panel of medical researchers who were tasked with identifying any artificially generated abstracts. The findings revealed that abstracts generated by ChatGPT seamlessly passed through the plagiarism detection software, registering a median originality score of 100%, indicating the absence of detected plagiarism. In contrast, the AI-output checker only identified 66% of the generated abstracts [21].

While ChatGPT and other AI tools hold promise in various applications, their deployment in medical writing raises ethical and legal considerations. These concerns encompass potential violations of copyright laws, medico-legal complexities, and the risk of inaccuracies or biases in the generated content. It is crucial to recognize and confront the limitations and challenges linked to the use of AI in medical writing [20,22,23].

Limitations and Future Suggestions

The sample size used in our study was relatively small, and as a result, we recommend that future investigations incorporate larger sample sizes to enhance the robustness of the findings. It is worth noting that our study was conducted using ChatGPT version 3.5, which was a publicly available version at the time of our research. Unfortunately, we did not have access to ChatGPT version 4, preventing us from evaluating the efficacy of this updated version in terms of paraphrasing capabilities.

It is essential to acknowledge that our study exclusively focused on providing medical content to ChatGPT. We encourage other researchers to explore the impact of using different content types on the efficacy of ChatGPT. This would allow for a comprehensive understanding of whether the effectiveness of ChatGPT is influenced by the specific domain or topic of the content it receives. Conducting such investigations will provide valuable insights into the generalizability and adaptability of ChatGPT across various subject matters.

Moreover, a recognized limitation of ChatGPT is its tendency to produce inconsistent results with the same prompts [24]. To relatively address this challenge, we used a comprehensive approach. Each prompt was provided with nine texts, varying paragraph structures (text one with 1 paragraph, text one with 3 paragraphs, text two with 1 paragraph, text two with 3 paragraphs, text two with 5 paragraphs, text three with 1 paragraph, text three with 3 paragraphs, text three with 5 paragraphs, and text three with 7 paragraphs). Furthermore, we

requested ChatGPT to paraphrase each of these texts twice using the same prompt. We then calculated the mean plagiarism rates for both the first and second attempts, along with the overall mean plagiarism rate for each prompt (Table 2).

Nevertheless, we recommend that future studies take this limitation into account and explore additional measures to enhance the robustness of assessments. Specifically, researchers may consider providing ChatGPT with a greater number of texts exhibiting different paragraph structures and incorporating a higher frequency of repetitions in the paraphrasing process.

We used similar prompts and provided them to ChatGPT. We recommend that future studies adopt a broader range of prompts to assess ChatGPT's performance across different input variations. This approach allows for a more comprehensive evaluation and facilitates the identification of optimal prompts to minimize plagiarism rates.

An important consideration with ChatGPT lies in the potential for hallucination and biases, particularly in the generation of medical content [25]. In our study, two independent researchers evaluated the content provided by ChatGPT, comparing it with the original texts. However, we acknowledge that the texts used

in our assessment may not have been sufficiently complex. To address this limitation, we recommend that future studies incorporate both simple and more intricate texts to thoroughly evaluate the biases that ChatGPT may introduce during the paraphrasing of medical content. This approach will provide a more nuanced understanding of the model's performance.

Conclusion

While ChatGPT has been shown to significantly reduce plagiarism in texts, it is important to note that the resulting plagiarism rates of the provided texts may still be considered high, which may not meet the acceptance criteria of most scientific journals. Therefore, medical writers and professionals should carefully consider this issue when using ChatGPT for paraphrasing their texts. There are a couple of strategies authors can use to improve the paraphrasing efficacy of ChatGPT. Presenting the texts in a single-paragraph format and repeating the requesting procedure with ChatGPT. By considering these strategies and being mindful of the potential limitations, authors can strive to improve the paraphrasing efficacy of ChatGPT and address the challenge of high plagiarism rates associated with its outputs.

Abstract

Background: The persistence of diagnostic errors, despite advances in medical knowledge and diagnostics, highlights the importance of understanding atypical disease presentations and their contribution to mortality and morbidity. Artificial intelligence (AI), particularly generative pre-trained transformers like GPT-4, holds promise for improving diagnostic accuracy, but requires further exploration in handling atypical presentations.

Objective: This study aimed to assess the diagnostic accuracy of ChatGPT in generating differential diagnoses for atypical presentations of common diseases, with a focus on the model's reliance on patient history during the diagnostic process.

Methods: We used 25 clinical vignettes from the *Journal of Generalist Medicine* characterizing atypical manifestations of common diseases. Two general medicine physicians categorized the cases based on atypicality. ChatGPT was then used to generate differential diagnoses based on the clinical information provided. The concordance between AI-generated and final diagnoses was measured, with a focus on the top-ranked disease (top 1) and the top 5 differential diagnoses (top 5).

Results: ChatGPT's diagnostic accuracy decreased with an increase in atypical presentation. For category 1 (C1) cases, the concordance rates were 17% (n=1) for the top 1 and 67% (n=4) for the top 5. Categories 3 (C3) and 4 (C4) showed a 0% concordance for top 1 and markedly lower rates for the top 5, indicating difficulties in handling highly atypical cases. The χ^2 test revealed no significant difference in the top 1 differential diagnosis accuracy between less atypical (C1+C2) and more atypical (C3+C4) groups ($\chi^2_1=2.07$; n=25; $P=.13$). However, a significant difference was found in the top 5 analyses, with less atypical cases showing higher accuracy ($\chi^2_1=4.01$; n=25; $P=.048$).

Conclusions: ChatGPT-4 demonstrates potential as an auxiliary tool for diagnosing typical and mildly atypical presentations of common diseases. However, its performance declines with greater atypicality. The study findings underscore the need for AI systems to encompass a broader range of linguistic capabilities, cultural understanding, and diverse clinical scenarios to improve diagnostic utility in real-world settings.

KEYWORDS

atypical presentation; ChatGPT; common disease; diagnostic accuracy; diagnosis; patient safety

Introduction

For the past decade, medical knowledge and diagnostic techniques have expanded worldwide, becoming more accessible with remarkable advancements in clinical testing and useful reference systems [1]. Despite these advancements, misdiagnosis significantly contributes to mortality, making it a noteworthy public health issue [2,3]. Studies have revealed discrepancies between clinical and postmortem autopsy diagnoses in at least 25% of cases, with diagnostic errors contributing to approximately 10% of deaths and to 6% - 17% of hospital adverse events [4-8]. The significance of atypical presentations as a contributor to diagnostic errors is especially notable, with recent findings suggesting that such presentations are prevalent in a substantial portion of outpatient consultations and are associated with a higher risk of diagnostic inaccuracies [9]. This underscores the persistent challenge in diagnosing patients correctly due to the variability in disease presentation and due to the reliance on medical history, which is the basis for approximately 80% of the medical diagnosis [10,11].

The advent of artificial intelligence (AI) in health care, particularly through natural language processing (NLP) models such as generative pre-trained transformers (GPTs), has opened new avenues in medical diagnosis [12]. Recent studies on AI medical diagnosis across various specialties—including neurology [13], dermatology [14], radiology [15], and pediatrics [16]—have shown promising results and improved diagnostic accuracy, efficiency, and safety. Among these developments, GPT-4, a state-of-the-art AI model developed by OpenAI, has demonstrated remarkable capabilities in understanding and processing medical language, significantly outperforming its predecessors in medical knowledge assessments and potentially transforming medical education and clinical decision support systems [12,17].

Notably, one study found that ChatGPT (OpenAI) could pass the United States Medical Licensing Examination (USMLE), highlighting its potential in medical education and medical diagnosis [18,19]. Moreover, in controlled settings, ChatGPT has shown over 90% accuracy in diagnosing common diseases with typical presentations based on chief concerns and patient history [20]. However, while research has examined the diagnostic accuracy of AI chatbots, including ChatGPT, in generating differential diagnoses for complex clinical vignettes derived from general internal medicine (GIM) department case reports, their diagnostic accuracy in handling atypical presentations of common diseases remains less explored [21,22]. There has been a notable study aimed at evaluating the accuracy of the differential diagnosis lists generated by both third- and fourth-generation ChatGPT models using case vignettes from case reports published by the Department of General Internal Medicine of Dokkyo Medical University Hospital, Japan. ChatGPT with GPT-4 was found to achieve a correct diagnosis rate in the top 10 differential diagnosis lists, top 5 lists, and top diagnoses of 83%, 81%, and 60%, respectively—rates comparable to those of physicians. Although the study highlights the potential of ChatGPT as a supplementary tool for physicians, particularly in the context of GIM, it also underlines the importance of further investigation into the diagnostic accuracy of ChatGPT with atypical disease presentations (Figure 1). Given the crucial role of patient history in diagnosis and the inherent variability in disease presentation, our study expands upon this foundation to assess the accuracy of ChatGPT in diagnosing common diseases with atypical presentations [23].

More specifically, this study aims to evaluate the hypothesis that the diagnostic accuracy of AI, exemplified by ChatGPT, declines when dealing with atypical presentations of common diseases. We hypothesize that despite the known capabilities of AI in recognizing typical disease patterns, its performance will be significantly challenged when presented with clinical

cases that deviate from these patterns, leading to reduced diagnostic precision. Consequently, this study seeks to systematically assess this hypothesis and explore its implications for the integration of AI in clinical practice. By exploring the contribution of AI-assisted medical diagnoses to common diseases with atypical presentations and patient history, the

study assesses the accuracy of ChatGPT in reaching a clinical diagnosis based on the medical information provided. By reevaluating the significance of medical information, our study contributes to the ongoing discourse on optimizing diagnostic processes—both conventional and AI assisted.

Figure 1. Study motivation. AI: artificial intelligence; USMLE: United States Medical Licensing Examination.

Methods

Study Design, Settings, and Participants

This study used a series of 25 clinical vignettes from a special issue of the *Journal of Generalist Medicine*, a Japanese journal, published on March 5, 2024. These vignettes, which exemplify atypical presentations of common diseases, were selected for

their alignment with our research aim to explore the impact of atypical disease presentations in AI-assisted diagnosis. The clinical vignettes were derived from real patient cases and curated by an editorial team specializing in GIM, with final edits by KS. Each case included comprehensive details such as age, gender, chief concern, medical history, medication history, current illness, and physical examination findings, along with the ultimate and initial misdiagnoses.

An expert panel comprising 2 general medicine and medical education physicians, T Shimizu and Y Otsuka, initially reviewed these cases. After deliberation, they selected all 25 cases that exemplified atypical presentations of common diseases. Subsequently, T Shimizu and Y Otsuka evaluated their degree of atypicality and categorized them into 4 distinct levels, using the following definition as a guide: “Atypical presentations have a shortage of prototypical features. These can be defined as features that are most frequently encountered in patients with the disease, features encountered in advanced presentations of the disease, or simply features of the disease commonly listed in medical textbooks. Atypical presentations may also have features with unexpected values” [24]. Category 1 was assigned to cases that were closest to the typical presentations of common diseases, whereas category 4 was designated for those that were markedly atypical. In instances where T Shimizu and Y Otsuka did not reach consensus, a third expert, KS, was consulted. Through collaborative discussions, the panel reached a consensus on the final category for each case, ensuring a

systematic and comprehensive evaluation of the atypical presentations of common diseases (Figure 2).

Our analysis was conducted on March 12, 2024, using ChatGPT’s proficiency in Japanese. The language processing was enabled by the standard capabilities of the ChatGPT model, requiring no additional adaptation or programming by our team. We exclusively used text-based input for the generative AI, excluding tables or images to maintain a focus on linguistic data. This approach is consistent with the typical constraints of language-based AI diagnostic tools. Inputs to ChatGPT consisted of direct transcriptions of the original case reports in Japanese, ensuring the authenticity of the medical information was preserved. We measured the concordance between AI-generated differential diagnoses and the vignettes’ final diagnoses, as well as the initial misdiagnoses. Our investigation entailed inputting clinical information—including medical history, physical examination, and laboratory data—into ChatGPT, followed by posing this request: “List of differential diagnoses in order of likelihood, based on the provided vignettes’ information,” labeled as “GAI [generative AI] differential diagnoses.”

Figure 2. Categories of common diseases with atypical presentations (n=25).

Data Collection and Measurements

We assigned the correct diagnosis for each of these 25 cases as “final diagnosis.” We then used ChatGPT to generate differential diagnoses (“GAI differential diagnoses”). For each case, ChatGPT was prompted to create a list of differential diagnoses. Patient information was provided in full each time, without incremental inputs. The concordance rate between “final

diagnosis,” “misdiagnosis,” and “GAI differential diagnoses” was then assessed. To extract a list of diagnoses from ChatGPT, we concluded each input session with the phrase “List of differential diagnoses in order of likelihood, based on the provided vignettes’ information.” We measured the percentage at which the final diagnosis or misdiagnosis was included in the top-ranked disease (top 1) and within the top 5 differential diagnoses (top 5) generated by ChatGPT (Figure 3).

Figure 3. Study flow. C: category.

Data Analysis

Two board-certified physicians working in the medical diagnostic department of our facility judged the concordance between the AI-proposed diagnoses and the final diagnosis. The 2 physicians are GIM board-certified. The number of years after graduation of the physicians was 7 and 17, respectively. A diagnosis was considered to match if the 2 physicians agreed to the concordance. We measured the interrater reliability with the κ coefficient (0.8 - 1.0=almost perfect; 0.6 - 0.8=substantial; 0.4 - 0.6=moderate; and 0.2 - 0.4=fair) [25]. To further analyze the accuracy of the top 1 and top 5 diagnoses, we used the χ^2 or Fisher exact test, as appropriate. Statistical analyses were

conducted using SPSS Statistics (version 26.0; IBM Corp) with the level of significance set at $P<.05$.

Ethics Approval

Our research did not involve humans, medical records, patient information, observations of public behaviors, or secondary data analyses; thus, it was exempt from ethical approval, informed consent requirements, and institutional review board approval. Additionally, as no identifying information was included, the data did not need to be anonymized or deidentified. We did not offer any compensation because there were no human participants in the study.

Results

The 25 clinical vignettes comprised 11 male and 14 female patients, with ages ranging from 21 to 92 years. All individuals were older than 20 years, and 8 were older than 65 years. [Table 1](#), [Multimedia Appendix 1](#), and [Multimedia Appendix 2](#) present these results. The correct final diagnosis listed in the *Journal of Generalist Medicine* clinical vignette as a common disease presenting atypical symptoms (labeled as “final diagnosis”) showed that “GAI differential diagnoses” and “final diagnosis” coincided in 12% (3/12) of cases within the first list of differential diagnoses, while “GAI differential diagnoses” and “final diagnosis” had a concordance rate of 44% (11/25) in 5 differential diagnoses. The interrater reliability was substantial (Cohen $\kappa=0.84$).

The analysis of the concordance rates between the “GAI differential diagnoses” generated by ChatGPT and the “final diagnosis” from the *Journal of Generalist Medicine* revealed distinct patterns across the 4 categories of atypical presentations ([Table 2](#)). For the top 1 differential diagnosis, that is, category 1 (C1) cases, which were closest to a typical presentation, the concordance rate was 7% (n=1), whereas category 2 (C2) cases exhibited a slightly higher rate of 22% (n=2). Remarkably, categories 3 (C3) and 4 (C4), which represent more atypical

cases, demonstrated no concordance (0%) in the top 1 differential diagnosis.

When the analysis was expanded to the top 5 differential diagnoses, the concordance rates varied across categories. C1 cases showed a significant increase in concordance, to 67% (n=4), indicating better performance of the “GAI differential diagnoses” when considering a broader range of possibilities. C2 cases had a concordance rate of 44% (n=4), followed by C3 cases at 25% (n=1) and C4 cases at 17% (n=1).

To assess the diagnostic accuracy of ChatGPT across varying levels of atypical presentations, we used the χ^2 test. Specifically, we compared the frequency of correct diagnoses in the top 1 and top 5 differential diagnoses provided by ChatGPT for cases categorized as C1+C2 (less atypical) versus C3+C4 (more atypical). For the top 1 differential diagnosis, there was no statistically significant difference in the number of correct diagnoses between the less atypical (C1+C2) and more atypical (C3+C4) groups ($\chi^2_1=2.07$; n=25; $P=.13$). However, when expanding the analysis to the top 5 differential diagnoses, we found a statistically significant difference, with the less atypical group (C1+C2) demonstrating a higher number of correct diagnoses compared to the more atypical group (C3+C4) ($\chi^2_1=4.01$; n=25; $P=.048$).

Table . List of answers and diagnoses provided by ChatGPT. Category 1 was closest to typical, and category 4 was most atypical.

Case	Age (years)	Gender	Final diagnosis ^a	Category	GAI ^b diagnosis rank ^c

C4	0	0	0	1	0	5	0	17

Discussion

Principal Findings

This study provides insightful data on the performance of ChatGPT in diagnosing common diseases with atypical presentations. Our findings offer a nuanced view of the capacity of AI-driven differential diagnoses across varying levels of atypicality. In the analysis of the concordance rates between “GAI differential diagnoses” and “final diagnosis,” we observed a decrease in diagnostic accuracy as the degree of atypical presentation increased.

The performance of ChatGPT in C1 cases, which are the closest to typical presentations, was moderately successful, with a concordance rate of 17% for the top 1 diagnosis and 67% within the top 5. This suggests that when the disease presentation closely aligns with the typical characteristics known to the model, ChatGPT is relatively reliable at identifying a differential diagnosis list that coincides with the final diagnosis. However, the utility of ChatGPT appears to decrease as atypicality increases, as evidenced by the lower concordance rates in C2, and notably more so in C3 and C4, where the concordance rates for the top 1 diagnosis fell to 0%. Similar challenges were observed in another 2024 study [26], where the diagnostic accuracy of ChatGPT varied depending on the disease etiology, particularly in differentiating between central nervous system and non-central nervous system tumors.

It is particularly revealing that in the more atypical presentations of common diseases (C3 and C4), the AI struggled to provide a correct diagnosis, even within the top 5 differential diagnoses, with concordance rates of 25% and 17%, respectively. These categories highlight the current limitations of AI in medical diagnosis when faced with cases that deviate significantly from the established patterns within its training data [27].

By leveraging the comprehensive understanding and diagnostic capabilities of ChatGPT, this study aims to reevaluate the significance of patient history in AI-assisted medical diagnosis and contribute to optimizing diagnostic processes [28]. Our exploration of ChatGPT’s performance in processing atypical disease presentations not only advances our understanding of AI’s potential in medical diagnosis [23] but also underscores the importance of integrating advanced AI technologies with traditional diagnostic methodologies to enhance patient care and reduce diagnostic errors.

The contrast in performance between the C1 and C4 cases can be seen as indicative of the challenges AI systems currently face with complex clinical reasoning requiring pattern recognition. Atypical presentations can include uncommon symptoms, rare complications, or unexpected demographic characteristics, which may not be well represented in the data sets used to train the AI systems [29]. Furthermore, these findings can inform the development of future versions of AI medical diagnosis systems and guide training curricula to include a broader spectrum of atypical presentations.

This study underscores the importance of the continued refinement of AI medical diagnosis systems, as highlighted by the recent advances in AI technologies and their applications

in medicine. Studies published in 2024 [30-32] provide evidence of the rapidly increasing capabilities of large language models (LLMs) like GPT-4 in various medical domains, including oncology, where AI is expected to significantly impact precision medicine [30]. The convergence of text and image processing, as seen in multimodal AI models, suggests a qualitative leap in AI’s ability to process complex medical information, which is particularly relevant for our findings on AI-assisted medical diagnostics [30]. These developments reinforce the potential of AI tools like ChatGPT in bridging the knowledge gap between machine learning developers and practitioners, as well as their role in simplifying complex data analyses in medical research and practice [31]. However, as these systems evolve, it is crucial to remain aware of their limitations and the need for rigorous verification processes to mitigate the risk of errors, which can have significant implications in clinical settings [32]. This aligns with our observation of decreased diagnostic accuracy in atypical presentations and the necessity for cautious integration of AI into clinical practice. It also points to the potential benefits of combining AI with human expertise to compensate for current AI limitations and enhance diagnostic accuracy [33].

Our research suggests that while AI, particularly ChatGPT, shows promise as a supplementary tool for medical diagnosis, reliance on this technology should be balanced with expert clinical judgment, especially in complex and atypical cases [28,29]. The observed concordance rate of 67% for C1 cases indicates that even when not dealing with extremely atypical presentations, cases with potential pitfalls may result in AI medical diagnosis accuracy lower than the 80% - 90% estimated by existing studies [10,11]. This revelation highlights the need for cautious integration of AI in clinical settings, acknowledging that its diagnostic capabilities, while robust, may still fall short in certain scenarios [34,35].

Limitations

Despite the strengths of our research, the study has certain limitations that must be noted when contextualizing our findings. First, the external validity of the results may be limited, as our data set comprises only 25 clinical vignettes sourced from a special issue of the *Journal of Generalist Medicine*. While these vignettes were chosen for their relevance to the study’s hypothesis on atypical presentations of common diseases, the size of the data set and its origin as mock scenarios rather than real patient data may limit the generalizability of our findings. This sample size may not adequately capture the variability and complexities typically encountered in broader clinical practice and thus might not be sufficient to firmly establish statistical generalizations. This limitation is compounded by the exclusion of pediatric vignettes, which narrows the demographic range of our findings and potentially reduces their applicability across diverse age groups.

Second, ChatGPT’s current linguistic capabilities predominantly cater to English, presenting significant barriers to patient-provider interactions that may occur in other languages. This raises concerns about the potential for miscommunication and subsequent misdiagnosis in non-English medical consultations. This underscores the essential need for future AI models to exhibit a multilingual capacity that can grasp the

subtleties inherent in various languages and dialects, as well as the cultural contexts within which they are used.

Finally, the diagnostic prioritization process of ChatGPT did not always align with clinical probabilities, potentially skewing the perceived effectiveness of the AI model. Additionally, it must be acknowledged that our research used ChatGPT based on GPT-4, which is not a publicly available model. Consequently, the result may not be directly generalizable to other LLMs, especially open-source models like Llama3 (Meta Platforms, Inc), which might have different underlying architectures and training data sets. Moreover, since our study relied on clinical vignettes that were mock scenarios, the potential for bias based on the cases is significant. The lack of real demographic diversity in these vignettes means that the findings may not accurately reflect social or regional nuances, such as ethnicity, prevalence of disease, or cultural practices, that could influence diagnostic outcomes. This limitation suggests a need for careful consideration when applying these AI tools across different geographic and demographic contexts to ensure the findings are appropriately adapted to local populations. This emphasizes the necessity for AI systems to

be evaluated in diverse real-world settings to understand their effectiveness comprehensively and mitigate any bias. This distinction is important to consider when extrapolating our study's findings to other AI systems. Future studies should not only refine AI's diagnostic reasoning, but also explore the interpretability of its decision-making process, especially when errors occur. ChatGPT should be considered as a supplementary tool in medical diagnosis, rather than a standalone solution. This reinforces the necessity for combined expertise, where AI supports—but does not replace—human clinical judgment. Further research should expand these findings to a wider range of conditions, especially prevalent diseases with significant public health impacts, to thoroughly assess the practical utility and limitations of AI in medical diagnosis.

Conclusions

Our study contributes valuable evidence for the ongoing discourse on the role of AI in medical diagnosis. This study provides a foundation for future research to explore the extent to which AI can be trained to recognize increasingly complex and atypical presentations, which is critical for its successful integration into clinical practice.

Acknowledgments

The authors thank the members of Igaku-Shoin, Tokyo, Japan, for permission to use the clinical vignettes. Igaku-Shoin did not participate in designing and conducting the study; data analysis and interpretation; preparation, review, or approval of the paper; or the decision to submit the paper for publication. The authors thank Dr Mai Hongo, Saka General Hospital, for providing a clinical vignette. The authors also thank Editage for the English language review.

Data Availability

The data sets generated and analyzed in this study are available from the corresponding author upon reasonable request.

Disclaimer

In this study, generative artificial intelligence was used to create differential diagnoses for cases published in medical journals. However, it was not used in actual clinical practice. Similarly, no generative artificial intelligence was used in our manuscript writing.

Authors' Contributions

KS, T Watari, T Shimizu, Y Otsuka, M Tago, H Takahashi, YS, and YT designed the study. T Shimizu and Y Otsuka checked the atypical case categories. M Tago and H Takahashi confirmed the diagnoses. KS wrote the first draft and analyzed the research data. All authors created atypical common clinical vignettes and published them in the *Journal of General Medicine*. KS, T Shimizu, and H Takahashi critically revised the manuscript. All authors checked the final version of the manuscript.

Abstract

Background: Medical history contributes approximately 80% to a diagnosis, although physical examinations and laboratory investigations increase a physician's confidence in the medical diagnosis. The concept of artificial intelligence (AI) was first proposed more than 70 years ago. Recently, its role in various fields of medicine has grown remarkably. However, no studies have evaluated the importance of patient history in AI-assisted medical diagnosis.

Objective: This study explored the contribution of patient history to AI-assisted medical diagnoses and assessed the accuracy of ChatGPT in reaching a clinical diagnosis based on the medical history provided.

Methods: Using clinical vignettes of 30 cases identified in *The BMJ*, we evaluated the accuracy of diagnoses generated by ChatGPT. We compared the diagnoses made by ChatGPT based solely on medical history with the correct diagnoses. We also compared the diagnoses made by ChatGPT after incorporating additional physical examination findings and laboratory data alongside history with the correct diagnoses.

Results: ChatGPT accurately diagnosed 76.6% (23/30) of the cases with only the medical history, consistent with previous research targeting physicians. We also found that this rate was 93.3% (28/30) when additional information was included.

Conclusions: Although adding additional information improves diagnostic accuracy, patient history remains a significant factor in AI-assisted medical diagnosis. Thus, when using AI in medical diagnosis, it is crucial to include pertinent and correct patient histories for an accurate diagnosis. Our findings emphasize the continued significance of patient history in clinical diagnoses in this age and highlight the need for its integration into AI-assisted medical diagnosis systems.

Introduction

Over the past decade, medical knowledge and diagnostic techniques have expanded globally and have become more accessible with remarkable advancements in clinical testing and useful reference systems. Despite these advancements, misdiagnosis significantly contributes to mortality, making it a significant public health issue [1,2]. Studies have shown discrepancies between clinical and postmortem autopsy diagnoses in at least 25% of patients [3-7]. One study suggests that approximately 40,500 adult patients in intensive care units in the United States die of misdiagnoses annually, and the predicted prevalence of potentially lethal misdiagnoses is 6.3% [8]. Another report suggests that diagnostic errors contribute to

approximately 10% of deaths and 6% to 17% of hospital adverse events, and are the leading cause of medical malpractice claims [7]. Considering the operative characteristics of clinical investigations combined with the inherent variability in disease presentation, it is often challenging to diagnose patients correctly—an issue that has concerned physicians perennially. Decades ago, a pivotal study proposed that patient history contributes to approximately 80% of the diagnostic process [9,10]. Medical history remains crucial for diagnosis [11,12] and is vital in contemporary physicians' clinical diagnoses.

With the advent of artificial intelligence (AI) in recent years, numerous studies have focused on AI-assisted diagnoses, including cancer screening and treatment [13-15], diagnostic ultrasound imaging [16-19], x-ray imaging [20], computed

tomography [21], magnetic resonance imaging [22], and endoscopy [15,23]. Other reports on AI-assisted imaging diagnoses include AI's applications in radiology, pathology, and dermatological imaging [13,24]. There have also been reports on the use of AI in diagnosing specific conditions [25-27]. However, while several studies have reported that AI is useful in screening, diagnosing, and even treating certain medical conditions, to the best of our knowledge, no study has examined the importance of patient history in AI-assisted medical diagnosis. In addition, the extent to which AI considers patient history in its diagnostic processes remains to be fully understood.

This study aimed to investigate the importance of patient history in an AI-assisted medical diagnostic process aided by ChatGPT (version 4.0; June 2, 2023), one of the most well-known large language models that was released on March 14, 2023, to better understand the future of diagnostic medicine where AI is predicted to play an increasingly prominent role. Our study explored the contribution of patient history to AI-assisted medical diagnoses and assessed the accuracy of ChatGPT in reaching a clinical diagnosis based on the medical history that was provided. By reevaluating the significance of patient history, our study contributes to the ongoing discourse on optimizing diagnostic processes, both conventional and AI-assisted.

Methods

Study Design, Settings, and Participants

In our study, we used some of the 45 standardized clinical vignettes in *The BMJ* (Multimedia Appendix 1) to evaluate the diagnostic and triage accuracy of web-based symptom checkers [28]. These vignettes were published on June 5, 2015. They offer a balanced set of cases, with 15 cases requiring immediate attention, 15 cases requiring consultation but not immediately, and 15 cases not requiring immediate attention or consultation. They were identified from various clinical sources, including materials used to educate health professionals as well as a medical resource website, with content provided by a panel of physicians. Researchers have used these clinical vignettes to evaluate the usefulness of web-based symptom checkers and self-triage [28-31]. We chose these vignettes because of their varied severity levels, their origins from multiple resources rather than just 1 resource, and their credibility, having been used in prior studies. They also include some of the most commonly observed conditions in outpatient settings. Of the 45 cases, we selected those that included physical examination findings, test data, and medical history and provided a single distinct diagnosis. As illustrated in Figure 1, we excluded patients with no distinct diagnoses within the vignettes to serve as a reference (3 cases) and those who did not undergo any physical examination or laboratory tests (12 cases). Finally, the remaining 30 cases were used in this study.

Figure 1. Inclusion and exclusion criteria.

Data Collection and Measurements

We assigned the correct diagnosis for each of these 30 cases to “Answer.” We then used the AI model, ChatGPT, to generate 2 diagnoses: the first, labeled “History,” was obtained by inputting only the medical history into ChatGPT; the second set, labeled “All,” was produced by inputting the medical history and all the other additional information in the clinical vignettes. Each time ChatGPT was prompted to generate a diagnosis, a separate chat window was used ([Multimedia Appendix 2](#)). Thus, we used 2 chat windows for each case—one for the “History” diagnosis and the other for the “All” diagnosis. Additionally, the patients’ information was not inputted incrementally.

The concordance rate was assessed among “Answer,” “History,” and “All.” To extract a diagnosis from ChatGPT, we ended each input session with the phrase “What is the most likely diagnosis?” For both the “History” and “All,” the session was deemed complete when the AI returned the single most likely diagnosis. If ChatGPT suggested multiple diagnoses or indicated that it did not provide the most likely diagnosis, we repeated the process under the same conditions for a maximum of 5 attempts. Cases for which a single diagnosis could not be obtained even after 5 attempts were excluded without making further attempts.

Ethical Considerations

Our research does not involve humans, medical records, patient information, observations of public behaviors, or secondary data analyses; hence, it is exempt from ethical approval, the requirement of informed consent, and institutional review board approval. Additionally, as no identifying information was included, the data did not need to be anonymized or deidentified, and the need for compensation did not arise because no human participants were included in the study.

Data Analysis

Three board-certified physicians working in a medical diagnostic department at our facility assessed the concordance among the 3 AI-proposed diagnoses (“Answer,” “History,” and “All”). Of the 3 physicians, 1 is general medicine board-certified, 1 is internal medicine board-certified, and 1 is internal medicine-, general internal medicine-, and family medicine board-certified; their postgraduate education spanned 7, 9, and 11 years, respectively. A diagnosis was considered to match if at least 2 of the 3 physicians agreed upon the correspondence. Distinguishing between acute pharyngitis and acute upper respiratory tract infection necessitated determining whether to consider diseases resulting from similar pathologies as correct

diagnoses. In contrast, for diseases that are essentially the same but have different nomenclatures, such as oral ulcers and canker sores, we considered them correct diagnoses.

Results

Among the 30 cases, 19 patients were male and 11 were female, with ages ranging from 18 months to 65 years. In total, 12 individuals were younger than 20 years.

The results are shown in [Table 1](#). Cases 1-15 of the original vignette represent those requiring emergent care, cases 16-30 represent those requiring nonemergent care, and cases 31-45 represent those that are appropriate for self-care. A comparison with the correct diagnosis listed in *The BMJ* vignettes (labeled as “Answer”) showed that “Answer” and “History” coincided 76.6% of the time, while “Answer” and “All” had a concordance rate of 93.3%. Five (16.7%) patients could not be diagnosed on the basis of medical history alone but were diagnosed when additional information was provided. In 1 (3.3%) case, the diagnosis was different and incorrect under both conditions (“History” and “All”). In 1 (3.3%) case, the incorrect diagnosis was the same under both conditions (“History” and “All”).

Table . List of answers and diagnoses made by ChatGPT^a.

Case number of the original vignette	Original diagnosis (Answer)	Output from history only (History) ^b	Output from all information (All) ^c

Case number of the original vignette	Original diagnosis (Answer)	Output from history only (History) ^b	Output from all information (All) ^c
44	Viral upper respiratory tract infection	Common viral illness, such as the common cold or influenza ^d	Viral upper respiratory tract infection ^d

^aWe repeated outputs until a single plausible diagnosis was made, with a maximum of 5 attempts.

^bMatching answers between Answer and History: 23/30 (76.6%); median trial count 1 (Q1 1, Q2 1, Q3 1).

^cMatching answers between History and All: 28/30 (93.3%); median trial count 1 (Q1 1, Q2 1, Q3 1).

^dThe output matched with that of "Answer."

^eN/A: not applicable.

^fWe attempted to obtain a diagnosis 5 times but failed.

^gWe attempted to obtain a diagnosis twice but failed.

Figure 2 presents details regarding the number of attempts required. On average, 1.27 attempts were needed for inputs involving only medical history followed by the question "What is the most likely diagnosis?" When all possible information, including physical examination findings and laboratory data, were inputted, followed by the same question, an average of

1.00 attempt was required. Regarding the 2 cases shown in Figure 2 that required 5 attempts, ChatGPT was unable to narrow down the diagnosis to the single most likely option. Consequently, these cases were counted as mismatches with the correct diagnoses listed in *The BMJ* vignettes.

Figure 2. Data collection and measurements.

Discussion

Principal Findings

Despite the advancements in medical knowledge and diagnostic techniques, misdiagnosis remains a significant issue. AI has shown promise in the diagnosis and treatment of medical conditions; however, there is limited understanding of how AI uses patient history for diagnostic purposes. Our study aimed to investigate the extent to which AI (ChatGPT) can use information from medical history to accurately diagnose common diseases, which are frequently encountered in general outpatient, emergency, and ward management settings. Although some studies have investigated the accuracy of AI-based medical diagnosis, our study is novel because it emphasizes the

importance of patient history. We compared the diagnostic accuracy of diagnoses made on the basis of only patient history and those made using all the information; this makes our study unique. To the best of our knowledge, no previous research has been conducted on this topic.

Our study investigated the role of patient history in AI-assisted medical diagnoses using ChatGPT. We analyzed 30 standardized patient vignettes from *The BMJ* to assess the concordance rates between AI-proposed diagnoses based on medical history only and those based on both medical history and additional information. Our results showed high concordance rates of 76.6% between the “Answer” and “History” groups, suggesting the importance of patient history in AI-assisted diagnoses and highlighting the potential of AI in improving diagnostic

accuracy. This result is similar to that of a previous study that involved actual physicians instead of ChatGPT [9,10].

Characteristics of cases that did not lead to appropriate diagnoses based on history alone include, for instance, the following: an appendicitis case (case 2 in [Multimedia Appendix 1](#)) for which there was no documentation of pain migration in the medical history, a meningitis case (case 10 in [Multimedia Appendix 1](#)) wherein only headache and fever were documented, an otitis media case (case 16 in [Multimedia Appendix 1](#)) wherein only upper respiratory symptoms were recorded with no mention of ear-related symptoms, errors in identifying the causative agent in a case of acute gastroenteritis (case 27 in [Multimedia Appendix 1](#)), and an acute pharyngitis case (case 34 in [Multimedia Appendix 1](#)) that lacked the necessary medical history to determine the Centor score. Such omissions in the medical history could be considered contributing factors to the misdiagnoses. When physical findings and test data were added, an accurate diagnosis was achieved in 28 out of 30 cases (93.3%), showing a 16.7% increase in the accuracy rate. These two cases were of acute pharyngitis diagnosed as acute upper respiratory tract infection and *Salmonella* enteritis diagnosed as acute gastroenteritis. While we considered these incorrect diagnoses for the purpose of this study, they could have been deemed correct under certain criteria. Of the 7 cases that did not match between “Answer” and “History,” 6 were of infectious diseases (21 of 30 cases were of infectious diseases). These included cases where appendicitis was mistaken for acute gastroenteritis, acute otitis media and acute pharyngitis were mistaken for upper respiratory infections, and a *Salmonella* infection was mistaken for a *Campylobacter* infection. Physical examinations or tests may help identify the site of infection or pathogen in cases of intra-abdominal or head and neck infections.

There are situations in which physical examination and clinical test information may not be available in clinical settings. For instance, digital patient encounters owing to the impact of the COVID-19 pandemic often preclude physical examinations and clinical tests. The widespread use of telemedicine approaches in COVID-19 management, from screening to follow-up, has demonstrated the community’s acceptance and interest in telehealth solutions [32]. Moreover, even in face-to-face consultations, there are scenarios, such as in clinics, where detailed clinical tests may not be feasible depending on the setting. Furthermore, we cannot perform all physical examinations and tests on all patients. Therefore, we should consider potential differential diagnoses and decide which pertinent physical examinations or tests are the most suitable and should be performed. Most importantly, it has been reported that one rarely makes a correct diagnosis when one cannot make a differential diagnosis based on history [11]. In addition, accurately predicting the diagnosis based on medical history is associated with a higher diagnostic accuracy of the physical examination, whereas incorrect prediction of the diagnosis based on medical history is associated with a lower diagnostic accuracy of the physical examination [33]. Based on these findings and suggestions, medical diagnosis using ChatGPT is considered heavily dependent on history.

Using AI for diagnosis can enhance diagnostic accuracy by more efficiently collecting medical histories. For instance, diagnosing acute appendicitis is sometimes challenging. AI may face the same challenge as that observed when, in our study, AI mistakenly identified acute appendicitis as acute gastroenteritis. This misdiagnosis may have occurred because the case lacked specific medical histories characteristic of appendicitis, such as pain migration. By configuring AI systems to verify pain migration in patients with abdominal pain, especially for such common conditions, diagnostic precision may improve.

There are 2 possible limitations in our study. First, it remains unclear whether similar results could be obtained with other vignettes or actual patients. Unlike using preprovided vignettes, among which we included 30 cases, diagnosis can be more challenging in clinical settings because it requires taking a medical history from patients. We included 30 cases from among the vignettes, which include some of the most commonly observed conditions in the outpatient setting. Although covering all the existing conditions is not feasible, we do not know if the case volume in our study is sufficiently high. This study included relatively simple cases in which patients had very few comorbidities, potentially making the diagnosis less challenging. Moreover, patients with psychiatric conditions tend to present with complex and lengthy case histories, and the wording used by mental health clinicians may differ, be inconsistent, be vague, or fail to pinpoint a diagnosis. Our vignettes did not include a diagnosis of any mental illness. Due to the abovementioned reasons, our results may not apply to all clinical settings. Furthermore, when we consider what the patient reports, results may differ if languages other than English are used since ChatGPT does not recognize some languages, and each language may have its unique nuance. This highlights the importance of linguistic diversity and cultural context in AI applications, particularly in medical diagnoses where patient communication and history are critical. Future iterations of AI systems should aim to incorporate a broader range of languages and understand cultural nuances to ensure more accurate and inclusive diagnostic support. This idea is important in the context of health inequality. Furthermore, disparities in technology access may pose some challenges. Future research should address these barriers to ensure equitable access to AI-assisted diagnostic tools.

Second, we encountered cases where the input of medical history followed by the question, “What is the most likely diagnosis?” failed to yield a single most likely diagnosis even after 5 attempts, which could have introduced bias into our results, although we only had 2 such cases.

In the future, studies should focus on training AI by implementing evidence-based medical information, enabling it to present the underlying reasons and guidelines for diagnoses. In the event of a misdiagnosis, analyzing the process that led to the false diagnosis could be challenging in an AI-assisted medical diagnosis. Given the current situation where reflection on misdiagnoses is not always feasible, AI should be used as an auxiliary tool in medical diagnosis. This approach underscores the importance of AI, deeming it a support system rather than a definitive diagnostic solution. This area needs

further investigation. Future studies should also verify our results with certain common conditions or diseases, such as the top 10 diseases identified in the Global Burden of Diseases study [34], potentially leveraging the benefits and limitations of AI-assisted medical diagnosis.

Conclusions

Relevant patient history is essential for AI-assisted diagnosis. The input of relevant patient history or the development of AI systems capable of obtaining comprehensive medical histories is vital for AI-assisted medical diagnosis. Furthermore, even in the modern era of advanced medical knowledge and clinical testing, the significance of patient history in diagnosis remains crucial.

Data Availability

All of our clinical vignettes, results, and prompts used are provided in [Multimedia Appendix 1](#).

Authors' Contributions

FF conceptualized the study, designed the methodology, collected the data, and drafted the manuscript. YY, DY, and SU conceptualized the study, designed the methodology, and reviewed and edited the manuscript. SY, YL, KS, TT, KN, TU, and MI conceptualized the study and reviewed and edited the manuscript. No generative artificial intelligence was used in writing the manuscript.

Abstract

Background: Artificial intelligence (AI) and machine learning (ML) are poised to have a substantial impact in the health care space. While a plethora of web-based resources exist to teach programming skills and ML model development, there are few introductory curricula specifically tailored to medical students without a background in data science or programming. Programs that do exist are often restricted to a specific specialty.

Objective: We hypothesized that a 1-month elective for fourth-year medical students, composed of high-quality existing web-based resources and a project-based structure, would empower students to learn about the impact of AI and ML in their chosen specialty and begin contributing to innovation in their field of interest. This study aims to evaluate the success of this elective in improving self-reported confidence scores in AI and ML. The authors also share our curriculum with other educators who may be interested in its adoption.

Methods: This elective was offered in 2 tracks: technical (for students who were already competent programmers) and nontechnical (with no technical prerequisites, focusing on building a conceptual understanding of AI and ML). Students established a conceptual foundation of knowledge using curated web-based resources and relevant research papers, and were then tasked with completing 3 projects in their chosen specialty: a data set analysis, a literature review, and an AI project proposal. The project-based nature of the elective was designed to be self-guided and flexible to each student's interest area and career goals. Students' success was measured by self-reported confidence in AI and ML skills in pre and postsurveys. Qualitative feedback on students' experiences was also collected.

Results: This web-based, self-directed elective was offered on a pass-or-fail basis each month to fourth-year students at Emory University School of Medicine beginning in May 2021. As of June 2022, a total of 19 students had successfully completed the elective, representing a wide range of chosen specialties: diagnostic radiology (n=3), general surgery (n=1), internal medicine (n=5), neurology (n=2), obstetrics and gynecology (n=1), ophthalmology (n=1), orthopedic surgery (n=1), otolaryngology (n=2), pathology (n=2), and pediatrics (n=1). Students' self-reported confidence scores for AI and ML rose by 66% after this 1-month elective. In qualitative surveys, students overwhelmingly reported enthusiasm and satisfaction with the course and commented that the self-direction and flexibility and the project-based design of the course were essential.

Conclusions: Course participants were successful in diving deep into applications of AI in their widely-ranging specialties, produced substantial project deliverables, and generally reported satisfaction with their elective experience. The authors are

hopeful that a brief, 1-month investment in AI and ML education during medical school will empower this next generation of physicians to pave the way for AI and ML innovation in health care.

Introduction

Artificial intelligence (AI) and machine learning (ML) are poised to have a substantial impact in the health care space with many disruptive technologies on the horizon. Innovations in clinical care are increasingly impacted by the development and implementation of AI and ML, and as future clinicians, medical students need to become innovators and active participants in technological changes that will affect how they provide care for their patients. There is much excitement and curiosity among medical students about these technologies [1]. However, few programs exist to deliberately expose future physicians to their role in medicine, let alone to empower students to actively participate in AI and ML innovation [2]. While a plethora of high-quality web-based resources exist to teach programming skills and ML model development, there are few introductory curricula specifically tailored to medical students without a background in data science or programming. Additionally, there is little guidance provided to medical students on where to begin. Some medical societies do have AI outreach activities, but these are limited to trainees within their specialty [3-5].

The authors theorized that a 1-month elective for fourth-year students, composed of existing web-based resources and a project-based structure, would empower students to learn about the impact of AI and ML in their chosen specialty and begin contributing to innovation in their field of interest. The authors also aimed for the elective to be specialty-agnostic and customizable to each student's career goals. The goal of this senior elective is to demystify AI and ML in health care, enabling students to have informed conversations about these technologies and participate in their clinical advancement. The target participant in the elective is any senior medical student with an interest in AI, with no prerequisites for technical, mathematical, or engineering skills.

In this paper, we evaluate the success of this elective over a 2-year period based on self-reported confidence scores in AI and ML. We also publish our curriculum for other educators who may be interested in its adoption.

Methods

Design

We built our elective following advice on designing medical electives with the principles articulated by Ramalho et al [6], which emphasize that a one-size-fits-all approach is often inadequate and that electives benefit from allowing students to carve their own paths. Creating a medical elective in an overloaded, overworked environment is nontrivial, but prior

studies on peer-organized coursework gave us insights into the effectiveness of peer-organized research in building academic confidence, as well as the importance of clearly defined learning objectives [7,8].

Technical and Nontechnical Tracks

Given the wide-ranging skill sets that medical students are equipped with before coming to medical school, this elective was offered in 2 tracks: Technical and Nontechnical. The Technical track was intended for the subset of students who were already competent computer programmers. This course did not aim to teach noncoding students how to code because it was expected that 1 month would not be sufficient time for students to make meaningful progress. Therefore, the Nontechnical track was offered to students with no technical background and focused on building a conceptual understanding of AI. Our goal for the Nontechnical track was to help students without a technical background develop a skill set and vocabulary that would enable them to participate in AI and ML evaluation and implementation processes in future collaborations with technical colleagues.

For both the Technical and Nontechnical tracks, the course was designed to address the following learning objectives:

1. Compare and contrast AI and ML.
2. State and differentiate various ML techniques (supervised/unsupervised, classification/regression, etc).
3. Appreciate the growing impact of ML in medicine, broadly and in the student's chosen specialty.
4. Develop an intuition of how machines "learn." Describe how neural networks are structured, trained, and evaluated. Learn vocabulary and concepts used to describe model training (loss functions, gradient descent, and backpropagation).
5. Understand the limitations and pitfalls of ML (reproducibility, interpretability, and bias).
6. Understand what kinds of medical problems can and cannot be solved by ML.
7. Describe issues that may arise in the implementation of an ML algorithm in clinical practice.
8. Discuss ethical issues that concern the use of ML in health care.

Didactic and Project-Based Components

In this self-guided, web-based course, students were referred to existing web-based courses and relevant research papers to supplement these learning objectives ([Multimedia Appendix 1 \[9-22\]](#)) but were expected to guide their own learning beyond this. Students were asked to share and write down their personal

goals at the beginning of the elective to guide their learning. They were also encouraged to spend time after each section on independent research to address lingering questions. The learning objectives and course resources were provided to students on a central document and students were able to follow along at their own pace. Because the course aimed to empower an individual student's interests and career goals, the elective was designed to establish a baseline level of understanding for all students, while also allowing students the freedom to dive deeper into the areas they were drawn to. Students were supported by the course's faculty advisor, a physician with substantial leadership and experience in AI and ML research.

Project Deliverables

Students were then tasked with completing at least 1 of the following project-based deliverables, and encouraged to complete others as their interests dictated:

1. Complete a literature review on the state of AI and ML in the student's chosen specialty.
2. Find and analyze 3 open-source health care data sets, considering strengths, weaknesses, and sources of error and bias.
3. Write a Project Proposal addressing a problem in the student's chosen specialty that can be solved with AI, with a discussion surrounding the implementation complexities.
4. Technical track only: Train and evaluate a clinical ML algorithm.

Details on these projects are provided in [Multimedia Appendix 2](#) [23].

The full curriculum is hosted on the Emory Health Care Innovations and Translational Informatics Lab GitHub repository [24].

This course was initially designed during the COVID-19 pandemic, and maintained a web-based format throughout the 2 years it has been offered. All recommended resources were freely available to students on the web, although some required institutional access. The students attended weekly web-based laboratory meetings to discuss their progress and to be exposed to more advanced research in AI and ML. Students were also encouraged to identify an additional advisor (beyond the elective director, who they met with once a week) within their chosen specialty, who could provide domain expertise for their projects.

Qualitative Survey Data

Initially, the authors collected feedback from students qualitatively through one-on-one meetings; this feedback was used to improve the format and support structure of the elective. Beginning in October 2021, students were also asked for open-ended feedback on the strengths and weaknesses of the elective through anonymous surveys. They were asked:

- What was the most meaningful project or experience you completed during the elective? Do you intend to continue work on it past the end of the elective?
- Did you gain what you hoped to get out of this elective? Please explain.
- What resources were most useful to you during the elective?

- What could be most improved in the curriculum design of this elective?

Quantitative Survey Data

Beginning in October 2021, quantitative pre and postelective surveys were implemented using Google Forms to assess the effectiveness of the elective format and resources provided. Students were asked to fill out formal surveys to rate their confidence in AI and ML concepts and in technical data science and coding skills.

Before starting the elective, students were asked:

- How familiar are you with AI or ML concepts? (Likert scale, 1-5)
- How would you rate your technical data science or coding experience? (Likert scale, 1-5)

After completing the elective, students were asked:

- Did you choose the Technical or Nontechnical Track?
- After completing this elective, how familiar are you with AI or ML concepts? (Likert scale, 1-5)
- After completing this elective, how would you rate your technical data science or coding experience? (Likert scale, 1-5)

Statistical Analysis

Quantitative and discrete data from self-reported confidence scores was analyzed using the Wilcoxon rank sum test. Qualitative survey responses were reviewed in a descriptive manner rather than undergoing a formal analysis. Responses were manually examined for common themes, trends, and noteworthy insights, but no systematic coding framework was used and representative responses are included in the "Results" section.

Ethical Considerations

This study was deemed exempt from review by Emory University's institutional review board, under the category "Educational Tests, Surveys, Interviews, Observations." This is justified based on anonymity and minimal risk to survey participants. All participants were able to opt out of this educational experience and from data collection. Survey data were collected anonymously. Students were not compensated for participation.

Results

Overview

This web-based, self-directed elective was offered on a pass-or-fail basis each month to fourth-year students at Emory University School of Medicine beginning in May 2021. A maximum of 3 students were allowed to enroll each month. As of June 2022, a total of 19 students had signed up and completed the elective. All students successfully met elective requirements and passed the course. The students represented a diverse range of chosen specialties: diagnostic radiology (n=3), general surgery (n=1), internal medicine (n=5), neurology (n=2), obstetrics and gynecology (n=1), ophthalmology (n=1),

orthopedic surgery (n=1), otolaryngology (n=2), pathology (n=2), and pediatrics (n=1).

Given the limited time and open-ended nature of the course, students elected to spend varying amounts of time on each of the project components based on their interests and were not required to complete all 3 projects as long as they produced at least 1 significant deliverable. The vast majority of students (17 out of 19 students) chose the Nontechnical track. Most students (11/19, 58%) chose to focus their efforts on 2 of the 3 projects; 8 (42%) completed all 3 projects, and 1 (5%) submitted only a project proposal. Since the elective was intended to be flexible to students' interests, students were evaluated on a pass-or-fail basis based on demonstrated effort as determined by the faculty advisor, rather than strict adherence to project deliverables. All students received a passing grade. Project proposals submitted by students were wide-ranging, including AI applications such as "Smartphone Detection of Anterior Uveitis," "Predicting Postpartum Hemorrhage," "Image Enhancement in Video Laryngoscopy," and "Audiometry for Pediatric Heart Murmur Screening." Four (25%) students indicated that they intended to continue working on their projects beyond the end of the elective.

Qualitative Survey Results

Qualitative feedback collected from students before October 2021 (n=4) indicated that students wanted more support and guidance in their field of interest; given this feedback, the authors created more structure for the elective and encouraged students to find an additional specialty-specific mentor who could contribute domain expertise.

Students were asked if they gained what they hoped for from their elective experience. Students who sought a basic conceptual understanding reported satisfaction, but some reported an unmet desire for a deeper technical understanding:

- "I wanted to learn more generally how AI/ML can be used and is being used in medicine. I definitely achieved this goal."
- "I feel that I learned AI/ML fundamentals, am now able to better read and understand AI/ML medical literature, and have thought through the essential design elements of an AI/ML proposal."
- "I learned about the clinical applications of ML and how it is used to help rather than replace radiologists. I also have learned that the technology is advanced, but the application is still early in medicine."
- "I found the course very valuable as an introduction to what ML is and how it is used. However, I had hoped to gain more insight into what research is being conducted in ML from a technical perspective and what these advances may mean from a translational perspective."

Students were also asked what aspects of the course were most beneficial. Four students commented that the self-directed and flexible nature of the course was essential. Two students commented that the project proposal was the most essential element. Five (26%) students reported that they intended to continue working on their projects after the end of the elective month.

When asked for constructive feedback, 2 students commented that they desired more concrete guidance on the projects. Some students felt strained to finish the project proposal within 1 month, with one commenting that students should not expect to finish the proposal in 1 month, and 2 recommending future students pick a project as early as possible, rather than waiting until after the literature review and data set project.

Quantitative Survey Results

After October 2021, students were asked to fill out formal surveys collecting feedback and self-reported confidence in skills gained during the elective. Fifteen students filled out the preintervention survey, and 12 students completed the postintervention survey. These results are shown in [Table 1](#).

Table 1. Pre- and postintervention confidence scores in AI^a or ML^b concepts and technical skills.

	Mean (SD)	Median (IQR)
"On a scale of 1-5, how well do you understand AI or ML concepts?"^c		
Preintervention (n=15)	2.5 (1.3)	2 (3)
Postintervention (n=12)	4.1 (0.7)	4 (3)
"On a scale of 1-5, rate your technical data science skills"^d		
Preintervention (n=15)	2.6 (1.4)	3 (0.25)
Postintervention (n=12)	1.9 (1.3)	1 (2)

^aAI: artificial intelligence.

^bML: machine learning.

^cRelative difference is 66% and Wilcoxon rank sum *P* value is .003.

^dRelative difference is -26% and Wilcoxon rank sum *P* value is .20.

Discussion

Principal Results

Students who participated in this elective were successful in diving deep into the potential of AI and ML in their area of interest and generally reported satisfaction with their elective experience. Students were asked to quantitatively rate their familiarity with both AI and ML concepts and coding or data science; the self-reported confidence scores for AI and ML rose by 66%, and these results were found to be statistically significant when analyzed by the Wilcoxon rank sum test. This exposure to AI and ML is a substantial improvement from the status quo, in which most medical students receive little to no exposure during the course of their training; in 1 study from 2022, 66.5% of students reported 0 hours of AI or ML teaching, and 43.4% had never heard the term “machine learning” [25]. Previous literature includes effective AI curricula developed for other types of health care trainees, such as radiology residents, but there is little to no literature on curricula evaluated for a fourth-year medical student audience as described in this paper [26,27].

Self-reported confidence in technical skills (coding and data science) fell by 26%, although this result was not found to be statistically significant. The authors attribute these results to an initial overconfidence prior to the elective, followed by an increased awareness of the technical complexity of model development after the elective.

Because this was a self-guided elective, student output varied with each student’s level of motivation and goals prior to entering the elective. Students who had defined a specific area of interest tended to benefit more from their experience than students who came in with no clear goals set. This course could be improved by providing further assistance early on in helping students to finalize a project area early so that they feel less strained by time toward the end of the month.

Students produced a wide range of deliverables in their chosen specialty. Since most fourth-year students have chosen their specialty and have established connections with faculty in their field, the self-guided nature of the course allowed flexibility for students to seek out appropriate mentors and propose reasonable projects in their areas of interest.

Limitations and Future Directions

Limitations of this study include the small number of participants, especially in the Technical track, restricting the generalizability of this study. Only 2 (11%) students chose the Technical track, so there is insufficient data to evaluate this curriculum; this was likely due to the requirement that students interested in the Technical track have in-depth coding experience and receive approval from the course director to ensure a high likelihood of success. However, the authors recommend screening applicants to make sure that they do in fact possess the required level of comfort in coding before attempting to develop an ML model, as we observed a tendency for students to underestimate the complexity of this task. Based on qualitative observations that students spent more time than expected preparing data for training, the authors suggest providing select, cleaned data sets for students in the Technical track, allowing them to focus on model building, training, and testing.

Another substantial limitation is that assessments relied only on students’ self-reported confidence, which has been shown to be a flawed metric [28]. Further studies would benefit from a refined objective assessment tool of students’ competencies, as well as replication of this study at other medical schools.

Since launching this fourth-year elective, we have also adapted this curriculum to a shorter elective targeting second-year medical students and were invited to participate in a National Academies forum on AI for Health Profession Education to disseminate this curriculum to other learners [29].

Conclusions

Overall, in the 2 years since launching the elective at Emory University School of Medicine, the authors have already seen substantial excitement and appreciation from senior medical students, with continued excitement in the elective’s third year. Most students entered the elective with minimal previous experience in AI and ML and were successful in completing self-guided research and proposing creative and realistic AI and ML projects. The authors are hopeful that a brief, 1-month investment in AI and ML education during medical school can lay the groundwork for these future physicians to continue to engage with AI and ML research and empower this next generation of physicians to pave the way for AI and ML innovation in health care.

Acknowledgments

This study would not have been possible without the support of Emory University School of Medicine. The authors are grateful to Meredith Greer for her guidance in curricular development.

Data Availability

The data sets generated or analyzed during this study are not publicly available due to ensure participant confidentiality and privacy in compliance with the institutional review board exemption status, but are available from the corresponding author on reasonable request.

Authors' Contributions

AA and JG contributed to the conceptualization, investigation, and methodology; analysis of results; and the writing of the manuscript. AM contributed to the conceptualization and design of the course, along with the review and editing of the manuscript. IB, SP, and HT contributed to the administration of the elective and review and editing of the manuscript.

Conflicts of Interest

Abstract

Background: Large language models (LLMs) have revolutionized natural language processing with their ability to generate human-like text through extensive training on large data sets. These models, including Generative Pre-trained Transformers (GPT)-3.5 (OpenAI), GPT-4 (OpenAI), and Bard (Google LLC), find applications beyond natural language processing, attracting interest from academia and industry. Students are actively leveraging LLMs to enhance learning experiences and prepare for high-stakes exams, such as the National Eligibility cum Entrance Test (NEET) in India.

Objective: This comparative analysis aims to evaluate the performance of GPT-3.5, GPT-4, and Bard in answering NEET-2023 questions.

Methods: In this paper, we evaluated the performance of the 3 mainstream LLMs, namely GPT-3.5, GPT-4, and Google Bard, in answering questions related to the NEET-2023 exam. The questions of the NEET were provided to these artificial intelligence models, and the responses were recorded and compared against the correct answers from the official answer key. Consensus was used to evaluate the performance of all 3 models.

Results: It was evident that GPT-4 passed the entrance test with flying colors (300/700, 42.9%), showcasing exceptional performance. On the other hand, GPT-3.5 managed to meet the qualifying criteria, but with a substantially lower score (145/700, 20.7%). However, Bard (115/700, 16.4%) failed to meet the qualifying criteria and did not pass the test. GPT-4 demonstrated consistent superiority over Bard and GPT-3.5 in all 3 subjects. Specifically, GPT-4 achieved accuracy rates of 73% (29/40) in physics, 44% (16/36) in chemistry, and 51% (50/99) in biology. Conversely, GPT-3.5 attained an accuracy rate of 45% (18/40) in physics, 33% (13/26) in chemistry, and 34% (34/99) in biology. The accuracy consensus metric showed that the matching responses between GPT-4 and Bard, as well as GPT-4 and GPT-3.5, had higher incidences of being correct, at 0.56 and 0.57, respectively, compared to the matching responses between Bard and GPT-3.5, which stood at 0.42. When all 3 models were considered together, their matching responses reached the highest accuracy consensus of 0.59.

Conclusions: The study's findings provide valuable insights into the performance of GPT-3.5, GPT-4, and Bard in answering NEET-2023 questions. GPT-4 emerged as the most accurate model, highlighting its potential for educational applications. Cross-checking responses across models may result in confusion as the compared models (as duos or a trio) tend to agree on only a little over half of the correct responses. Using GPT-4 as one of the compared models will result in higher accuracy consensus. The results underscore the suitability of LLMs for high-stakes exams and their positive impact on education. Additionally, the

study establishes a benchmark for evaluating and enhancing LLMs' performance in educational tasks, promoting responsible and informed use of these models in diverse learning environments.

KEYWORDS

accuracy; AI model; artificial intelligence; Bard; ChatGPT; educational task; GPT-4; Generative Pre-trained Transformers; large language models; medical education, medical exam; natural language processing; performance; premedical exams; suitability

Introduction

Large language models (LLMs) are potent natural language processing tools, excelling in a range of artificial intelligence (AI) tasks, from news writing to product descriptions. They have garnered widespread attention across academia and industry [1,2], going beyond the scope of natural language processing into tasks related to health care [3], neuroscience [4], philosophy [5], marketing and finance [6,7], sociology [8], education, and others [9,10]. The development of LLMs and chatbots is experiencing an upsurge, with established companies and emerging start-ups actively engaged in their creation [11], catering to general or specific purposes [12]. Prominent examples include Generative Pre-trained Transformers (GPT)-3.5 (OpenAI), GPT-4 (OpenAI), and Bard (Google LLC) [13,14]. Other notable examples are BlenderBot, Galactica, LLaMA (FAIR) [15], Alpaca (Stanford), BloombergGPT [16], Chinchilla (DeepMind), and PaLM [17], heralding the emergence of even more chatbots in the future [12].

The public release of ChatGPT in November 2022 and Bard in March 2023 has garnered significant attention due to their general purpose and flexible nature. ChatGPT [18], built on the GPT-3.5 architecture, has become popular for its remarkable ability to generate coherent and human-like responses. GPT-4.0 represents the latest iteration, incorporating enhanced language generation and improved multiturn conversation handling. Both GPT-3.5 and GPT-4.0 have been specifically trained to interact with users in a conversational manner, maintaining context, handling follow-up questions, and even correcting themselves. Bard, on the other hand, leverages Google's LaMDA [19], enabling it to handle a diverse range of language-related tasks and provide in-depth information.

In educational settings, students are using LLMs such as Bard, GPT-3.5, and GPT-4 to enrich their daily learning experiences [20,21]. They aid students in test preparation, offer research assistance, and contribute to their overall performance improvement and knowledge acquisition [22]. It has been observed that LLMs, despite their impressive performance, can sometimes generate text that includes fabricated or incorrect information [13,23]. Consequently, researchers have directed their attention toward investigating the test-taking capabilities of different LLMs. Numerous research studies have delved into the assessment of GPT-3.5's efficacy in multiple-choice exams in higher education domains [24]. Some investigations have specifically focused on ChatGPT's test-taking performance in diverse professional fields, including business [25], accounting [26], law [27], and medicine [28]. In the medical realm, authors in Bommineni et al [29] examined its competence in tackling the Medical College Admissions Test, which serves as a

prerequisite for admission to most medical schools in the United States. In Gilson et al [30] and Kung et al [31], authors have scrutinized ChatGPT's aptitude in the United States Medical Licensing Examination (USMLE), while Teebagy et al [32] conducted a comparative study of GPT-3.5 and GPT-4's performance in the Ophthalmic Knowledge Assessment Program exam. Additionally, Ali et al [33] undertook a comparison of GPT-3.5, GPT-4, and Google Bard, using questions specifically prepared for neurosurgery oral board examinations. Similarly, Zhu et al [28] investigated ChatGPT's performance in several medical topics, namely, the American Heart Association, advanced cardiovascular life support, and basic life support exams.

Despite the successful integration of LLMs in educational environments, a crucial question remains: can LLMs provide the necessary accuracy and reliability required for critical assessments? The published studies predominantly focus on specialized fields within medicine, with few investigations addressing the effectiveness of AI tools for medical school entrance examinations [29]. Additionally, such comparisons made in the literature typically revolve around the performance of a solitary LLM against human abilities [24,34], with limited exploration of how they compare against other LLMs or baseline models, which could provide valuable insights into the strengths and weaknesses of different LLMs. Our primary objective is to bridge this knowledge gap by undertaking a comparative analysis of 3 notable chatbots: GPT-3.5, GPT-4, and Bard, for a standardized medical school exam known as the National Eligibility cum Entrance Test (NEET).

NEET [35] is a competitive entrance exam in India for Bachelor of Medicine and Bachelor of Dental Surgery programs in both government and private colleges. Introduced in 2013 by the Medical Council of India, NEET replaced various state-level and institution-specific tests to standardize medical admissions. Since 2019, the National Testing Agency (NTA) has been responsible for conducting and supervising the NEET. The exam comprises a total of 200 multiple-choice questions aimed at testing knowledge, understanding, and aptitude in 4 subjects: physics, chemistry, botany, and zoology. Candidates can only attempt a maximum of 45 questions per subject, for a total of 180 out of 200 questions. Correct answers are awarded 4 points, while each incorrect response leads to a 1-point deduction. Candidates are allotted 3 hours to complete the examination. To qualify for admission to a medical school, candidates must obtain a minimum or cutoff score, which can change year by year. The cutoff score for NEET-2023 was 137 out of 720. In 2023, over 2.03 million students took the NEET exam [24], a number that has been rising annually by 10% to 16.5%, highlighting the exam's widespread popularity and importance.

Among the 1.15 million candidates who qualified in 2023, only 2 scored full marks (720/720), only 1 scored 716 out of 720, a total of 17 scored 715 out of 720, and 6 scored 711 out of 720 [36]. NEET's rigorous nature, coupled with its widespread adoption, underscores its importance as the primary evaluation tool for determining students' knowledge, aptitude, and readiness for pursuing medical and dental education at the undergraduate level [35].

In this investigation, to evaluate the performance of the 3 mainstream LLMs, namely GPT-3.5, GPT-4, and Google Bard, in answering questions related to the NEET 2023 exam, we used rigorous statistical analyses. We scrutinized each model's performance across 3 pivotal frameworks: overall comparison, subject-level comparison, and topic-level comparison. The outcomes of this study can help premed students make informed decisions about incorporating LLMs into their test preparation strategies. To the best of our knowledge, this marks the first endeavor to undertake such a study.

Methods

Question Set Selection and Preparation

In this paper, we tested the performance of the 3 LLMs on NEET-2023, which was obtained as a portable document file. Although the exam consists of 200 questions, due to the presence of illustrations and diagrams, it was not possible to process all the questions. As a result, we excluded questions with illustrations, resulting in a set of 175 questions for this study. This sample size is large enough to statistically justify each model's performance on the entire exam, with a 95% CI and a 5% margin of error. The selected questions were then manually presented to Bard, GPT-3.5, and GPT-4, and the responses were documented in Excel (Microsoft Corporation).

Data Analysis

We compared responses generated by each model against the correct answers from the official answer key on the NEET website. Based on this comparison, the responses were either marked as correct (1) or incorrect (0).

Prediction Performance

Excel's built-in functionalities were then used to generate the following comparison metrics to assess predictive performance of the LLMs:

1. Accuracy is defined as the percentage of correct responses obtained by a model. In the context of this research, accuracy was obtained using the formula:

$$\text{Accuracy} = \text{Correct Responses} / \text{Total Responses}$$

2. Accuracy consensus is defined as the ratio between correct answers upon which the compared models agree to all the answers (correct and incorrect) upon which the compared models agree. The formula is

$$\text{Accuracy consensus} = \text{Correct Responses} / \text{Total Consensus}$$

Scoring Performance

Next, we calculated the overall, subject-level, and topic-level percentage scores for each LLM following the NTA's scoring rules. Each correct answer was awarded 4 points, while each incorrect answer resulted in a deduction of 1 point. We merged zoology and botany into a single biology category, as the topic-level analysis included questions from both fields. The overall score percentage for each model was determined by dividing the total points scored by the maximum possible points, which was 700. Subject-level percentages were derived by dividing each model's total points by the maximum points available in that subject. Similarly, topic-level percentages were calculated by dividing the total points scored in each topic by the maximum points available for that topic, which varied across different topics.

Results

Prediction Performance

The results demonstrated that GPT-4 had higher accuracy and consensus compared to GPT-3.5 and Bard. It also consistently outperformed the other models across subjects and topics. GPT-3.5 and Bard showed variations in their performances, with specific strengths in certain subjects and topics.

Overall Accuracy

The overall accuracy rates of the models were as follows:

1. GPT-4 achieved the highest accuracy rate of approximately 54.3% by correctly identifying 95 out of 175 responses.
2. GPT-3.5 demonstrated an accuracy of 36.7%, with 64 out of 175 correct responses.
3. Bard achieved the lowest accuracy of approximately 33.1%, based on 58 out of 175 correct answers.

Subject-Level Accuracy

Table 1 presents the number of correct responses obtained by each model in each of the 3 subject areas covered by NEET. It was evident that GPT-4 is consistently more accurate than both Bard and GPT-3.5 in all 3 subjects. For each subject, the number of correct responses obtained by GPT-3.5 and Bard differed by ± 3 , indicating relatively similar subject-level accuracy rates. On the other hand, GPT-4 was substantially more accurate than the other models, generating 4 to 16 more correct answers per subject. In physics, GPT-4 achieved 73% (29/40) accuracy, followed by GPT-3.5 with 45% (18/40), and Bard with 38% (15/40). Similarly, in chemistry, GPT-4's accuracy rate was 44% (16/36), while GPT-3.5 and Bard achieved an accuracy rate of 33% (12/36). Shifting to biology, GPT-4 maintained its lead with 51% (50/99) accuracy, followed by GPT-3.5 with 34% (34/99), and then Bard with 31% (31/99).

Table 1. Number of correct responses (n) and accuracy rates in each subject per model.

Subject	GPT ^a -4, n (%)	GPT-3.5, n (%)	Bard, n (%)
Biology (n=99)	50 (51)	34 (34)	31 (31)
Chemistry (n=36)	16 (44)	12 (33)	12 (33)
Physics (n=40)	29 (73)	18 (45)	15 (38)

^aGPT: Generative Pre-trained Transformers.

Topic-Level Accuracy

Table 2 displays the number of correct responses obtained from each model on various topics. GPT-4 was the most accurate in 9 (50%) out of 18 topics. Moreover, for at least half (2-4) of the topics in each subject, GPT-4 demonstrated the highest accuracy. GPT-3.5 was the most accurate (8/15, 53%) in inorganic chemistry. In addition, it was more accurate than Bard in 7 topics across the 3 subjects. However, it had a 0% accuracy in population and ecology (biology) and simple harmonic motion and waves (physics). Bard was the most accurate in the topics on plant kingdom and ecosystem and environment issues. Furthermore, it was more accurate than GPT-3.5 in 5 topics

across all 3 subjects. However, it has a 0% accuracy for 2 physics topics, namely modern physics and electronics and optics. GPT-4 and GPT-3.5 had similar accuracies in 1 physics topic (modern physics and electronics: 2/4, 50%) and 2 biology topics (cell biology and genetics: 7/16, 44%; and ecosystem and environmental issues: 2/5, 40%). GPT-4 and Bard are 100% accurate in the topics on simple harmonic motion and waves. All 3 models were at the same level of accuracy in the topics on biomolecules and heat and thermodynamics.

In a nutshell, GPT-4 had a higher accuracy across a wide range of topics (15/18, 83%), while GPT-3.5's and Bard's accuracies were well below GPT-4's. Moreover, they showed variations in their accuracies across topics.

Table 2. Number of correct responses for each topic per model.

Topic	GPT ^a -4, n (%)	GPT-3.5, n (%)	Bard, n (%)
Biotechnology (n=11)	7 (64) ^b	6 (55)	4 (36)

^a GPT: Generative Pre-trained Transformers.

^bHighest accuracy within a topic.

Accuracy Consensus

Overall Accuracy Consensus

The accuracy consensus for the pairs were approximately as follows:

1. Bard and GPT-3.5 were correct on 29 out of 69 matching responses, giving the pair an accuracy consensus of 0.42 and an accuracy of 29 (16.6%) out of 175.
2. Bard and GPT-4 were correct on 42 out of 75 matching responses, resulting in an accuracy consensus of 0.56 and an accuracy of 42 (24%) out of 175.
3. GPT-3.5 and GPT-4 were correct on 45 out of 79 matching responses, giving the pair an accuracy consensus of 0.57 and an accuracy of 45 (25.7%) out of 175.

4. All 3 models were correct on 29 out of 49 matched responses. The accuracy consensus of the trio was approximately 0.59 and an accuracy of 29 (16.6%) out of 175.

This ascending trend in accuracy consensus indicated that GPT-4 enhanced the agreement on correct responses, especially when used in conjunction with either Bard or GPT-3.5. The best accuracy consensus and accuracy were obtained when GPT-3.5 and GPT-4 were considered together. Moreover, the collective intelligence of these models was as good as the weakest duo, that is, Bard and GPT-3.5 combined.

Subject-Level Accuracy Consensus

Table 3 shows the total number of correct matching responses and accuracy consensus at the subject level for each model.

Table 3. Subject-level total correct matching responses and accuracy consensus across compared models.

Subject	GPT ^a -3.5 vs Bard		Bard vs GPT-4		GPT-3.5 vs GPT-4		Bard, GPT-3.5, and GPT-4	
	Total correct matching responses, n	Accuracy consensus	Total correct matching responses, n	Accuracy consensus	Total correct matching responses, n	Accuracy consensus	Total correct matching responses, n	Accuracy consensus
Biology	17	0.4	22	0.46	23	0.48 ^b	17	0.52
Chemistry	4	0.31	7	0.50	8	0.50 ^b	4	0.50
Physics	8	0.58	13	1.00	14	0.93 ^b	8	1.00

^aGPT: Generative Pre-trained Transformers.

^bHighest accuracy within a subject.

The subject-level accuracy consensus revealed following insights.

For biology, the highest accuracy consensus was observed between GPT-3.5 and GPT-4 (n=23, ratio of 0.48), indicating GPT-4's superior performance. This duo also produced the highest accuracy, that is, 23 (23%) out of 99. Even though the accuracy consensus of the trio was the highest, it did not correspond to the highest accuracy (17/99, 17%).

For chemistry, both comparisons involving GPT-4 (Bard vs GPT-4 and GPT-3.5 vs GPT-4) yielded a higher accuracy consensus ratio of 0.50. However, the duo of GPT-3.5 and GPT-4 resulted in highest accuracy, that is, 8 (22%) out of 36.

For physics, Bard versus GPT-4 and the collective comparison of all models achieved a perfect accuracy consensus of 1.00 and an accuracy of 13 (32%) out of 40. However, the highest accuracy (14/40, 35%) was shown by GPT-3.5 versus GPT-4, with comparable accuracy consensus of 0.93.

These points demonstrate GPT-4's dominance across subjects, with physics showcasing the highest consensus scores. This

suggests that when GPT-4 is used in tandem with any other model, the duo or trio will corroborate each other's responses more than when Bard and GPT-3.5 are considered together.

Topic-Level Accuracy Consensus

Table 4 shows the total number of correct matching responses and accuracy consensus at the topic level for each model.

The following observations can be made about data presented in Table 4.

GPT-3.5 versus GPT-4 demonstrated the highest accuracy consensus and number of correct matching responses in 11 (61%) out of 18 topics. This trend was followed by the Bard versus GPT-4 duo, which showed the highest number of accurate responses and accuracy consensus in 7 (39%) out of 18 topics.

“Biomolecules,” “heat and thermodynamics,” “optics,” and “simple harmonic motion and waves” had low or zero accuracy consensus for all or most comparisons.

Hence, the combined intelligence of the models cannot help with the preparation of all the topics, if the goal is to seek consensus or confirmation of responses across models.

Table 4. Topic-level correct matching responses and accuracy consensus across compared models.

Topic	GPT ^a -3.5 vs Bard		Bard vs GPT-4		GPT-3.5 vs GPT-4		Bard, GPT-3.5, and GPT-4	
	Total correct matching responses, n	Accuracy consensus	Total correct matching responses, n	Accuracy consensus	Total correct matching responses, n	Accuracy consensus	Total correct matching responses, n	Accuracy consensus

^aGPT: Generative Pre-trained Transformers.

^bHighest combination of accurate responses and accuracy consensus in a topic.

^cN/A: not applicable.

Scoring Performance

Overall Scores

GPT-4 achieved the highest score with 300 (42.9%) out of 700 points, outperforming GPT-3.5, which scored 145 (20.7%) out of 700 points, and Bard, which obtained 115 (16.4%) out of 700 points. To qualify for the NEET-2023 entrance test, candidates needed to secure at least 137 out of 720 points, which represents 19.6% of the total points. It was evident that GPT-4 passed the entrance test with flying colors, showcasing exceptional performance. On the other hand, GPT-3.5 managed

to meet the qualifying criteria, but with a substantially lower score. However, Bard failed to meet the qualifying criteria and, hence, did not pass the test.

Subject-Level Scores

The subject-level scores, as per NEET's grading rubric, are detailed in Table 5. GPT-4 achieved the highest overall score of 42.9% (300/700), outperforming both GPT-3.5 (145/700, 20.7%) and Bard (115/700, 16.4%). In all 3 subjects, GPT-4 obtained the highest scores. GPT-3.5 scored higher than Bard in biology and physics but tied with Bard in chemistry.

Table 5. Subject and topic level scores for Bard, Generative Pre-trained Transformers (GPT)-3.5, and GPT-4.

Subject and topic	Scores obtained		
	Bard	GPT-3.5	GPT-4
Overall (n=700), n (%)	115 (16.4%) ^a	145 (20.7%)	300 (42.9%) ^b
Biology (n=396)

Heat and thermodynamics	2 ^b	2 ^b	2 ^b
Mechanics	18	18	28 ^b

^aLowest scorer within the topic.

^bTop scorer within the topic.

We then analyzed the breakdown of the total scores obtained by Bard, GPT-3.5, and GPT-4, categorized by subject. Of the total GPT-4 score, 50.3% (151/300) came from biology, 35% (105/300) came from physics, and 14.7% (44/300) came from chemistry. For GPT-3.5, biology contributed 49% (71/145) of the score, physics contributed 34.5% (50/145), and chemistry contributed 16.6% (24/145). Lastly, Bard's score breakdown showed that 48.7% (56/115) from biology, 30.4% (35/115) came from physics, and 20.9% (24/115) came from chemistry.

These results show that GPT-4 outperformed both GPT-3.5 and Bard in the NEET grading rubric, achieving the highest overall score and the top scores in each individual subject. While GPT-3.5 demonstrated better performance than Bard in biology

and physics, it tied with Bard in chemistry. The breakdown of scores by subject revealed that for all 3 models, the largest portion of their scores came from biology (understandably, because there were twice as many questions in this category), followed by physics, and then chemistry, indicating a consistent pattern in their relative strengths across these subjects.

Topic-Level Scores

The results in Table 5 shows that GPT-4 exhibited strong performance across all topics in physics but showed a relative weakness in inorganic chemistry within the chemistry subject. Bard, compared to the GPT versions, excelled specifically in the biology topics of the plant kingdom and ecosystem and

environmental issues. Both GPT models performed equally well in cell biology and genetics (biology) and in modern physics and electronics (physics). Additionally, GPT-3.5 stood out for its excellent performance in inorganic chemistry, highlighting its strength in this area of the chemistry subject.

Discussion

Overview

We evaluated the decision-making performance of 3 models—Bard, GPT, and GPT-4—using accuracy, accuracy consensus, and test scores for the NEET-2023 entrance test. Subject-wise and topic-wise analyses were also conducted. GPT-4 consistently outperformed Bard and GPT across all subjects, achieving the highest accuracy rates: 73% (29/40) in physics, 44% (16/36) in chemistry, and 51% (50/99) in biology. Topic-wise comparisons also demonstrated GPT-4's excellence in 15 (79%) out of 19 topics, with Bard and GPT excelling in certain topics. Particularly, Bard excelled in simple harmonic motion and waves, while GPT showed strength in inorganic chemistry. Overall, GPT-4 emerged as the top performer, excelling in both subjects and specific topics. Our findings are in line with previous studies that have also examined how LLMs perform on exams related to medical education. Bommineni et al [29] found that GPT-3.5 performs at or above the median performance of the Medical College Admissions Test takers. Ali et al [33] reported that GPT-4 outperformed both GPT-3.5 and Bard by achieving the highest score of 82.6% in specialized questions prepared for neurosurgery oral board examinations. Friederichs et al [34] found that GPT-3.5 answered about two-thirds of the multiple-choice questions correctly and outperformed nearly all medical students in years 1-3 of their studies. Gilson et al [30] reported that GPT-3.5's performance on the USMLE was either at or near the minimum passing threshold, even without domain-specific fine-tuning. Below, we present both practical and research implications of our findings to enrich the existing literature.

Implications

Practical Implications

The findings have important implications for users who need to select a model based on specific requirements and their desired score. The subject- and topic-level scores highlight the suitability of different models for different domains. GPT-4 appears to have the highest score (300/700, 42.9%), followed by GPT-3.5 (145/700, 20.7%), and then Bard (115/700, 16.4%). This demonstrates that Bard was not able to pass the NEET-2023 admission exam, and GPT-3.5 was only 2% (14/700) away from the cutoff score, which is 19% (133/700).

Although GPT-4 appears to be the preferred choice for NEET preparation, it is important to note that GPT-4 is a subscription-based service and the pricing model is uniform across the globe, which makes this model less accessible to the general audience in some parts of the world, particularly low-income countries. When cost is an issue, prospective medical school students might consider using GPT-3.5 and Bard in tandem to develop specialized knowledge and expertise in specific subject topics. The accuracy consensus metric

demonstrates that the duo was correct on 29 (42%) out of 69 matching responses, reaching 16.6% (29/175) overall accuracy. However, this duo did not excel in any of the subjects, compared to the other duos. Moreover, at the topic level, it only excelled in "evolution and health." These results suggest that, in the absence of GPT-4, while students may consider both GPT-3.5 and Bard together for exam preparation, due to the low level of consensus between these models, the total score would still fall below the cutoff score. Moreover, students would be more often confused about the correct responses while cross-checking answers with these models. Therefore, it is recommended that, for exam preparation, students do not solely rely on these models or model duos; instead, they should consult primary sources in conjunction with these models.

Research Implications

While scoring performance comparisons help us evaluate whether these models are able to ace the NEET-2023 exam or not, prediction performance comparisons help us evaluate their long-term performance beyond NEET 2023. The models' predictive accuracy rates match their scoring performance. GPT-4 demonstrated the highest accuracy rate among the 3 models, indicating its superior capability to provide correct responses and its reliability as an accurate study partner. However, there is still plenty of room for improvement since its accuracy was only at 54.3% (95/175), suggesting that anyone using this model for exam preparation would be exposed to a little over 50% (100/200) of accurate information. GPT-3.5 (64/175, 37.6%) and Bard (58/175, 33.1%) had similar overall accuracy rates that are much lower compared to GPT-4's, suggesting that these 2 models would require significant fine-tuning to qualify as reliable study aids for NEET.

The subject- and topic-level accuracy comparisons highlight specific areas where these models could benefit from domain-specific enhancements. GPT-4 demonstrated superior accuracy across all 3 subjects and 15 topics but required further improvements in 3 topics, that is, ecosystem and environmental issues, plant kingdom, and inorganic chemistry. GPT-4 excelled in at least 1 topic from each subject category, including simple harmonic motion and waves and optics in physics, physical chemistry in chemistry, and evolution and biotechnology in biology. Bard excelled in simple harmonic motion and waves, and GPT-3.5 notably excelled in inorganic chemistry. GPT-3.5, besides requiring improvements in its overall prediction capabilities, needs to develop predictive expertise in population and ecology (biology) and simple harmonic motion and waves (physics). Similarly, Bard needs to develop predictive capabilities in modern physics and electronics and optics, in addition to requiring substantial enhancements in its overall predictive capabilities.

In summary, the implications and applications of this study on LLM and education are far-reaching. First, it could serve as a benchmark for evaluating and improving LLMs' performance in exams and other educational tasks, enhancing the overall effectiveness of these models in educational settings. Second, the use of LLMs as tutors, mentors, or peers has the potential to significantly enhance students' learning outcomes and motivation, particularly in a country such as India with a vast

student population and diverse learning needs. Last, this approach could serve as a platform to explore and address ethical and social concerns related to LLMs in education, such as issues of fairness, bias, privacy, and accountability, ensuring responsible and informed use of these models in educational contexts.

Limitations and Further Research

Similar to any other research, this study has certain limitations that should be considered carefully. It is important to note that this study did not involve direct input from actual students, teachers, or medical school boards to understand their perspectives on these mainstream LLMs' capability to answer questions on basic science concepts. Moreover, we do not know how prospective examinees are using these models for exam preparation or whether they trust them for critical issues such as exam preparation.

LLMs have evolved considerably just in the last 6 months. Therefore, the results of this study will have to be revisited at a later stage. For example, it is possible (and likely) that the relative performance of the different models will change over time. While Bard is currently lagging GPT-3.5 in this area, improvements to the model could mean that it might catch up to GPT-3.5 in the future. Since there is currently an "AI race" among many technology firms, it is only a matter of time before new models are introduced that could perform better on these types of questions.

Conclusion

In this study, we conducted a comparative analysis of 3 notable chatbots, Bard, GPT-3.5, and GPT-4, to evaluate their performance on NEET-2023, a highly competitive medical school entrance examination in India. The study involved the preparation of NEET-2023 questions for the chatbots, data collection, data analysis, and scoring performance assessments.

Our results indicate that GPT-4 not only passed the NEET-2023 entrance test with a score of 42.9% (300/700) but also demonstrated higher accuracy and consensus compared to both GPT-3.5 and Bard. Particularly, GPT-4 consistently outperformed the other models across subjects and topics, achieving an overall accuracy of approximately 54.3% (95/175).

GPT-3.5 and Bard, on the other hand, showed variations in their performances, with specific strengths in certain subjects and topics. Regarding subject-wise scoring, GPT-4 excelled in physics and biology while Bard performed well in chemistry.

These findings shed light on the proficiency of LLMs in answering high-stakes examination questions, particularly in the context of medical entrance exams such as the NEET. GPT-4's superior performance and accuracy suggest its potential utility as a valuable resource for medical students seeking assistance in test preparation and knowledge acquisition. However, it is essential to note that despite their impressive performance, LLMs such as Bard, GPT-3.5 and GPT-4 can sometimes generate text containing fabricated or incorrect information. This raises concerns about the credibility of information produced by LLMs, especially in educational settings where accuracy is crucial.

It is also important to acknowledge that LLMs, including GPT, come with both positive and negative consequences [37,38]. Friederichs et al [34] argue that the ability to acquire knowledge is a basic determinant of a physician's performance, and GPT-3.5 should be looked upon as a tool that provides easy access to a lot of relevant information, eventually aiding in clinical decision-making processes. On the other hand, Mbakwe et al [39] have commented that GPT-3.5's success on exams such as the USMLE demonstrates the flaws of medical education, which is "mostly focused on the rote memorization of mechanistic models of health and disease" and does not reward critical thinking to the same extent.

Further research and development are warranted to address the limitations and challenges posed by LLMs and ensure their reliable and accurate use in education and other domains. Moreover, future investigations can explore the suitability of LLMs for addressing the needs of diverse professional fields beyond medical entrance exams.

In conclusion, this study contributes valuable insights into the capabilities of Bard, GPT-3.5, and GPT-4 in handling high-stakes examination questions. As LLMs continue to evolve, their potential to revolutionize education and other industries remains promising, albeit with the need for continuous improvements and validation of their accuracy and reliability.

Abstract

Background: Previous research applying large language models (LLMs) to medicine was focused on text-based information. Recently, multimodal variants of LLMs acquired the capability of recognizing images.

Objective: We aim to evaluate the image recognition capability of generative pretrained transformer (GPT)-4V, a recent multimodal LLM developed by OpenAI, in the medical field by testing how visual information affects its performance to answer questions in the 117th Japanese National Medical Licensing Examination.

Methods: We focused on 108 questions that had 1 or more images as part of a question and presented GPT-4V with the same questions under two conditions: (1) with both the question text and associated images and (2) with the question text only. We then compared the difference in accuracy between the 2 conditions using the exact McNemar test.

Results: Among the 108 questions with images, GPT-4V's accuracy was 68% (73/108) when presented with images and 72% (78/108) when presented without images ($P=.36$). For the 2 question categories, clinical and general, the accuracies with and those without images were 71% (70/98) versus 78% (76/98; $P=.21$) and 30% (3/10) versus 20% (2/10; $P\geq.99$), respectively.

Conclusions: The additional information from the images did not significantly improve the performance of GPT-4V in the Japanese National Medical Licensing Examination.

Introduction

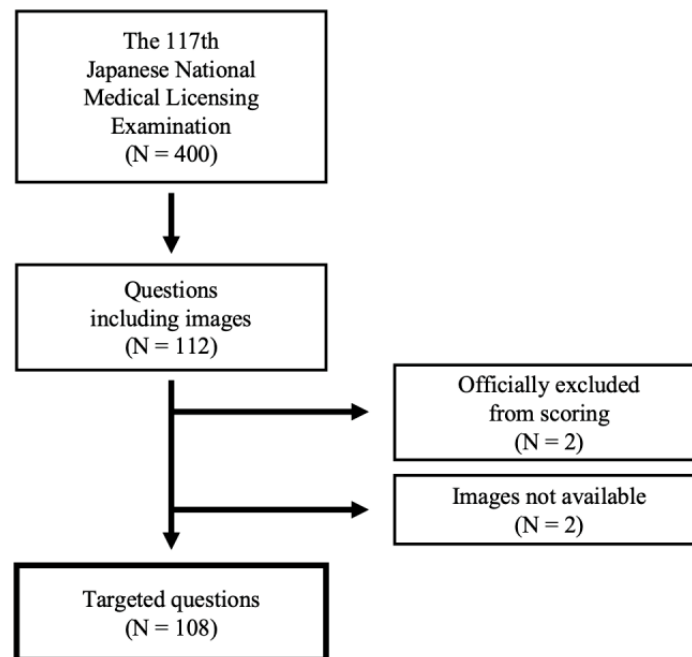

The field of natural language processing is rapidly developing with the advent of large language models (LLMs). LLMs are models trained with massive text data sets and achieve the capability to understand and generate text in natural languages. With the introduction of ChatGPT (OpenAI) [1] and other LLM-based chatbot services, many people have started to benefit

from the use of LLMs. Although ChatGPT and its underlying model, generative pretrained transformer (GPT) [2,3], were not specifically developed for medical purposes, they possess a considerable amount of medical knowledge. They have achieved good scores in the United States Medical Licensing Examination [4] and are being explored for various applications for clinical and educational purposes [5-7]. GPT can also understand languages other than English. The latest model, GPT-4, has

been reported to achieve passing scores in medical licensing examinations in non-English speaking countries such as Japan, China, Poland, and Peru [8-13].

Despite these successes, there is still a significant challenge in applying LLMs to real-world problems with non-text-based information. Radiological, pathological, and many other types of visual information play a crucial role in determining a patient's management. Very recently, researchers have proposed multimodal variants of LLMs that can handle not only text but various types of input including images [14]. Providing medical images to multimodal LLMs may realize an even higher accuracy in solving medical-related problems. However, in previous studies on the accuracy rate of medical licensing examinations, questions with images were either not mentioned at all or explicitly excluded from the studies. To the best of our knowledge, no study directly evaluated the performance in solving questions with images. Therefore, in this study, we investigated the image recognition capabilities and limitations of GPT-4V [3,15], one of the most potent publicly available multimodal (vision and language) models, in solving medical questions. We focused on the Japanese National Medical Licensing Examination to examine how the visual information affects GPT-4V's performance.

Figure 1. Summary of the questions included in this study.

The questions in the Japanese National Medical Licensing Examination were divided into 2 categories: clinical questions and general questions. In clinical questions, clinical information about a specific case is first presented, such as medical history and test results, and answers to questions about the case are required. General questions are about basic medical knowledge, and one is required to choose the correct answer among options for a short question text (typically of 1 or 2 sentences) with an image.

Some clinical questions consisted of multiple subquestions, in which case the background common to all the subquestions was

Methods

Overview

From the questions of the 117th Japanese National Medical Licensing Examination, held in February 2023, we focused on those that included images as part of a question. Since some of these questions can be answered correctly without interpreting images, we measured the benefit of adding image information by comparing the accuracy rates of ChatGPT under two different conditions: (1) with both the question text and associated images and (2) with the question text only.

Data Set Details

Figure 1 shows the summary of our data set. The questions and correct answers of the 117th Japanese National Medical Licensing Examination are publicly available for download on the official website of the Ministry of Health, Labour and Welfare [16]. All the questions are in a format in which a specified number of choices, typically 1, are to be selected from 5 options. Of the questions that had images, 2 were officially excluded from scoring because they were either too difficult or inappropriate. Additionally, for 2 questions, images of female genitals were not made public on the aforementioned website. These 4 questions were excluded from our study.

first described, followed by the subquestions. In such cases, each subquestion was individually included in the following analysis if either the subquestion itself or the background part contained an image.

As a result, counting subquestions individually, out of 400 questions, we collected 108 questions that had images, such as photographs of lesions, radiographic images, histopathological images, electrocardiograms, and graphs representing statistical data. Among them, 98 were clinical questions and 10 were general questions.

Experimental Details

We used ChatGPT (September 25, 2023, version) enabled with GPT-4V, which is a multimodal model capable of processing both text and images. This version of ChatGPT asserts it was trained with information up to January 2022, meaning that it had no direct prior knowledge about our target examination. All the question statements and images were manually entered through ChatGPT's web interface. One of the authors, TN, who has 10 years of experience as a medical doctor, reviewed the outputs to interpret the response output by ChatGPT.

A new chat session was created for each question and each condition (ie, with or without images). For questions that comprised multiple subquestions, the background information part and each subquestion were entered into ChatGPT in this order within the same chat session. Subquestions without images were also input to provide ChatGPT with enough context, but they were excluded from the accuracy calculations and the subsequent statistical analysis described below.

The questions were presented to ChatGPT without any preceding or custom instructions. Sometimes, ChatGPT did not respond with the specified number of choices, in which case an additional instruction, such as "select only one option" or "select two options," was provided in Japanese. This additional instruction produced the correct number of options for all the questions.

Statistical Analysis

The difference in ChatGPT's performance between the 2 conditions (ie, with or without images) was analyzed using the

exact McNemar test. A P value of less than .05 was considered statistically significant. The analysis was conducted using R (version 4.3.1; R Foundation for Statistical Computing).

Ethical Considerations

This study was conducted solely using publicly available resources, therefore, approval from the institutional review board of our institution was not required.

Results

Table 1 shows the results of our experiment. ChatGPT correctly answered 68% (73/108) of image-based questions when provided with both the question text and images, whereas it correctly answered 72% (78/108) of image-based questions when only the question text was provided. There was no significant difference in accuracy between these 2 conditions ($P=.36$). For the clinical questions, the accuracies when presented with and without images were 71% (70/98) and 78% (76/98), respectively. For the general questions, the accuracies were 30% (3/10) when presented with images and 20% (2/10) without images. We have included examples of the input and output along with their English translations in [Multimedia Appendix 1](#), and we have also provided a summary of image interpretation for each question where the results differed depending on the presence of image input (N=7+12) in [Multimedia Appendix 2](#).

Table 1. Performance of ChatGPT in answering questions from the 117th Japanese National Medical Licensing Examination, when presented with or without associated images for each question.

	With images		Total
	Correct	Incorrect	
Overall ($P=.36$)			
Without images, n (%)			
Correct	66 (61)	12 (11)	78 (72)
Incorrect	7 (6)	23 (21)	30 (28)
Total	73 (68)	35 (32)	108 (100)
Clinical ($P=.21$)			
Without images, n (%)			
Correct	65 (66)	11 (11)	76 (78)
Incorrect	5 (5)	17 (17)	22 (22)
Total	70 (71)	28 (29)	98 (100)
General ($P\geq.99$)			
Without images, n (%)			
Correct	1 (10)	1 (10)	2 (20)
Incorrect	2 (20)	6 (60)	8 (80)
Total	3 (30)	7 (70)	10 (100)

Discussion

Principal Results

In this study, we examined the image recognition capabilities of GPT-4V using questions associated with images from the Japanese National Medical Licensing Examination. To the best of our knowledge, this is the first study in which the capability of multimodal LLM for the Japanese National Medical Licensing Examination was investigated. Contrary to our initial expectations, the inclusion of image information did not result in any improvement in accuracy. Instead, we even observed a slight decrease, albeit not significant. This indicates that, at the moment, GPT-4V cannot effectively interpret images related to medicine. The passing score rate for the 117th Japanese National Medical Licensing Examination is approximately 75% (and 80% for some questions marked as “essential”) [16]. In this study, GPT-4V failed to reach this passing score rate for the questions it was tested on. Considering that 92% of human candidates passed, it implies that the image interpretation skills of GPT-4V will fall short of those possessed by many medical students.

For the clinical questions, in which sufficient clinical information including patient history was available in the text form, GPT-4V was able to choose the correct answers solely from the textual information in the majority (76/98, 78%) of questions, but the addition of images did not improve the accuracy. On the other hand, for the general questions, there was little information in the question text, and GPT-4V had to determine the correct answer by interpreting the images. For these, GPT-4V yielded an accuracy rate that was hardly any better than random guessing even when presented with images. Our results suggest that, for both categories of questions, GPT-4V failed to use visual information to improve its accuracy. We observed that GPT-4V often either explicitly stated that it was unable to interpret the images or failed to provide information beyond what was evident from the question text. In our retrospective review, even in questions where GPT-4V gave correct answers only when presented with images, there were only 2 out of 7 questions where it provided a correct interpretation of the image and used that as a critical clue. Conversely, in questions where GPT-4V provided incorrect answers only when presented with images, it sometimes made incorrect or insufficient interpretations of the images, leading to incorrect answers (4 out of 12).

ChatGPT may serve as a valuable teaching assistant in medical education; however, the inaccuracies in its responses are a significant concern [5,7]. Our current findings suggest that, especially with medical-related images, GPT-4V should not be relied upon as a primary source of information for medical education or practice. If used, extreme caution should be exercised regarding the accuracy of its responses. OpenAI officially states [15] that they “do not consider the current version of GPT-4V to be fit for performing any medical function or substituting professional medical advice, diagnosis, or treatment, or judgment” due to its imperfect performance in the medical domain. Yang et al [17] have comprehensively examined the capabilities of GPT-4V in various tasks including

medical image understanding and radiology report generation, and they stated that GPT-4V could correctly diagnose some medical images. However, as they acknowledge, their results contained a considerable number of errors, such as overlooking obvious lesions and errors in laterality. According to the case studies by Wu et al [18], GPT-4V could recognize the modality and anatomy of medical images, but it could hardly make accurate diagnoses and its prediction relied heavily on the patient’s medical history. The results of our experiment supported these previous reports.

Considering the well-known high performance of GPT-4V in more generic image recognition tasks [3,17], the most probable reason for its limited image recognition performance in the medical field is that it may simply not have been trained with a sufficient number of medical-related images. LLMs are trained with a vast data set available on the internet, but medical images are not as readily accessible, partly due to privacy concerns. Some researchers are now working on developing multimodal LLMs specialized for medicine based on open-source LLMs [19,20]. These models use publicly available data sets that combine medical images and text, including MIMIC-CXR [21], which contains chest x-ray images with their associated reports, and PMC-OA [22], a compilation of the figures and captions from open-access medical journal papers. The rise of multimodal LLMs is expected to stimulate the publication of more such data sets, thereby advancing the development of multimodal LLMs in the medical field. Moreover, although there are limited medical-related images publicly available on the internet, hospitals have a vast amount of image data. A large part of this is accompanied by textual interpretations in the form of reports or medical records, which may serve as an ideal data set for training multimodal LLMs. In highly specialized domains such as medicine, there remains a significant value in developing domain-specific models using such medical data sets.

Limitations

This study had several limitations. First, ChatGPT was not provided any prior instructions and was directly presented with only the questions themselves. This might have negatively affected its capability to interpret images as the capabilities of LLMs are known to be affected by such “prompt engineering.” This will be a subject for future investigation. Second, this study specifically targeted the Japanese National Medical Licensing Examination, and thus, further analysis is necessary to determine whether its conclusions can be generalized to questions in other languages or of different types. However, as mentioned earlier, the limited capability of GPT-4V to interpret medical images has also been demonstrated in other studies focusing on English [17,18], and our results are consistent with those findings. Since ChatGPT’s proficiency in non-English interpretation is known to be inferior to that in English interpretation, translating the question text into English before inputting it to ChatGPT might have improved the model’s image interpretation capability. However, in a previous study by Yanagita et al [10], in which nonimage questions from the Japanese National Medical Licensing Examination were the target, satisfactory results were achieved even when the questions were input in Japanese. Thus, we adopted the same approach in our study. Third, although our results were based on the same version of ChatGPT and the

same question was evaluated with and without images on the same day, we cannot exclude the possibility that different models were used internally. Lastly, only a single evaluation was conducted for each condition and question. ChatGPT's outputs have some randomness, and responses may differ across multiple evaluations. With ChatGPT's application programming interface, users can programmatically control the degree of randomness by specifying a parameter called *temperature* and

obtain mostly deterministic responses. However, during the time of this study, the application programming interface for GPT-4V was not available.

Conclusions

At present, GPT-4V's capability to interpret medical images may be insufficient. In highly specialized fields such as medicine, it is considered meaningful to develop field-specific multimodal models.

Abstract

Background: Artificial intelligence models can learn from medical literature and clinical cases and generate answers that rival human experts. However, challenges remain in the analysis of complex data containing images and diagrams.

Objective: This study aims to assess the answering capabilities and accuracy of ChatGPT-4 Vision (GPT-4V) for a set of 100 questions, including image-based questions, from the 2023 otolaryngology board certification examination.

Methods: Answers to 100 questions from the 2023 otolaryngology board certification examination, including image-based questions, were generated using GPT-4V. The accuracy rate was evaluated using different prompts, and the presence of images, clinical area of the questions, and variations in the answer content were examined.

Results: The accuracy rate for text-only input was, on average, 24.7% but improved to 47.3% with the addition of English translation and prompts ($P < .001$). The average nonresponse rate for text-only input was 46.3%; this decreased to 2.7% with the addition of English translation and prompts ($P < .001$). The accuracy rate was lower for image-based questions than for text-only questions across all types of input, with a relatively high nonresponse rate. General questions and questions from the fields of head and neck allergies and nasal allergies had relatively high accuracy rates, which increased with the addition of translation and prompts. In terms of content, questions related to anatomy had the highest accuracy rate. For all content types, the addition of translation and prompts increased the accuracy rate. As for the performance based on image-based questions, the average of correct answer rate with text-only input was 30.4%, and that with text-plus-image input was 41.3% ($P = .02$).

Conclusions: Examination of artificial intelligence's answering capabilities for the otolaryngology board certification examination improves our understanding of its potential and limitations in this field. Although the improvement was noted with the addition of translation and prompts, the accuracy rate for image-based questions was lower than that for text-based questions, suggesting room for improvement in GPT-4V at this stage. Furthermore, text-plus-image input answers a higher rate in image-based questions. Our findings imply the usefulness and potential of GPT-4V in medicine; however, future consideration of safe use methods is needed.

Introduction

Advancements in artificial intelligence (AI) in the field of medicine have led to revolutionary changes in diagnosis, treatment, and education. The evolution of natural language processing technologies has significantly affected medical education and evaluation methods [1,2]. The use of large-scale language models contributes to the optimization of complex problem-solving and learning processes, and the effectiveness of these models has been reported in Japanese medicine [3-5]. These AI models can learn from medical literature and clinical cases and generate answers that rival those of human experts.

We have verified the effectiveness of large-scale language-processing models in medical licensing and otolaryngology board certification examinations [6]. Although a certain level of accuracy has been achieved through prompt engineering, these validations have been primarily limited to text-based information processing, and challenges remain in

the analysis of complex medical data containing images and diagrams.

ChatGPT-4 Vision (GPT-4V), announced on September 25, 2023, includes the addition of image input capabilities, potentially expanding its application in the medical field [7]. The current version of the model includes information up to April 2023; it does not encompass the 2023 board examination.

In this study, we aimed to assess the answering capabilities and accuracy of GPT-4V using 100 questions, including image-based questions, from the 2023 otolaryngology board certification examination.

Methods

We evaluated the performance of GPT-4V (Open AI), the latest version of the generative pretrained transformer (GPT) model, using 100 questions from the 2023 otolaryngology specialist examination, which was held on August 5, 2023 (54 text-only and 46 image-based questions; Figure 1).

Figure 1. Study overview. GPT-4V: ChatGPT-4 Vision.

The study design was based on previously reported methods and compared the effectiveness of the following four GPT-4V input approaches: (1) direct input of the question text and images, (2) input of the question text with Japanese prompts added, (3) input of the question text after translation to English, and (4) input of the translated question text with English prompts added [5,6,8] (examples images of prompts for English translation and answering medical questions; Figure S1 in Multimedia Appendix 1).

Each approach was implemented 3 times to evaluate its accuracy. All inputs were entered manually, and both questions and answers were independently scrutinized by otolaryngology specialists (MN and TU) to ensure medical validity [9].

We compiled the correct answer rate and the number of answered and unanswered questions, then conducted an analysis based on the presence of images, the different prompts, the content of the questions, and the associated fields. In addition, the case in which the respondent with no options, and refrained from giving a medical answer was counted as “Output errors.”

Questions were categorized into fields, such as ear; nasal allergy; speech, swallowing, and larynx; oropharynx; head and neck; general; and infectious disease. Question content was classified as treatment, details of the disease and diagnosis, examination,

anatomy, systems, and others. Image-based questions were classified as photographs (endoscopic images, microscopic images, and gross photographs), radiological images (computed tomography, magnetic resonance imaging, and positron emission tomography), graphs (audiogram, olfactometry, polysomnography, electronystagmography, etc), and histopathological images.

Finally, to examine the impact of image-based questions on the program’s ability to respond, we compared the responses to text-only questions with those to questions that included figures. We then added an English translation of the text (including the text provided along with figures) and analyzed the difference.

Regarding statistical methods, comparisons among 3 or more groups were performed using 1-way ANOVA. Subsequently, multiple comparison tests (Bonferroni method) were used to compare each group, while comparisons between 2 groups were conducted using the 2-tailed Student *t* test. A significance level of .05 was set for determination.

Results

Performance Evaluation Based on Prompt Type

Input of only the question text resulted in an average correct answer rate of 24.7% (23%, 26%, and 25% in the first, second, and third rounds, respectively). When Japanese prompts were

added, the average increased to 36.7% (38%, 33%, and 39%, respectively; $P=.002$); with translation to English, the average rate was 31.3% (33%, 31%, and 30%, respectively; $P=.06$); and with the addition of English translation and English prompts, the average increased to 47.3% (44%, 49%, and 49%, respectively; $P<.001$). The results of all input methods are shown in [Table 1](#).

Table 1. Results of each input method.

Results	Japanese			Japanese with prompt			English			English with prompt		
	Text-only	Image-based	Total	Text-only	Image-based	Total	Text-only	Image-based	Total	Text-only	Image-based	Total
Questions, n	54	46	100	54	46	100	54	46	100	54	46	100
Correct answers, n (%)	23.0 (41.5)	1.7 (3.7)	24.7 (24.7)	25.0 (46.3)	11.7 (25.4)	36.7 (36.7)	23.7 (43.8)	7.7 (16.7)	31.3 (31.3)	28.3 (52.5)	19.0 (41.3)	47.3 (47.3)
Incorrect answers, n	26.0	3.0	29.0	26.0	15.7	41.7	26.3	14.7	41.0	25.3	24.3	50.0
Output errors, n (%)	6.3 (11.4)	40.0 (89.6)	46.3 (46.3)	3.0 (5.6)	18.7 (39.1)	21.7 (21.7)	4.0 (7.4)	23.7 (51.5)	27.7 (27.7)	0.3 (0.6)	2.7 (5.8)	2.7 (2.7)

The nonresponse rate after input of only the question text was, on average, 46.3%. With Japanese prompts, it was 21.7% ($P<.001$). After translation to English, the average was 27.7% ($P=.002$), and with English prompts, it decreased to an average of 2.7% ($P<.001$).

Performance Based on the Presence of Images

There were 46 questions with images, and 54 were text-only. Text-only questions had a higher correct answer rate than that for image-based questions. However, the addition of English translation and prompts significantly increased the correct answer rate, even for questions with images.

The nonresponse rate for image-based questions was higher than that for text-only questions (11.4% vs 89.6%, respectively; [Table 1](#)). With Japanese prompts, the nonresponse rates were 5.6% and 39.1%, respectively. With English translation, they were 7.4% and 51.5%, respectively. With the addition of English translation and prompts, they significantly decreased to 0.6% and 5.8%, respectively.

Correct Answer Rates Based on the Question's Field

As shown in [Table 2](#), general questions and those from the fields of head and neck and nasal allergies had relatively high correct answer rates.

Table 2. Results based on the question's field.

Results	Ear	Nasal allergy	Speech, swallowing, and larynx	Oropharynx	Head and neck	General	Infectious disease
Questions, n	29	18	18	11	10	11	3
Japanese							
Correct answers, n (%)	5.0 (17.2)	6.0 (33.3)	1.7 (9.3)	2.0 (18.2)	3.0 (30)	8.0 (72.7)	0.0 (0)
Incorrect answers, n	9.7	7.0	5.0	2.3	2.0	2.0	0.0
Japanese with prompt							
Correct answers, n (%)	7.7 (26.4)	10.3 (57.4)	3.7 (20.4)	3.0 (27.3)	4.3 (43.3)	6.3 (57.6)	1.3 (44.4)
Incorrect answers, n	13.7	4.0	9.7	6.0	3.7	3.3	1.3
English							
Correct answers, n (%)	8.3 (28.7)	9.0 (50)	1.3 (7.4)	4.0 (36.4)	4.7 (46.7)	6.7 (60.6)	0.3 (11.1)
Incorrect answers, n	14.0	1.7	8.7	4.7	3.7	3.3	2.0
English with prompt							
Correct answers, n (%)	9.7 (33.3)	11.3 (63)	7.0 (38.9)	4.7 (42.4)	7.3 (73.3)	6.3 (57.6)	1.0 (33.3)
Incorrect answers, n	18.3	6.0	11.0	6.3	2.7	3.7	2.0

For the fields of head and neck and nasal allergies, respectively, with text-only input, the rates were 72.7%, 30%, and 33.3%, respectively. With Japanese prompts, they were 57.6%, 43.3%, and 57.4%, respectively. With English translation, they were 60.6%, 46.7%, and 50%, respectively. With English translation and prompts, they were 57.6%, 73.3%, and 63%, respectively. Furthermore, in all fields, the correct answer rate improved with the addition of English translation and prompts.

Correct Answer Rates Based on Question Content

As shown in [Table 3](#), questions related to anatomy had the highest correct answer rates: 44.4% for question text only, 55.6% with Japanese prompts, 51.9% with English translation, and 66.7% with English translation and prompts. The correct answer rates for all question content categories improved with the addition of English translation and prompts.

Table 3. Results based on question content.

Results	Treatment	Details of the disease and diagnosis	Examination	Anatomy	Systems	Others
Questions, n	37	32	13	9	7	2
Japanese						
Correct answers, n (%)	6.7 (18)	7.0 (21.9)	3.0 (23.1)	4.0 (44.4)	3.0 (42.9)	2.0 (100)
Incorrect answers, n	13.7	9.3	7.0	2.0	1.0	0.0
Japanese with prompt						
Correct answers, n (%)	12.7 (34.2)	11.0 (34.4)	4.0 (30.8)	5.0 (55.6)	2.0 (28.6)	2.0 (100)
Incorrect answers, n	14.7	15.7	8.0	1.7	1.7	0.0
English						
Correct answers, n (%)	10.0 (27)	10.7 (33.3)	4.0 (30.8)	4.7 (51.9)	3.0 (42.9)	2.0 (100)
Incorrect answers, n	14.7	13.3	7.0	2.0	1.0	0.0
English with prompt						
Correct answers, n (%)	16.7 (45)	14.3 (44.8)	4.7 (35.9)	6.0 (66.7)	3.7 (52.4)	2.0 (100)
Incorrect answers, n	19.7	17.0	8.3	2.7	2.3	0.0

Correct Answer Rates of Image-Based Questions According to the Type of Image

Table 4 shows the results for each type of figure among the 46 image-based questions. There were 23 questions based on photographs, 11 questions based on radiological images, 8 questions based on graphs, and 4 questions based on

histopathological images. While the percentage of correct answers for questions based on radiological images was relatively high, this percentage was low for questions based on graphs, such as physiological tests. In the English translation and prompts, the percentage of correct answers for questions based on radiological images was 51.5%, while that for questions based on graphs was 29.2%.

Table 4. Results for image-based questions discriminated according to the type of image.

Results	Photograph	Radiological image	Graph	Histopathological image
Questions, n	23	11	8	4
Japanese				
Correct answers, n (%)	0.7 (2.9)	0.0 (0)	1.0 (12.5)	0.0 (0)
Incorrect answers, n	0.0	2.0	1.0	0.0
Japanese with prompt				
Correct answers, n (%)	5.7 (24.6)	3.3 (30.3)	2.0 (25)	0.7 (16.7)
Incorrect answers, n	7.7	4.0	1.3	1.7
English				
Correct answers, n (%)	2.7 (11.6)	2.7 (24.2)	2.0 (25)	0.3 (8.3)
Incorrect answers, n	8.3	4.0	1.7	1.0
English with prompt				
Correct answers, n (%)	9.3 (40.6)	5.7 (51.5)	2.3 (29.2)	1.7 (41.7)
Incorrect answers, n	12.0	5.0	5.0	2.3

Performance Based on Image-Based Questions Text-Only Input Versus Text-Plus-Image Input

Figure 2 shows the performance of GPT-4V based on imaged-based questions with text-only input and with text-plus

image input. On image-based questions with text-only input, the average correct answer rate was 30.4%; and with text-plus-image input, the average correct answer rate was 41.3% ($P=.02$; Figure 2).

Figure 2. Performance of ChatGPT-4 Vision on image-based questions.

Discussion

Principal Results

In this study, we evaluated the accuracy of GPT-4V in answering 100 questions, including 46 image-based and 54 text-only questions, from the 2023 otolaryngology board certification examination. The results confirmed that the accuracy was higher for text-only questions than for image-based questions. As for the performance of figure recognition, the correct answer rate with text-plus-image input was higher than that with text-only-input. Moreover, we found that the accuracy improved with the addition of English translations and prompts, but responses were often avoided for simple question inputs, suggesting limitations in medical responses. Variability in accuracy was also evident depending on the field and content of the questions.

Our findings showed that the accuracy of GPT-4V for image-based questions was lower than that for text-only questions. This suggests that, although AI excels at analyzing textual information, it still has limitations in analyzing image-based data [10]. Medical images contain complex and diverse information that requires specialized knowledge for interpretation. Therefore, AI remains inferior to human experts. To improve the accuracy of AI for image analysis, further studies on specialized prompts, the development of more advanced image-recognition technologies, and training focused on medical images are necessary.

Comparison With Prior Work

In relation to medical education, the performance of GPT on licensing examinations and specialist-level medical examinations has been verified and reported [1,11-14]. In English-speaking regions, relatively high accuracy rates have been reported [1,14], whereas in non-English-speaking regions, there is variability [11-13,15]. In addition, accuracy rates differ not only by language but also by the type of examination. Generally, there are more favorable reports for national medical licensing examinations, while there are comparatively poorer reports for

specialist-level exams [16,17]. Even when looking at Japanese language reports, while national examinations and general practice examinations have shown good results [3-5,18], ophthalmology, pharmacist, nursing, and dentistry examinations have around a 50%-70% accuracy rate [19-22], with the otolaryngology field in this study showing comparable results [6]. In our previous study, the otolaryngology field tended to have a higher frequency of wrong answers for questions about the ear, larynx, and voice, as well as for questions about examination and treatment. This trend has not changed, suggesting that there are strengths and weaknesses within the specialty. Although the percentage of correct answers was lower for image-based questions than for text-only questions, the percentage of correct answers for text-only questions was higher for general and nasal allergy questions compared with those associated with other question areas, which may have affected the difference in the percentage of correct answers according to the specific field. It is believed that there is room for improvement in GPT's performance, especially in highly specialized fields.

Regarding the effectiveness of prompts for image-based questions, there are reports that the additional input of figures is no different from the input of text only in the Japanese National Medical Practitioners' Examination [23]. On the other hand, in our study, the percentage of correct answers was approximately 10% higher when figures and text were added compared with text-only input. In addition, among the image-based questions, the percentage of correct responses was lower for questions related to physiological tests such as hearing tests and polysomnography than for questions related to radiography and microscopy images.

Although there are likely to be differences in the ability to recognize diagrams depending on the field and specialization, it is thought that the search for dedicated prompts, the development of more advanced image recognition techniques, and training specific to medical images will be necessary to further improve the accuracy of image analysis. Converting the physiological tests so that they can be recognized as numerical

values rather than image recognition could further increase the percentage of correct responses.

The fact that accuracy improved with the addition of English translations and prompts suggests AI is optimized for specific formats and languages. The processing capabilities of GPT-4 for text are specialized in English, and the addition of English prompts was believed to increase the likelihood of generating more accurate answers. Our findings further showed that prompts can enhance the quality of AI answers. This effect was valid for image-based as well as text-only questions, emphasizing the need for effective prompts for medical images.

Limitations

The frequent avoidance of generating answers for simple inputs indicates the limitations of AI in terms of complex medical concepts and specialized knowledge. In the medical field, many problems require specific expertise and contexts, making it challenging for AI to provide adequate answers. Furthermore, the issue of hallucinations, where incorrect answers are presented as if they were correct, has become problematic. This includes instances where AI ignores specific facts, engages in illogical reasoning, or fails to apply concepts to new situations [14,24,25]. There is also concern that such inaccuracies could present barriers to direct comprehension by patients,

necessitating careful consideration of how AI is used in practice [26].

In addition, the correlation between the difficulty level for specialists and the difficulty level for GPT-4V is not clear, since neither the percentage of correct answers per question nor the minimum number of correct answers required to pass the examination have been reported. Understanding the difference would allow for further consideration of the situations in which the GPT-4V is used. This highlights the importance of understanding these limitations and appropriately using AI in medical education and clinical diagnoses within the otolaryngology field. Though AI suggestions should be considered when making medical judgments, medical professionals need to make the final decisions.

Conclusions

GPT-4V demonstrated a certain level of accuracy for the 2023 otolaryngology board certification examination, and text-plus-image input increased the accuracy of image-based questions. However, the capabilities of AI for image-based questions were limited. Our findings can form the basis for further research and development of the application of AI in the medical field. Future studies should focus on improving the capabilities of AI in image analysis, designing more effective prompts, and developing multilingual support.

Abstract

ChatGPT (OpenAI), a cutting-edge natural language processing model, holds immense promise for revolutionizing medical education. With its remarkable performance in language-related tasks, ChatGPT offers personalized and efficient learning experiences for medical students and doctors. Through training, it enhances clinical reasoning and decision-making skills, leading to improved case analysis and diagnosis. The model facilitates simulated dialogues, intelligent tutoring, and automated question-answering, enabling the practical application of medical knowledge. However, integrating ChatGPT into medical education raises ethical and legal concerns. Safeguarding patient data and adhering to data protection regulations are critical. Transparent communication with students, physicians, and patients is essential to ensure their understanding of the technology's purpose and implications, as well as the potential risks and benefits. Maintaining a balance between personalized learning and face-to-face interactions is crucial to avoid hindering critical thinking and communication skills. Despite challenges, ChatGPT offers transformative opportunities. Integrating it with problem-based learning, team-based learning, and case-based learning methodologies can further enhance medical education. With proper regulation and supervision, ChatGPT can contribute to a well-rounded learning environment, nurturing skilled and knowledgeable medical professionals ready to tackle health care challenges. By emphasizing ethical considerations and human-centric approaches, ChatGPT's potential can be fully harnessed in medical education, benefiting both students and patients alike.

KEYWORDS

artificial intelligence; AI; ChatGPT; medical education; doctors; medical students

Introduction

ChatGPT, whose name is derived from “generative pre-trained transformer,” is a large natural language processing model grounded in artificial intelligence (AI) technology, demonstrating remarkable performance across various language-related tasks [1]. Within the realm of medical education, ChatGPT emerges as a highly promising tool with considerable potential [2]. Through training in the ChatGPT model, medical students and doctors can enhance their clinical

reasoning and decision-making capabilities, consequently leading to improved performance in case analysis and diagnosis. Moreover, ChatGPT offers personalized and efficient learning experiences for medical learners by facilitating simulated dialogues, providing intelligent tutoring, and offering automated question-answering, thereby deepening students' comprehension of medical knowledge [3].

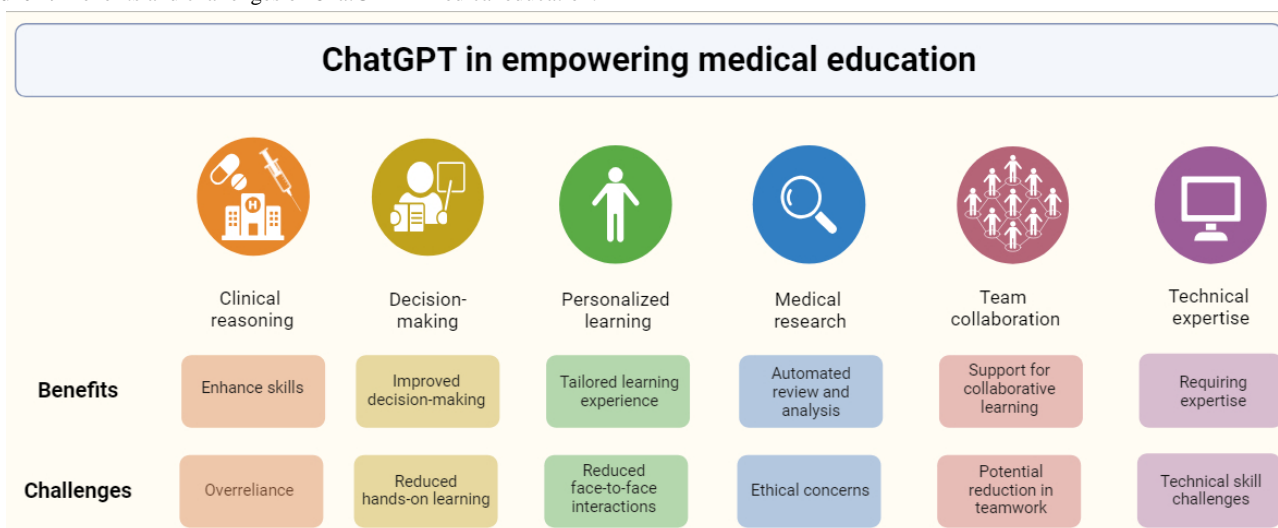

In the realm of transformative technologies in medical education, ChatGPT prominently distinguishes itself, standing out from other large language models by virtue of its unique architecture

and comprehensive training data [4,5]. A pivotal factor setting ChatGPT apart is its monumental scale, boasting an impressive 175 billion parameters. This scale-driven proficiency contrasts starkly with smaller models that may struggle when confronted with complicated queries or tasked with producing coherent replies. With its intricate architectural foundation, ChatGPT possesses the capability to comprehend and generate human-like text across a diverse spectrum of topics, showcasing remarkable coherence and context awareness. What renders the ChatGPT truly distinctive is its specialized focus on fostering dynamic and coherent conversations, thereby excelling in maintaining context over extended interactions. This stands in stark contrast to models primarily designed for single-turn tasks. In educational contexts such as problem-based learning (PBL), team-based learning (TBL), case-based learning (CBL), and precision medical education, ChatGPT takes center stage as a focal point,

primarily due to its potential to elevate dynamic learning experiences.

Nevertheless, obstacles occur in the implementation of ChatGPT [6]. On the one hand, the effective training and use of the model requires a high level of technical expertise and skill. On the other hand, concerns related to data security and ethical considerations demand careful attention. To fully harness the potential of ChatGPT in medical education, these challenges must be overcome and concerted efforts should be directed toward integrating AI technology with medical education. By leveraging the capabilities of ChatGPT alongside these innovative teaching approaches, medical education can achieve new heights, fostering a generation of skilled and knowledgeable medical professionals ready to tackle the challenges of the health care field. This paper aims to illuminate both the benefits and the challenges of ChatGPT in medical education (Figure 1).

Figure 1. Benefits and challenges of ChatGPT in medical education.

Potential Benefits of ChatGPT in Medical Education

Overview

In the context of medical education, ChatGPT holds immense promise for bolstering the clinical reasoning and decision-making abilities of medical students and physicians [7]. By training the ChatGPT model, medical learners can tap into its powerful natural language generation and understanding capabilities to master the methods and skills of clinical reasoning and decision-making [8,9]. These competencies are critical components of medical education and fundamental skills that medical students and physicians must possess.

Educational Paradigms: Traditional Vs Enhanced by ChatGPT

Traditional medical education typically follows a teacher-centric approach, where the content and pace of learning are determined

mainly by instructors. This often leads to passive student engagement and a lack of personalized education that caters to individual differences. However, the introduction of ChatGPT allows for more personalized and efficient medical education (Table 1). By generating learning materials based on each student's learning status and needs, ChatGPT empowers students to take a more autonomous approach to learning and gain a customized educational experience aligned with their preferences [10,11]. For instance, students can engage in simulated dialogues with ChatGPT, discussing medical cases and diagnostic approaches. Additionally, ChatGPT can adapt based on students' feedback and performance, providing personalized intelligent tutoring and answering questions. This personalized dialogue approach can be tailored to each student's unique needs and interests, thereby enhancing their grasp of medical knowledge and skills.

Table 1. Comparison between traditional medical education and medical education with ChatGPT.

Aspect	Traditional medical education	Medical education with ChatGPT
Clinical reasoning	Instructor-led lectures and traditional case discussions	Enhanced clinical reasoning, personalized dialogues, and simulated case analyses
Decision-making	Limited case exposure	Diverse cases and diagnostic approaches
Personalized learning	One-size-fits-all learning materials and standardized assessments	Tailored learning materials, intelligent tutoring, and automated question-answering based on individual progress
Interaction with educators	Limited face-to-face interactions	Continuous personalized feedback
Medical research support	Manual review and analysis	Automated literature review, study design proposals, and statistical analysis
Team collaboration	Emphasizes group discussions and teamwork	Balancing personalized learning and team-based activities
Technical expertise and challenges	Less reliance on technology	Skill in using ChatGPT
Ethical considerations	Data privacy and consent	Addressing ethical implications

ChatGPT Intelligent Tutoring in PBL Integration

The integration of ChatGPT holds promising implications for PBL in medical education. ChatGPT's capacity to offer personalized guidance and stimulate critical thinking aligns seamlessly with the core principles of PBL [12]. In this context, ChatGPT functions as an intelligent tutor, adept at steering students through intricate problems by furnishing pertinent information, detailed explanations, and insightful suggestions. The model's ability to dynamically adjust responses to student queries contributes to creating a vibrant and responsive learning environment. Students can leverage ChatGPT to brainstorm potential solutions, collect relevant research, or validate hypotheses during the problem-solving process [13]. Furthermore, the model can generate patient cases or clinical scenarios based on real-world data, enabling students to apply their knowledge to practical situations. It is essential to design PBL activities that seamlessly incorporate both the advantages offered by ChatGPT and the indispensable experience derived from clinical practice. By maintaining a focus on group discussions and collaborative problem-solving based on actual patient cases, educators ensure that students reap the benefits of ChatGPT's enhancements while retaining the essential skills cultivated through hands-on clinical interactions and in-depth case analyses. As technology continues to advance, it remains imperative to uphold patient-based learning as the cornerstone of medical education. Recognizing that, at its current stage, ChatGPT cannot entirely replace the critical skills honed through genuine patient interactions and the nuanced analysis of complex cases is vital for preserving the integrity and effectiveness of medical education.

Synergizing ChatGPT With Other Collaborative Teaching Methods

ChatGPT's application in medical education should be complemented by other teaching methods, such as CBL, TBL, and small-group sessions. The model's ability to generate diverse perspectives and solutions enhances the overall TBL experience [14]. In CBL scenarios, ChatGPT can function as a case facilitator, generating realistic scenarios, asking probing questions, and providing nuanced feedback. It can simulate authentic patient interactions or complex business dilemmas,

allowing learners to apply theoretical knowledge to practical situations. The model's adaptability ensures that the cases presented are tailored to the evolving needs and understanding of the learners. Within the TBL framework, ChatGPT can facilitate collaboration among team members by offering real-time assistance and promoting knowledge sharing. It can contribute to group discussions, help clarify concepts, and prompt critical thinking among team members. ChatGPT can also facilitate preclass preparation by providing students with foundational knowledge and resources related to the upcoming TBL session. By integrating ChatGPT with these methods, medical educators can create a well-rounded learning experience that maximizes the benefits of both individualized learning and TBL. To enhance team collaboration abilities, medical institutions should prioritize the development of medical students through interprofessional education, where students from different health care disciplines collaborate. Encouraging student-led initiatives and group projects also fosters collaboration, leadership, and effective communication among future medical professionals. This multifaceted approach ensures a well-rounded learning experience, maximizing the benefits of both individualized and collaborative learning while preparing students for the complex challenges of the health care field.

ChatGPT in Precision Medical Education

In the evolving landscape of medical education, the concept of precision medical education has gained prominence [15]. This approach aligns with current trends, notably competency-based medical education (CBME) and pedagogical approaches such as PBL, CBL, and TBL [16]. Precision medical education emphasizes tailoring learning experiences to individual student needs, aligning with the principles of personalized and adaptive learning championed by ChatGPT. CBME focuses on learners progressing at their own pace, demonstrating proficiency in specific competencies. ChatGPT's intelligent tutoring and adaptability make it a valuable tool in supporting this competency-based model. By providing personalized guidance, generating relevant content, and fostering critical thinking, ChatGPT contributes to a more precise and effective medical education tailored to each learner's requirements [17]. Furthermore, the integration of ChatGPT with collaborative teaching methods enhances the multifaceted nature of precision

medical education. In scenarios like CBL and TBL, ChatGPT assists learners in navigating complex medical cases, fostering collaborative problem-solving skills essential for modern health care practice. This approach ensures that students not only acquire essential competencies but also develop the ability to collaborate across health care disciplines, aligning with the interprofessional education framework.

As medical education continues to advance, the incorporation of precision medical education, supported by technologies like ChatGPT, becomes imperative. This tailored approach ensures that medical professionals are equipped with the diverse skills needed to address the complexities of contemporary health care, providing a comprehensive and forward-thinking educational experience.

Empowering Medical Research With ChatGPT

ChatGPT proves to be a valuable asset in medical research [18]. The intricate relationship between medical research and education, as aligned with the standards and roles outlined by the World Federation for Medical Education (WFME) [19] and Canadian Medical Education Direction System (CanMEDS) [20], not only provides a profound and practical foundation for medical education but also aligns with the comprehensive development requirements for medical professionals. This close connection ensures that medical education remains consistent with the latest advancements in medical science, fostering the cultivation of well-rounded medical practitioners. Medical research relies heavily on extensive literature to support its content and conclusions. However, reading and analyzing vast amounts of literature can be time-consuming and labor-intensive. ChatGPT streamlines research by automating literature review and analysis. Additionally, ChatGPT aids medical researchers in study design and data analysis [21]. By expediting data processing, extracting data features and patterns, generating research design proposals, and offering statistical analysis methods and data visualization tools, ChatGPT facilitates improved experiment design and data analysis.

Challenges of ChatGPT in Medical Education

Overview

While ChatGPT offers substantial benefits to medical education, it faces a spectrum of challenges [22]. The rapid pace of knowledge evolution within the medical field presents a significant hurdle. New research and clinical guidelines continually emerge, demanding constant updates to ChatGPT to ensure that students are provided with the most current and accurate medical information. This necessitates not only the ability to keep up with knowledge updates but also to ensure their accuracy and credibility.

Potential Devaluation of Collaboration

A notable concern emerges regarding the potential devaluation of the collaborative aspect of learning in medical education, particularly in traditional methodologies such as PBL, CBL, and TBL. Collaboration and teamwork are pivotal in these approaches [23], and ChatGPT may inadvertently diminish the

importance of human-to-human interaction. Maintaining a balance between technology and interpersonal relationships is vital for effective learning. While ChatGPT enhances PBL through personalized guidance, educators must underscore the enduring importance of patient-based learning and teamwork. Despite its simulation capabilities and theoretical insights, ChatGPT cannot replace practical experiences gained through real-world interactions, especially in medical education. Acknowledging the model's limitations is crucial to prevent an overreliance on simulated learning. Embedding ChatGPT seamlessly into existing curricula presents a challenge, requiring educators to invest time in designing and integrating AI-driven components aligned with overall learning goals.

Overreliance

Importantly, overreliance on technology may hinder critical thinking and hands-on learning, potentially lowering the quality of education. ChatGPT's answers can vary or even contradict themselves with each query, further impacting student learning [24]. Learning through ChatGPT might inadvertently reduce face-to-face interactions with educators and peers, impacting effective communication skills in clinical practice. ChatGPT may occasionally disseminate inaccurate medical information, making the prompt recognition and correction of such errors critical [25,26]. The establishment of supervision and feedback mechanisms to enhance ChatGPT's accuracy is imperative.

Challenge of Personalized Learning

The challenge of personalized learning is a crucial consideration. Every student has distinct needs and academic levels, requiring ChatGPT to offer tailored education that aligns with individual requirements and progress. Achieving this may necessitate the development of more sophisticated algorithms and technologies. Cultural diversity and inclusivity should also be addressed. Medical education needs to accommodate students from different cultural backgrounds. ChatGPT should be capable of delivering information and using teaching methods that ensure effective comprehension and benefits for all students.

Ethical Considerations

The ethical and privacy dimensions of using ChatGPT in medical education are paramount [27,28]. Handling patient data in an educational context and safeguarding patient privacy are complex and vital concerns. This entails strict adherence to regulatory and ethical guidelines. Identifying and rectifying errors is another noteworthy challenge.

Technological Accessibility

Technological accessibility poses a challenge. The effective use of ChatGPT depends on network connectivity and device availability, which can be problematic in various regions and among specific student populations [29]. Strategies must be devised to use ChatGPT in diverse technological environments.

Future Directions of ChatGPT in Medical Education

Overview

To mitigate these issues, appropriate regulation and supervision are essential. Students should receive training in interpersonal interactions to engage effectively with patients and efforts should be made to provide equal access to technology and learning resources, promoting fair and inclusive medical education. Moving forward, research in this field should explore various promising avenues to enhance our comprehension and application of ChatGPT.

Strategies to Tackle Present Challenges

To specifically address the challenges of ChatGPT on PBL, TBL, and CBL, measures should be taken to mitigate potential drawbacks on collective capabilities. Introducing targeted interventions, such as incorporating collaborative exercises and feedback mechanisms, can help balance individual contributions within a team setting. Emphasizing the importance of teamwork in medical education [30], alongside the integration of ChatGPT, can foster a collaborative learning environment.

There is a pressing need to investigate methods that can augment ChatGPT's capacity to deliver contextually relevant and up-to-date medical information. This involves developing mechanisms for real-time knowledge updates and refining the curation of medical data. Besides, it is crucial to address the ethical and privacy challenges associated with ChatGPT [31]. Future research can focus on devising robust protocols and AI-driven solutions to protect patient data while seamlessly

integrating ChatGPT into medical education. Furthermore, exploring innovative approaches for personalizing medical education with ChatGPT presents an exciting opportunity. Research can delve into adaptive learning algorithms and inventive teaching strategies tailored to individual student needs and learning styles. Additionally, there is a need for research on improving ChatGPT's error identification and correction mechanisms, ensuring the highest level of accuracy and reliability in medical content. Finally, we should examine ways to enhance ChatGPT's cultural sensitivity and inclusivity in medical education and acknowledge the diversity of student backgrounds and learning requirements. This holistic approach ensures that ChatGPT not only provides accurate medical information but also aligns with the broader goals of medical education in promoting collaboration, ethical considerations, and cultural competence.

Conclusions

In conclusion, ChatGPT enhances medical education by improving clinical reasoning, personalizing learning, promoting precision medical education, and supporting medical research. However, a balanced and responsible integration requires a focus on ethics and human-centered approaches. Medical educators can achieve this balance by customizing learning paths, blending personalization with group activities, assigning team projects, guiding ChatGPT use, and emphasizing ethics and critical thinking training. These steps create a holistic learning environment that prepares students to excel as independent thinkers and team players in health care, optimizing ChatGPT's role in medical education while maintaining its integrity.

Abstract

Background: The rapid evolution of ChatGPT has generated substantial interest and led to extensive discussions in both public and academic domains, particularly in the context of medical education.

Objective: This study aimed to evaluate ChatGPT's performance in a pulmonology examination through a comparative analysis with that of third-year medical students.

Methods: In this cross-sectional study, we conducted a comparative analysis with 2 distinct groups. The first group comprised 244 third-year medical students who had previously taken our institution's 2020 pulmonology examination, which was conducted in French. The second group involved ChatGPT-3.5 in 2 separate sets of conversations: without contextualization (V1) and with contextualization (V2). In both V1 and V2, ChatGPT received the same set of questions administered to the students.

Results: V1 demonstrated exceptional proficiency in radiology, microbiology, and thoracic surgery, surpassing the majority of medical students in these domains. However, it faced challenges in pathology, pharmacology, and clinical pneumology. In contrast, V2 consistently delivered more accurate responses across various question categories, regardless of the specialization. ChatGPT exhibited suboptimal performance in multiple choice questions compared to medical students. V2 excelled in responding to structured open-ended questions. Both ChatGPT conversations, particularly V2, outperformed students in addressing questions of low and intermediate difficulty. Interestingly, students showcased enhanced proficiency when confronted with highly challenging questions. V1 fell short of passing the examination. Conversely, V2 successfully achieved examination success, outperforming 139 (62.1%) medical students.

Conclusions: While ChatGPT has access to a comprehensive web-based data set, its performance closely mirrors that of an average medical student. Outcomes are influenced by question format, item complexity, and contextual nuances. The model faces challenges in medical contexts requiring information synthesis, advanced analytical aptitude, and clinical judgment, as well as in non-English language assessments and when confronted with data outside mainstream internet sources.

Introduction

Artificial intelligence (AI) has emerged as a transformative force across various aspects of modern life. Within the realm of AI, natural language processing (NLP) has gained significant attention as it involves the use of devices to replicate human cognitive processes, encompassing learning, problem-solving, and practical application [1,2]. An exemplary NLP model is ChatGPT, developed by OpenAI. This model uses deep learning algorithms trained on extensive data sets to generate responses simulating human-like interactions. This versatile dialogic agent holds promise in diverse applications, including customer service and chatbots [3,4].

Launched on November 30, 2022, ChatGPT quickly gained popularity, attracting a million users within its first week and achieving unprecedented growth. In June 2023 alone, the ChatGPT website received 1.66 billion visits, underscoring its widespread appeal and use [5,6].

While this rapid development of ChatGPT has generated both excitement and concern across various fields, the impact on medical education has been particularly intriguing [7]. This chatbot technology may present opportunities to revolutionize medical education, offering enhanced efficiency, interactivity, and realism in training scenarios [8,9]. However, these benefits come with significant challenges and uncertainties that need to be carefully addressed and navigated [10,11].

A paramount examination in the medical school curriculum is the pneumology examination. This pivotal assessment evaluates the comprehensive understanding of respiratory diseases and their management—a core competency for any medical practitioner.

Our study aims to evaluate the performance of ChatGPT in the context of pneumology examinations through a comparative analysis with that of third-year medical students.

Methods

Study Design and Participants

This research adopts a cross-sectional design and was conducted at the pneumology teaching section of the Faculty of Medicine of Tunis (FMT), Tunisia, in June 2023. The study uses a comparative approach, involving 2 distinct groups: ChatGPT and medical students.

The first group comprises 244 third-year medical students registered at the FMT. These students had previously taken the pulmonology examination in January 2020. The second group consists of ChatGPT-3.5, a freely available version of ChatGPT, which undertook the same pneumology examination in June 2023.

Pneumology Examination

Question Selection

The pneumology examination of FMT of 2020 is a 90-minute test comprising 50 questions, written in French. These questions underwent validation within the pneumology section of FMT to cover a diverse range of knowledge levels, including both fundamental and advanced concepts. The examination assesses candidates' competency in various fields of pneumology, such as clinical pneumology, microbiology, respiratory radiology, pharmacology, pathology, and thoracic surgery.

The administered version of the examination involved only 45 text-based questions to align with ChatGPT's processing capabilities. Thus, 5 questions based on visual components (images, graphs, and illustrations) were excluded since ChatGPT lacks the ability to process this material within its conversational scope.

A comprehensive mapping of assessment parameters for the administered pneumology examination is presented in [Table 1](#). It encompasses a total of 9 multiple choice questions (MCQs), 13 short open-ended questions (SOEQs), and 7 clinical scenarios. Among the clinical scenarios, 2 were structured with MCQs, while the remaining 5 were constructed with SOEQs.

Table 1. Assessment parameters and question distribution in pneumology examination.

Mapping of pulmonology examination	Findings
Parameters	
Academic year	2020
Target examinees	Third-year medical students
Timing	90 minutes
Grading scale	0-100
Questions, n	45
Question topics, n (%)	
Clinical pneumology	27 (60)
Radiology	7 (16)
Pharmacology	5 (11)
Pathology	3 (7)
Microbiology	2 (4)
Thoracic surgery	1 (2)
Question formats, n (%)	
Independent MCQs ^a	9 (20)
Independent SOEQs ^b	13 (29)
MCQ-structured clinical cases	7 (16)
SOEQ-structured clinical cases	16 (35)
Distribution by difficulty index, n (%)	
Low difficulty index items	12 (27)
Intermediate difficulty index items	25 (56)
High difficulty index items	8 (18)
Distribution by discrimination index, n (%)	
Low discrimination index items	21 (47)
Intermediate discrimination index items	13 (29)
High discrimination index items	11 (24)

^aMCQ: multiple choice question.

^bSOEQ: short answer open-ended question.

Item Performance Indexes

Item performance indexes are crucial statistical measures used to assess the effectiveness and quality of test questions, ensuring the reliability and validity of the assessment. These indexes provide valuable insights into the performance of each item concerning difficulty level, discrimination, and its ability to differentiate between high- and low-performing students. In this study, we used common item performance indexes, including the difficulty index (D1) and the discrimination index (D2) [12,13].

The D1 represents the proportion of students who answered an item correctly, calculated by dividing the number of correct responses by the total number of students attempting the item. While the optimal item difficulty may vary based on the specific test format and intended learning outcomes, a value within the 0.3 to 0.7 range is generally preferred [14,15].

On the other hand, the D2 measures an item's capability to differentiate between high-performing and low-performing students. It is determined by comparing the performance of students who achieved high scores on the overall test with those who scored low on the same test for a particular item. D2 levels are classified as follows: high discrimination ($D2 > 0.7$), intermediate discrimination (D2 values between 0.3 and 0.7), and low discrimination ($D2 < 0.3$) [14,15].

Data Collection and Score System

The database, containing the results and scores of medical students who took the pneumology examination in 2020, along with corresponding performance indexes, was accessible in the pneumology section and used in our comparative analysis.

Two authors (HC and CM) conducted separate conversations with ChatGPT-3.5. In the first conversation, CM presented questions to the chatbot without contextualization (V1). In the

second conversation, conducted by HC, suitable context was provided before posing the questions (V2). The questions were presented in exactly the same order as given to the students. Figures 1 and 2 show illustrations of the dual chat conversations conducted by HC and CM and the respective responses from ChatGPT.

The responses generated by both V1 and V2 were meticulously transcribed and stored in separate files. To ensure objectivity and independence, an impartial pneumology teacher, not involved in this study, conducted the evaluation. This teacher used the same grading scale specifically designed for evaluating

student performance in the 2020 examination, ensuring an unbiased and rigorous assessment process.

Each question is assigned 1 point. For MCQs, the grading scale was as follows: an incorrect response concealed a correct answer. The assigned grades were 0, 1, or 0.5, based on the nature of the answer provided. SOEQs were assessed as follows: 1 point is awarded for a correct response, 0 points for an incorrect response, and 0.5 points for an omission. For clarity, the global scores achieved by both third-year medical students, and ChatGPT were transformed into a score out of 100 (maximum score). To successfully pass the examination, candidates needed to achieve a global score of ≥ 50 points.

Figure 1. Illustration of the first version of the conversation with ChatGPT. The question was directly posed to ChatGPT without any context. ChatGPT responded by introducing the answer, emphasizing the necessity for a health care provider to address the case, and provide 4 probable diagnoses as demanded: sarcoidosis, idiopathic pulmonary fibrosis, mediastinal lymphoma, and atypical pulmonary infection. The bubbles in the figure represent the English translation of the conversations conducted in French.

You

Cas clinique n°7

Une patiente âgée de 45 ans, sans antécédent particulier, consulte pour une dyspnée d'effort avec une toux sèche. L'examen physique est sans particularité. La saturation en oxygène à l'air ambiant est à 98%. Il n'a pas été observé d'hippocratisme digital. L'imagerie a montré des adénopathies médiastinales bilatérales ainsi qu'un syndrome interstitiel au niveau des sommets.

Question n°43 : Citez 4 diagnostics à évoquer chez cette patiente ?

ChatGPT

Face à la symptomatologie présentée par la patiente, plusieurs diagnostics peuvent être envisagés. Cependant, il est important de noter que seul un professionnel de la santé peut poser un diagnostic précis après une évaluation complète. Voici quatre diagnostics qui pourraient être envisagés dans ce contexte :

- Sarcoidose :** La présence d'adénopathies médiastinales bilatérales et d'un syndrome interstitiel aux sommets pourrait être suggestive de la sarcoidose, une maladie inflammatoire systémique qui affecte fréquemment les poumons.
- Fibrose pulmonaire idiopathique (FPI) :** La toux sèche et le syndrome interstitiel observé pourraient être liés à une fibrose pulmonaire idiopathique, une maladie pulmonaire progressive caractérisée par une cicatrisation des tissus pulmonaires.
- Lymphome médiastinal :** Les adénopathies médiastinales bilatérales pourraient être associées à un lymphome médiastinal, une forme de cancer lymphatique qui peut provoquer des symptômes respiratoires.
- Infection pulmonaire atypique :** Bien que les symptômes et les résultats d'imagerie soient plus évocateurs de causes non infectieuses, une infection pulmonaire atypique, telle qu'une mycobactérie, pourrait être considérée compte tenu de la dyspnée et de la toux.

Il est essentiel de souligner que ces diagnostics ne sont que des suggestions et qu'une évaluation approfondie, incluant des examens complémentaires et des analyses plus poussées, est nécessaire pour confirmer le diagnostic. La patiente devrait consulter un professionnel de la santé pour un suivi approprié.

Figure 2. Illustration of the second version of the conversation with ChatGPT. The chatbot was asked the same question (in a separate chat session) but preceded by a briefing about the context of the question, which pertains to a pneumology examination for Tunisian medical students. A clear instruction on how to answer was provided. In light of this context, ChatGPT altered its response, explicitly stating pulmonary tuberculosis, likely due to the endemic nature of *Mycobacterium tuberculosis* in Tunisia and other African countries. The bubbles in the figure represent the English translation of the conversations conducted in French.

Hello, you are now taking a written exam in pneumology with third-year medical students from Tunisia. Attached is a case study in the form of open-ended questions. Focus well and try to respond accurately and concisely to the questions related to this clinical situation.

Clinical Case #7 A 45-year-old female with no specific medical history presents with exertional dyspnea and a dry cough. The physical examination is unremarkable. Oxygen saturation in ambient air is 98%. No digital clubbing is observed. Imaging reveals bilateral mediastinal adenopathy and an interstitial syndrome at the lung apices.

Question #43: List 4 potential diagnoses to consider for this patient?

You

Bonjour, vous êtes maintenant entrain de passer une épreuve écrite de pneumologie avec des étudiants tunisien en 3ème année médecine. Ci joint un cas clinique style QROC, concentrez-vous bien et essayez de répondre de manière précise et concise aux questions relatives à cette situation cliniques

Cas cliniquen°7

Une patiente âgée de 45 ans, sans antécédent particulier, consulte pour une dyspnée d'effort avec une toux sèche. L'examen physique est sans particularité. La saturation en oxygène à l'air ambiant est à 98%. Il n'a pas été observé d'hippocratisme digital. L'imagerie a montré des adénopathies médiastinales bilatérales ainsi qu'un syndrome interstitiel au niveau des sommets.

Question n°43 :Citez 4 diagnostics à évoquer chez cette patiente ?

Hello! Let's examine the diagnoses to consider for this patient presenting with exertional dyspnea, a dry cough, bilateral mediastinal adenopathy, and an interstitial syndrome at the lung apices:

1. **Sarcoidosis:** Due to bilateral mediastinal adenopathy and interstitial syndrome.
2. **Mediastinal lymphoma:** Due to mediastinal adenopathy, which could be Hodgkin's or non-Hodgkin's lymphoma.
3. **Pulmonary tuberculosis:** Because of the high prevalence of tuberculosis in Tunisia and the respiratory symptoms.
4. **Idiopathic interstitial pneumonia:** Due to the interstitial syndrome at the lung apices, although this could also be attributed to other causes.

This selection aims to cover the most probable causes given the provided clinical data.

ChatGPT

Bonjour! Examions les diagnostics à évoquer pour cette patiente présentant une dyspnée d'effort, une toux sèche, des adénopathies médiastinales bilatérales, et un syndrome interstitiel au niveau des sommets :

1. **Sarcoidose :** En raison des adénopathies médiastinales bilatérales et du syndrome interstitiel.
2. **Lymphome médiastinal :** En raison des adénopathies médiastinales, pouvant être hodgkinien ou non hodgkinien.
3. **Tuberculose pulmonaire :** En raison de la prévalence élevée de la tuberculose en Tunisie et des symptômes respiratoires.
4. **Pneumopathie interstitielle idiopathique :** En raison du syndrome interstitiel aux sommets, bien que cela puisse également être attribué à d'autres causes.

Cette sélection vise à couvrir les causes les plus probables compte tenu des données cliniques fournies.

Data Analysis

The collected data underwent statistical analysis using SPSS (version 25.0; IBM Corp). Nominal values were expressed as frequencies and percentages, while continuous variables were represented using means and SDs for normally distributed data and medians and quartiles for non-normally distributed data.

A comparative analysis was conducted, evaluating student scores alongside those V1 and V2. This analysis encompassed various factors, including question formats (MCQs, SOEQs, and clinical scenarios), topics (clinical pneumology, microbiology, respiratory radiology, pharmacology, pathology, and thoracic surgery), and item performance indexes. To accurately portray the performance levels of each ChatGPT conversation, we presented results as percentages of the maximum scale attributed to each studied item, along with the ranking of ChatGPT scores among those of third-year medical students.

Ethical Considerations

We have obtained approval from both the Medical Education Committee and the Ethics Committee of the Faculty of Medicine of Tunis to access the data (file number CE-FMT/2024/04/FSI/V2). This approval ensures confidentiality and restricting external use.

Results

Performance of Students in the Pneumology Examination

The median overall score achieved by medical students in the pulmonology examination was 48.9 out of 100 (IQR 40.0-54.7; [Table 2](#)). Among the participants (N=244), a modest cohort of 107 students reached the necessary threshold for successful completion of the examination, resulting in an overall success rate of 43.9%.

Table 2. Pneumology examination performance comparison: medical students versus ChatGPT with (V1) and without (V2) contextualization.

Parameters and categories	Maximum category score	Medical students' performance				V2 performance		
		Score, median (IQR)	Score	Percentage score	Rank among students (percentile)	Score	Percentage score	Rank among students (percentile)
Examination topics								
Pathology	3	2.5 (2-3)	2	66.7	133 (40.6)	2.5	83.3	84 (62.5)
Pharmacology	5	3.5 (2.5-4)	3	60	137 (38.8)	3.5	70	96 (57.1)
Microbiology	2	1.5 (1-1.5)	1.5	75	48 (78.6)	1.5	75	48 (78.6)
Radiology	7	3.5 (2.1-4.5)	3.5	50	93 (58.5)	4	57.1	64 (71.4)
Thoracic surgery	1	0 (0-0)	1	100	1 (99.6)	0	0	29 (87.1)
Clinical pneumology	27	11 (9-13)	10	37	133 (40.6)	11.5	42.6	97 (56.7)
Question formats								
Independent MCQs ^a	9	4.5 (3.5-5.5)	4	44.4	138 (38.4)	3	33.3	191 (14.7)
Independent SOEQs ^b	13	5 (3.5-6)	4.5	34.6	120 (46.4)	6.5	50	30 (86.6)
MCQ-structured clinical cases	7	2.8 (2-3.5)	1.5	21.4	181 (19.2)	2	28.6	149 (33.5)
SOEQ-structured clinical cases	16	9.5 (7.6-11)	11	68.8	51 (77.2)	11.5	71.9	36 (83.9)
Overall examination score	100	48.9 (40-54.4)	46.7	46.7	133 (40.6)	51.1	51.1	85 (62.1)

^aMCQ: multiple choice question.

^bSOEQ: short answer open-ended question.

Significant variations in performance emerged across different question categories. Notably, students (N=244) demonstrated pronounced proficiency in the domains of pathology, pharmacology, and microbiology, with scores exceeding 50% in 88.5% (n=216), 77.5% (n=189), and 74.6% (n=182), respectively. A moderate level of accomplishment was observed in the field of radiology. In contrast, the weakest performances were evident in questions related to thoracic surgery and clinical pneumology, with only 11.5% (n=28) and 22.5% (n=55) of students surpassing the 50% threshold of the maximum score in these areas.

The question format also appeared to significantly influence students' performance. Candidates (N=244) excelled in SOEQ-structured clinical cases and independent MCQs, with 68.9% (n=212) and 56.1% (n=137), respectively, achieving marks exceeding 50% of the maximum achievable. Conversely, the performance in MCQ-structured clinical cases lagged, with only 31.1% (n=76) of candidates reaching scores beyond 50% of the highest attainable mark for this question format. The most challenging performance was observed in independent SOEQs, as only 19.3% (n=47) of students achieved marks surpassing the 50% threshold of the maximum attainable for this particular question format.

Based on these students' outcomes, item performance indexes were computed. A significant proportion of questions (25/45, 56%) exhibited moderate difficulty indexes, while only 18% (8/45) of the questions demonstrated elevated levels of difficulty. Additionally, a substantial fraction of the items (21/45, 47%) showed limited discriminatory power in contrast to 24% (11/45) that displayed a pronounced D2 (Table 1).

Assessment of ChatGPT-3.5 Performance in the Pneumology Examination

V1 performed well, achieving scores exceeding 50% in all question categories except for clinical pneumology. A similar trend emerged with V2, even though it faced challenges in reaching scores above 50% in thoracic surgery and clinical pneumology (Table 2).

The question format significantly impacted ChatGPT's performance. In cases where questions lacked contextualization, V1 fell short of reaching the 50% mark for the maximum score in all question formats, except for SOEQ-structured clinical cases. Similarly, in the responses generated by V2, even when provided with appropriate context, limitations were evident in both independent MCQs and MCQs integrated into clinical cases. Interestingly, V2 demonstrated a higher level of accuracy

in SOEQ-structured clinical cases. Both conversations displayed improved performance in questions with higher D1 and D2 (Table 3).

Considering the overall examination scores, V1 did not meet the passing threshold, achieving a total score of 46.7 out of 100. In contrast, V2 secured a global score of 51.5 out of 100, narrowly achieving success in this examination.

Table 3. Achievement quotient of ChatGPT with (V1) and without (V2) contextualization in the pneumology examination by difficulty and discrimination indexes.

	V1 (%)	V2 (%)
Low difficulty index terms	20.8	16.7
Intermediate difficulty index terms	54	62
High difficulty index terms	62.5	68
Low discrimination index items	31	38.1
Intermediate discrimination index items	61.5	61.5
High discrimination index items	59.1	63.6

Comparative Analysis of ChatGPT Performance and Medical Students' Performance

Question Topic

Comparing the performance of ChatGPT with that of medical students, distinct patterns emerge. V1 demonstrated heightened proficiency in specialized pneumology fields, especially radiology, microbiology, and thoracic surgery. Notably, V1 outperformed 131 (58.5%), 176 (78.6%), and 223 (99.6%) medical students in these respective domains. ChatGPT faced challenges in this conversation when addressing questions related to pathology, pharmacology, and clinical pneumology, achieving lower scores than most medical students. In opposition to that, V2 consistently provided more accurate responses than the majority of medical students across various question categories, regardless of their specialized fields. Noteworthy excellence was observed, particularly in microbiology and thoracic surgery.

Question Format

V1 demonstrated strong proficiency in SOEQ-structured clinical cases, surpassing the performance of 173 (77.2%) medical students. However, its performance weakened in independent

MCQs and SOEQs, and it performed less optimally in MCQ-structured clinical cases compared to third-year medical students. In the case of V2, commendable performance was observed in responding to both independent and structured SOEQs within clinical cases. Yet, a notable deficiency emerged in accurately answering all formats of MCQs, ranking only above 33 (14.7%) and 75 (33.5%) students in independent MCQs and MCQ-structured clinical cases, respectively.

Item Performance Indexes

Both conversations with ChatGPT, particularly V2, performed better than students in handling questions of low and intermediate difficulty. Remarkably, students demonstrated stronger proficiency when tackling highly difficult questions. Regarding the D2, V1 showed similar performance to participants in accurately addressing questions with low and high D2 index values. Additionally, V1 slightly exceeded participants' performance in questions with an intermediate D2 index. V2 consistently outperformed medical students across all question discrimination categories (Figure 3).

In summary, V1 did not pass the examination, but its score surpassed that of 91 (40.6%) students. In contrast, V2 successfully passed the examination, outperforming 139 (62.1%) medical students.

Figure 3. Percentile rank of ChatGPT with (ChatGPT-V1) and without (ChatGPT-V2) contextualization among medical students in the pneumology examination based on difficulty and discrimination indexes. Percentages represent the percentile rank of ChatGPT-V1 and ChatGPT-V2 among medical students.

Discussion

Principal Findings

The cognitive capabilities and knowledge processing of ChatGPT have generated significant discussions in both public and academic circles. This NLP tool has gained attention for its prompt and coherent responses across various subjects, showcasing an impressive capacity to generate essays and offer explanations. However, there is a lack of comprehensive investigations into ChatGPT's performance in medical education and examinations. To address this, this study evaluates ChatGPT using a previously collected data set of pneumology examinations from FMT, enabling direct comparisons between ChatGPT's performance and that of third-year medical students.

Our findings highlight ChatGPT's proficiency in handling diverse biomedical information and clinical data. Powered by a vast corpus of internet text data, ChatGPT demonstrates remarkable expertise in pneumology, particularly excelling in radiology and microbiology. It outperformed a significant proportion of medical students in these paraclinical specialties.

Comparable high performance of AI-powered tools in paraclinical sciences has been previously documented before. Rodriguez-Ruiz et al [16], using data from 9 diverse data sets (2652 examinations), including 653 malignancies, found that their AI system exhibited cancer detection accuracy on par with the average breast radiologist, surpassing the performance of 61.4% of the radiologists in their retrospective analysis.

Das et al [17] assessed ChatGPT's accuracy in addressing a test based on the competency-based medical education (CBME) curriculum for microbiology. ChatGPT showcased the ability to answer both first- and second-order knowledge questions related to microbiology. The model exhibited significant potential as an automated question-answering tool in the field of microbiology, achieving an accuracy rate of approximately 80%. In another investigation, ChatGPT demonstrated proficiency in medical biochemistry, another paraclinical specialty. It successfully responded to 200 random medical biochemistry reasoning questions from the CBME curriculum's competency modules [8].

In fields like clinical pneumology that demand careful processing of medical data, ChatGPT shows some limitations when compared to medical students. However, these shortcomings can be improved through adequate contextualization, as seen in the enhanced proficiency of V2. Our findings about clinical pneumology align with previous studies that highlight ChatGPT's challenges in similar medical disciplines requiring advanced judgment and nuanced clinical reasoning, such as neurology and traumatology. For instance, ChatGPT 3.5 achieved an overall accuracy rate of 57%, just below the 58% passing threshold set for the 2022 UK Specialty Certificate Neurology Examination [18].

Moreover, ChatGPT scored 35.8%, which is notably lower than the pass rate for the Fellowship of the Royal College of Surgeons examination in trauma surgery by 30%. This performance was also 8.2% below the average score of participants at all training levels [19]. In a study conducted in India, ChatGPT demonstrated a limited ability to translate basic pharmacology knowledge into clear clinical concepts. It exhibited inconsistency in predicting and explaining common drug interactions [20]. This observation aligns with ChatGPT's modest accuracy in questions related to pharmacology applied to pneumology in our FMT examination.

The way questions are presented greatly affects how well both medical students and AI tools like ChatGPT perform [21,22]. ChatGPT struggled to match the performance of medical students in all question styles, except for SOEQs integrated into clinical scenarios. Even after contextualization, ChatGPT still had a hard time answering MCQs in pulmonology compared to medical students. Zhu et al [23] addressed this concern, suggesting that ChatGPT may be more suitable for responding to open-ended questions than for being presented with a predefined set of options. Considering the ChatGPT's occasional inconsistency in providing identical responses for the same question, the authors recommended posing the question 3 times to ensure response stability.

Other research generally shows good performance by ChatGPT when handling MCQs. For example, a 2023 study by Duong and Solomon [24] revealed ChatGPT's comparable performance to human beings in responding to MCQs on human genetics. ChatGPT also successfully passed the 2022 Italian Residency Admission National Exam, which consists solely of MCQs. Additionally, in the 2022 European Examination in Core Cardiology, ChatGPT answered over 60% of questions correctly, displaying consistency across various MCQs [25]. In this study, the discrepancy in ChatGPT's performance across question formats may be attributed to the high difficulty level of these questions, even for third-year medical students.

ChatGPT clearly outperformed medical students in tasks that required detailed responses, particularly SOEQs integrated into clinical scenarios. This was supported by Qu et al [26], who also emphasized the impressive capability of this NLP software in handling otorhinolaryngology clinical scenarios [26]. Indeed, ChatGPT consistently provided accurate differential diagnoses and well-justified treatment strategies for recognized clinical conditions. It used specialized medical terminology and carefully curated relevant medical history, physical examination,

radiological, and laboratory findings. This proficiency can be explained by the similarity between the scenarios in our pneumology examination and the writing style commonly found in textbooks, scientific literature, and other data sources used to train the AI model.

Unlike third-year medical students, ChatGPT surprisingly exhibited limited performance on questions with a high difficulty index. These questions necessitate skills in navigating intricate concepts, synthesizing information, and using strategic analytical abilities. Bhayana et al [27] subjected this chatbot to the Canadian Royal College and American Board of Radiology examinations and their conclusions match our findings. Although ChatGPT successfully passed these examinations, it faced difficulties with questions demanding higher order thinking, such as describing radiological findings, classification, and application of concepts [27]. While certain questions can help tell the difference between students with different levels of ability or knowledge, this D2 might not apply directly to AI-powered models like ChatGPT. A noteworthy observation is ChatGPT's enhanced performance when provided with adequate context, outperforming students irrespective of the theoretical item discrimination.

Ultimately, the findings reveal unexpected limits in ChatGPT's performance during our pneumology examination. It barely passed in the part with contextualized chats, giving an overall modest score of 51.1%. This is different from past research where ChatGPT consistently demonstrates strong performance in English-language medical assessments like the United States Medical Licensing Examination, CBME evaluations, and the European Examination in Core Cardiology [17,25,28]. It appears that its effectiveness diminishes when dealing with evaluations from non-Western institutions and non-English language examinations like our Tunisian examination, written in French. Similarly, this AI chatbot faced challenges in both the Taiwanese pharmacist licensing and Taiwanese family medicine board examinations [29,30]. It also scored below the level of students in a Korean parasitology examination, the Japanese National Medical Licensing Examination, and the Chinese National Medical Licensing Examination [31,32]. This discrepancy likely arises from ChatGPT's limited ability to grasp linguistic nuances in non-English texts, exacerbated by the prevalence of Western-centric internet data. In certain contexts, these data may not fully apply to African and Asian populations, which exhibit slight variations in clinical presentations and disease epidemiology.

Strengths and Limitations of the Study

Our research constitutes the initial exploration of ChatGPT's capabilities in French-language medical examinations, providing a valuable addition to the expanding body of research in medical AI assessment. A notable strength of this study lies in its comparative approach, effectively evaluating ChatGPT's performance alongside that of medical students in a comprehensive pneumology examination. This examination covers various question formats and topics, offering a realistic assessment of the AI's competencies.

However, the study acknowledges several limitations. Conducted at a single institution with a highly homogeneous

population concerning demographics, educational background, and medical curricula, there may be a potential selection bias that affects the external validity of the findings, particularly when extrapolating to more diverse student groups, even from other French-speaking medical universities. Additionally, focusing solely on the pneumology field may limit the generalizability of the findings to a broader academic context.

ChatGPT's inability to process visual elements also introduces an inherent selection bias concerning the administered questions, hindering a comprehensive evaluation of its proficiency in clinical scenarios where visual cues, radiology data, and histological images are significant. It is crucial to recognize that the specific findings related to ChatGPT-3.5 may not necessarily extend to other iterations of ChatGPT or alternative AI models. Furthermore, the absence of cultural adaptation and the scarcity of relevant data for non-Western contexts impeded a thorough

exploration of ChatGPT's capabilities, potentially introducing a cultural bias.

Conclusions

In summary, despite its access to a comprehensive web-based data set and quick response generation, ChatGPT performs similarly to an average medical student, with outcomes influenced by question format, item complexity, and contextual factors. Notably, ChatGPT struggles in specific medical contexts requiring information synthesis, advanced analytical skills, and nuanced clinical judgment. Its efficiency also diminishes in non-English language assessments and when confronted with data outside dominant internet sources. These findings suggest the need for further exploration and improvement in the application of AI tools like ChatGPT in medical education, training, and evaluation. It also emphasizes the importance of enhancing its performance across cultural and linguistic contexts.

Acknowledgments

We extend our deep appreciation to Dr Toujani Sonia for his invaluable assistance in impartially and objectively evaluating the responses generated by V1 and V2, thereby ensuring an unbiased and rigorous assessment process. All authors declared that they had insufficient or no funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Abstract

Background: ChatGPT showcases exceptional conversational capabilities and extensive cross-disciplinary knowledge. In addition, it can perform multiple roles in a single chat session. This unique multirole-playing feature positions ChatGPT as a promising tool for exploring interdisciplinary subjects.

Objective: The aim of this study was to evaluate ChatGPT's competency in addressing interdisciplinary inquiries based on a case study exploring the opportunities and challenges of chatbot uses in sports rehabilitation.

Methods: We developed a model termed PanelGPT to assess ChatGPT's competency in addressing interdisciplinary topics through simulated panel discussions. Taking chatbot uses in sports rehabilitation as an example of an interdisciplinary topic, we prompted ChatGPT through PanelGPT to role-play a physiotherapist, psychologist, nutritionist, artificial intelligence expert, and athlete in a simulated panel discussion. During the simulation, we posed questions to the panel while ChatGPT acted as both the panelists for responses and the moderator for steering the discussion. We performed the simulation using ChatGPT-4 and evaluated the responses by referring to the literature and our human expertise.

Results: By tackling questions related to chatbot uses in sports rehabilitation with respect to patient education, physiotherapy, physiology, nutrition, and ethical considerations, responses from the ChatGPT-simulated panel discussion reasonably pointed to various benefits such as 24/7 support, personalized advice, automated tracking, and reminders. ChatGPT also correctly emphasized the importance of patient education, and identified challenges such as limited interaction modes, inaccuracies in emotion-related advice, assurance of data privacy and security, transparency in data handling, and fairness in model training. It also stressed that chatbots are to assist as a copilot, not to replace human health care professionals in the rehabilitation process.

Conclusions: ChatGPT exhibits strong competency in addressing interdisciplinary inquiry by simulating multiple experts from complementary backgrounds, with significant implications in assisting medical education.

KEYWORDS

ChatGPT; chatbots; multirole-playing; interdisciplinary inquiry; medical education; sports medicine

Introduction

The sports industry is a significant economic contributor in the United States, which was projected to generate US \$83.1 billion in revenue in 2023 [1]. Concurrently, sports/recreation-related injuries are prevalent, with an estimated rate of 34 per 1000 individuals, accumulating to an annual total of 8.6 million cases [2]. Sports rehabilitation, aiming to facilitate full recovery, minimize sports downtime, and prevent future injuries, is a process of coordinated efforts between the athlete and health care professionals across various disciplines [3]. However, the rehabilitation process often spans a lengthy period and demands expensive medical and psychological support, making it inaccessible for many patients. In recent years, the integration of artificial intelligence (AI) in sports medicine has shown promise in enhancing both the accessibility to service and the efficacy of treatment outcomes [4,5]. Nevertheless, the use of chatbots in assisting sports rehabilitation is still in its formative stages, with many potential benefits and pitfalls yet to be explored and understood.

ChatGPT, a sophisticated large language model (LLM)-based chatbot, is capable of human-like dialogue [6]. This chatbot exhibits promise as a virtual assistant in medical education by providing real-time personalized feedback and enhancing student engagement [7]. However, controlled assessments in medical education have identified considerable limitations such as the need for precise prompts (also known as prompt engineering), instances of hallucination, and a lack of critical thinking in its responses [8-10]. Another challenge is that many of the topics in health care are interdisciplinary, involving multiple contributors such as physicians, pharmacists, and social workers to ensure better treatment outcomes and patient satisfaction. Unfortunately, current evaluations of ChatGPT are often confined to tasks from a specific discipline, leaving its

competency in addressing interdisciplinary topics largely unexplored [11,12], especially in medical education fields such as sports rehabilitation [5,13].

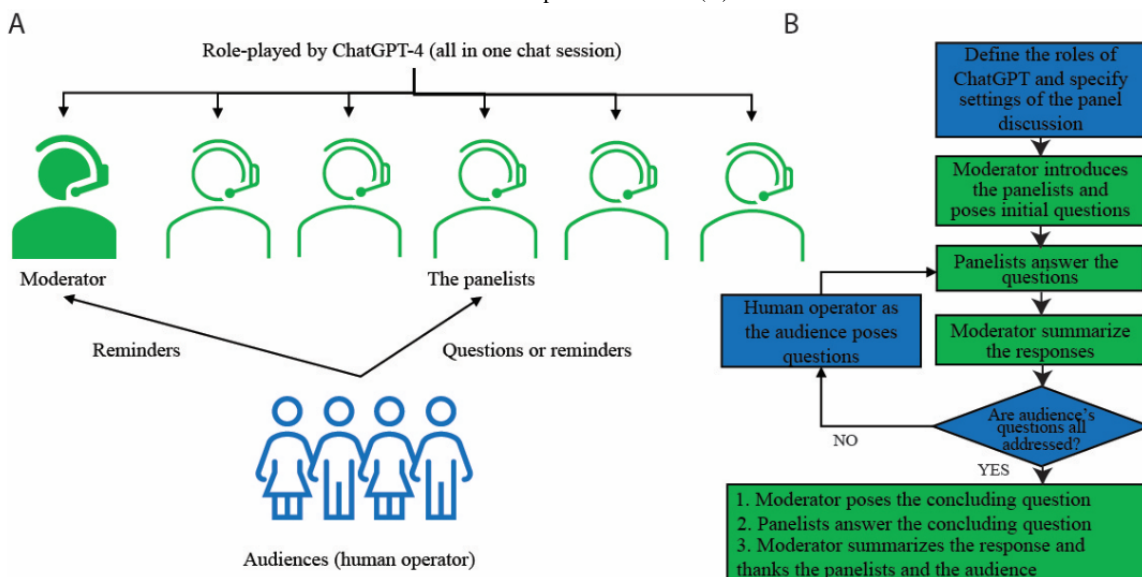

Here, we highlight an attractive feature of ChatGPT in addressing interdisciplinary questions via multirole-playing, which allows the chatbot to assume the roles of several discipline-specific experts simultaneously in one chat session. This unique feature inspired us to propose a model named PanelGPT for exploring interdisciplinary topics through a simulated panel discussion, where ChatGPT assumes the roles of a moderator and various experts on the panel. The aim of the study was to evaluate ChatGPT’s competency through PanelGPT in addressing the opportunities and challenges of chatbot uses in sports rehabilitation, an interdisciplinary field that covers topics on patient education, physical therapy, psychological support, nutrition, and ethics.

Methods

The PanelGPT Model

We developed a model named PanelGPT to evaluate ChatGPT’s competency in addressing interdisciplinary inquiry (Figure 1A). In this model, ChatGPT assumes the roles of both the moderator and panel experts, while a human operator, representing the audience, poses questions and sends reminders to the moderator or the panelists. Questions from the human operator are directly copied and pasted into the chat session, with ChatGPT determining which panel member(s) should respond. If the discussion stalls, the human operator prompts the moderator or panelists to continue by sending reminders. After each round of discussion, the moderator summarizes the comments before moving to the next question from the audience. Upon conclusion of the discussion, we summarized and evaluated the chatbot’s responses based on the literature and our expertise.

Figure 1. Overview of the PanelGPT model for a ChatGPT-simulated panel discussion (A) and a flowchart that delineates the simulation process (B).

Application to Chatbots in Sports Rehabilitation

We applied PanelGPT to explore the pros and cons of chatbot uses in sports rehabilitation. The simulated panelists included 4 experts representing essential disciplines related to the topic: a physiotherapist, psychologist, nutritionist, and AI expert specializing in clinical applications. In addition, a virtual athlete who had successfully recovered from a severe injury participated in the panel. We formulated 4 main questions based on personal experience and/or a literature review. After reviewing the responses from pilot simulations, we added 2 more questions ([Multimedia Appendix 1 \[14-16\]](#)). During one of the pilot simulations, ChatGPT autonomously introduced opening questions, which we subsequently included in the final simulations. This finding also inspired us to instruct the chatbot to ask closing questions at the end of each simulation.

To clarify, our focus is not on using ChatGPT to provide sports rehabilitation advice. Instead, we centered on using ChatGPT to drive a panel discussion titled “Chatbots in sports rehabilitation” in a “self-consistency” manner [17]. The prompts used to steer the final simulations are detailed in [Multimedia Appendix 2](#). A flowchart that outlines the process of the simulation is shown in [Figure 1B](#). At the beginning of the prompts, we instructed ChatGPT to undertake multiple roles and specified other settings in the simulation ([Multimedia Appendix 2](#)). Next, the moderator was prompted to introduce the panelists and kick off the discussion with opening questions. Following the responses to these initial questions from the panelists, the moderator was tasked to summarize the responses and open the platform for questions from the audience. In response, the human operator copied each question from the audience directly into the chat session, allowing ChatGPT to select which expert should respond autonomously. After each round of questions and answers, the moderator was prompted to summarize the responses and call for the next question. This process was iterated until all of the audience’s questions had

been addressed. At the end of the panel discussion, the moderator was asked to propose a closing question and provide a summary of the responses. Additional prompts were introduced as needed to ensure a smooth progression of the panel discussion ([Multimedia Appendix 2](#)). We repeated the simulation 3 times using ChatGPT-4 (May 24, 2023, version) with its online web interface [18].

As shown in [Multimedia Appendix 1](#), we initiated the simulation with an opening question and concluded with a closing question. During the simulation, we prompted ChatGPT to simulate a panel discussion on topics from chatbot uses in sports rehabilitation in the order of “patient education,” “physical therapy,” “psychological support,” “nutrition,” “tracking & other alternatives,” and “ethics.” After 3 rounds of simulations, we manually evaluated the panel’s response to questions from each topic by referring to the literature and our human expertise.

Ethical Considerations

This work was based on analyzing ChatGPT’s response to designed prompts. As the work is classified as not human subjects research, review of the Institutional Review Board of West Virginia University was not required [19].

Results

Overview

The complete chat histories, including prompts and ChatGPT’s response from the simulated panel discussion, are accessible in [Multimedia Appendices 3-5](#) (audio versions are available upon request). As expected, 2 or more experts responded to each question ([Table 1](#)); the experts generally offered insights from their respective fields of expertise. We evaluated the responses by citing relevant references and according to our own expertise. The most relevant findings are compiled and summarized below for each question.

Table 1. Records of direct responses to questions during the simulation.^a

Question	Physiotherapist	Psychologist	Nutritionist	Athlete	AI ^b expert
Opening question	1, 2, 3	1, 2, 3	1, 2, 3	1, 2, 3	1, 2, 3
Patient education	1, 2, 3	1, 2, -	-, -, -	1, -, 3	1, 2, 3
Physical therapy	1, 2, 3	-, -, -	-, -, -	-, -, -	1, 2, 3
Psychological support	-, -, -	1, 2, 3	-, -, -	1, -, -	1, 2, 3
Nutrition	-, -, -	-, -, -	1, 2, 3	-, -, -	1, 2, 3
Tracking and other alternatives	1, 2, 3	1, 2, -	-, -, -	1, 2, -	1, 2, 3
Ethics	1, 2, 3	1, 2, -	1, 2, -	1, -, -	1, 2, 3
Closing question	1, 2, 3	1, 2, 3	1, 2, 3	1, 2, 3	1, 2, 3

^aNumbers 1, 2, and 3 indicate when a response directly targeting the question was made for rounds 1, 2, and 3 of the simulation, respectively, whereas “-” denotes the absence of such a response.

^bAI: artificial intelligence.

Opening Question

The simulated panel discussion began with introductions and requests for the panelists’ perspectives on the role of chatbots in sports rehabilitation, to which all panel members responded

([Table 1](#)). The ensuing dialogue identified chatbots as round-the-clock support systems, adept at monitoring, offering reminders, consulting, and nurturing a positive mindset in athletes during their recovery. Similar observations have been reported for orthopedic patients with AI assistance in the

literature [14,20,21]. Looking into the future and consistent with expectations, chatbots might grow increasingly adept at analyzing biomechanical data, emotional indicators, and nutritional needs, thus providing personalized feedback that helps athletes better comprehend their bodies and healing journeys.

Patient Education

The conversation pinpointed several critical factors in educating athletes on using chatbots for rehabilitation. Both the athlete and the psychologist touched on the importance of understanding the benefits of using a chatbot, such as a readily available source of advice and mental support [22]. The AI expert emphasized the education on transparency, including how data are collected, processed, stored, and protected. Effective communication with a chatbot is a nontrivial task [23]. The physiotherapist focused on how to guide users to interact with the chatbot effectively and how to interpret the responses. The discussion also underscored that the chatbot system is designed to enhance recovery, not to replace the human touch. Through education, athletes need to be able to identify situations that call for direct communication with health care professionals.

Physical Therapy

The primary focus of these questions was on the chatbot's potential to facilitate physical therapy by analyzing movements and weight distributions [15]. Relevant responses were from the physiotherapist and the AI expert, who acknowledged that current chatbots primarily interact with users through text and voice, which restricts their direct applicability to the question. However, the AI expert envisioned integrating chatbots, wearables, cameras, and smart devices to analyze an athlete's movement patterns and provide real-time, personalized feedback. A good example, as has also been noted in the literature, is computer vision-based analysis that has been applied to monitor and improve sports performance [24]. The AI expert further highlighted that the accuracy of this application depends on the size and quality of the training data, as well as advances in AI technologies such as machine learning and computer vision.

Psychological Support

This round of discussion explored the role of chatbots in analyzing emotional cues via sentiment analysis, a technique previously shown to enhance patient satisfaction in several medical chatbot applications [16,25,26] and other applications [27]. The panel's responses aligned with the existing literature: by delivering tailored responses to emotions, chatbots offer athletes emotional support and reduce their feelings of isolation. Nevertheless, the panel did not explore the impact of chatbots on psychological outcome measures such as improvements in communication skills, cognitive level, motivation, and abilities in coping with the injury. The psychologist and the AI expert cautioned that sentiment analysis may not always capture human emotions accurately. Thus, the psychological support provided via chatbots should be regarded as a complement to human interventions, which, in our opinion, can extend from health care professionals to coaches, teammates, friends, and family members.

Nutrition

Chatbots have been used for nutrition advice [28-30]. The nutritionist outlined multiple roles for chatbots in nutritional management, such as reminding athletes to stay hydrated, tracking dietary intake, and suggesting meal plans. A personalized dietary plan could use an advanced AI algorithm to analyze factors such as demographics, injury type, recovery stage, allergy history, and signals from wearable devices or health-tracking apps. The AI expert emphasized that building a personalized nutrition model demands a precise understanding of nutritional science, human physiology, and high-quality training data. However, given that chatbots might make mistakes such as recommending diets containing allergens [31] or harmful diet tips that promote eating disorders [32], they should be regarded as supplementary tools to human nutritionists rather than as their replacements.

Tracking and Other Alternatives

Responses from the physiotherapist and the AI expert to this topic largely echoed those provided during the "physical therapy" round. The athlete noted that the automated tracking, recording, and reminding function helps reduce stress, echoing the psychologist's comments. In line with remarks made by other researchers [33], the simulation highlighted several advantages of chatbots over traditional methods in sports medicine. These included reducing the need for manual reporting, offering convenient cloud-based access to records, real-time data collection, instantaneous analysis, and providing immediate advice. Despite these benefits, the simulation lacked a discussion on how chatbots could potentially enhance treatment outcomes over alternative tools such as increasing patient satisfaction or reducing the recovery duration. In addition, the questions were designed to invoke engagement from all panelists. However, the nutritionist unexpectedly did not respond (Table 1).

Ethics

Distinct from other audience-initiated topics, questions regarding ethics prompted responses from all panelists (Table 1). Some comments reiterated points from previous discussions, particularly regarding patient education. The conversation emphasized the need for stringent adherence to medical privacy regulations such as the Health Insurance Portability and Accountability Act in the United States or the General Data Protection Regulation in Europe [34]. This discussion highlighted the necessity of robust protocols for data encryption and storage to ensure security, as well as the need for transparency on data collection, processing, and accessibility. However, the panel did not delve into the merits and drawbacks of open-source, locally deployed chatbots (especially those furnished with domain-specific knowledge) versus commercial and online chatbots about privacy and security [35].

Regarding bias and fairness, it was stressed that chatbot training should use diverse and representative datasets. As users, athletes should retain complete discretion on whether to use chatbots, alternative methods, or a combination of both. The psychologist highlighted the need to implement chatbots in a manner that avoids triggering anxiety or other negative emotions. All the

comments align with the 5 ethical principles proposed by AI4People: beneficence, nonmaleficence, justice, autonomy, and explicability [36].

Closing Question

The moderator was prompted to steer the panel discussion toward its end with a final question. As anticipated, the questions were all forward-thinking (Multimedia Appendix 1). Panelists offered predictions drawing from their respective fields of expertise. Foreseeing rapid advancements in AI and complementary technologies, the panel envisaged a future of precision sports rehabilitation in the chatbot era. In this vision, the rehabilitation program would be tailored to individual needs, bolstered by health care providers, and empowered by chatbots. According to responses from the simulated athlete, this form of personalized support would make rehabilitation feel like a natural part of the recovery process, and the athlete would take charge of the rehabilitation journey.

Discussion

Principal Findings

We evaluated ChatGPT's competency in addressing interdisciplinary inquiry using sports rehabilitation as an example. Using a novel model named PanelGPT, we prompted ChatGPT to explore the pros and cons of chatbot use in sports rehabilitation. ChatGPT answered questions via a simulated panel discussion where it role-played multiple experts, including a physiotherapist, psychologist, nutritionist, AI expert, and athlete. Our analysis of its responses highlighted benefits such as 24/7 support, personalized advice, and automated tracking, as well as challenges such as limited interaction modes, inaccuracies in emotion-related advice, and data privacy concerns. We repeated the experiments with the most recent version, GPT-4o (May 2024), and obtained generally similar results. Thus, our findings highlight the potential of using ChatGPT through PanelGPT to enhance appreciation of any interdisciplinary topic.

The interdisciplinary approach through PanelGPT brings several benefits with significant implications in medical education. First, the responses come from a panelist of experts with complementary expertise, providing different perspectives that are automatically categorized and offering a comprehensive view of the topic in question. For instance, including an athlete on the panel yielded a unique user perspective that could be overlooked in simple prompts. For example, a simple prompt of the questions on "psychological support" to ChatGPT yielded responses rooted in knowledge based on a psychologist (Multimedia Appendix 6). Thus, PanelGPT can offer students a holistic view of a complex interdisciplinary topic and integrates insights that might be missed from traditional educational settings.

Second, as LLMs become increasingly adapted in education, it is important to educate students on alternative, innovative ways of using chatbots. Compared to conventional communication with a chatbot, PanelGPT is novel in that it focuses the chatbot's attention on the question and provides critical contexts for responding to the questions. For instance, when the "physical

therapy" questions were simply prompted to ChatGPT, the responses quickly drifted toward other topics such as education and mental health (see Multimedia Appendix 7). With PanelGPT, the response involved a discussion between a physiotherapist and an AI expert, and the topic remained in the context of sports rehabilitation.

Third, the multirole-playing feature of ChatGPT through PanelGPT makes learning more interactive and engaging by encouraging active participation from learners. It also helps learners develop critical thinking skills such as synthesizing information from multiple simulated experts from different backgrounds and evaluating their credibility. This is particularly important when addressing the pros and cons of implementing new technologies in health care settings on topics that are interdisciplinary by nature.

Finally, having a panel of experts enables students to form a balanced view on a specific topic. For example, in addressing the "physical therapy" questions, the physiologist's response highlighted the current limitations of chatbots in text or voice communication, while the AI expert expanded the discussion to the integration of real-time video analysis (Multimedia Appendices 3-5). This balanced view is crucial in medical education, as it allows students to understand both the potential and the limitations of any emerging technology (such as chatbots) that are poised for health care applications.

Limitations

The breadth and depth of a panelist's response depend on the training dataset in the field. In several discussions, such as the "patient education" and "tracking and other alternatives" topics, where we expected feedback from all panelists, there was a noticeable lack of direct responses from the nutritionist. It could be that the dataset used to train ChatGPT for the nutritionist was underrepresented in the rehabilitation field. Indeed, a combined search for "rehabilitation" (or "rehab") and "nutritionist" (or "nutrition") on PubMed yielded 6-8 times fewer hits compared to searches involving the terms "physiotherapist" (or "physiotherapy") or "psychologist" (or "psychology") (as of July 7, 2023). To address this limitation, the human operator could send reminders to the nutritionist to elicit a response. In contrast to the nutritionist, the AI expert responded to questions on all topics. This is expected because of the inherent need for AI expertise in creating such chatbot systems.

The data used to train ChatGPT at the time of our experiments only extended up to September 2021. As such, ChatGPT could not provide comments that would reference more recent developments in chatbots such as ChatGPT itself or BARD (now known as Gemini). The feature to activate Bing within ChatGPT does allow for real-time information browsing from the internet. However, in practice, this disrupted the panel discussion's flow, resulting in a shift back to the regular ChatGPT conversation format and a subsequent loss of the expert identities after several exchanges (as shown in Multimedia Appendices 8-10).

We observed instances where the response to a question from the same expert was vague in one simulation but detailed in

another. This observation suggests that conducting multiple simulations could enhance the efficacy of PanelGPT in providing a well-rounded understanding of the knowledge landscape surrounding an interdisciplinary topic. This practice enables self-consistency checking, which has been shown to improve the reasoning performance of language models [17]. Additionally, summarizing diverse responses from multiple simulations facilitates the identification of contrasting viewpoints and emergent trends in the panel discussion.

Hallucination, the generation of unsupported or false information, is a prevalent issue with LLM-based chatbots. The multiperspective approach of PanelGPT allows the chatbot to draw on the strengths and mitigate the weaknesses of each panelist when responding to specific questions. The current model is constrained by the same chatbot simulating all the panelists in a given chat session. With advances in chatbot development, this model could be extended by integrating responses from other LLM chatbots, especially those possessing domain-specific knowledge. In fact, cross-referencing responses from different experts on the panel powered by distinct models helps mitigate hallucination [37]. Nonetheless, it remains crucial to cross-verify the conclusions drawn from the simulation with literature findings or opinions from human experts to ensure the accuracy of the information.

Throughout the simulation, we noted instances where comments from one expert were acknowledged by another. Intriguingly, contradictory comments between experts were not observed. The richness and depth of the discussion can be further enhanced by using additional prompting strategies. For instance, after each response round, panelists could be prompted to critically evaluate each other's comments to foster consensus or highlight disagreements. Panelists may also be prompted to pose questions to one another, such as seeking clarifications or requesting further details on a given response. Moreover, panelists could prompt the audience to clarify their questions if necessary. These additional prompting tactics make the panel discussion more engaging and mirror a real-life scenario, increasing the likelihood of obtaining a thorough appreciation of the topic.

Conclusions

We presented PanelGPT, an innovative method that capitalizes on the multirole-playing feature of ChatGPT through simulated panel discussions, and applied it to evaluate ChatGPT's competency in addressing interdisciplinary inquiry. In our case study, ChatGPT adequately addressed the opportunities and challenges on chatbot uses in sports rehabilitation. As a generalizable model, we envision PanelGPT as a supplementary tool in the classroom, aiding students in understanding complex interdisciplinary topics in medical education, such as nursing care, sports rehabilitation, stroke rehabilitation, and the management of recurrent pneumonia in long-term care facilities.

Acknowledgments

This study is supported by the National Institutes of Health (NIH)-National Institute of General Medical Sciences (NIGMS) (grants P20 GM103434 and U54 GM-104942 to GH), National Science Foundation (grant 2125872 to GH and DAA), and NIH-National Library of Medicine (NLM) (grant R01LM013438 to LL and grant 5R01LM013392 to DX). JCM is supported by the West Virginia University Cancer Institute summer undergraduate research program. We thank Zien Cheng and Evelyn Shue from GH's lab for proofreading. ChatGPT and Grammarly were used to help polish the writing of the manuscript. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Authors' Contributions

GH performed the formal analysis and wrote the original draft of the manuscript. All authors contributed to formal analysis and review and editing of the manuscript.

Abstract

Background: Evaluating the accuracy and educational utility of artificial intelligence-generated medical cases, especially those produced by large language models such as ChatGPT-4 (developed by OpenAI), is crucial yet underexplored.

Objective: This study aimed to assess the educational utility of ChatGPT-4-generated clinical vignettes and their applicability in educational settings.

Methods: Using a convergent mixed methods design, a web-based survey was conducted from January 8 to 28, 2024, to evaluate 18 medical cases generated by ChatGPT-4 in Japanese. In the survey, 6 main question items were used to evaluate the quality of the generated clinical vignettes and their educational utility, which are information quality, information accuracy, educational usefulness, clinical match, terminology accuracy (TA), and diagnosis difficulty. Feedback was solicited from physicians specializing in general internal medicine or general medicine and experienced in medical education. Chi-square and Mann-Whitney *U* tests were performed to identify differences among cases, and linear regression was used to examine trends associated with physicians' experience. Thematic analysis of qualitative feedback was performed to identify areas for improvement and confirm the educational utility of the cases.

Results: Of the 73 invited participants, 71 (97%) responded. The respondents, primarily male (64/71, 90%), spanned a broad range of practice years (from 1976 to 2017) and represented diverse hospital sizes throughout Japan. The majority deemed the information quality (mean 0.77, 95% CI 0.75-0.79) and information accuracy (mean 0.68, 95% CI 0.65-0.71) to be satisfactory, with these responses being based on binary data. The average scores assigned were 3.55 (95% CI 3.49-3.60) for educational usefulness, 3.70 (95% CI 3.65-3.75) for clinical match, 3.49 (95% CI 3.44-3.55) for TA, and 2.34 (95% CI 2.28-2.40) for diagnosis difficulty, based on a 5-point Likert scale. Statistical analysis showed significant variability in content quality and relevance across the cases ($P < .001$ after Bonferroni correction). Participants suggested improvements in generating physical findings, using natural language, and enhancing medical TA. The thematic analysis highlighted the need for clearer documentation, clinical information consistency, content relevance, and patient-centered case presentations.

Conclusions: ChatGPT-4-generated medical cases written in Japanese possess considerable potential as resources in medical education, with recognized adequacy in quality and accuracy. Nevertheless, there is a notable need for enhancements in the precision and realism of case details. This study emphasizes ChatGPT-4's value as an adjunctive educational tool in the medical field, requiring expert oversight for optimal application.

generative AI; ChatGPT-4; medical case generation; medical education; clinical vignettes; AI; artificial intelligence; Japanese; Japan

Introduction

The field of medical artificial intelligence (AI) has seen significant innovations, especially with the development of large language models such as ChatGPT, developed by OpenAI [1,2]. These technologies are being explored for applications across various items, including medical education [3-6], diagnostic assistance [7-9], patient health monitoring [10], and automated document creation [11,12]. However, the use of ChatGPT in health care raises serious concerns about the quality and accuracy of the information generated [13]. Accurate and reliable information is essential in health care, and inaccurate information can have harmful effects on patient health [6].

The importance of case-based learning in medicine has been well established [14]. This teaching approach is vital for medical students and health care professionals to extend their theoretical knowledge and understand the complexity and diversity of the clinical scenarios they will encounter. It fosters essential clinical reasoning and decision-making skills for accurate diagnoses and treatment plans [15,16]. Engaging with real cases helps learners develop the flexibility and adaptability needed in medical practice and encourages a more empathetic and human approach to care for patients and their families [17]. However, in teaching that involves handling actual clinical cases, creating scenarios requires a significant amount of labor, and conducting training using simulated patients can be costly, resulting in limited resources practically usable for education.

ChatGPT can easily create detailed and varied clinical scenarios that mirror actual situations, including disease types, symptom complexity, and patients' backgrounds, without incurring high costs [18]. If it becomes clear that ChatGPT can create clinical vignettes of a level suitable for educational use, it could reduce the labor and costs for educators, allowing learners to engage with a variety of cases. Exposure to a wide range of cases allows learners to deepen their understanding of specific pathologies and treatments, strengthen their clinical judgment and problem-solving skills, and enhance their overall clinical competence, from diagnosis to treatment planning.

Moreover, in Japan, recent reforms in physicians' work styles have mandated significant reductions in physicians' working hours, as part of a national effort to improve work-life balance and reduce instances of overwork. These changes, although beneficial for physician well-being, have created a pressing challenge for medical education, because less time is now available for traditional in-person training and supervision. This situation underscores the urgency of using AI technologies such as generative models to efficiently supplement and enhance the training of medical professionals. However, the extent to which AI can accurately replicate clinical information and scenarios remains a critical question.

To harness the potential of AI in enhancing medical education, this study investigated the educational utility of AI-generated clinical vignettes. These clinical vignettes have the potential to be used in educational scenarios, such as simulated patient interactions, clinical reasoning, and problem-solving exercises. The integration of such AI-generated materials into medical training programs poses significant questions regarding their quality and applicability in real-world educational settings. Thus, several evaluation items were set, and a questionnaire survey of physicians specialized in general internal medicine (GIM) or general medicine (GM) was conducted, to ensure these materials meet the requisite educational standards.

First, information quality (IQ) and information accuracy (IA) were assessed to determine if the clinical vignettes adhered to fundamental quality standards, which are crucial for maintaining educational integrity. Furthermore, the metric of education usefulness (EU) was introduced to explore the actual educational value of these AI-generated clinical vignettes in medical education. Recognizing the potential disparity between AI-generated clinical vignettes and actual clinical scenarios, clinical match (CM) was evaluated to confirm the relevance and applicability of these clinical vignettes in a realistic educational framework.

Furthermore, despite the potential accuracy of the content, the precision of medical terminology and the use of the Japanese language in AI-generated cases raised concerns, necessitating a separate evaluation of terminology accuracy (TA). In addition, diagnosis difficulty (DD) was assessed to understand how variations in the complexity of presented diagnoses might affect both the accuracy of the information and its overall educational value.

This study aimed to contribute to a fundamental understanding of clinical educational content created using ChatGPT-4 by evaluating the quality and EU of clinical vignettes generated in Japanese. The objective was to determine whether the ChatGPT-4-generated vignettes effectively simulate real-life clinical scenarios, thus potentially serving as a valuable resource for medical education and training.

Methods

Study Design

This was an exploratory, web-based, prospective, questionnaire-based survey conducted from January 8 to 28, 2024, using a convergent mixed methods design [19].

Selection of a Generative AI Model

ChatGPT-4 was selected for this study primarily because of its extensive use in previous medical AI research, unlike newer models such as Claude by Anthropic or Llama by Meta. This decision was driven by the availability of a robust body of

literature, enabling us to directly compare our findings with well-established studies in the field.

Medical Case Selection and Case Generation by ChatGPT-4

A total of 18 medical cases were created in Japanese using ChatGPT-4. The selection of cases was based on the 191 fundamental diseases listed in the 2022 revised *Model Core Curriculum for Medical Education* drafted by Japan's Ministry of Education, Culture, Sports, Science, and Technology [20]. These diseases were categorized into 19 areas by organ system, and 1 disease per area was selected for this study. If an area had multiple foundational diseases, the research team chose diseases that, based on patient history and physical findings, seemed

likely to suggest a diagnosis. Since 1 area (breast diseases) did not have a foundational disease listed, a total of 18 cases were included (Table 1). Each case was created through a 4-step process. Initially, the output format was set, and ChatGPT-4 was instructed to generate patient histories and physical findings based on the diagnoses. Next, whether the generated cases were typical for the diagnoses based on patient history and physical findings was verified with ChatGPT-4. The third step involved checking for the inclusion of any nonexistent information. Finally, the accuracy of the terminology used in the patient history was assessed. At no point was the generation of specific findings or histories beyond the diagnosis directed (Multimedia Appendix 1).

Table 1. A total of 18 cases selected from the Model Core Curriculum for Medical Education in Japan.

Case	System	Disease name
Case 1	Blood, hematopoietic, and lymphatic system	Vitamin B ₁₂ deficiency anemia
Case 2	Nervous system	Parkinson disease
Case 3	Skin system	Cellulitis
Case 4	Musculoskeletal system	Spinal disc herniation
Case 5	Circulatory system	Acute aortic dissection
Case 6	Respiratory system	Pulmonary thromboembolism
Case 7	Digestive system	Acute appendicitis
Case 8	Renal-urinary system	Urinary stone disease
Case 9	Reproductive system	Benign prostatic hyperplasia
Case 10	Pregnancy and childbirth	Pregnancy-induced hypertension
Case 11	Pediatrics	Febrile seizures
Case 12	Endocrine, nutritional, and metabolic system	Hyperthyroidism
Case 13	Eye and visual system	Glaucoma
Case 14	Ear, nose, throat, and oral system	Meniere disease
Case 15	Psychiatric and psychosomatic disorders	Schizophrenia
Case 16	Immune system and allergy	Systemic lupus erythematosus
Case 17	Infectious diseases	Pneumonia
Case 18	Oncology	Cervical cancer

Study Participants

GIM or GM experts were recruited to evaluate the validity of the cases created with ChatGPT-4. Since the cases covered various specialties, the evaluators were physicians with cross-specialty knowledge in GIM or GM, all of whom had experience in medical education. The participants were recruited through mailing lists from the Japanese Society of Hospital General Medicine (JSHGM) [21], the Japan Primary Care Association (JPCA) [22], and the JHospitalist Network (JHN) [23], aiming to disseminate GIM education nationwide. Consent for participation was obtained through a Google Form.

Questionnaire and Survey Distribution

The survey, created in Google Forms, included questions about the responding physicians' backgrounds and questions evaluating the AI-generated cases. Background questions covered sex, year of medical license acquisition, specialty qualifications, hospital size, and work location. The evaluation of the generated cases focused on 6 aspects, which are IQ, IA, EU, CM, TA, and DD (Table 2). IQ and IA were assessed on a binary scale (yes or no), and EU, CM, TA, and DD were rated on a 5-point Likert scale (1: strongly disagree; 2: disagree; 3: neither agree nor disagree; 4: agree; 5: strongly agree). Binary responses were analyzed by converting yes to 1 and no to 0 (Multimedia Appendix 2).

Table 2. Contents and explanations of the 6 main questions of the questionnaire.

Item	Question	Measurement method	Scale explanation
Information quality	Do you think the medical history and physical findings provide enough quality information to recall the diagnosis?	Binary (yes or no)	Enough quality information forms the basis for accurate diagnosis process, thus answering yes or no clarifies the evaluator's stance on the quality of information.
Information accuracy	Is the information presented in the case accurate and without contradictions?	Binary (yes or no)	Accurate information ensures reliability and effectiveness in medical education, and answering yes or no clarifies the evaluator's stance on the accuracy of the information.
Education usefulness	Do you consider the quality of information in this case sufficient for educational purposes?	Likert scale (1-5) ^a	The usefulness of clinical vignettes in an educational context has a strong subjective element, so a Likert scale is used to capture finer impressions.
Clinical match	Does this case information reflect the medical history and physical findings you would encounter in clinical practice?	Likert scale (1-5)	Imitating realistic clinical scenarios enables learners to better prepare for situations they might face in the field. A variety of opinions and clinical experiences is important, so the Likert scale is adopted.
Terminology accuracy	Is the case information presented using appropriate medical terminology and expressions?	Likert scale (1-5)	Even if the information is accurate, the language may not be, which is why this item was included. A Likert scale is used to grade the level of language generated.
Diagnosis difficulty	How difficult do you find the diagnosis of this case?	Likert scale (1-5)	The difficulty of diagnosis serves as an indicator of the case's complexity. A Likert scale is used to more precisely assess the level of diagnostic difficulty.

^a1: strongly disagree; 5: strongly agree.

Respondents who rated the IQ insufficient were asked to specify reasons from among 7 options (inadequate medical history, unclear medical history, incorrect medical history, inadequate physical examination findings, unclear physical examination findings, incorrect physical examination findings, and others), allowing for multiple responses. Those who found the IA insufficient provided reasons in free-text format.

To reduce survey fatigue, the questionnaire was divided into 3 parts, each covering 6 cases, with a week allocated for each part. Responses were collected over 3 weeks, with reminders sent to nonresponders to increase response rates.

Item-Based Data Analysis

For the 6 main items in the survey, response trends were evaluated by comparing response rates. The overall mean, SD, and 95% CI values were calculated for these rates across the 18 cases to gauge general trends and identify outliers. The calculation of mean and SD values is crucial because it helps understand the central tendency and variability of data, which supports the reliability and generalizability of the findings. All statistical analyses were performed using R (version 4.4.0; R Foundation for Statistical Computing).

Case-Based Data Analysis

For each case, the mean and 95% CI values were calculated for responses to the 6 main items to understand case-specific response trends. Chi-square tests were conducted on binary data (IQ and IA) to evaluate whether the observed differences between groups were significant. The chi-square test was specifically chosen for its efficacy in analyzing categorical data,

and it was used to determine if variations in responses were due to chance or if they reflected true differences in the medical applicability of AI-generated cases.

For items scored on a 5-point Likert scale (EU, CM, TA, and DD), which typically do not adhere to a normal distribution, the Shapiro-Wilk test was first used to confirm the nonparametric distribution of the data. Since all 4 assessed items did not follow a normal distribution, nonparametric Kruskal-Wallis tests were conducted.

In instances of significant findings, post hoc analyses were carried out using Mann-Whitney *U* tests with Bonferroni correction to adjust for multiple comparisons. This approach allowed the effective assessment of the significance of differences in perceptions across different cases, highlighting specific cases that elicited higher or lower evaluations from medical professionals.

The Mann-Whitney *U* test was used for the Likert scale items due to its appropriateness in handling data that do not meet the assumptions of normality, thus providing a more accurate measure of central tendencies across diverse case scenarios. The significant outcomes derived from these tests provide information about the consistency and variation of clinical judgments among the cases, offering critical insights into the quality of AI-generated case presentations.

Medical Experience and Response Trends

To evaluate the relationship between medical experience and response trends, scatter plots were created, and regression lines were drawn. Linear regression analysis was conducted to

determine if there was a significant association of response trends with years of medical licensure, treating the year of licensure as an independent variable and the average score for each assessment indicator as a dependent variable, calculating the slope (regression coefficient), intercept, coefficient of determination (R value), and P value.

Qualitative Analysis

Thematic analysis of free-text responses regarding reasons for deeming IA insufficient was performed using ChatGPT-4 [24]. ChatGPT-4 processed the free-text survey results, generating a list of codes and corresponding quotations related to the research question. Themes and subthemes were then developed from these codes. Coding and theme development were validated and, if necessary, revised by 2 authors (HT and KS) using the results obtained from ChatGPT-4 [25]. The coauthors responsible for this task were physicians knowledgeable in convergent mixed methods research [26,27].

Ethical Considerations

This study was reviewed and approved by the Juntendo University School of Medicine Research Ethics Committee, approval E23-0245, on November 10, 2023.

Results

Respondents

The participants were recruited through mailing lists from the JSHGM (2325 members), the JPCA (4607 members), and the JHN (3965 members), gathering 73 respondents. All 73 respondents were confirmed to be suitable. Of these, 97% (71/73) completed all surveys. The 71 participants included 64 (90%) male respondents and 7 (10%) female respondents, with licensure years ranging from 1976 to 2017. By specialty, there

were 61 GIM experts, 5 GM experts, and 5 experts with both qualifications. Hospital sizes were diverse, including 35 (49%) experts from hospitals with more than 500 beds, 16 (23%) from those with 201-500 beds, 11 (15%) from those with 101-200 beds, 3 (4%) from those with fewer than 100 beds, and 6 (8%) from clinics. Respondents came from 28 (60%) of the 47 prefectures in Japan, with 1 participant from outside Japan.

Item-Specific Questionnaires

Across the 18 cases, 76.8% (982/1278) of respondents found IQ sufficient, and 67.9% (868/1278) found IA sufficient. For the EU, 45.9% (587/1278) of respondents rated the cases as highly educational, with scores of 4. Another 15.1% (193/1278) awarded the highest score of 5. Conversely, around 19% (246/1278) expressed skepticism, giving scores of 1 or 2. CM saw a strong consensus, with over half of the participants (671/1278, 52.5%) rating the cases as highly relevant clinically, with scores of 4. Another 16% (201/1278) awarded the highest score of 5. The minority, about 13% (163/1278), gave scores of 1 or 2. TA was highly rated, with 46.2% (590/1278) of physicians expressing confidence in the accuracy of the language used (score 4), 58.7% (750/1278) expressing overall satisfaction with the TA (scores 4 and 5), and 19.6% (251/1278) providing lower scores (1 or 2). The responses to DD were more varied, since 59.5% (760/1278) of respondents found the cases relatively straightforward (scores 1 and 2), whereas higher difficulty levels (scores 4 and 5) were less frequently selected, at 13.2% (168/1278; Table 3).

Average ratings on the binary scale were 0.77 (95% CI 0.75-0.79) for IQ and 0.68 (95% CI 0.65-0.71) for IA. On the 5-point Likert scale, the averages were 3.55 (95% CI 3.49-3.60) for EU, 3.70 (95% CI 3.65-3.75) for CM, 3.49 (95% CI 3.44-3.55) for TA, and 2.34 (95% CI 2.28-2.40) for DD (Table 4).

Table 3. Percentage of all responses to 6 items (information quality, information accuracy, education usefulness, clinical match, terminology accuracy, and diagnosis difficulty).

Category and answer	Responses (N=1278), n (%)
Information quality	
Yes	982 (76.8)
No	297 (23.2)
Information accuracy	
Yes	868 (67.9)
No	410 (32.1)
Education usefulness	
1	28 (2.2)
2	218 (17.1)
3	252 (19.7)
4	587 (45.9)
5	193 (15.1)
Clinical match	
1	15 (1.2)
2	148 (11.6)
3	243 (19)
4	671 (52.5)
5	201 (15.7)
Terminology accuracy	
1	32 (2.5)
2	219 (17.1)
3	277 (21.7)
4	590 (46.2)
5	160 (12.5)
Diagnosis difficulty	
1	281 (22)
2	479 (37.5)
3	350 (27.4)
4	139 (10.9)
5	29 (2.3)

Table 4. Summary statistics of physician evaluations for AI-generated case scenarios. Information quality and information accuracy were evaluated on a binary scale of 0 or 1. Education usefulness, clinical match, terminology accuracy, and diagnosis difficulty were assessed using a Likert scale ranging from 1 to 5.

Item	Value, mean (95% CI)	Value, SD
Information quality (0 or 1)	0.77 (0.72-0.79)	0.42
Information accuracy (0 or 1)	0.68 (0.65-0.71)	0.47
Educational usefulness, Likert scale (1-5) ^a	3.55 (3.49-3.60)	1.01
Clinical match, Likert scale (1-5)	3.7 (3.65-3.75)	0.91
Terminology accuracy, Likert scale (1-5)	3.49 (3.44-3.55)	1
Diagnosis difficulty, Likert scale (1-5)	2.34 (2.28-2.40)	1.01

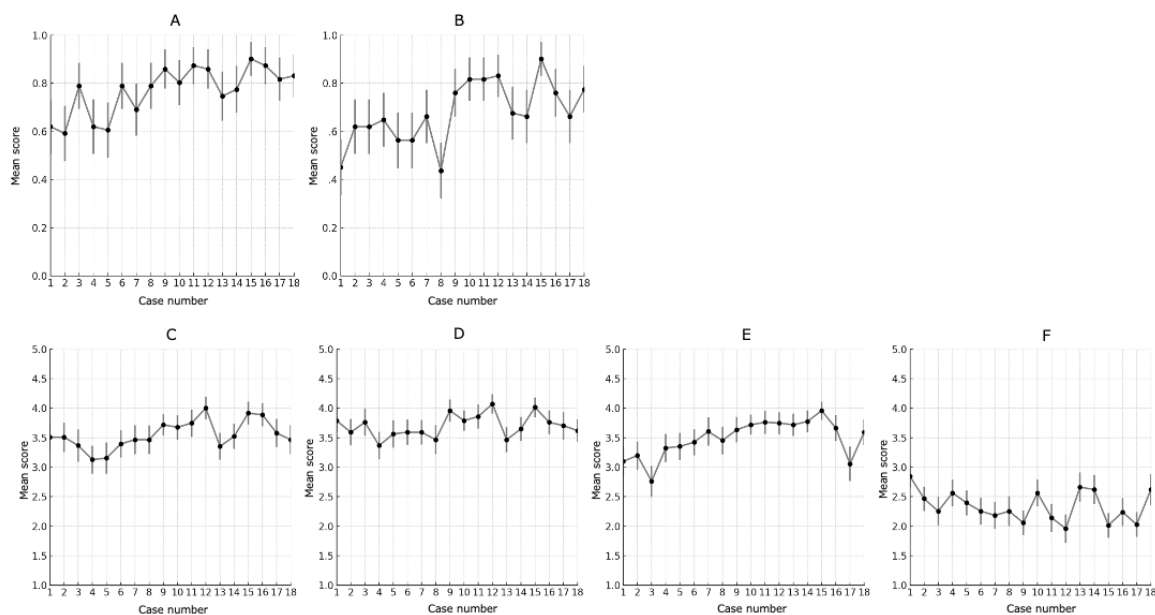

^a1: strongly disagree; 5: strongly agree.

Case-Specific Questionnaires

Mean and 95% CI values for the 6 items (IQ, IA, EU, TA, CM, and DD) were analyzed for each of the 18 cases ([Multimedia Appendix 3](#); [Figure 1](#)). Data analysis for each case showed significant differences in responses across all 6 items ($P < .001$ after Bonferroni correction) using chi-square tests for IQ and IA and Kruskal-Wallis tests for EU, CM, TA, and DD. Significance after correction for multiple comparisons varied, with 6 variations (6/153, 3.9% in all pairs) for IQ, 18 variations

(18/153, 11.8% in all pairs) for IA, 9 variations (9/153, 5.9% in all pairs) for EU, 5 variations (5/153, 3.3% in all pairs) for CM, 22 variations (22/153, 14.4% in all pairs) for TA, and 16 variations (16/153, 10.5% in all pairs) for DD ([Multimedia Appendix 4](#)). Cases most frequently showing significant differences were case 15 (23 times), case 1 (22 times), case 12 (15 times), case 3 (13 times), and case 4 (10 times), with case 15 having the lowest P value combinations across all 6 main items.

Figure 1. Mean and 95% CI values per case for the 6 items: (A) information quality, (B) information accuracy, (C) education usefulness, (D) clinical match, (E) terminology accuracy, and (F) diagnosis difficulty. Information quality and information accuracy were evaluated on a binary scale of 0 or 1. Education usefulness, clinical match, terminology accuracy, and diagnosis difficulty were assessed using a Likert scale ranging from 1 to 5.

Comparing the highest and lowest average scores for each item showed significant differences: (1) IQ: 0.31 between case 15 (SD 0.90) and case 2 (SD 0.59; $P < .001$); (2) IA: 0.46 between case 15 (SD 0.90) and case 8 (SD 0.44; $P < .001$); (3) EU: 0.87 between case 12 (SD 4.00) and case 4 (SD 3.13; $P < .001$); (4) CM: 0.70 between case 12 (SD 4.07) and case 4 (SD 3.37; $P < .001$); (5) TA: 1.20 between case 15 (SD 3.96) and case 3 (SD 2.76; $P < .001$); and (6) DD: 0.89 between case 1 (SD 2.85) and case 12 (SD 1.96; $P < .001$).

Reasons for Insufficient IQ

Overall, 23.2% (297/1278) of respondents who scored the IQ insufficient cited incorrect patient history (23/1278, 1.8% of all cases) and incorrect physical findings (19/1278, 1.5% of all

cases). Other responses indicated that, although AI-generated cases were useful for generating patient histories, improvements were needed in generating physical findings, the naturalness of language, and the accuracy of medical terminology ([Multimedia Appendix 5](#)).

Reasons for Insufficient IA

In exploring the reasons for inadequate IA as reported by respondents (410/1278, 32.1%), thematic analysis of open-ended responses identified 5 primary themes, which are (1) documentation clarity and precision, (2) consistency and reliability of clinical information, (3) appropriateness and contextual relevance, (4) comprehensiveness of diagnostic and treatment insights, and (5) patient-centered reporting ([Table 5](#)).

Table 5. Results of thematic analysis of the reasons for respondents' answers that information is insufficiently accurate.

Themes and subthemes	Quotes
Documentation clarity and precision	
Detail and specificity	I would like to know about gastrectomy.
Appropriate terminology	Do not use the expression "mesh-like sensation."
Consistency and reliability of clinical information	
Avoiding contradictions	Patient had a checkup at a nearby clinic, and no abnormalities were found. The details of the examination are unknown, but it is likely that a blood count was performed even if vitamins were not measured. Given that iron supplements were prescribed, it can be inferred that anemia was observed in the blood test. The statement "no abnormalities were found" is contradictory.
Ensuring accuracy in descriptions	The description "oral cavity: erythema of the tongue, normal dental health" is hard to understand.
Appropriateness and contextual relevance	
Contextual relevance to the patient's condition	It mentions obstetric history despite being about a male.
Practicality in clinical settings	I think the case itself is typical, but it seems unlikely that there would be time to conduct such a detailed physical examination on a patient experiencing severe chest pain accompanied by shortness of breath and cold sweats, and who has abnormally high blood pressure.
Comprehensiveness in diagnosis and treatment insights	
Diagnostic clarity	The name of the prescribed antibiotic is needed.
Logical treatment choices	It says an antianxiety medication was prescribed, but it is clearly a case of auditory hallucinations. It is unlikely any doctor would prescribe just an antianxiety medication in such a situation.
Patient-centered reporting	
Incorporating patient history and experience	It is strange to get a pneumococcal vaccine at 60 with only a history of high blood pressure.
Detailed symptom documentation	The main complaint is fatigue, but the details of the fatigue (changes in ADL ^a , IADL ^b , etc) are not described.

^aADL: activities of daily living.

^bIADL: instrumental activities of daily living.

Documentation Clarity and Precision

Concerning documentation clarity and precision, issues were highlighted regarding the vagueness of specific information, such as details of surgeries and explanations of adjunct treatments. It was also noted that consistent use of medical terminology is demanded, with unclear or incorrect use of specialized terms leading to misunderstanding of information.

Consistency and Reliability of Clinical Information

For the consistency and reliability of clinical information, reported instances raised doubts about the trustworthiness of information, including contradictions in clinical findings and discrepancies in physical examinations. Medical documents should contain information relevant to the specific situations or conditions of patients, yet instances of unnecessary or irrelevant information were observed.

Appropriateness and Contextual Relevance

Concerns about appropriateness and contextual relevance were particularly noted in examples, such as the practicality of clinical tests in emergencies and the inclusion of information unrelated to patients' medical histories.

Comprehensiveness of Diagnostic and Treatment Insights

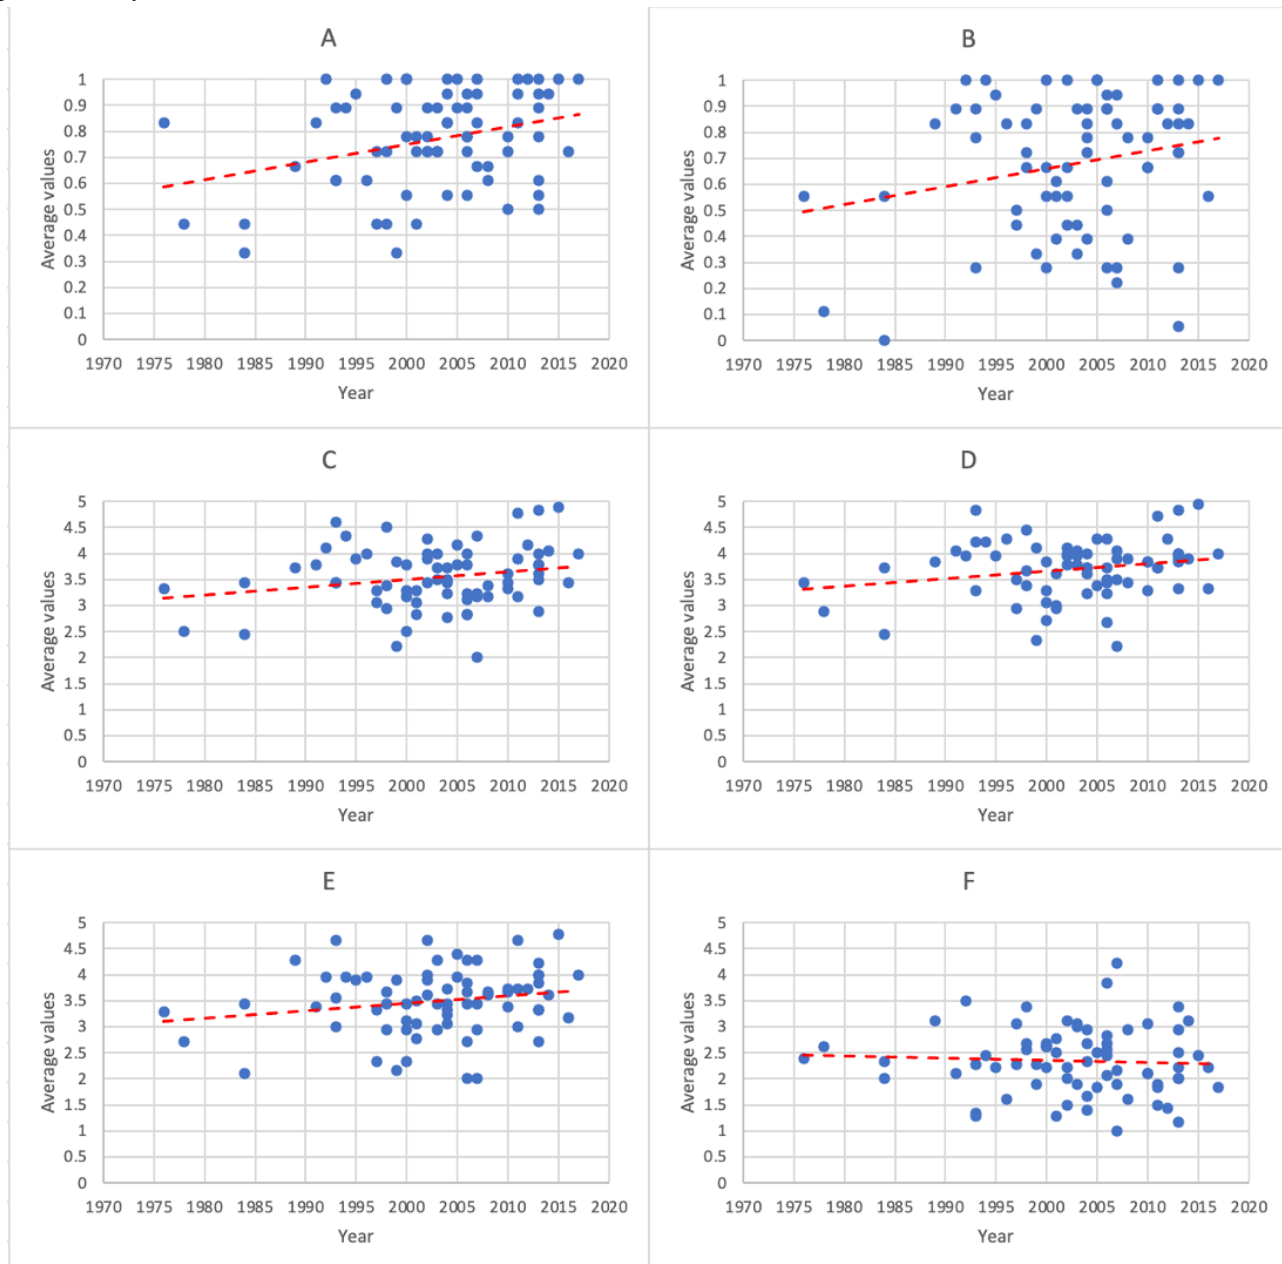

In diagnostic and treatment insights, comprehensive and detailed information is required. However, instances were observed where descriptions of specific medications were lacking or the rationale for treatment choices was questioned. It was pointed out that, in AI-generated case scenarios, detailed clinical data and clear justifications for treatment choices are crucial. Comprehensive documentation of patients' histories and experiences is essential for delivering patient-centered care, yet deficiencies were noted in the detailed reporting of specific symptoms or the consistency of patients' actions and histories, indicating insufficient patient-centered perspectives in reporting.

Medical Experience and Response Trends

In the scatter plots and regression lines of the years since obtaining a medical license, the 6 main items, IQ, IA, EU, CM, and TA, were all rated lower by physicians with longer careers and higher by those with shorter careers. DD, although mostly horizontal, was slightly inclined downward, indicating a trend where physicians with longer experience rated it more difficult, and those with shorter experience rated it easier (Figure 2). Linear regression analysis showed a significant association for IQ ($P=.01$), IA ($P=.06$), EU ($P=.07$), CM ($P=.06$), and TA ($P=.10$) did not show significant associations, although the P

values were low. The difficulty of diagnosis ($P=.62$) showed no relationship with the length of medical experience (Multimedia Appendix 6).

Figure 2. Scatter plot with regression lines showing the relationship between years since obtaining the medical license and average values for the 6 evaluated items: (A) information quality, (B) information accuracy, (C) education usefulness, (D) clinical match, (E) terminology accuracy, and (F) diagnosis difficulty.

Discussion

Principal Findings

In this study, Japanese medical cases generated by ChatGPT-4 were evaluated by GIM or GM experts. A high response rate (71/73, 97%) and a diverse participant demographic in terms of years of medical licensure, hospital size, and geographical location of affiliated organizations support the reliability of current findings. Evaluations across 6 key items (IQ, IA, EU, CM, TA, and DD) indicated that AI-generated medical cases possess a certain level of quality and accuracy suitable for use as clinical educational materials.

Overall, 76.8% (982/1278) of GIM or GM experts rated the IQ of the AI-generated cases as adequate. A very small percentage of cases were noted for having clear errors in medical history (23/1278, 1.8%) and physical examination findings (19/1278, 1.5%), with the total percentage of cases with clear errors in either item being only 3.3% (42/1278). This suggests that, despite some mistakes and lack of information, the majority of specialists found no significant issues with the quality of the generated cases, indicating that ChatGPT-4's case generation likely has fundamental reliability and accuracy. Similar to this study, research using ChatGPT-4 to generate 202 clinical vignettes in Japanese also involved evaluation by three physicians for medical and linguistic accuracy. It was found that 97% (196/202) of these clinical vignettes required some

modifications to be deemed usable, supporting these findings [28].

The 5-point Likert scale used rates “1” as the lowest and “5” as the highest evaluation, with “3” representing a neutral or undecided assessment. Each item rated as “4” suggests effectiveness. The scores for EU (3.55), CM (3.70), and TA (3.49) were between 3 and 4, indicating a level requiring modifications for practical educational use. In addition, the score for DD ranged between 2 and 3, suggesting it was easier than average. This implies that, with appropriate modifications, even relatively simple clinical vignettes could be effectively used for educational purposes.

The analysis of responses scored as insufficient IA (410/1278, 32.1%) showed that the AI-generated cases sometimes failed to provide medical information deemed necessary by GIM or GM experts, lacking specific information depending on the disease or not aligning with what the GIM or GM experts considered relevant clinical information. This suggests that, although ChatGPT-4 can generate disease information to some extent, it may not accurately represent actual clinical scenarios. Furthermore, instances of inappropriate use of Japanese language and expressions were also pointed out, highlighting the need for verification of the appropriateness and accuracy of medical information, representation of clinical scenarios, and use of Japanese language when using ChatGPT-4-generated cases for educational purposes.

The analysis of the responses to the 18 cases across the 6 key items showed significant variance through multigroup chi-square and Kruskal-Wallis tests. Specifically, case 15 was included in the combination that showed significance for all 6 items but was rated the third easiest in terms of diagnostic difficulty, and it ranked in the top 2 for the other 5 items, indicating a high evaluation. This suggests that case 15, a psychiatric case, was recognized from the medical history as a psychiatric disorder, and physical examination findings were not involved in the diagnosis. Among the reasons for inadequate IA ratings, the responses that the cases produced by ChatGPT-4 indicated that the history was accurate, but that the physical examination findings remained a challenge, supporting the reason why case 15 received a high rating.

Comparing cases with the highest and lowest mean values across all 6 items, not only were there significant differences across all items, but there were also substantial differences between the highest and lowest values. For instance, there was a 0.46 difference in the accuracy of information between case 15 and case 8, representing a significant difference, with 33 (46%) out of 71 respondents answering “yes.” Similarly, a significant difference of 1.20 was observed in TA between case 15 and case 3. These results suggest that, although AI-generated cases generally maintained a certain level of accuracy, there was significant variability in quality across cases for the 6 key items.

Analysis of scatter plots and regression lines of the relationship between years of medical licensure and response trends per case suggested a potential correlation between the length of medical practice and response tendencies. Not only IQ, which was significant on linear regression analysis, but also IA, EU, CM, and TA had low *P* values, suggesting that longer-practicing physicians developed more stringent criteria over time due to their increased knowledge and experience. It might also indicate that less experienced physicians are more receptive to new technologies and tools, valuing the utility of AI-generated cases more highly.

Limitations

This study focused on 18 cases of basic diseases and did not evaluate the maintenance of IQ and accuracy in complex cases. In addition, the evaluations were conducted by GIM or GM experts without obtaining assessments from specialists in various fields. Actual interaction and testing with learners are necessary to assess the usefulness of teaching clinical vignettes, but no interaction or testing with learners was conducted in this study. It is also important to note that this study was based on the use of ChatGPT-4 and that different outcomes might have been observed with other AI models, such as Claude by Anthropic or Llama by Meta. The evaluation structure was designed to ensure a comprehensive assessment of the AI-generated clinical vignettes. However, the absence of clear evaluative standards for respondents remains a limitation, potentially leading to variability in their interpretations and affecting the validity of the findings. The proportion of female respondents in this study was 9.5% (7/71). According to the 2020 data from the Ministry of Health, Labour, and Welfare, female physicians make up 22.8% (77,546/339,623) of all physicians in Japan, indicating a disproportionately higher number of male respondents in this study [29]. Finally, the questionnaire used was newly created and did not undergo a pilot test.

In this study, it was suggested that when creating clinical vignettes using the current ChatGPT-4, user corrections are necessary. Given the potential risks associated with the long-term use of AI, such as the homogenization of medical knowledge and the perpetuation of errors present in the training data, implementing this approach may be crucial in mitigating these risks.

Conclusions

This study showed that, although ChatGPT-4-generated medical cases contain minor mistakes, the likelihood of significant errors is low, and they possess a certain level of quality and accuracy of information. However, when evaluating individual cases, there is considerable variability in accuracy, underscoring the need for verification of the provision of appropriate medical information, representation of clinical scenarios, and accuracy of the Japanese language when using these AI-generated cases for educational purposes.

Acknowledgments

The authors would like to express their gratitude to the 71 general internists and family medicine specialists who participated in this study.

Abstract

Background: ChatGPT was not intended for use in health care, but it has potential benefits that depend on end-user understanding and acceptability, which is where health care students become crucial. There is still a limited amount of research in this area.

Objective: The primary aim of our study was to assess the frequency of ChatGPT use, the perceived level of knowledge, the perceived risks associated with its use, and the ethical issues, as well as attitudes toward the use of ChatGPT in the context of education in the field of health. In addition, we aimed to examine whether there were differences across groups based on demographic variables. The second part of the study aimed to assess the association between the frequency of use, the level of perceived knowledge, the level of risk perception, and the level of perception of ethics as predictive factors for participants' attitudes toward the use of ChatGPT.

Methods: A cross-sectional survey was conducted from May to June 2023 encompassing students of medicine, nursing, dentistry, nutrition, and laboratory science across the Americas. The study used descriptive analysis, chi-square tests, and ANOVA to assess statistical significance across different categories. The study used several ordinal logistic regression models to analyze the impact of predictive factors (frequency of use, perception of knowledge, perception of risk, and ethics perception scores) on attitude as the dependent variable. The models were adjusted for gender, institution type, major, and country. Stata was used to conduct all the analyses.

Results: Of 2661 health care students, 42.99% (n=1144) were unaware of ChatGPT. The median score of knowledge was “minimal” (median 2.00, IQR 1.00-3.00). Most respondents (median 2.61, IQR 2.11-3.11) regarded ChatGPT as neither ethical nor unethical. Most participants (median 3.89, IQR 3.44-4.34) “somewhat agreed” that ChatGPT (1) benefits health care settings, (2) provides trustworthy data, (3) is a helpful tool for clinical and educational medical information access, and (4) makes the work easier. In total, 70% (7/10) of people used it for homework. As the perceived knowledge of ChatGPT increased, there was a stronger tendency with regard to having a favorable attitude toward ChatGPT. Higher ethical consideration perception ratings increased the likelihood of considering ChatGPT as a source of trustworthy health care information (odds ratio [OR] 1.620, 95% CI 1.498-1.752), beneficial in medical issues (OR 1.495, 95% CI 1.452-1.539), and useful for medical literature (OR 1.494, 95% CI 1.426-1.564; $P < .001$ for all results).

Conclusions: Over 40% of American health care students (1144/2661, 42.99%) were unaware of ChatGPT despite its extensive use in the health field. Our data revealed the positive attitudes toward ChatGPT and the desire to learn more about it. Medical educators must explore how chatbots may be included in undergraduate health care education programs.

KEYWORDS

artificial intelligence; ChatGPT; education; health care; students

Introduction

Background

Artificial intelligence (AI) and machine learning technologies have transformed various sectors of contemporary society, including health care [1]. Among these developments, AI-powered large language models (LLMs) such as OpenAI's ChatGPT have shown significant promise in revolutionizing numerous aspects of health care services [2]. ChatGPT is a variation of OpenAI's language model that generates humanlike writing in a conversational situation [3].

As of January 2023, the population using ChatGPT exceeded 100 million [4]. While ChatGPT was not originally intended for application in health care settings, it is possible that some of these users comprise students or health care practitioners [5]. Consequently, the insights derived from their interactions with ChatGPT may offer valuable information in patient communication, information management, electronic health records, diagnostics, decision-making assistance, and, potentially, therapeutic interventions [6].

LLMs have shown to be beneficial to health care provision [7]. ChatGPT has demonstrated strong, human-level performance supporting decision-making, data management, and patient education in many specialties, such as internal medicine, surgery, and oncology [8,9]. The upcoming generations of health professionals comprise students who undergo training in conditions with plenty of easily accessible technology resources [10]. Some students may assume roles as directors of health institutes, whereas others may engage in research or work as health care professionals. Nevertheless, it is crucial to recognize that the quality of education received will directly impact the caliber of professionals in the future. Consequently, it is imperative to understand the interests that occupy their thoughts

concerning the use of tools such as LLMs. This comprehension is essential in determining how these tools can either enhance or fail to enhance their academic and educational competencies as well as their professional application soon after [11].

Objectives

In light of this, the primary aim of our study was to assess the frequency of ChatGPT use, the perceived level of knowledge, the perceived risks associated with its use, and the ethical issues, as well as attitudes toward the use of ChatGPT in the context of health care education. The second part of the study aimed to assess the association between the frequency of use, the level of perceived knowledge, the level of risk perception, and the level of perception of ethics as predictive factors for participants' attitudes toward the use of ChatGPT.

Methods

Design

This study used a cross-sectional survey among students of health care-related college programs across the Americas to assess their perceptions, attitude, patterns of use, and further learning regarding ChatGPT. This study was conducted from May to June 2023 across all participating countries.

Sample Size Calculation

The sample size for this study was calculated using the following formula: $n = (Estimated\ Design\ Effect\ Factor \times Np[1 - p]) / (d^2 / Z_{1 - \alpha/2}^2 \times [N - 1] + p \times [1 - p])$. Accounting for a population size of 1 million, a hypothetical frequency of 50% with a 5% margin of error, and a confidence level of 99.99%, the calculated sample size was 1512.

Recruitment

Our study focused on individuals aged >18 years enrolled in diverse health care–related college programs such as medicine, nursing, dentistry, nutrition and dietetics, and medical laboratory science. Through a convenience sampling method, we gathered responses from 2661 participants. We adopted a multifaceted recruitment approach to ensure a varied sample of health care students. We reached out to potential participants through email, student networks, social media, on-campus events, academic institutions, and student associations.

We expanded our sample by including universities across the Americas, specifically in Argentina, Mexico, Colombia, Chile, and Ecuador. By disseminating study links to these institutions, we achieved a diverse representation of health care students from different countries and fields.

Bias

To minimize potential biases, we adopted a comprehensive recruitment strategy targeting a wide range of universities across the Americas, hence reducing selection bias. Response bias was mitigated by conducting anonymous surveys, encouraging honest responses from the participants. In addition, to limit information bias, the survey questions were designed to be straightforward and used standardized Likert-scale responses.

Questionnaire

The questionnaire was developed following the recommendations by Passmore et al [12] and Eysenbach [13]. A steering committee composed of 4 experts and heads from 4 specialized centers worldwide reviewed the literature and developed the survey items, which integrated all constructs to be assessed. The first section of the survey gathered the demographics and medical education of the participants. The second section of the survey aimed to assess the students' perceptions, attitudes, patterns of use, and further learning regarding ChatGPT.

The perception domain was further categorized into *self-perceived knowledge*, *ethics*, and *beliefs of perceived risk* subdomains. The subdomain of self-perceived knowledge was assessed on a 5-point Likert scale ranging from 1 (*no knowledge*) to 5 (*superior knowledge*). The scale of self-perception of knowledge about ChatGPT was recategorized as follows: (1) “No knowledge”—this category included participants who either answered “No” to the question “Have you heard of ChatGPT before?” or selected “No Knowledge” in response to the question “How would you rate your knowledge of ChatGPT and its applications in health care?”; (2) “Minimal knowledge”—participants falling into this category included those who answered with options such as “Minimal” or “Basic knowledge” on the Likert scale; and (3) “Adequate knowledge”—this category encompassed participants who selected options such as “Adequate” or “Superior” knowledge on the Likert scale.

The *ethical perception* subdomain featured 3 items, which respondents were asked to score on a 5-point Likert scale ranging from 1 (*totally unethical*) to 5 (*totally ethical*). The *beliefs of perceived risk* subdomain had 3 items, which

respondents were asked to score on a 5-point Likert scale (1 [*strongly disagree*] to 5 [*strongly agree*]). The attitude domain included 5 statements reflecting evaluations and opinions on ChatGPT. On a 5-point Likert scale, respondents were asked to score these statements (1 [*strongly disagree*] to 5 [*strongly agree*]). The domain of further learning consisted of 4 questions inquiring as to whether respondents wanted to learn more about ChatGPT. Respondents were asked to choose the resources or educational materials that they believed would be the most beneficial in learning about ChatGPT and its potential applications in health care. Those who did not want to learn more about ChatGPT were requested to explain their reasons.

In total, 2 questions assessed the “Pattern of Use” domain: one assessing the frequency of use using a 5-point Likert scale ranging from 1 (*less than once a month*) to 5 (*more than once a day*) and one assessing the applications of ChatGPT in health care settings with a choice of 8 alternatives.

The questionnaire is shown in [Multimedia Appendix 1](#). A pilot study was performed by the steering committee with colleagues and a sample of 20 students. After drafting the survey, it was distributed to the study population in May and June 2023. The survey was available in English and Spanish.

Ethical Considerations

Ethics approval was obtained from the Human Research Ethics Committee from Ecuador with approval HCK-CEISH-2022-006. All participants provided informed consent to take part in the study. They were informed about the purpose of the research, their rights as participants, and the voluntary nature of their participation. We ensured the privacy and confidentiality of participant data throughout the study. The survey responses were anonymized, and no personally identifiable information was collected. No compensation was provided to participants for their involvement in the study. It is important to note that the approval obtained from the Human Research Ethics Committee in Ecuador was deemed sufficient to expand recruitment to all Latin American countries included in the study. This decision was made based on the similarity of ethical standards and regulations across these countries, as well as the collaborative nature of the research conducted within the region.

Variables

Demographic Variables

The demographic variables selected for this study are pivotal for examining the diversity of health care students' attitudes toward using ChatGPT. They are used in both the descriptive (for sample composition purposes) and regression (as control variables) tables. Each variable is thoughtfully coded to capture the nuanced differences among the survey participants, facilitating a detailed analysis of their responses.

Age was recorded as a continuous variable. This allowed for precise analysis of trends across different age groups, helping identify whether younger students are more adept and receptive to AI technologies such as ChatGPT compared to their older counterparts [14].

Gender was categorized into several groups: male, female, nonbinary or third gender, prefer not to say, and other. This

categorization ensured that the study could address and respect the diversity of gender identities. It allowed for an analysis of whether perceptions of ChatGPT vary significantly across different gender groups, which could indicate targeted approaches for technology integration based on gender-specific preferences or concerns [15].

The type of university was divided into public and private. This classification helped investigate whether the institutional context influences students' familiarity with and attitudes toward ChatGPT. Differences in resources, exposure to technology, and educational priorities between public and private universities might contribute to distinct attitudes observed among the students from these institutions [16].

Region was split into Central America and South America. By distinguishing between these 2 regions, the study could explore regional differences that might affect students' acceptance and use of AI technologies. Such differences could stem from varying levels of technology integration in health care education, regional cultural attitudes toward technology, and economic factors [17].

The field of study was specified as medicine, nursing, nutrition, dentistry, therapy, psychology, pharmacology, and other. This detailed categorization allowed the study to determine whether students in certain fields are more likely to perceive ChatGPT as a beneficial tool [18]. For instance, fields requiring up-to-date information and quick data retrieval might show higher appreciation for AI assistance compared to fields that are more focused on personal patient interactions [19].

Outcome Variables

The outcomes of this study focused on the health care students' attitudes toward using ChatGPT quantified through a series of statements. These statements were designed to capture various dimensions of the perceived utility and reliability of ChatGPT in health care contexts. Each outcome variable was measured using Likert scales ranging from "strongly disagree" to "strongly agree" in order to have a granular view of respondents' attitudes and, through detailed statistical analysis, assess trends and influences on these perceptions.

Specifically, the outcomes assessed were (1) "I think that ChatGPT makes my job easier."—this statement evaluated the perceived practical utility of ChatGPT in simplifying tasks within health care settings; (2) "ChatGPT can be beneficial in health care settings."—this statement assessed broader benefits, looking at whether students believe ChatGPT can positively impact health care environments; (3) "ChatGPT provides trustworthy health care information or guidance."—this statement measured trust in the accuracy and reliability of the information provided by ChatGPT; (4) "ChatGPT is a useful tool when I need to search for information on specific medical questions."—this statement evaluated the usefulness of ChatGPT as a resource for specific, actionable medical inquiries; and (5) "ChatGPT is a useful tool when I need to search for medical literature."—this outcome explored the utility of ChatGPT in supporting academic and professional research within medical fields.

Focusing on these specific attitudes toward using ChatGPT helps us understand how health care students perceive the integration of AI into their practices. The statements target various dimensions of AI's role—from enhancing efficiency and providing reliable information to supporting academic research—highlighting areas where ChatGPT could be particularly impactful or face resistance. This nuanced approach not only sheds light on current acceptance levels but also pinpoints areas where further education or system improvements might increase trust in and the utility of AI applications within health care environments.

Exposure (Predictor) Variables

Overview

In this study, several key predictor variables were used to explore the factors influencing health care students' attitudes toward using ChatGPT. These predictors included knowledge of ChatGPT, perceptions of risk, ethical considerations, and the frequency of use of ChatGPT. A detailed overview of each predictor is presented in the following sections.

Knowledge About ChatGPT

For the regression model, this predictor measured the participants' self-reported knowledge about ChatGPT, assessing their understanding of its functionalities and potential applications in health care. It was quantified using a 5-point Likert scale ranging from 1 (*no knowledge*) to 5 (*superior knowledge*). The understanding of ChatGPT's functionalities and potential applications is crucial as it directly influences how students perceive its utility and limitations [20]. Higher levels of knowledge might correlate with more positive attitudes as students are better able to appreciate the benefits and manage the limitations of AI in health care [21].

Beliefs of Perceived Risk

This variable is a composite score derived from the median of the agreement on a 5-point scale with three specific statements assessing perceived risks associated with AI: (1) "I think my job could be replaced in the future because of AI," (2) "In the future, ChatGPT (or some similar technology) will play an even more important role in my job," and (3) "Using AI like ChatGPT in clinical practice raises ethical concerns."

Perceptions of risk are vital to consider because they shape how students weigh the advantages against the potential drawbacks of using AI technologies [22]. Concerns about job security, the increasing role of AI in health care, and ethical implications could negatively influence their attitudes toward ChatGPT, making it essential to analyze how these perceptions impact their overall acceptance [23].

Ethics

The ethical factors were assessed by calculating the median score based on the replies' level of agreement, ranging from *totally ethical* to *totally unethical* on a 5-point scale, to the following three statements that address ethical concerns about using AI in health care: (1) "Revising the language of a scientific manuscript?" (2) "Writing text in a scientific manuscript?" (3) "The sole source of information for the clinical practice?"

Ethical considerations are paramount in the adoption of any new technology, especially in sensitive fields such as health care. Evaluating how students perceive the ethical dimensions of using ChatGPT for tasks such as manuscript writing or as a clinical information source can provide insights into the ethical acceptability of AI tools in professional health care practices [24].

Frequency of Use

The frequency of use was directly measured by asking participants how often they used ChatGPT, with options on a 5-point Likert scale ranging from 1 (*less than once a month*) to 5 (*more than once a day*). The frequency of use is indicative of both familiarity and dependency on the technology. Regular use of ChatGPT might suggest greater comfort and perceived utility, possibly leading to more favorable attitudes [25]. Conversely, infrequent use might indicate skepticism or perceived inadequacies in the technology's ability to meet professional needs [26].

Statistical Analysis

Descriptive Analysis

In the descriptive analysis, we examined the demographic information and survey responses of the participants. This part of the analysis comprised 2 main components. First, the demographic characteristics of the participants were assessed and stratified according to the participants' self-rated knowledge of AI. These categories of knowledge were "No knowledge," "Minimal Knowledge," and "Adequate Knowledge." Demographic variables such as age, gender, type of university (public vs private), region, and major were analyzed across these knowledge strata. Statistical significance for differences across the knowledge categories was tested using a chi-square test for categorical variables and an ANOVA for continuous variables, with a P value of $<.05$ indicating statistical significance.

In the second part of the descriptive analysis, given the ordinal nature of the variables, we assessed the range, median, and IQR of scores for each item in the survey. The survey items were grouped into 3 primary domains: perception, ethics, and attitudes, with the perception domain further divided into 2 subdomains: knowledge and beliefs of perceived risk. In addition, the frequency of use of ChatGPT for various tasks was analyzed. Each item was assessed on a Likert scale ranging from 1 to 5 except for the use tasks, which were reported as percentages. The total median scores for each domain and subdomain were calculated and included in the report. This analysis helped provide a clear picture of the participants' perceptions, ethical considerations, attitudes, and use habits related to ChatGPT.

Regression Analysis

Our analysis of the impact of perception scores on attitude variables involved the use of multiple ordinal logistic regression models. Each model evaluated the attitudes of health care students toward the use of ChatGPT, with individual attitude statements serving as dependent variables. These statements included perceptions of ChatGPT in terms of its ease of use, its

utility in health care settings, the trustworthiness of its health information, its usefulness in finding answers to specific medical questions, and its helpfulness in searching for medical literature.

For each attitude statement, three perception subdomains were considered as independent variables: knowledge, beliefs of risk, and ethical considerations. The coefficient, SE, 1-tailed t test, and P value were all calculated for each perception subdomain under each attitude statement. All models were adjusted for control variables, including gender, whether the institution attended was private or public, the field of study, and the country of the student. All analyses were carried out using Stata (version 18.0; StataCorp).

Missing Data

Although our web-based survey, which required complete responses, effectively eliminated the need to handle missing data, the self-selecting nature of web-based surveys could introduce some bias. Participants more comfortable with or having better access to technology might be overrepresented. However, the completeness of the data set ensured the accuracy of our analysis and the robustness of the findings.

Sensitivity Analyses

In the analytical procedure, we used a set of 20 ordinal logistic regression models. Importantly, SEs were clustered by country to account for potential intracountry correlations. The proportional odds assumption, pivotal for the conventional interpretation of ordinal logistic regression, was violated in half (10/20, 50%) of these models. This breach was primarily attributed to the coefficient of the main predictor in the affected models.

To address this violation and offer a more fitting statistical representation, we used the partial proportional odds model for instances in which the main predictor was unconstrained. Even after this adjustment, our results suggested that the interpretation did not differ significantly from models in which every coefficient was constrained, even when faced with assumption violations. Due to this slight difference in interpretation, and in the interest of consistency, we chose to present the outcomes of all models using ordinal logit with all constraints.

For further refinement of our analysis, and to account for potential clustering effects, we introduced random-intercept and slope models. In this setup, schools were treated as nested entities within countries. This multilevel modeling approach produced results that differed only minimally from those of our initial models, underscoring the reliability of our findings.

Results

Demographic Information

This study included 2661 health care students in total. Most were female ($n=1764$, 66.29%), in dentistry ($n=1466$, 55.09%), from South America ($n=2442$, 91.77%), and from private universities ($n=1836$, 68.99%), as indicated in [Table 1](#). The average age was 21.65 (SD 3.42) years. [Multimedia Appendix 2](#) provides a full overview of the sample's demographics.

Table 1. Demographic information (N=2661).

Variable	No knowledge (n=1142)	Minimal knowledge (n=578)	Adequate knowledge (n=941)	Total	P value
Age (y), mean (SD)	22.01 (3.41)	21.45 (3.81)	21.34 (3.12)	21.34 (3.12)	<.001
Gender, n (%)					<.001
Male	277 (31.66)	203 (23.2)	395 (45.14)	875 (32.88)

Perception of Knowledge, Beliefs of Perceived Risks, and Ethics

Among all participants, 42.92% (1142/2661) did not know about ChatGPT. Male students knew more about ChatGPT than female students (598/875, 68.3% vs 907/1765, 51.39%, $P<.001$). Most of the group of participants who had adequate knowledge of ChatGPT were from South America. With the exception of medicine and therapy students, most health care students were unaware of ChatGPT (Table 1).

Table 2 presents findings from our survey assessing participants across multiple domains related to their perception, attitudes, and use of AI, with a particular focus on ChatGPT. In the “Perception” domain, participants were queried about their knowledge, with scores ranging from 1 to 5. They reported a median score of 2.00, which implies a minimal knowledge of ChatGPT. Delving into beliefs about the perceived risk linked to AI, respondents “somewhat agreed” that using ChatGPT

raises potential ethical concerns and that AI will play a more important role in their jobs in the future.

Moving to the “Ethics” domain, participants considered the use of ChatGPT for writing text within a scientific manuscript and using ChatGPT as the sole information source for clinical practice “neither ethical nor unethical.” In terms of “Attitudes” toward ChatGPT, the median score was 4.00 among all statements, showing that most participants “somewhat agreed” with the advantages and utility of ChatGPT in health care contexts.

The “Use” domain had respondents spotlight the frequency with which they engaged with ChatGPT, reporting a median score of 2.00 (once a month) on a scale of 1 to 5, with an IQR of 1.00-3.00. Regarding distinct tasks, most participants used ChatGPT for homework support (1078/1519, 70.97%), research paper writing (637/1519, 41.94%), and medical and health care education (349/1519, 22.98%); for more information, see Multimedia Appendix 3.

Table 2. Range, median, and IQR of the scores of the survey domains^a.

Items	Scores, median (IQR; range)
Perception	
Knowledge	2.00 (1.00-3.00; 1-5)
Beliefs of perceived risk	
“I think my job could be replaced in the future because of AI.”	3.00 (1.50-4.50; 1-5)
“In the future, ChatGPT (or some similar technology) will play an even more important role in my job.”	4.00 (3.50-4.50; 1-5)
“Using AI like ChatGPT in clinical practice raises ethical concerns.”	4.00 (3.50-4.50; 1-5)
Total median score	3.28 (2.76-3.81; 1-5)
Ethics	
Revising the language of a scientific manuscript	2.00 (1.00-3.00; 1-5)
Writing text in a scientific manuscript	3.00 (2.50-3.50; 1-5)
The sole source of information for clinical practice	3.00 (2.00-4.00; 1-5)
Total median score	2.61 (2.11-3.11; 1-5)
Attitudes	
I think that ChatGPT makes my job easier.	4.00 (3.48-4.52; 1-5)
ChatGPT can be beneficial in health care settings.	4.00 (3.00-5.00; 1-5)
ChatGPT provides trustworthy health care information or guidance.	4.00 (3.50-4.50; 1-5)
ChatGPT is a useful tool when I need to search for information on specific medical questions.	4.00 (3.00-5.00; 1-5)
ChatGPT is a useful tool when I need to search for medical literature.	4.00 (3.00-5.00; 1-5)
Total median score	3.89 (3.44-4.34; 1-5)
Use	
Frequency of use	2.00 (1.00-3.00; 1-5)

^an=1519, which corresponds to students who were aware of ChatGPT.

Further Learning Regarding ChatGPT

Of the participants willing to learn more about ChatGPT, 67.98% (1809/2661) wanted to learn about the applications of ChatGPT in particular cases of medical practice, followed by homework support and understanding the benefits and limits of ChatGPT (Table 3). Less than 30% (745/2661, 27.99%) were interested in learning about “data privacy and security measures”

and “ethical considerations.” Participants found that the most interesting educational materials for learning more about this topic were research articles and case studies (426/2661, 69.16%), internet-based demonstrations or hands-on experience (1301/2661, 48.91%), workshops or conferences (1211/2661, 45.52%), and webinars or web-based courses (968/2661, 36.37%).

Table 3. Further learning domain showing aspects of ChatGPT and its applications in health care that students are more interested in learning about (N=2661).

Aspect	Students, n (%)
Specific use cases in medical practice	1832 (68.85)
Academic homework support	1241 (46.6)
Potential benefits and limitations	1158 (43.51)
Integration with existing health care systems	1078 (40.51)
Data privacy and security measures	755 (28.38)
Ethical considerations	750 (28.2)
Other	37 (1.39)

The main reasons for the 16.49% (439/2661) of participants who did not want to learn more about ChatGPT were lack of time (1234/2661, 46.37%); preference to consult with peers, mentors, and teachers (617/2661, 23.19%); not enough

knowledge about these technologies (492/2661, 18.5%); and lack of relevance to their medical specialty (335/2661, 12.59%; Table 4).

Table 4. Reasons for lack of interest in learning more about ChatGPT and its potential applications in health care (N=2661).

Reason	Students, n (%)
Lack of time	1233 (46.37)
I prefer to consult with my peers, mentors, and teachers	617 (23.19)
Not enough knowledge of these technologies	492 (18.5)
Lack of relevance to my medical specialty	336 (12.65)
Skepticism about the benefits of AI ^a in health care	299 (11.24)
Already overwhelmed with existing medical knowledge and skills	249 (9.37)
Difficulty or discomfort using computer technology	155 (5.85)
Other	143 (5.39)

^aAI: artificial intelligence.

Association Between Perception (Knowledge, Belief, and Ethics) and Frequency of Use and Attitude

The ordinal logistic regression analysis (Tables 5 and 6) illustrates the relationship between predictors such as knowledge, beliefs about risks, ethics, frequency of use, age, gender, institution type, and professional background and their impact on health care students' perceptions of ChatGPT's utility.

An enhanced understanding of ChatGPT consistently showed a positive correlation with more favorable views across all outcomes. For instance, as knowledge increased, the odds of believing that ChatGPT makes one's job easier went up, with odds ratios (ORs) ranging from 1.259 (95% CI 1.047-1.513) to 1.468 (95% CI 1.289-1.672). This trend persisted across other perceptions, such as ChatGPT's potential benefits in health care settings and its trustworthiness in providing health care information.

Beliefs about risk followed a distinctive pattern. Those with heightened risk beliefs felt that ChatGPT made their job easier and could play a beneficial role in health care settings, including obtaining information on medical questions and as a tool for searching medical literature, as evidenced by ORs of 2.040 (95% CI 1.765-2.358), 1.106 (95% CI 1.031-1.186), 1.179 (95% CI 1.110-1.255), and 1.138 (95% CI 1.076-1.203), respectively. This finding suggests that recognizing potential risks does not negate belief in the tool's utility. Ethical considerations played

a significant role. Students with higher ethical concerns perceived ChatGPT's potential in health care more favorably. The ORs for these associations were notable, especially in the context of trustworthiness and specific medical queries (OR 1.620, 95% CI 1.498-1.752).

The frequency of ChatGPT use was a significant determinant. Regular users were more optimistic about its utility, which was evident across all outcomes, such as its benefits in health care (OR 1.540, 95% CI 1.420-1.670) and its efficacy in searching for medical information (OR 1.438, 95% CI 1.311-1.577).

Age influenced perceptions. Older individuals generally had a higher OR across the outcome variables, suggesting a more positive perception of ChatGPT's utility in their profession. Gender-based analysis revealed that female individuals, compared to male individuals, were generally more likely to believe that ChatGPT can help in their job. However, perceptions varied when it came to broader benefits in health care and other outcomes. Those identifying as nonbinary or third gender or those who preferred not to specify their gender showcased diverse perceptions, sometimes differing from those of both male and female individuals.

Institutional type and major played a role. Individuals from private institutions, compared to their public institution counterparts, had varied perceptions. Students from nursing and nutrition exhibited unique outlooks on ChatGPT, highlighting the influence of professional background on shaping perceptions.

Table 5. Estimates from ordinal logistic regression models for the effect of perception scores on attitude variables^a.

Variables and outcomes	Predictor: knowledge					Predictor: beliefs of risk				
	I think that ChatGPT makes my job easier.	ChatGPT can be beneficial in health care settings.	ChatGPT provides trustworthy health care information or guidance. Discussion

Principal Findings

The aim of this study was to determine the perception, attitudes, and uses of ChatGPT among health care students, as well as their willingness to learn more about it. Given that chatbots powered by AI are widely accepted by students [27], our findings provide critical insights into the possibilities of integrating them into undergraduate health care teaching programs. More than half (1419/2661, 53.32%) of the participants knew about ChatGPT according to our data, with male students being more knowledgeable than female students. In May 2023, the Pew Research Center released the findings of a web-based study that showed that, compared to our results

(1142/2661, 42.92%), 33% of young people had never heard of ChatGPT. Most participants felt that they knew little to nothing about ChatGPT [28]. According to the study by Buabbas et al [29], 84% of Kuwaiti medical students did not have any training on the use of AI. It is worth noting that >80% of our participants (2160/2661, 81.17%) indicated an interest in learning more about ChatGPT's health care applications, with time restrictions being the primary barrier to learning more for 39.98% (1064/2661) of them.

Despite the widespread use of AI chatbots such as ChatGPT for self-diagnosing illnesses (up to 78%) [30] and the recognition of the value and user-friendliness of the information they provide, health care career students in the Americas maintained a neutral stance on whether ChatGPT will replace their jobs.

They neither agreed nor disagreed with the notion. This aligns with the findings of the studies by Buabbas et al [29] and Moldt et al [31], where 78.7% and 83% of participants, respectively, expressed skepticism about AI eventually replacing the roles of physicians in the future.

Only 22.98% (349/1519) of our students reported using AI for medical and health care education and training, but >70% (1101/1519, 72.48%) said that they used it for homework support. Although some colleges prohibit the use of ChatGPT and consider it plagiarism [32], teachers are investigating its utility during learning. For example, the students of Mullen [33] used ChatGPT to improve the quality of an essay in English (their nonnative language), and the participants felt that the experience left them better equipped to produce future academic output without the use of these tools.

Our study revealed that health care students displayed positive attitudes and acceptance toward ChatGPT and that most were willing to learn more about it, similar to the studies by Buabbas et al [29] and Moldt et al [31]. Although we did not inquire about the specific version of ChatGPT used by participants, and as ChatGPT's primary function is not to be used as a web search engine, it is evident that, within the context of higher education, particularly in the field of health, there has been a significant increase in the adoption of disruptive technologies [34], including ChatGPT, as both formal or informal tools for enhancing skills and achieving educational objectives [35].

Respondents perceived ChatGPT as a valuable tool in health care settings, highlighting its usefulness in providing information on specific medical questions and facilitating access to relevant literature. Interestingly, the attitudes toward ChatGPT appeared to be influenced by the participants' self-perceived knowledge about the chatbot. Those who had a better understanding of ChatGPT tended to perceive it as providing trustworthy health care information or guidance. Notably, participants' willingness to use ChatGPT in the health care setting is heavily influenced by the level of trust they have in the system [6]. Interestingly, we found a significant association between increased perceived risk scores and the following attitude statement: "ChatGPT provides trustworthy health care information or guidance." Establishing trust is crucial to ensuring the responsible and effective use of ChatGPT, thereby maximizing its benefits while mitigating any associated risks.

Indeed, this study revealed that users' attitudes toward ChatGPT are positively influenced by the frequency of use. Individuals who use ChatGPT more frequently have higher possibilities of believing that ChatGPT makes their job easier and finding it beneficial in health care settings, as well as considering it a useful tool for searching specific medical questions and medical literature. Despite students being somewhat concerned about the perceived risk of the ethical implications of using ChatGPT, they still used it once a month, especially for homework support, research paper writing support, medical or health care education and training, and mental health support. Our study differs from previous research, and Firaina and Sulisworo [36] found that most respondents preferred frequent use of ChatGPT.

Despite the many changes that have occurred in medicine over the last few decades, medical education is still largely based on

traditional teaching methods [37,38]. The release of ChatGPT caused concerns and debates in health care due to ethical issues, misinformation, misuse, and challenges in practice and academic writing. Concerns include the quality and dependability of medical information, the chatbot model's transparency, the ethics of user information, and potential biases in the ChatGPT algorithms [35]. While several studies have demonstrated ChatGPT's ability to answer medical questions [39-42], many correct answers have been deemed inadequate [39,40].

Limitations

Our study has several limitations that must be considered when interpreting the results. First, our sampling strategy did not capture all health care students from the Americas. Despite our efforts to include universities across the Americas, we encountered a limited recruitment response from Central America. This low number may limit the representativeness of our findings for this specific region. As a result, the findings from Central America should be considered as preliminary and require validation through larger-scale research conducted in this region. Second, this study was cross-sectional in nature, and, therefore, we cannot establish causality among perceptions, beliefs, ethics, and attitudes. Longitudinal studies are needed to determine the temporal relationship between these variables. Third, although, during the course of this study, there were 2 available versions of ChatGPT (3.5 and 4.0), the participants were not specifically queried on which version they used. However, given their status as students, it can be reasonably deduced that they predominantly used the free version rather than the premium version. The disparities between the 2 versions lie mostly in the payment requirement associated with version 4.0. It has been said that this particular version offers enhanced safety measures, more valuable responses, and a heightened comprehension of the contextual nuances pertaining to the posed queries. On the basis of the aforementioned findings, certain worries emerge regarding the potential use of ChatGPT by students within their educational institutions but in an informal manner despite the absence of official integration of ChatGPT as an explicitly disruptive technological tool within their educational system. It is also possible that academic institutions are incorporating this technology within their instructional settings. At present, there remain unanswered inquiries pertaining to the subject matter. However, these discoveries indicate potential gaps in knowledge, warranting an assessment of whether the acquired information satisfies the minimum criteria for quality in the field of health and possesses genuine value in terms of gathering competent professionals in the near future.

Conclusions

The current debate revolves around the potential advantages and disadvantages of incorporating ChatGPT and other LLMs into the teaching and learning process. The age of AI has arrived. It is important to be aware of how it may be used and misused. Research in health care education looks bright in the future due to the essential integrity that drives the vast majority of researchers. A medical educator must remain current with the rapid advancements in technology and consider how they affect

their teaching practices, curriculum development, and evaluation techniques.

Acknowledgments

The authors would like to extend special thanks to all members of the RespiraLab Research Group for their initial input on this project. The authors would like to also express their gratitude to Universidad Espíritu Santo for their continuous support in their research endeavors. RespiraLab Research Group financed this study. The sponsor did not design the study or collect, analyze, or interpret the data.

Data Availability

All data generated or analyzed during this study are included in this published article and its supplementary information files.

Abstract

Background: ChatGPT has been tested in health care, including the US Medical Licensing Examination and specialty exams, showing near-passing results. Its performance in the field of anesthesiology has been assessed using English board examination questions; however, its effectiveness in Korea remains unexplored.

Objective: This study investigated the problem-solving performance of ChatGPT in the fields of anesthesiology and pain medicine in the Korean language context, highlighted advancements in artificial intelligence (AI), and explored its potential applications in medical education.

Methods: We investigated the performance (number of correct answers/number of questions) of GPT-4, GPT-3.5, and CLOVA X in the fields of anesthesiology and pain medicine, using in-training examinations that have been administered to Korean anesthesiology residents over the past 5 years, with an annual composition of 100 questions. Questions containing images, diagrams, or photographs were excluded from the analysis. Furthermore, to assess the performance differences of the GPT across different languages, we conducted a comparative analysis of the GPT-4's problem-solving proficiency using both the original Korean texts and their English translations.

Results: A total of 398 questions were analyzed. GPT-4 (67.8%) demonstrated a significantly better overall performance than GPT-3.5 (37.2%) and CLOVA-X (36.7%). However, GPT-3.5 and CLOVA X did not show significant differences in their overall performance. Additionally, the GPT-4 showed superior performance on questions translated into English, indicating a language processing discrepancy (English: 75.4% vs Korean: 67.8%; difference 7.5%; 95% CI 3.1%-11.9%; $P=0.001$).

Conclusions: This study underscores the potential of AI tools, such as ChatGPT, in medical education and practice but emphasizes the need for cautious application and further refinement, especially in non-English medical contexts. The findings suggest that although AI advancements are promising, they require careful evaluation and development to ensure acceptable performance across diverse linguistic and professional settings.

Introduction

ChatGPT is an artificial intelligence (AI) service for conversations based on the generated pretrained transformer and a large-scale generative language model [1]. Since the release of ChatGPT, numerous attempts have been made to apply it in health care practices [2]. In this context, its medical knowledge and thinking skills have been evaluated through a range of medical examinations including the US Medical Licensing Examination and various specialty examinations. The results indicate a performance close to the passing threshold [3]. In the field of anesthesiology, ChatGPT has been evaluated using questions from several question banks designed for English-language board examination preparation. However, doubts remain regarding their ability to complete board examinations [4,5].

GPT-4 is the successor of GPT-3.5, which formed the basis of ChatGPT after its launch. OpenAI, the developer of ChatGPT, reported that GPT-4 not only outperformed GPT-3.5 but also often scored higher than most human test-takers, demonstrating a particularly strong performance in languages other than English [6]. Indeed, in previous studies using written board examinations for neurosurgery and ophthalmology, GPT-4 exhibited a significantly higher proportion of correct responses compared to GPT-3.5 [7,8]. The superiority of GPT-4 over GPT-3.5 was also noted in the field of anesthesiology, as assessed using 27 questions from the Royal College of Anaesthetists [9]. Furthermore, a comparative study evaluating the performance of GPT-3.5 and GPT-4 on the Japanese Medical Licensing Examination revealed that GPT-4 achieved a significantly higher rate of correct responses [10], indicating its advanced performance in non-English languages.

Given the emergence and development of ChatGPT, it is crucial to examine the knowledge levels and reasoning abilities of AI language models in the fields of anesthesiology and pain medicine in Korea to estimate their potential to aid medical professionals. However, to date, no study has explored the performance of ChatGPT in the fields of anesthesiology and pain medicine in a Korean language context. Therefore, this study aimed to investigate the performance of ChatGPT, including both GPT-3.5 and GPT-4, using the in-training examination administered by the Korean Society of Anesthesiologists (KSA). This study also aimed to compare the performance of ChatGPT with that of CLOVA X, a new generative AI service in South Korea.

Methods

Data Source and Contents

This study evaluated the performance of AI services by using the metric “number of correct answers/number of questions” [3], using the KSA in-training examinations from 2018 to 2022, each comprising 100 annual questions. The KSA conducts annual in-training tests for residents to assess their readiness and prepare them for specialist certification examinations. Beginning in 2019, a cutoff point system was introduced: if an examinee scored below a certain threshold for each year’s grade, they were considered to have failed and were required to retake

the examination. The cutoff points are set at 50 in the first year of training, 55 in the second year, and 60 in the third and fourth years. The full texts of the questionnaires, correct answers, and commentaries provided by the society are accessible only to members via official websites [11]. Each question consisted of one query and five choices, each with one correct answer. Because ChatGPT only accepts text as input, we excluded questions with images, diagrams, or photographs within the question content.

To compare the performance of ChatGPT with that of the actual examinees, we requested anonymized data from the Training and Education Committee of the KSA on the scores achieved by residents over the past 5 years, both overall and for each training year.

Initially, we focused solely on evaluating the performance of ChatGPT. However, a new generative AI service, CLOVA X, was launched in South Korea by Naver Corporation in August 2023 during our study period; therefore, we decided to expand our investigation to include an examination of its performance. CLOVA X was developed based on the Korean large language model HyperCLOVA X. HyperCLOVA X was trained on a vast corpus of high-quality data primarily sourced from Korean text content. This makes the training data particularly rich in terms of Korean culture and lifestyle, unlike the more diverse multilingual data sets used for ChatGPT. In addition, HyperCLOVA X uses specific alignment techniques, such as supervised fine-tuning and reinforcement learning from human feedback, to enhance its ability to follow instructions and align with human values [12].

Ethical Considerations

The ethical review of the study was exempted by the institutional review board of Seoul National University Hospital (E-2308-102-1459). This study used only in-training examinations that are already available on the KSA website and did not involve human participants or use any personal information.

Testing Process

We compared the performances of GPT-3.5, GPT-4, and CLOVA X in solving problems in the fields of anesthesiology and pain medicine using the following process: to ensure that both models were tested under identical conditions, the following command in Korean was entered before posing the questions: “(Translated) Below are the in-training assessment questions for the specialty of anesthesiology and pain medicine. Please complete the questions and describe your solution in detail. There is only one answer for each question” (Figure S1A in [Multimedia Appendix 1](#)). Previously, there were instances in which multiple answers were provided by ChatGPT when the prompt did not explicitly state a single correct answer. In addition, answers were sometimes provided without explanation, when the prompt did not request detailed steps. Therefore, we implemented these commands to address these issues. The included questions were then individually entered into the prompt in the order of their question numbers, exactly as they were written in Korean ([Multimedia Appendix 1](#)). This is because we determined that within the same window, previously

entered questions could influence the answers to subsequent questions. If a question or choice included a table, we transcribed the content and maintained the same arrangement, using spaces and hyphens. After completing the set of questions, a new window was opened, the same command was entered, and questions from another year were entered. This process was identical for both ChatGPT and CLOVA X.

For each question input, we recorded the answers chosen by GPT-3.5, GPT-4, and CLOVA X and the explanation for the selection. After completing the problem-solving process for all the questions in both models, we compared their responses to the answer keys provided by the KSA. An answer was recorded as correct if the first response matched the actual response. It was recorded as incorrect if no answer was selected, if the answer was incorrect, or if multiple answers were selected, even if the correct answer was among them. After scoring, we calculated the overall and yearly scores for GPT-3.5, GPT-4, and CLOVA X, as well as the percentage of questions answered correctly relative to the total number of questions.

To compare the performance of GPT-4 in Korean and English, we translated the questions into English and conducted additional problem-solving. This process was conducted in 2 stages. First, the English translation was initially performed by inputting the original Korean questions one by one, along with the command, "Please translate the following into English." All questions included in this study were translated, and the translated texts were recorded separately (Figure S1A in [Multimedia Appendix 2](#)). Two authors (SHY and HJL) reviewed the accuracy of English translations. In the second stage, we entered the initial instruction commands used for the Korean questions in English into a new window (Figure S1B in [Multimedia Appendix 2](#)), followed by the translated English questions individually (Figure S1C in [Multimedia Appendix 2](#)). The process of answering the questions, recording the answers and explanations, and scoring was identical to that used for the Korean questions.

Two authors (SHY and HJL) conducted the task of having AI services solve problems, and all authors reviewed the results. Two authors (SHY and HJL) were using the paid version of ChatGPT-4 at their own expense, independently of this study. ChatGPT-3.5 and CLOVA X were used free of charge. Therefore, no additional costs were incurred when using the three programs.

Outcome Measure and Analysis

The primary outcome of this study was to assess the performance difference between GPT-3.5, GPT-4, and CLOVA-X, as measured by the overall score on the 5 years of in-training examination for residents of anesthesiology and pain medicine in Korea. Secondary outcomes included performance on the ChatGPT and CLOVA-X according to the examination year, subfields within anesthesiology and pain medicine, inclusion of clinical cases, and level of logical thinking required by the questions. Additionally, the performance of GPT-4 on the English-translated questions was compared to its performance on the original Korean version.

The analytical methods used in this study were first used to compare the overall performances of GPT-3.5, GPT-4, and CLOVA X for each year. As a performance reference, we calculated the mean and SD of the examinees' scores both overall and for each training year. However, a direct comparison of the scores was not possible because the study excluded questions involving images, diagrams, and photographs. Second, the questions were categorized into the subfields of anesthesiology and pain medicine following the taxonomy outlined by the KSA. Third, we classified the questions based on the inclusion of clinical cases or the level of logical thinking required (Figure S1B-D in [Multimedia Appendix 1](#)). A question was classified as containing a clinical case if it described a specific situation involving patient information, such as demographics, medical history, surgery, and anesthesia, requiring the use of this information to answer the question. If the question dealt only with theoretical knowledge or if there was some mention of a patient but it was not necessary to apply this information to answer the question, we classified the question as not containing a clinical case. The level of logical thinking was categorized as either first-order or higher-order problem-solving based on a previous study design that evaluated the performance of GPT-3.5 and GPT-4 on the self-assessment examination of neurosurgery [7]. A question was classified as first order if it required direct use of the conditions or circumstances of the question, simple recall of facts, selection of an answer from a set of choices, or determination of the truth or falsity of each option. When a question required additional logical steps to select the correct answer, such as estimating a diagnosis, applying guidelines, or calculating with formulas, it was classified in the higher order. Fourth, we compared the differences in GPT-4 performance between the original Korean questions and their English-translated versions. Additionally, we measured self-agreement, which refers to the number and percentage of questions for which ChatGPT chose the same answer in Korean and English, irrespective of the accuracy of the response.

During the revision process, we further analyzed the explanations for the incorrect answers of each model. A classification system from a previous study was used to categorize the reasons for each incorrect choice as logical, informational, or statistical errors [13]. In cases where two errors occurred simultaneously, both errors were identified. This process was conducted independently by two authors (SHY and HJL), and discrepancies in labeling were resolved through a post hoc discussion involving all authors.

Statistics

When comparing the performances of GPT-3.5, GPT-4, and CLOVA X in Korean, we used the Cochran Q test; in cases where there was a significant difference among the 3 tools, the comparison between the two groups was investigated by calculating the minimum required difference for a significant difference between the 2 groups [14]. The significance level of Cochran Q test for the three language models was 0.05, while a Bonferroni correction was applied to set the significance level to 0.017 when comparing the two groups, considering that there were three combinations for comparisons. Additionally, although we used the KSA classification to compare the performances

of GPT-3.5, GPT-4, and CLOVA-X across various subfields, we recognized that the number of questions per field was too limited for a statistical comparison. Descriptive statistics were used to analyze these factors. A chi-square test was conducted to compare the inclusion of clinical cases and the level of logical thinking in the questions. Finally, to compare the performance of GPT-4 in Korean and English, we used McNemar's test and calculated Poisson 95% CIs for the two performances. All statistical analyses were performed using MedCalc Statistical Software (version 18.6; MedCalc Software bvba).

Results

A total of 398 questions were included in the analysis, selected from a set of 500 questions used over the past 5 years, excluding those containing images, diagrams, or photographs. The

performances of GPT-3.5, GPT-4, and CLOVA X are presented in [Table 1](#). The overall performance of GPT-4 (67.8%) was significantly higher than that of GPT-3.5 (37.7%) and CLOVA X (37.2%), surpassing the minimum required difference of 9.1% in Cochran Q test. However, GPT-3.5 and CLOVA X did not show significant differences in their overall performance. In the year-by-year analysis, GPT-4 consistently showed a significantly higher performance than GPT-3.5 and CLOVA-X, except in 2022 when only the difference between GPT-4 and GPT-3.5 was significant. [Multimedia Appendix 3](#) shows the actual scores of Korean anesthesiology residents in 2022, 2021, and 2019. However, due to the unavailability of data for 2018 and the inapplicability of the 2020 data for estimating the mean and SD of the residents' scores, these years were excluded from the analysis.

^aPerformances of ChatGPT and CLOVA X are presented as the number of correct answers for each category, along with the percentage of correct answers out of the total number of questions in parentheses.

^bA chi-square test was conducted to compare each performance of GPT-3.5, GPT-4, and CLOVA X according to the inclusion of cases and the level of logical thinking, and the *P* values are presented.

Table 4 presents the differences in GPT-4 performance between the original Korean questions and their English versions. All

examination questions translated from Korean to English using ChatGPT-4 were accurate and appropriate. Overall, GPT-4

performed significantly better on English-translated questions than on Korean originals (75.4% vs 67.8%; difference 7.5%; 95% CI 3.1%-11.9%; $P=.001$). When analyzed by year, the performance was consistently higher in English than in Korean, with the difference reaching statistical significance only in 2019 (75.3% vs 62.3%; $P=.01$). Furthermore, the overall

self-agreement rate between the Korean and English-translated versions was 72.6%. In 14.1% of cases, correct answers were derived only from the English-translated version, and in 6.5% of cases, correct answers were derived solely from the original Korean questions.

Table 4. Performance of GPT-4 on Korean and English versions.

Year (questions) ^a	Korean ^b , n (%)	English ^b , n (%)	Difference (95% CI) ^c	P value ^c	Correct answers in each language ^d			Self-agreement ^d , n (%)
					Both language, n (%)	Korean only, n (%)	English only, n (%)

Discussion

Principal Findings

This study assessed the proficiency of ChatGPT in the fields of anesthesiology and pain medicine by analyzing its performance on in-training examinations administered to Korean anesthesiology residents over the past 5 years. Our findings revealed that GPT-4 performed better in solving Korean-language problems in this field than its predecessors, GPT-3.5 and CLOVA X, which were trained using a Korean-language database. An interesting observation emerged when examination questions originally written in Korean were translated into English. In this scenario, GPT-4 exhibits higher performance levels. This suggests an enhanced capability of GPT-4 to process and respond to questions in English compared

to Korean. However, it is important to note that despite this improved performance in the English-translated examinations, GPT-4 did not meet the recommended performance level for educational tools (>95%) [15].

Comparison to the Literature

In the fields of anesthesiology and pain medicine, the ChatGPT knowledge base has been rigorously evaluated using various practical questions. A previous report involving 1321 questions from the American Board of Anesthesiology (ABA) examination preparation book revealed that GPT-3.5 attained a correct answer rate of 56.2% [4]. A recent follow-up report with the same set of questions in GPT-4 discovered a remarkable improvement, with a correct answer rate of 72.1% [16]. In a separate evaluation using 3705 questions from the Fellowship of the Royal College of Anaesthetists Primary examination, GPT-3.5 achieved a

higher correct answer rate of 69.7% [5]. Furthermore, in a study that used a mock ABA examination comprising questions from the ABA website and examination preparation book, GPT-4 was the only tool among its peers, including GPT-3.5 and Google Bard, to pass all three stages of the examination [17]. However, these studies focused on English-language questions. This study differs by examining ChatGPT's performance on non-English questions, encompassing both translated versions and the original Korean questions. Additionally, this study provides a unique perspective by presenting the scoring results of Korean anesthesiology residents, facilitating a direct comparison between human performance and ChatGPT.

Additionally, our results reaffirmed the performance disparities of ChatGPT on English and Korean questions, as observed in recently reported studies in medicine. A notable study in the field of dermatology that used the Korean dermatology specialty certificate examination found that the English-translated version of the questions yielded significantly higher performance than the original Korean version (69.0% vs 57.0%) [18]. Another study assessed the performance differentials between GPT-3.5 and GPT-4 by translating cirrhosis-related questions into multiple languages including English, Korean, Mandarin, and Spanish [19]. This study revealed that GPT-4 consistently outperformed GPT-3.5 across all languages, with the performance gap being more pronounced in the Korean and Mandarin versions than in English. Notably, even GPT-4 demonstrated lower performance in Korean than in English, which is consistent with the trends observed in this study. The GPT-4 technical report by OpenAI provides further insight, indicating that while GPT-4's performance in Korean surpassed that of GPT-3.5 in English (77% vs 70.1%), it fell short compared to GPT-4's performance in English (85.5% vs 77.0%) [6]. This disparity in the language-specific performance of ChatGPT can be attributed to the predominance of English-based text in the GPT training data. This is particularly significant in the medical field, where there is more English literature than Korean literature. Consequently, the process of translating Korean questions into English for answer generation, followed by retranslation into Korean, likely affected performance. This is due to potential losses or alterations in meaning inherent in the translation process [20].

Implications of Findings

To the best of our knowledge, this is the first study to investigate the problem-solving performance of CLOVA X using medical knowledge. Although CLOVA X is a generative AI tool developed based on the Korean large-scale language model AI HyperCLOVA X, its performance in solving anesthesiology and pain medicine problems posed in Korea was inferior to that of GPT-4 and similar to that of GPT-3.5. This likely resulted from the HyperCLOVA X being trained exclusively on Korean data. The size of medical knowledge data sets likely varies by language [21], and English is presumed to contain more extensive medical knowledge data than other languages. Therefore, while CLOVA X might have advantages in processing Korean compared with ChatGPT, its limitations in specialized medical knowledge areas could be attributed to the limitations of its training data set.

In the results of the subfields of anesthesiology and pain medicine, the highest performances were observed in "geriatric anesthesia" in all three tools, whereas the subfield with the lowest performance was "neuromuscular blocking agents" in GPT-3.5 and CLOVA X, and "anesthesia equipment and monitoring" in GPT-4. This may be because the contents on neuromuscular blocking agents, anesthesia equipment, and monitoring are generally included in specialized textbooks that are less publicly accessible. However, neuromuscular blocking agents, which showed lower performance in GPT-3.5 and CLOVA X, showed higher-than-average performances in GPT-4.0. This improvement in GPT-4.0 suggests the potential for more sophisticated language-understanding models in these specialized fields. On the other hand, for questions about anesthesia equipment and monitoring or intravenous anesthesia, CLOVA X scored higher than both GPT-3.5 and GPT-4. It can be assumed that this prominent deviation from the overall score pattern reflects the differences in the data on which each language model was trained. Although this study did not have enough questions in each subfield to investigate the differences between them, further research on the performance differences of ChatGPT or CLOVA X across specific subfields is necessary for the future use of AI in anesthesiology and pain medicine.

The results of this study indicate that GPT-4 has the potential to surpass the correct answer rate of Korean anesthesiology residents for both Korean and English examination questions, thus meeting the passing criteria. Despite this achievement, GPT-4 failed to show acceptable performance as a reliable educational tool (>95%) [3,15] and also had the following limitations stemming from the fundamental operational mechanisms of large language models such as GPT [22]. Unlike human reasoning processes, these models generate responses based on probability distributions and likely word combinations rather than a genuine understanding of the learned content. Moreover, the possibility of incorrect GPT learning could not be ignored. Consequently, despite training with large data sets, the generated responses may be erroneous. Moreover, the model's tendency to provide plausible yet erroneous explanations for incorrect answers poses a significant risk of disseminating misinformation to anesthesiology residents. Therefore, we conclude that these models are inadequate for medical education applications, owing to their inherent limitations.

Opportunities for Future Work

Although GPT-4 demonstrated a higher level of knowledge in solving anesthesiology problems than Korean anesthesiology residents, its performance was not sufficiently reliable to be taken at face value. This performance shortfall is primarily attributed to the lack of training data in specialized fields such as medicine. Our analysis of incorrect answers also revealed that misinformation was the most common cause of error. If accurate information from professional medical texts is included in the training data of generative AI and is continuously updated, its performance in the medical field can be improved. However, the potential legal implications of using copyrighted textbooks, such as copyright infringement [23], further complicate the prospects of incorporating specialized medical texts into generative AI training in the future. Addressing these issues is

essential to enhance the medical knowledge of generative AI models.

Limitations

This study, while pioneering in its exploration of ChatGPT performance in Korean anesthesiology questions, had several limitations. First, the representativeness of the in-training examinations for Korean anesthesiology residents as a comprehensive measure of anesthesiology knowledge remains controversial. However, this examination was selected because it is the only test that is readily accessible to Korean anesthesiologists. Second, due to the inherent limitations of ChatGPT, our analysis excluded questions that incorporated images, diagrams, or photographs. Therefore, we were unable to directly compare the actual examination results of the residents with the performance of the AI services. Additionally, this limitation hinders our ability to fully evaluate the performance of AI services during anesthesiology examinations. This exclusion also potentially limits the scope of our findings as these elements are integral to many medical questions. Third, we used a selective data set that may not have fully captured the performance of AI across a broad range of medical scenarios in the field of anesthesiology. Future research should incorporate nonselective data sets to ensure a more comprehensive and generalizable evaluation of AI performance. Ultimately, owing to these limitations, we could only investigate a partial aspect of AI performance in understanding anesthesiology knowledge. Despite these limitations, this study is the first to assess the

capabilities of ChatGPT in handling anesthesiology questions in Korean. We expect our findings to stimulate discussion and consideration among Korean anesthesiologists regarding the potential roles and limitations of AI tools, such as ChatGPT, in the field of anesthesiology. In addition, by demonstrating performance differences in GPT in English and Korean, this study raises the issue of narrowing the performance gap across different languages.

Conclusions

In summary, this study demonstrated that, although GPT-4 is advanced compared to its predecessors in processing Korean anesthesiology examination questions, it has yet to reach a level of reliability that would justify its use as a standalone educational tool in the medical domain. Specifically, our research highlights the significant performance disparity between English and Korean ChatGPT outputs, drawing attention to the challenges inherent in evaluating proficiency in non-English medical content. This investigation of the capabilities of ChatGPT in Korean anesthesiology is a pioneering effort, and the potential of this tool to assist medical professionals is promising. However, our findings necessitate a cautious approach to their application in clinical and educational settings. This study serves as a call for continued research and development in this area to enhance the performance of AI tools, such as ChatGPT, in diverse linguistic and professional contexts.

Acknowledgments

This study used data on the examination scores of residents provided by the Training and Education Committee of the Korean Society of Anesthesia.

(*JMIR Med Educ* 2024;10:e57594) doi:[10.2196/57594](https://doi.org/10.2196/57594)

In “How Does ChatGPT Perform on the United States Medical Licensing Examination (USMLE)? The Implications of Large Language Models for Medical Education and Knowledge” (*MIR Med Educ* 2023;9:e45312) three additions were made to enhance discoverability.

The title originally appeared as:

How Does ChatGPT Perform on the United States Medical Licensing Examination? The Implications of Large Language Models for Medical Education and Knowledge Assessment

And has been changed to:

How Does ChatGPT Perform on the United States Medical Licensing Examination (USMLE)? The Implications of Large Language Models for Medical Education and Knowledge

In the “Objective” section of the Abstract, the following sentence:

This study aimed to evaluate the performance of ChatGPT on questions within the scope of the United States Medical Licensing Examination Step 1 and Step 2 exams, as well as to analyze responses for user interpretability.

Has been changed to read as:

This study aimed to evaluate the performance of ChatGPT on questions within the scope of the United States Medical Licensing Examination (USMLE) Step 1 and Step 2 exams, as well as to analyze responses for user interpretability.

Finally, the abbreviation “USMLE” has been added to the Keywords section.

The correction will appear in the online version of the paper on the JMIR Publications website on February 27, 2024 together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Submitted 20.02.24; this is a non-peer-reviewed article; accepted 20.02.24; published 27.02.24.

Abstract

Artificial intelligence (AI) in health care has the promise of providing accurate and efficient results. However, AI can also be a black box, where the logic behind its results is nonrational. There are concerns if these questionable results are used in patient care. As physicians have the duty to provide care based on their clinical judgment in addition to their patients' values and preferences, it is crucial that physicians validate the results from AI. Yet, there are some physicians who exhibit a phenomenon known as automation bias, where there is an assumption from the user that AI is always right. This is a dangerous mindset, as users exhibiting automation bias will not validate the results, given their trust in AI systems. Several factors impact a user's susceptibility to automation bias, such as inexperience or being born in the digital age. In this editorial, I argue that these factors and a lack of AI education in the medical school curriculum cause automation bias. I also explore the harms of automation bias and why prospective physicians need to be vigilant when using AI. Furthermore, it is important to consider what attitudes are being taught to students when introducing ChatGPT, which could be some students' first time using AI, prior to their use of AI in the clinical setting. Therefore, in attempts to avoid the problem of automation bias in the long-term, in addition to incorporating AI education into the curriculum, as is necessary, the use of ChatGPT in medical education should be limited to certain tasks. Otherwise, having no constraints on what ChatGPT should be used for could lead to automation bias.

(*JMIR Med Educ* 2024;10:e50174) doi:[10.2196/50174](https://doi.org/10.2196/50174)

KEYWORDS

ChatGPT; artificial intelligence; AI; medical students; residents; medical school curriculum; medical education; automation bias; large language models; LLMs; bias

Introduction

With the introduction of artificial intelligence (AI), automated processes for nearly most tasks have become the norm. In the clinical environment, AI has been used for diagnosis, prognosis, and administrative tasks. Given the popularity of other forms of AI—as seen most recently with ChatGPT, a large language model developed by the company OpenAI—there are suggestions for its potential role in medical education. Users of ChatGPT boast its efficiency and relative accuracy, such as in the generation of a patient's discharge summary or the conduction of literature reviews [1]. As advancements in medicine continue to arise, medical students are burdened with the impossible task of balancing the need to continuously learn and retain competencies and the need to provide compassionate patient care. As a result, some medical students might feel an incentive to use ChatGPT to save them time in their busy

schedules. However, despite the novel acclaim, the technical and ethical issues seen with AI, such as biased results or nonsensical outputs, also plague ChatGPT. These problems become exacerbated when medical students inadvertently develop automation bias, where they overrely on AI, and continue to have this mentality when they become residents, at which point they have the potential to harm patients if the AI provides an erroneous outcome. In this editorial, I argue the justification for AI education in the medical school curriculum and how the lack of it leads to the problem of automation bias, as well as the other harms from automation bias. Subsequently, I connect the implications of students using ChatGPT with automation bias. Finally, I provide recommendations for when ChatGPT use is appropriate.

The Need for AI Education in the Medical School Curriculum

As the health care landscape has drastically changed through the years, physicians have had to quickly adapt to the digital age. Given the amount of information physicians are required to retain and the new information they must continue to learn, such as information on emerging diseases and the health data of the patients they track, physicians are expected to interact with computer systems in some capacity, whether it is for charting their patients' information or consulting clinical decision support systems. However, the lack of content on the technological systems in the health care setting inhibits prospective physicians from understanding the benefits of using these technologies, the ethical issues that can arise with their use, and future innovations, along with the wider implications of AI. In Civaner et al's [2] survey of medical students' opinions on AI education, they found that 75.6% of students had either limited or no education on the topic of AI. These participants also noted not feeling well equipped to work with AI in the clinical setting. Additionally, in Yun et al's [3] proposal for future internal medicine physicians, they suggested that these prospective physicians should be able to appreciate the roles of big data and AI in health care. Clearly, there is a desire from students, as well as residency and fellowship programs, to incorporate AI education into the medical school curriculum and training. AI education and training cannot continue to be delayed, as some forms of AI have already been deployed in the clinical setting.

Although several studies have provided proposals for implementing AI education into the medical school curriculum, they have also noted the difficulties of developing AI education, such as schedule constraints and the challenges of deciding the material that should be covered [4,5]. Additionally, this task should not solely be deferred to the attending physicians, as they themselves might not have the adequate training with AI to teach others [5]. Although these challenges serve as barriers to implementing quality AI education into the curriculum, an attempt to include at least some type of education on or educational resources about AI is needed to prepare students and potentially prevent problems in the clinical setting, as further explored in the following section. Therefore, future physicians, medical students, and residents should be trained on the use of AI in health care and other related topics, such as big data or machine learning, to understand the tools they will be working with. Even though medical students should not be expected to be experts in AI and know every technical aspect of these technologies, they should at least feel comfortable with navigating how and when to use AI.

The Problem of Automation Bias

Although AI is supposed to aid physicians in various processes to decrease their workload and give them more time with their patients, AI can also cause unintended ethical issues. One of the common ethical concerns with AI is that it can essentially be a black box, where the results from the AI are illogical, and the AI developer cannot track how it produced those erroneous

results. This problem becomes exacerbated when automation bias arises. Automation bias occurs when a user overrelies on AI systems. Therefore, if a physician exhibits automation bias, then they will not question the results from the AI, potentially leading to bad medical care. In Lyell et al's [6] study, the error rate associated with a clinical decision support system when it was inaccurate was higher (86.6%) in comparison to the rate it had when it was accurate (58.8%). Although automated processes aid in decision-making and can provide accurate results, there is also the possibility of these systems providing incorrect results and causing irreversible harm on a much larger scale. An example includes the Prescription Drug Monitoring Program (PDMP), a machine learning system that provides risk scores for patients' likelihood to misuse prescription drugs, which can cause both testimonial injustice and physical harm [7,8]. Testimonial injustice, a form of epistemic injustice, develops when a patient's account of their health is unfairly dismissed by their physician [8]. Testimonial injustice invalidates the credibility of patients and further implies that their care is dependent on how physicians deem their trustworthiness [8]. A patient's risk scores can be negatively affected if their chart becomes commingled, which is also known as *overlay*, where a specific person's electronic health record erroneously pulls in the data of other patients with similar demographic characteristics and compiles these data into 1 chart [7,9]. As such, a patient with chronic pain may not receive the medication they need due to the PDMP providing an incorrect risk score. If a physician uses the risk scores of the PDMP without validating the results or considering their patients' testimonies, then physical harm, as well as patients' mistrust toward the physician and the potential deterrence of seeking health care, will ensue. Although AI can aid in the decision-making process, ultimately it is the duty of the physician to ensure that their decisions are based on sound clinical judgment. As such, if a physician with automation bias applies an erroneous outcome to a patient's care, then the physician becomes accountable for that outcome instead of the AI, as they are the party that used the outcome. To clarify, more sophisticated AI and machine learning systems have been proposed, of which the results would be difficult for users to verify, as these systems use advanced techniques that do not rely on predefined rules. However, the AI systems described in this section are known as *expert systems*, which use a coded set of rules and rely on predefined rules [10]. Even though the verification process might essentially be beyond the scope of some physicians' expertise regarding future AI and machine learning, physicians should remain attentive to results from AI.

The Implications for Medical Students and Residents

As seen with the case of the PDMP, automation bias can lead to various harms. Therefore, the systemic issue of automation bias in health care must be addressed. The mentality that AI is always right is often associated with medical students and residents [6,11]. As these groups have grown up in the digital age, they are more comfortable with embracing technology into their practice than older physicians (who either lack digital literacy or are resistant to change). In addition to their openness

to using AI, medical students and residents might be prone to automation bias, as they lack experience or are not confident in their skills [11]. Multiple studies have found that algorithmic appreciation—a user's valuing of an algorithm's outputs—is lower for users who have more experience in a task than for those who are considered nonexperts in that task [12,13]. A combination of factors, such as newer physicians being digital natives, insufficient expertise, and less overall confidence, highlights how the systemic problem of automation bias came to be. Therefore, the deficiency of AI education in medical school and beyond sets up users to become susceptible to automation bias, as they might be unaware of the technical problems with AI. These users will come into the clinical setting with the assumption that AI systems are always accurate, which will cloud their clinical judgment.

In addition to the broader discussion of AI in health care, which students will inevitably have to interact with at some point in their professional careers, I want to focus on an AI that is accessible to students now—ChatGPT. The fact that ChatGPT has passed the US Medical Licensing Examination could entice students to use ChatGPT [14]. Moreover, Tiwari et al [15], who applied the Technology Acceptance Model to ChatGPT, found that students generally had positive views (in terms of perceived usefulness, credibility, social presence, and hedonic motivation) of ChatGPT based on their previous experiences with using the tool. However, just as AI can be a black-box algorithm, so too can ChatGPT, with respect to its hallucinations. ChatGPT's hallucinations are results that are seemingly feasible but do not actually exist [1,16]. For example, it is commonly known that ChatGPT can make up citations [16,17]. Additionally, in an editorial, ChatGPT had to be prompted several times by the author to finally respond that it cannot generate visual diagrams [18]. Further, ChatGPT's data sources only cover data from 2021 and prior years, and as its scope is limited to this context, ChatGPT can provide outdated information [19]. Therefore, despite the acclaim, ChatGPT is not as perfect as some claim it to be. Given the push for ChatGPT use, there is a risk that users might develop an AI solutionism mentality, where users assume that AI has the answer to all problems [10]. AI solutionism is closely related to automation bias, as users with the preconceived notion that AI is always right are more willing to turn to AI. As such, if we train medical students to use ChatGPT, will they be more predisposed to automation bias in the future when they become residents? Although there is no direct answer to this question, given what is known about the medical school curriculum, the context of the student population being composed of digital natives, and the AI solutionism mentality, the possibility of this happening seems likely. Some medical students will take their past, positive interactions with ChatGPT, wherein they received the right response, as confirmation that ChatGPT is reliable. The concern here is that students' perceptions of the reliability of ChatGPT dictate their views on AI, including AI in the clinical setting, making it easier for them to become susceptible to automation bias. Although some suggest using AI suppression, an approach where an AI's recommendations are not provided if there is "a higher misleading probability," to mitigate the risk of automation bias, there appears to be no concrete solutions to solving this problem, especially in the context of the "novice" medical student and

resident population [20]. It must also be acknowledged that sometimes, AI use cannot be completely avoided in the health care setting. Thus, in controlling the reoccurrence of automation bias, I believe that students must not only be aware of this potential problem but also build the skills required to prevent this mentality. When addressing the risks of AI in the medical school curriculum, automation bias needs to be a discussion topic. Besides teaching about automation bias, when training medical students, it is important to consider the "hidden curriculum" about using AI, that is, the implied lessons, cultures, and views that students learn in lectures or from observations of faculty [21]. If faculty also fall into the trap of AI solutionism, this will lead to a biased perspective on AI and contribute to the "hidden curriculum." Faculty should serve as an example for students by ensuring that students have the right critical analysis skills and are comfortable with questioning results instead of accepting what is being given to them. This builds students' confidence in trusting their instincts, which could deter them from automation bias.

When Should ChatGPT Be Used in Medical Schools?

Although this editorial takes a more critical stance on AI and ChatGPT, I want to clarify that this does not mean that these tools should never be used or that their functionalities are ineffective. Notably, in the preclinical phase, the medical school curriculum is not catered to students, as the focus is on ensuring that students have expertise on basic medical concepts, the structure and functions of the body, diseases, diagnoses, and treatment concepts [22,23]. This might be a challenge for some students who prefer different learning methods as opposed to the typical didactic method. ChatGPT can be a beneficial tool for students who prefer student-centered or self-directed learning, as it excels in summarizing information and generating practice questions [18,19,24,25]. Students who struggle with a concept in class or want further explanations could also use ChatGPT as an additional resource. Being able to personalize their learning experiences encourages students toward incorporating ChatGPT into their studies. As such, banning the use of ChatGPT could result in students being even more enticed to seek out the "forbidden" chatbot. Therefore, in addition to integrating AI education into the medical school curriculum and avoiding the "hidden curriculum" about AI, students should feel encouraged to use ChatGPT but only to a certain extent.

Despite the advantages of ChatGPT use, students should not be compelled to turn to ChatGPT for every task. For example, assignments that involve students writing about their firsthand experiences would not be appropriate for ChatGPT. With regard to a hypothetical student who delegated such an assignment to ChatGPT, van de Ridder et al [26] stated that "[r]eflections contribute to a learner's professional development, but this learner robbed themselves of an innate self-reflective opportunity." Students lose a potential outlet for their emotions and the humanistic aspect of care when they delegate ChatGPT to the task of writing a self-reflection piece [27]. Notably, ChatGPT appears to be popular in the context of scientific writing for the following reasons: "efficiency and versatility in writing with

text of high quality, improved language, readability, and translation promoting research equity, and accelerated literature review” [1]. However, Blanco-Gonzalez et al [28] argue that “...ChatGPT is not a useful tool for writing reliable scientific texts without strong human intervention. It lacks the knowledge and expertise necessary to accurately and adequately convey complex scientific concepts and information.” There are also concerns about plagiarism with ChatGPT, as it can fabricate citations, fail to disclose all references, and provide inaccurate content (as it only uses information from 2021 and prior years) [1,17]. Therefore, ChatGPT should not be used for writing, as it deprives students of the opportunity to engage in their professional identity and, for those wanting to go into research, the necessary research skills to conduct empirical or conceptual work. Additionally, some web-based educational resources, such as modules or augmented reality, might help supplement students’ experiences during the clinical phase [29]. However, the use of these resources, including ChatGPT, should not be the only learning experience that students have in the clinical phase. In order to build their interpersonal skills and practice humanistic care, students must interact with real patients and other professionals in the clinical setting. Although some students might feel prepared for these interactions (based on their experiences of working through case scenarios that ChatGPT generated for them), they will soon realize that they cannot predict or account for how patients or others (eg, a patient’s family, members of the care team, etc) react in real time. Learning to accommodate patients’ needs and working in a team cannot realistically be achieved with ChatGPT. Instead, these skills are cultivated through students’ experiences in the clinical setting.

The focus should not be on deciding whether to use ChatGPT but on determining the best contexts that ChatGPT can be

applied to. As seen in this editorial, ChatGPT excels at particular tasks, such as summarizing information and creating study materials [18,19,24]. Ideally, students should use ChatGPT to supplement their learning experience rather than use it as their sole resource for medical science education. Students should still validate the results (to the extent that they can) from ChatGPT, because it can provide inaccurate results and the problem of hallucinations persists, before they wholeheartedly study or apply the wrong information. When used in this context, ChatGPT plays a lesser role in students’ education, thereby further enhancing their ability to discern results and avoiding AI solutionism.

Conclusion

To minimize the risk of students developing automation bias, we need to ensure that students receive proper AI education, in which the courses and lessons will teach them about the ethical issues surrounding AI technologies, as well as the problem of automation bias, and encourage the moderate use of AI. ChatGPT should only be used for certain tasks, and it should not be the default resource that students turn to, as this could cause a domino effect, where students develop the automation bias mentality as a result of developing the AI solutionism mentality. Therefore, training medical students to avoid falling into these traps of AI solutionism and automation bias starts in the classroom. Again, the medical school curriculum must reflect the current needs of the students. Furthermore, faculty serve as an example for students; therefore, they should also be proactive in deterring the use of ChatGPT for all tasks and be careful not to contribute to the “hidden curriculum” about AI. Overall, ChatGPT is an assistive tool but only when used in the right context.

Abstract

Background: As part of the residency application process in the United States, many medical specialties now offer applicants the opportunity to send program signals that indicate high interest to a limited number of residency programs. To determine which residency programs to apply to, and which programs to send signals to, applicants need accurate information to determine which programs align with their future training goals. Most applicants use a program's website to review program characteristics and criteria, so describing the current state of residency program websites can inform programs of best practices.

Objective: This study aims to characterize information available on obstetrics and gynecology residency program websites and to determine whether there are differences in information available between different types of residency programs.

Methods: This was a cross-sectional observational study of all US obstetrics and gynecology residency program website content. The authorship group identified factors that would be useful for residency applicants around program demographics and learner trajectories; application criteria including standardized testing metrics, residency statistics, and benefits; and diversity, equity, and inclusion mission statements and values. Two authors examined all available websites from November 2011 through March 2022. Data analysis consisted of descriptive statistics and one-way ANOVA, with $P < .05$ considered significant.

Results: Among 290 programs, 283 (97.6%) had websites; 238 (82.1%) listed medical schools of current residents; 158 (54.5%) described residency alumni trajectories; 107 (36.9%) included guidance related to the preferred United States Medical Licensing Examination Step 1 scores; 53 (18.3%) included guidance related to the Comprehensive Osteopathic Medical Licensing Examination Level 1 scores; 185 (63.8%) included international applicant guidance; 132 (45.5%) included a program-specific mission statement; 84 (29%) included a diversity, equity, and inclusion statement; and 167 (57.6%) included program-specific media or links to program social media on their websites. University-based programs were more likely to include a variety of information compared to community-based university-affiliated and community-based programs, including medical schools of current residents (113/123, 91.9%, university-based; 85/111, 76.6%, community-based university-affiliated; 40/56, 71.4%, community-based; $P < .001$); alumni trajectories (90/123, 73.2%, university-based; 51/111, 45.9%, community-based university-affiliated; 17/56, 30.4%, community-based; $P < .001$); the United States Medical Licensing Examination Step 1 score guidance (58/123, 47.2%, university-based; 36/111, 32.4%, community-based university-affiliated; 13/56, 23.2%, community-based; $P = .004$); and diversity, equity, and inclusion statements (57/123, 46.3%, university-based; 19/111, 17.1%, community-based university-affiliated; 8/56, 14.3%, community-based; $P < .001$).

Conclusions: There are opportunities to improve the quantity and quality of data on residency websites. From this work, we propose best practices for what information should be included on residency websites that will enable applicants to make informed decisions.

obstetrics and gynecology; residency program; residency application; website; program signals; communication best practices

Introduction

In the United States, becoming an accredited physician is a rigorous and competitive process where candidates complete undergraduate training, medical school education, and residency training in a chosen specialty. Typically, individuals first obtain an undergraduate degree to gain admittance to a medical school. Next, they must earn a medical doctorate (MD) or doctor of osteopathic medicine (DO) from an accredited medical school or an equivalent international medical degree. Finally, they must complete postgraduate residency training; to fulfill this requirement, individuals apply to a residency program in their intended specialty. In the United States, many residency applicants are medical students in their final year of training, but individuals may also apply if they previously completed an MD or DO degree or completed medical school outside the United States and obtained certification from the Educational Commission for Foreign Medical Graduates [1]. All residency programs fulfill requirements set by the Accreditation Council for Graduate Medical Education, but programs have different strengths. Residency programs may be based in large university academic centers, community medical centers, or medical centers in a community setting that are affiliated with universities and often consequently emphasize clinical service to communities versus academic pursuits in training. Applying for residency is a competitive step in the physician training process; qualified applicants often apply to programs in a matching system that algorithmically matches applicants into programs that rank the applicant. In 2022, a total of 42,549 applicants were matched into 36,943 residency positions in the National Resident Matching Program Main Residency Match, making the overall match rate for all active applicants 86.8% [2]. This match rate, however, does not illustrate the full story; there is a wide range of match rates for different types of applicants and specialties, and the number of applicants who do not match into their top programs of interest is increasing [3].

Due to this competitiveness, now more than ever, residency applicants need transparent data to make informed decisions during the residency application process. Applicants determine where to apply, and among an increasing number of specialties, they must also decide where to send program signals—electronic tokens indicating high interest in a program—at the time of application submission. In the 2022 - 2023 application cycle, 17 specialties opted to include program signaling [4-7]. Ideally, applicants should apply and send signals to programs that align with their values and priorities and to programs where they have a reasonable chance of matching [4]. Determining which programs meet these criteria is a challenge for applicants; they rely on a variety of nationally available data sources [8,9] and have particularly valued information from program websites for their application decision-making [10-12]. Therefore, our study sought to characterize content available on obstetrics and

gynecology (OBGYN) residency program websites and to determine whether there were differences in website content according to program type and geographic location. Our goal was to use this information to inform best practices for residency program websites.

Methods

Study Design

This was a cross-sectional observational study of US OBGYN residency program websites. We examined programs listed on the Electronic Residency Application Service (ERAS) 2022 Participating Specialties and Programs website. All programs listed on March 22, 2022, were included. Data for whether the type or program was university-based, community-based university-affiliated, or community-based were obtained by searching for the program in the American Medical Association's Fellowship and Residency Electronic Interactive Database Access System. Data for the census region and division of programs were determined based on the US Census Bureau Regions and Divisions with State FIPS Codes document.

Two authors (PMD and OA) collected data between November 2021 and March 2022. After obtaining the list of residency programs, we searched for a website associated with the program through a direct link from the ERAS list. In cases where a link was unavailable or incorrect, a Google search was conducted to attempt to find a website. Individual programs were not contacted directly by the study team.

The authorship group identified factors that would be useful for residency applicants. This group consisted of OBGYN faculty with education leadership roles, an OBGYN resident, and an OBGYN medical student applicant. The group used experiences from these roles to iteratively create a list of factors to consider, including program demographics and learner trajectories, application criteria including standardized testing metrics, residency salary and benefits, and diversity, equity, and inclusion mission statements and values. Variables described whether particular information was available on websites and were classified as yes or no. Variable information needed to be available on the program website and its website pages, or via a direct link from the program website and pages. Each website page linked from the main page of the residency website was reviewed for content, and direct links that were judged likely to be relevant were also opened. Data were entered in a Google spreadsheet for collection. In cases of ambiguity, PMD and OA discussed the content and agreed on the determination. To confirm accuracy and interrater reliability, after completing data collection, 10% of records as determined by random number generation were checked, with no systematic errors identified. Interrater reliability was not formally calculated; however, a few data entries were incongruent. All collected variables are described in [Table 1](#).

Table . Content of obstetrics and gynecology residency program websites and comparison by type of residency program (N=290).

Data were exported from the Google spreadsheet as an .xlsx file and uploaded into JMP Pro 17.0.0 (SAS Institute, Inc), which was used to conduct statistical analysis. Descriptive statistics and one-way ANOVA were performed to determine differences among the three types of programs using a significance level of .05. Post hoc comparisons used the Tukey-Kramer honest significant difference (global *P*=.05).

Ethical Considerations

This study was considered by the University of Michigan's IRBMED institutional review board (study identification HUM00218409). The board determined that, in accordance with the board and federal regulations, the study did not require institutional review board approval because it considered publicly available data that could not be identified with a human subject.

Results

Of 290 OBGYN residency programs, 123 (42.4%) were university-based programs, 111 (38.3%) were community-based university-affiliated, and 56 (19%) were community-based. Most programs (283/290, 97.6%) had websites. Many programs did not include information about whether standardized testing filtering metrics are applied to applications (details are in [Table 1](#)). Notably, less than half (143/290, 49.3%) included any information about the Comprehensive Osteopathic Medical Licensing Examination (COMLEX). A majority of programs (238/290, 82.1%) listed the medical school of current residents, but fewer (158/290, 54.5%) described alumni trajectories. No programs discussed whether applicants with Deferred Action for Childhood Arrivals status would be considered.

When comparing types of programs, university-based programs were more likely to include a variety of information on their websites compared to community-based university-affiliated programs and community-based programs, including medical schools of current residents (113/123, 91.9%, university-based; 85/111, 76.6%, community-based university-affiliated; 40/56, 71.4%, community-based; *P*<.001); alumni trajectories (90/123, 73.2%, university-based; 51/111, 45.9%, community-based

university-affiliated; 17/56, 30.4%, community-based; *P*<.001); statements about whether the United States Medical Licensing Examination (USMLE) Step 1 is required (108/123, 87.8%, university-based; 77/111, 69.4%, community-based university-affiliated; 40/56, 71.4%, community-based; *P*=.001); statements about no minimum USMLE score (36/123, 29.3%, university-based; 10/111, 9%, community-based university-affiliated; 2/56, 3.6%, community-based; *P*<.001); any USMLE score guidance other than a passing grade (58/123, 47.2%, university-based; 36/111, 32.4%, community-based university-affiliated; 13/56, 23.2%, community-based; *P*=.004); diversity, equity, and inclusion statements (57/123, 46.3%, university-based; 19/111, 17.1%, community-based university-affiliated; 8/56, 14.3%, community-based; *P*<.001); discussion of availability of fellowships at the same institution (96/123, 78%, university-based; 27/111, 24.3%, community-based university-affiliated; 5/56, 8.9%, community-based; *P*<.001); and whether the average or estimated number of interview invitations were disclosed (17/123, 13.8%, university-based; 6/111, 5.4%, community-based university-affiliated; 0/56, 0%, community-based; *P*=.003).

On post hoc analysis, there were several characteristics with overall significantly different representation on the websites of different types of programs but not between all types of programs. On post hoc comparison, university-based programs had websites significantly more often than community-based programs, but not significantly more often than community-based university-affiliated programs (123/123, 100%, university-based; 108/111, 97.3%, community-based university-affiliated; 52/56, 92.9%, community-based; *P*=.02). University-based program websites indicated whether international applicants were considered significantly more often than community-based university-affiliated programs, but not significantly more often than community-based programs (93/123, 75.6%, university-based; 57/111, 51.4%, community-based university-affiliated; 35/56, 62.5%, community-based; *P*<.001). University-based program websites had significantly more program-specific videos or links to social media than community-based programs, but not

community-based university-affiliated programs (80/123, 65%, university-based; 62/111, 55.9%, community-based university-affiliated; 25/56, 44.6%, community-based; $P=.03$).

Additionally, on post hoc comparison of significant findings, two of the 25 characteristics studied had a different pattern of presence on program websites. Community-based program websites noted whether COMLEX Level 1 attempts were considered significantly more often than university-based program websites, but not more often than community-based-university affiliated programs (9/123, 7.3%, university-based; 16/111, 14.4%, community-based university-affiliated; 14/56, 25%, community-based; $P=.005$), and community-based program websites noted benefits or directly linked to benefits significantly more often than community-based university-affiliated programs, but not more often than university-based programs (89/123, 72.4%, university-based; 66/111, 59.5%, community-based university-affiliated; 45/56, 80.4%, community-based; $P=.01$). Further description is listed in [Table 1](#). There were minimal differences based on geographic location.

Discussion

Principal Results

Many OBGYN residency program websites lack information that is necessary for applicants to make informed decisions about where to apply and send program signals. When comparing types of programs, we found significant differences in website content, with many factors more often included by university-based programs than by community-based university-affiliated and community-based programs. Although this study was limited to OBGYN, these findings are relevant to all specialties, especially given the need for multiple intervention points for widespread residency application reform [3].

At this important educational transition point, applicants should ideally select residency programs that will enable them to thrive, both personally and professionally, during and after residency training. Many factors should be considered in learners' self-reflection processes, including whether they want to practice in an academic or community setting, their goals for research and fellowship training, and their individual learning styles. For residency programs to facilitate this decision-making process, this information should be available on program websites, particularly given applicants' reliance on this source [10-12]. Our work suggests that community-based university-affiliated programs and community-based programs currently lag behind university-based programs in several factors on their websites; consequently, applicants may miss an opportunity to learn about whether these programs align with their needs.

Our work is particularly salient given the widespread adoption of program signaling by many specialties. Transparency around

application criteria is necessary if this meaningful residency application reform is to be successful. Notably, detailed standardized testing score guidance was not included on many program websites. These criteria are especially important for applicants who have historically applied to more residency programs and had lower match rates, such as osteopathic medical school and international medical graduate applicants [3,13]. About half of the programs did not include information about alumni trajectories, which can be valuable for applicants trying to determine whether their professional goals around practice setting or fellowship align with those of prior residents. Program signaling presents an exciting opportunity for equity, but it is important for applicants to have the opportunity to send signals to programs that will consider their applications and align with their goals.

Improving transparency could also reduce residency programs' burden of reviewing large volumes of applications. By describing more criteria on websites, programs could communicate which applications will be considered—before applicants have spent resources on applying or signaling. In the National Resident Matching Program's Program Director Survey results, OBGYN residency program directors reported that an average of over 45% of applications are rejected based on standardized screening tools, before holistic review [14]. Failing to transparently describe criteria for standard screening tools can perpetuate rising application numbers and costs if applicants unknowingly apply to programs where their applications are automatically screened out of consideration.

From this work, we propose best practices for residency program websites in [Figure 1](#). The practices are informed by the authors' perspectives as applicant, resident, and OBGYN faculty stakeholders in the residency application process. These practices include describing transparent application criteria to help applicants understand if they qualify for consideration, statements about values and outcomes that illuminate program priorities, and logistic considerations that can influence whether a program is a feasible option for an applicant. If applicants have access to this information, they may identify a more targeted list of programs to which they can apply and send signals, which will ultimately aid in improving the residency application process for applicants and programs alike.

The US residency application process needs multiple reforms to improve match rates and increase favorable outcomes for applicants [3]. Signaling may prove to be an important component of this reform, but signaling can only be successful if applicants can send informed signals to programs that align with their goals and values. One opportunity for residency programs to contribute to the success of this reform is sharing information, such as our residency website best practices, that help applicants determine whether the program aligns with their qualifications, desires, and goals.

Figure 1. Best practices of what should be included in obstetrics and gynecology residency program websites. DO: doctor of osteopathic medicine.

Limitations

Some programs may not control their website content; instead, they may follow graduate medical education or organization-specified templates. Nevertheless, our work provides important information for these groups to make choices about website content and we propose best practices to consider in [Figure 1](#).

In this study, we collected data regarding USMLE Step 1 and COMLEX Level 1 examination scores. However, both exams have transitioned to a pass-or-fail grading system—USMLE Step 1 in January 2022 and COMLEX Level 1 in May 2022. Therefore, our data regarding USMLE Step 1 and COMLEX Level 1 scores may not apply to future applicants. Effects of a

pass or fail grading system in the application process are yet to be determined, but other criteria, such as USMLE Step 2 and COMLEX Level 2 scores, may take on increasing importance. Websites must be updated to accurately reflect program requirements, so we suggest this is an excellent opportunity to provide increased information to applicants, such as clearly stating testing requirements, whether multiple attempts at exams are accepted, and if there are USMLE Step 2 or COMLEX Level 2 score thresholds or guidelines for applicants.

Comparison With Prior Work

This work aligns with findings in other specialties and illustrates key findings that will be of value given the evolving state of residency application processes. OBGYN programs' websites

had rates of listing residents' medical schools, salary, benefits, and rotation schedules that are similar to those of other specialties [15-20]. Application selection criteria were more difficult to compare because definitions varied across studies. However, like several other specialties, less than half of OBGYN residency programs included specific USMLE Step 1 score guidance [15-18,21]. Additionally, OBGYN programs, like several other specialties, do not universally indicate whether programs consider international medical graduate students and can sponsor visas [20,21]. However, some OBGYN program websites do stand out for including diversity, equity, and inclusion information and case numbers more often than some other specialties [16,22].

Our comparison of different types of programs is less common. Studies in two other specialties compared academic and non-academic programs and found academic programs included more of the characteristics they studied, which aligns with our

findings in OBGYN [20,22]. Given the inherent value and differences in all programs, we believe that comparing types of residency programs presents an opportunity to understand which programs can improve in communicating with applicants.

Conclusions

In this competitive application landscape, it is crucial that applicants are provided equitable access to information that allows them to determine where to apply and send signals to optimize their success in matching at a program aligned with their values. Applicants use websites to determine residency program qualities, but the onus of deciphering the best fit should not rest entirely on them. A robust presentation of residency program personnel, curriculum, values, benefits, and application criteria can help applicants understand where their applications will be considered, and possibly where their signals are most strategic. Increased information sharing on program websites could contribute to an improved application process.

Abstract

Background: Many academic medical centers transitioned from in-person to remote conferences due to the COVID-19 pandemic, but the impact on faculty attendance is unknown.

Objective: This study aims to evaluate changes in attendance at medical grand rounds (MGR) following the transition from an in-person to remote format and as a function of the COVID-19 census at Vanderbilt Medical Center.

Methods: We obtained the faculty attendee characteristics from Department of Medicine records. Attendance was recorded using a SMS text message-based system. The daily COVID-19 census was recorded independently by hospital administration. The main attendance metric was the proportion of eligible faculty that attended each MGR. Comparisons were made for the entire cohort and for individual faculty.

Results: The observation period was from March 2019 to June 2021 and included 101 MGR conferences with more than 600 eligible faculty. Overall attendance was unchanged during the in-person and remote formats (12,536/25,808, 48.6% vs 16,727/32,680, 51.2%; $P=.44$) and did not change significantly during a surge in the COVID-19 census. Individual faculty members attendance rates varied widely. Absolute differences between formats were less than -20% or greater than 20% for one-third (160/476, 33.6%) of faculty. Pulmonary or critical care faculty attendance increased during the remote format compared to in person (1450/2616, 55.4% vs 1004/2045, 49.1%; $P<.001$). A cloud-based digital archive of MGR lectures was accessed by <1% of faculty per conference.

Conclusions: Overall faculty attendance at MGR did not change following the transition to a remote format, regardless of the COVID-19 census, but individual attendance habits fluctuated in a bidirectional manner. Incentivizing the use of a digital archive may represent an opportunity to increase faculty consumption of MGR.

KEYWORDS

continuing medical education; COVID-19; distance education; professional development; virtual learning

Introduction

Medical grand rounds (MGR) has evolved from the bedside [1] to a weekly presentation to the entire department [2]. Due to the COVID-19 pandemic, the format of MGR has undergone another transition, from in person to remote. While MGR attendance patterns for in-person conferences have been reported [3], the impact of remote conferences on faculty attendance at

MGR is unknown. The analysis of remote surgical conferences [4,5] has been limited by sample size and aggregate data.

We propose that including more faculty from multiple specialties and individual conference or attendee data will provide more robust analysis that may inform returning to an in-person format, maintaining a remote format, or using a hybrid approach. Therefore, using our institution's cloud-based attendance recording database, we (1) evaluated MGR attendance over time

before and after the transition to the remote format and (2) assessed the temporal relationship between our institution's COVID-19 census and attendance at MGR conferences.

Methods

Study Design, Participants, and Setting

We performed a retrospective cohort study of MGR attendance for all Department of Medicine (DOM) clinical faculty at Vanderbilt Medical Center active between March 2019 and June 2021. All conferences before March 12, 2020, were in person, and all conferences on or following this date were remote.

Attendee Characteristics

For each division within the DOM, the number of faculty eligible to attend each conference as well as the number of faculty that attended each conference were available, as was each faculty member's academic rank (assistant, associate, or full professor).

Recording of Conference Attendance

Attendance was recorded by a cloud-based continuing medical education (CME) system during the entire observation period. Faculty indicate their attendance by sending an SMS text message containing the unique numeric code for that conference to a specific CME number. Conference attendance is registered as a binary outcome. The number of faculty considered to have attended a conference was obtained directly from this system. The number of faculty considered not to have attended was defined as the difference between the number of faculty eligible to attend and the number for whom attendance was recorded. The proportion of attendance was defined as the ratio of those who attended to those who were eligible over a given time frame (ie, in person or remote).

Individual-Level Attendance Data

For each faculty member, the CME system generates a unique user number that is not related to any other identification mechanism or coupled to any other database. By removing all identifying information from faculty members' attendance data except this user number, we could track individual attendance over time without the capability of linking these data to a given faculty member's actual identity.

Archived Conferences

Beginning in November 2019, digital recordings became available shortly after each MGR. Attendance credit was not given for consuming MGR in this manner. The number of faculty members that accessed a given MGR and the date on which each faculty member accessed the conference were available from the archive.

Acquisition of COVID-19-Related Data

Our institution tracked the census of hospital inpatients with positive COVID-19 tests as well as the subset of that group that required intensive care unit (ICU) care or mechanical ventilation. The COVID-19 burden on a given day included the total number of COVID-19 patients (cases) relative to the peak observed during the observation period (calculated as cases or peak), the proportion of patients with COVID-19 requiring ICU care relative to the number of cases (calculated as ICU or cases), and the proportion of patients with COVID-19 requiring mechanical ventilation (calculated as ventilator or cases). We defined the "surge" as the interval between December 2020 and January 2021, when COVID-19 cases were at their maximum.

Statistical Analysis

The main analyses compared the attendance rates during the entire in-person and remote periods as well as during the surge. Additional analyses stratified attendance by academic rank. All comparisons were made using the chi-square test in GraphPad Prism (version 9.2.0; GraphPad Software). For individual attendees, the difference between attendance rates at in-person and remote conferences was calculated, as were the characteristics of the resulting distribution.

Ethical Considerations

This investigation was considered nonresearch activity by the Vanderbilt Medical Center's institutional review board (number 211362). The need for informed consent was waived because of the retrospective nature of the study.

Results

Cohort Characteristics and Overall Attendance Observations

Characteristics of the MGR conferences, speakers, and faculty attendees are displayed in [Table 1](#).

Table 1. Conference and attendee characteristics.

Characteristics	Value	Value at the end of the observation (range during observation period)
Conferences, n		
Total during observation period	101	N/A ^a
In person (prepandemic)	47	N/A
Remote (intrapandemic)	54	N/A

Pulmonary or critical care	46 (2)	46 (42-49)
Rheumatology	22 (1)	23 (21-23)
Assistant professor	328 (16)	349 (279-350)
Associate professor	107 (1)	109 (105-109)
Full professor	143 (11)	149 (107-151)

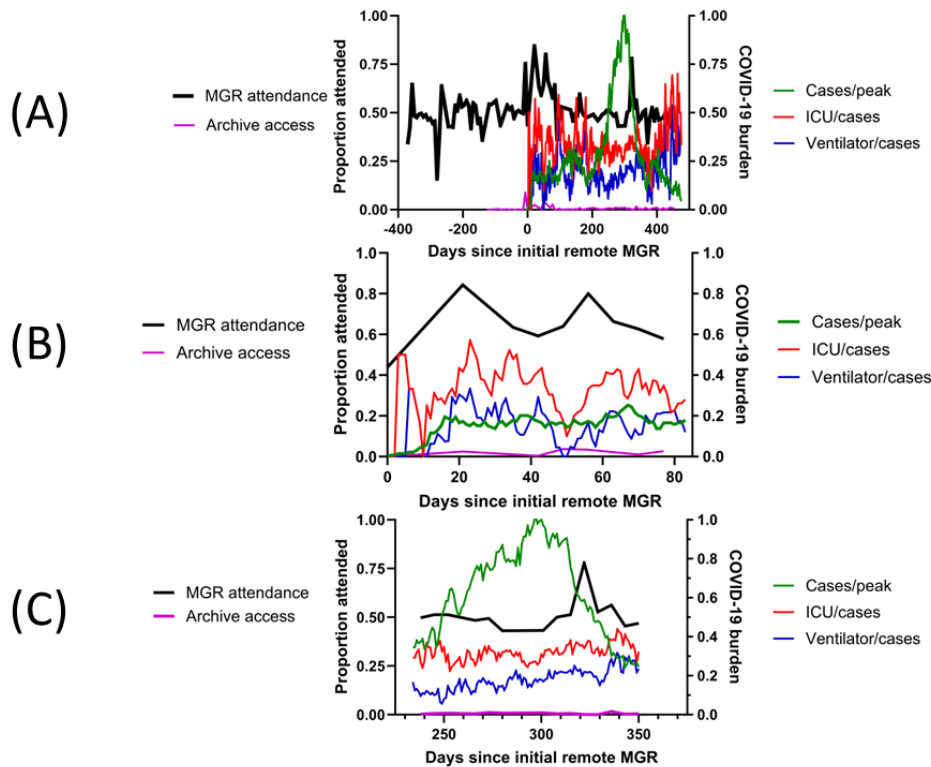

^aN/A: not applicable.

^bThe number of faculty in the subspecialties is fewer than the total due to not listing smaller divisions. Faculty categorized by academic rank may not sum to the total due to a small number of transitions between ranks.

Figure 1A shows (1) the time series of MGR attendance over the entire observation period and the number of times a given MGR was accessed from the cloud-based archive within 1 month of the conference, (2) the concurrent time series of COVID-19 cases as a proportion of the peak number recorded during the observation period, and (3) the time series of COVID-19 cases requiring ICU care and ICU cases requiring mechanical ventilation, both as proportions of the number of COVID-19 cases. Despite increases in remote attendance during the

beginning of the pandemic (Figure 1B) and a brief increase as the surge began to subside (Figure 1C), there was no difference in attendance at MGR during the in-person format and the remote format over the entire observation period (12,536/25,808, 48.6% vs 16,727/32,680, 51.2%; $P=.44$). The proportion of faculty accessing the MGR digital archive remained low throughout the observation period, never exceeding 5% for any lecture and often not exceeding 1% (mean 0.7%, SD 1.3%).

Figure 1. Time series of medical grand rounds (MGR) attendance and concurrent COVID-19 burden. (A) The entire observation period, (B) focus on the beginning of the remote format, and (C) focus on the surge. At the onset of the remote format, there is a nonsustained increase in attendance. As the COVID-19 census increased rapidly leading up to the peak census, there was no change in attendance. During the peak of the surge, there is a very small transient reduction in attendance followed by an extremely brief increase in attendance during a period of rapid decline in the COVID-19 census. Access to archived MGR lectures remained low during the entire observation period. ICU: intensive care unit.

MGR attendance stratified by academic rank across the in-person and remote formats is shown in Figure 2. Associate professor (3249/5788, 56.1% vs 2515/4989, 50.4%; $P<.001$) and full professor (3309/7718, 42.9% vs 2433/6757, 36%; $P<.001$) attendance was higher at MGR during the remote format relative to the in-person format.

Figure 2. Attendance at medical grand rounds stratified by academic rank. Assistant professor attendance was the same regardless of conference format, whereas associate and full professor attendance increased during the remote format relative to in person. $*P<.001$.

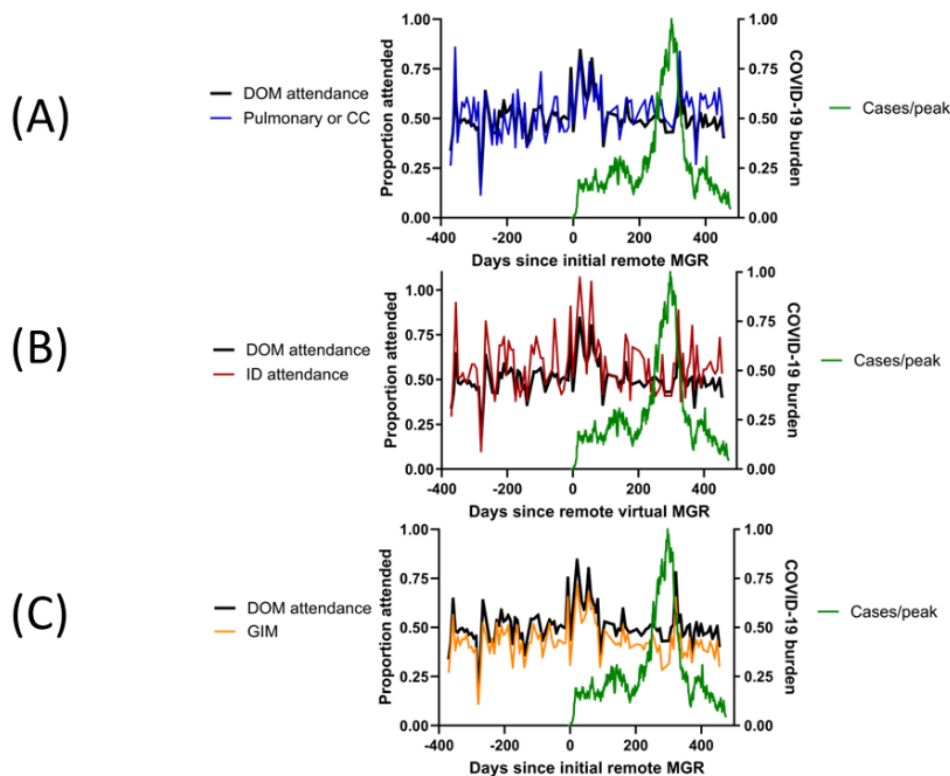

Subinterval and Subgroup Analyses

There was no difference in attendance during the surge compared to the 2 months before (October to November 2020; 2071/4218, 49.1% vs 2194/4229, 51.9%; $P=.38$) or 1 year before (December 2019 to January 2020; 2028/3990, 50.8% vs 2194/4229, 51.9%; $P=.34$).

The attendance trends of DOM subspecialties that were particularly impacted by the pandemic are superimposed on the overall DOM trend in Figure 3 for pulmonary or critical care (CC), infectious diseases (ID), and general internal medicine (GIM).

Figure 3. Selected subspecialty attendance trends. There are distinct qualitative patterns of medical grand rounds (MGR) attendance relative to the entire Department of Medicine (DOM) cohort for faculty in (A) pulmonary or critical care (CC), (B) infectious diseases (ID), and (C) general internal medicine (GIM).

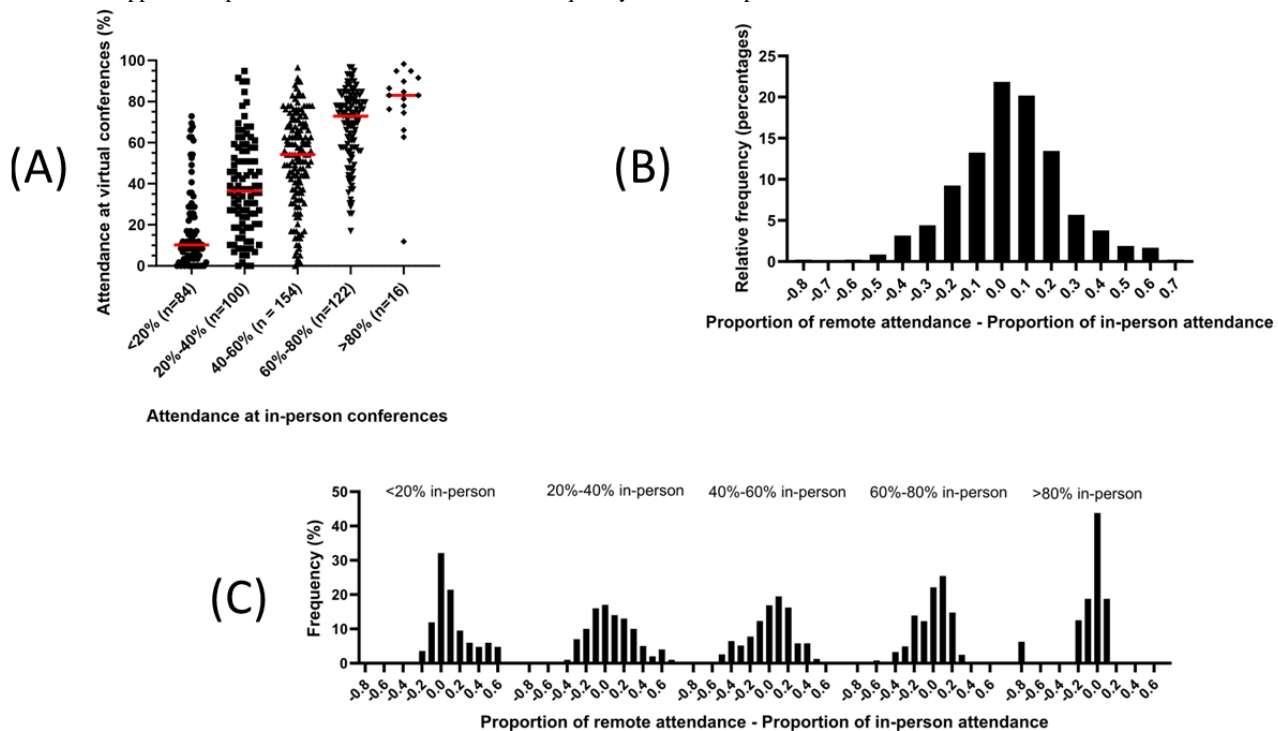

Pulmonary or CC attendance during the remote format was higher than during the in-person format (1450/2616, 55.4% vs 1004/2045, 49.1%; $P < .001$). This attendance pattern persisted while cases were rising and peaking during the surge, when demands on this portion of the faculty were likely greater than prepandemic. ID faculty had higher attendance throughout the entire observation period relative to the whole DOM cohort. The GIM faculty consistently attended MGR less frequently than the rest of the DOM cohort, including a sizable decrease during the peak of the surge.

Individual-Level Analyses

Data were available for 476 faculty eligible to attend all the MGR during the observation period. As shown in Figure 4A, attendance rates during in-person conferences did not predict attendance rates for remote conferences. As displayed in Figure

4B, the distribution of the absolute difference between remote and in-person attendance rates is relatively symmetric around the null, but outliers at both tails are noted. Attendance decreased by at least 20% for nearly 15% (64/476; 13.4%) of faculty and increased by at least that amount for 20.2% (96/476) of faculty. The distribution of the differences in individual faculty attendance between remote and in-person conferences is shown in Figure 4C, stratified by in-person attendance rates. The distributions of the 2 lowest categories of in-person attendance exhibit positive skewness, while the remaining categories demonstrate negative skewness, indicating that the direction of the changes in individual attendance patterns observed with the transition in conference format varied based on in-person attendance. Lastly, 4.8% (23/476) of faculty exhibited absolute differences of 50% in attendance between formats.

Figure 4. Individual-level attendance at in-person and remote medical grand rounds (MGR). (A) For a given level of attendance at in-person MGR, individual faculty member attendance at remote MGR fluctuated widely. (B) The distribution of the difference in attendance rates between conference formats for the entire cohort is relatively symmetric around the null, as expected given the overall lack of change. Nonetheless, extreme values of changes in attendance at the tails are noted. (C) Faculty that attended in-person MGR less frequently generally increased their attendance at remote MGR, while the opposite response was observed for those that frequently attended in-person MGR. Red bars indicate the mean.

Discussion

Principal Findings

Overall faculty attendance at MGR remained constant regardless of conference format, suggesting no disadvantage to the remote format. In addition, there may be substantial cost savings [6] and beneficial environmental impacts [7] associated with the remote format as it pertains to external speakers, who comprised the majority (60/101, 59.4%) of this cohort.

The increase in attendance of associate and full professors during the remote format may indicate fewer concurrent clinical obligations for these groups compared to their more junior colleagues. COVID-19-related MGR lectures at the beginning of the remote period may have led to the concurrent initial increase in attendance [8], but attendance quickly regressed to the mean, which was maintained even during a subsequent period of rapid rise and peak in COVID-19 burden.

Paradoxically, pulmonary or CC faculty attendance increased during the pandemic. It is possible that the attendance of the subgroup of non-ICU providers within pulmonary or CC may have increased during the pandemic while the attendance of their ICU-based colleagues declined. We speculate that the decreased attendance of the division of GIM was contributed to by lower attendance within the section of hospital medicine, perhaps because of burnout [9].

Individual faculty attendance habits did not remain static in response to the change in conference format. The pandemic or the remote format may have motivated faculty to attend MGR

who did not regularly do so, thus taking the place of faculty that were unable to attend due to increased clinical or administrative responsibilities. The presence of outliers at both extremes of attendance shifts may enrich further investigations of specific drivers of conference attendance, which could inform decisions regarding conference format moving forward.

Archived conferences were infrequently accessed throughout the observation period. Encouraging asynchronous viewing may increase consumption of MGR among faculty who are unable to do so in real time. Offering attendance credit for viewing MGR asynchronously could incentivize otherwise nonattending faculty.

Limitations

This study did not use surveys or other methods of obtaining feedback from faculty regarding their attendance patterns relative to the mode of MGR presentation, as collecting these data was not feasible given the study's retrospective design.

Attendance does not guarantee the observer has learned from MGR, although mandatory evaluations may not assess this objective either [10].

Conclusions

Overall faculty attendance at MGR was neither durably affected by a pandemic-related transition from in-person to a remote format nor by concurrent COVID-19 burden, although individual attendance behaviors varied considerably. If coupled with archived conference recordings, the remote format may be an equally attended and more cost-effective option for presenting MGR in a postpandemic era.

Acknowledgments

The authors wish to thank Attallah Stout and Joseph Braeuner for assistance with medical grand rounds topic, speaker, and attendance data; Ariel Dunham for assistance with the medical grand rounds digital archive; and Brandi Cherry and Chad Fitzgerald for assistance with COVID-19 census data.

Abstract

This study outlines the development of an electronic portfolio (e-portfolio) designed to capture and record the overall academic performance of medical undergraduate students throughout their educational journey. Additionally, it facilitates the capture of narratives on lived experiences and sharing of reflections, fostering collaboration between students and their mentors.

Introduction

The Brazilian curriculum guidelines for medical schools incorporate competencies in information technology, emphasizing students' co-responsibility in acquiring soft skills such as leadership, teamwork, and continuous professional development [1]. The curriculum experience must foster critical and reflective skills [2].

Ribeirão Preto Medical School at University of São Paulo, Brazil (FMRP-USP), is a 72-year-old traditional institution that initiated a curriculum change in January 2023. In this new proposal, we introduced a longitudinal axis and curricular unit called personal and professional development (PPD). The primary objective of PPD is to foster self-reflection on lived experiences, regular self-assessment, and monitoring of the students' progress in curricular and extracurricular activities, with a mentor's support.

To support the implementation of the PPD curricular unit, we collaboratively developed a software to serve as the electronic portfolio (e-portfolio) and record the overall academic performance of undergraduate medical students throughout their educational journey. An additional expectation is to encourage and guide teachers to provide and register formative assessments in their disciplines and rotations, and to document their experiences and reflections.

Methods

The collaborative development of the system involved developers, health educators, and students, which was crucial to ensure that the e-portfolio meets the needs and expectations of all stakeholders. Developers contributed technical expertise for functionality and accessibility, while educators shaped content based on educational principles. Students, as primary users, provided valuable feedback.

The main challenge in developing the e-portfolio was to create an initial set of requirements. With various participants bringing different ideas, there was a multitude of perspectives in the initial phase, which brought fundamental enrichment during development but also increased the difficulty of integrating all perspectives.

These challenges were overcome with Scrum [3] integrated with socio-technical research methodology to facilitate the collaborative environment. We implement Scrum practices, such as daily 5-minute meetings and biweekly 30-minute sprint reviews, ensuring incremental and continuous deliveries and communication between the development team and stakeholders, mainly regarding system development. Additionally, we integrated the socio-technical research methodology [4] into SCRUM, aiming to understand the software requirements as well as the various social and technological factors involved.

Regarding software development technologies, we used HTML, CSS, PHP, and the MySQL database management system.

Ethics Approval

The study received approval from the research ethics committee of the Clinical Hospital of FMRP-USP (CAAE: 67577523.1.0000.5440).

Results

The e-portfolio utilizes a web application architecture (Figure 1). Initially, we developed a structure to manage the registration of all the programs within the medical school, different curricular units, and offerings. We created a registration module for students and faculty members, allowing those to act as mentors, teachers, and discipline coordinators. Additionally, e-portfolio enables the recording of direct observed assessments in clinical settings, using preregistered forms based on methods such as mini-clinical evaluation exercise (Mini-CEx) [5],

360-degree assessment [6], One-Minute Preceptor, direct observation of procedural skills (DOPS), and case-based discussion/chart-stimulated recall (CBD/CSR) [7].

For narratives in medicine [8], there is a specific form to guide students on how to report a lived experience followed by a meaningful reflection, based on the REFLECT rubric for assessing reflective writing [9] (Figure 2).

Students are allowed to fill in data in their private profile (Figure 1), access their disciplines and received assessments, respond to formative assessments, record significant events for their education, check and compare their performance with their cohort, register extracurricular activities, and consult critical incidents recorded.

e-Portfolio enables students, discipline coordinators, and members of the student assessment committee to track assessments and feedback received, providing a longitudinal and progressive view of the student's cognitive, psychomotor (skills), and attitudinal development (Figures 1 and 2).

Figure 1. Profile and performance report of the medical student in the electronic portfolio (e-portfolio). (A) Profile created by the student in the e-portfolio. (B) Student's performance in various subjects is presented in relation to the radar chart: the blue line represents a comparison with the cohort mean (depicted by the gray area).

Figure 2. Evaluation form in the electronic portfolio (e-portfolio) with narratives and the adapted REFLECT rubric to guide the medical student and the mentor.

Discussion

This work presents the successful development of an e-portfolio at FMRP-USP. The e-portfolio is continuously enhanced and updated, and it is currently in a state suitable for use in a pilot study. The use of similar tools has been recognized for stimulating personal reflection, fostering collaboration, and strengthening digital literacy among students, encouraging active participation in the learning process [10].

The application of Scrum offered an adaptable framework, promoting efficient collaboration among stakeholders. Additionally, socio-technical research methods, such as

qualitative interviews involving in-depth conversations with individuals or groups to explore their experiences related to technology, provided valuable insights into the needs and dynamics of end users in the educational context. The use of Scrum with socio-technical research methods enables a more integrated, collaborative, and reflective approach during development.

Future Steps

We intend to evaluate e-portfolio usability, effectiveness, acceptance, and satisfaction in practical contexts with the objective of consistently enhancing the system and its outcomes.

Acknowledgments

We would like to express our gratitude to the Ribeirão Preto Medical School, University of São Paulo, and the startup Intersection (Ribeirão Preto, Brazil) for their partnership in software development. We would like to thank Prof Francisco S Guimarães for all the support and follow-up with the medical students and mentors. Additionally, we extend our appreciation to the Conselho Nacional de Desenvolvimento Científico e Tecnológico – Brasil (CNPq). This study was financed in part by CNPq (process no.: 001). Furthermore, this study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior – Brasil (CAPES) – Finance Code 001.

Authors' Contributions

LRAS and VRB contributed to the study concept and design, data acquisition, analysis, interpretation, and manuscript writing. AMO, LMACS, GJA, WDLC, and DCBD contributed to the interpretation, manuscript writing, and critical review of the manuscript for important intellectual content. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

ChatGPT; medical licensing examination; generative artificial intelligence; medical education; large language model; images; tables; artificial intelligence; AI; Japanese; reliability; medical application; medical applications; diagnostic; diagnostics; online data; web-based data

Introduction

OpenAI's ChatGPT, a leading large language model (LLM), has shown promise for medical purposes. The program can pass the United States Medical Licensing Examination (USMLE) and the Japanese Medical Licensing Exam (JMLE) [1-3]. However, previous studies regarding this software have focused on its text-based capabilities. ChatGPT-4 Vision (ChatGPT-4V), announced on September 25, 2023, includes image input features, potentially expanding the medical applications of the program [4]. To assess the multimodal performance of ChatGPT-4V in medicine, its performance on JMLE questions involving clinical images and tables was tested.

Methods

Overview

ChatGPT-4V was used to complete the 117th JMLE in the Japanese language (Figure S1 in [Multimedia Appendix 1](#)). Its responses were compared to the passing criteria and mean human examinee score of the JMLE. This study, conducted from October 12 to 14, 2023, used the September 25, 2023, version of the LLM (ChatGPT-4V) with a knowledge cutoff date of January 2022 ([Multimedia Appendix 2](#) [5]). Human examinees' correct response rates were obtained from statistics based on reports from actual JMLE examinees, calculated by medu4, a preparatory school for the JMLE [5,6].

Statistical Analysis

The mean and 95% CIs of the test scores are provided. A one-sample proportion test was used to compare the correct response rate of the human examinees with that of ChatGPT-4V. Statistical significance was set at $P < .05$ for all 2-tailed tests. All statistical analyses were conducted using Stata statistical software (version 17; StataCor).

Ethical Considerations

This study used previously available web-based data and did not include human participants. Therefore, Shimane University's Institutional Review Board did not mandate ethics approval.

Results

Evaluation Outcomes

The responses to 386 questions from the 117th JMLE were used in this study. Using the Ministry of Health, Labor, and Welfare criteria, GPT-4V scored 85.1% on the essential knowledge section and 76.5% on the other sections of the JMLE, meeting the passing criteria [6]. For text-only questions, ChatGPT-4V achieved a correct response rate of 84.5%, similar to the mean human examinee score ([Table 1](#)). The correct response rate for questions with images was 71.9% for ChatGPT-4V, 13.1 points below the mean human examinee score ($P < .001$). The correct response rate for questions with tables (including figures) was 35.0% for ChatGPT-4V, which was significantly lower than the mean human examinee score (83.9%; $P < .001$).

Table . Correct response rates of ChatGPT-4 Vision (ChatGPT-4V) and human examinees on the Japanese Medical Licensing Examination (JMLE).

Characteristics	Total, n (%)	Examinees ^a , mean	GPT-4V, mean	95% CI	Difference	<i>P</i> value
All questions	386 (100)	84.9	78.2	74.1-82.4	-6.7	.003
Question category						
Essential knowledge	96 (24.9)	89.6	83.3	75.9-90.8	-6.3	.04
General clinical knowledge	144 (37.3)	83.1	70.8	63.4-78.3	-12.3	<.001
Specific diseases	146 (37.8)	83.5	82.2	76.0-88.4	-1.3	.67
Type						
General	190 (49.2)	84.6	78.9	73.2-84.7	-5.7	.03
Clinical	149 (38.6)	84.1	77.2	70.4-83.0	-6.9	.02
Clinical sentence	47 (12.2)	88.5	78.7	67.0-90.4	-9.8	.04
Imaging and table questions						
Text only	252 (65.3)	84.9	84.5	80.1-89.0	-0.4	.87
With images	114 (29.5)	85.0	71.9	63.7-80.2	-13.1	<.001
With tables	20 (5.2)	83.9	35.0	14.1-55.9	-48.9	<.001

^aThe correct response rates of human examinees are based on a survey of actual human examinees, reported by medu4, a preparatory school for the JMLE [5].

Discussion

Principal Results

Although ChatGPT-4V demonstrated proficiency in text-centric questions, the correct response rates were significantly lower for image and table-oriented questions. ChatGPT-4V may have poorer text comprehension skills compared to ChatGPT-4, even when image processing is not required [7]. Additionally, a language bias may obscure the image context when interpreting images and texts simultaneously, potentially leading to an overreliance on prior text information, even when it contradicts the image context, a phenomenon called “hallucination” [8]. These factors may have led to ChatGPT-4V’s lower rate of correct responses to questions involving images.

Furthermore, responding to questions with tables requires interpreting the Japanese characters within the tables. OpenAI has verified that its GPT-4V model misrecognizes symbols, including image characters [4]. Previous studies have noted that GPT-4V relies on text-based information rather than an analysis of tables when answering questions [8]. In addition, the program’s performance diminishes when interpreting characters in non-Latin languages [9]. These factors may explain the observed decline in performance when interpreting tables containing Japanese characters.

The multimodal LLM GPT-4V is unreliable in interpreting information presented in image or tables, especially for medical

purposes [4]. Further development of the program is required for diagnostic applications.

Limitations

This study has several limitations. First, different results may be obtained even when using the same methods owing to the inherent randomness of ChatGPT or version changes in ChatGPT. A report indicates that test results can vary with repeated responses from ChatGPT [10]. Furthermore, when providing images to ChatGPT, we did not remove blank spaces, indicating that the quality of images sent to ChatGPT could also affect the outcomes. Second, the JMLE includes options that, if selected twice or more, will result in failure. However, these options are not publicly disclosed, making them unaccounted for in this study [5]. Finally, although this study focused on ChatGPT, ongoing advancements in other multimodal LLMs should also be considered.

Conclusions

ChatGPT-4V successfully passed the 117th JMLE, demonstrating proficiency in handling including image- and table-based questions. However, more developments are needed to improve its ability to interpret tables. Further research should assess the safety and efficacy of ChatGPT-4V as a multimodal LLM in supporting medical practice, facilitating learning in clinical environments and advancing medical education.

Acknowledgments

We would like to thank Dr Kota Sakaguchi, Shimane University Hospital, for his careful support throughout this study. We would also like to thank Dr Sanjay Saint, a professor at the University of Michigan, for his numerous contributions and support in this work.

Abstract

To assess the utility of wearable cameras in medical examinations, we created a physician-view video-based examination question and explanation, and the survey results indicated that these cameras can enhance the evaluation and educational capabilities of medical examinations.

(*JMIR Med Educ* 2024;10:e53193) doi:[10.2196/53193](https://doi.org/10.2196/53193)

KEYWORDS

medical education; medical technology; wearable device; wearable camera; medical examination; exam; examination; exams; examinations; physical; resident physicians; wearable; wearables; camera; cameras; video; videos; innovation; innovations; innovative; recording; recordings; survey; surveys

Introduction

Wearable devices have been increasingly used in medicine [1]. Wearable video cameras differ from conventional cameras in that they simulate the perspectives of health care professionals rather than the view of observers. In medical education, wearable video cameras have shown their usefulness in patient interviews [2], virtual physical examination training [3], educational live-streaming ward rounds [4], basic clinical procedures (eg, vascular access) [2], and endoscopic and surgical procedures [5,6]. Wearable cameras, capable of capturing highly realistic situations, can be effective in assessing practical knowledge and providing educational feedback. However, they have not been used in medical examinations. This study aimed to examine the utility of wearable cameras in creating examination questions and answers.

Methods

Development of an Examination Question and Its Explanation

We developed a single examination question focusing on physical examination skills for resident physicians. In October 2021, authors YN and TS created a simulated outpatient case of appendicitis: a middle-aged man with abdominal pain and localized peritoneal irritation in the right lower quadrant. A volunteer physician played the role of the simulated patient. A physician examined the patient with a wearable camera on his head, recording physician-patient interactions. A compact wide-angle wearable camera (Insta360 ONE R) was used to reproduce a high-resolution physician view, including peripheral view fields (Figure 1).

Using the recorded footage, we created 5 concise videos (about 10 seconds each) depicting various physical examination scenes, including (1) indirect abdominal percussion, (2) checking

peritoneal irritation by coughing in the supine position, (3) direct abdominal percussion, (4) the heel drop test, and (5) abdominal palpation; [Multimedia Appendices 1, 2, 3, 4, and 5](#). The examination question asked for the correct sequence of the physical examination. Based on the patient's position (standing to supine position) and the invasiveness of the examination

procedure, 4-2-1-3-5 was considered a correct answer upon the authors' agreement.

Additionally, we produced an explanatory physician-view answer video in which an experienced physician (TS) explained the proper sequence and key points in abdominal examinations ([Multimedia Appendix 6](#)).

Figure 1. Schematic description of (A) recording physical examination with a wearable camera and (B) its recoded image from the physician's view.

Study Participants, Examination, and Subsequent Survey

The General Medicine In-Training Examination (GM-ITE) for the academic year 2021, a validated nationwide computer-based examination in Japan, was conducted in January and February 2022 [7]. After completing GM-ITE, participants were given

the voluntary option to participate in this study on their computer monitors. If agreed, they were requested to answer the question and view the explanatory video. To evaluate the utility of wearable cameras from the examinees' perspective, participants were asked to complete a subsequent questionnaire survey using the same computers.

Data Analysis

We described participant characteristics, examination results, and survey results using descriptive statistics.

Ethical Consideration

We obtained informed consent from the person who played the simulated patient's role and all other participants before the examination. All data were anonymized, and no honorarium was provided to participants. This study was approved by the Ethics Review Board of the Japan Organization of Advancing Medical Education (approval number: 21 - 10).

Results

A total of 43 resident physicians from multiple Japanese institutions who completed the examination and survey were

included. Of these, 28 (65.1%) participants were postgraduate year-1 and 15 (34.9%) were postgraduate year-2 residents; 19 (44%) participants correctly answered the question.

In the postexamination survey, 32 (74%) participants agreed that they could envision real patients better compared to text-based questions (question 1); 26 (61%) were satisfied with the question (question 2); 29 (67%) stated that physician-view videos were more suitable for evaluating clinical competency than observer-view videos (question 3); and 34 (79%) answered that physician-view explanatory video was a more effective educational approach than text-based explanations (question 4; [Table 1](#)).

Table . Results of the survey about the examination and explanatory videos.

Survey questions	Total (N=43), n (%)
Question 1: Are you able to envision real patients better with this examination compared to a text-based question?	
Strongly agree	11 (26)
Agree	21 (49)
Neutral	5 (12)
Disagree	5 (12)
Strongly disagree	1 (2)
Question 2: Are you satisfied with this question?	
Strongly agree	8 (19)
Agree	18 (42)
Neutral	13 (30)
Disagree	4 (9)
Strongly disagree	0 (0)
Question 3: Are physician-view videos more suitable for evaluating clinical competency than observer-view videos?	
Strongly agree	13 (30)
Agree	16 (37)
Neutral	11 (26)
Disagree	3 (7)
Strongly disagree	0 (0)
Question 4: Is an explanatory video from a physician's viewpoint more effective for learning the content than traditional text-based explanations?	
Strongly agree	13 (30)
Agree	21 (49)
Neutral	5 (12)
Disagree	4 (9)
Strongly disagree	0 (0)

Discussion

This study used wearable cameras to create examination questions and subsequent answer explanations; the survey

suggested the potential utility of physician-view videos in medical examinations.

This study's results align with previous research, which showed the effectiveness of chest-mounted point-of-view footage over observer-view videos in physical examination training [3]. For

teaching physical examination, video-based e-learning was superior to illustrated text-based e-learning [8]. Moreover, a clinical simulation video successfully assessed clinical competencies across multiple domains in resident physicians [9]. Wearable cameras can provide learners with “immersion,” a sense that one is participating in realistic experiences, which enhances situated learning [10]. Physician-view videos of real clinical situations may emphasize diverse (eg, nonverbal) information. Furthermore, physician-view videos can motivate

examinees to learn more actively by regarding themselves as practitioners rather than observers.

This pilot study had limitations. We used a simple subjective survey in a small cohort of volunteer participants. Additionally, the participants’ detailed characteristics were not collected. More quantitative research with objective outcomes will be required to verify the educational value of incorporating wearable cameras into medical examinations.

Acknowledgments

The authors would like to express their deep appreciation to Dr Soshi Mano for his cooperation in assisting with this study. Generative artificial intelligence was not used in our manuscript. This study was supported by the Health, Labor, and Welfare Policy Grants of Research on Region Medical (21IA2004) from the Ministry of Health, Labor, and Welfare (MHLW). The MHLW did not participate in any part of the study process, including the designing, data analysis, data interpretation, review, and approval of the manuscript.

Data Availability

The data used in this study are not available because participants of this study did not consent to public sharing of their data.

Conflicts of Interest

FS, TS, KS, and YY received honoraria from Japan Institute for Advancement of Medical Education Program (JAMEP) as General Medicine In-Training Examination (GM-ITE) exam preparers. YN received an honorarium from JAMEP as GM-ITE project manager. YT is the JAMEP director and received an honorarium from JAMEP as a speaker at a JAMEP lecture. KS and HK also received honoraria from JAMEP as speakers at JAMEP lectures.

Abstract

Our research letter investigates the potential, as well as the current limitations, of widely available text-to-image tools in generating images for medical education. We focused on illustrations of important physical signs in the face (for which confidentiality issues in conventional patient photograph use may be a particular concern) that medics should know about, and we used facial images of hypothyroidism and Horner syndrome as examples.

(*JMIR Med Educ* 2024;10:e52155) doi:[10.2196/52155](https://doi.org/10.2196/52155)

KEYWORDS

Introduction

Artificial intelligence (AI) has become integral in medicine, outperforming skilled radiologists in certain domains [1]. However, there is limited exploration of AI's potential in producing illustrations for medical education [2,3]. Confidentiality concerns can limit traditional patient photo use, especially when facial features are essential [4]. Using widely available AI text-to-image tools, we aimed to create images portraying distinct facial signs important for medical trainees—hypothyroidism (myxedema) and Horner syndrome [5,6]. These tools generate unique, high-quality images based on text prompts, utilizing learned probability distributions rather than pre-existing images [7].

Methods

ChatGPT was used to generate prompts for the two AI text-to-image tools used in this study—DALL·E 2 and

Midjourney ([Multimedia Appendix 1](#)) [8-10], with which the prompts were used to generate images for hypothyroidism and Horner syndrome. The images were assessed and selected, using the following suitability criteria:

1. Images were excluded if any of the following features were present: insufficient coverage of the face, blurred images, a lack of realistic or humanoid features, a lack of continuity of edges, background noise, cloning errors, and geometrical and shadow inconsistencies.
2. Remaining images were accepted if they adequately represented the facial features of hypothyroidism or Horner syndrome, as judged by the coauthors (all were experienced physicians).

If adequate images could not be generated via the above methods, additional prompts, which were not generated with ChatGPT, were used. If adequate images were still not generated, then secondary editing via Microsoft Paint and GNU

Image Manipulation Program (GIMP) was performed on the best image to try and meet the criteria listed above.

Results

Facial Features of Hypothyroidism

Using ChatGPT, the following text prompt was generated (restricted to the DALL·E 2 prompt word limit):

Generate an image depicting a middle-aged Caucasian woman with hypothyroidism presenting with facial myxedema. The woman should be shown

in a frontal view, focusing on her face, scalp, and neck, without any makeup. The face must be very rounded and extreme scalp balding with coarse hair. Skin looks dry and pale. Outer eyebrows have a paucity of hairs, eyelids look very puffy. She looks tired.

The prompt was used to generate 120 images. Of these, 53 were removed, using our preset exclusion criteria. Of the remaining 67, only 17 met some of the criteria for adequately representing facial features of hypothyroidism. The best image was selected as [Figure 1](#) [9], with no additional editing needed.

Figure 1. Artificial intelligence text-to-image production of facial features typical of hypothyroidism (myxedema) showing classical clinical features, including a rounded face with dry, pale skin; puffy eyelids; a general appearance of tiredness; and partial balding with coarse hair and loss of hair in the eyebrows (especially in the outer third). This image was produced by using DALL·E 2 [9] alone and without additional editing.

Horner Syndrome

The following prompt was obtained from ChatGPT:

Create an illustrative depiction of a patient displaying Horner's syndrome, emphasizing the key clinical features, such as ptosis (drooping of the upper eyelid), miosis (constricted pupil), and anhidrosis (lack of sweating) on one side of the face. Ensure the image

is clear and medically accurate, aiding in the understanding of this neurological condition.

Of the 120 images, 85 met our exclusion criteria, but none met our inclusion criteria, even after alternative prompts and DALL·E 2 were used. We therefore selected the best image (produced by Midjourney) and then performed secondary editing with Microsoft Paint and GIMP ([Figure 2](#) [10]). This produced an image of Horner syndrome that was judged as adequate.

Figure 2. Generated illustration of Horner syndrome. Image 1 was produced by using Midjourney [10]. Image 2 shows the result after minor image editing (as described in our *Methods* section) to attenuate the key teaching features, which are labeled in image 3 (A: ptosis; B: miosis; C: apparent enophthalmos; D: upside-down ptosis).

Discussion

We aimed to explore the potential, as well as the current limits, of AI text-to-image generation in producing illustrations of medical conditions affecting the face. Without the use of high-quality medical images, it can be more challenging to teach others about these important conditions [11]. We showed that AI text-to-image generation is readily possible for hypothyroidism—a condition with symmetrical features. However, for Horner syndrome—a condition with asymmetrical features—adequate images could only be produced after some additional slight editing, reflecting a possible limiting factor of these tools. Ours are the first AI-generated images of classical

facial features of hypothyroidism and Horner syndrome that we are aware of.

Confidentiality has become an increasing concern in the use of medical images over the last few decades. Text-to-image tools have ethical issues, including issues of consent for the original photos used to train these tools. Additionally, issues of accuracy are key. Nonmedics might be misled on medical signs by using such tools. Targets for future research are the potential for biases with these tools and the danger of stereotypes being perpetuated. Despite these limitations, AI-generated images may enhance case-based learning, allowing students to study and analyze a diverse range of medical cases. Text-to-image tools show exciting potential and may allow easier access to high-quality images in medical education [12,13].

Abstract

Background: Incremental advancements in artificial intelligence (AI) technology have facilitated its integration into various disciplines. In particular, the infusion of AI into medical education has emerged as a significant trend, with noteworthy research findings. Consequently, a comprehensive review and analysis of the current research landscape of AI in medical education is warranted.

Objective: This study aims to conduct a bibliometric analysis of pertinent papers, spanning the years 2013 - 2022, using CiteSpace and VOSviewer. The study visually represents the existing research status and trends of AI in medical education.

Methods: Articles related to AI and medical education, published between 2013 and 2022, were systematically searched in the Web of Science core database. Two reviewers scrutinized the initially retrieved papers, based on their titles and abstracts, to eliminate papers unrelated to the topic. The selected papers were then analyzed and visualized for country, institution, author, reference, and keywords using CiteSpace and VOSviewer.

Results: A total of 195 papers pertaining to AI in medical education were identified from 2013 to 2022. The annual publications demonstrated an increasing trend over time. The United States emerged as the most active country in this research arena, and Harvard Medical School and the University of Toronto were the most active institutions. Prolific authors in this field included Vincent Bissonnette, Charlotte Blacketer, Rolando F Del Maestro, Nicole Ledows, Nykan Mirchi, Alexander Winkler-Schwartz, and Recai Yilmaz. The paper with the highest citation was “Medical Students’ Attitude Towards Artificial Intelligence: A Multicentre Survey.” Keyword analysis revealed that “radiology,” “medical physics,” “ehealth,” “surgery,” and “specialty” were the primary focus, whereas “big data” and “management” emerged as research frontiers.

Conclusions: The study underscores the promising potential of AI in medical education research. Current research directions encompass radiology, medical information management, and other aspects. Technological progress is expected to broaden these directions further. There is an urgent need to bolster interregional collaboration and enhance research quality. These findings offer valuable insights for researchers to identify perspectives and guide future research directions.

KEYWORDS

artificial intelligence; medical education; bibliometric analysis; CiteSpace; VOSviewer

Introduction

The concept of artificial intelligence (AI), referring to machines and systems capable of emulating human intelligence, was first introduced at an academic conference in 1956. Its extensive research fields encompass numerous domains, including intelligent expert systems, language processing, intelligent data retrieval, and intelligent control. AI stands as one of the three groundbreaking technologies of the 21st century, sharing the pedestal with genetic engineering and nanoscience technologies [1-3]. The ultimate aim of AI is to facilitate the use of machines in replicating and expanding human intelligence. In doing so, machines are empowered to listen, see, speak, think, and make decisions in a manner akin to humans, thus elevating the quality of human life [4,5].

The sustained evolution of AI has resulted in a paradigm shift in medical practice, transitioning from traditional methods to digital health care, with AI finding applications in diverse realms of medical and health care. AI can generate pathological diagnostic reports through integrated data analysis, aid psychologists in diagnosing mental disorders by simulating human thinking patterns, and perform imaging evaluations via deep learning. Moreover, AI can be used to manage clinical patients, and deliver doctor-prescribed treatment plans through records of patient history and treatment processes [6]. Research in AI has demonstrated that the output-input ratio in the medical field holds more promise than other disciplines [7]. As such, the advancement of medical education is imperative, and, over the past several decades, research and development in the application of AI in medical education has escalated [8].

Bibliometrics serves as a tool for the quantitative analysis of published literature, determining the relationship between research statements and emerging research frontiers, based on co-occurrence, citation, and cocitation [9]. Numerous global bibliometric analyses have been conducted using CiteSpace and VOSviewer in recent years. These analyses have focused on the comprehensive rehabilitation statuses and research trends of diseases such as cancer, ankylosing spondylitis, motor and neuropathic pain, and osteoarthritis [10-13]. However, to the best of our knowledge, a bibliometric analysis of AI's application in medical education has yet to be implemented.

Consequently, this study leverages CiteSpace and VOSviewer to assess the current research status and emergent trends of AI in medical education over the past decade.

Methods

All data for this research were procured from the Web of Science. The search parameters for data retrieval encompassed

the topics “artificial intelligence” and “medical education” (refer to Table 1), with a publication date range from 2013 to 2022. The search results were subsequently analyzed using CiteSpace and VOSviewer. CiteSpace, a visual analysis software developed by Chaomei Chen, was used to analyze the total number of papers related to the topic, the trend of changes over the years, the frequency of keywords, and centrality. This software allowed for a more convenient and intuitive analysis of the structure, rules, and distribution of subject knowledge. A scientific knowledge map facilitated the identification of research hotspots, progress, and the current situation within a specific field. VOSviewer, a software tool primarily oriented toward document data processing, enabled the analysis of the country, institution, author, journal, keywords, and co-occurrence knowledge graph of country, institution, journal, and document in the literature. Each node on the knowledge graph represented a unique element, with the connection width between nodes indicating collaboration strength, node size reflecting the number of publications, and larger nodes indicating more frequent releases.

Table . Search queries.

Set	Results, n	Search query
#1	140,447	(((TS ^a =(generative AI)) ^b OR TS=(AI)) OR TS=(Artificial Intelligence)) OR TS=(generative Artificial Intelligence) Indexes=Web of Science, timespan=2013-2022

#3	580	#1 and #2

^aTS: topic.

^bAI: artificial intelligence.

The papers for this study were downloaded in .txt format from the Web of Science database. Two expert researchers examined the title, keywords, and abstract, and screened the papers based on inclusion and exclusion criteria. In cases of disagreement or difficulty in paper inclusion, a third reviewer made the final decision via discussion. Initially, a total of 580 papers were searched, of which 385 papers that did not meet the study's topic were excluded, resulting in the retention of 195 papers.

Ethical Considerations

According to the Regulations of the People's Republic of China on Ethical Review of Science and Technology (Trial), Number 167 of the State Science and Technology Development Supervision (2023), scientific research activities involving humans or other animals need to undergo ethical review. This thesis does not involve humans or other animals, nor does it pose risks to life and health, the ecological environment, public

order, or sustainable development. Therefore, ethical approval is not required.

Results

Annual Publications

Figure 1 shows that a total of 195 papers on AI and medical education have been published in the past decade, showing an overall upward trend. The publications saw a significant surge from 2020 to 2021, reaching a peak in 2021, although the number of related papers published in 2022 decreased. The development of AI presented unprecedented opportunities and challenges to the medical and health industry. Medical education, being the cornerstone of medical industry development, can benefit from the application of AI, driving continual innovation.

Figure 1. Chart of the number of years issued.

National Analysis

Based on a comprehensive national analysis, 57 countries globally contributed to the exploration of AI within the field of medical education from 2013 to 2022. The United States took the lead by publishing 66 papers, thereby establishing itself as the most actively engaged country in this domain. The subsequent countries, albeit with lesser contributions, were Canada (24 papers), China (17 papers), England (13 papers), Singapore (12 papers), Australia (12 papers), India (9 papers), Germany (8 papers), the Netherlands (8 papers), and Spain (7

papers). The most cited countries were the United States (845 citations), Singapore (489 citations), and China (435 citations). When evaluated in terms of total link strength, the United States (44), the Netherlands (29), and Belgium (26) emerged as the top 3 countries (Table 2). Figure 2 shows that a clear inclination of North American and European countries toward the application of AI in medical education is evident, possibly due to their technological advancement. The United States has been a front-runner in this arena, publishing a multitude of relevant papers. Concurrently, it has fostered collaborative relationships with various countries for related research.

Table . Top 10 publications, centrality, and citations of countries.

Rank	Documents	Countries	Citations	Countries	Total link strength	Countries
1	66	United States	845	United States	44	United States
2	24	Canada	489	Singapore	29	The Netherlands
3	17	People's Republic of China	435	People's Republic of China	26	Belgium
4	13	England	371	Canada	23	Germany
5	12	Australia	155	England	22	England
6	12	Singapore	108	Spain	20	France
7	9	India	101	Germany	19	Italy
8	8	Germany	94	The Netherlands	19	Switzerland
9	8	The Netherlands	94	Belgium	18	Spain
10	7	Spain	85	Iran	16	Greece

Figure 2. National and regional co-occurrence map.

Institutional Analysis

Shifting the focus to an institutional analysis reveals that from 2013 to 2022, 77 institutions were engaged in research on AI in medical education. The two institutions that topped the list in terms of the number of publications were Harvard Medical School and the University of Toronto, each with 7 contributions, followed by McGill University and the National University of

California, San Francisco (5 contributions each) (Table 3). The institutions receiving the most citations were Nanyang Technological University (396 citations), McGill University (149 citations), and the University of Chicago (127 citations). Figure 3 shows that Leiden University and Harvard Medical School demonstrated more collaboration with other institutions, both exhibiting a link strength of 15.

Table . Top 10 publications, centrality, and citations of organizations.

Rank	Documents	Organization	Citations	Organization	Total link strength	Organization
1	7	Harvard Medical School	396	Nanyang Technological University	15	Leiden University
2	7	University of Toronto	149	McGill University	15	Harvard Medical School
3	5	McGill University	127	University of Chicago	11	Oregon Health and Science University
4	5	National University Singapore	104	University of British Columbia	10	University of Toronto
5	5	Oregon Health and Science University	86	Guy's and St Thomas' NHS Foundation Trust	9	University of British Columbia
6	5	Queens University	83	Kings College London	9	Stanford University
7	5	Stanford University	68	University California San Francisco	9	Queens University
8	5	University of California San Francisco	67	National University Singapore	8	Imperial College London
9	4	Emory University	66	Sultan Qaboos University	8	Johns Hopkins University
10	4	Leiden University	60	University of Maryland	7	Ludwig Maximilians University Munchen

Figure 3. Organizations co-occurrence map.

Author Analysis

In the span of the last decade, research on AI and medical education has seen the involvement of a total of 53 authors. The authors most frequently contributing to the documents included Vincent Bissonnette, Charlotte Blacketer, Rolando F Del Maestro, Nicole Ledwos, Nykan Mirchi, Alexander Winkler-Schwartz, and Recai Yilmaz, each writing 3 papers.

The authors garnering the highest citations encompassed the same group, with each achieving 143 citations (Table 4). As discerned from the VOSviewer image, there are no researchers with a significantly high number of publications, indicating that the volume of published papers remains relatively minimal. Figure 4 shows that research in this field is still nascent, with no particular research team outperforming others.

Table . Top 10 publications, centrality, and citations of authors.

Rank	Documents	Author	Citations	Author	Total link strength	Author
1	3	Bissonnette, Vincent	143	Bissonnette, Vincent	22	Bacchi, Stephen
2	3	Blacketer, Charlotte	143	Del Maestro, Rolando F	22	Duggan, Paul
3	3	Del Maestro, Rolando F	143	Ledwos, Nicole	22	Gallagher, Steve
4	3	Ledwos, Nicole	143	Mirchi, Nykan	22	Licinio, Julio
5	3	Mirchi, Nykan	143	Winkler-Schwartz, Alexander	22	Parnis, Roger
6	3	Winkler-Schwartz, Alexander	143	Yilmaz, Recai	22	Perry, Seth W
7	3	Yilmaz, Recai	56	Culp, Melissa P	22	Symonds, Ian
8	2	Bacchi, Stephen	56	Mollura, Daniel J	22	Tan, Yiran
9	2	Bulatov, Sergey	47	Sapci, A Hasan	22	Thomas, Josephine
10	2	Caliskan, S Ayhan	47	Sapci, H Aylin	22	Wagner, Morganne

Figure 4. Authors' co-occurrence map.

References Analysis

In accordance with [Table 5](#), there are 15 papers that serve as primary references in the research of AI and medical education. The paper titled “Medical Students’ Attitude Towards Artificial

Intelligence: A Multicenter Survey” emerged as the most frequently cited and most pertinent literature, garnering 36 and 109 citations, respectively. It primarily evaluates the attitudes of undergraduate medical students toward radiology and medical AI.

Table . Top 10 publications, centrality, and citations of cited reference.

Rank	Citations	Cited reference, year	Total link strength	Cited reference, year
1	36	Dos Santos et al [14], 2019	109	Dos Santos et al [14], 2019
2	23	Kolachalama and Garg [15], 2018	103	Wartman and Combs [16], 2018
3	23	Sit et al [17], 2020	98	Kolachalama and Garg, 2018 [15]
4	21	Gong et al [18], 2019	96	Sit et al [17], 2019
5	21	Wartman and Combs [16], 2018	85	Masters [19], 2019
6	19	Paranjape K et al [20], 2019	81	Paranjape K et al [20], 2019
7	19	Topol [21], 2019	78	Topol [21], 2019
8	16	Chan and Zary [8], 2019	78	Wartman and Combs [22], 2019
9	16	Masters [19], 2019	78	McCoy et al [23], 2020
10	15	Wartman and Combs [22], 2019	75	Park et al [24], 2019

The papers “Machine Learning and Medical Education” and “Attitudes and Perceptions of UK Medical Students Towards Artificial Intelligence and Radiology: A Multicenter Survey” are the second most frequently cited. The papers “Medical

Education Must Move From the Information Age to the Age of Artificial Intelligence” and “Machine Learning and Medical Education” occupy the second position in terms of total link strength. [Figure 5](#) illustrates this information.

Figure 5. Cited reference co-occurrence map.**Keywords Analysis**

The study examining AI and medical education from 2013 to 2022 concentrated on 39 primary keywords (Table 6). Figure

6 shows that AI (100), education (47), and medical education (45) have the highest frequency and connection intensity.

Table . Top 10 keywords related to AI in medical education.

Rank	Occurrence (%)	Keywords	Total link strength	Keywords
1	100	AI ^a	259	AI ^a
2	47	Education	131	Education
3	45	Medical education	114	Medical education
4	33	Machine learning	107	Machine learning
5	23	Technology	94	Technology
6	15	Radiology	56	Curriculum
7	14	Artificial intelligence	43	Radiology
8	13	Curriculum	43	Artificial-intelligence
9	12	Health	41	Performance
10	12	Medical students	38	Health

^aAI: artificial intelligence.

Figure 6. Keywords co-occurrence map.

Research Status

Figure 7 shows that the analysis of references with high citation frequency and centrality enables us to understand highly

respected research results in the application of AI in medical education.

Figure 7. Research status map.

In clusters 0 and 1, the swift advancement of AI has led to its application across all medical sectors, notably radiology [25-27]. Despite radiologists, residents, and medical students increasingly recognizing the importance of understanding AI, medical education that targets future radiologists is only just commencing [14,20,28]. Current investigations fall into 3 categories, that are (1) methods to facilitate medical students in learning AI knowledge, (2) using AI technology to augment radiology teaching efficiency and assist medical students in identifying clinical images, and (3) medical students' attitudes toward AI application in radiology. An AI curriculum (Artificial Intelligence in Radiology [AI-RADS]) has been devised to equip residents devoid of computing backgrounds with basic AI knowledge and its radiology application. The curriculum was

highly rated (9.8 out of 10) by residents for overall satisfaction and significantly increased students' confidence in interpreting AI-related journal papers. There was a marked improvement in residents' comprehension of AI's fundamental concepts [29]. Some institutions emphasize integrating AI frameworks to strengthen radiology education. For example, after scanning, the patient's condition will be interpreted by artificial intelligence to give a preliminary diagnosis. AI assigns cases to interns whose personal profiles indicate that they will benefit the most. Interns cooperate with artificial intelligence and use equivalent tools for diagnosis. Interns and attending radiologists elaborate on the final report. AI uses natural language processing to anonymize new cases, add them to the teaching archive, and update the personal profiles of trainees after new cases are

completed. When trainees review cases similar to new cases, AI will provide them with corresponding cases from the teaching archive.[30]. As this framework continues to evolve, it may be possible to achieve “precise medical education” tailored to the individual learning styles and needs of the students [30]. A multicenter survey assessing UK medical students’ attitudes and perceptions of AI and radiology revealed that students recognize the significance of AI and are eager to engage [17]. This prompts the need to integrate relevant AI courses into medical education to acquaint students with practical AI applications and constraints, thereby maintaining their learning enthusiasm and preventing AI-related panic.

Natural language processing is an important direction in the fields of computer science and AI. It studies various theories and methods that enable effective communication between humans and computers using natural language. Its main function here is to distinguish rare cases

In cluster 2, eHealth refers to the use of information and communication technologies to fulfill health care needs in various domains, including AI, telemedicine, Internet of Things, connected devices, and mobile health (mHealth) [31]. eHealth technologies provide access to health care in rural areas and support the management of numerous health conditions [32-36]. Following the release of the World Health Organization’s national eHealth strategy tool in 2012, it is imperative for future medical students to receive eHealth education and training. Current medical education primarily includes conceptual courses while neglecting practical training [37]. While emphasizing the inclusion of eHealth in medical education, it is also important to recognize the potential adverse outcomes of over-reliance on AI technology [38]. Hence, identifying the optimal eHealth application areas in health care is necessary [39].

In cluster 3, the integration of medical education and AI holds significant value and potential beyond radiology, extending into surgical education and surgery. AI’s earliest medical applications were in image-based specialties, such as radiology, pathology, ophthalmology, and dermatology. However, its application in procedural professions such as surgery may require more time [40,41]. The benefits of AI application in surgery mainly include integrating preoperative, intraoperative, and postoperative data to improve the accuracy of the clinical decision-making system and predict postoperative complications more efficiently and applying surgical knowledge and education to interact with surgeons and patients through virtual or augmented reality. For instance, virtual reality simulators were

initially used in laparoscopic surgery training [42]. A study involving 176 medical students was conducted to assess the accuracy of robot-assisted virtual surgical simulations after integrated deep learning, showing improved accuracy [43]. In 2022 and 2023, AI application breakthroughs were achieved in oral and maxillofacial surgery education [44] and orthopedic surgery [45]. While AI proves beneficial in surgery and surgical education, especially in surgical ability assessment, it raises questions regarding whether AI can ever match the intelligence and audacity of the human educators. Although advanced AI teaching tools can be incorporated into surgical education, current technology cannot fully replace multifaceted surgeons or surgical educators. Addressing the transparency and responsibility of AI application in medical education and resolving ethical issues may require more time and effort.

In cluster 5, the rapid AI development profoundly impacts medical education. Modern medical education must accommodate various health care systems, including digital health systems and big data generation in a highly connected world [46]. A Canadian survey of medical students’ perceptions of AI’s impact on radiology in 2018 showed that anxiety induced by the prospect of AI replacing radiologists deterred many students from considering radiology [18]. The radiology community should appreciate AI’s potential impact on the profession, educate students appropriately about AI’s role, and ensure radiology’s viability as a long-term career option. While AI’s benefits in medicine include eliminating human bias and enhancing pattern recognition and decision-making, its drawbacks, such as the inability to provide warmth and empathy to patients and absorb the wisdom of human educators, should not be underestimated. The confusion about whether AI’s role in medical education is supplementary or replacement-based is another concern [47]. In summary, while AI promises great advances and changes in medicine, it also poses numerous challenges and problems. The medical community needs to proactively address these challenges, leverage AI technology benefits, and promote continuous innovation and improvement in medical services.

Research Frontier

Figure 8 shows that big data has a significant intensity of 2.01, firmly at the top of the list, and has become the focus of medical education in the past 3 years. The emergence and proliferation of COVID-19 in 2019 ushered in the big data epoch in medicine, with telemedicine systems, clinical intelligent decision-making, and management systems taking on pivotal roles.

Figure 8. Top 20 keywords with strongest citation bursts.

First, the advent of big data has catalyzed the innovation of medical teaching paradigms: what does the future hold for medical education in the digital age? A study conducted by Han et al zeroes in on a future medical education model that leans heavily on big data, cutting-edge technology, and AI, with the aim to cultivate a new breed of medical students who display enhanced humanistic attributes, co-operation capacity, patient-needs sensitivity, and societal and global orientation [46].

Second, big data has stimulated innovation in clinical medicine models: the integration of advanced technologies like machine learning, clinical intelligent decision and management systems, and electronic medical records has propelled shifts, innovation, and advancement within clinical medicine paradigms. The study

by Kolachalama and Garg posits that AI, fueled by machine learning algorithms, is an emerging computer science branch that is swiftly gaining traction in health care. AI is anticipated to play an instrumental role in precision medicine and health [15]. In 2022, Watson and Wilkinson released a paper entitled “Digital Healthcare in COPD Management: A Narrative Review on the Advantages, Pitfalls, and Need for Further Research,” illustrating the vast potential of digital health care innovation [48]. During the COVID-19 pandemic, it was expected that big data would mitigate the workload for doctors interpreting digital data, enhance their diagnostic and prognostic abilities, equip clinicians with intelligent decision-making and management systems, and offer patients optimal clinical care and self-management strategies.

Undeniably, big data, akin to many emergent tools, is a double-edged sword. Ensuring its tailored use and dialectical treatment constitutes a crucial aspect of digital health, striving to exploit its merits while circumventing its demerits. The pursuit of enduring, comprehensive, and precise population health data management emerges as a long-term strategy.

The recent surge in terms indicates that “management” is intimately linked to “big data.” Confronting the colossal medical data of today, the incorporation of AI technology can enhance management efficiency in spheres, such as hospital medical management, disease surgery management, and chronic disease management, among others. AI algorithms are used to scrutinize data pertaining to patients’ hospitalization duration, hospitalization route, and climatic and temporal factors, which effectively curtail the hospitalization duration and significantly rectify issues, such as the misallocation of medical resources [49]. Leveraging a diabetic retinopathy automatic grading and training system furnished with an AI-driven diagnosis algorithm to groom budding doctors can augment diagnostic accuracy, thereby strengthening DR management [50]. Surgical video, a crucial data source for medical education, should be systematically stored and managed. A system intended to assist doctors in managing surgical videos can heighten the efficiency of continuing education by dissecting surgical videos and marking critical segments or frames to generate AI reports [51].

Discussion

In this investigation, a bibliometric evaluation of 195 pertinent papers over the preceding decade was meticulously executed using CiteSpace and VOSviewer. This research illustrates the findings related to countries, institutions, authors, citations, and keywords using tables and diagrams, offering an analytical perspective on the current research status and emerging frontiers in this domain. The outcomes were exhaustively analyzed.

Initially, examining the annual publication count, authors, institutions, and countries, it was identified that from 2019 onwards, global interest and recognition of AI’s applicability in medical education experienced an upswing. Second, superficially, collaboration in this arena might appear limited, an aspect that can be attributed to this field’s unique nature and the diverse modalities of medical education across different regions. For future progress, it is recommended that countries focus on harmonizing their approaches while acknowledging their differences, fostering collective advancement, and advocating for a mutual elevation of medical education standards.

Furthermore, an evaluation of the current research status and prevalent research themes highlighted that the extent of AI technology integration in medical education is significantly inadequate, with a rather limited focus area. Consequently, it is advocated that future efforts should aim at active exploration to unearth novel advancements.

Finally, AI, being inherently enigmatic, evokes uncertainty among both educators and learners about its future potentialities. Therefore, the immediate concern should be to strategically leverage its potential while mitigating its drawbacks, which, indeed, becomes the highest priority for future advancement.

Some limitations should be considered. The search strategies used can potentially yield divergent results, and the strategy opted for in this study might not encompass all pertinent literature. With the swift advancement of AI, several papers in this domain were brought to light in 2023. However, the temporal span of this study extends from 2013 to 2022, thus excluding the contributions from 2023.

The study highlights the promising potential of AI in medical education research, emphasizing the need for enhanced interregional collaboration and improved research quality. These insights provide valuable guidance for future research directions.

Acknowledgments

The authors would like to give their heartfelt thanks to all the people who helped them with this paper. All authors are grateful for the support of all present and future participants or participants as well as institutions. This study is funded by Major Science and Technology Special Plan of Science and Technology Department of Yunnan Province (project number 202102AA100016), Yunnan Provincial Department of Science and Technology—Yunnan University of Chinese Medicine Joint Special Project of Applied Basic Research (project number 201901AI070004), Yunnan Provincial Department of Science and Technology—Yunnan University of Chinese Medicine Joint Special Project of Applied Basic Research (project number 202101AZ070001-059), and Key Laboratory of Acupuncture and Massage for Prevention and Treatment of Encephalopathy in Universities of Yunnan Province (project number 2019YGZ04). The funding agencies do not play any role in the design, collection, analysis, or writing manuscript.

Data Availability

The data sets generated or analyzed in this study will not be publicly available. Consent and ethical approval do not include a provision for the sharing of data from this study.

Authors' Contributions

XT and XZ were the main investigators, mainly responsible for the overall framework and design of the paper. SW contributed to data processing and mapping. LY and ML supervised article writing and table design. All authors participated in the revision and approved the final manuscript.

Abstract

Background: Australian nursing programs aim to introduce students to digital health requirements for practice. However, innovation in digital health is more dynamic than education providers' ability to respond. It is uncertain whether what is taught and demonstrated in nursing programs meets the needs and expectations of clinicians with regard to the capability of the nurse graduates.

Objective: This study aims to identify gaps in the National Nursing and Midwifery Digital Health Capability Framework, based on the perspectives of clinical nurses, and in nurse educators' confidence and knowledge to teach. The findings will direct a future co-design process.

Methods: This study triangulated the findings from 2 studies of the Digital Awareness in Simulated Health project and the National Nursing and Midwifery Digital Capability Framework. The first was a qualitative study that considered the experiences of nurses with digital health technologies during the COVID-19 pandemic, and the second was a survey of nurse educators who identified their confidence and knowledge to teach and demonstrate digital health concepts.

Results: The results were categorized by and presented from the perspectives of nurse clinicians, nurse graduates, and nurse educators. Findings were listed against each of the framework capabilities, and omissions from the framework were identified. A series of statements and questions were formulated from the gap analysis to direct a future co-design process with nursing stakeholders to develop a digital health capability curriculum for nurse educators.

Conclusions: Further work to evaluate nursing digital health opportunities for nurse educators is indicated by the gaps identified in this study.

Introduction

It is widely recognized that digital health technologies have advanced at a rate greater than education about digital health [1]. Indeed, digital health has barely been established in the nursing curriculum, let alone evaluated to match what is needed in the clinical setting [2]. This is a somewhat unusual phenomenon wherein the application of a practice has happened in advance of the evidence that supports it. Digital technologies are constantly evolving to improve access efficiency, safety, and communication, and in turn, the scope of nursing informatics is rapidly evolving at the intersection of health care and information technology [3]. The adoption and optimization of electronic health records (EHRs) continue to be a major focus in nursing informatics, with a growing knowledge base on the

importance of user-centered design to improve the usability and functionality of EHRs, ultimately leading to better care and safety [4]. The COVID-19 pandemic accelerated the use of technologies such as EHRs, which led to reported burnout in the nursing profession [5]. Further during the pandemic, there was an increase in the adoption of telehealth technologies, with nurse clinicians playing a crucial role in facilitating telemedicine care, including remote monitoring and consultation [6]. The integration of telehealth into nursing practice has raised the importance of developing telehealth capabilities in nursing graduates and clinicians [7]. However, within health care, digital technologies have been adopted at a pace faster than they can be taught. As a result, digital health technologies are firmly embedded in clinical practice (eg, the electronic medical record, telehealth, and remote monitoring) while they are rarely used

or taught in the nursing curriculum [8]. There is consensus [9] that digital health technologies will improve the safety, efficiency, and quality of health care when implemented appropriately. It is essential that nursing graduates are not only skilled in the safe use of these technologies but also aware of the professional, ethical, and potential benefits and risks of these technologies.

The Australian Nursing and Midwifery Accreditation Council Registered Nurse Accreditation standards [10] state that digital health in the curriculum should be informed by the domains of the National Nursing and Midwifery Digital Health Capability Framework [11], at the level of implementation the extent to which these domains are applied is difficult to assess. In order to determine what education is needed at an undergraduate level to provide adequate digital awareness, knowledge, and skills, first it must be understood what is known, what is taught, and what health care expects of graduate nurses.

The Digital Awareness in Simulated Health (DASH) project has, through several successive and iterative phases, examined the current digital health education needs in nursing training in order to address knowledge and skill needs for nurses in the clinical arena. The project aimed to uncover and quantify what is needed in nursing entry to practice degrees regarding digital health through the different lenses of nursing, nurse educators, nurse clinicians, and nurse graduates. The project has been designed based on the Learning Health System model and includes 3 main cyclical phases: practice to data, data to knowledge, and knowledge to practice. The three phases of the project were (1) a systematic review [12]; (2) an interview study of nurses in clinical practice about their digital health use, digital health application, and related challenges during COVID-19, as well as the needs of the graduate nurse [13]; and (3) a survey of nurse educators in Australian universities regarding their knowledge and confidence in teaching aspects of digital health to entry to practice nursing students [14]. The aim of this paper is to present an analysis of the gaps identified through the triangulation of this past research. The process of identifying the gaps was important to assist in understanding ways to develop, plan, and implement educational strategies to bridge the divide and meet the digital health needs within clinical nursing practice [15].

Methods

Overview

This gap analysis triangulated the findings from 2 studies of the DASH project. The source of the data is described in each of the papers previously cited in this paper. Although processes for gap analysis can be found in the literature, they represent a

wide context of settings and study types that did not directly translate to the anticipated needs of this project. In fact, the learning needs analysis literature provided more direction in developing a process to identify the gaps [16]. In particular, the learning needs process paid attention to the range of contexts of study participants, focused on knowledge skills and attitudes, considered capabilities, and provided an opportunity to reflect on resources [15]. All these elements were important to understand in determining the requirements for nurses entering practice and the capabilities of nurse educators to teach and provide practice opportunities to learners. In addition to the findings from the interviews and survey, the results were triangulated against the National Nursing and Midwifery Digital Capability Framework [11]. (This framework represents the work of key stakeholders in digital health within Australia and aims to define the digital health knowledge skills and attitudes required for nursing and midwifery practice while providing a basis against which to tailor learning.

The gap analysis was undertaken by the DASH project team. The research team consisted of 4 nurse educators, a digital health academic, and a postdoctoral research fellow. The team collectively reviewed the data from both the interview and survey studies to discern what gaps existed between the interview data, the survey data, and the framework. The review resulted in several questions that formed the basis of the methods, as follows: (1) How knowledgeable and confident are nurse educators to provide the education expected by the framework? (2) What are the barriers encountered by nurse clinicians reflected in the expectations of the framework? (3) What are the nurse clinicians' expectations of nurse graduates' digital health capability reflected in the expectations of the framework? (4) What do nurse clinicians identify as challenges that are identified in the framework, but nurse educators lack confidence in teaching? (5) What do nurse clinicians identify as challenges that are missing from the framework? (6) What do nurse educators identify they do not have confidence or knowledge in teaching, but nurse clinicians do not identify it as an adoption challenge and therefore does it need to be in the framework? (7) What do nurse clinicians identify as graduate competencies that are not in the framework? (8) What do nurse clinicians identify as graduate competencies that are in the framework, but educators lack the confidence and knowledge in teaching?

These questions were mapped in [Figure 1](#) to show how the gaps were identified through the triangulation process, whereby the number represents each of the above questions, and those in green examined items present in the framework as opposed to those in orange that identified items that were missing from the framework.

Figure 1. Model of gap analysis.

The procedure to answer each question involved several steps. The first step was to identify the contexts and tools of the nurses who participated in the interview study. There were a range of contexts including nurses in clinical settings, chief nursing information officers, clinical educators, nurse representatives in digital health vendor companies, and nurse representatives in government. The types of digital tools participants had identified using during the COVID-19 pandemic were also identified. The second step involved mapping the barriers to digital health use encountered by those stakeholders during the COVID-19 pandemic to the framework (questions 1, 2, and 3). The survey was devised using concepts from both the framework and the TIGER (Technology Informatics Guiding Education Reform) core nursing informatics competency framework [17],

with the method described in a paper by Zhao et al [14]. Survey items that respondents (n=119) had reported “no or minimal knowledge and confidence” were categorized as high where more than 70% of responses chose no or minimum knowledge, medium where 31% - 69% of responses chose no or minimum knowledge, and low where less than 30% of responses indicated no or minimum knowledge. To identify only those items that relate to the Australian framework and remove those that only relate to the TIGER framework, these high and medium items were mapped against the items identified by the nurse educator that appeared in the framework (question 1). The items identified by nurse clinicians as challenges to adoption (question 2) and requirements of the nurse graduate (question 3) in the interviews were mapped to items in the framework. Last, the items

identified as challenges to adoption identified by nurse clinicians were mapped against those items that nurse educators identified as lacking the knowledge or confidence to teach (question 4), which resulted in a list of items that need to be taught, but nurse educators lack the knowledge or confidence to teach.

Once these items were mapped to each other and the framework (questions 1-4), the gaps could be identified. This included the items the nurse clinicians identified as challenges that were missing from the framework (question 5); the items nurse educators identified they do not have confidence or knowledge in teaching, but nurse clinicians did not identify as an adoption challenge and raise whether they need to be in the framework

(question 6); and the items nurse clinicians identified as nurse graduate competencies that are not in the framework (question 7).

The last part of the triangulation was to identify the items that nurse graduates require to work in health, as identified by nurse clinicians; map them to the framework; and then map them against items that the nurse educators lacked the confidence and knowledge to teach, as identified by the nurse educators themselves (question 8). This resulted in a list of items that nurse graduates need to know, but nurse educators lack the knowledge or confidence to teach. The steps of the procedure linked to the question numbers are summarized in [Table 1](#).

Table 1. Procedure for each of the method questions.

Question number	Procedures
Questions 1, 2, and 3	Mapped the qualitative nurse clinician data to the capability statements.
Question 4	Mapped items from the capability statements linked to the nurse clinician's qualitative data to the nurse educator survey items that scored M ^a or H ^b .
Question 5	Identified the qualitative nurse clinician data that did not have a competency statement assigned.
Question 6	Compared the H and M items from the nurse educators to the qualitative nurse clinician data where there is no corresponding item in the framework.
Question 7	Mapped the qualitative nurse clinician data about expectations for nurse graduates and identified omissions in the framework.
Question 8	Identified the qualitative nurse clinician data about nurse graduates that mapped to the framework and the nurse educator data that scored an H or an M.

^aM: medium.

^bH: high.

Ethical Considerations

Institutional ethics approval (via the Low Risk Committee; reference number: 2022-25054-16817) was provided for each phase of the studies cited. The studies undertaken used informed consent and the ability for participants to opt out in accordance with the ethical standards of the Low Risk Committee and with the Helsinki Declaration.

Results

The results of the gap analysis were analyzed and presented through the 3 lenses: nurse educator, nurse clinician, and nurse graduate.

Nurse Educator

Several items were identified by nurse educators that they lacked confidence and knowledge to teach and were related to only the Australian framework (question 1), as summarized in [Table 1](#). No items relating to the domain of "Technology" were identified. The numbers in brackets show the capability statements in the framework the items were mapped against, and the number of participants that reported the lack of knowledge or confidence are reported as medium (M) or high (H), as defined in the *Methods* section.

Nurse Clinician

There was a strong alignment between the challenges identified by the nurse clinician and the framework across all the domains (question 2; [Table 2](#)). Several areas were identified as challenges by nurse clinicians that were not apparent in the framework (question 5). These were classified as either resource or nursing informatics specialist items, as summarized in the last row of [Table 2](#).

There were several areas that nurse clinicians had identified as challenges that were aligned with the framework and nurse educators identified they have a lack of confidence to teach (question 4; summarized in [Table 3](#)). When examined at a domain level, every domain except "Technology" contained competency statements that were identified by the nurse clinicians and nurse educators. However, not all statements in these other 4 domains were identified by the nurse clinician and the nurse educators, indicating not all statements are an identified challenge or they are a challenge, but the nurse educators are confident to teach ([Table 4](#)). Areas that nurse educators identified they do not have confidence in but were not identified as a challenge by nurse clinicians (question 6; [Table 3](#)) were limited and did not include the domains of "Leadership and advocacy" or "Data and information quality." The "Technology" domain featured the most, however, items related to information systems (eg, radiology, pharmacy, and

laboratory) were identified by nurse educators but not by nurse clinicians.

Table . Alignment of items nurse educators report they lack confidence and knowledge to teach and the framework.

National Nursing and Midwifery Digital Capability Framework domain	Items nurse educators report they lack confidence and knowledge (numbers in brackets represent the capability statement number in the framework; M ^a =31% - 69%, H ^b ≥70%)
Digital professionalism	<ul style="list-style-type: none"> • Prescribing and referral rights as it relates to electronic identity (M) (1.2) • Cybersecurity and risk management (M) (1.3) • Cultural and socioeconomic factors in digital health (M) (1.2) • Dynamic consent (H) (1.2) • Digital identity (M) (1.2)
Leadership and advocacy	<ul style="list-style-type: none"> • Digital health governance (M) (2.2, 2.3) • Patient digital health advocacy (M) (2.1)

Nurse Graduate

There were a significant number of items the nurse clinicians identified the nurse graduate needs to know that align with the framework (question 3), summarized in . No items were identified in the domains of “Data and information quality” and “Technology.” More importantly, when all the results were triangulated, it identified the items the nurse clinician identified the nurse graduate needs to know, yet the nurse educators lack

the knowledge or confidence to teach (question 8; Table 5). Only 1 item was identified—“Students should learn about rules and regulations of data security, privacy, and social media in using digital health (1.2, 1.3).” Clinicians wanted students and graduates to learn about rules and regulations of data security, privacy, and social media in using digital health. This corresponded to the survey item cybersecurity and risk management, which scored 41% for knowledge and 35% for confidence to teach by nurse educators.

Table . Comparison of items that were identified by nurse clinicians that nurse graduates need to know, that aligned with the framework, and that nurse educators lack knowledge or confidence to teach.

National Nursing and Midwifery Digital Capability Framework domain	Nurse clinician expectations of nurse graduates (numbers in brackets represent the capability statement number in the framework; M ^a =31% - 69%, H ^b ≥70%)
Digital professionalism	<ul style="list-style-type: none"> • Students should learn about rules and regulations of data security, privacy, and social media in using digital health (1.2, 1.3)^c • Students should be taught about nursing's digital health capabilities before coming into practice (1.2, 4.3) • The use of academic EMR^d should be a requirement in nursing programs (1.1) • Nursing students should learn about digital health systems in more detail than only data entry. For example, about data exchange, security, and analytics (1.1) • Students should be taught about real-world digital health challenges in nursing in addition to the theoretical concepts (1.1) • Universities should foster digital health training to be responsive to the new generation of technologies (1.1)
Leadership and advocacy	<ul style="list-style-type: none"> • There is a need for investment in the digitally enabled nursing workforce, as they are the only providers in the remote areas of Australia (2.1, 2.2)
Information-enabled care	<ul style="list-style-type: none"> • The concept of a multidisciplinary approach should be embedded in digital health training for nursing students. They need to learn how to interact with internal and external stakeholders (4.1, 4.2) • Universities can embed training content about analytics to foster critical thinking and curiosity among nurses about digital health technologies (4.1, 4.2) • Students should be taught about nursing's digital health capabilities before coming into practice. (1.2, 4.3)

^cIdentified as a need by nurse clinicians but nurse educators do not have the confidence or knowledge to teach.

^dEMR: electronic health record.

Discussion

Principal Findings

The triangulation of results from previous studies examined the items identified by nurse clinicians as challenges in digital health adoption in practice, capability needs of nurse graduates, and items nurse educators lack confidence or knowledge to teach (Tables 2-5). These were then mapped to the Australian National Nursing and Midwifery Digital Health Capability Framework [11], and several gaps were identified. These gaps were the main findings of this paper.

A significant difference between the framework and the other reference point, the TIGER study [17] for the development of survey items for nurse educators, is the extent of detail outlining elements within the competency domains in the latter. The international recommendations of the TIGER study identify capabilities associated with recognized nursing informatics roles, which the Australian framework does not identify. The framework with 5 domains and limited detail is open to interpretation as to which domain an area of digital knowledge would best be mapped to. The nurse researchers in the study required advice from digital health academics on the team to clarify the best fit when undertaking this mapping, indicating

nurse educators may not be able to implement the framework within their own curriculum without digital health expertise guidance.

The alignment between the challenges identified by the nurse clinician and the framework (Table 4) confirmed the necessity of those items in the framework. Further to the criticism listed above about the framework being open to interpretation is that users of the framework are unable to gauge the depth of knowledge required to achieve capability, as these will vary depending on the statement and the functions of the Clinical Nurse. These items, identified by nurse clinicians (Table 3), can guide users of the framework on the depth of knowledge required for nurse graduates and nurse clinicians for these particular items. The small number of items identified by both the nurse educator and the nurse clinicians, and in particular the lack of items related to the domain "Technology" (Table 3, last row), should not be assumed to mean the other statements are not relevant to practice and should be removed from the framework. Instead, this finding can guide the depth of knowledge required for the nurse graduate. Some areas related to technology are subject to their own programs of graduate study, for example, cybersecurity, and nurses entering practice in a field like this would require a high level of knowledge. The identification of different information systems by nurse

educators (Table 4), which were not identified as a challenge by nurse clinicians, may be related to the vendor nature of these information systems. Training is generally provided by the vendor for tendered information system adoption, whereas noninformation system capabilities that a graduate nurse needs to have to be able to work safely and responsibly with technology or data needs to be developed either through graduate training or on the job.

Nurse clinician expectations of nurse graduates did not map to the framework, with the exception of 1 item (Table 5). The significance of this is speculative but likely relates to the questions used in the interview study [13]. As no reference was made to the framework, the responses were not provided that specifically addressed it. Additionally, the questions were broad, and the answers provided also lacked detail. In general, nurse clinician responses generally focussed on global capabilities, such as using an electronic medical record, rather than detailed responses. Further, the framework did not identify several areas identified by nurse clinicians related to resources (Table 3). These resources could be categorized as either physical or human. For example, clinicians spoke about specialist digital or informatics roles that provide support for digital health initiatives, which is not addressed in the framework. Additionally, nurse clinicians spoke about being able to access the correct tools appropriate for the task, including having access to secure internet services. While Standard 5.1 covers recommending appropriate digital technologies and staff and consumers being able to use these where available, the framework does not address a requirement for availability. The growth of digital capacity among nurses in practice will continue to be hampered by under-resourcing. Nurse clinicians called out expertise and human support by other nurses as a barrier in practice. These items cannot be addressed educationally and therefore were not included in the survey of nurse educators (Table 2). Nonetheless, the silence in the framework may result in a missed opportunity to recognize and support specialist nurse practice in digital health. Booth et al [8] suggest support from all levels of nurse leadership to invest in resources and champion and support nurses in their practice and research. The complexity of health environments and the rapid rate of change and development in health care, inevitably result in nurses with a wide range of knowledge and confidence in digital technology use and complex differences in demands and access to digital tools [8,18].

There are several implications for both education and practice. While this gap analysis has identified there was only 1 item that the nurse clinicians identified is required for the nurse graduate but the nurse educator lacked the knowledge or confidence to teach (“Students should learn about rules and regulations of data security, privacy, and social media in using digital health”), there are several items across the domains that nurse educators reported they will be unable to teach but are important skills or knowledge for practice. Given the nurse researchers in this project needed to consult with the digital health experts on the team to interpret elements of the framework highlighted this challenge. It implies that digital health expertise may be required for graduate training providers to meet the Australian Nursing and Midwifery Accreditation Council Registered Nurse

Accreditation standards requirements related to digital health. The practicality is most graduate training providers do not have this resource available and it was not the intention of the framework. Nurse educators need to be upskilled in digital health, so they have the confidence and knowledge to design and deliver the necessary digital health curriculum.

The nurse clinicians identified practice barriers relevant to their own context during the COVID-19 pandemic. Nazeha et al [18] recommend that frameworks for digital health be updated regularly in line with innovation. However, the applicability of digital tools and technologies is never going to be universal or static and will always be context-specific. Therefore, considering those items that nurse clinicians did not identify as barriers and nurse educators lacked confidence or knowledge to teach, may be as simple as being out of context of experience for those practitioners and educators. For example, robotic surgery is a very defined digital technology, whereas EHRs are a generic concept. Educators may have an oversight or awareness of a specific digital tool but have answered negatively in the survey as their knowledge is global rather than specific and would not be sufficient to teach or demonstrate to learners.

The items that educators lacked confidence or knowledge to teach should be examined for their value in a crowded, busy curriculum. Nurses, as lifelong learners, continue to develop, and many enter and exit the education system more than once across their careers [19]. Postgraduate study requirements may include specialist knowledge not apparent for entry to practice minimum standards. Risling [20] predicted exponential increases in technology use in the coming decade and warned that nurse educators need to lead the evolution in practice and education. Changes to curriculum, while challenging, will need to be carefully considered for their worth at the same time as recognizing the rapidity of change likely to be required.

The findings from the interview and survey studies informing this analysis may have been influenced by the mixed progress of digital health roll out nationally. A co-design process to develop an educational intervention will be undertaken as the next stage of this DASH research project. The following questions and statements will form the basis for discussion with a broader panel to validate the findings of this analysis and develop strategies to overcome the challenges and weaknesses in clinical practice and educational delivery settings:

- Digital health expertise and guidance are required for nurse educators to develop curricula in digital health.
- The framework requires augmentation to describe the depth of knowledge and experience.
- Should specific technologies be inherent within the framework?
- How should differences in experience, exposure, and resources related to digital health be addressed in nursing education?
- Which of the items that educators lacked knowledge or confidence to teach should be addressed in the curriculum for nurse educators teaching entry-to-practice nursing courses?

Limitations

In the interview study, we did not ask what skills students were noted to have in digital health, rather, the approach was aspirational for what clinicians desired. The extent to which those aspirations for students are achieved is unknown. It is suggested that a further study investigating the actual capability of nurse graduates in digital health be undertaken.

Conclusion

This analysis took the outputs of 2 studies investigating the digital health perspectives of nurses in practice environments and their expectations of graduates' digital health capabilities,

with the second paper investigating the capabilities of nurse educators to teach and practice digital health, and mapped these findings with the National Nursing and Midwifery Digital Capability Framework. The outcomes of this analysis will inform a co-design process to create a curriculum for nurse educators to uplift capability in teaching and simulation for entry-to-practice nursing programs in Australia. A series of 8 questions directed the process to triangulate the findings and identify which factors were and were not included in the framework. A series of statements and questions were then formed from the analysis as recommendations to direct the co-design phase of this national research project.

Abstract

Virtual care appointments expanded rapidly during COVID-19 out of necessity and to enable access and continuity of care for many patients. While previous work has explored health care providers' experiences with telehealth usage on small-scale projects, the broad-level adoption of virtual care during the pandemic has expounded opportunities for a better understanding of how to enhance the integration of telehealth as a regular mode of health care services delivery. Training and education for health care providers on the effective use of virtual care technologies are factors that can help facilitate improved adoption and use. We describe our approach to designing and developing an accredited continuing professional development (CPD) program using e-learning technologies to foster better knowledge and comfort among health care providers with the use of virtual care technologies. First, we discuss our approach to undertaking a systematic needs assessment study using a survey questionnaire of providers, key informant interviews, and a patient focus group. Next, we describe our steps in consulting with key stakeholder groups in the health system and arranging committees to inform the design of the program and address accreditation requirements. The instructional design features and aspects of the e-learning module are then described in depth, and our plan for evaluating the program is shared as well. As a CPD modality, e-learning offers the opportunity to enhance access to timely continuing professional education for health care providers who may be geographically dispersed across rural and remote communities.

Introduction

Most provincial health care systems across Canada responded to the COVID-19 pandemic with a rapid adoption of digital tools and technologies, including virtual care appointments. The Canadian Institute for Health Information (CIHI) reported that between March to September 2020, the percentage of patients availing virtual care services increased from 6% to 56% [1]. Virtual care refers to the delivery of health care services digitally or at a distance using information and communications technology [2-4]. During COVID-19, a variety of virtual care types were used, with synchronous and asynchronous appointments being the most common [3,4]. Synchronous virtual care refers to communication between the health care provider and patient that occurs in real time and can include the use of telephone or videoconferencing. Asynchronous communication does not occur live and may include the use of e-mail messaging, messages left for patients in a portal site, and e-consultations [3-5]. Considering the goal of reducing COVID-19 exposure during the recent global pandemic, virtual care proved to be

most effective in that it minimized exposure and risk to health care providers by reducing the movement of people [2-7]. In addition, virtual care helped patients stay home who may have otherwise traveled to a health care site and incurred the risk of unnecessary exposure [3,4,6,7]. Virtual care was also used for control and triage during COVID-19, remote monitoring of patients, treatment and management, and provision of online health services [3,4].

In Canada, considerable work during and after the COVID-19 pandemic was undertaken to develop guidelines to inform physicians, health care providers, and patients on how they could best use virtual care. The Canadian Medical Association (CMA) and Royal College of Physicians and Surgeons of Canada (RCPSC) developed resources for both physicians and health care providers, as well as patients. The "Virtual Care Playbook" provided virtual care guidance for providers and connected patients to the "Virtual Care Guidelines for Patients" [8,9]. Canada Health Infoway has also undertaken significant work regarding virtual care support for physicians and health care providers. In particular, Infoway's "Clinician Change

Management” project provided support in the form of virtual care tools and training [10]. The Canadian Medical Protective Association (CMPA) has also supported providers by disseminating virtual care informational resources for physicians and health care providers through their website [11].

With the rapid introduction of virtual care across many jurisdictions during the COVID-19 pandemic, both health care providers and patients alike were not always adequately trained on how to use virtual care appropriately. Previous research has suggested that a lack of training around virtual care tools and software was a challenge for providers. A lack of understanding and training may have contributed to lower confidence levels among providers and a reluctance to use virtual care, thereby negatively influencing virtual care adoption [3,4,12-15]. Adjusting clinical approaches to caring for patients remotely can also be challenging, including how to virtually examine patients by videoconferencing or telephony systems [3,4,16,17]. The use of new digital health systems like virtual care also requires knowledge and competence in how to incorporate the technology within a provider’s practice workflow. This includes understanding how to use the technology effectively, as well as the privacy and security issues surrounding the use of the technology. Providers also need to be able to adapt their techniques and clinical acumen to build rapport with their patients while using virtual care technologies. Given this, consideration of the potential continuing professional development (CPD) needs of health care providers is critical to ensuring that proper support systems and training are available to enable and empower providers to adopt and use virtual care most effectively and efficiently.

e-Learning has been defined as any educational intervention mediated electronically via the internet [18] and has become a popular modality for providing CPD in the health professions, with offerings across a diverse array of topics and subject areas [18,19]. The advantages and benefits of e-learning have been described as including lower costs, widespread distribution, increased accessibility to information, frequent content updates, and personalized instruction in terms of content and pace of learning [18]. Several systematic reviews of e-learning effectiveness in health professions’ education, including CPD, have been published. Key findings of these reviews suggest that e-learning is associated with large positive effects when compared with no interventions [20]; e-learning can be as effective as traditional methods of teaching and instruction [20-22]; e-learning and traditional educational interventions take similar time to participate in or complete [23]; and interactivity, practice exercises, repetition, and feedback are important design features of effective e-learning approaches and appear to be associated with improved learning outcomes [23].

CPD encompasses the multiple educational and developmental activities pursued by health care providers to maintain and enhance their knowledge, skills, performance, and relationships in the provision of health care [4,24]. For many regulated health care providers around the world, CPD participation is often mandated and required throughout the extensive postlicensure phase of the provider’s career. It is viewed as a key means for providers to stay current and up to date with evidence-based

practices in their professional field. The evidence for CPD participation suggests that health care providers who participate in formal CPD activities are more likely to provide better care than their peers who do not participate [4,25]. CPD, which is designed to be interactive, practice-based, and longitudinal in nature, is also believed to yield better outcomes [4,25]. A needs assessment–driven approach to the development of CPD is more likely to lead to a change in practice, largely as a result of the learning being directly linked to personal and practice needs [4,26].

Edirippulige and Armfield [4,27] reviewed a number of studies describing the delivery and evaluation of education and training in telehealth. They identified 9 peer-reviewed studies describing education and training in telehealth that included several CPD-level courses on telehealth. Online learning was the most common delivery format described across the studies, with course duration ranging from 1 week to 6 months [4]. More recently, several studies conducted during the COVID-19 pandemic have reported on CPD in virtual care also using online delivery formats [28-31]. Both synchronous and asynchronous modalities were used in providing CPD on virtual care or telehealth; however, the most common delivery format was the use of web conferencing (eg, Zoom and Skype). Topics covered across these programs included introduction to virtual care, advantages and disadvantages of virtual care, types of virtual care, ensuring privacy during appointments, and legal and technological requirements for virtual care. One interesting method described by Hayden et al [30] was the use of web conferencing to facilitate simulated telehealth appointments with standardized patients. Participants found the use of standardized patients to simulate a virtual care appointment enhanced their confidence in focused telehealth skills. The use of online learning formats was perceived favorably by participants across the studies and was found to be particularly useful in accommodating the busy schedules of providers [28].

The purpose of this paper is to describe our efforts to design and develop an accredited e-learning CPD module on virtual care for physicians and health care providers. First, we discuss our approach to systematically exploring the needs of health care providers in learning to use virtual care effectively and efficiently in their practices. We describe results from a survey questionnaire we administered to a sample of health care providers in Newfoundland and Labrador, Canada, findings from key informant interviews with several experts in virtual care, and key themes emerging from a focus group with patient representatives. We then describe our approach to designing and developing this e-learning module, including key interactivity and design features to foster effective learning. Finally, we describe our approach and plan to evaluate the effectiveness and impact of this e-learning module on health care providers’ adoption and use of virtual care. The work described in the paper was undertaken by our team with the Office of Professional & Educational Development (OPED), Faculty of Medicine, Memorial University of Newfoundland. The Faculty of Medicine at Memorial University has long been a pioneer in research and development in the fields of telemedicine, tele-education, and digital learning for physicians and rural health care providers. Our Professional Development

office was one of the first CPD units in North America to introduce accredited e-learning programming for physicians through our MDcme [32] learning management platform [33].

Methods

Needs Assessment Study

We undertook a needs assessment study initially as a first phase of our project to design and develop an e-learning CPD module on virtual care. The needs assessment encompassed a web-based survey, key informant interviews with experts in virtual care, and a focus group with patient representatives [3,4,34]. The goal of the web-based survey was to explore the experiences, perceptions, and satisfaction of health care providers with the adoption and use of virtual care during COVID-19. We developed and distributed this survey to physicians, nurses, and allied health professionals across the province of Newfoundland and Labrador, Canada, to explore their CPD needs and preferences as well.

In total, 51% of respondents (n=432) in our survey indicated they were currently offering virtual care and a majority (68.9%) reported it had improved their work experience [3]. The telephone was the most used method and respondents reported the most comfort and satisfaction with telephone appointments [3]. The most challenging aspects of telephone appointments were the inability to conduct physical exams to the degree required, the inability to assess physical health status, and the patient's or client's cell phone service being unreliable [3]. Respondents rated the importance of a variety of CPD topics on effective use of virtual care, and the highest rated topics included compliance with regulatory standards or rules for virtual care, understanding boundaries (eg, personal telephone numbers used to call patients or clients), and developing and maintaining competency and professionalism while engaging in virtual care [3]. Other important topics for virtual care CPD included CPD on how to use the technology, the best or easiest platforms for providing virtual care and how to use them effectively, and assessment skills and aids for doing assessments virtually. Ethical issues and legalities of virtual care were also identified by respondents as valuable as well [3].

The second component of our needs assessment was a qualitative study to explore experts' ascribed opinions on health care providers' CPD needs in virtual care [4]. We conducted semistructured interviews with a purposive sample of key informants representing Canadian provincial and national organizations with expertise in virtual care delivery. According to the key informant respondents, lack of training specific to virtual care tools and software was a challenge for health care providers, particularly videoconferencing appointments. All key informants identified technology as a main barrier or challenge, not only for health care providers but also for administrative staff. The main areas of knowledge, skills, and abilities deemed most important for health care providers in adopting and using virtual care identified by the key informants included effective use of technology, knowledge of how to integrate technology and virtual care in the practice workflow, privacy and security aspects of the technology, and adaptation

of examination skills to virtual care and how to build effective rapport with patients [4].

A focus group study was also conducted with a purposive sample of patient representatives to explore patients' experiences and perspectives on the adoption and use of virtual care during COVID-19, and identify the education and informational needs of patients [34]. The findings from the patient focus group were useful in informing the types of topics to include in CPD on virtual care. Patient respondents felt that virtual care was beneficial and enabled greater convenience, flexibility, and access to health care services. Key barriers and challenges in adopting and using virtual care appeared to primarily arise from patients' lack of knowledge, understanding, and familiarity with it. Cost, technological access, connectivity, and low digital literacy were challenges for some patients, particularly in rural communities and among older patients. Patient education and support were critical and needed to be inclusive, easy to understand, and include information regarding privacy, security, consent, and the technology itself.

Approach to Mainpro+ and MainCert Accreditations for CPD Credit

The OPEd, Faculty of Medicine at Memorial University is an accredited provider of CPD that targets the needs and competency development of health care providers within Newfoundland and Labrador and beyond. OPEd is an accredited provider of university CPD by the Committee on Accreditation of Continuing Medical Education (CACME) and the Association of Faculties of Medicine of Canada (AFMC). As an accredited CPD provider, OPEd is permitted to accredit CPD activities that meet the administrative, educational, and ethical standards of the College of Family Physicians of Canada (CFPC) Mainpro+ Certification program [35] and the RCPSC Maintenance of Certification program [36]. Key requirements for accrediting CPD activities include a needs assessment and the formation of a scientific planning committee (SPC) to oversee and advise on the development of the accredited CPD activity. An SPC is a group of target audience representatives responsible for identifying the educational needs of the intended target audience; developing educational objectives; selecting educational methods; selecting speakers, moderators, facilitators, and/or authors; developing and delivering content; and evaluating the outcomes of an accredited CPD activity. Requirements for accredited e-learning activities also include a means for participants to interact with the material, with each other, and with faculty members or a facilitator and the ability for participants to track their progress, provide evaluation feedback, register, and receive a record of registration. Such programs must also be offered within a definitive period of time communicated before the start of the program.

e-Learning Module Design

We ensured our e-learning module met the requirements of Newfoundland and Labrador's primary health care providers by establishing 2 guiding committees during its design and development. The first, an advisory committee, ensured alignment with policy and practices within the provincial health care system. This committee included representation from the Newfoundland and Labrador Centre for Health Information,

the provincial government's department of health, Memorial University's Faculty of Medicine, the College of Physicians and Surgeons of Newfoundland and Labrador, the College of Registered Nurses of Newfoundland and Labrador, and the Newfoundland and Labrador Medical Association. The second committee structure, an SPC, oversaw the design and development of the module and was responsible for ensuring that the learning experience reflected the needs of the primary health care providers [35]. This committee included a family physician, registered nurse, nurse practitioner, specialist physician, and emergency medicine physician.

We provided the advisory committee with the information collected through our needs assessment process and asked the members to offer feedback in terms of system-level needs. We then engaged with the SPC to review the needs assessment findings and advisory committee feedback and to develop a set of learning objectives we would use to guide the development of the module. Next, we engaged with several subject matter experts in virtual care to draft instructional materials and activities that would enable us to meet our stated objectives. This instructional material was used to develop a prototype of the e-learning module that we shared with the SPC and advisory committee for review and feedback. We compiled the feedback received and adjusted the prototype accordingly. We then proceeded to launch the prototype on the MDcme learning platform, a proprietary learning management system developed by OPED to house our accredited CPD activities. The MDcme environment provides user registration, asynchronous communications, technical support, and transcript or certificate issuance. The module is developed as a series of web pages using PHP (Hypertext Preprocessor) scripting and leverages responsive design to adapt its presentation based on the device used to access. The module will undergo an annual review process during which the assessment and evaluation data are reviewed, and any requisite modifications will be made, including updates and modifications to content and approach.

Van Hecke et al [37] developed the Criteria for Reporting on Development and Evaluation of Professional Training interventions in Healthcare (CRe-DEPTH) as a way to systematically report on the development and evaluation of training interventions for health care professionals. These criteria consist of 12 items representing 4 categories, which are the development of the training, characteristics of the training, characteristics of the providers, and assessment of the training outcomes. The following description of the e-learning module on virtual care outlines aspects of the development and evaluation of this educational program according to these criteria.

In developing the e-learning module, we followed the phases of the ADDIE model of instructional design. The ADDIE model is a systematic instructional design framework widely used in the creation and development of educational and training programs. The acronym "ADDIE" stands for 5 sequential key stages in the instructional design process, which are Analysis, Design, Development, Implementation, and Evaluation [38]. While sometimes criticized as being too linear in its approach, we have found that this framework delivers a consistent approach to educational development and aligns well with the

requirements of the Mainpro+ and Maintenance of Certification accreditation programs. Gagne's "Nine Events of Instruction" model was also followed as an overarching approach in the development of content for the module [39].

We adopted an asynchronous e-learning design for this module. The asynchronous model assumes that learners taking the program will access the content at different times and from different locations. This approach allows primary care providers across the province to access the instructional material at their convenience, thereby providing the flexibility needed to balance professional learning with varied work hours, family, and other personal or professional commitments [40-42]. Results from our needs assessment survey of potential participants indicated that a large proportion of survey respondents preferred "E-Modules (self-paced/online learning)" as the delivery format [3].

Learners access the module by creating an account on the MDcme platform. The e-learning module provides a 90-minute introduction to the delivery of virtual care in a primary care setting and addresses the learning objectives, which are: (1) describe the benefits and key considerations of conducting virtual care appointments; (2) identify the technological requirements and setup required to conduct optimal virtual care; (3) recognize how to integrate virtual care delivery into your existing practice workflows; (4) discuss the clinical implications for delivering optimal virtual care encounters; (5) explain how to prepare patients for virtual care sessions; and (6) summarize the key regulatory and legal considerations in providing virtual care in Newfoundland and Labrador.

Our experience has been that a 60- to 90-minute duration for online CPD modules is an appropriate length to increase completion rates and reduce participant attrition.

The module is organized into three primary sections: (1) virtual care technologies, (2) the incorporation of virtual care into one's practice, and (3) the regulatory landscape. While the content is structured in a sequential fashion for learners to progress through, a comprehensive course menu tree is available, enabling learners to access any section of the module whenever they wish (Figure 1).

The module design uses several strategies to enhance learner engagement and support multimodal learning [43-45]. First, a variety of media are used in the presentation of module content, including text, images or graphics, and short video clips (Figure 2). Second, user interface design elements such as clickable tabs and dropdowns or flyouts are used where appropriate to encourage the learner to physically interact with the module. Finally, several interactive instructional design components are included, such as pre- and posttest assessments and interactive case scenarios. Several accessibility standards are also included in module design, including the use of descriptive alt tags for all graphical elements and the inclusion of closed captions for all audio or video elements for people with hearing impediments.

The pre- and posttest assessments are interactive quizzes that present a number of multiple choice questions designed to evaluate learner knowledge of the subject matter and enable self-assessment and reflection, as well as several Likert scale

measures of learner confidence in performing the learning objectives (Figure 3). The assessment is presented once at the beginning of the module and then again at the end of the learning experience. The learner receives immediate feedback after submitting each assessment; correct or incorrect data are presented as feedback to the pretest, and correct or incorrect data along with a brief rationale for the correct response are presented as feedback to the posttest.

An interactive case scenario is presented as a final learning activity in the module (Figure 4 and Figure 5). The case scenario models the application of module content to the primary care practice context. The learner is first presented with an overall scenario and then asked a series of “What would you do?”

questions designed to prompt reflection. The learner enters their response and is presented with immediate feedback including the response of peer learners in the system as well as a model answer summarizing how the concepts covered in the module could be applied to the given situation.

Given the asynchronous approach used in the module design, learners are able to view peer responses to the interactive case scenario but are not able to engage in a dialog with other learners taking the course. Learners can interact with subject matter experts if they have questions related to the content presented in the module. In that case, a learner can enter a question or comment through the “Ask the Expert” feature in the module and will receive a response via email within 48 hours.

Figure 3. Learning assessment.

Figure 4. Interactive case scenario.

Figure 5. Interactive case scenario (continued).

Evaluation Approach

An evaluation approach has been designed around Curran and Fleet's [46] use of Kirkpatrick's levels of evaluation. The levels comprising the evaluation approach of the e-learning module include pre- and postknowledge and confidence assessments, satisfaction surveys, and a postmodule outcomes survey.

Pre- and Postknowledge and Confidence Assessments

A pre- and posttest assessment is embedded directly into the e-learning module. The assessment includes measures of both learner knowledge of the content covered and learner confidence in the ability to achieve the stated learning objectives. The knowledge items were developed by content experts and consist of a bank of one-best-answer multiple-choice questions. The

confidence items consist of several statements related to the learning objectives for the online module.

Satisfaction Surveys

An online satisfaction survey is provided to the learner at the end of the module. A combination of close- and open-ended questions related to the module content and overall impressions are used to gauge satisfaction and to allow for continuous improvement of subsequent deliveries of the program. The survey enables participants to provide feedback on the module related to relevancy, appropriateness, practicality of the content, and whether they would recommend the module to others.

Postmodule Outcomes Survey

An online survey will be distributed to participants 6-8 months after the completion of the module. The purpose of this survey will be to further explore the impact of participation in the module on participants' adoption and use of virtual care in their practice.

Discussion

Through our systematic needs assessment study, we were able to specify several areas of knowledge, skills, and/or abilities that would be most helpful for physicians and health care providers as they sought to adopt and use virtual care in their practices and patient care. Respondents highlighted 3 main areas. First, the use of technology necessitates knowledge of how to integrate technology and virtual care into the practice workflow. This includes knowing how to use technology and knowledge relating to the privacy and security of the systems being used. There is an increased emphasis for providers to ensure they are meeting the standard of care, adequately obtaining consent, and embracing values of equity and fairness. Next, respondents identified the importance of being able to adapt clinical skills to virtual care and building rapport through good communication with patients. Finally, providers need to be able to adapt their examination skills for virtual care environments.

According to Edirippulige and Armfield [4,27], because using telehealth implies a change in practice, it should be supported by an appropriate level of evidence-based education for health care providers. An appropriate way to do this should start with educating and training future health care providers by incorporating telehealth education as a standard component in the prelicensure curriculum. At a CPD level, online education may be particularly attractive for busy practitioners who choose to participate in short CPD courses to develop knowledge and skills. However, it also seems that the practice of virtual care requires certain hands-on skills. Practical sessions can be helpful in developing such skills, as well as the observation of real-life or simulated virtual care appointments to gain exposure to the modality [22]. Our approach involves the development and provision of an accredited CPD e-learning module, designed to

enhance the confidence and competencies of primary health care providers in virtual care adoption and use in their practices. An ongoing evaluation will be conducted with the findings used to improve e-learning approaches to teaching this important area for health care providers and health care delivery systems around the world.

The current evidence surrounding the most effective e-learning modalities is limited by the fact that the reported program designs differ with variation in the types of modalities used to deliver virtual care CPD. There are also limited studies on the effectiveness of asynchronous approaches like those described in this paper. This variation makes it difficult to draw conclusions around the most effective approach, although future comparative type studies could contribute to our understanding of the most effective approaches or combinations of modalities. Another notable observation of the existing literature is the general lack of evaluation at a "knowledge level." Most evaluation studies have not reported assessment of knowledge as a key evaluative outcome from virtual care CPD, whether online or in person. Calleja et al [47] suggest this lack of standardized knowledge evaluation is common among virtual care training programs. The field would benefit from more consistent application of systematic evaluation frameworks, such as Kirkpatrick's [48] or Moore et al's [49] models of evaluation.

The need for virtual care is greater than ever, and health care providers must receive appropriate and meaningful education and training to understand the best ways to conduct virtual care appointments. The current evidence suggests online CPD approaches have been a more common approach, particularly during and after the COVID-19 pandemic. Online CPD on virtual care appears to have been well received by participants; however, there is a lack of evidence surrounding the effectiveness of interactive asynchronous online learning designs like that described in this paper. Asynchronous designs afford greater convenience and flexibility for providers in accessing CPD at times that are best for them. An adaptation of Kirkpatrick's [46] levels of evaluation model is being applied to understand the effectiveness of our asynchronous design, and this will offer further evidence around this online learning modality for CPD on virtual care.

Acknowledgments

We would like to acknowledge the many different health care provider representatives and stakeholders from key governmental and professional association organizations advising on the needs assessment study, design, and development of the e-learning module. Ms Megan Clemens also contributed to the literature review cited in the paper.

This work was supported by the Newfoundland and Labrador Centre for Health Information and Department of Health and Community Services, Government of Newfoundland and Labrador.

Data Availability

The data generated during and/or analyzed during the current study are available from the corresponding author on reasonable request.

Authors' Contributions

VC and AH were responsible for the conception and design of the needs assessment study and reporting of results. VC, RG, and CW were responsible for project conceptualization and overseeing design and development of the e-learning module. VC and RG were responsible for manuscript writing as well as final approval of the manuscript. AH and CW reviewed and approved the final version of the manuscript.

Conflicts of Interest

Abstract

Background: The Global Specialist Digital Health Workforce Census is the largest workforce survey of the specialist roles that support the development, use, management, and governance of health data, health information, health knowledge, and health technology.

Objective: This paper aims to present an analysis of the roles and functions reported by respondents in the 2023 census.

Methods: The 2023 census was deployed using Qualtrics and was open from July 1 to August 13, 2023. A broad definition was provided to guide respondents about who is in the specialist digital health workforce. Anyone who self-identifies as being part of this workforce could undertake the survey. The data was analyzed using descriptive statistical analysis and thematic analysis of the functions respondents reported in their roles.

Results: A total of 1103 respondents completed the census, with data reported about their demographic information and their roles. The majority of respondents lived in Australia (n=870, 78.9%) or New Zealand (n=130, 11.8%), with most (n=620, 56.3%) aged 35 - 54 years and identifying as female (n=720, 65.3%). The top four occupational specialties were health informatics (n=179, 20.2%), health information management (n=175, 19.8%), health information technology (n=128, 14.4%), and health librarianship (n=104, 11.7%). Nearly all (n=797, 90%) participants identified as a manager or professional. Less than half (430/1019, 42.2%) had a formal qualification in a specialist digital health area, and only one-quarter (244/938, 26%) held a credential in a digital health area. While two-thirds (502/763, 65.7%) reported undertaking professional development in the last year, most were self-directed activities, such as seeking information or consuming online content. Work undertaken by specialist digital health workers could be classified as either leadership, functional, occupational, or technological.

Conclusions: Future specialist digital health workforce capability frameworks should include the aspects of leadership, function, occupation, and technology. This largely unqualified workforce is undertaking little formal professional development to upskill them to continue to support the safe delivery and management of health and care through the use of digital data and technology.

Introduction

The importance of a specialist digital health workforce to support the development, use, management, and governance of health data, health information, health knowledge, and health technology has been well-documented [1], particularly through the transformation of digital health during the COVID-19 pandemic. This largely hidden workforce [2] supports the digital health needs for care delivery and management. They are the clinical coders, health informaticians, health information managers, health librarians, health technologists, and so many other occupational specialties who work behind the clinical

scenes to ensure that care providers and health managers have the right data, information, and knowledge at the right time and right place [1]. However, there is a lack of accurate data about this specialist digital health workforce to understand their educational needs, their roles and functions, and their professional development needs. This gap in evidence creates challenges for workforce and education planning and forecasting.

The Global Digital Health Workforce Census was launched in 2018 following a rigorous development process [3]. The census stemmed from a collaborative effort between the University of Tasmania and the University of Melbourne using a Delphi

approach. A 10-member expert panel, comprising representatives from key stakeholders, identified issues during a focus group, forming the basis for a health information workforce minimum data set. The items in the census tool were based on existing workforce data items from other surveys and census data sets, and were initially developed with Australian and New Zealand experts. Based on the Health Workforce Australia Report [4], which called for improved data collection about the workforce, the census was referred to as the Australian Health Information Workforce Census. Following the 2018 census [1], the project undertook a validation study to globalize data items with the 2021 census, a smaller pilot with a more global group of participants [5]. The census was referred to as the Global Health Informatics, Digital, Data, Information, and Knowledge (HIDDIN) Workforce Census. The 2023 census was the first full census with global participants, renamed to the Global Specialist Digital Health Workforce, as defined by Butler-Henderson et al [6]. In addition, the census project team worked with Telstra Health to incorporate their Women and Digital Health [7] survey questions into the census. The purpose

of this paper is to present the data from the 2023 census related to the roles and functions of the various specialist occupational groups in the specialist digital health workforce.

Methods

Ethical Considerations

The census was held online from July 1 to August 13, 2023. The census project was approved by the RMIT University Human Research Ethics Committee (#26607). No identifiable information is collected in the census and the survey system automatically allocated a unique identifier code to each response. For any questions with <5 responses, the number of responses is not reported to maintain confidentiality. Participants were not compensated for completing the census.

Survey Instrument

The census is a survey deployed through the Qualtrics survey system at RMIT University. It consists of 186 questions across 9 sections, as outlined in [Textbox 1](#).

Textbox 1. Census sections and question topics in each section.

Demographic

- Country, state, and postcode of residence
- Country of birth and citizenship status
- Year of birth
- Gender
- Indigenous or ethnic group
- Disability

Professional membership and health practitioner registration

- What digital health memberships they hold
- If they are a registered health professional and field
- Hours worked in clinical role

Formal education

- Specialist digital health formal education at vocational or higher education level
- Clinical qualifications
- Other relevant qualifications

Credentials

- Relevant credentials

Occupation and paid employment information

- Discipline group
- Time worked in the specialist digital health workforce
- Seeking work
- Current digital health role(s)—for up to two roles, including country, state, postcode, role title, time in role, role intentions next 12 months, top 5 functions, permanency, organization type (both public/private and service type, eg, hospital, educational, department, not for profit), and remuneration
- How many different roles they have

Unpaid and voluntary work

- Voluntary roles and other unpaid related work

Professional development

- What professional development they have done in the last 12 months
- Needs and plans for next three years

Workforce intentions

- How much longer they plan to stay in the workforce
- Why they will leave
- If they will continue to volunteer or do unpaid specialist digital health work

Women and digital health

- Questions from the Women and Digital Health survey

Recruitment

The promotion of the census occurred in multiple ways. The 2023 census was supported by the Australian Digital Health Cooperative Research Centre, Australian Department of Health

and Aged Care, Telstra Health, Australasian Institute of Digital Health, Australian Library and Information Association Health Libraries Australia, and the Health Information Management Association of Australia, all of which promoted the census to their networks. The census was launched at the 2023

international health and medical informatics conference, MedInfo. It was also promoted through other professional membership organizations, such as the International Federation of Health Information Management Associations and several other national organizations, such as ANDHealth, and through academic organizations. The census was advertised in several different publications, such as Pulse+ IT and What the Health. Several posts were shared on the census LinkedIn channel and X (formerly Twitter) account. Lastly, individuals could register for a distribution list, which received 2 alerts about the census.

Completion of the census was open to those who self-identified as part of the specialist digital health workforce. The following general guidance was provided:

You are part of the workforce if any part of your role (including volunteer or actively seeking) includes a function (listed below) related to health data, information, or knowledge. You may undertake a role that has both a Specialist Digital Health component and another component (for example, clinical or management). For this Census, only consider the Specialist Digital Health component. Functions could include analysing, designing, developing, implementing, maintaining, managing, operating, evaluating, or governing the data, technology, systems, and services for the health sector. You might not identify as part of the Specialist Digital Health workforce if the primary function of your role is limited to using health data, information, or knowledge but none of the other functions listed above.

An information sheet was provided so that participants could make an informed decision about participation. At the start of the census, participants were reminded about the information sheet and asked to review the questions with regard to providing consent. If they did not consent to participate in the study, they were taken out of the survey. The census took an average of 14

minutes to complete; however, this varied depending on how much detail the participant chose to provide.

Statistical Analysis

Once the survey was closed, the data for all responses was cleaned and only responses that completed section 1 were included in the analysis. Most data items were analyzed using descriptive statistics, such as the number and percentage of responses. When there were fewer than 5 responses, the data is presented as “<5.” Only items relevant to capabilities and skills were analyzed for this manuscript, and not all sections of the census are presented in this paper due to the relevance of the topic.

Participants were asked to provide up to 5 functions related to their primary specialist digital health role. All responses were grouped and, using NVivo 14.23 (Lumivero), analyzed for word frequency. The top 5% of the most frequently reported terms were then thematically analyzed, using a modification of the themes identified by Prommegger et al [8]. While Prommegger et al [8] examined occupational aspects, human aspects, and technological aspects, this study examined leadership aspects, functional aspects, occupational aspects, and technological aspects. The top 4 occupational specialties were identified, and the functions listed by respondents who identified with those occupational specialties were then extracted and thematically analyzed in the same fashion, where 5 or more participants identified the term.

Results

Overview

Complete responses for all of section 1 were received from 1103 participants. The majority of responses were from Australia (n=870, 78.9%). Countries with more than 5 responses are shown in [Table 1](#). More than half (n=620, 56.3%) of participants were aged 35 - 54 years, and two-thirds (n=720, 65.3%) identified as female. A total of 73 (7.1%) participants identified as Indigenous and 42 (3.8%) as living with a disability.

Table . Participants' characteristics of the 2023 Global Specialist Digital Health Workforce Census (N=1103).

Characteristic and selections	Participants, n (%)
Countries (>5 respondents)	
Australia	870 (78.9)
New Zealand	130 (11.8)
United States	33 (3.0)
England	9 (0.8)
Nigeria	8 (0.7)
Saudi Arabia	6 (0.5)
Spain	5 (0.5)
India	5 (0.5)
Age group (years)	
<25	15 (1.4)
25 - 34	123 (11.2)
35 - 44	283 (25.7)
45 - 54	337 (30.6)
55 - 64	273 (24.8)
≥65	72 (6.5)
Gender

Occupational Specialization

Respondents were asked to select which occupational specialty they identified with from a list of 16 occupation areas previously identified through the analysis of responses to the 2018 census. The top four occupational specialties were health informatics (n=179, 20.2%), health information management (n=175, 19.8%), health information technology (n=128, 14.4%), and health librarianship (n=104, 11.7%; [Table 2](#)). When asked how they classify their occupation against the major categories used by the Australian Bureau of Statistics (ABS) [9], 90% (n=797) of participants identified as managers or professionals. While these classifications are based on the Australian context, the census recognized the international nature of the digital health workforce. Respondents from other countries were encouraged to align their occupations with the provided categories, acknowledging that the ABS classifications served as a reference point for a standardized comparable analysis across diverse geographical contexts. This approach facilitated a more inclusive representation of the global specialist digital health workforce while maintaining a structured framework for analysis.

Respondents also were asked to review the definition of 8 digital health profiles developed by the Australian Digital Health Agency (ADHA) [10] and to select which one they identified as most aligning with their work. These 8 digital health profiles capture the diverse perspectives of the health workforce based on individual roles in the design, development, implementation, and adoption of digital technologies. The profiles include patient, carer, and consumer; frontline clinical; digital champion; clinical and technology bridging; education and research; technologist; leadership and executive; and business, administration, and clinical support [10]. There is no known analysis of the ADHA profiles previously published. In this 2023 census, there was a distribution across a range of profiles, with the top four being leadership and executive (n=174, 19.6%); education and research (n=162, 18.3%); business, administration, and clinical support (n=159, 17.9%); and clinical and technology bridging (n=136, 15.3%). Only 16.7% (n=148) of respondents identified as either a technologist or digital champion.

[Table 2](#) summarizes respondents' categorization of their occupations.

Table . Occupational specializations and classifications in the 2023 Global Specialist Digital Health Workforce Census (n=886).

Occupation area	Participants, n (%)
Biomedical engineering	<5
Clinical coding	47 (5.3)
Clinical documentation improvement	31 (3.5)
Epidemiology	5 (0.6)
Health artificial intelligence	7 (0.8)
Health cybersecurity	<5
Health data science/analytics	53 (6.0)
Health informatics	179 (20.2)
Health information management	175 (19.8)
Health information technology	128 (14.4)
Health innovation	56 (6.3)
Health interoperability	28 (3.2)
Health librarianship	104 (11.7)
Health simulation	<5
Health technology assessment	7 (0.8)
Translational bioinformatics	<5
Unable to classify	54 (6.1)
Occupation classification	
Clerical or administrative worker	35 (4.0)
Community or personal service worker	<5
Laborer	<5
Manager	323 (36.5)
Professional	474 (53.5)
Sales worker	<5
Technician or trades worker	10 (1.1)
Unable to classify	38 (4.3)
Australian Digital Health Agency classification	
Business, administration, and clinical support	159 (17.9)
Clinical and technology bridging	136 (15.3)
Digital champion	54 (6.1)
Education and research	162 (18.3)
Frontline clinical	34 (3.8)
Leadership and executive	174 (19.6)
Patient, consumer, and carer	27 (3.0)
Technologist	94 (10.6)
Unable to classify	45 (5.1)

Qualifications

Participants were asked about their qualifications. With regard to a qualification in a specialist digital health area, the majority (589/1019, 57.8%) of respondents reported no formal educational qualification in a specialist digital health area.

Further, only one-quarter (244/938, 26%) reported any industry-issued credential in a digital health area. Of 1033 responses, 30% (n=310) reported that they were a registered clinician.

With regard to professional development activities undertaken in the last year, 65.7% (502/763) reported undertaking some form of professional development. Participants were given the option to identify where they had undertaken the activity and could select more than one organization that delivered that

professional development activity. Self-directed professional development activities, such as information seeking, reading/listening/watching blogs/podcasts/vodcasts, and other self-directed activities, were the most reported (676/2438, 27.7%) form of professional development activity (Table 3).

Table . Sources of professional development activities reported in the 2023 Global Specialist Digital Health Workforce Census.

Organization delivering activity	Participants, n (% ^a)
Government	223 (9.1)
Industry organization	509 (20.9)
Membership organization	511 (21.0)
Self	676 (27.7)
Training provider	162 (6.6)
Workplace	357 (14.6)

^aPercentages are based on the total number of reported professional development activities (N=2438).

Employment

With regard to their primary specialist digital health role, more than half (n=487, 55%) of respondents reported that they had worked in their current role for <10 years (Table 4). Three-quarters (n=607, 76.5%) of respondents reported that

they were in a permanent specialist digital health role. Representing two-thirds (n=544, 68.6%) of respondents, the top four organizational types were hospital (n=300, 37.8%), health technology organization (n=96, 12.1%), state health department (n=83, 10.5%), and educational facility (n=65, 8.2%). Most (n=552, 69.6%) were public organizations.

Table . Employment characteristics of primary specialist digital health role in the 2023 Global Specialist Digital Health Workforce Census.

Characteristic and selections	Participants, n (%)
Years in current role (n=886)	
<5	244 (27.5)
5 - 9	184 (20.8)
10 - 14	142 (16.0)
15 - 19	84 (9.5)
20 - 24	87 (9.8)
≥25	145 (16.4)
Employment status (n=793)	
Casual	28 (3.5)
Contract	142 (17.9)

Not-for-profit	73 (9.2)
Private	147 (18.5)
Public	552 (69.6)
Public/private partnership	21 (2.6)

Functions

The Census asked respondents to list the top five functions of their primary specialist digital health role; 792 respondents provided between one to five functions. Thematic analysis of these functions (as described in the Methods section using a modified list of themes [8]) identified four broad ways of describing their work responsibilities, with example terms shown in [Textbox 2](#).

1. Leadership aspects: these are functions related to leadership.

2. Functional aspects: these are functions related to the operational aspects of roles.
3. Occupational aspects: these are functions that describe the occupation.
4. Technological aspects: these are functions related to the technological aspects of the occupation.

The analysis identified that there was a broad range of functions across these themes, which is to be expected when analyzing the functions across 4 occupational specialist groups representing more than half of the workforce. There was a total of 1353 functions provided across these 4 groups. The functions

of health informatics (n=183 responses for functions), health information management (n=175), health information technology (n=135), and health librarian (n=104) were themed.

Textbox 2. Example terms for describing work responsibilities in the 2023 Global Specialist Digital Health Workforce Census.

<p>Leadership aspects</p> <p>Leadership, policy, strategic, strategy</p> <p>Functional aspects</p> <p>Advice, analysis, governance, manage, searching, teaching</p> <p>Occupational aspects</p> <p>Design, development, plans, research, support, service</p> <p>Technological aspects</p> <p>Applications, data, digital, software, systems, user</p>
--

Discussion

Traditionally, throughout the world, capability and competency frameworks have been developed by experts based on their many years of experience. Thus the existing frameworks for digital health specialist occupational areas in many countries, including but not limited to those shown in [Table 5](#), have been developed by industry and academic experts. However, it is crucial to acknowledge the limitation of our findings, as nearly 80% of responses came from Australia. This geographic concentration may limit the generalizability of the results, particularly for countries with single-digit responses. We recognize that while the census provides valuable insights, its predominantly Australian data set may impact the applicability of our conclusion globally. Therefore, it is imperative to interpret our framework recommendations within the context of this

geographic bias. Nevertheless, this approach was once the only way to develop these frameworks; today, we have access to a large resource of data about the workforce to inform these frameworks. The Global Specialist Digital Health Workforce Census is one such source.

This paper shows how capability frameworks can be informed by data from those working in these roles. The insights from this analysis not only inform the types of roles and their functions and responsibilities but also help validate expert-originated frameworks and identify new emerging roles with the analysis of census data over time. The four themes identified in this review, leadership aspects, functional aspects, occupational aspects, and technological aspects, and associated functions within each theme, could guide future capability framework development for the specialist digital health workforce ([Textbox 3](#)).

Table . Distribution of work responsibilities by occupational group and theme in the 2023 Global Specialist Digital Health Workforce Census.

Occupational specialist	Responses, n	Functions listed, n	Functions included in theme analysis, n	Leadership aspects, n (%)	Functional aspects, n (%)	Occupational aspects, n (%)	Technological aspects, n (%)
Health informatics	183	584	141	7 (5.34)	44 (33.59)	39 (29.77)	41 (31.30)
Health information management	175	610	127	6 (4.88)	44 (35.77)	36 (29.27)	37 (30.08)
Health information technology	135	477	85	4 (4.88)	20 (24.39)	30 (36.59)	28 (34.15)
Health librarian	104	432	106	6 (5.88)	33 (32.35)	26 (25.49)	37 (36.27)

Of critical concern, this census identified that the broad specialist digital health workforce is largely untrained in digital health capabilities, with more than half (589/1019, 57.8%) reporting that they did not have a specialist digital health qualification. Further, this workforce is not developing these skills consistently through a credentialing program (only 26% hold a credential) or through professional development activities (65.7% reported undertaking professional development in digital health in the past year).

While it could be assumed that most respondents were developing these skills on the job, most (55%) have only been in their role for <10 years, and one-quarter (27.5%) have been in their role for <5 years. On-the-job training is an important factor in improving the quality of health care [25], and the time it takes to become fully productive in a new job is significantly longer in the health workforce, varying depending on the complexity of the job, the individual's prior experience and skills, and the organization's orientation and induction process. While the first 90 days are important, it can take years for a new recruit to a role to be fully productive [26].

There is unquestioned recognition that qualifications to practice and continue professional development are critical for safe health care [27]. Yet amid the ever-increasing digital transformation of the health and care sector, this census shows that professional training and continuing professional development of digital health specialists is at least underreported or at worst absent [28-30].

This is the largest known analysis of the functions of the specialist digital health workforce; however, it is acknowledged

that this analysis is of 792 respondents and is largely an Australian data set. It is important to note that the recruitment process may introduce response bias, as those who chose to participate may differ systematically from those who did not. The Australian-centric focus of this data set could limit the generalizability of findings to a broader global context. Future censuses, with a more diverse and extensive respondent pool, will be essential to mitigate potential biases and enhance the robustness and representativeness of the analysis.

The specialist digital health workforce has dedicated roles where their primary function is to support the development, use, management, and destruction of health data, health information, health knowledge, and health technology. The Global Specialist Digital Health Workforce Census is the only survey of its kind to capture critical information about this workforce, including the functions and the capabilities required for them to undertake their roles. However, to enhance the depth of this work, it is essential to provide greater granularity about the specific functions these roles entail. Understanding the intricacies of their daily tasks and responsibilities is crucial for a more comprehensive analysis. This overview emphasizes the largely unqualified nature of the workforce and their limited engagement in formal professional development. This underscores the need for a detailed exploration of the functions performed by these roles, which will not only shed light on the current state but also inform the creation of a more nuanced and informed capability framework. Future frameworks should encompass leadership, function, occupation, and technology aspects to offer a holistic perspective on the specialist digital health workforce.

Acknowledgments

The Global Specialist Digital Health Workforce Census project was funded through the Digital Health Cooperative Research Centre, with funding support from RMIT University, the Australian Department of Health and Aged Care, and Telstra Health, and in kind support from the University of Melbourne, Australian Digital Health Agency, Australasian Institute of Digital Health, Australian Library and Information Association Health Libraries Australia, and the Health Information Management Association of Australia. The authors wish to acknowledge the representatives of each of these organizations and their support as members of the Census Steering Committee: Allison Clarke, Clare Morgan, Gemma Siemensma, James Katte, Joycelyn Linh, Maureen McCarthy, Paul Creech, Sonya Hilberts, and Vickie Irving.

Abstract

Background: Digital health has been taught at medical faculties for a few years. However, in general, the teaching of digital competencies in medical education and training is still underrepresented.

Objective: This study aims to analyze the objective acquisition of digital competencies through the implementation of a transdisciplinary digital health curriculum as a compulsory elective subject at a German university. The main subject areas of digital leadership and management, digital learning and didactics, digital communication, robotics, and generative artificial intelligence were developed and taught in a transdisciplinary manner over a period of 1 semester.

Methods: The participants evaluated the relevant content of the curriculum regarding the competencies already taught in advance during the study, using a Likert scale. The participants' increase in digital competencies were examined with a pre-post test consisting of 12 questions. Statistical analysis was performed using an unpaired 2-tailed Student *t* test. A *P* value of $<.05$ was considered statistically significant. Furthermore, an analysis of the acceptance of the transdisciplinary approach as well as the application of an alternative examination method (term paper instead of a test with closed and open questions) was carried out.

Results: In the first year after the introduction of the compulsory elective subject, students of human medicine ($n=15$), dentistry ($n=3$), and medical biotechnology ($n=2$) participated in the curriculum. In total, 13 participants were women (7 men), and 61.1% ($n=11$) of the participants in human medicine and dentistry were in the preclinical study stage (clinical: $n=7$, 38.9%). All the aforementioned learning objectives were largely absent in all study sections (preclinical: mean 4.2; clinical: mean 4.4; $P=.02$). The pre-post test comparison revealed a significant increase of 106% in knowledge ($P<.001$) among the participants.

Conclusions: The transdisciplinary teaching of a digital health curriculum, including digital teaching methods, considers perspectives and skills from different disciplines. Our new curriculum facilitates an objective increase in knowledge regarding the complex challenges of the digital transformation of our health care system. Of the 16 student term papers arising from the course, robotics and artificial intelligence attracted the most interest, accounting for 9 of the submissions.

Introduction

Background

With the Digital Healthcare Act (German: Digitale-Versorgung-Gesetz), the spectrum of digitalization in the health care system was expanded in Germany in 2019. It includes, among others, the promotion of telemedicine and the expansion of the telematics infrastructure. In addition, a legal framework was created, which, for the first time, entitles insured persons to digital health applications. Digital health applications belong to low-risk medical devices and are primarily intended

to support the detection, monitoring, treatment, or alleviation of diseases, injuries, or disabilities. Since January 2021, patients have also been entitled to have access to their data, which have generated during hospital treatment and stored in their electronic patient record. This facilitates electronic provision of medical information, in particular findings, diagnoses, treatment measures carried out and planned, as well as treatment reports for use across facilities, disciplines, and sectors [1,2].

These and further developments show that digital health is creating a new form of health care and is changing the way medicine is delivered and managed [3].

For medical educators, this evolution presents a 2-fold challenge: first, to understand and keep up with the rapidly evolving digital health landscape; and second, to effectively integrate this knowledge into medical curricula to prepare the next generation of health care professionals. Recognizing this gap and the opportunity it presents, the implementation of a comprehensive digital health curriculum is paramount.

Previous studies have suggested that digital health education should be integrated into medical school curricula, with a special emphasis on topics related to knowledge, skills, and attitudes [4].

Several other studies have emphasised the need for medical schools to prepare students for a future in digital health by incorporating digital health competencies into their curricula [4-7].

However, the transdisciplinary approach within university (digital) teaching is still not widespread. The need for such an approach arises from the potential for innovation [8] and is based on professional policy framework conditions such as the new dental licencing regulations [9]. Elective classes seem to be suitable formats for timely introduction, but a longitudinal implementation in mandatory curricula should be the goal [5].

The Implementation of a Transdisciplinary “Digital Health” Curriculum at Our University

The curriculum “Digital Health - Digitalisation and Digital Transformation of Medicine” was offered for the first time at our university in the winter semester of 2022-2023. Students from all faculties and all semesters of the university were eligible to participate.

The learning objectives were developed on the basis of existing literature [4-6,10] and interviews with transdisciplinary experts in the areas of human medicine, dental medicine, medical didactics, computer science, business administration, theology, and ethics. The curriculum is divided into the 4 subareas of digital didactics, namely digital communication, management and digital leadership, and robotics and generative artificial intelligence (AI), each with 14 weekly lessons as well as an introductory event and a final examination and evaluation event. The lessons particularly encompassed the following topics: augmented or virtual reality, big data or generative AI, data protection or information security, digital leadership, digital didactics, ethical aspects of digital health, new work, robotics, social media, open educational resources, digital health applications, wearables, simulation training, and telemedicine (Table 1).

Table . Digital health curriculum.

Topics	Goals, subareas, and time
Digital communication	<ul style="list-style-type: none"> • Goal: knowledge transfer regarding modern communication systems, consideration of legal framework conditions, and ethical aspects during transdisciplinary implementation and application • Subareas: telemedicine, digital patient files, ethics, messenger apps, digital health applications • Time: 3 lessons, each lasting 90 minutes
Digital didactics	<ul style="list-style-type: none"> • Goal: application of modern teaching and learning methods and creating a nondiscriminatory framework for studies • Subareas: open educational resources, virtual or augmented reality, simulation training • Time: 3 lessons, each lasting 90 minutes
Management and digital leadership	<ul style="list-style-type: none"> • Goal: knowledge transfer regarding digital transformation including economic aspects as well as the importance of innovative leadership styles • Subareas: leadership, information security, data protection, economy, social media, and mobile working • Time: 3 lessons, each lasting 90 minutes
Robotics and artificial intelligence	<ul style="list-style-type: none"> • Goal: knowledge transfer about possible applications of surgical robots, individualized medicine, and possible uses of generative artificial intelligence in teaching, research, and patient treatment • Subareas: robotics, generative artificial intelligence, wearables, and big data • Time: 3 lessons, each lasting 90 minutes

The aims of this digital health curriculum are as follows: (1) integrating basic digital health content into the curriculum of a university in northern Germany; in a transdisciplinary approach, students will be taught the necessary competencies to be able to apply digital health technologies in their later work; (2) considering the new licencing regulations for dentists; dental students, in particular, should be encouraged to use the newly

implemented compulsory elective subject to gain knowledge in the field of digital health; and (3) to encourage students to critically engage with the topic of digital health within the framework of a scientific thesis; this also intended to reflect currently relevant digital health topics from the students’ perspective as a basis for further curriculum development.

The curriculum contents were taught over a period of 1 semester within the framework of a compulsory elective subject.

Furthermore, this study aims to analyze the objective acquisition of digital competencies through the implementation of a transdisciplinary digital health curriculum at a German university.

Methods

Ethical Considerations

The study has been reviewed by the ethics committee of the Faculty of Medicine of the University of Rostock, Germany, and has been approved (A 2022-0137).

Demographics and Previous Teaching of Digital Health

Student-related data about educational level, gender distribution, and career goals were analyzed. At the beginning of the semester, students were asked whether digital health learning objectives had already been taught in previous courses, using a Likert scale (1=very well taught to 5=not taught at all).

Students' Assessment and a New Examination Approach for Further Development

To measure the allocation of knowledge of the participants, the participants' prior knowledge was assessed during the introductory lesson through a theoretical test (pretest) consisting of 12 questions. Ten questions were multiple-choice and 2 were open questions. The test was specifically related to the topics covered in the curriculum. Multiple-choice questions assessed knowledge on the topics of digital transformation, ethics, change management, data protection, robot-assisted surgery, digital patient files, video consultation, and simulation training. The didactics section was covered by 2 open questions and 1 multiple-choice question. At the final seminar, the theoretical test was repeated with similar questions (posttest).

In addition to the standardized questions, students were asked to write a scientific paper. The topic could be chosen

independently. However, a prerequisite was a content-related reference to the overarching topic of digital health. The objectives of the examination are to (1) encourage students to critically engage with a digital health topic of their choice, (2) promote scientific work, and (3) obtain an insight into the topics of digital health perceived as relevant by the students as a basis for further curriculum development.

For further structuring of the curriculum, the scientific papers were assigned to one of the main topic areas based on the selected headings and abstract contents.

Statistical Analysis

The data were analyzed using SPSS (version 27; IBM Corp) software. The gender distribution, career goals, intended subject area, and scientific papers were analyzed descriptively. Statistical analysis of pre-post test results and previous teaching of learning objectives was performed using an unpaired (learning objectives) and paired (pre-post test results) 2-tailed Student *t* test. A *P* value of <.05 was considered statistically significant.

Results

Educational Level of the Participants

Within the first year, a total of 20 students (5 in the winter term and 15 in the summer term) participated in the digital health curriculum. The average age of the participants was 22.3 (range 19-30) years. At the time of participation, 15 participants studied human medicine, 3 participants were studying dentistry, and 2 participants were studying medical biotechnology. In total, 11 (61.1%) students in human and dental medicine were in the preclinical phase and 7 (38.9%) were in the clinical phase.

Gender Distribution

Figure 1 shows the gender ratio according to the subjects of study among the participants. In total, 13 participants were female and 7 were male. Among human medicine students, 10 were female and 5 were male. Two dentistry students were male and 1 was female. Both biotechnology students were female.

Figure 1. Gender distribution by study subject.

Career Goals

Two questions were aligned with the focus on future professional activities. The first question asked whether the respondents wanted to work in an inpatient or outpatient setting. The options “other” and “don’t know yet” could also be selected. Furthermore, the students were asked about their desired goal of becoming a specialist doctor. As shown in [Multimedia Appendix 1](#), the majority of participants are still undecided on whether they want to work in the outpatient or inpatient sector in future. [Multimedia Appendix 2](#) shows the answers to the

question about the goal of becoming a medical specialist, which was answered by the participating human medicine students. According to this, most of the participants who already know their career goal intended to become a specialist in surgery (n=4).

Previous Teaching of Digital Health

During the first lesson, students were asked whether digital health learning objectives have already been taught in previous courses, using a Likert scale (1=very well taught to 5=not taught at all). [Table 2](#) shows the corresponding evaluations.

Table . Evaluation of the learning objectives of previous teaching of the digital health curriculum.

Learning objectives	Clinical, mean	Preclinical, mean	<i>P</i> value
All	4.2	4.4	.02
Big data	4.9	4.7	.36
Artificial intelligence	4.7	4.6	.84
Digital health applications	4.1	4.3	.80
Messenger apps	4.3	4.7	.26
Wearables	4.4	4.8	.18
Telemedicine	4.1	4.7	.20
Data protection and information security	3.6	3.7	.82
Digital ethics	4.0	4.1	.87
Simulation training	3.9	4.5	.28
Virtual or augmented reality	3.8	4.6	.10
Economy	3.7	4.6	.09
Digital didactics	3.0	3.6	.41
Robotics	4.6	4.5	.83
Digital leadership	4.6	4.8	.46
Mobile working	4.7	4.7	.97
Social media	4.6	4.4	.69
Open educational resources	3.9	4.3	.55

Among clinical students, significantly better overall coverage of the digital health learning objectives is evident.

Pre-Post Test Results and Term Paper Evaluation

In the pretest, the participants scored an average of 4 points compared to 8.3 points in the posttest. Consequently, there was a significant increase of 106% in knowledge ($P < .001$; [Table 3](#)).

Table . Increase in knowledge determined via a pre-post test (maximum achievable score 12; 106% increase in knowledge by 4.3 points; $P < .001$).

Increase in knowledge	Pretest ^a	Posttest ^b
Total score	4.0	8.3
Clinical	4.1	8.7
Preclinical	4.2	8.2
Female participants	3.6	8.3
Male participants	4.7	8.1

^aDifference in pretest scores between clinical and preclinical participants: $P = .96$; differences in posttest scores between clinical and preclinical participants: $P = .38$.

^bDifference in pretest scores between male and female participants: $P = .11$; difference in posttest scores between male and female participants: $P = .17$.

Neither gender nor study phase affected pre- or posttest results. As shown in [Table 4](#), the most frequently selected main topic was robotics and AI.

Table . Digital health topics selected by students for their term papers.

Titles of the students' term papers	Digital health main topic
Progress of computer-assisted procedures and robotics in implantology	Robotics and AI ^a
Mind reading with functional magnetic resonance imaging and AI	Robotics and AI
To what extent can the Da Vinci Robot help reduce postoperative complications?	Robotics and AI
Algorithms against prejudice? The role of AI in combating gender discrimination in the health sector	Robotics and AI
What opportunities arise from the use of AI in medicine and what are the associated problems?	Robotics and AI
Applications of AI in Radiology	Robotics and AI
AI and robotics in Orthopaedics and Trauma Surgery	Robotics and AI
Opportunities and limits of AI in the health sector	Robotics and AI
Use of AI for early detection of dementia	Robotics and AI
Data ethics in the digital world	Management and leadership
Does digitalisation in medicine lead to a loss of skills and knowledge among medical staff?	Digital didactics

^aAI: artificial intelligence.

Discussion

Overview

Current social, political, and economic developments in Germany require a reorientation of university teaching, considering digital learning and teaching strategies. The necessity is also reflected in the restructuring of established framework conditions, such as the amendment of dental and medical licencing regulations [9,11].

This study aimed to analyze the objective acquisition of digital competencies through the implementation of a transdisciplinary digital health curriculum at a German university.

The learning objectives were imparted on the main topics of management and digital leadership, robotics and AI, digital communication, and digital didactics within the framework of a 1-semester curriculum. Objective knowledge gain was determined using a pre-post test design. In addition, the extent to which the approach of transdisciplinary networking could be implemented was analyzed. This was quantified by the disciplines and the number of clinical and preclinical participants. Overall, the results were analysed over 1 year (2 cohorts). In the second run, the number of participants has already tripled.

Characterization of the Participants

According to the Federal Statistical Office, 64.8% of students in human medicine in 2021 were female [12]. This corresponds to the distribution of participants in our curriculum, even when

considering the isolated subject group of human medicine being the most frequently represented. Consequently, it can be assumed that the topic is not gender-specific and is of equal interest to male and female students. This cannot be confirmed for participants from the fields of dentistry and medical biotechnology. However, the small number of participants must be considered here.

Previous Teaching of Digital Health

Evaluation of the students at the beginning of the semester revealed that all the content of the curriculum has not been taught at all or only to a very limited extent. Even though there was a significant difference in knowledge between the clinical and preclinical sections, this concerns all participants. Consequently, it can be assumed that this deficit will not be sufficiently compensated for in higher semesters with regard to the clinical phase.

The results also indicate that most participants are still open about their career goals. This applies both to the future field of work (outpatient vs inpatient) and to the intended specialization. Therefore, the general approach to teaching content can be considered suitable.

Assessment of the Increase in Knowledge

As reported by studies with a similar study design, a significant objective increase in knowledge could be achieved among participants through the curricular dissemination of knowledge on relevant digital health topics. It should be noted that some students participated in the curriculum out of interest in the content but without aiming to achieve a good grade.

Consequently, it can be assumed that some students did not prepare for the posttest. The fact that summative assessment of the intended learning objectives at the beginning of the curriculum increases learning success has previously been described [13].

Regarding the current evidence in the development of digital literacy, the focus is increasingly on social interaction and lifelong learning skills in an innovative teaching and learning culture, in addition to subject knowledge [5].

Term Paper Evaluation

When analyzing the selected term papers, it quickly became clear that the topic of AI is of outstanding importance among digital health topics. This seems to be explained, in particular, by the strong media presence of the topic. The rapid development of generative AI has received special media attention with the launch of ChatGPT in 2022 [14-16]. Two challenges arise, in particular, for the curriculum. Although the special importance of flexible and adaptive teaching formats to be able to integrate innovations into teaching without delay is becoming apparent, the establishment of framework conditions for the application of generative AI in teaching, research, and clinical practice is coming into focus. Both focal points and associated challenges were already considered and will be further developed for our future digital health curriculum.

The Role of Leadership in a Digital Health Training Culture

Digital transformation is a continuous process that is better accepted by those who perceive digitalization as relevant to their own work. Digital leadership describes the special role of managers in the implementation of digital transformation. It is up to managers in the health care sector to align the strategic orientation to digital transformation with the company's goals and needs and to create an appropriate digital culture. Regarding the provision of early access to the necessary knowledge on topics related to digital health, managers in the field of education have a special responsibility [17].

The transdisciplinary approach of the digital health curriculum acknowledges the current evidence for the success of digital transformation. In particular, evidence from economic evaluations has shown that in a networked environment, the opening of boundaries is necessary to create innovation and exploit synergies [8].

With an average value of 5 on the Likert scale, the results of the initial evaluation show that this knowledge has not yet been imparted in the participants' previous curricula. Consideration of the transdisciplinary digital health curriculum is, therefore, of particular importance.

Digitalization Connects: the Necessity of a Transdisciplinary Digital Health Curriculum

The goal of opening of the curriculum to all faculties is to expand the transdisciplinary network to promote an innovation-driven teaching and learning environment. This basic idea represents a unique selling point for previously established digital health curricula.

Our results indicate that this opportunity was already realized in the first year by students from 3 different disciplines, such as human medicine, dentistry, and medical biotechnology. The distribution of clinical and preclinical students also shows cross-semester interest.

In the future, an increase in the participation of dental medicine students is expected. This is due to the new orientation of the dental licencing regulations, which mandate participating in curricula by choosing from among the elective subject areas (to which the compulsory digital health elective subject is assigned), both for the preclinical and clinical study phases [9].

It should be noted, however, that only 5 out of 20 students did not belong to the field of human medicine. These results suggest that the transdisciplinary approach needs to be further promoted, addressed, and implemented to achieve an even better transdisciplinary exchange.

Social media use may present an opportunity for increasing the visibility of our transdisciplinary curriculum and its learning objectives. The curriculum is currently already accompanied by a social media channel. The importance of social media in teaching and research is currently the focus of social debates and scientific studies [18,19]. For better assessment of the importance of social media in a modern academic teaching and learning culture, the authors believe that further studies are needed.

Emerging Technologies in a Transforming Health Care System

The use of modern technologies has enormous potential for optimizing patient treatment [20,21]. In surgery, in particular, there is a wide range of applications in the operating theater and perioperative management.

A recent editorial describes current emerging innovations with particular potential, which are also included in the digital health curriculum [20]. In particular, this involves the contents of machine learning-enabled clinical decision-making support, computer vision and augmented reality, as well as wearable devices and remote patient monitoring. The dynamic nature of these developments, among others, shows the particular importance of a flexible and adaptive curriculum to be able to integrate emerging technologies into teaching without delay.

Robot-assisted surgery, including approaches to telesurgery, is of particular importance, especially in surgery. The special importance of robotics for patient care has already been described several times and is now an integral part of numerous hospitals [22,23].

The special importance of robotics is also reflected in the selection of homework topics. Three of the 16 papers submitted focus on robotics in medicine.

However, the increasing use of robotics in the operating theater also requires special skills that can and must be practised extensively in a simulation-based setting [24]. This requires time and financial resources, as well as training in a supervised setting [25]. In teaching and further education, these prerequisites represent a hurdle. In particular, cost-intensive virtual and augmented reality simulators are often only rarely

available; their use in teaching is generally yet not structured [26]. User acceptance is indisputably high and can increase satisfaction in addition to learning success [27]. However, the topic requires economic reflection and a basic understanding of project management—an aspect that was addressed in the curriculum section of Management and Digital Leadership.

In addition to the implementation and continuous further development of technical innovations in clinical applications, achievements with disruptive innovation power also play a special role in future teaching and research. The disruptive potential of digital transformation is currently manifesting itself in particular in the launch of generative AI, such as ChatGPT [14].

Generative AI, Web-Based Meetings, and the Challenge of Flexible Adaptive Training

The examination of digital teaching methods has experienced a surge in innovation, particularly in the context of the COVID-19 pandemic [28]. Experience in the field of telemedicine has provided a blueprint for web-based teaching with simultaneous integration of knowledge content in telemedicine. Thus, knowledge transfer could be extended by the achievement of local flexibility [28].

But approaches that account for time flexibility are also described: the “flipped classroom” model, for example, is an approach to active self-directed learning in which students acquire the basic concepts themselves before class—for example, through recorded lectures or interactional learning modules provided by a learning management system—so that class time can be used for active learning activities such as exercises, projects, or discussions. Valuable time spent in presence is used for the application, rather than acquisition, of knowledge. This can increase both student performance and student satisfaction [29,30].

In addition to the flexibility of location and time, there are often limits to accessing real-world working environments. To be able to train practical and theoretical skills in a realistic setting, such as an operating theater, teaching using virtual and augmented reality offers promising potential.

Virtual reality refers to complete visual immersion in an artificial, computer-generated environment. In augmented reality, holograms, which often also enable interaction, appear projected into the room through semitransparent glasses. Mixed reality is the combination of digital screens with projected

interactional holograms. The user sees the real world while simultaneously manipulating the digital content generated by the device [31].

Both technologies are increasingly being integrated in the clinical setting, but also in teaching, such as the visualization of organs. In clinical applications, augmented reality enables the simulation of patient encounters to train communication skills or intraoperative decision-making to increase safety during surgery [32].

Limitations

This study’s limitations particularly include its single-center design and the small number of participants at the time of analysis. In addition, the final test only examined excerpts from topics that cannot represent the full scope of the curriculum. The choice of term paper is also subject to numerous influencing factors, so the motivation for choosing the topic cannot be clearly identified.

Conclusions

This study aims to analyze the objective acquisition of digital competencies through the implementation of a transdisciplinary digital health curriculum at a German university. The results show that relevant content on digital health topics has not been taught sufficiently at the university outside our new digital health curriculum. The objective increase in the knowledge on these topics within the framework of the digital health curriculum could be verified as significant via a pre-post test design.

The approach of transdisciplinary development of a digital health curriculum seems especially promising. We provided dentistry students a platform to complete their recently compulsory elective subject. We observed that dentistry students could complete their recently compulsory elective subject when using an appropriate digital platform.

The integration of written assignments as a special examination element can promote critical engagement with digital health content. This also facilitates gaining insight into digital health topics and issues that are relevant to students. We can harness these insights in further developing our curriculum.

Together with the current literature, our data indicate that the content of digital health curricula must be transferred into standard teaching for all health science students.

Acknowledgments

We would like to thank all the speakers who supported the digital health curriculum with their presentations and expert knowledge.

Abstract

Background: The relationship between educational outcomes and the use of web-based clinical knowledge support systems in teaching hospitals remains unknown in Japan. A previous study on this topic could have been affected by recall bias because of the use of a self-reported questionnaire.

Objective: We aimed to explore the relationship between the use of the Wolters Kluwer UpToDate clinical knowledge support system in teaching hospitals and residents' General Medicine In-Training Examination (GM-ITE) scores. In this study, we objectively evaluated the relationship between the total number of UpToDate hospital use logs and the GM-ITE scores.

Methods: This nationwide cross-sectional study included postgraduate year-1 and -2 residents who had taken the examination in the 2020 academic year. Hospital-level information was obtained from published web pages, and UpToDate hospital use logs were provided by Wolters Kluwer. We evaluated the relationship between the total number of UpToDate hospital use logs and residents' GM-ITE scores. We analyzed 215 teaching hospitals with at least 5 GM-ITE examinees and hospital use logs from 2017 to 2019.

Results: The study population consisted of 3013 residents from 215 teaching hospitals with at least 5 GM-ITE examinees and web-based resource use log data from 2017 to 2019. High-use hospital residents had significantly higher GM-ITE scores than low-use hospital residents (mean 26.9, SD 2.0 vs mean 26.2, SD 2.3; $P=.009$; Cohen $d=0.35$, 95% CI 0.08-0.62). The GM-ITE scores were significantly correlated with the total number of hospital use logs (Pearson $r=0.28$; $P<.001$). The multilevel analysis revealed a positive association between the total number of logs divided by the number of hospital physicians and the GM-ITE scores (estimated coefficient=0.36, 95% CI 0.14-0.59; $P=.001$).

Conclusions: The findings suggest that the development of residents' clinical reasoning abilities through UpToDate is associated with high GM-ITE scores. Thus, higher use of UpToDate may lead physicians and residents in high-use hospitals to increase the implementation of evidence-based medicine, leading to high educational outcomes.

Introduction

Sir William Osler [1] stated that “to study the phenomena of disease without books is to sail in an uncharted sea, while to study books without patients is not to go to sea at all.” Self-learning is known to develop basic clinical skills [2-4], and several studies have demonstrated the effectiveness of web-based clinical knowledge support systems. For example, a study examining the US Residency Internal Medicine In-Training Examination (IM-ITE) score reports a 3.7% increase in the IM-ITE score per 100 hours of UpToDate use [5]. In addition, UpToDate users are more satisfied with their answer accuracy, interaction, and overall satisfaction than PubMed Clinical Queries users [6]. Thus, UpToDate may be effective at the hospital level because hospitals using UpToDate have been reported to show a significantly shorter length of stay for patients [7-9]. UpToDate is already the most widely used web-based clinical knowledge support system among residents (65.5%) and the third most used system among physicians (40.4%) [9].

The General Medicine In-Training Examination (GM-ITE) is an in-training examination developed to provide residents and training program directors with an objective, reliable, and valid assessment of clinical knowledge during training. It uses the same methodology as the IM-ITE [10-12] and comprises the following 4 domains: medical interview/professionalism, symptomatology/clinical reasoning, clinical procedures, and disease knowledge. The examinations consist of 60 questions (6 on medical interview/professionalism, 15 on symptomatology/clinical reasoning, 15 on clinical procedure, and 24 on disease knowledge) and include video- and audio-format questions. The GM-ITE was first introduced in 2011 by the Japan Institute for Advancement of the Medical Education Program (JAMEP), a nonprofit organization, and is administered annually. The questions are prepared annually by a committee of experienced physicians, and peers are reviewed by an independent committee. The examinations are open to the residents of teaching hospitals that have applied to offer the examinations [13,14].

We previously reported that self-study time and use of UpToDate had positive relationships with GM-ITE scores [4]. However, those findings could have been affected by recall bias because of the use of a self-reported questionnaire, which meant that objectivity could not be guaranteed. In this study, therefore, we objectively evaluated the relationship between the total number of hospital use logs in UpToDate and the GM-ITE scores of hospital residents.

Hospital use logs were used because residents have several opportunities to acquire second-hand knowledge from their supervisors, reflecting the evidence-based medicine (EBM)

culture of teaching hospitals. The introduction of clinical knowledge support systems has recently increased among resident and senior doctors, although the frequency of use is low because of language barriers and is far from the global standard [9]. The postgraduate 2-year residency system was established in 2004 in Japan. The use of the *Yanegawara* (“tiled roof” in Japanese) style of education, in which senior doctors teach resident physicians and postgraduate year (PGY)–2 residents teach PGY-1 residents based on EBM using web-based medical resources, such as UpToDate, has also become widespread [15]. The merit of the *Yanegawara*-style education is the aspect of teaching among residents with close grade levels. Internationally, peer teaching or peer tutor systems have been shown to be effective in medical education [16,17].

The aim of this study was to evaluate the correlation between the total number of UpToDate hospital use logs and the GM-ITE scores of resident physicians objectively.

Methods

Study Design and Population

We conducted a nationwide observational study of postgraduate residents in Japan using both mean GM-ITE scores and the total number of UpToDate hospital use logs to examine their relationship. The 2020 GM-ITE and self-reported questionnaire were conducted between January 13 and 31, 2021, and the data were collected during the same period. We accessed the data set for research purposes on June 16, 2021.

In Japan, postgraduate resident physicians are required to undergo at minimum a 2-year postgraduate residency program after 6 years of undergraduate medical school. In the program, the resident physicians rotate around 7 clinical departments: internal medicine, surgery, emergency medicine, pediatrics, obstetrics and gynecology, psychiatry, and community-based medicine. The Ministry of Health, Labour and Welfare has established guidelines for postgraduate clinical training programs to teach communication skills, professionalism, and ethics, in addition to basic clinical knowledge and skills, to resident physicians. Medical students in their final year of an undergraduate medical program can apply for the postgraduate residency program at more than approximately 1000 clinical teaching hospitals in Japan using a web-based matching system [18].

Measurements

We collected hospital-level information (number of physicians, monthly salary, number of ambulances, number of permitted beds, type of tertiary emergency care, location, and type of hospital) from published web pages. The hospital use logs of the web-based clinical knowledge support system (UpToDate) in the 3 years from 2017 to 2019 were provided by Wolters

Kluwer. UpToDate log data were defined as the number of topic review page views. We also collected GM-ITE scores. We hypothesized that supervisors' use of UpToDate reflects the culture of EBM resident education at each teaching hospital. Furthermore, we decided to use UpToDate hospital use logs from 2017 to 2019 to examine their association with the 2020 GM-ITE scores because educational effects are not immediately reflected after an intervention. Resident-level information (sex, grade, number of monthly emergency department duties, average number of patients in charge, general medicine department rotation, self-study time, and weekly duty hours) were obtained using a self-reported questionnaire administered immediately after the GM-ITE. These variables were selected based on previous studies [19-21].

Statistical Analyses

Hospitals were classified as low or high use according to their UpToDate hospital use logs. The total number of use logs was divided by the number of physicians and was log-transformed into base 2. The monthly salary, number of ambulances, and number of permitted beds were also log-transformed into base 2. Low-use hospitals were defined as those with fewer than the median log-transformed number of hospital use logs, whereas high-use hospitals were defined as those with greater than or equal to the median log-transformed number of hospital use logs. Differences between low-use and high-use hospitals were examined for statistical significance using the Student 2-tailed t test. Categorical variables were compared using the χ^2 test and presented as frequencies with percentages. The effect size (Cohen d) was estimated using the median difference between low- and high-use hospitals divided by the pooled SD—a value of 0.2 was considered a small effect, 0.5 was considered a medium effect, and 0.8 was considered a large effect [22]. Hospital-level analysis was performed using scatter plots to examine the association between the mean GM-ITE score and the number of UpToDate hospital use logs aggregated at the hospital level. We analyzed the association between the GM-ITE scores and the total number of UpToDate hospital use logs in each hospital over 3 years, using a linear multilevel regression model. The multilevel analysis was adjusted for sex, location, and type of hospital in addition to statistically significant factors in the univariate analysis. In those analyses, the domain of medical interview/professionalism in the GM-ITE was excluded from the analysis because we believed that it was not a clinical skill that could be improved using UpToDate. All analyses were performed using SAS software (version 9.4; SAS Institute Inc).

Ethical Considerations

This study was performed in accordance with the principles of the Declaration of Helsinki and STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines. All the methods followed the *Ethical Guidelines for Medical and Health Research Involving Human Subjects*. Informed consent was obtained from each participant after clarifying the explanatory research document, including data anonymization and voluntary participation. Only participants who provided consent were included in this study, and they were also provided an opportunity to opt out. The study was approved by the Ethics Review Board of JAMEP (approval 21-1).

Results

The 2020 GM-ITE was offered at 593 teaching hospitals nationwide, and 7669 residents took the exams. A total of 6816 residents from 588 teaching hospitals participated in the survey on the training environment. The study population consisted of 3013 residents from 215 teaching hospitals with at least 5 GM-ITE examinees and web-based resource use log data from 2017 to 2019. Hospitals in all regions of Japan, namely Hokkaido, Tohoku, Kanto, Chubu, Kinki, Chugoku, Shikoku, Kyushu, and Okinawa, were included. The mean number of GM-ITE examinees per hospital was 14.1 (SD 8.6).

The hospital-level information is presented in [Table 1](#). The mean GM-ITE score of all the hospitals was 26.5 (SD 2.2); of the 215 hospitals, 115 (53.5%) were secondary care hospitals, 159 (74%) were located in rural areas, and 204 (94.9%) were community-based hospitals. Residents of high-use hospitals achieved significantly higher GM-ITE scores than those of low-use hospitals (mean 26.9, SD 2.0 vs mean 26.2, SD 2.3; $P=.009$; Cohen $d=0.35$, 95% CI 0.08-0.62). Monthly salary (in JPY ¥100,000; JPY ¥100=US \$0.64) was significantly higher in low-use hospitals than high-use hospitals (mean 3.7, SD 0.8 vs mean 3.3, SD 0.7; $P<.001$). The resident-level information is presented in [Multimedia Appendix 1](#); 68.5% (2076/3031) were male and 50.5% (1531/3031) were PGY-2 residents.

Correlations between total use in 3 years divided by the number of physicians and GM-ITE scores were analyzed ([Figure 1](#)). The mean GM-ITE hospital score was significantly correlated with the total number of UpToDate hospital use logs (Pearson $r=0.28$, $P<.001$; Spearman $r=0.27$, $P<.001$). The linear regression function was $y = 24.13 + 0.66 \times \log_2(\text{total use/number of physicians})$; therefore, the difference in the mean GM-ITE score between the total use divided by the number of physicians at values of 8 and 128 was 2.64 ([Figure 1](#)). [Multimedia Appendix 2](#) shows the relationship between GM-ITE scores and hospital- and resident-level information using an univariate analysis. The statistically significant factors were log-transformed total number of hospital use logs in 3 years divided by the number of physicians ($P<.001$), log-transformed number of ambulances ($P<.001$), log-transformed number of permitted beds ($P=.005$), type of tertiary emergency care ($P=.01$), grade ($P<.001$), number of monthly emergency department duty ($P=.004$ -.046), average number of patients in charge (from $P<.001$ to $P=.01$), general medicine department rotation ($P=.004$), self-study time ($P=.02$ -.04), and weekly duty hours ($P<.001$). The multilevel analysis was adjusted for all these factors in addition to sex, location, and type of hospital. [Table 2](#) shows the relationship between GM-ITE scores and hospital- and resident-level information using a multilevel analysis. The multilevel analysis revealed a positive association between 3-year total hospital use logs and GM-ITE scores (estimated coefficient=0.36, 95% CI 0.14-0.59; $P=.001$). [Multimedia Appendix 3](#) shows the results of the analysis of all 4 domains (medical interview/professionalism, symptomatology/clinical reasoning, clinical procedures, and disease knowledge). The result also revealed a positive association between the use of UpToDate and GM-ITE scores (estimated coefficient=0.41, 95% CI 0.18-0.65; $P<.001$).

Table . Background characteristics of the teaching hospitals.

Hospital-level information	Total (N=215)	Low-use hospitals (n=107)	High-use hospitals (n=108)	P value
Total number of use logs of UpToDate, mean (SD)	10,485.1 (20,231.4)	2578.7 (2,278.2)	18,318.2 (26,249.5)	<.001

Discussion

We objectively evaluated the relationship between hospital use logs of the web-based clinical knowledge support system, UpToDate, at teaching hospitals and residents' GM-ITE scores. Residents of high-use hospitals achieved significantly higher GM-ITE scores, an objective index of the basic clinical ability of residents, than those of low-use hospitals. There are 2 main situations in which residents use web-based clinical knowledge support systems such as UpToDate: "actual clinical sittings such as bedside and outpatient care" and "self-improvement." UpToDate is useful in situations where immediate evidence-based care must be provided to the patient in front of a resident [23]. In terms of self-improvement, among both residents and senior doctors, web-based clinical knowledge support systems could lead to the development of basic clinical abilities because they can collect the latest information more efficiently than from textbooks [9].

The use of a web-based clinical knowledge support system is associated with high GM-ITE scores owing to the residents' knowledge of clinical reasoning. The clinical training guidelines of the Ministry of Health, Labour and Welfare highlight the importance of studying clinical reasoning and problem-solving abilities, and residents are required to have the ability to (1) make a differential diagnosis and initial response to high-frequency symptoms through an appropriate clinical reasoning process and (2) collect patient information and make clinical decisions in consideration of the patient's intentions and quality of life based on the latest medical knowledge. Residents constantly acquire the latest medical knowledge and use evidence-based and their own experiences to solve clinical problems. The questions in the GM-ITE include clinical reasoning questions in accordance with the guidelines of the Ministry of Health, Labour and Welfare. As UpToDate contains a series of flows that "list differential diagnoses from symptoms and link them to accurate diagnoses," we believe the use of UpToDate would help residents develop their clinical reasoning abilities. Therefore, we speculate that the development of residents' clinical reasoning abilities through UpToDate is associated with high GM-ITE scores.

Japanese residents are required to gain greater outpatient clinical experience to acquire basic clinical skills, including communication and clinical reasoning, during this 2-year training period. The postgraduate clinical residency system has been revised regularly, and the latest revision in 2020 requires a 1-month general outpatient training rotation for residents.

Therefore, outpatient training is becoming increasingly important in Japanese clinical resident education programs.

Previous studies have demonstrated the usefulness of web-based clinical knowledge support systems in outpatient care. A comparison of outpatient diagnostic errors made by physicians with and without the use of UpToDate shows that diagnostic errors were significantly reduced in the case of physicians who used UpToDate [24]. Internal medicine residents' responses to patient-specific questions encountered in outpatient settings have been known to improve their clinical skills and patient care decisions. UpToDate has been reported to be the second most commonly used tool for gathering information after MEDLINE and is an extremely helpful information source [25]. We speculate that the GM-ITE includes questions regarding outpatient care that are associated with the development of clinical residents' outpatient care abilities and high GM-ITE scores.

Factors significantly and positively associated with GM-ITE scores in the multilevel analysis results, besides the use of UpToDate, were location, PGY-2 grade, average number of patients in charge, and weekly duty hours. Residents of rural teaching hospitals may have the opportunity to examine more patients, because the number of physicians affiliated with rural teaching hospitals is lower than that with urban teaching hospitals. Consequently, they may acquire greater clinical experience and knowledge [26]. Regarding the difference in grades, we believe that the difference in clinical experience is directly reflected in GM-ITE scores. This finding is consistent with the results of our previous study [4]. We recommend that residents develop a proactive attitude toward patient care because basic clinical skills tend to develop with daily patient management. The results of the multilevel analysis showed that 60-79 weekly duty hours were significantly and positively associated with GM-ITE scores. This finding supports our previous results [20]; we believe there are optimal working hours for improving clinical competency.

The development of residents' basic clinical skills does not require many supervisors; however, high-quality and highly productive education is necessary. A previous Japanese study showed that education delivered by a limited number of supervisors was more likely to develop residents' basic clinical skills [27]. Furthermore, residents who rotated in general medicine achieved higher GM-ITE scores [4]. We believe the following factors are required for future residency education: generalist residency education by general medicine specialists; use of productive web-based clinical knowledge support

systems, such as UpToDate; EBM culture; and the *Yanegawara*-style educational system.

This study has a few limitations. First, the scores were examined among a limited number of GM-ITE examinees. Although there are approximately 18,000 PGY-1 and -2 residents in Japan, only 3013 residents were analyzed in this study, accounting for approximately one-sixth (16.7%) of the total population. In addition, as the GM-ITE is a voluntary examination, a bias toward highly motivated residents taking the exam may exist. Therefore, the generalizability of this study is not ensured. Second, causal relationships could not be guaranteed because the study design was cross-sectional. To control for selection bias and to assess causality, we believe that planning a randomized controlled trial targeting nationwide resident physicians is necessary. In this randomized controlled trial, the GM-ITE scores would be the primary end point, and the intervention would control for the presence or absence of web-based clinical knowledge support systems. Third, we did not assess the baseline clinical skills of the GM-ITE examinees in this study, and differences in undergraduate medical school education could have impacted the study results. Fourth, the hospital use logs did not include detailed information, such as user information and access time. It was not possible to identify user-specific information, such as residents, physicians, and

co-medical professionals (eg, nurses), from the log data. Fifth, the results came from a single web-based clinical knowledge support system. Although there are other web-based clinical knowledge support systems that aid residents, physicians, and paramedical workers, we did not compare UpToDate with them. Some resident physicians in Japan may use web-based clinical knowledge support systems other than UpToDate. Although we could not obtain data on systems other than UpToDate for this study, we aim to include them in our next research project to validate the current results.

In conclusion, residents in high-use hospitals had significantly higher GM-ITE scores than those in low-use hospitals, indicating that GM-ITE scores are associated with web-based resource use logs. A previous study showed an association between web-based resource use and resident GM-ITE scores using data from a self-reported survey of clinical residents [4]. Our findings are consistent with those of previous studies and include data that ensure objectivity. Frequent use of web-based clinical knowledge support systems will increase the likelihood of physicians, including faculty, senior, and junior residents, implementing EBM and senior physicians teaching juniors using the *Yanegawara*-style education, which may lead to higher educational outcomes.

Acknowledgments

We thank the members of Japan Institute for Advancement of Medical Education Program (JAMEP) for their assistance. We would like to thank Editage for English language editing and Wolters Kluwer for providing log data on web-based resource use. This work was supported by the Health, Labour and Welfare Policy Grants from the Ministry of Health, Labour and Welfare's Research on Region Medical (21IA2004).

Data Availability

The data are not available for sharing because we did not obtain relevant consent from the participants to publish them. The corresponding author will respond to inquiries on data analyses.

Authors' Contributions

K Kataoka and MN had full access to all data in the study and take responsibility for the integrity of the data and accuracy of the data analysis. YN and YT contributed to study concept and design. K Kataoka, YN, TS, YY, KS, MN, KN, SF, SN, K Katayama, MK, RU, HK, and YT contributed to the acquisition, analysis, and interpretation of data. K Kataoka and YN contributed to manuscript drafting. YN, HK, and YT contributed to critical revision of the manuscript for important intellectual content. K Kataoka and MN contribute to statistical analysis. RU and YN contributed to administrative, technical, or material support. YN, HK, and YT contributed to supervision.

Conflicts of Interest

YN received an honorarium from the Japan Institute for Advancement of Medical Education Program (JAMEP) as a General Medicine In-Training Examination (GM-ITE) project manager. YT is a director of JAMEP. YT, HK, and KS received honoraria for delivering lectures for JAMEP. TS, YY, KS, and SF received honoraria from JAMEP as exam preparers for the GM-ITE. YN and YT received honoraria from Wolters Kluwer for delivering the Wolters Kluwer lecture. K Kataoka, MN, KN, SN, K Katayama, MK, and RU declare no competing interests.

Abstract

A momentous amount of health data has been and is being collected. Across all levels of health care, data are driving decision-making and impacting patient care. A new field of knowledge and role for those in health care is emerging—the need for a health data–informed workforce. In this viewpoint, we describe the approaches needed to build a health data–informed workforce, a new and critical skill for the health care ecosystem.

(*JMIR Med Educ* 2024;10:e52290) doi:[10.2196/52290](https://doi.org/10.2196/52290)

KEYWORDS

health data–informed workforce; health data; health informaticist; data literacy; workforce development

Background

Health care has become a data-driven business. It is no longer acceptable that both incoming and current health care professionals and business leaders lack an understanding of the influence data has on health care delivery. The clinician coauthors listed here represent this sphere and are still learning every day. We represent the diverse background of professionals that exist in the health data space, with a wide variety of journeys into this arena [1]. “Health data” is a broad term, often referring to data collected and exchanged in electronic systems. Everyday health data are entered, exchanged, and used to make important decisions from the patient level to the systems level. Health care professionals today need an understanding of the utilization and impact of health data to optimize care delivery and interact with the many systems they encounter daily.

When we entered the health care industry over 20 years ago, we were hopeful clinicians excited to impact patients’ lives. For many of us, we quickly became disillusioned by a system that was driven not by patient outcomes but by reimbursement. Yet, we regained hope with pivotal moments, including when Don Berwick challenged health care organizations to promote quality and evidence-based medicine with the Institute for Healthcare Improvement; the proliferation of electronic health record (EHR) usage leading to the potential to share patient information across systems [2-4]; and the opportunity to move from fee-for-service to value-based payment [5]. We continue to grow in hope, as many openly discuss health equity and social determinants and drivers of health. In addition, the conversations

and investments in workforce related to health data knowledge and expertise are ongoing and receiving national attention. Opportunities abound with the expansive growth of artificial intelligence and machine learning.

However, none of these impending innovations can grow and disseminate without understanding data. Gaining an understanding about health data and their use by clinicians is critical to promote the key structural aspects necessary to improve health care delivery, including interoperability, data standards, quality measures, and reimbursement for health outcomes. When we started in health care, the understanding of the impact of health data did not truly and widely exist. In our experience, we find that many clinicians are unconsciously incompetent—lacking a basic understanding of how health data are used, what health data consist of, and where data flow [6]. Unconscious incompetence occurs when the decision makers lack the true information and expertise needed to make an informed decision [6]. This lack of competence causes uninformed decision-making in the health care ecosystem, which causes more challenge. Technology and data become a burden and not a solution.

In health care, a health data–informed workforce is needed to remedy the gaps and make the important connections for positive change. In our experiences and those of our peers, we interact with clinicians who learned about informatics and health data on the job [1]. Many stories start with an interest in data and technology or some savviness with technology. These are individuals willing to lean into innovation and learn through failure. Yet, their learning curve is steep and lacks the efficiency

that a health data-informed workforce could address. The understanding of health data has become a shared team value critical to growing and expanding the evidence to support interprofessional practice. Now is the time to move beyond the early adopters and explore how we can expand the health data-informed workforce. We acknowledge previous authors that have called for this momentum to grow and call for ongoing and widespread engagement. In this viewpoint, we attempt to define the health data-informed workforce at the micro-, meso-, and macrolevels. We then offer suggestions for clinicians wanting to level up their competence in health data.

What Is a Health Data-Informed Workforce?

A health data-informed workforce includes clinicians with a basic understanding of data along with their exchange and influence on decision-making. The ideal would be to move clinicians from being unconsciously incompetent to consciously competent. However, the amount of knowledge expected is overwhelming. The complexity of health data has evolved into the field of health informatics. Multiple studies have indicated that the field of health informatics is diverse, with a wide variety of education and workplace requirements [1,7,8]. Health informatics is a field that explores the use of health data for “scientific inquiry, problem-solving, decision making” with the intent to improve health care delivery and impact [9]. Yet, health data impact every level of health care, from the micro- to macrolevel, calling upon all clinicians to hold a basic understanding.

For the purposes of this viewpoint, we consider the microlevel to be interactions with patients and clinicians; the mesolevel focuses on the infrastructure and systems in place for health data sharing; and the macrolevel addresses the impact of policy on health data. Clinicians who are data informed at each of these levels will improve the impact of health data utility and ensure that decisions made around health data and technology will facilitate positive change.

At the clinician and patient level (ie, the microlevel), data are used to make clinical decisions. The widespread adoption of EHR systems supported by the 21st Century Cures Act and provisions against information blocking in the Office of the National Coordinator of Health Information Technology’s Final Rule place a premium on data, and data literacy, in health care delivery [10]. The availability of data and the ability for patients to access their health data through patient portals and other digital applications can advance shared decision-making, promoting improved health outcomes while empowering patient’s involvement in their care. Yet, EHRs have introduced burden, and many clinicians are under information overload, which can result in health care errors [9,11]. A recent piece in the *Journal of the American Medical Association* titled “Death by Patient Portal” illustrates the love-hate relationship that occurs with much of health technology and data [12]. Data are flowing and being shared, but questions remain on how much and how to make information usable for patients and clinicians. Despite these challenges, data and technology are reported to only continue to grow in health care. This calls on clinicians to

know how to access patient data in their EHRs, understand where patients track and record data, and feel comfortable translating health information to multiple levels of digital and health literacy. A health data-informed clinician knows to use tools such as health information exchanges (HIEs) to ensure that they are making clinical decisions with comprehensive patient data beyond the EHR [13]. An HIE extracts data from multiple EHRs and matches that data into a comprehensive patient record. In some health care organizations, HIEs are integrated into the EHR. They can provide quick and comprehensive patient data for clinical decision-making [14]. Due to HIEs, health care becomes more proactive and less reactive when clinicians are aware of a recent emergency department visit, for example. At the same time, HIEs can lead to information overload for providers. In addition, clinicians improve their patient experience when they have information about the patient journey and history, which an HIE can provide [15]. Patients also report a better patient experience when they are not forced to “repeat their story” or re-enter information they have already reported.

Many health care organizations use data for various reasons, including use by health care delivery systems, payers, and academic researchers. When it comes to the mesolevel, the health data-informed workforce needs to understand data governance, including understanding how, why, and when data are shared and recognizing the importance of privacy and security. Patient consent remains important to ensure patients know when and where their data are being shared and how they are being used. In addition, health technology selection and vetting, along with vendor management, is critical. Vendors can offer solutions, yet at the same time, these tools can have unintended consequences from data being entered into multiple systems, causing burden on clinicians and a lack of data completeness in a patient’s record. Clinicians need to recognize the importance of interoperability as it impacts data access and use between systems. Interoperability refers to the ability to exchange data in a useful manner. An interoperable approach reduces double documentation and siloed health data [16]. At the same time, health data have extensive protections under the Health Insurance Portability and Accountability Act (HIPAA), which requires thoughtfulness to the exchange and use of data across systems. We have witnessed too many clinicians enamored with a piece of technology without vetting its ability to further health care. Great technology that further siloes data into multiple systems and lacks expanded adoption can cause more burden and potential patient harm. We need a workforce that questions the benefits and challenges how additional technology and data can actually improve health care delivery along with their interoperability.

Health data-informed clinicians also recognize the importance and value of data standards [17]. Data standards provide a critical foundation for data exchange. Decisions are being made daily in health care organizations without the recognition or use of data standards. One example is choosing to create a health-related social need screener without considerations of existing tools or data standards work, such as that led by the Gravity Project [18]. These approaches further denigrate the system and cause a myriad of challenges to interoperability.

For the macrolevel, understanding and advocating for local and federal policies that support the proliferation of growing workforce expertise is critical for the health data-informed clinician. Clinicians need a basic recognition and understanding of how policy drives health data utility [19]. The gaps in the workforce around health informatics have been identified and acknowledged [7,20,21]. Efforts in this area have been made by the American Medical Informatics Association's 10×10 program and the federal funding to support the Public Health Informatics and Technology Workforce Program by the Office of National Coordinator of Health Information Technology. These policies and investments provide opportunities to support both current professionals and those entering the workforce, representing examples of the impact of policy on health data.

How Do Clinicians Level Up?

Overview

If this sparks something inside you, the next step is to be curious about how to develop into a health data-informed clinician. All clinicians should be on a journey as lifelong learners. Health and health care constantly change, not to mention technology and data use. Becoming more data informed does not mean getting a new degree, even though that is an option. In this next section, we share some basic aspects for those desiring to become a health data-informed clinician. Certainly, we cannot go into extensive depth, but we hope this plants seeds to grow the health data-informed workforce. Some strategies to level up are as follows.

Get to Know a Health Informaticist

No one can or is expected to know everything, which is why health care is a team sport. One strategy to help build a health data-informed workforce is for clinicians to learn the role of health informaticists. Health informatics “is the interprofessional field that studies and pursues the effective uses of biomedical data, information, and knowledge for scientific inquiry, problem-solving, decision making, motivated by efforts to improve human health” [9]. In other words, health informatics is a wide field focused on health data and their utility to impact health care outcomes. Health informaticists hold expertise in data management, security, privacy, and governance requirements to support safe handling of protected health information [1]. They are also challenged to ensure that health data are interpreted and presented meaningfully to stakeholders, including clinicians; health care leaders; and most importantly, patients [22]. Health informaticists go by different names in different organizations, including clinical informaticist, data analyst, business analyst, etc [23,24]. Their roles and demands

may vary based on where they work. However, many organizations have informatics expertise in their organization. The next step would be to include an informaticist as part of the team. They can be invaluable in selecting health technology, vendor management, training and implementation, and project implementation, not to mention data handling! They offer a wide variety of skills to a team interacting with health technology and data, including data extraction, quality metrics, data analysis, dashboard builds, etc [1].

Use an HIE

HIEs are state-based or regional infrastructures that match data across multiple EHRs to provide a comprehensive patient record [25]. The sophistication of HIEs vary, yet they are a tool available to clinicians in multiple health systems that often go underutilized. In some cases, HIEs can be queried for information on the patient. They can also be used to send and receive information on a patient to allow for more comprehensive decision-making [14,15]. Clinicians can find out if their health care organization is part of their local HIE to gain access and training on how to use an HIE to improve clinical decision-making.

Recognize the Importance of Data Standards

Clinicians have an important role in entering health data, which impacts the ability to analyze data from health data utilities. Recognizing the importance of the use of appropriate data standards is important for clinicians. In the informatics field, you often hear the term “garbage in, garbage out,” and much effort has been made to extract and clean data to show the impact of quality payment programs, which have induced new health care system burden. Clinicians can work with their informatics team to ensure documentation is structured in a meaningful way. The United States Core Data for Interoperability offers guidance around common ways to document that can promote data sharing [26].

Get Some Training

There is a variety of professional organizations that can support the learning and growing of professionals targeted at clinicians. These organizations offer conferences, web-based trainings, and certifications. Some federal resources also exist, including the Office of the National Coordinator for Health Information Technology, who offers webinars and other valuable resources. Table 1 calls out some of these resources. Each organization offers a variety of training opportunities. Another option is to seek a mentor in health informatics, partnering with someone with experience to learn from.

Table 1. Organizations and resources.

Resource	Website
American Health Information Management Association (AHIMA)	[27]
American Medical Informatics Association (AMIA)	[28]
Civitas Networks for Health	[29]
Healthcare Information and Management Systems Society (HIMSS)	[30]
Office of the National Coordinator for Health Information Technology	[31]

For some, upskilling may be entering the field of health informatics. Academic programs exist in health information management and health informatics across the country. Many professional organizations offer discipline-tailored programming in health informatics specifically in medicine and nursing. Many programs offer web-based options and teach core skills.

It is normal to feel intimidated by the terminology and concepts. However, it is important to remember that health data are being used to drive lots of decisions. Garnering a basic understanding will improve clinical skills and help with patient advocacy to improve care delivery. Everyone can take some simple steps to become more health data informed.

What Can Educators Do?

Overview

It is impossible to know everything about the field of informatics and health data. Instead, the intent should not be about teaching all the skills but instead the critical thinking skills necessary to consider how and why technology and data can be used in health care. As a society, we need to cultivate minds that can think and problem solve for a future we do not yet exist in. As educators, we need to encourage the ability to embrace ambiguity and innovation while recognizing that human beings approach these elements in different ways that can cultivate adoption at different rates of speed. Educating a health data-informed workforce requires educators to recognize that technical and technology skills are important but not enough. The focus should include the following.

Promotion of Data Literacy

Basic data literacy involves understanding how data can be used to effect positive change in patient outcomes, cost reduction, and mitigation of caregiver burnout, among other applications. Data literacy is the ability to read and understand data. For those advanced in this area, data literacy includes communicating and sharing data in ways appropriate to the audience. Health data literacy in an informed health care workforce includes training on effective data management throughout the health data life cycle and how to traverse the knowledge discovery process, from data to information to knowledge and, ultimately, wisdom and actionable insights. The Data, Information, Knowledge and Wisdom Model provides a theoretical framework that spans from reviewing data to applying data in impactful ways [32]. A significant amount of health data is collected, and deciding what to do with it requires a deeper understanding. Educators should push learners to move beyond reviewing data to deeply engaging with them in meaningful ways to improve health care.

Ethical Use of Health Data

Data, especially health data, require a high level of care and stewardship. Educators need to focus on the ethics of data use; data governance, including privacy and security along with appropriate data-sharing strategies; and the importance of recognizing data literacy for key stakeholders, including patients,

policy makers, payers, clinicians, and health care executives. Data brokering and its impact on health care continue to evolve.

The infusion of artificial intelligence will continue to generate new ethical questions, opportunities, and concerns [33]. In addition, gaps in data and new data areas such as social determinants and drivers of health offer new and interesting challenges to consider [18]. Furthermore, innovation should always be grounded in asking the “what if” questions to ensure that ethical considerations are always an aspect of data use.

Focus on Data Utility

Health data are being collected at a momentous rate. Educators must focus on preparing a health data-informed workforce to recognize the utility of data for the audience. This must also be considered in implementing health information technology mechanisms focused on user experience and human-centered design to ensure that health data are used thoughtfully and ethically. Data standards are also critical to utility, such as the United States Core Data for Interoperability [26]. We have witnessed many implementations without the consideration of data standards, causing barriers to interoperability that can produce harm in patient care. We can name multiple examples where technology is purchased without even considering how systems will share or integrate data, causing myriad other challenges in health care.

Recognize the Impact of the System

Health care is a large system within systems. Health technology and data are driven by systems, whether they be legal, policy, or reimbursement. Implementing data and technology without a strong understanding of the mechanisms and systems thinking is problematic. A health data-informed workforce recognizes the many layered systems impacting health information technology and data use implementation. Ensuring that the workforce engages in systems thinking and searching for “the why” in implementation and data use is a critical skill. In addition, clinicians should not feel disempowered and instead recognize the role they can play at the microlevel in patient interactions to improve the use of health data for improved outcomes.

Conclusion

Our hope is to promote a conversation and spark innovation around the need to expand and grow the health data-informed workforce. We certainly cannot provide every piece of advice or suggestion here. Yet, we hope to spark a revolution to grow the cadre of passionate advocates for the proliferation of health data and technology in ways that truly support equity, reduce burden, and improve health care delivery. Additionally, we are not saying that data skills are not critical—they are. We recognize that we need more than that. We need a workforce that asks questions about where data go and how they are used and that becomes more informed on the data tools of their patients. We need a health data-informed workforce now and into the future.

Acknowledgments

The project described is supported by the National Institute of General Medical Sciences (U54 GM115458), which funds the Great Plains IDeA-CTR (Institutional Development Award–Clinical & Translational Research) Network. Abstract

The continued demand for digital health requires that providers adapt thought processes to enable sound clinical decision-making in digital settings. Providers report that lack of training is a barrier to providing digital health care. Physical examination techniques and hands-on interventions must be adjusted in safe, reliable, and feasible ways to provide digital care, and decision-making may be impacted by modifications made to these techniques. We have proposed a framework to determine whether a procedure can be modified to obtain a comparable result in a digital environment or whether a referral to in-person care is required. The decision-making framework was developed using program outcomes of a digital physical therapy platform and aims to alleviate barriers to delivering digital care that providers may experience. This paper describes the unique considerations a provider must make when collecting background information, selecting and executing procedures, assessing results, and determining whether they can proceed with clinical care in digital settings.

clinical decision-making; digital health; telehealth; telerehab; framework; digital medicine; cognitive process; telemedicine; clinical training

Introduction

Background

Digital health is revolutionizing health care, and the COVID-19 pandemic has led to rapid acceleration of the use of digital health technologies, particularly the adoption of telehealth. Digital health, including the use of telehealth or telemedicine, allows health care practitioners to provide services without being in the same physical location as the patient. Telehealth can include synchronous or asynchronous messaging with providers, video calls, audio-only calls, and the secure transmission of information over the internet between patients and their providers [1]. Digital health can also include information gathered by medical devices, wearable sensors, apps, or other software [2]. The application of technology in health care has a vast potential to increase access to care and improve quality.

Research indicates that telehealth outcomes are equivalent to in-person care in rehabilitation [3-5] and can be an effective intervention for addressing pain and function limitations in a variety of musculoskeletal conditions [6]. Clinical outcomes from telehealth episodes of care are comparable with in-person rehabilitation for conditions such as osteoarthritis, low-back pain, hip and knee replacement, multiple sclerosis, and cardiac and pulmonary rehabilitation [3]. Increasing evidence supports that telehealth physical therapy delivered by a mobile app provides clinical outcomes comparable with those of in-person

care [3,4,7]. Research also reveals that telehealth decreases travel time and costs [8]. It is well documented that patients recognize the benefits of telehealth as well, demonstrating high engagement [9-11] and high levels of satisfaction across multiple metrics, including quality of care, convenient access to multiple specialists, improved care and coordination with digital care, and outcomes similar to in-person care [12-17].

Despite evidence of the benefits of telehealth, there are barriers to the integration of telehealth into traditional health care models. For example, physical therapists (PTs) report apprehension toward utilizing telehealth in their practice, reporting insufficient preparation and inadequate knowledge about how to implement telehealth visits, influencing providers' acceptance, preferences, and outcomes [12,18,19]. Further, less than half (42%) of health care providers surveyed believed telehealth was as effective as face-to-face care, and 21% reported insufficient training [18,19]. Another significant barrier to digital health adoption is the belief that lack of physical contact hampers accurate diagnosis and management [12,18,19]. Successful integration of telehealth into traditional health care models will only be achieved through addressing provider beliefs about the efficacy of telehealth and instruction in providing equivalent care through a new model.

Telehealth requires the translation of traditional clinical skills to a new medium [20,21]. Remote patient care is characterized by dynamic patient environments, unique safety concerns, and

a lack of traditional patient care tools, forcing the provider to act in new and dynamic ways to provide effective care. When encountering new clinical scenarios, many providers look for guidance through decision-making frameworks. Frameworks outline a structured and systematic approach to problem-solving that incorporates evidence and specific context, and promotes informed decisions [22]. When used in health care, decision-making frameworks can ensure consistency, reduce bias, and enhance the quality of decisions and quality of care [22-24]. A standardized process assists health care professionals in assessing risks and benefits, improves outcomes, and provides patient-centered evidence-based care [24].

Delivering effective care in a digital health setting requires that health care providers adapt their thought processes to account for the nuance of the interactions between technology and the patient to enable sound clinical decision-making in the digital health setting. This paper introduces a decision-making framework to determine whether a clinical procedure is feasible in a telehealth setting with similar quality, accuracy, and reliability as in-person encounters, or when the use of an equivalent but alternative procedure is most appropriate. We propose that utilizing a clinical decision-making framework can alleviate clinicians' concerns about the efficacy of digital health and assist the implementation of clinical best practices in a digital setting. The purpose of this paper is threefold: (1) to propose a decision-making framework to train and inform health care providers that increases provider efficacy with the translation of skills to this new medium; (2) to propose a thought model that allows quantitative testing through implementation research; and (3) to realize the potential for telehealth for patients and providers to improve access to care independent of geography.

Development of the Framework

This framework was the result of a review of the current literature and the authors' combined expertise in providing telehealth physical therapy. The authors have a combined 18 years of experience in telehealth, including providing patient care, designing and implementing training for providers, as well as managing a nationwide network of telehealth PTs. This framework has been applied to clinical practice and refined based on the outcomes of over 10,000 patient cases.

Analysis of program outcomes and the identification of PT behaviors that lead to positive clinical outcomes influenced the development of this framework. Program data confirmed that provider behavior during telehealth episodes directly impacts clinical outcomes in an app-based telehealth physical therapy program [4] and that when interventions provide high value, patients will be highly engaged [11] resulting in cost savings [25]. Prior literature describes how to translate specific evidence-based evaluation techniques for the application of telehealth and how to utilize established clinical practice

guidelines for telehealth episodes [26-32]. However, procedure-specific training cannot prepare providers for the dynamic nature of telehealth encounters that include variations in the patient's environment, health status, caregiver support, digital literacy, equipment availability, and other factors. In response to the ever-changing context of telehealth visits and to fully equip health care providers working in a digital environment, a decision-making framework was developed. This framework was designed to help providers identify the relevant factors in the clinical picture, assess possible actions, and make decisions that lead to positive clinical outcomes. The process of defining this framework was iterative, data-driven, and emphasized patient-centered design. We incorporated an understanding of the users on our platform, the tasks they completed, and the digital environment; development was driven and refined by patient surveys, feedback, and outcomes. We believe this framework will assist clinicians in translating their clinical skills to digital practice to enable optimal clinical outcomes, convenience, and satisfaction. Initially, learning to leverage the steps of the framework may increase time in decision-making but as the clinician becomes experienced the process will become efficient and give more options for the telehealth environment.

Utilizing the Framework

Appropriate application of a decision-making framework in a clinical setting requires that certain conditions are met. First, the clinical problem must be within the scope of the clinician's practice. This ensures the clinician is appropriately trained and licensed to provide care and make clinical decisions. In the case of digital health, appropriate training includes proficiency with digital tools, technology, and website manner in addition to medical or clinical training [33,34]. Second, the patient must be appropriate for digital care. Appropriateness for care requires that the patient's cognition level, medical status, digital literacy, communication abilities, technology access, physical environment, and preference all support safe digital care interactions. Finally, providers must consider the security and regulatory implications of digital care, including ensuring compliance with HIPAA (Health Insurance Portability and Accountability Act), local and federal privacy regulations, and data security requirements. If the provider, patient, and technology all meet these conditions, the application of this framework is appropriate.

At each step of the process, the provider must determine whether telehealth is the most appropriate method of providing care. When a provider determines that telehealth is not appropriate for the patient, they should inform the patient of the next steps, which may include activation of emergency services, coordination of care to facilitate referral to a specialist, in-person visit, or obtaining labs or imaging. Figure 1 provides a visual representation of the steps included in this decision making framework.

Figure 1. The decision-making path. At every step of the patient encounter, providers must determine whether telehealth is the best option for the clinical scenario. The determination process should be the same whether the provider is using a traditional procedure or a procedure that has been modified for the patient's environment. At each step, the provider must determine whether they can continue down the decision-making path, or if they need to return to the start of the decision-making process using an alternative procedure. If no acceptable digital option exists at any step, they must refer to in-person care.

Description of the Decision-Making Framework

Step 1: Collect Background Information

Clinicians may collect relevant clinical information using data from chart review and review of a digital intake form. The subjective interview of a telehealth visit should proceed as it does in an in-person visit, with emphasis on the chief complaint, relevant health history, current and past medical conditions, and social history. The subjective portion of the examination may

also include a visual assessment of the patient's environment, inquiry about equipment availability, and availability of caregiver support, which are factors unique to telehealth but enhance the clinical picture. If at the conclusion of the subjective interview, the provider has identified an urgent medical need, or that telehealth is not appropriate then the patient may be referred to in-person care at this time. If the provider is confident that they have collected the information needed to inform the objective examination and that it is safe and appropriate to continue with a telehealth objective examination, they will move to the next step.

Step 2: Select an Examination Procedure

Providers will select the examination procedures based on the information gathered in the subjective examination. Procedures should be evidence-based and relevant to the differential diagnosis process. Once a procedure has been selected, the provider must consider the feasibility, reliability, and validity of the procedure when performed in a digital setting.

To evaluate feasibility, we consider whether the patient has the resources, space, ability, and knowledge necessary to complete the procedure safely. The provider will consider information gathered in the subjective portion regarding the patient's cognitive status, physical ability, social support, environment and technological resources, and time available to determine if the procedure can be accurately performed. If the setup for a test is complicated or the instructions are lengthy, the time constraints of a patient visit may make a test not feasible.

Reliability is the quality of a measure that produces reproducible scores on repeat administrations of a test. Reliability is thus a prerequisite for test validity [35]. Validity is the measure of how accurately a test measures the underlying trait of interest [35,36]. When assessing patients in-person, reliability is supported by a clinical environment standardized for all sessions. In digital health settings, tests are performed in the patient's environment and providers must look for alternative ways to ensure results are reliable and valid. If a traditional procedure cannot be performed with acceptable feasibility and reliability, then providers should consider if an alternative procedure can provide the same clinical information. Alternative methods will be unique to the patient's resources, abilities, and environment, but alternatives should be assessed for feasibility and reliability. Functional testing is often an acceptable alternative for traditional tests when the equipment or environment is standardized.

The reliability of functional tests can be increased if the same equipment in the home is used for subsequent testing. For example, a 30-second sit-to-stand test [37] using the same chair in the patient's home will give a clinician reliable data for each assessment. Further, measurements such as joint range of motion, can be tracked by having the patient reach to low, medium, or high shelves in their home and reassessed using the same shelves. This technique allows the provider to monitor and document progress in an easily accessible, functional and standardized way within the patient's environment.

Selecting a procedure means that the provider will make dynamic decisions unique to the patient they are seeing. For example, during an in-person visit, manual muscle testing of internal rotation of the shoulder is often used to indicate subscapularis muscle rupture or dysfunction. In digital settings, the provider cannot provide manual resistance, but the same information can be obtained using the Gerber test [38]. If the patient is unable to achieve the testing position for a Gerber test, a provider could consider functional strength testing such as lifting canned goods. In this scenario, the provider will ensure reliability by using the same number of cans at each assessment. To ensure validity, the provider must ensure that the patient is performing the test correctly; in this example, a patient lifting the canned goods with a straight arm would provide an invalid

result but lifting with a bent elbow would appropriately stress the biceps and give a valid result.

If there is no procedure that can be performed that is feasible and reliable in the digital setting, and this information is required for clinical decision-making, then a referral to in-person care would be indicated. For example, if a clinician suspects rupture of the anterior cruciate ligament and determines that a Lachman test is necessary, but is not feasible via telehealth, then a referral for in-person assessment is required.

Step 3: Execute the Clinical Procedure

Performing the clinical procedures in digital settings requires different skills than in in-person settings. Digital settings require the provider to assist the patient in managing their environment and any relevant equipment needed during the visit. Therefore, it is incumbent on the provider to communicate with the patient explicitly about the procedure prior to execution and ensure they have the relevant equipment and can use it appropriately.

The provider should communicate what equipment is needed (eg, a sturdy chair with arms). Providers should give clear directions to the patient on how to set up any equipment and where the patient should be positioned. Additionally, the provider must describe how to utilize technology during the procedure. Appropriate audio, video, and lighting setup ensures the provider can see and hear the patient adequately while they perform the tasks. The provider should review each step of the procedure with the patient prior to performing it and allow the patient to ask questions or clarify instructions. The patient should have a good understanding of what information the procedure is gathering so that the patient can monitor and report the appropriate variable during the procedure. For example, during a balance assessment, the patient should understand if they are balancing for as long as they can without toe touches, or if they should count the number of toe touches within the given time frame. The provider should document the method used for the procedure, equipment, setup, and outcome to ensure subsequent tests can be performed in a standard way. If the patient is unable to perform the procedure as directed by the provider, then the provider should consider alternative procedures or referral to in-person care.

Step 4: Assess Results

Once the procedure has been performed, the provider determines whether the result answers the original clinical question and their confidence level in the result. Confidence will be affected by how accurately the patient was able to follow the provider's instructions, and if technology worked as expected. If the patient performed the test incorrectly or if there was video or audio lag or poor clarity available, the provider may have low confidence in the result. A procedure that was performed as instructed in an environment that was reliably standardized using the same equipment and set up with technology that worked without disruption will provide high confidence.

Step 5: Proceed With Clinical Care, Repeat, or Refer

High confidence in the outcome allows the provider to continue care in the digital setting. If the provider has low confidence in the result, they can repeat steps 1 through 4 again using an

alternative procedure to achieve a result that provides high confidence. If the provider is seeking information that is essential to the care of the patient and no procedure can be performed in a manner that provides a result that is reliable,

reproducible, and yields high confidence, then a referral to in-person care is needed. [Table 1](#) provides a list of the factors that should be considered when making clinical decisions in digital settings.

Table 1. The relevant factors the provider should consider as they progress through the decision-making process. At each stage, the provider must determine whether telehealth is appropriate for this clinical scenario.

Factors	Key points
Collect background information	<ul style="list-style-type: none"> Subjective history may include chief complaint and health history as well as: <ul style="list-style-type: none"> Cognition level Digital literacy Communication abilities Technology access Features of physical environment Patient preference for digital health tools If each criterion is not met, then the patient must be referred to in-person care
Select procedures	<ul style="list-style-type: none"> Traditional procedures, digital alternatives, or functional tests may be used if they are: <ul style="list-style-type: none"> Necessary for clinical reasoning Evidence-based Feasible Reliable If no procedure meets these criteria, then the patient must be referred to in-person care
Execute procedures	<ul style="list-style-type: none"> Instruct the patient about: <ul style="list-style-type: none"> Equipment required Technology settings Environment set up Performance of the procedure Outcome reporting If execution of the procedure is impeded by any of these factors, the provider will consider alternative procedures or refer to in-person care

Clinical Application

Overview

The application of this decision-making framework can be illustrated through clinical examples. This example provides descriptions of how procedures can be modified but provides

high-value clinical information when feasibility, reliability, and reproducibility are considered. Assessment of confidence allows providers to determine the value of the result prior to proceeding with clinical care or referring to in-person care. [Figure 2](#) provides a visual representation of the decision-making process used in the patient scenario.

Figure 2. Description of clinical application of proposed decision-making framework using the timed up and go test and modified test. The provider proceeded through the first process but had low confidence in performance. They then repeated the decision-making process with modifications made to the test environment and procedure. The modified test produced a high-confidence result and allowed clinical care to proceed.

Patient Scenario

Consider a hypothetical case of a 79-year-old woman living in a rural community who scheduled a telehealth visit with her primary care provider (PCP) to discuss concerns regarding mobility. Mobility assessment is within the scope of the provider in this example, who has the appropriate training and expertise to perform telehealth visits. The visit will take place on the platform provided by the health system and meet applicable HIPAA and data security requirements. The provider has access to the patient's medical history as a part of the software platform.

Step 1: Collect Background Information

The patient's chief complaint is frequent stumbling, often the result of catching her toe while walking, which has resulted in loss of balance, frequently holding onto furniture or walls while walking, and avoiding walking in the community due to fear of falling. She reports no falls to the ground and no other health status changes but is concerned that her balance will continue to decline. The provider assesses the patient's cognitive status, communication ability, and preference for digital health during the subjective assessment. As part of the telehealth visit, the provider completes red flag screening and review of systems and finds no neurological deficits, no indication of cardiac

impairment, and no history to suggest that the mobility concerns are the result of sinister pathology. Her PCP would like to quantify the mobility impairments in a standardized way during the telehealth visit and the patient agrees to this. The patient reports that her husband is available during the telehealth visit to assist if needed. As the patient has no current history of falls, health history is clear, and the patient has a caregiver present, the PCP feels confident that they can complete a mobility assessment safely via telehealth.

Step 2: Select Procedure

The PCP chooses the Timed Up and Go (TUG) test [39] as it is evidenced-based and recommended by the Center for Disease Control STEADI protocol [40]. TUG is a timed mobility test in which patients rise from a standard chair, walk to a line on the floor 10 feet away, turn, return to the chair, and sit. Patients are instructed to wear their regular footwear and can use a walking aid during the test if needed.

The PCP assesses feasibility by asking if the patient has access to the equipment needed: a sturdy chair such as a dining chair, stopwatch, tape measure, and tape. The PCP describes the test to the patient and husband and asks if they feel able to achieve the setup and execute the test. The PCP will be able to gather qualitative information about gait during the test by having the patient face their device's camera toward the test area. The outcome of the TUG is time-based, which the PCP determines to be reliable through digital means. The PCP decides that the caregiver will manage the stopwatch to mitigate any lag in the internet connection during the test. Using a tape measure to define distance and using the same chair in the same location will ensure that the test setup is reproducible for subsequent testing. The provider educates the patient's caregiver on the start or stop timing procedure of the TUG, further ensuring reliability. The PCP will assess qualitative mobility by visually assessing movement during the test using the camera of the mobile device. The PCP determines that the TUG is feasible and reliable in a digital setting and provides the clinical information required to make clinical decisions about treatments for this patient, so no alternative is necessary.

Step 3: Execute Procedure

The PCP instructs the patient's husband to gather a sturdy chair and stopwatch, measure 10 feet on the floor, and mark it with a line of tape. The provider instructs the patient and caregiver to arrange the camera of their mobile device in a manner that allows the PCP to observe the test. The caregiver is instructed on starting or stopping the stopwatch. The patient is instructed on the test procedure according to the standard TUG instructions. The caregiver is instructed to report the time to completion of the procedure to the PCP. The provider answers clarifying questions for the patient and caregiver, and they perform the test. During the test the provider can hear that the caregiver fumbles with the stopwatch, and the patient leaves the video frame.

Step 4: Assess Results

While the environment setup was standardized supporting reliability, the caregiver reported difficulty with starting or stopping the timer, impacting the accuracy of the timed result.

The patient left the visual frame during the test, impacting the ability to assess qualitative aspects of gait such as stopping and changing directions. The provider determines they have low confidence in the result and is unable to determine if the patient exceeded the recommended time of <12 seconds for test completion, or if there are mobility deficits that prompt recommendations for assistive device use.

Step 5: Proceed With Clinical Care, Repeat or Refer

The provider has low confidence in the result of the test and does not feel they can proceed with clinical care based on the results. The need for mobility assessment remains, and the provider feels that modifications of the testing scenario may allow them to gain the clinical information they need, so a referral to in-person care is not necessary. The home environment had only one area where a 10-foot space was available to complete the TUG, however, the family was unable to position the camera in a manner that allowed the whole area to be seen by the provider. Additionally, the caregiver had difficulty starting and stopping the timer, decreasing the accuracy of the result. The provider determines that the variables measured by the TUG test appropriately provide the clinical information they need, but he will need to utilize an alternative testing method to enable him to address the limitations. He will repeat decision-making steps using a digital alternative to gain the information he needs from the mobility assessment.

Background information remains the same, so the provider can proceed to select an alternative procedure. They decide to address the limitations of the first attempt by choosing a new testing location where they can standardize the test using landmarks in the patient's home. The caregiver is instructed to position the front legs of the chair even with a door frame and will have the patient walk to the end of the hallway, touch the wall, and return to the chair. The distance walked is less than the 10 feet required of the TUG, but the patient is visible to the provider the whole distance. Additionally, the provider will give audio cues to start and stop the test while he manages the timer remotely. The provider and patient determine together that this setup is feasible and easily reproducible for subsequent testing. The modifications will allow the provider to assess movement quality as well as ensure timed results are accurate, which addresses the limitations of the prior test.

Execution of the modified procedure requires instruction regarding chair location and placement of the mobile device so the camera captures the whole testing area. The patient is instructed on how to perform the modified test procedure. The performance of the modified test proceeds without audio or video lag or distortion. After the second test provider feels confident that the timed result was successful. The provider was able to assess the quality of mobility throughout the whole test. Because the provider has high confidence in the clinical information they obtained through the alternative test, they can proceed with clinical care. The provider determines that the patient would benefit from using a single-point cane to improve balance with changing directions when walking. The PCP also prescribes physical therapy to address balance, gait, and lower extremity strength. The patient will schedule a follow-up telehealth visit with the PCP in 4 weeks and they will repeat

the modified mobility test at that time using the same setup to assess the effect of these interventions.

Discussion

Principal Findings

Providing a decision-making framework for clinicians to utilize in digital care can alleviate clinicians' concerns about implementing digital care in their practice. To our knowledge, a framework that assists providers in translating in-person clinical skills to digital care does not exist. This framework enables clinicians to practice effectively in the most accessible environment for the patient while prioritizing evidence-based practice, assessing risks, and providing patient-centered care. As digital care is increasingly desired by patients [19,23,41,42], it is imperative that providers are confident in decision-making in digital settings so telehealth remains safe, efficient, and equivalent to in-person care.

The value of a clinical procedure is reliant upon the feasibility, reliability, and clinician confidence, as well as the interaction of those variables with digital technology. A procedure that is feasible, reliable, and reproducible, but is performed poorly and provides low confidence has less value in clinical decision-making than an alternative digital procedure that deviates from standard performance but instills high confidence in clinical decision-making. This improves patient safety by determining whether a patient can remain in a digital care environment or should be referred to in-person care. Additionally, the framework encourages clinicians to use evidence-based practice guidelines as the basis for care, modifying procedures in a feasible and reliable manner to improve outcomes. This will ensure consistency, reduce bias, and enhance the quality of decisions in digital care [22-24]. The application example demonstrated that modifications made based on the patient's environment and technology limitations enabled the provider to proceed with digital care in a manner consistent with clinical best practices and supported the provision of safe, effective, and quality care.

Time is a valuable resource in medical care, and providers must be confident in decisions made during clinical encounters. In situations where decisions must be made quickly, utilizing a framework can assist with decision-making efficiency [22-24]. Novice clinicians or providers who are transitioning to digital care may benefit from a framework to help them determine the best course of action in a timely manner. With increased provider experience and repetition, the decision-making process will be more efficient and timelier. For example, experienced telehealth clinicians become proficient in scanning the patient environment, determining feasibility based on available resources, as well as becoming efficient at modifying traditional procedures based on the patient's environment, and instructing patients on camera setup and how to utilize technology efficiently. In scenarios like the clinical application described above, an experienced provider may identify potential barriers prior to execution and decide to utilize a modified procedure from the start to save time.

This framework builds on the existing literature that shows similar diagnostic accuracy between in-person and digital examination techniques [26,29-31]. Lack of physical contact when working through telehealth was perceived to hamper accurate and effective diagnosis and management [18]. However, many commonly performed physical examination techniques have poor sensitivity and interrater reliability. This is evident in the poor interrater reliability scores of techniques such as palpation of lumbar structures [43] and assessment of breath sounds [44]. Decision-making tools that enable providers to evaluate alternative methods for gathering clinical information help to overcome these barriers and increase confidence that practitioners are providing effective, safe care. Additionally, adapting procedures allows patients the full benefit of telehealth, including convenience, cost-savings, better adherence, higher engagement, and improved access to care in rural or underserved areas [20].

Future Research

Avenues for further research should include randomized control trials comparing trained versus untrained providers to determine whether the utilization of this framework leads to improved clinical outcomes, provider self-efficacy, and patient satisfaction scores, and would provide insight to overcoming the barriers to digital health that providers may experience. Research is needed in implementation science to determine if training clinicians in using a framework will increase treatment fidelity. Similarly, this framework can be considered in future studies to provide further evidence of the efficacy of digital care and enable the full potential of telehealth for all stakeholders.

Further understanding of how providers make decisions to include digital tools in patient care is needed. Understanding provider confidence in modifying in-person techniques and clinical problem-solving in digital settings may improve providers' willingness to utilize digital care with their patients. Provider training about how to modify traditional procedures, evaluating the efficacy of modified procedures, and assessing confidence in results may increase provider self-efficacy in digital settings. Best practices and standardized education for health care providers on how to effectively use digital tools should be established.

Limitations

There are limitations of this framework as it is broad in scope and cannot address every situation. Independent tests should be performed to evaluate the usability of the framework and its effectiveness in improving guideline implementation. We recognize that no single framework can be used for all guidelines or contexts. Provider behavior will be influenced by environment, resources, technology, and other factors despite training in using a decision-making framework.

Conclusion

We created a framework for clinicians to determine whether a particular procedure can be performed feasibly in a digital health setting with the same quality, accuracy, and reliability as in a traditional setting. Utilizing a framework to assist in clinical decision-making is important to alleviate clinicians' concerns

about using digital tools and help guide the translation of the best available evidence from traditional care to digital care. The increased demand by patients for digital care requires a new set

of clinical skills, and this framework enables providers to comply with clinical best practices and offer high-quality care for patients who want to receive their care via telehealth.

Abstract

Santé Numérique Rouen-Nice (SaNuRN; “Digital Health Rouen-Nice” in English) is a 5-year project by the University of Rouen Normandy (URN) and Côte d’Azur University (CAU) consortium to optimize digital health education for medical and paramedical students, professionals, and administrators. The project includes a skills framework, training modules, and teaching resources. In 2027, SaNuRN is expected to train a significant portion of the 400,000 health and paramedical students at the French national level. Our purpose is to give a synopsis of the SaNuRN initiative, emphasizing its novel educational methods and how they will enhance the delivery of digital health education. Our goals include showcasing SaNuRN as a comprehensive program consisting of a proficiency framework, instructional modules, and educational materials and explaining how SaNuRN is implemented in the participating academic institutions. SaNuRN is aimed at educating and training health and paramedical students in digital health. The project is a cooperative effort between URN and CAU, covering 4 French departments. It is based on the *French National Referential on Digital Health (FNRDH)*, which defines the skills and competencies to be acquired and validated by every student in the health, paramedical, and social professions curricula. The SaNuRN team is currently adapting the existing URN and CAU syllabi to *FNRDH* and developing short-duration video capsules of 20-30 minutes to teach all the relevant material. The project aims to ensure that the largest student population earns the necessary skills, and it has developed a 2-tier system involving facilitators who will enable the efficient expansion of the project’s educational outreach and support the students in learning the needed material efficiently. With a focus on real-world scenarios and innovative teaching activities integrating telemedicine devices and virtual professionals, SaNuRN is committed to enabling continuous learning for health care professionals in clinical practice. The SaNuRN team introduced new ways of evaluating health care professionals by shifting from a knowledge-based to a competencies-based evaluation, aligning with the Miller teaching pyramid and using the Objective Structured Clinical Examination and Script Concordance Test in digital health education. Drawing on the expertise of URN, CAU, and their public health and digital research laboratories and partners, SaNuRN represents a platform for continuous innovation, including telemedicine training and living labs with virtual and interactive professional activities. SaNuRN provides a comprehensive, personalized, 30-hour training package for health and paramedical students, addressing all 70 *FNRDH* competencies. The project is enhanced using artificial intelligence and natural language processing to create virtual patients and professionals for digital health care simulation. SaNuRN teaching materials are open access. It collaborates with academic institutions worldwide to develop educational material on digital health in English and multilingual formats. SaNuRN offers a practical and persuasive training approach to meet the current digital health education requirements.

Introduction and Background

Digital health and health informatics are at the crossroads of medicine and health sciences, computer science and engineering, information and communication sciences, mathematics, statistics, technology, and innovation management [1]. Digital health has been a component of regular training in medical schools for 40 years [2-4] under different labels, such as medical informatics [5], medical computing (in the United States) [6], and e-health [7], with high heterogeneity in content at the national level. In France, digital health is a subdomain of public health, which is also part of the training in medical and paramedical schools [8].

In 2022, the French Ministry of Health, and in particular its Delegation of Digital Health, published an open call for project proposals to support innovative approaches to develop initial academic and continuing professional education in digital health to health-related students, professionals and administrators; law specialists; computer scientists; and data protection officers. "Health-related students and professionals" was mainly referring to students enrolled in health-related programs, including medicine; odontology; pharmacy; midwifery; and paramedical fields such as nursing, physiotherapy, speech therapy, and hearing-aid technician, as well as training programs for social workers [9]. A budget of €71 million (US \$75.73 million) has been secured to achieve this specific call to deal with the expected need to train over 400,000 health and paramedical professions students in 2027 at the national level.

The University of Rouen Normandy (URN) and the Côte d'Azur University (CAU), as a consortium, have successfully answered this call by getting a 5-year grant for their joint project, *Santé Numérique Rouen-Nice* (SaNuRN; "Digital Health Rouen-Nice" in English) [10]. SaNuRN began on September 1, 2022, with a cost estimate of €6,891,923 (US \$7,351,441) and a grant contribution of €3,951,200 (US \$4,214,646), with the goal of training around 30,000 students by 2027.

Before the initiation of this national project in France, there was a notable deficiency in digital health training for health students and practically none in paramedical schools. The primary focus was on health students pursuing master's degrees, such as medicine, pharmacy, dentistry, and midwifery. For instance, a national master's program in medical informatics has been established at Sorbonne University for the past 25 years. However, up until 2020, there was no existing digital health training curriculum for health students at the bachelor's degree level. Consequently, a comprehensive curriculum in digital health had to be developed from scratch for both health and paramedical students at the bachelor's degree level.

Before the SaNuRN project, a 10-hour module was introduced for all first-year medical students in CAU in 2020, and in URN, a 20-hour module was implemented for some first-year medical students in 2021. The open call from the Delegation of Digital Health at the French Ministry of Health emphasized allocating 80% of the training effort to the bachelor's degree level. One of the challenges of the SaNuRN project was assembling a team of digital health specialists to train all health-related students. The initial 2 years of the SaNuRN project (2022-2024) were

dedicated to implementing a digital health teaching module for all health-related students, including both health and paramedical programs, at the bachelor's degree level.

This paper aims to provide an overview of the SaNuRN project, highlighting its pedagogical innovations and how its implementation will optimize digital health education. Our objectives are to present SaNuRN as a whole, comprising a skills framework, training modules, and teaching resources, and to describe how SaNuRN is and will be deployed in the consortium institutions. Below, we describe the SaNuRN project and its objectives. Next, we detail the skills framework and training modules, explaining the teaching resources and how they are deployed. Finally, we discuss the pedagogical innovations and expected impact of the SaNuRN project on digital health education and the quality of care and patient outcomes.

Building a Digital Health Education Lifelong Platform (SaNuRN) as a Cooperation Achievement

Overview

The SaNuRN project emerged in the context of a long-lasting cooperation between URN and CAU in *digital health* (SJD and PS), *medical simulation* (Professors Louis Sibert and Jean-Paul Fournier), and *general practice* (Professors Matthieu Schuers and David Darmon), as a primary use case for teaching digital health during postgraduate studies and residency. From our perspective, this extensive cooperation was a decisive factor in the grant application's success. URN is located in the northwest of France and CAU is located in the southeast. The distance between them is around 1000 km, and this points out the challenges related to the SaNuRN consortium, which is well managed by using as much dematerialized infrastructure as possible to deliver digital health teaching and learning content. Thus, the first-stage objective of SaNuRN is to educate and train all students in health-related fields in digital health at 4 French departments (Seine-Maritime and Eure in Normandy for URN, and Alpes-Maritimes and Var in Provence-Alpes-Côte d'Azur for CAU), to cover a population of 4 million inhabitants; the target of SaNuRN is to train about 2800 health-related students each year.

Targeted Skills and Competencies

To support this effort, the SaNuRN team activities are based on the *French National Referential on Digital Health (FNRDH)* [11]. Created and published in 2021, this referential gives a framework and defines the skills and competencies to be acquired and validated by every student in the health, paramedical, and social professions curricula [8]. The exhaustive list of skills and competencies of the FNRDH is detailed in [Multimedia Appendix 1](#). The skills defined in the FNRDH are organized into five competency categories: (1) security, (2) health data, (3) communication in health, (4) digital tools in health, and (5) telehealth and teleactivities. FNRDH is built around a three-level hierarchy: (1) the 5 competencies as introduced above, (2) a total of 25 subcompetencies (eg, to identify an end user or a health professional and to characterize

and manage nominative data, applying the European rules such as the General Data Protection Regulation [GPDR]), and (3) a total of 70 different abilities (eg, to understand the life cycle of the digital health data and to take actions against virus and malware). In June 2023, *FNRDH* was integrated [12] into the HeTOP terminology server [13] to create a Catalog and Index of Health Digital Teaching Resources (CIDHR) [14-16] to be usable by all French health and paramedical students.

Adapting Existing Resources to the *FNRDH* Framework

Since the beginning of the project in October 2022, the primary need has consisted of adapting the existing URN and CAU syllabi to *FNRDH*. The SaNuRN project builds in a matrix format to adapt *FNRDH* for each degree (bachelor's, master's, doctorate, or residency) and each field of study (eg, medicine, nursing, or physiotherapy). Furthermore, the course focuses on digital health in each field of study and, at each degree level, is limited to 30 hours of lectures and practices to address the 70 competencies of the *FNRDH* skills framework. To manage this challenge, the SaNuRN team is developing short-duration video capsules of 20-30 minutes to teach all the relevant material adapted to the degree levels and fields of study by taking into account the expectations within each degree, discipline, and potential learning sites (URN, CAU, and their partners).

It is essential to notice that the pedagogical components of the SaNuRN project are derived from existing teaching resources previously developed by the 2 Departments of Digital Health at URN and CAU. For example, West Normandy has 7 nursing schools (partners of URN), and the SaNuRN project has adapted its training to each of them specifically.

Since the inception of the SaNuRN project, additional teaching modules have been introduced to address the list of *FNRDH*

skills and competencies. Among these modules, one is dedicated to cybersecurity and another to health data. This supplementary course emphasizes practical applications, featuring instructional videos on the use of specific tools aligned with the skills and competencies of the *FNRDH*. These tools include (1) a secure email tool, (2) guidance on accessing Mon Espace Santé—a digital platform designed for citizens and patients to manage their digital documents actively, (3) Health French National Identification, and (4) ethics in health (refer to Figure 1). The SaNuRN consortium used existing videos from the French National Digital Health Agency to develop these new teaching resources.

As of January 2024, the personalized 30-hour module is accessible in 2 modes: as freely available teaching resources for any health-related student through an open data website [17] and as specific video capsules within the URN and CAU private teaching environments. A total of 24 hours of preexisting resources, predating the SaNuRN project, were adapted to cater to various audiences, focusing on nurses and pharmacists. Overall, 80% (56/70) of the *FNRDH* competencies are covered by at least 1 SaNuRN teaching resource [17].

In line with the strategic decision made by the SaNuRN consortium in response to the French Delegation of Digital Health, all teaching materials generated during the project will be openly accessible on a website (“teaching open data”) [17]. Furthermore, from these teaching materials (eg, cybersecurity), several short-duration capsules were developed to suit the specific needs of students in various specialties, including medicine, pharmacy, and nursing.

A significant advantage of SaNuRN is that all these resources are freely accessible to everyone, aiming to benefit health and paramedical students and professionals.

Figure 1. Overall schema of the SaNuRN project timeline. DES: Diplôme d'Etudes Spécialisées (Residency Program); OSCE: Objective Structured Clinical Examination; SaNuRN: Santé Numérique Rouen-Nice (Digital Health Rouen-Nice).

Facilitating Digital Health Education Adoption and Improvement

To ensure that the largest student population earns the necessary skills, the SaNuRN project has developed a 2-tier system. The first tier involves selecting teaching staff in each professional specialty field involved in the project that will act as facilitators. They will enable the efficient expansion of the project's educational outreach and facilitate periodic updating of the skills framework within each professional specialty. Additionally, these facilitators will support the students in learning the needed material efficiently. The training of these facilitators began in May 2023 for a year.

Based on the outcomes of the first tier, the second tier will consist of adjusting the educational resources that were initially only based on the *FNRDH*. This will facilitate the deployment, student and teaching staff engagement, and adoption of the digital health teaching modules in all health and paramedical specialties.

The SaNuRN Approach to Digital Health Education Innovation

Overview

As a part of the requirements of the SaNuRN's grant, 80% of the funding is dedicated to first-degree students (bachelor's), corresponding to most of the health and paramedical students

that are enrolled. The SaNuRN consortium has already largely fulfilled this objective by massively educating and training in traditional classroom settings or through self-training.

In the next 3 and half years (see [Figure 1](#)), the SaNuRN consortium will focus on pedagogical digital health innovations for the second and third degrees of all health-related fields of study. For example, the consortium has already planned pluriprofessional training sessions for the first semester of 2024 (eg, medicine residents with nursing students, both involved in specific teleconsultations). The first scheduled training session is about clinical data warehouses from various health and paramedical perspectives.

New paradigms are already present in the SaNuRN digital health syllabus and have been introduced to public health residents, particularly the paradigm of “One Digital Health” [18], defined as the intersection of *one health* and *digital health*. The SaNuRN team has developed two other innovations: (1) modification of the evaluation process with a shift from a knowledge-based to a competencies-based evaluation, as proposed by the Miller teaching pyramid [19], such as the Objective Structured Clinical Examination, and (2) Script Concordance Test in digital health, using a Health Professional Connected Office (see [Figure 1](#)).

Furthermore, several aspects will be mainly at the heart of the innovation of the SaNuRN project, as presented below.

Interactive and Innovative Components of Courses

The characteristics of the SaNuRN project are primarily the combination of knowledge and expertise from URN, CAU, and their public health and digital research laboratories and partners.

Integrated Telemedicine Devices

Two medical simulation centers, at URN [20] and at CAU [21], have already established living labs. These labs include simulated professional offices and patient apartments, providing a platform to test various software in different health situations, especially in general practice. Soon, 2 integrated telemedicine units will be available for health and paramedical students to test different health situations using scenarios of simulated patients.

By 2027, the SaNuRN project aims to implement several teaching modules that will be financially self-sustainable (ie, that will run in the future without the financial support available for the grant period). These modules will offer digital health training for continuous learning in general practice and private companies, including big pharma and health technology (or “medtech”) companies. For instance, a full-day teaching module has been developed to help private companies handle clinical data warehouses. The medical simulation centers in Rouen (URN) and Nice (CAU) will be used to conduct most of these training sessions.

Living Labs With Virtual and Interactive Professional Activities

The SaNuRN program includes a conversational virtual clinical simulator using artificial intelligence techniques combined with natural language processing, with the modeling of clinical

situations defined for the training of all health care professionals (eg, physicians, pharmacists, nurses, and physiotherapists).

Analogous to expert systems, this tool, on the one hand, will be able to play the role of a professional (ie, backward chaining), asking questions to a patient while adjusting to the patient’s responses (similarly to a computer-assisted diagnostic aid). On the other hand, the system will play the role of the patient (ie, forward chaining), answering a professional’s questions (simulated clinical examination of the virtual patient).

A Comprehensive Overview of SaNuRN’s First Achievements

Digital Health Education Before SaNuRN (September 2022)

Before SaNuRN (September 2022), digital health was already taught in URN and CAU. Indeed, for example, first-year students at the health schools at URN and CAU received an initial and primary education on digital health. Specifically, since 2021, a total of 15% (150/1000) of the students at URN took a 20-hour course as a part of a minor in health digital science, and since 2020, a total of 100% (1000/1000) at CAU received a 10-hour mandatory course. These digital health courses are performed in a traditional large classroom setting at URN and CAU.

Adaptations in Nursing Schools

In West Normandy, a teaching self-learning module was provided to the 7 nursing schools, representing 600 nursing students. In the first semester of 2022, the teaching module was directly derived from the one provided for health students, with an identical duration of 20 hours. Very quickly, in response to the feedback from nursing students, the SaNuRN consortium analyzed the teaching discrepancies between the real needs of these nursing students and the content of the digital health teaching module. Therefore, a 6-hour training was reorganized for the second semester. Furthermore, for each teaching module, all the examples provided were modified and adapted to the nursing student’s needs (eg, to demonstrate the need for health smart cards in their specific practice).

Implementation and Expansion During SaNuRN’s First Year

During the first academic year of the SaNuRN project (2022-2023), around 2000 students specializing in health care and paramedical specialties were trained. According to our knowledge and the various national agencies involved in the program, this number is significantly higher than those at other French universities. The West Normandy nursing schools provided only 20 hours of digital health training. These schools have requested an additional 10-hour course in the third year of the curriculum to fulfill the 30-hour teaching requirement.

Expansion and Hybrid Learning

In the ongoing academic year (2023-2024), the SaNuRN consortium has engaged several new student cohorts. At URN, 200 second-year medical students (ie, students who passed the first highly selective year at the school of health and chose to

study medicine) have participated in hybrid training, including 4 hours of face-to-face organized courses and 25 hours of self-training (see [Figure 1](#)). Additionally, around 100 second-year pharmacy students (ie, similar to students who chose to study medicine, except they chose to study pharmacy instead) may opt for this digital health teaching module. A total of 100 physiotherapy and ergotherapy students are also involved in the project, dedicating 24 hours to self-training. For all these new URN students, the SaNuRN team proposes the following module: a 2-hour introduction teaching (see [Figure 1](#)).

At CAU, 400 nursing students from 4 nursing schools will participate in the SaNuRN project in 2024. Lastly, 20 public health residents from URN and CAU will have access to advanced teaching resources. Thus, 100% of medical and paramedical students will be trained in digital health at both universities in 2025.

The Delegation of Digital Health of the French Ministry of Health aims to educate and train 400,000 students in digital health by 2027 using a 30-hour module based on the *FNRDH* guideline. The SaNuRN project plans to teach 13,200 students over 5 years.

The overall SaNuRN project during the 5 years is summarized in [Figure 1](#); most of the effort is made for students in the first degree of their studies to attain the 100% rate of trained students in digital health. The SaNuRN consortium will fit this goal in June 2025. Then, specific contents are available for second and third degrees to improve the knowledge and competencies in specific situations and medical and paramedical disciplines (eg, videos and live demonstrations of teleconsulting with nurses, physicians, or physiotherapists).

Training Trainers

Goals and Framework

Since May 2023, specific training sessions have been performed for digital health trainers. The “Training the Trainers” component of the SaNuRN project is instrumental to attaining the project’s primary goal, that is, providing education on digital health for undergraduate students of all medical, paramedical, and social disciplines in the academic year 2024-2025. The goals of this component are to obtain from the trainees—who all are faculty members actively teaching in the various academic programs and institutions responsible for undergraduate education in medicine, paramedicine, and social work—the most accurate information about their students such as their profiles, schedules and course works, and preparation for the discipline of digital health.

Program Structure and Implementation

This information is further used to:

- Design the most appropriate pedagogical resources in terms of format, depth of knowledge, types of learning activities, and modes of assessment.
- Evaluate and train the faculty members in the discipline of digital health.
- Train them in the design of e-learning curricula and the use of digital pedagogical resources.

- Prepare them for the integration of the 30 hours of education to digital health in their respective programs.

Core Activities and Learning Objectives

The “Training the Trainers” program has been organized as a yearlong, ongoing, asynchronous, and remote training activity primarily to respond to the significant disparity regarding the trainees’ availability, who, for the most part, could not commit to a fixed time slot, and to allow for an extensive immersion within the discipline itself and consistent exposure to digital technologies. All the collaborative and remote tools used in the development and course of this program were unknown to the trainees, and it took time and practice for all of them to attain a good level of proficiency and confidence.

This model allowed the program to admit new trainees at different stages and moments of its development.

Development of Pedagogical Resources

The program started in May 2023 with 15 faculty members enrolled. It is scheduled to last until the end of May 2024, with, as of today, 34 members representing all the disciplines concerned with the integration of new courses in digital health.

The core activity of the program consists of the complete understanding of the reference framework (*FNRDH*; [Multimedia Appendix 1](#)) and the planning and design of its integration within existing courses and academic programs. Through a collective explication of all capacities included in the *FNRDH*, the group of trainees has identified 5 learning topics forming the core common foundation shared by all health-related disciplines: “cybersecurity,” the “digital health system,” “digital communication,” “digital professional communication,” and “further developments of digital health.” In order to accommodate the various specificities of the existing academic programs, each of these topics has been divided into teaching modules of roughly 20 minutes, allowing easy customization and integration into existing curricula.

All program trainees contribute to designing and producing these 30 modules, representing the first 10 hours of education in digital health for first-year undergraduate students in health-related disciplines. These modules are designed to be delivered as autonomous self-teaching, asynchronous modules, thus allowing all faculty members to monitor students’ activity and progress with their own methods and tools.

Together with these modules, the trainees are producing web-based interactive resources with the help of a partner of the SaNuRN program, IKIGAI, a nonprofit game design company. Two types of such interactive resources are currently being produced: a gamified quiz and a set of flashcards for practice and memorization.

Innovative Pedagogical Tools: Introduction of Learning and Assessment Scenario

The “Training the Trainers” program provides trainees with a fully immersive experience in digital communication and education and an in-depth analysis of the *FNRDH*, allowing them to clearly envision the multiple ramifications of the new discipline of e-health.

With the “Training the Trainers” program (see [Figure 1](#)), the SaNuRN project has introduced, at the undergraduate level, one major innovative pedagogical tool, the Learning and Assessment Scenario. This tool consists of a detailed outline of a complex professional situation involving digital tools and technologies and the collaboration of professionals from other disciplines. The students presented with this situation must engage in collaborative activities to assess the situation’s multiple dimensions and propose a coordinated plan of action to solve the issue. This teaching tool prefigures tools used at the graduate and postgraduate levels, such as the Objective Structured Clinical Examination and Script Concordance Test. The Learning and Assessment Scenario also serves as an efficient tool to teach the much-needed interprofessional collaboration skills that are brought to higher levels of complexity and depth by digital technologies. With this progressive strategy, the educational program created by SaNuRN, covering the 3 cycles of medical, paramedical, and social work studies, creates a consistent continuum of educational engagement for faculty members and students in meaningful interactions with digital technologies.

Evaluation Plans

Currently, no formal (qualitative or quantitative) evaluation has been performed in the SaNuRN project; 2 qualitative evaluations have already been planned: in URN and CAU, 1 for medical students and 1 for nurse students. One indirect positive measure is the presence of health-related students in URN and CAU during the first year’s training sessions. However, the presence was not mandatory, and over 90% of health-related students were present in the 20-hour training module in URN and 10-hour training module in CAU.

Discussion

Overview

During the first academic year of the SaNuRN project (2022-2023), around 2000 students specializing in health care and paramedical specialties received training, a significantly higher number than other French universities. In the ongoing academic year (2023-2024), various new student cohorts are participating in the project, including medical, pharmacy, physiotherapy, and ergotherapy students and public health residents. The SaNuRN project aims to educate 13,200 students over 5 years, contributing to the Delegation of Digital Health’s goal of training 400,000 students by 2027.

The project primarily focuses on first-degree students in the initial years (bachelor’s), with specific content for second- and third-degree students (master’s and PhD or residency) to enhance knowledge and competencies in various medical and paramedical disciplines.

The SaNuRN consortium plans to introduce innovative teaching methods, including interprofessional training sessions, competency-based evaluations, and the use of telemedicine devices. Interactive and innovative course components, combined with living labs and virtual clinical simulators, form the core of the project’s innovations.

The key strengths and limitations of the SaNuRN project rely on (1) the fulfillment of the French Ministry of Health’s aim to make digital health learning mandatory and (2) compliance with professional international recommendations, even when the specificities for the French higher education system make it challenging.

Strengths

Fulfilling National Commitments With the SaNuRN Project

By September 2024, learning digital health will be mandatory for all health and paramedical students in France. At that time, the SaNuRN project will be able to fulfill the national commitment to teaching digital health by addressing the 70 *FNRDH* competencies in a 30-hour training package.

Fitting Global Trends in Digital Health Education

In addition to France, several countries are proposing digital health training at the national level. However, only a handful of countries have established such competencies for clinical practice in their core medical school curriculum [22]. In England, the National Health Service has launched the Digital Readiness Education program [23]. It aims to improve digital skills, understanding, knowledge, and awareness across the multidisciplinary health and care workforce to support new working methods. This program focuses on continuous training. A qualitative study evaluated digital competencies in Singapore for its national medical school curriculum (which included 4 medical schools) [22]. One of the main conclusions was the need to enhance the sharing of educational resources and expertise. This point is also crucial in the French program, so the SaNuRN project has decided to create “open access” and “open data” teaching resources that are shareable with all French health and paramedical schools. An experiment was also conducted in Italy, using Petri-Nets to improve digital health literacy [24].

Looking at Internationalizing the SaNuRN’s Concept

An essential advantage of SaNuRN is that all teaching materials created during the project are freely available to anyone, even explicitly targeting all health and paramedical students and professionals [17]. Most of the teaching material is created in French. However, thanks to international collaborations with institutions such as the Holon Institute of Technology (HIT) in Israel, a large part of the SaNuRN material is coproduced and available in English. This approach allows these partners, URN and CAU, to use the relevant SaNuRN resources in their curricula. For example, some SaNuRN resources (lessons) have been cocreated or coenhanced with lecturers in charge of health data science courses of the Department of Digital Medical Technologies at the HIT in Israel [25].

Complying With the International Medical Informatics Association Recommendations

The International Medical Informatics Association has published 2 versions of its international recommendations in biomedical and health informatics education, initially in 2000 and revised in 2010 and 2023 [26]. The International Medical Informatics Association recommendations are a framework for national

initiatives in biomedical and health informatics education and for constituting international programs and exchange of students and teachers in this digital health field. Zainal et al [27] have proposed a scoping review on clinical informatics training in medical school education curricula; these authors proposed 4 main recommendations that are very similar to those used in the SaNuRN project: situating digital health curriculum within specific contexts, developing evidence-based guidelines for robust digital health education, developing validated assessment techniques to evaluate curriculum effectiveness, and equipping educators with relevant digital health training.

Limitations

Needing to Align With Other International Standards

The teaching model may not be entirely compatible with other international approaches; drawing inspiration from experiences in other countries and attempting to fit within a shared framework would be advisable.

Temporarily Focusing on Undergraduate Students

Because the project was principally focusing its efforts on undergraduate degrees for its first 2 years, no international collaboration was initiated, apart from a cooperation with the HIT in Israel, as such collaboration usually targets graduate and postgraduate levels. At the national level, for the master's and PhD degrees, the SaNuRN consortium is planning to cooperate

in 2024 with several French universities (Sorbonne Université, Paris Cité, Besançon Université, and Rennes Université), as well as European universities, in particular University for Health Sciences, Medical Informatics and Technology in Austria and continuing its cooperation with the HIT in Israel.

Conclusion

The SaNuRN project addresses France's national commitment to teaching digital health. SaNuRN addresses all 70 *FNRDH* skills and competencies ([Multimedia Appendix 1](#)) with a comprehensive, personalized, 30-hour training package for each health or paramedical student according to their degree level, field of study, and university curriculum. This innovative approach is enhanced by using artificial intelligence and natural language processing to create virtual patients and professionals for digital health care simulation, allowing each student to replay and practice various clinical situations. SaNuRN teaching materials are openly accessible. Moreover, SaNuRN, aiming to answer new needs of the French health schools and paramedical professions, is collaborating with academic institutions worldwide to develop educational material in digital health in English and multilingual formats. SaNuRN offers an enhanced training approach that is both effective and persuasive, making it a challenging solution to the current digital health education requirements in France and potentially Europe and worldwide.

Acknowledgments

This work was supported by the Santé Numérique Rouen-Nice (SaNuRN) project (ANR_22-CMAS-0014 3.951.200), granted by the Delegation of Digital Health of the French Ministry of Health and the French National Research Agency.

Abstract

Background: The COVID-19 pandemic underscored the necessity for innovative educational methods in nursing. Our study takes a unique approach using a multidisciplinary simulation design, which offers a systematic and comprehensive strategy for developing virtual reality (VR) simulations in nursing education.

Objective: The aim of this study is to develop VR simulation content for a pediatric nursing module based on a multidisciplinary simulation design and to evaluate its feasibility for nursing education.

Methods: This study used a 1-group, posttest-only design. VR content for pediatric nursing practice was developed by integrating the technological characteristics of a multimodal VR system with the learning elements of traditional nursing simulation, combining various disciplines, including education, engineering, and nursing. A user test was conducted with 12 nursing graduates (preservice nurses) followed by post hoc surveys (assessing presence, VR systems, VR sickness, and simulation satisfaction) and in-depth, one-on-one interviews.

Results: User tests showed mean scores of 4.01 (SD 1.43) for presence, 4.91 (SD 0.81) for the VR system, 0.64 (SD 0.35) for VR sickness, and 5.00 (SD 1.00) for simulation satisfaction. In-depth interviews revealed that the main strengths of the immersive VR simulation for pediatric pneumonia nursing were effective visualization and direct experience through hands-on manipulation; the drawback was keyword-based voice interaction. To improve VR simulation quality, participants suggested increasing the number of nursing techniques and refining them in more detail.

Conclusions: This VR simulation content for a pediatric nursing practice using a multidisciplinary educational design model was confirmed to have positive educational potential. Further research is needed to confirm the specific learning effects of immersive nursing content based on multidisciplinary design models.

Introduction

Overview

Virtual reality simulation (VRS) education, which integrates the latest information and communications technology innovations into simulation education, is a cost-effective solution for nursing practice education. It allows for attainable and predictable results without limitations of time and place. Consequently, VRS is expected to be extensively used in nursing curricula [1]. The demand for immersive education is growing rapidly following the clinical practice challenges experienced during the COVID-19 pandemic [2]. Various studies have been conducted to enhance immersion, a major advantage of virtual reality (VR)-based educational content; increase the educational efficacy of VR-based content; and minimize the side effects of the technology [3].

VR technology for on-site nursing simulation education is in its early stages and is centered on 2D web-based simulations, primarily using computers and monitors [4]. Even in realistic 3D simulation education, most studies are based on fragmentary skill-oriented scenarios using handheld devices [5].

It is essential to clarify the desired direction of immersive education, learning situational elements, and skill levels required for students to use immersive simulations in practical nursing training effectively. This approach should be based on an optimal theoretical framework and educational design [6]. Since immersive simulation is an educational method that integrates elements of traditional nursing simulation education and engineering elements, to maximize the effect of education using immersive simulation, the learning design must consider various elements of each area.

Despite significant advancements in IT and a growing interest in immersive content, little research exists on multidisciplinary design models for immersive education and the feasibility of design model-based content [7-9].

This study aimed to systematically develop 3D nursing simulation content based on a VR educational design model and the National League for Nursing (NLN) Jeffries Simulation Theory. It also conducted user tests to evaluate its feasibility in nursing education. We propose a multidisciplinary VRS content development model and provide the basis for future VR-based nursing education.

Theoretical Framework

The VR-based nursing simulation content was developed using the NLN Jeffries Simulation Theory [10] and Han's [11] VR-based Educational Simulation Model. The selection of these 2 theories as a framework for this study was a strategic approach to systematically consider the characteristics of VR media and educational elements to maximize learning effectiveness. Rather than simply borrowing VR technical elements for nursing education, we sought to develop the most effective educational content in a multidisciplinary manner by integrating technology, educational elements, and nursing. The NLN Jeffries Simulation Theory provides a well-established foundation in nursing education, while Han's [11] VR-based Educational Simulation

Model offers specific guidelines for creating immersive and user-centered VR experiences.

The NLN Jeffries Simulation Theory is widely used in nursing education to guide the development of simulation-based learning experiences. This theory presents components as participant factors, facilitator factors, educational strategies factors, and expected outcomes, offering versatility in their application in nursing education. By outlining specific components that can be tailored to the needs and objectives of learners, the theory provides a robust framework for educators. It maximizes the effectiveness of simulation as a teaching strategy, ensuring that educational goals are met and that learners are better prepared for clinical practice. Especially as educational strategies factors, this includes the design and execution aspects of simulation activities, such as the complexity of simulations, feedback mechanisms, and debriefing methods. These factors are key to optimizing the learning environment and supporting the achievement of educational goals. Endorsed by the NLN, this theory has become a cornerstone in the field, guiding educators on how to integrate simulation into their teaching practices effectively.

Han's [11] research aims to develop and validate design principles for optimizing VR-based educational simulations. It explores ways to use VR to extend users' learning experiences into realistic contexts. Han's [11] model comprises 12 design principles based on the 3 categories of contextual scenario, affordance in the simulation, and user activity and response. These categories emphasize creating immersive learning experiences that more closely resemble real-life situations, thereby enhancing the learner's engagement and facilitating a deeper understanding of the subject matter. The 12 design principles encompass creating realistic scenarios, engaging user actions, and reflective activities closely mirroring real-life contexts. Applying these principles to nursing education simulations is justified as they enhance experiential learning, improve critical thinking and decision-making skills, and provide a safe environment for clinical practice. The principles ensure that the simulations are relevant, technologically apt, and realistically mimic health care settings, thereby making theoretical knowledge tangible and facilitating embodied learning.

This theoretical framework can provide a structured approach to developing simulations that are both educational and reflective of actual nursing practice. Thus, Han's [11] model has 2 main advantages when applied to develop this nursing simulation content. First, it comprehensively considers educational engineering elements and the technical characteristics of VR. Second, it is subdivided into 3 clear categories and 12 subcategories, specifying the characteristics of each area. This structure allows for the provision of specific and clear guidelines for application in developing this nursing simulation content. We comprehensively considered the characteristics of VR, a technical element, as well as nursing and educational engineering elements, and selected an appropriate model to develop optimal immersive content based on a multidisciplinary perspective (Textbox 1).

Textbox 1. Immersive content development based on virtual reality (VR) education engineering design principles.

Principle of replicating real-life problems:

- To reflect the nature and importance of real-life problems, a contextual scenario was constructed using the clinical pathway of a disease to allow the learner to experience the entire flow of actual clinical practice for a specific disease and the corresponding nursing care.

Principle of adequacy of VR technology:

- Technique to perform nursing skills with bare hands without a hand device was applied through a variety of technologies, allowing the learner to have experiences similar to clinical practice.
- Using deep learning technology, the virtual caregiver was configured to give feedback to the learner with a verbal response.

Principle of similarity to real environment:

- To construct a practice environment as similar to real-life situations as possible; actual photos were provided as reference materials when creating virtual objects, which was refined through several revisions.

Principle of structural planning:

- Based on the Jeffries Simulation Theory template, learning goals for each module were set, upon which simulation elements and specific learning contents were organized.
- A flowchart was designed to show the VR simulation (VRS) content deployment order according to the user's activities.

Principle of implementing a professional approach:

- The content was algorithmically designed to recognize appropriate or inappropriate nursing procedures performed by learners and to provide feedback according to their level of performance, allowing them to ultimately embody the knowledge, skills, attitudes, and so forth, that was required of a nurse.

Principle of structured activity deployment:

- Contents and screens were designed according to the expected progress of the learner's activities, and a storyboard including the main contents was constructed according to the progress of the simulation activities.

Principle of simple-to-complex process:

- The modules were structured to align with the sequential order of patient care from admission to discharge, ensuring that activities are carried out in a systematic and sequential manner.

Principle of virtual recognition:

- To enhance the learner's sense of presence and awareness of activity direction in the VR space, the simulation modules were designed to display the learner's hands or body parts on the screen.

Principle of the reality of operation and selection:

- To enable realistic exploration, manipulation, and selection activities, real-life activities and voice responses were presented.
- The nursing outcomes were algorithmically configured to vary depending on the learner's VRS activities.

Principle of providing relevant information:

- The content was designed to assist the learner with the initial orientation and facilitate nursing activities by providing information on the envisaged simulation activities.
- In the introduction stage, instructional materials and preinstructional videos were provided.
- In the activity stage, pop-up quizzes or audio formats were used to provide information on the elements and procedures that the learner needed to consider during simulation performance.

Principle of promoting critical thinking:

- The problem situations related to pediatric patients hospitalized with pneumonia, learning objectives, and framework for required nursing interventions were presented.
- Critical thinking was promoted by allowing for decision-making and implementation within the presented situation.
- Use of tablet devices was included in the content to allow the learner to retrieve information on the patient's conditions and related information whenever necessary.

Principle of encouraging critical reflection:

- Feedback was provided to the learner during the simulation process through quizzes or a virtual agent's responses in a manner to give them the opportunity to reflect on the appropriateness of their own nursing actions.
- A performance checklist was displayed on the screen just before the end of the VRS, and feedback videos were provided after the simulation ended to allow the learner to reflect on their nursing performance again.

Objectives

Therefore, this study's theoretical framework, which integrates nursing theory and educational technology models, can provide a structured approach to developing VRSs for educational purposes that reflect actual nursing practice situations.

Methods

Study Design

The study used a 1-group, posttest-only design to develop and evaluate immersive simulation content in nursing education.

Figure 1. Research overview. VR: virtual reality.

Part 1: Development of Immersive Simulation Content

Step 1: Team Building

The 5 developers (2 nursing experts, 2 IT developers, and 1 3D-modeling expert) produced the immersive content throughout the study from October 2020 to April 2021. A total of 8 nursing professionals (3 professors and 5 clinicians) supported the scenario development process.

First, the project team drafted a pediatric pneumonia nursing scenario using VR-based educational design principles and the Jeffries Simulation Theory. The 8 experts evaluated the validity of the scenario's content.

The project team followed the design process throughout the content development and technical work. The final prototype content was iteratively refined via expert group meetings. It has been modified several times to better reflect possible clinical situations at a level that can be implemented in a virtual environment. The content validity of the developed scenario was confirmed by experts. The prototypes were categorized into 2 groups—low-fidelity prototypes using 2D materials, such as printed matter, and high-fidelity prototypes using content development programming techniques to reflect the actual environment accurately [12]. In this study, high-fidelity prototypes were developed to provide a training experience

Procedures

The VRS content was developed via (1) team building, (2) literature review, (3) VR content design, (4) development of the initial scenario, (5) expert consultation and content validity testing, (6) scenario completion, (7) development of prototype content, and (8) user evaluation (Figure 1). This process can be broadly divided into 2 parts—development of content and user evaluation.

similar to that in a real clinical environment to evaluate the content applicability to nursing education.

Step 2: Literature Review

The project team conducted an extensive literature review to gather and analyze existing research on VR-based educational simulations. This review provided a foundation for developing the scenario and identifying best practices and potential challenges in VRS.

Step 3: VR Content Design

This design phase included defining the learning objectives, creating detailed storyboards for each scenario, and outlining the technical requirements for the VR environment. The design ensured that the content was pedagogically sound and technically feasible. The design phase also involved specifying the interactive elements and feedback mechanisms that would be integrated into the VR experience to enhance engagement and learning efficacy.

Step 4: Development of the Initial Scenario

Detailed flowcharts were created to visualize the learner's journey through the simulation, ensuring that each step aligned with the intended learning outcomes. The initial scenario for pediatric pneumonia was developed, integrating the educational design principles and the Jeffries simulation theory. This

scenario included specific nursing tasks and clinical decisions that learners would need to perform and make during the simulation.

Step 5: Expert Consultation and Content Validity Testing

An expert group of 8 nursing professionals with practical clinical training in pediatric nursing, including 3 pediatric nursing professors, evaluated the adequacy of the assessment data, nursing diagnoses, nursing interventions, and content relevance of the nursing evaluation algorithms. Scenario content validity testing resulted in an overall content validity index of 0.99 and 1 of 32 items was removed as “not relevant” or “somewhat relevant.” In module 4, among the assessment data to make a nursing diagnosis of skin integrity disorder, unnecessary assessment data were deleted according to expert opinion. The

final version of the scenario was developed after modifications and refinements based on expert opinions.

Step 6: Scenario Completion

The simulation scenario included 6 modules, covering the period from admission to discharge for a child with pneumonia (Table 1). First, a disease clinical path for pneumonia was created, and based on this, 6 modules were constructed focusing on the medical treatment and nursing intervention that a 7-year-old child diagnosed with pneumonia would receive from the first day of hospitalization to the day of discharge. The scenario consisted of 6 modules following the clinical pathway of pediatric pneumonia; the nursing process was applied to each module based on detailed learning goals. The scenarios were configured to provide feedback on each learner’s performance.

Table 1. Virtual reality simulation modules.

Module	Day	Nursing task
Module 1	Admission	Admission assessment
Module 2	Hospital day 1-1	Fever management and medication
Module 3	Hospital day 1-2	Oxygen therapy and monitoring
Module 4	Hospital day 2	Antibiotic skin test and intravenous injection
Module 5	Hospital day 3	Respiratory therapy (nebulizer application)
Module 6	Discharge	Discharge nursing care

Step 7: Development of Prototype Content

The final prototype content was developed using Unreal Engine 4.25 (Epic Games) and includes 2 unique technical features. First, learners performed all procedures using their hands directly without handheld devices. Second, learners could use voice interaction with virtual agents to enhance communication competencies. To implement the VR experience, Vive Pro HMD (HTC) and a hand-tracking software development kit was used to obtain the user’s natural hand position information. Voice communication was implemented using Google’s speech kit and application programming interface.

Each module took 20-30 minutes to complete and included key nursing procedures. After completing the scenario simulation, the learner received system feedback using a visual checklist. In summary, the developed prototype provides an immersive and interactive VR experience for enhancing nursing

competencies through hands-on practice and voice communication with virtual objects.

Specifically, we tested this prototype content based on feedback from the nursing expert. They indicated difficulties with voice recognition, as the system did not always accurately recognize spoken keywords. To address this, we incorporated a synonym learning algorithm using Google’s synonym crawling technology to enhance the system’s ability to understand and respond to varied inputs. This improvement aimed to provide a more seamless and intuitive user experience.

Part 2: User Testing

The feasibility of this VRS content was evaluated using a survey (quantitative method) and an interview (qualitative method). Before user evaluation, the participant’s health was assessed. Immediately following the VRS experience, participants completed a survey and semistructured, in-depth, one-on-one interviews (Figure 2). Part 2 began in April 2021 (Figure 3).

Figure 2. Flow of the user test.

Figure 3. Example of screens from the developed virtual reality content.

Participants

Participants were recruited by convenience sampling of nursing graduates of a university in Hanyang. Selection criteria included preservice nurses with clinical practice and simulation training experience. After obtaining approval from the institutional review board, a recruitment notice was posted in the university's KakaoTalk chat room for nursing graduates. Those who volunteered to participate were given explanations of the study's purpose and procedures, and all participants provided written consent. A total of 12 nursing students were selected for participation to assess the feasibility of, and satisfaction with, the developed VRS content and identify areas for improvement [13].

Measurement

Overview

Participants completed an 85-item questionnaire based on previous studies; items included presence, VR technological elements, cybersickness, learning satisfaction, and participant characteristics (age, sex, general health status, experience of motion sickness, VR experience, practical experience, and satisfaction with practical training). With permission from their developers, individual survey tools were modified to suit the study characteristics and translated and back-translated by 2 bilingual translators.

Checklist for Participant Health Status

A total of 3 items were used to assess the participants' current health, including 2 items from the Screening Questionnaire by Costa et al [14] and 1 item related to dizziness.

Postexperience Evaluation Questionnaire

Presence Questionnaire

The Presence Questionnaire (PQ) was developed by Witmer and Singer [15] to measure presence in a virtual environment. It consists of 5 subscales—realism, the possibility of acting, interface quality, the possibility of examination, and self-evaluation of performance. The PQ comprises 32 items, each rated on a 7-point Likert scale (1=not at all and 7=completely).

Virtual Reality Systems Questionnaire

The Virtual Reality Systems Questionnaire (VRSQ) is a 22-item tool developed by Norman [16] to evaluate VR games. It consists of 7 technical elements, each rated on a 9-point Likert scale. The original VRSQ was modified to suit this study and consisted of 20 items.

Simulator Sickness Questionnaire

The Simulator Sickness Questionnaire (SSQ) is a cybersickness scale developed by Kennedy et al [17] to measure symptoms of discomfort in VR environments using 16 items rated on a 4-point Likert scale ranging from 0 (none) to 3 (severe). The scores for each item were summed to obtain a total score indicating the overall level of discomfort experienced by individuals in the VR environment.

Simulation Satisfaction Questionnaire

User satisfaction was measured using a simulation satisfaction tool developed by Wotton et al [18]. It consists of 8 items rated on a 7-point Likert scale (1=not at all and 7=very much).

In-Depth Interviews: Core Questions

The in-depth interviews consisted of 4 open-ended questions (1-4) first used by Servotte et al [19] in their VRS study and 2 additional questions (5 and 6). The questions were (1) what was your first impression and feeling about the VRS experience? (2) What did you find enjoyable during the VRS experience? (3) What did you find uncomfortable during the VRS experience? (4) What improvements would you suggest? (5) Compared with your previous clinical practice experience, what aspects were useful? and (6) Compared with your previous clinical practice experience, what aspects were lacking?

Data Collection

Data collection was conducted on April 15 and 16, 2021. Led by the principal researcher, a professor in the Department of Nursing, a total of 3 researchers conducted a user test of this VRS content. Of the 3 researchers, 2 were nursing majors and 1 was an engineering major. Strict COVID-19 infection control guidelines, such as fever checks and social distancing, were followed. Using the health checklist, only participants without nausea, vomiting, or physical discomfort in the 48 hours prior to the VRS experience took part.

In our study, to minimize cybersickness, the duration of wearing the equipment per person was limited to less than 1 hour at a time. Based on these internal test guidelines, each participant was allowed to experience only 1 module of 6 pediatric pneumonia contents through random assignment using a computer in advance. Participants received the scenario via email the day before the simulation. On the day of the VRS experience, participants watched an orientation video about all 6 modules and prepracticed for approximately 40 minutes. After a 20-minute break in an open space, they participated in a user test. When the simulation experience was over, participants filled out a questionnaire and had a one-on-one personal interview with the principal researcher.

Data Analysis

Quantitative data were analyzed using SPSS Statistics software (version 25.0; IBM Corp) with descriptive statistics, such as means, SDs, and frequencies. Qualitative interview data were analyzed using thematic analysis by Braun and Clarke [20]. Interview transcripts were coded using NVivo 12.0 Pro software (Lumivero), and member checking, continuous comparison, and interrater verification processes were implemented to enhance the reliability and validity of the analyzed qualitative data. All researchers participated in the iterative analysis process.

Ethical Considerations

This study was conducted after obtaining approval from the institutional review board of Hanyang University (HYUIRB-202103-017). To ensure anonymity and to protect participants' personal information, all data collected were immediately encoded in compliance with the Declaration of Helsinki.

Results

Participant Demographics

A total of 12 licensed nurses, 3 (25%) male nurses and 9 (75%) female nurses with a mean age of 24.3 (SD 1.23) years, participated in the VRS training (Table 2). Most respondents reported good health on a regular basis (n=11, 92%) and did not experience motion sickness in their daily lives (n=9, 75%). Only 1 person subjectively assessed her health status as unhealthy due to her underlying disease, and there were no problems during the preliminary health check. One-third of participants (n=4, 33%) had experience with VR through games or other means, and all had previous clinical training with high-fidelity simulation (HFS) using mannequins and web-based simulation with vSim for Nursing. All participants had no problems checking the preliminary health checklist.

Table 2. General characteristics of participants (N=12).

Characteristics and categories	Values
Sex, n (%)	
Female	9 (75)
Male	3 (25)
Age (years), mean (SD)	24.3 (1.23)
General health status, n (%)	
Very unhealthy	0 (0)
Unhealthy	1 (8)
Healthy	7 (58)
Very healthy	4 (33)
Experience of motion sickness when traveling in a car, n (%)	
Always	0 (0)
Mostly	3 (25)
Rarely	9 (75)
Never	0 (0)

^bHFS: high-fidelity simulation.

Presence

The mean presence score during the VRS training was 4.01 (SD 1.43) out of 7 points, which is moderate. High scores were achieved for the following items: “How well could you identify sounds?” (mean 5.50, SD 1.09), “How well could you localize sounds?” (mean 5.42, SD 1.68), “How proficient in moving and interacting with the virtual environment did you feel at the end

of the experience?” (mean 5.17, SD 1.53), and “To what extent did the visual aspects of the environment produce user involvement?” (mean 5.10, SD 1.20). Items with low scores were “How natural was the mechanism that controlled movement through the environment?” (mean 2.40, SD 0.90) and “How compelling was your sense of moving around inside the virtual environment?” (mean 2.50, SD 1.24; [Table 3](#)).

Table 3. Presence (N=12)^a.

Item	Values, mean (SD)
How much were you able to control events?	3.30 (1.20)
How responsive was the environment to actions that you initiated (or performed)?	3.10 (0.80)
How natural did your interactions with the environment seem?	3.10 (1.10)
How completely were all of your senses engaged?	4.80 (1.40)
How much did the visual aspects of the environment involve you?	5.10 (1.20)
How much did the auditory aspects of the environment involve you?	4.00 (1.30)
How natural was the mechanism which controlled movement through the environment?	2.40 (0.90)
How aware were you of events occurring in the real world around you?	3.80 (1.60)
How aware were you of your display and control devices?	4.80 (1.50)
How compelling was your sense of objects moving through space?	3.75 (1.55)
How inconsistent or disconnected was the information coming from your various senses?	3.83 (1.03)
How much did your experiences in the virtual environment seem consistent with your real-world experiences?	3.75 (1.42)
Were you able to anticipate what would happen next in response to the actions that you performed?	4.67 (1.50)
How completely were you able to actively survey or search the environment using vision?	4.42 (1.78)
How well could you identify sounds?	5.50 (1.09)
How well could you localize sounds?	5.42 (1.68)
How well could you actively survey or search the virtual environment using touch?	3.00 (1.41)
How compelling was your sense of moving around inside the virtual environment?	2.50 (1.24)
How closely were you able to examine objects?	3.75 (1.60)
How well could you examine objects from multiple viewpoints?	4.00 (1.71)
How well could you move or manipulate objects in the virtual environment?	3.67 (0.98)
To what degree did you feel confused or disoriented at the beginning of breaks or at the end of the experimental session?	3.00 (1.54)
How involved were you in the virtual environment experience?	4.92 (1.68)
How distracting was the control mechanism?	4.17 (1.70)
How much delay did you experience between your actions and expected outcomes?	3.75 (1.96)
How quickly did you adjust to the virtual environment experience?	4.58 (1.24)
How proficient in moving and interacting with the virtual environment did you feel at the end of the experience?	5.17 (1.53)
How much did the visual display quality interfere or distract you from performing assigned tasks or required activities?	3.33 (1.23)
How much did the control devices interfere with the performance of assigned tasks or with other activities?	4.92 (1.31)
How well could you concentrate on the assigned tasks or required activities rather than on the mechanisms used to perform those tasks or activities?	2.75 (1.66)
Did you learn new techniques that enabled you to improve your performance?	3.33 (1.78)
Were you involved in the experimental task to the extent that you lost track of time?	4.67 (2.06)

^aTotal: mean 4.01 (SD 1.43).

VR Systems

The mean score for technical elements of the VR system was 4.91 (SD 0.81) out of 9. High scores were achieved for “Auditory glitches” (mean 7.30, SD 1.70), “Trying to locate the source of sounds” (mean 6.92, SD 1.73), “Trying to turn and see what is to the left or right” (mean 6.58, SD 1.93), and “Trying to turn and see what is behind” (mean 6.42, SD 2.02), which indicates a few technical problems. Low scores were

achieved for “Trying to aim or point targets with skeletal hands” (mean 3.83, SD 2.29), “Calibrating the system and tracking” (mean 3.80, SD 1.80), and “Trying to aim or point targets with robotic hands” (mean 3.42, SD 1.93).

VR Sickness (Simulator Sickness)

The mean score for VR sickness during the training was 0.64 (SD 0.35) out of 3, indicating that most participants did not experience cybersickness. Only minimal discomfort (1 point)

was reported for most items. However, scores for eye strain (mean 1.60, SD 1.20), fatigue (mean 1.40, SD 0.80), and head

fullness (mean 1.0, SD 0.95) were ≥ 1 point, indicating some symptoms (Table 4).

Table 4. Virtual reality sickness (N=12)^a.

Item	Values, mean (SD)
General discomfort	0.40 (0.70)
Fatigue	1.40 (0.80)
Headache	0.80 (1.00)
Eyestrain	1.60 (1.20)
Difficulty focusing	0.80 (0.80)
Increased salivation	0.00 (0.00)
Sweating	0.40 (0.90)
Nausea	0.30 (0.90)
Difficulty concentrating	0.40 (0.70)
Fullness of head	1.00 (0.95)
Blurred vision	0.75 (1.06)
Dizzy (eyes open)	0.92 (0.67)
Dizzy (eyes closed)	0.83 (0.94)
Vertigo	0.50 (0.67)
Stomach awareness	0.00 (0.00)
Burping	0.00 (0.00)

^aTotal: mean 0.64 (SD 0.35).

Simulation Satisfaction

The overall mean score (8 items) for user satisfaction with the VRS training program was 5.00 (SD 1.00) out of 7. The highest scores (mean 5.30, SD 1.20) were related to experience enjoyment and problem-solving opportunities provided by the

VRS training program. Items that received lower scores were those asking whether the participants could concentrate during the VRS training (mean 4.80, SD 1.40), whether the challenges were appropriate (mean 4.80, SD 1.40), and whether feedback provided during the VRS training helped them improve nursing knowledge (mean 4.80, SD 1.70; Table 5).

Table 5. Simulation satisfaction^a.

Item	Values, mean (SD)
Enjoyment of the virtual reality simulation practice	5.30 (1.20)
Ability to concentrate during the virtual reality simulation	4.80 (2.00)
Provision of appropriate challenges	4.80 (1.40)
Opportunity for problem-solving	5.30 (1.20)
Usefulness in learning on hospitalized children with pneumonia	5.10 (1.20)
Usefulness in improving pediatric nursing practice skills	4.90 (1.40)
Usefulness of feedback in patient care	4.90 (1.50)
Usefulness of feedback in enhancing nursing knowledge	4.80 (1.70)

^aTotal: mean 5.00 (SD 1.00).

Qualitative Evaluation

Overview

By analyzing the one-on-one in-depth interview data of the 12 participants, the strengths, weaknesses, improvement requirements, and comparison points of the content developed in this study were confirmed.

Strengths of VRS Content

Of the 12 participants, 9 (75%) responded that the visual features were well implemented, and they enjoyed manipulating and moving objects with their hands in the virtual environment. Some participants also found the virtual interactive experiences fascinating and were pleased to apply what they learned in practice.

I enjoyed the feeling of interaction and communication in the virtual environment as if I were observing the patient's reactions during real practice. [Participant 7]

Weaknesses of VRS Content

Participants reported difficulties with voice recognition because communication centered on specific keywords and with technical aspects of virtual object manipulation. Additionally, some participants experienced disruptions during the nursing procedure owing to instability in certain virtual spaces.

It was frustrating when my words were not recognized properly, resulting in a generic response such as "Yes, I understand" to whatever I said. [Participant 6]

Comparison With Existing Practical Training

Strengths of VRS Content

Participants noted that traditional hospital-based clinical training often involves fragmented training based on situational needs, whereas they mentioned the most significant advantage of VRS is the ability to experience independent nursing practice from beginning to end. They also found it highly beneficial to experience the entire continuum of nursing care, from admission to discharge, for specific diseases, and they highly appreciated the absence of time and space constraints in VRS.

In the actual clinical practice setting, we surround the patient like a folding screen, and there are many things we cannot see due to patient privacy. This makes us feel like we are gathering skills bit by bit rather than acquiring them systematically. However, with VR, we can perform the entire procedure from start to finish. In that sense, it is better than clinical practice. [Comparison with clinical practice: participant 11]

Our group consisted of only 4 members, with some taking on the roles of nurse or doctor, while others were responsible for taking pictures or did not have the opportunity to perform nursing skills, which was disappointing. However, doing everything by myself allowed me to focus on improving my nursing skills. [Comparison with HFS: participant 4]

Other programs like vSim for Nursing do not provide two-way communication. However, with this program, I felt like there was some two-way communication depending on what I said or did. It was fun and felt like I was a real nurse in the virtual environment, communicating and receiving reactions from a caregiver in my presence. [Comparison with web-based simulations: participant 10]

Weaknesses of VRS Content

Compared with actual clinical practice, the limited manipulation of nursing supplies was evaluated as disappointing in that students were unable to perform detailed movements. Some pointed out that they had difficulty immersing themselves in

the virtual clinical situation because they were concentrating on manipulating objects.

The simulations were limited to predetermined scenarios, whereas unexpected situations and various patient reactions may be encountered in a hospital setting. The tension that accompanies these situations may be lacking in simulations because all students are required to complete the same simulation from start to finish. [Comparison with clinical practice: participant 2]

During the simulation, I was able to practice communication while working with my friends as a team. Unfortunately, I was doing everything alone in this program. [Comparison with HFS: participant 5]

Communicating as if it were reality was helpful, but it was uncomfortable when my words were not accurately recognized. [Comparison with a simple web-based simulation: participant 4]

Discussion

Principal Findings

VRS can provide realistic learning experiences through lifelike 3D environments, enhancing immersion and presence [21]. In this study, we sought to develop effective immersive nursing content by maximizing the advantages of VR and the learning effect in nursing through a multidisciplinary approach.

The content was developed using VR-based simulation design to create a realistic environment, considering clinical issues and contextual factors, while incorporating learning elements, such as clues and hints for learning and evaluation. Emphasis was placed on technical features, including visual implementation, to enhance immersion and presence and the educational design of the content [9]. Immersion relates to the technical aspect of VRS as an objective characteristic of the development environment, whereas presence refers to the user's psychological and subjective perception that they are present in the immersive virtual environment [19]. Immersion can evoke a feeling of physical "presence" by providing an experience similar to real-world ones [22].

The research team held numerous discussions and participated in refinement with modeling experts to enhance immersion by increasing visual fidelity and creating a more realistic environment. Because vision is the primary sense for perceiving information, high immersion and presence are needed in educational content design [23]. Most respondents rated the visual implementation as excellent, which helped them maintain high levels of immersion. However, some participants noted that engagement was hampered in part by the unsophisticated nursing supplies and the racial inconsistency of the caregiver avatars. This mismatch partially disrupted their immersion [24]. In future VR content production, it will be essential to consider not only the color, brightness, and spatial perception of virtual objects but also learners' cultural characteristics.

The main goal of the content development in this study was to enhance the sense of presence and provide a practice environment that would allow learners to perform nursing

procedures with their own hands and provide emotional support to a virtual patient through verbal communication. According to user evaluations, multimodal interaction with voice communication and implementation of direct actions in the environment were viewed as positive and provided a moderate level of presence. However, communication accuracy and technical features related to virtual object manipulation required improvement. To the best of our knowledge, this is the first study to combine voice interactions with direct hand manipulations in practical nursing training. Multimodal interaction technology can increase resemblance to reality and provide a deeper sense of immersion, enhancing learning effectiveness [25,26]. Future studies should aim to improve the accuracy of multimodal interactions.

Despite the demand for improvement of virtual object manipulation and communication accuracy, satisfaction with the VRS program was relatively high, rated as moderate or better. The 2 most highly rated items were related to joyful experiences and problem-solving opportunities. These results align with the work by Lin et al [27] on multimodal interactions in VR for thoracic diagnostic scenarios, underscoring the effectiveness of such technologies in creating immersive educational experiences. This indicates the strong educational potential of immersive VRS. If immersive simulation content is developed by focusing on the strengths of VRS compared with existing training methods, it will be more effective in future nursing practice education.

The participants stated that the biggest advantage of VRS compared with traditional clinical practice was the opportunity to directly experience nursing procedures independently from start to finish. This finding is consistent with a previous study on multiuser virtual environment simulation experiences for nursing students [28], which highlighted building a “frame of thinking like a nurse” as a major theme. This self-directed nursing experience can facilitate learners’ metacognition and enhance competence [28,29]. The participants suggested that this immersive content could improve nursing students’ critical thinking and problem-solving skills. In VRS training, learners make clinical decisions and perform nursing activities based on their own judgments, which can effectively enhance critical thinking and problem-solving skills [5]. A previous study on nursing students [30] also confirmed the usefulness of VRS for developing clinical decision-making skills. However, this preliminary study was limited by time, and each participant experienced only 1 module. Follow-up studies are required to confirm the effectiveness of VR-based training.

Another strength of VRS pointed out by participants was the ability of students to experience the entire nursing process for patient care based on theoretical knowledge. In this study, participants were unable to experience all 6 modules due to time constraints while wearing VR, but the entire flow of all 6 modules was shown through video material during orientation on the day of the experience. Participants experienced the entire nursing process on a specific day on their own within 1 randomly selected module. This highlights the value of the full-cycle scenario design based on the clinical pathway of a corresponding illness. Traditional clinical training often limits nursing students to fragmented or random opportunities

situations rather than structured, comprehensive practice sessions for a given condition [31]. Although traditional clinical training allows for an experience of unexpected situations, it lacks structure. Well-structured VRS practical training content design allows learners to apply their theoretical knowledge to practical situations systematically. Thus, VRS will be useful for reducing gaps between theoretical knowledge and practical skills.

Because VRS has some drawbacks, that is, lack of actual clinical practice and teamwork scenarios, it may be more effective to integrate VRS into traditional clinical training, allowing the two training methods to complement one another. Immersive VRS content can expand learning experiences into previously inaccessible quantitative and qualitative areas [32]. To improve the quality of practical nursing training in the post-COVID-19 era, a systematic education design model that leverages the advantages of VR and real-world training to optimize nursing education is needed.

Limitations and Future Research

The COVID-19 pandemic posed certain challenges for this study, particularly regarding participant recruitment and experiment execution. These constraints resulted in a smaller sample size, affecting the findings’ generalizability. Additionally, the duration of the VR simulation was limited to minimize the cybersickness risk, and each participant experienced only 1 module instead of the entire hospitalization scenario.

Despite these limitations, the study significantly contributes by systematically developing immersive VRS educational content for nursing. Using the Jeffries Simulation Theory template and VRS education design principles, the study confirmed the feasibility of this content in practical nursing training. Importantly, the study implemented multimodal interaction, enabling learners to use their hands directly and engage in voice communication, thereby closely simulating real clinical nursing practices.

Future research should address these limitations by recruiting a larger and more diverse sample population. Allowing participants to experience full-cycle clinical pathways of diseases will facilitate a more comprehensive verification of learning effects, enhancing the validity and applicability of the results. Furthermore, expanding the scope of multimodal interactions and refining the VR environment will improve the realism and effectiveness of the education, establishing it as an even more robust tool for nursing education.

Conclusions

We developed multidisciplinary VRS educational content that integrates the characteristics of nursing, education, and engineering and confirmed its feasibility as effective simulation education. Compared with conventional practical nursing training, this VRS content was valuable, allowing students to perform tasks independently and to experience the overall flow of nursing. The physical training environment was well-implemented visually, and the multimodal interaction increased immersion and presence. The VRS was also useful for enhancing individual nursing competencies through one-on-one training. However, keyword-based voice interactions

were a major obstacle to immersion, highlighting the need for additional research. Future research should explore the detailed learning effects and educational possibilities of immersive content using multidisciplinary design models. In conjunction

with conventional clinical practice and HFS, VRS content based on a multidisciplinary educational model can be used in practical nursing training in the post-pandemic era to optimize clinical competency.

Abstract

Background: Regulatory and professional nursing associations have an important role in ensuring that nurses provide safe, competent, and ethical care and are capable of adapting to emerging phenomena that influence society and population health needs. Telehealth and more recently virtual care are 2 digital health modalities that have gained momentum during the COVID-19 pandemic. Telehealth refers to telecommunications and digital communication technologies used to deliver health care, support health care provider and patient education, and facilitate self-care. Virtual care facilitates the delivery of health care services via any remote communication between patients and health care providers and among health care providers, either synchronously or asynchronously, through information and communication technologies. Despite nurses' adaptability to delivering virtual care, many have also reported challenges.

Objective: This study aims to describe resources about virtual care, digital health, and nursing informatics (ie, practice guidelines and fact sheets) available to Canadian nurses through their regulatory and professional associations.

Methods: An environmental scan was conducted between March and July 2023. The websites of nursing regulatory bodies across 13 Canadian provinces and territories and relevant nursing and a few nonnursing professional associations were searched. Data were extracted from the websites of these organizations to map out educational materials, training opportunities, and guidelines made available for nurses to learn and adapt to the ongoing digitalization of the health care system. Information from each source was summarized and analyzed using an inductive content analysis approach to identify categories and themes. The Virtual Health Competency Framework was applied to support the analysis process.

Results: Seven themes were identified: (1) types of resources available about virtual care, (2) terminologies used in virtual care resources, (3) currency of virtual care resources identified, (4) requirements for providing virtual care between provinces, (5) resources through professional nursing associations and other relevant organizations, (6) regulatory guidance versus competency in virtual care, and (7) resources about digital health and nursing informatics. Results also revealed that practice guidance for delivering telehealth existed before the COVID-19 pandemic, but it was further expanded during the pandemic. Differences were noted across available resources with respect to terms used (eg, telenursing, telehealth, or virtual care), types of documents (eg, guideline vs fact sheet), and the depth of information shared. Only 2 associations provided comprehensive telenursing practice guidelines. Resources relative to digital health and nursing informatics exist, but variations between provinces were also noted.

Conclusions: The use of telehealth and virtual care services is becoming mainstream in Canadian health care. Despite variations across jurisdictions, the existing nursing practice guidance resources for delivering telehealth and virtual care are substantial and

can serve as a beginning step for developing a standardized set of practice requirements or competencies to inform nursing practice and the education of future nurses.

KEYWORDS

virtual care; digital health; nursing practice; environmental scan; telehealth; nurses; Canada; health care

Introduction

Background

Telehealth refers to the “delivery and facilitation of health and health-related services including medical care, provider and patient education, health information services, and self-care via telecommunications and digital communication technologies. Examples of the technologies used in telehealth include, but are not limited to, live video conferencing, mobile health apps, ‘store and forward’ electronic transmission, and remote patient monitoring.” [1]. During the COVID-19 pandemic, a transition to virtual care became necessary to protect the public and ensure the continuity of health services. Virtual health denotes the facilitation of the delivery of care services through any remote interactions between patients and health care providers and among health care providers themselves, whether synchronous or asynchronous, using information and communication technologies (ICTs) [2]. Various technologies were applied to facilitate virtual care such as SMS text messaging and email; phone; mobile health applications; electronic medical records; chatbots; remote monitoring technologies; and telecommunication applications such as Zoom (Zoom Video Communications), Skype (Skype Communications), FaceTime (Apple Inc), and WhatsApp (WhatsApp LLC) for video consultations [3-9]. Both modalities are subsumed under the umbrella term of digital health, which denotes the proper use of technology to improve the health and wellbeing of people at all levels.

Nurses providing care across a diversity of health care settings had to adapt to virtual care delivery. Despite their engagement and adaptability to this new form of care, many nurses also reported challenges. Those who have not previously used digital health technologies to deliver care had to quickly adapt and learn new skills, and some reported receiving limited guidance or best practice guidelines on how to provide care through these new modalities [10-13]. Before the COVID-19 pandemic, the most recent survey of practicing Canadian nurses’ use of technology identified that only 60% of nurses surveyed about the use of virtual care reported having adequate knowledge and skills to use these technologies [14]. A secondary analysis comparing data from the 2017 and 2020 versions of this survey identified that virtual care was predominantly delivered by nurse practitioners. Several factors were found to predict Canadian nurses’ use of virtual care, including their professional designation, perceived quality of care in the facility where they worked, the type of electronic record used, their perceptions of the quality of care they delivered through virtual care technologies, and their perceptions of the skills and knowledge needed to use these technologies [15]. In addition to gaps among practicing nurses, research has also identified that while new

graduate nurses have high digital literacy skills, they struggle to understand the broad spectrum of digital health technologies and their applications in health care [16]. Other studies identified that digital competence, organizational support, prior education about technology, and ongoing training and support are essential factors for effective and safe use and adoption of health information technologies [17-20].

Nurses are integral to the successful implementation and use of technology in health care. Currently, there are >459,000 regulated nurses represented by the Canadian Nurses Association (CNA) at the national level [21]. Provincial regulatory associations also exist across all 13 Canadian provinces and territories. As part of their mandate, nursing regulatory bodies address the registration requirements, standards for education and practice, code of ethics, and continuing competency to ensure nurses are qualified and competent to provide safe, ethical, and evidence-informed practice as well as are prepared to respond to emerging phenomena that influence population health needs and nursing professional practice roles [22,23]. They also develop documents (eg, practice guidelines and practice directives) that outline the activities the regulated nurses are authorized to perform [23]. Professional nursing associations are available to all nurses, nursing students, and nurse retirees, enabling these groups to have a voice in the policy and advocacy work related to profession-wide and societal issues that may have broader impacts on health and health care. In addition to these associations, nursing specialty practice organizations and interest groups serve to provide resources and support for professional development in a specialty practice area such as critical care [24]. Considering the expanded and ongoing use of virtual care and for nurses to thrive when providing care in this increasingly digitalized health care environment, it is important to understand how professional and regulatory nursing associations are contributing to supporting nurses in this area and what knowledge gaps exist in offering necessary support, training, and professional guidance for optimal nursing practice with technology. Addressing this knowledge gap could serve to encourage nursing regulatory and professional bodies to update existing resources or develop new ones, which may consequently contribute to motivating nurses to develop their competency in digital health and virtual care.

Objective

This study aims to describe resources about virtual care, digital health, and nursing informatics (ie, practice guidelines and fact sheets) available to Canadian nurses through their regulatory and professional associations.

Methods

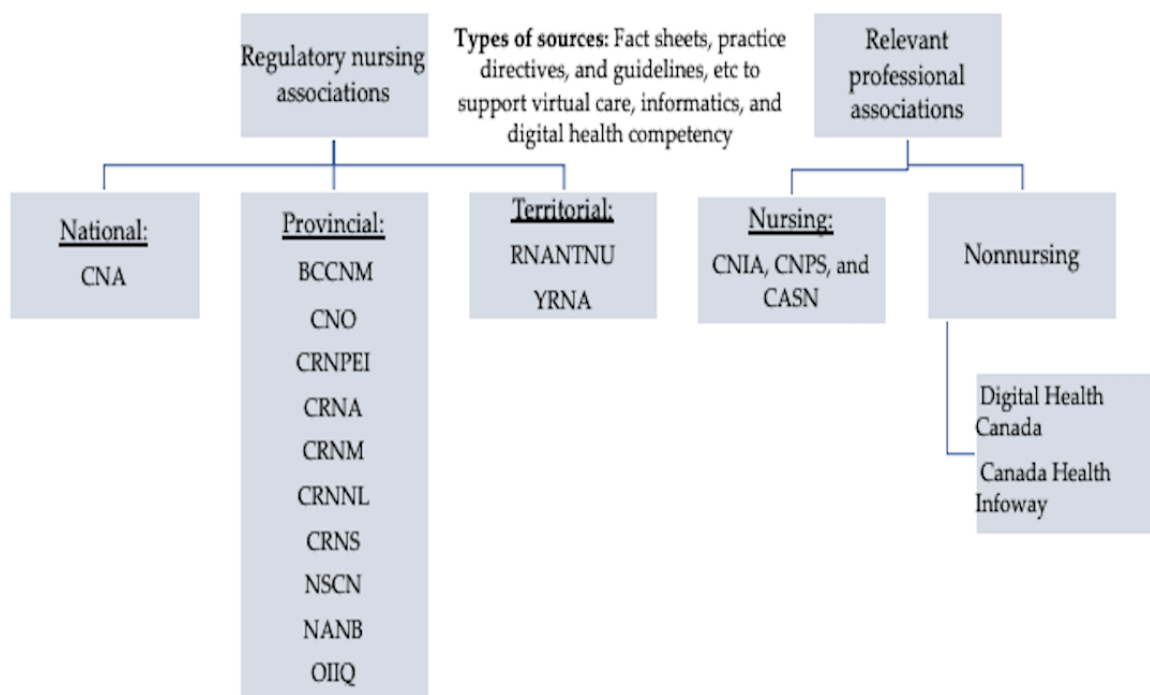

Overview

This study used an environmental scan method [25,26]. An environmental scan is often undertaken when there are emerging issues that necessitate an immediate investigation to determine their potential impact. Environmental scans originated in the business industry as a tool to inform strategic planning and policy decision-making by gathering, interpreting, and using information about the internal and external environment of an organization to guide future actions. Frameworks such as Strengths, Weakness, Opportunities, and Threats analysis or Political, Economic, Social, Technological, Legal, and Environmental are often used to guide this process [25,26]. In health care, environmental scans serve to collect, organize, and analyze information on issues in health care to make evidence-informed decisions, guide program planning, and inform public policy decisions [25]. Environmental scans are also different from other systematic literature searches such as scoping or systematic reviews and may incorporate different and diverse data sources and approaches for collecting information to answer questions of interest. Although the use of environmental scanning has increased in health service research, there is limited methodological guidance on its application. However, because scanning the environment can be extensive, determining the most relevant information sources

and outlining the scope of the scan by identifying clear objectives is recommended [25]. In this project, the environmental scan was guided by the following steps: (1) determining the scope of the environmental scan and data sources to be included, (2) scanning resources identified for information that is relevant to the focus of the research, and (3) analyzing and summarizing the information to identify strengths and limitations.

The environmental scan was conducted between March 2023 and July 2023 to identify and retrieve pertinent information and resources available to guide nursing practice or education about virtual care, digital health, and informatics for Canadian nurses. A search of the websites of national, provincial, and territorial Canadian nursing regulatory bodies and the websites of selected professional nursing associations, nursing specialty practice organizations, and some nonnursing organizations and associations was conducted. To locate the relevant available data on the websites of each organization and association, we used different search terms such as *digital health*, *nursing informatics (NI)*, *virtual care*, *telehealth*, *telenursing*, *telemedicine*, and *nurses*. The authors then examined what was reported in each record identified on each association website by reviewing the content, date, relevance, and the type of the resource. Nursing unions were excluded from this scan because their mandate is not related to professional development or regulation. Only information published in English was reviewed. Figure 1 summarizes the sources of data used in this scan.

Figure 1. Visual representation of the data sources used in the environmental scan. BCCNM: British Columbia College of Nurses and Midwives; CASN: Canadian Association of Schools of Nursing; CNA: Canadian Nurses Association; CNIA: Canadian Nursing Informatics Association; CNO: College of Nurses of Ontario; CNPS: Canadian Nurses Protective Society; CRNA: College of Registered Nurses of Alberta; CRNM: College of Registered Nurses of Manitoba; CRNNL: College of Registered Nurses of Newfoundland and Labrador; CRNPEI: College of Registered Nurses and Midwives of Prince Edward Island; CRNS: College of Registered Nurses of Saskatchewan; NANB: Nurses Association of New Brunswick; NSCN: Nova Scotia College of Nursing; OIIQ: Ordre des Infirmières et Infirmiers du Québec; RNANTNU: The Registered Nurses Association of the Northwest Territories and Nunavut; YRNA: Yukon Registered Nurses Association.

Data Analysis

We applied an inductive qualitative content analysis approach to categorize data extracted from the retrieved documents [27,28]. Inductive content analysis is an appropriate approach for descriptive qualitative analysis. It focuses on identifying easily observable items or data without the need to discern intent or identify deeper meaning. It uses a systematic approach to transform large amounts of data into a highly organized and concise summary of results that can be grouped into codes, categories, and themes. The Provincial Health Service Authority (PHSA) Virtual Health Competency Framework was also used to support the analysis and interpretation of the data [29]. Two reviewers independently completed the process of data abstraction and coding, and data were compared for accuracy to ensure consistency and rigor in the abstraction process.

Ethical Considerations

As per the ethics requirements at the University of Alberta [30], we did not seek ethics clearance because the research did not involve collecting input or information from human participants. We primarily relied on publicly available information that is legally accessible to the public.

Results

Overview

A total of 17 websites were included in this scan, of which 13 (76%) were for regulatory bodies (n=1, 8% national; n=10, 77% provincial; and n=2, 15% territorial), 2 (12%) were professional associations, and 2 (12%) were part of the relevant nonnursing organizations. On the basis of the nature of the information provided in the retrieved documents or resources, seven

overarching themes were identified: (1) types of resources available about virtual care, (2) terminologies used in virtual care resources, (3) currency of virtual care resources identified, (4) requirements for providing virtual care between provinces, (5) resources through professional nursing associations and other relevant organizations, (6) regulatory guidance versus competency in virtual care, and (7) resources about digital health and NI. These are discussed in detail in the subsequent sections.

Types of Resources Available About Virtual Care

Different types of guidance documents such as fact sheets, practice directives, guidance, practice guidelines, and general guidelines were identified on the web pages of nursing regulatory bodies (Table 1). The CNA issued a telehealth fact sheet in 2017 and did not provide national level guidance pertaining to telenursing practice or virtual care; however, it has identified virtual care as a priority advocacy area. Some associations provided documents in the form of fact sheets, guidance, and practice directives (College of Nurses of Ontario [CNO], College of Registered Nurses of Manitoba [CRNM], and College of Registered Nurses and Midwives of Prince Edward Island [CRNPEI]). Only 2 associations published telenursing practice guidelines for registered nurses and nurse practitioners (Nurses Association of New Brunswick [NANB] and the Nova Scotia College of Nursing [NSCN]). Some associations supplemented their guidelines with educational resources such as practice scenarios, case studies, and YouTube videos (NSCN and British Columbia College of Nurses and Midwives [BCCNM]), and some associations provided resources to support nurses' mental health and well-being (CNO). Some regulatory bodies provided external links to organizations, such as the Canadian Nurses Protective Society (CNPS), on their website.

Table 1. Websites of nursing and related organizations offering virtual care resources.

Organization	Virtual care	Concepts emphasized and general assessment
National and provincial regulatory nursing associations		
CNA ^a	<ul style="list-style-type: none"> Virtual care as an advocacy priority (2023) Telehealth fact sheet (2017) 	<ul style="list-style-type: none"> Virtual care has been identified as an advocacy priority Telepractice fact sheet has not been updated since 2017 No further guidance provided during or after the pandemic

Terminologies Used in Virtual Care Resources

Across the available resources, regulatory bodies used different terms and to some extent interchangeably, including telehealth, telepractice, telepractice nursing, virtual care, and technology.

In their fact sheet, the CNA used the term telehealth; similarly, the Registered Nurses Association of the Northwest Territories and Nunavut (RNANTNU) and the College of Registered Nurses of Saskatchewan (CRNS) used telehealth on their web pages to describe the care provided using ICTs. The CRNPEI, in their

practice directive document, used the terms telehealth nursing practice and technology in practice, whereas the CNO, in their fact sheet, used the term telepractice. In the CRNM guidance on telepractice, the term telepractice was used, but both the terms telepractice and virtual care were used on the web page. In describing telepractice, the CRNM also indicated that telepractice is also known as virtual care. Furthermore, the College of Registered Nurses of Newfoundland and Labrador (CRNNL), in a document provided on their website, used the term virtual nursing practice. The practice guidelines and guidelines provided by the NSCN and NANB, respectively, used the term telenursing and telenursing practice. At the same time, the College of Registered Nurses of Alberta (CRNA), on their web page, used the terms telepractice and virtual care simultaneously.

Some associations, including CNO, BCCNM, NANB, and CRNPEI, provided links to nurses' scope of practice and practice standards of practice documents on their web pages and in the documents. This implies that when providing virtual care or telehealth, nurses are also expected to abide by these overarching practice requirements; however, these documents do not explicitly discuss or guide nurses in understanding virtual care. Associations such as CNO, NANB, and NSCN had links to other registered nurse professional practice resources (eg, scope of practice, privacy of health information, code of ethics, code of conduct, and documentation practices) that are included in these documents, but these also did not have specific guidance on telehealth or virtual care.

Currency of Virtual Care Resources Identified

The information provided in the resources screened was evaluated using the Currency, Relevance, Authority, Accuracy and Purpose checklist [31]. This method evaluates different dimensions to ensure the credibility of a source of information. This scan used the description under the Currency, which examines the date of publication and the last date updated as well as the relevance of the topic or information, that is, determining if the information addresses current events. Relating to the description provided by the Currency, this scan focused on the COVID-19 pandemic, virtual care and nursing regulatory bodies, and professional associations' websites, as these sources are more likely to provide up-to-date and accurate information to their membership.

In 2023, the NSCN and NANB provided practice guidelines and guidelines to direct the provision of care in a safe, competent, and ethical manner. The current nature of these documents suggests that the NSCN and NANB noticed the increased use of virtual care and the importance of providing detailed guidelines to assist nurses in increasing their knowledge and capacity in telenursing. In addition, the CNO provided an updated version of their fact sheet on telepractice in 2023 while the guideline was being reviewed. Some of the associations have not updated their documents and information in recent times. The CNA last updated their telehealth fact sheet in 2017; CRNPEI updated their practice directive for telehealth nursing practice in 2019 and technology in practice in 2020; CRNA had information on telepractice and virtual care information on their web page dated 2020; CRNM guidance on telepractice was

published in 2020, an informational document on telepractice was also published in 2021, and the practice expectations spotlight—telepractice or virtual care—was posted in 2020; CRNNL published virtual nursing practice guidelines in 2020; and CRNS made the tag telehealth—nursing use of information and communication technologies available in 2020. As noted in the publication date of these documents, the surge for developing guidance about telehealth and virtual care occurred mainly during the COVID-19 pandemic.

Requirements for Providing Virtual Care Between Provinces

Regulatory bodies in 12 provinces provided a statement on the legislative requirement of practicing telehealth or virtual care in and out of the nurse's jurisdiction. Information from the Quebec's nursing regulatory body, which had the information in French, was not verified. The fundamental requirement, according to the regulatory bodies, is that nurses must have a valid registration in their jurisdiction. Most of the regulatory bodies, BCCNM, CNO, CRNPEI, CRNA, CRNM, CRNNL, NSCN, and NANB, described the legislative requirements around providing telehealth or virtual care when care is provided in the nurses' jurisdictions and across jurisdictions. The CRNNL, CRNM, CRNA, and CNO also provided additional information on the expectations for an out-of-province nurse in providing telepractice to residents outside their jurisdiction. Because of the variation in the registration requirement and the legal aspects involved, especially for out-of-province nurses, it is important for nurses to contact the appropriate authorities or organizations, such as the CNPS and regulatory bodies, before starting to practice in a virtual environment.

Resources Through Professional Nursing Associations and Other Relevant Organizations

The CNPS is a not-for-profit society that offers legal advice, risk management services, legal assistance, and professional liability protection to >140,000 nurses registered with it [32]. During the course of the pandemic, the CNPS took the initiative to look up regulatory and legal guidance available about virtual and telehealth practice for nurses in Canada and made these resources more accessible by providing the URL links to information already posted on the provincial nursing regulatory associations' websites. They also developed some educational resources in the form of case studies for nurses and nursing students to understand different scenarios and possible legal risks associated with virtual nursing practice. Most of these resources were freely accessible in the first 2 years of the pandemic, but now the learning portion of these resources is accessible to CNPS members only. The Canadian Nursing Informatics Association (CNIA) annual conference in 2023 focused on highlighting nurses' innovations and successes in delivering virtual care and directions toward accelerating nursing digital capacity. Digital Health Canada and Canada Health Infoway published up-to-date key resources related to virtual care and both organizations continue to hold regular webinars to facilitate and guide virtual care delivery.

Regulatory Guidance Versus Competency in Virtual Care

To ascertain whether current resources could be leveraged to further enhance nurses' competency in delivering virtual care, we compared the information provided by the regulatory nursing associations in the form of guidelines, practice directives, and fact sheets on telehealth or virtual care with the PHSA Virtual Health Competency Framework for health care providers delivering virtual health, which was developed based on a joint collaboration between the Office of Virtual Health in British Columbia, clinical partners, patients, and family partners. It also applied a comprehensive search of existing literature to identify the domains that reflect the foundational and functional

competencies needed to deliver safe care in a virtual environment [29]. As shown in Table 2, only the NANB and NSCN provided comprehensive guidelines, which to a large extent were congruent with most competency indicators proposed in the PHSA framework, although both associations used the term telenursing in their guidelines, as opposed to virtual health. The CRNPEI, in their practice directive, provided some competency expectations for nurses under the section virtual care modalities; however, the competencies identified were related to general technology use and policies without explicitly mentioning virtual care or telehealth. Similarly, the CRNM, in their guidance on telepractice, identified competency in relation to the use of technology and telepractice.

Table 2. Comparison between Provincial Health Service Authority (PHSA) virtual health competencies and the existing regulatory nursing guidance.

PHSA virtual health competencies Domains and competencies	Nursing associations		
	NANB ^a	NSCN ^b	CRNM ^c
Domain 1: virtual health practice requirements—encompasses awareness and understanding of legal, regulatory, and organizational virtual health policies			
<ul style="list-style-type: none"> • Demonstrates an awareness of the legal and regulatory requirements and practice standards that inform and guide delivery of virtual health 	✓	✓	
<ul style="list-style-type: none"> • Applies relevant organizational policies and decision support tools for safe and effective virtual health 	✓	✓	
Domain 2: technology for virtual health—encompasses an understanding of how to use organizational virtual health technologies appropriately and safely			
<ul style="list-style-type: none"> • Demonstrates the knowledge and skills needed to use virtual health tools 	✓	✓	✓
<ul style="list-style-type: none"> • Demonstrates an awareness and understanding of the privacy, security, and safety features of virtual health tools 	✓	✓	
Domain 3: equity-oriented care for virtual health—encompasses the ability to use equity-oriented care in virtual health practice			
<ul style="list-style-type: none"> • Applies principles of equity-oriented care to determine if virtual health can improve access or exacerbate barriers to care 	✓		
<ul style="list-style-type: none"> • Advocates for and leverages resources to ensure access to virtual health 	✓		
Domain 4: delivery of virtual health—encompasses knowledge and capacity to deliver safe, high-quality virtual health			
<ul style="list-style-type: none"> • Incorporate virtual health safely and appropriately into clinical practice 	✓	✓	
<ul style="list-style-type: none"> • Apply trauma awareness, cultural humility and sensitivity, and harm reduction in virtual health practice 	✓		
<ul style="list-style-type: none"> • Support patient's and family's informed decision-making on the risks and benefits of virtual health 	✓	✓	
<ul style="list-style-type: none"> • Determine what technological supports patients and families need when using virtual health tools 	✓	✓	
<ul style="list-style-type: none"> • Communicate clearly and respectfully in the virtual health environment 	✓	✓	
<ul style="list-style-type: none"> • Demonstrate the skills and judgment needed to safely and effectively complete a virtual health clinical interaction 	✓	✓	
<ul style="list-style-type: none"> • Recognize and respond appropriately to the patients' emotional, psychological, social, and physical needs in the virtual health environment 	✓	✓	
<ul style="list-style-type: none"> • Provide effective patient and family support and share education and follow-up recommendations in the virtual health environment 	✓	✓	
<ul style="list-style-type: none"> • Integrate into virtual health practice the appropriate referral process and documentation standards to ensure quality care 	✓	✓

^cCRNM: College of Registered Nurses of Manitoba.

Resources About Digital Health and NI

Within the Canadian context, NI competency involves the use of digital health tools to support information synthesis in accordance with professional and regulatory standards in care delivery [16]. As shown in Table 3, various resources are available on regulatory websites to strengthen nursing capacity in digital health and informatics. The CNA and CNIA in 2017

developed a joint position statement on NI, emphasizing the importance of embracing NI competencies to advance nursing practice and knowledge development. At the time of this writing, the development of a revised CNA and CNIA position statement is underway. Across the 13 provinces and territories, only 4 provinces had an NI group presence (Ontario, Alberta, Saskatchewan, and Nova Scotia). Some information could not be verified. For example, the New Brunswick NI group has a

Facebook account, but the last event posted on this page was in 2017. In addition, there is a web link on the Facebook page with a link to the NI group website, which is inactive. At the time of this writing, the Atlantic Canada Nursing Informatics Chapter has been created as part of CNIA in 2023, including the provinces of New Brunswick, Nova Scotia, Newfoundland and Labrador, and Prince Edward Island. The other association is the Association of Registered Nurses of Manitoba, which includes the Manitoba Nursing Informatics Association as a specialty group; however, the link to the Manitoba Nursing Informatics Association is inactive.

Most regulatory nursing associations included information related to the privacy of personal health information and electronic or paper-based documentation as part of standard practice documents such as the entry-to-practice competencies; however, there is limited discussion of NI or digital health concepts. Several associations, including the CRNS, CRNA,

and NANB, provided guidelines for social media and e-professionalism for nurses in 2021 and 2022, including the ethical and professional obligations of nurses. Although the Registered Nurses Association of the Northwest Territories and Nunavut also had a document on social media, this was before the pandemic, and it has not been updated recently. Professional nursing associations, including the CNIA and the Canadian Association of Schools of Nursing, have publicly available educational resources about digital health and NI standards such as “the Nursing Informatics Entry-to-Practice Competencies for Registered Nurses” to guide nursing practice and education. At the time of this writing, the development of a revised NI competencies is underway. Nonnursing organizations, such as including Digital Health Canada and Canada Health Infoway, offer extensive resources related to digital health in Canadian health care as well as health informatics competencies for health care providers. However, currently, it is not known how many nurses are actually using these resources.

Table 3. Websites of nursing and related organizations offering digital health and nursing informatics (NI) resources.

Discussion

Principal Findings

This environmental scan revealed several strengths and opportunities for improvement. The existing resources available to nurses for providing virtual care are mostly current and have evolved during the course of the COVID-19 pandemic. Despite variations in the types, depth of the information shared, and terms used to describe virtual care and guide nursing practice as described in the existing resources, the availability of such resources indicates that regulatory nursing associations were responsive to the needs of their members and to the evolving phenomena affecting health care and nursing practice in Canada.

Considering the ongoing use of virtual care and the potential risk of reverting to a large-scale use of this form of care delivery should events similar to the COVID-19 pandemic occur in the future, there might be benefits in adopting consistent terminologies as well as practice requirements and competencies. By having formalized standards of practice and competencies related to telehealth, telenursing, or virtual care and constantly updating them to reflect current needs across provinces, this will likely reduce uncertainties among nurses and minimize the tendency for taking a reactive approach to virtual care delivery. Such an approach will also better enable nurses to comprehensively develop their knowledge and competency in providing virtual care, as opposed to seeking information on a need-to-know basis. The PHSA Virtual Health Competency Framework and its compatibility with the existing comprehensive telenursing practice guidelines developed by the NANB and NSCN and the currency of these resources is promising. This framework can be used by regulatory nursing association to complement telenursing practice guidelines as well as by schools of nursing to teach nursing students about virtual health.

Having consensus on the scope of telenursing practice and virtual care across jurisdictions not only enables nurses to better respond to potential future events similar to the scale of the COVID-19 pandemic but also enables them to successfully adapt to the ongoing digital transformation taking place in Canadian health care [33-36]. This is important because upon reviewing available resources aimed at guiding and developing NI competencies as well as supporting nursing practice in digital health, it was found that these resources also varied. For example, some associations provided documentation guidelines to their members, but these were not consistently updated. In addition, they did not specifically address documentation in electronic health records or link to NI competencies.

Nurses represent the largest group of Canadian care providers, and regardless of their professional designation, they are at crossroads with digitalization [33,36]. As such, engaging the nursing workforce and supporting the development of new skills is vitally important to realize the full potential of digital innovations [35]. This will enable nurses to leverage digital technologies to further enhance nursing practice, facilitate accessibility to care, and improve overall health outcomes [33,36]. As part of their professional responsibility and

accountability, nurses must also pursue professional development opportunities in digital health and NI offered through their professional associations or other sources as well as to keep abreast with issues and phenomena that influence nursing practice and health care. It is also important that health systems critically reflect on lessons learned from the pandemic, including the benefits and challenges associated with virtual care delivery and proactively planning for what should be done differently going forward. Furthermore, it is incumbent upon health systems investing in digital health technologies to support nurses in adapting to this changing context of health care and to work collaboratively with regulatory and professional nursing associations and schools of nursing to develop digital care capacity among practicing and future nurses. An evidence of the commitment of health care governing authorities at the federal, provincial, and territorial levels to support efforts to increase technology adoption and virtual care is the report released by the Canadian Institute of Health Information, in which they developed a series of case studies based on semistructured interviews with representatives from provinces and territories [37]. These case studies addressed various aspects, including strategy, governance and direction setting, programs, and initiatives, providing an excellent resource to facilitate learning and policy direction regarding virtual care [37]. Similarly, Canadian Association of Schools of Nursing has recently secured funding from Health Canada to sponsor the project “Essential COVID-19 Skills for Graduating and New Nurses” [38]. Throughout the COVID-19 pandemic and continuing to the present, the CNA has engaged in focused advocacy work. This includes recommendations for implementing a pan-Canadian digital health strategy; investing in virtual care to support populations considered vulnerable; ensuring that health workers receive appropriate training; and providing financial support to help jurisdictions deploy essential infrastructure and access reliable, high-speed internet services [39].

Conclusions

Despite challenges during the COVID-19 pandemic, it also served as a catalyst for expanding access to care through digital health modalities such as telehealth and virtual care. Nursing associations play an important role in regulating and ensuring that nurses provide safe, competent, and ethical care. Considering that nursing practice with telehealth and virtual care has become mainstream, there are opportunities to build on these successes and mitigate potential risks in the future. Work completed to date to inform Canadian nursing practice in a virtual context is substantial and can serve as a beginning step for developing a standardized set of requirements to inform nursing practice in telehealth and virtual care and in the education of future nurses. This environmental scan followed a systematic search and provided important insights into the current state of resources available to nurses in Canada regarding virtual care through their professional and regulatory associations. To our knowledge, no prior work has been done on this topic. This scan may not be applicable to nurses outside Canada.

Acknowledgments

MK and AA received funding through the Social Sciences and Humanities Research Council Insight Development Grant, and a portion of this funding was used to pay for research assistantship costs.

Authors' Contributions

MK, AA, and LMN conceptualized the project idea, developed the initial draft, and led the discussion of findings. EMD, SI, SA, and DdC contributed to data searches, abstraction, and reviewing and editing the final paper.

Conflicts of Interest

None declared.

Abstract

Background: Clinical practice settings have increasingly become dependent on the use of digital or eHealth technologies such as electronic health records. It is vitally important to support nurses in adapting to digitalized health care systems; however, little is known about nursing graduates' experiences as they transition to the workplace.

Objective: This study aims to (1) describe newly qualified nurses' experiences with digital health in the workplace, and (2) identify strategies that could help support new graduates' transition and practice with digital health.

Methods: An exploratory descriptive qualitative design was used. A total of 14 nurses from Eastern and Western Canada participated in semistructured interviews and data were analyzed using inductive content analysis.

Results: Three themes were identified: (1) experiences before becoming a registered nurse, (2) experiences upon joining the workplace, and (3) suggestions for bridging the gap in transition to digital health practice. Findings revealed more similarities than differences between participants with respect to gaps in digital health education, technology-related challenges, and their influence on nursing practice.

Conclusions: Digital health is the foundation of contemporary health care; therefore, comprehensive education during nursing school and throughout professional nursing practice, as well as organizational support and policy, are critical pillars. Health systems investing in digital health technologies must create supportive work environments for nurses to thrive in technologically rich environments and increase their capacity to deliver the digital health future.

KEYWORDS

digital health; new graduate nurses; nursing practice; workplace; informatics

Introduction

Clinical practice settings have increasingly become dependent on the use of digital or eHealth technologies such as electronic health records, telehealth, mobile health, and medical devices to name a few [1,2]. The COVID-19 pandemic has also contributed to the increased use of digital technologies to facilitate virtual care delivery, creating both opportunities and challenges for care providers and patients [3-5]. Digital health

refers to the "proper use of technology for improving the health and well-being of people at the individual and population levels" [6]. According to the World Health Organization, digital health expands the concept of eHealth, with a wide range of smart devices and connected equipment. It also encompasses other uses of digital technologies for health such as the Internet of Things, artificial intelligence (AI), big data, and robotics [7].

Recognizing the increased use of digital health across health systems, the International Council of Nurses [8] has recently

released a position statement affirming the central role of digital health in contemporary nursing practice and the importance of developing the skills and competencies of nurses through the integration of digital health content in formal undergraduate and postgraduate curricula and participation in continuing professional development. These recommendations have also recently been echoed by the Canadian government [9] identifying digital preparedness as one dimension of actionable strategies that should be put into place to mitigate the administrative burden associated with the use of digital tools by nurses as primary users of these technologies.

Digital capabilities or informatics competencies are critical core requirements for safe nursing practice with technology. In Canadian health care, nurses must be able to use digital health technologies to support information synthesis and patient care in accordance with their professional and regulatory standards [10]. Despite efforts to enhance digital preparedness among future nurses, research involving senior-level nursing students identified that most learning about digital health is taking place in clinical settings with limited theoretical education in the classroom [11,12]. In a practice-based profession, such as nursing, it is inherent that nursing students are socialized into their professional roles by observing and interacting with nurses [13] in health care settings that they go to for their clinical education; however, practicing nurses involved in mentoring nursing students also have limited digital capabilities and report challenges with technology use, mostly among older nurses [14,15]. Assumptions also prevail that younger nurses are tech-savvy because they were mostly born in the digital age; however, despite being described as digital natives, research suggests that they do not naturally have positive views on using technology for care provision [16] nor do their digital skills easily transfer to the clinical context [13,17-19].

While nursing programs acknowledge the importance of integrating digital health content at all levels of nursing education, research involving nurse educators [20] and academic administrators [21] from across schools of nursing in Canada revealed that nurse educators have limited knowledge and capacity to teach informatics, limited awareness about informatics competencies, and limited resources to teach nursing students about digital health applications in clinical practice. For example, 65% of these schools indicated they do not have access to a training version of any electronic health record system to teach students about this technology. Although these observations are focused on Canadian nurses, similar gaps have been reported in other countries [18,19,22,23]. Potentially, these gaps can have a negative impact on nursing graduates as they transition to the workplace. According to a recent study [24] involving clinical managers and newly registered nurses (RNs) in the United Kingdom, researchers identified several factors impacting these nurses in the workplace including technology infrastructure, time, skills, digital literacy training, support, leadership, familiarity, and confidence: creating barriers to optimal nursing practice with technology. It is vitally important to support nurses in adapting to more digitalized health care systems; however, little is known about Canadian nursing graduates' experiences. This study sought to (1) describe newly qualified nurses' experiences with digital health in the

workplace, and (2) identify strategies that could help support their transition and clinical practice with digital health technologies.

Methods

Design

An exploratory descriptive qualitative design was most appropriate considering the limited research available [25]. This design aligns with the philosophical perspectives of pragmatism and constructionism and is concerned with understanding and describing the human experience within its unique context [25]. Through inductive and dynamic research processes, the researcher explores the subjective experiences of participants and their perceptions through a collection of data that describes the "who, what, and where of the events or experiences" [25]. In this study, qualitative data was collected from semistructured interviews with nurses, a technique suitable for collecting data that is open-ended and explores participants' thoughts, feelings, and beliefs about a particular topic [26].

Participants

Qualitative studies recommend 1-30 informants [25-28]. In this study, the number of participants was guided by the concept of information power to interview sampling, which indicates that if the sample holds more information that is relevant to the actual study, a lower number of participants is needed [27]. The five aspects of information power further supporting this approach were (1) the specific or narrow study aim, (2) participants holding characteristics that are specific to the study aim and identification supported by suitable recruitment strategies, (3) theoretical support, (4) the quality of dialogue with participants, and (5) a thematic cross-case analysis approach [27]. In addition, the concept of thematic saturation, which means researchers would stop data collection when there is no new information shared by participants [26], was also considered. Participants were newly qualified nurses who graduated from 2 undergraduate nursing programs in Eastern and Western Canada (WC) in the last 2 years and have been working in clinical settings that have digital health technologies, such as electronic health records, regardless of the stage of implementation. Purposive and snowball sampling techniques were applied to enroll interested participants with consideration of various sociodemographic backgrounds [28].

Data Collection

To recruit participants, administrative staff in the selected nursing programs circulated a recruitment poster invitation via a listserv email to graduates from these programs, and potential participants were asked to contact the researchers to express interest in participating in the research. An interview guide (Textbox 1) was developed by the researchers based on their expertise in this area and the general literature using open-ended questions and prompts to facilitate the discussion regarding aspects related to new graduates' experiences with digital health [26]. Pretesting of the interview schedule was accomplished by engaging 2 research assistants (RAs; RS and DC) involved in this project in a demo interview, as both were recent graduates. No further revisions were introduced to the initial interview

guide. In addition, sociodemographic data, including age, gender, and work setting, were collected at the beginning of interviews to understand the characteristics of participants and the context of their practice environments. Interviews were facilitated by RAs (RS and DC) without the presence of the researchers who were also faculty members and may have interacted with these participants when they were students, as such minimize undue discomfort to participants. The interviews were held via Zoom (Zoom Video Communications, Inc), each

lasting between 45 and 60 minutes, and participants had the option to turn their cameras off during the interview. Although options for in-person interviews were offered, participants preferred a digital approach considering their busy clinical schedules, and this mode did not impact the quality of dialogue between the participants and the interviewers. The audio-recorded interviews were then uploaded to a secured SharePoint (Microsoft Corp) drive and later transcribed verbatim by a professional transcriptionist service provider and records.

Textbox 1. Interview guide.

- Could you share what types of technologies do you currently use in your day-to-day practice as a registered nurse? Prompt: Could you share some examples?
- Could you describe your experiences when working with these technologies? Prompt: what makes your work easy/difficult?
- Could you describe your experiences of learning on how to use these technologies? Prompt: In the nursing school/in the workplace?
- What suggestions do you have to enhance newly graduated nurses' experiences of using digital health technologies? Prompt: in the nursing school, in the workplace, other?
- Is there anything else you would like to share?

Data Analysis

RAs (RS and DC) received training in qualitative data analysis and an orientation to the data management software. Data were uploaded into the NVivo software (Lumivero) in a deidentified format to facilitate data management and analysis. An inductive manifest content analysis was used considering the research is exploratory. In this approach, the goal is to “describe what the informants actually say, stay close to the text, use the words themselves, and describe the visible and obvious in the text” [28]. The unit of analysis (ie, the sample) involved analyzing data from all the participants in its entirety [28]. The two RAs were involved in data analysis, which began by having each one independently read the interview transcripts line by line, several times, to make sense of the data and whole and achieve familiarity [28-30]. Open coding (ie, identification of meaning units and labeling each with a code) was then done by having each RA independently analyze 2 transcripts. These pilot transcripts were then compared and discussed to enhance reliability before coding the remainder of the data. At this stage, we also created a coding list, including all the meaning units identified along with an explanation of the codes to enhance intercoder reliability and reduce cognitive fatigue. The initial coding was then done by the research team without additional changes introduced. Condensing of the meaning units was then done to identify categories and subcategories without losing the content of the unit, which was followed by grouping of categories with similar events into main categories. The researchers then constructed the themes based on the analysis of these data (Multimedia Appendix 1). The resulting analysis was reported in a narrative format. Rigor was enhanced by reviewing the coding scheme against the interview data and the involvement of all team members in the discussion and interpretation of the findings [28-30].

Ethical Considerations

Ethics approval was obtained from an Ethics Research Review Board in the WC research site (Pro00112596), and secondary approval from an ethics board at the university in Eastern Canada (EC; A12-E69-21B). Participants were provided with an information sheet along with the consent form and were given the opportunity to ask questions and verify any aspect related to the research before providing their consent for participation. Participants were also assured that they could opt out at any time without penalty. To protect privacy and confidentiality, the interview data were deidentified by using a code (eg, participant 01-E and participant 01-W). Each participant received a small gift certificate to convey appreciation of their time.

Results

Demographic Characteristics of Participants

A total of 14 participants were interviewed, 6 participants from WC and 8 participants from EC. Of those 14 participants, 8 participants were younger than 25 years old, 4 participants were in the age category of 26-30 years, and 2 participants were in the age category of 31-41 years. Participants were mostly females, except for 1 male participant. They worked in large urban hospitals in a variety of units including emergency room, intensive care, internal medicine, trauma surgery, and operating room.

Digital Health Technologies in the Workplace

In their current practice environments as RNs, participants indicated that they used different hardware (eg, laptops, mobile devices, workstations on wheels, and portable computers), clinical information systems (CIS), and medical devices and equipment (Table 1).

Table 1. Types of digital health technologies currently used in practice.

Technology	Western Canada site	Eastern Canada site
CIS ^a : new, old, and hybrid systems	<ul style="list-style-type: none"> • EPIC CIS/EMR^b EDIS or Millennium • NetCare Electronic Health Record Pyxis • Vax Meditech 	<ul style="list-style-type: none"> • OACIS (EMR used universally) • MedUrge (EMR used in acute care only) • VSign (mobile app to access Oacis remotely) • PANDAWebRx (formerly known as GESPHARxLite; eMAR used at some sites)
Medical devices and equipment (some devices are connected to newer CIS systems, and others are stand-alone with paper charting)	<ul style="list-style-type: none"> • Sphygmomanometer for blood pressure • Cardiac monitors • Glucometers • Bladder scanners • Transcutaneous bilirubin meter • Dopplers • ECG^c machines • Pulse oximeter for O2 Saturation • Temperature probe 	<ul style="list-style-type: none"> • Philips monitors (syncs to Oacis) • Nova glucometers (syncs to Oacis) • BBraun IV pumps • Apple watches (in terms of patient education and telemonitoring) • Continuous glucose monitors used by patients

^aCIS: clinical information system.

^bEMR: electronic medical record.

^cECG: electrocardiogram.

Key Findings

Overview

Data analysis revealed three themes: (1) experiences before becoming an RN, (2) experiences upon joining the workplace, and (3) suggestions for bridging the gap in the transition to digital health practice. These themes are discussed below with illustrative quotes from the participants.

Theme 1: Experiences Before Becoming an RN

This theme includes the categories: (1) academic, (2) clinical, and (3) personal experiences. Most participants stated having familiarity with technology before joining their schools, and perhaps because of that, it was assumed that they were highly literate with technology since they grew up with it and have used it frequently in their daily lives. In a way, this made learning about technology easier, but in other cases, it also created barriers. According to one participant:

...sometimes I feel like there's an assumption that maybe we know more than we do, just because of the age we are ... we know how to use things like a phone, or the computer, or whatever, but it's used in a different way in practice. [P5, WC]

This sentiment was shared by another participant who noted that individual differences should also be considered:

I think it's individual, some people are just a little bit more inclined to be using it [technology] and have an easier time. [P2, EC]

At the time participants were in school, they indicated being aware of the relevance of digital health technology (DHT) to nursing practice. Their education involved varied exposure to theoretical and laboratory training, with most learning taking place in clinical settings, but this was not without challenges. A participant described it as follows:

It was very much like somebody handed you a cheat sheet that just told you like, Type in these numbers,

and then you will find your [Laughs] ... your medication page for this patient, and you can enter your medications. So, we got that from our clinical instructor, and then different nurses had different workflows. They would show us, this is how to print out my MAR, or this is the time of day when I'll go and log that I've given my medications. [P1, WC]

The depth and breadth of these experiences were also noted by another participant who further elaborated:

At the beginning of every clinical, we had somewhat of an orientation on the first day where we would go into the unit where we'd be doing our stage and we would get a little session on how to use the different platforms that the unit uses ... They would show us a brief overview of the different tabs that are available and what kind of information you can get and that kind of stuff. [P3, EC]

Another participant added:

Even just things of like having to do an ECG on someone ... Where do I put the other ECG tab? Because that's an actual thing that happens ... nobody comes in looking perfectly healthy and pristine as like the students that are in the program. [P7, WC]

With respect to learning experiences in the classroom, the majority indicated receiving limited and broad education about DHT, with some having mixed feelings about these gaps. As described by one participant:

We would talk about it in lectures ... I don't really remember ever doing anything like digital in labs. [P5, WC]

Another participant agreed adding:

During my studies, it was less obvious ... it wasn't through my classes that I learned about these technologies, it was more when I was using it in practice. [P7, EC]

One participant went on saying:

There are so many unspoken things in nursing ... I always found myself, a lot of times, getting feedback from the instructor saying, "You should know this," and me being like, "I didn't know that I had to ... I didn't know that I didn't know that I was supposed to know this. [P7, WC]

Some participants did not make sense of DHT and its relevance to nursing practice until they had experienced its expanded use; somewhat creating a sense of urgency that they should learn more about it. A participant explained:

It wasn't until the pandemic, really, that I understood. Now, this is what telehealth is used for; this is the function, this is what it can do, it can bridge the gaps ... it was mostly the pandemic that really changed my mindset there. [P8, EC]

The large-scale transition to a new electronic record system was also mentioned:

...like not built into our curriculum, for example, when we would have guest speakers or informal discussions, we would always talk about electronic charting system because it was like a pretty big deal for the implementation of this provincial system in phases... [P4: WC]

Theme 2: Experiences Upon Joining the Workplace

This theme includes two categories: (1) facilitating and (2) hindering experiences regarding the use of DHT in the workplace.

Hindering experiences discussed by participants included aspects related to training on CIS and medical devices and support resources, the IT infrastructure, and the potential impact of these challenges on their practice. Upon starting their practice as novice nurses, most participants indicated receiving either limited or condensed DHT training over a short period, which despite their tech-savviness, found to be a little overwhelming. This thought was shared by a participant who mentioned:

Our orientation for [___] was fairly short ... it was a lot of self-learning on how the program works ... you just have to play around with the program to kind of understand how it works. [P1, EC]

Another participant added:

We never received any kind of formal training on how to interact with patients using telehealth. Not even in formal training, you are kind of thrown into that world and expected to pick up the phone and have these conversations. [P3, EC]

Another participant shared

They'll teach us if we're the nurse for that patient on how to use it [a medical device]. But it's not like a full unit thing ... it's kind of limited for 30 minutes ... and then the one nurse that has the patient that day. I mean, when that nurse leaves, another nurse comes in, how are they going to help the patient with this device? [P1, EC]

Participants also mentioned fragmentation of digital health across the health care system, exacerbated by a lack of interoperability, with less technology integration in rural settings. When working with hybrid or outdated systems, new graduates felt more prone to making errors while transferring patient information between different platforms. As one participant described:

I'm not looking to make my job easier. I'm looking to make myself more effective, and I would be significantly more effective if I had access to everything and could spend less time fumbling through papers and, you know, clicking on screens, and could do things faster; then, I can spend more time actually with my patients... [P1, WC]

Participants also discussed that patient care became less efficient when the system was not user-friendly, the technology was outdated, the system lagged, IT glitches were not solved quickly, and there were not enough computers on the unit. All these issues increased concerns regarding patient privacy and confidentiality, safety, and potential legal liabilities to the nurse and the organization. A participant explained:

Because sometimes that happens, you know, one computer at the nursing station is not working, you go on another one, everything is down. And it came back within like 15-20 minutes. That's a long time when I need to call a doctor to see a critical value. Maybe it doesn't sound like a lot, but 15 minutes for the system, the entire system to be down is a lot. And when that was going to happen, it was a near change of shift. So, we weren't sure if the care plans were going to print for the next shift. So, we had to start writing them out. This is not a feasible way to be doing this. In that case, we were all lost. Even the people who had been there for 20 years didn't know what to do. I was asking people, "What can I do here?" Nobody knew. So, not really good. [P8, EC]

These practices were perceived to consume valuable nursing time that could have been spent in the clinical care of patients as a participant explained:

When we take time trying to fix a machine that wasn't working so that we could take patients to monitor their cardiac function, then it takes away from our ability to get to know patients and to treat them more holistically. [P5, EC]

Multiple participants also voiced concerns regarding inconsistencies in how nurses documented electronically, and how these differences although sometimes helped them learn different strategies, also caused confusion and could potentially result in legal or patient safety issues as one participant described:

I think there are some discrepancies that could lead to some actual challenges for patient safety. [P5, EC]

Some also indicated redundant charting or copying electronic information from one platform to another, sometimes including an analog step requiring a physical document to be scanned. According to one participant:

Well, I know something happened that day, but nothing got charted about it, or there is not very complete charting about that incident, because that nurse prefers to chart everything in her flowsheets and doesn't write a lot in her note. [P2, WC]

These issues were further compounded by the limited support and resources available to new graduates during night shifts and on weekends such as access to clinical nurse educators (CNEs) and tech support as one participant explained:

When you are on a dayshift, there's lots of extra support. It is a little bit tougher if you are on evenings or nights because those extra supports, like the managers and educators, aren't around. [P2, WC]

On the other hand, participants discussed factors that facilitated their experiences with DHT including having access to a wide range of technologies to support care, being adaptable, and positive workplace culture. Having access to technology that worked well enhanced efficiency including time-saving actions such as the convenience of having prompt access to patient information in one system, which enabled prioritization of care, clinical decision-making, standardization, and continuity of care. According to one participant:

I think it [CIS] has definitely made me more detail-oriented, especially now that I've been using them for a little bit over a year ... there are so many things that you're thinking about day-to-day with every single patient, ... okay, what are the priorities for my patient, and what am I looking for? What could go wrong? What do I need to keep in mind? [P2, WC]

Some participants also talked about the technology being helpful in giving them prompts about things they have learned about but could not easily remember. For instance, some of the newer CIS systems provided help pages with information about managing patient care and relevant nursing actions, which facilitated their practice in busy clinical environments as they were also adapting to their new roles as independent RNs:

It's been a great facilitator in my learning experience as a new grad nurse because I'm able to stay on top of everything more easily ... it gives us the opportunity to focus on patient interaction and on what's important. [P5, EC]

Participants acknowledged that learning about technology is a learning curve and therefore being adaptable is key. In addition, ongoing learning about technology is important—not only upon orientation to the unit. As explained by participant:

...there was really just like a different learning curve ... now it's been like over two years since the system has been implemented, everyone is pretty much onboard ... there's still some of our staff that, you know, like need help with certain things, every now and then, something will surprise you and like you'll realize you're still learning, or like they'll update the software. [P4, WC]

New graduates' practice with DHT became easier through the support of nurses in the unit, accessibility to other resource persons, such as CNEs and superusers, having the opportunity

to learn from more experienced nurses and in exchange teaching them technology-related skills, and the mentoring behaviors of nurses toward the new hires. According to one participant:

The culture of the unit is so supportive in so many ways, I think that it exceeded all my expectations for the support that I feel in being able to ask questions and share knowledge with other people. [P5, EC]

Other factors contributing to positive experiences, as discussed by some participants who have transitioned to a new system, included working with integrated CIS systems and having access to a playground or a sandbox during their initial training. In addition, those who have had positive training and education experiences with DHT as nursing students were also more likely to support new incoming nurses as they transitioned to their new workplace as described by one participant:

Because I was a student when I started using [___] in practice, I got a little bit more of a transition into how the system worked ... when we've new hires come in who've never used electronic charting before, we always try to go around and see patients together, and we'll say like, "Okay, you'll chart with so-and-so today, so that, you know, you can get used to the system and play around with it, and just get comfortable." [P4, WC]

Theme 3: Suggestions for Bridging Gaps in Transitioning to Digital Health Practice

Participants shared different strategies on how to improve newly qualified nurses' practice with DHT discussing aspects related to improving the education of nursing students, and strategies that can be introduced to enhance new graduate nurses' experiences once they join the workplace.

With respect to nursing education and looking back at their own experiences as nursing students and recognizing the expanded use of technology in the health care system, participants would have appreciated if they had had adequate education and exposure to DHT during their school to help them make better sense of how DH relates to nursing practice and the clinical care of patients. One participant shared:

I feel like a lot of nursing school time was spent on different things that don't necessarily translate to current practice, nor does it translate to digital health information. I've never made a digital care plan in my time as a registered nurse, but we did spend a lot of time on care plans in school. [P3, WC]

They felt nursing education could be improved by providing relevant hands-on learning that goes beyond knowing how to use the system to critically think about why a nurse is doing these actions. The participant went on to share an example of how this looks like to them:

...Here's this patient that you have. These are the computer systems that you're using. What are the checks that you need to do on the computer system? What do you need to look at? What information do you need to pull out of the system? How would you chart for this specific patient? "How do you interact

with other disciplines within the specific computer system? ... Like that would have been very helpful. [P3, WC]

Recognizing the changes taking place in health care with respect to technology integration, participants stressed the importance of having both dedicated and focused theoretical and clinical education on core concepts relevant to DH in undergraduate nursing education. Examples of the topics that participants discussed included the “how” and “why” of DH technology, ethical issues involving the use of DH technology, privacy, confidentiality, information security, legal implications, medical devices, and the different DHTs currently in use in hospitals and community settings, as well as newer innovations, technologies, and services that will be introduced in the future. According to one participant:

The reality is that tech is really taking over, and it is the future. I'm hoping that manually writing in charts is going to be a thing of the past. And so, to integrate that as early on as possible, the better, it's a reality, it's there. There's no need to leave it on the sidebar until later. [P2, EC]

Another participant mentioned:

I think that having a whole course on digital health would be very interesting, because I feel the topic of artificial intelligence is a big topic, especially recently, and there's a lot of innovation happening with that ... I think it would need to be already applied in the hospitals though for them to fully absorb the information and see the practical application of what they're learning. [P1, EC]

Participants also emphasized the importance of exposing nursing students to DHT used in clinical practice; creating opportunities for hands-on learning while in the nursing program as opposed to learning about them when opportunities arise in clinical training sites. These experiential learning experiences were viewed as essential to enhance confidence and competence. One participant shared:

Definitely, built-in training in school for everyone, not just if you're going to a hospital that uses an EMR. I think everybody needs it. [P4, WC]

Another participant elaborated:

I think having maybe a seminar on how to use particular systems, such as MEDITECH, VAX, if these are systems that are widely used in hospitals, and then in your clinical settings, it'd be nice to kind of have that training beforehand, even just like an introduction to these types of things. Because at school, the training was mostly on the unit, for that specific clinical course. [P3, WC]

Regarding workplace strategies, participants emphasized the need for creating opportunities for nurses' engagement, particularly younger ones, in technology-related decisions and the role of nursing leadership in this process as one participant explained:

It seems like a lot of time, there's not a younger generation involved in the process [technology] ... they're much led by people with experience. [P7, WC]

Noting the expansive digitalization taking place in health care, another participant added:

I definitely think that there should be safety checks if you're really going to be pushing everything into Digital Health, everything needs to be looked after and evaluated or tested properly before it's implemented ... I think you can evaluate it from different ways, like patient outcomes, you could look at the nursing team, the people who are using it day-to-day, you can evaluate them, you can see where they're at with the use. [P8, EC]

Participants also emphasized the importance of creating opportunities for professional development and ongoing learning as the field of technology continues to evolve:

Continuous learning ... that's something that will always be necessary when it comes to technology, based on the advancements that are made every day and hopefully will continue to be made within these units. [P5, EC]

These strategies were viewed by participants as an indication of support and actions that convey commitment from the organizations and leaders toward enhancing new graduates' abilities to effectively adapt to the current technology-rich work environment and make full use of DHT to improve practice and patient outcomes. A participant described:

...that support looks like booking you in for paid training, which the managers do at the site that I'm in. Being advocates for change, and being advocates for a new system, answering concerns that people may have, and having an in-depth knowledge of the system that's coming, and not just, "Oh, this new system's rolling out, and other people will know how to use it. [P3, WC]

Discussion

Principal Findings

This study explored newly qualified nurses' experiences with digital health in the workplace. Results identified that participants' experiences in this study were influenced by inadequate education about digital health while in their nursing school in addition to challenges they faced upon joining the workplace including variable training and support, as well as technology infrastructure. Nonetheless, participants also identified several factors that facilitated their transition including having access to a wide range of technologies to support care, being adaptable, and positive workplace culture. Inadequate theoretical and clinical education about nursing informatics and digital health during nursing school creates unnecessary challenges for the already overwhelmed newly qualified nurse [5,23]. These nurses not only have to adjust to the complex practice setting and the team culture but also learn how to use the technology independently while providing care. To some of the participants, their abilities to connect the dots and

understand what digital health means were due to events, such as technology implementation or the COVID-19 pandemic, which also made them further question their readiness for digital health.

Educating nurses about digital health and nursing informatics is an area that has received much attention in the literature. Prior research has shown that educators and nursing programs are often challenged and confused about what informatics means, how it relates to nursing practice, and the application of digital health in care delivery [31,32]. In part, this may be attributed to the availability of multiple informatics competency lists; each presenting different perspectives on what to teach students and these are also getting dated with no focus on emerging technologies such as AI [33,34]. Other research has identified an urgent need for explicit and consistent teaching about digital health (existing and emerging technologies) concepts and their integration into clinical care [18,35,36].

Although there are efforts to bridge the theory-practice gap in relation to digital health education, clinical application experiences remain inconsistent and largely influenced by the availability of technology infrastructure in the schools of nursing and the clinical placement settings [11,13,18,20,21,23,34]. Additionally, limited or lacking professional and regulatory standards to inform nursing practice in digital health is also likely contributing to nurses' limited engagement with digital health beyond what is required in a specific work setting. These patterns are further reinforced by a persistent model of basic and condensed computer proficiency training programs in the workplace, limited on-site support and opportunities for continued learning, and vague organizational policies; collectively promoting a task-based approach to working with DHT. While the pandemic has served as a catalyst for more engagement in digital health overall, it also exposed several challenges as a result of abruptly transitioning to virtual care delivery with little support and training for care providers on the technologies used and the changing context of practice [5,37]. These factors raise concerns regarding nurses' capacity to actively participate in the evolving digital health ecosystem continuously being revolutionized by more sophisticated technologies such as AI [20,36-39]; further underscoring the importance of integrated and systematic strategies to address digital health readiness in nursing.

Despite these challenges, in this study, new graduates appreciated the benefits that DHT could provide to improve their practice and patient care. Furthermore, the positive role models and the supportive unit culture enabled a smoother transition, especially for those who experienced a system-wide technology implementation. In that case, senior nurses and newly qualified nurses found themselves in the same boat, and they had to uplift each other into the process. In exchange, new graduates offered to share their digital skills to support more senior nurses who are not as comfortable with technology; thereby, creating reciprocal benefits. Although these strategies proved useful for participants in this study and these behaviors should be encouraged, organizational support should be in place to facilitate nurses' work with DHT [8,24,40].

Newly qualified nurses in this study clearly recognized that technology integration in health care is on the rise and will likely continue to shape their practice and the practice of future nurses joining the profession in the years to come. Therefore, they emphasized the importance of continuing education, mentorship by nurse leaders, investment in quality CIS, ongoing support from health care organizations, and opportunities for nurses to be more engaged in the design, implementation, and evaluation of current and future DHT as paramount strategies to ensure that nurses are better prepared to effectively lead the digital health transformation. They also emphasized the importance of formal education about DH with meaningful linkage to clinical practice applications.

Academic and clinical learning experiences about digital health are intertwined and contribute to shaping nurses' perspectives about their practice in digital health. In educating the next generation of nurses, prelicensure nursing programs should provide early, comprehensive, and focused education about DH to enable nursing students to understand the full spectrum of digital health so they are work-ready upon joining the practice setting as independent practitioners [11,17,18,23,39,41,42]. Such education should also include core concepts of digital health, technological advancements and innovation, the benefits and potential impact of these technologies on the quality and safety of patient care, and professional nursing roles [36,37,39] with clear linkages to informatics competency requirements. This could be achieved by providing relevant theoretical content in the classroom and enriching that with experiential learning experiences in the laboratory, simulation, and clinical practicum throughout the program, as these experiences have been found to be beneficial for bridging the theory-practice gap, specifically in the context of learning about main DH technologies such as electronic records [12,22,39].

To improve nurses' practice in digital health, nursing organizations must also develop clearer and more consistent policies regarding existing and emerging digital health technologies and how these fit within nurses' scope of practice according to their professional roles [8,39]. Consequently, this translates to clearer digital health expectations for schools of nursing, nursing students, and employers [36,37,39,41]. In the workplace, as opposed to proficiency-based training upon onboarding and orientation to clinical practice settings, newly qualified nurses would benefit from structured educational courses to enhance their technology skill acquisition, as well as enable them to bridge their theoretical knowledge with workplace policies and expectations [17,39,43,44]. This also should include exposure to and education about the wide range of medical devices [45] used in the clinical setting (eg, infusion pumps, monitors, and parenteral nutrition devices), having access to consistent DHT support resources, particularly during night shifts and after hours, having opportunities for continuing education in digital health, and providing support for CNEs and nurses serving in clinical preceptor roles, and to all nurses according to their educational needs [4,11,17,39,40]. Collectively, this would improve nurses' inclination, uptake, and competency in digital health technologies, as well as facilitate a healthy organizational culture that values innovation,

change, and a growth mindset; hence, creating a win-win situation.

Furthermore, policies at the professional, organizational, and health system levels directly influence nursing practice in digital health and have implications for the quality of care, patient outcomes, health care service delivery, and quality improvement [1,8,9,38,39]. Currently, there is no digital health strategy for Canada and the eHealth strategy for nurses is outdated. Creating or updating these policies would help outline the digital health vision at the health system level, clarify the professional expectations for nurses according to their scope of practice, as well as other members of the health care team, facilitate the development of supporting and comprehensive digital health infrastructures including adequate funding, education, resource allocation, and strategies that promote innovation, creativity, continuous learning, and improvement, which ultimately facilitates optimal practice with DHT to improve patient and health care system outcomes [38-40]. More research is needed to explore how digital health knowledge gaps experienced by new graduates affect their entry to practice and transition to the workplace and their overall career trajectory. Interventional studies are also needed to evaluate new graduates' actual use of digital health technologies in the workplace and the impact on patient and organizational outcomes. Future studies are also needed to examine the role of clinical preceptors and clinical educators in developing competency in digital health. Although prior research has explored the status of digital health integration across Canadian schools of nursing [20,21], more research is needed that compares curricula between nursing programs and possibly other health professions.

Strengths and Limitations

To our knowledge, this is the first study involving newly graduated nurses and their practice with DHT in the workplace within the Canadian context involving participants from 2 provinces. In addition, the use of qualitative interviews enabled the collection of rich data about participants' experiences. Given that the data collected in this study is unique to the settings included in the research, this should be considered in the interpretation of the results and the transferability of findings to other contexts.

Conclusions

Although the study included participants from EC and WC, findings revealed more similarities rather than differences between participants with respect to digital health education, technology-related challenges, and their influence on nursing practice. Key strengths that newly qualified nurses in this study had included digital capabilities, awareness, and adaptability. However, inconsistent, or inadequate education about digital health during prelicensure nursing education, a proficiency-based approach to working with technology in the workplace, and variable technological infrastructure and support resources available created significant practice-related challenges that can detract nurses from patient care and limit optimal use of DHT. Digital health is the foundation of contemporary health care; therefore, comprehensive education about digital health during nursing school and throughout professional nursing practice, as well as organizational support and policy, are critical pillars. Health systems investing in DHT must also strive to create supportive work environments for nurses to thrive in technologically rich practice settings and further develop their capacity to deliver the digital health future.

Acknowledgments

MK and AA received funding through a Social Sciences and Humanities Research Council Insight Development Grant, a portion of this funding was used to pay for research assistantship costs. Creative artificial intelligence was not used in any part of the writing or analysis of this paper.

Authors' Contributions

MK, AA, and LMN conceptualized the project idea, developed the initial draft, and contributed to the discussion and interpretation of findings. RS and DdC contributed to data collection, analysis, reviewing, and editing of the final paper.

Conflicts of Interest

None declared.

Multimedia Appendix 1

Codes, categories and themes of interviews with new graduate nurses employed in the workplace.

Abstract

Background: Although digital health is essential for improving health care, its adoption remains slow due to the lack of literacy in this area. Therefore, it is crucial for health professionals to acquire digital skills and for a digital competence assessment and accreditation model to be implemented to make advances in this field.

Objective: This study had two objectives: (1) to create a specific map of digital competences for health professionals and (2) to define and test a digital competence assessment and accreditation model for health professionals.

Methods: We took an iterative mixed methods approach, which included a review of the gray literature and consultation with local experts. We used the arithmetic mean and SD in descriptive statistics, *P* values in hypothesis testing and subgroup comparisons, the greatest lower bound in test diagnosis, and the discrimination index in study instrument analysis.

Results: The assessment model designed in accordance with the competence content defined in the map of digital competences and based on scenarios had excellent internal consistency overall (greatest lower bound=0.91). Although most study participants (110/122, 90.2%) reported an intermediate self-perceived digital competence level, we found that the vast majority would not attain a level-2 Accreditation of Competence in Information and Communication Technologies.

Conclusions: Knowing the digital competence level of health professionals based on a defined competence framework should enable such professionals to be trained and updated to meet real needs in their specific professional contexts and, consequently, take full advantage of the potential of digital technologies. These results have informed the *Health Plan for Catalonia 2021-2025*, thus laying the foundations for creating and offering specific training to assess and certify the digital competence of such professionals.

Introduction

Background

The recent COVID-19 pandemic has highlighted the importance and potential of digital health in optimizing the quality, efficiency, and safety of health care [1-4]. Despite this, the adoption of digital tools and technologies in this field has been slow [5,6], and their full implementation in clinical practice has yet to occur [7]. Research has pointed to several factors as potential barriers, including technology, infrastructure, and financial resources [8,9]. However, it is the lack of digital health literacy that most commonly obstructs the implementation of digital health services [6]. Health professionals have been identified as a key factor in the digital transformation of health care [10]. Accordingly, they must be equipped with digital health competences, ranging from basic skills (eg, computer literacy) to more complex ones such as the ability to teach patients how to use technology and digital data sources safely and appropriately. Beyond informing patients about the availability and potential benefits of these technologies, physicians guide them on integrating these tools into their health care routines, playing a pivotal role in this process. For instance, they can guide patients on using portals for test results or mobile apps for medication adherence. However, for in-depth training on specific technologies, other professionals such as nurses or technical support staff may be better suited [2,6,9,11].

In 2016, a survey of 200 health professionals conducted by the European Health Parliament's Digital Skills for Health Professionals (COMPDIG-Salut) Committee found that, in most cases, health professionals felt that they lacked the appropriate skills to cope with the digital revolution in their professional practice [12,13]. Today, there is still a need for accessible, structured, and comprehensive education that will enable future health professionals to make the best use of technology and harness its full potential in terms of quality of care [5,14,15].

Health professionals need to develop digital health competences to keep up with new technologies and ensure that they can provide high-quality patient care [2,5,7,16,17]. To this end, we must first map the specific digital competences needed in health care (to provide the right kind of digital education) [18] and then create a model for assessing and accrediting such competences. While there is a growing number of individual digital health competence frameworks and reviews that focus on specific health care professions or settings [2], there is a lack of standardization in the definition of digital health competences themselves, including discrepancies and overlap among available frameworks and their approach to categorization [7]. This implies a need to continually update the competences required in this field as well as the methods used to assess them [7].

The Professional Dialogue Forum of Catalonia (northeastern Spain), one of the most advanced regions in Europe in the use of digital health technologies [19-21], highlighted "the need to improve information and communication technology (ICT) competences to advance in the use of ICT and the design of telehealth services" as one of the 17 primary current and future challenges facing health professionals [22]. The COMPDIG-Salut project was launched in response to the

identified needs, focusing on three aims: (1) defining a specific digital competence framework for health professionals, (2) creating a specific assessment and accreditation model for health professionals, and (3) designing actions to train and qualify health professionals in digital competences. Having determined the current digital competence level among Catalan health professionals [23], it is time to work toward achieving the aims of the COMPDIG-Salut project [12,24].

Objectives

This study had two objectives: (1) to create a specific map of digital competences for health professionals and (2) to define and test a digital competence assessment and accreditation model for health professionals.

Methods

Study Design

The research presented in this paper is the result of collaboration between the TIC Salut Social Foundation (Information and Communication Technologies in Health and Social Care Foundation) and the Universitat Oberta de Catalunya in Spain. As this was an observational exploratory study focusing on the analysis of digital competences in health care, a mixed qualitative and quantitative methodology was used following an iterative approach, and questionnaires were designed for data collection.

Specific Map of Digital Competences for Health Professionals

Narrative Review

A narrative review [25,26] was conducted to explore a broad range of existing digital competence frameworks in the field of health care and identify commonalities and strengths among the specific digital competences they included. We used the Google Scholar database to perform an iterative search for relevant frameworks based on a combination of search terms or keywords and appropriate Boolean operators.

Specifically, we searched for "digital competence framework" OR "digital capabilities framework" and "health professionals" within a search period spanning January 1, 2017, to October 13, 2021. The inclusion of potential frameworks of interest was based on the research team's knowledge and expertise on the topic. Only publications in English and Spanish were considered.

Inclusion and Exclusion Criteria

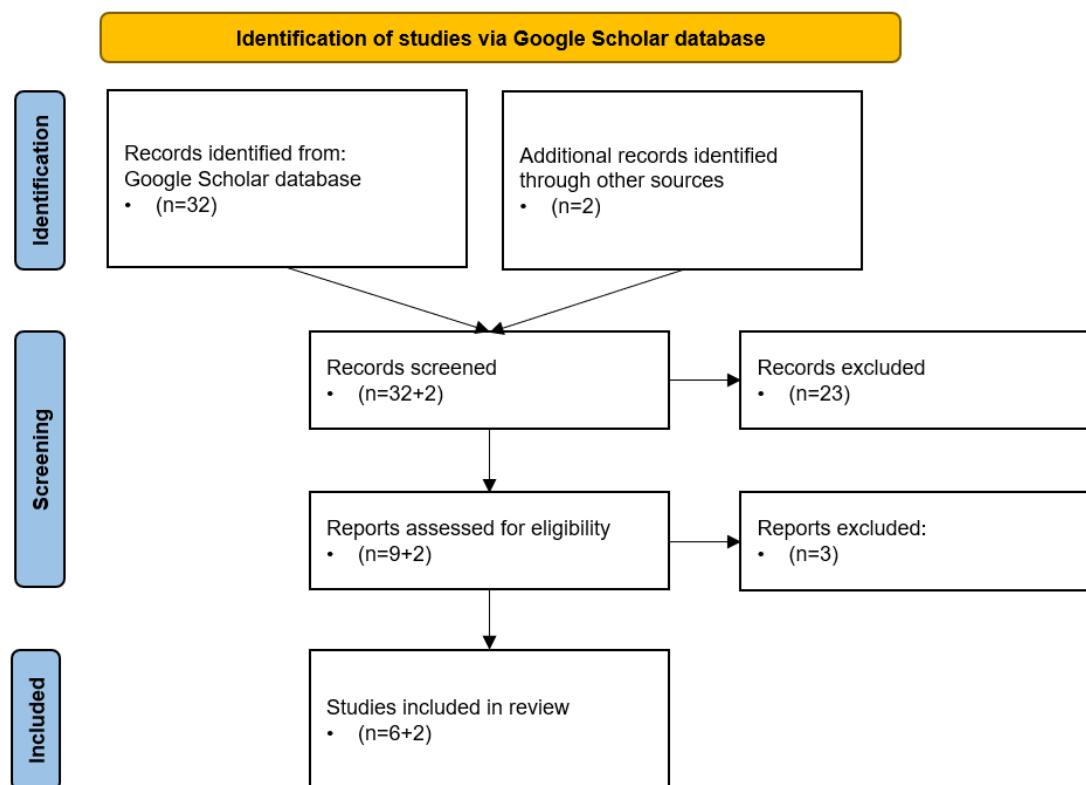

Deciding which frameworks to include in our review required careful and deliberate consideration to avoid bias and ensure valid results. To this end, we established explicit inclusion and exclusion criteria to select complete frameworks (eg, they needed to comprise digital competences specific to health care). Expert synthesis, discussion, and agreement among ≥ 2 reviewers were required to select frameworks for inclusion in the narrative review and ensure a consistent selection process.

To reduce selection bias and facilitate comparisons between frameworks, we ascertained the specific actions in thematic areas, the number of defined competences, the levels of achievement contained in them, and whether they distinguished

between health professions. We also looked for similarities between them and the European Digital Competence Framework for Citizens (DigComp) [27]. From the 32 results of the initial search, 9 (28%) frameworks were selected based on our inclusion and exclusion criteria. Of these 9 frameworks, 6 (67%) were selected for full-text analysis [28-33]. In total, 2 additional reference frameworks were included because of their relevance to mapping the digital competences of health professionals in Catalonia. These were the framework of digital competences

for health professionals developed by the working group of challenge 4 of the Professional Dialogue Forum [22] and the Accreditation of Competence in Information and Communication Technologies (ACTIC) [34], the government of Catalonia's framework for digital competence accreditation for citizens, which is currently in line with DigComp [27]. The latter was included because our proposed framework is closely related to it (Multimedia Appendix 1). The overview flowchart is shown in Figure 1.

Figure 1. Flowchart of the literature search.

Development of the Digital Competence Framework for Health Professionals and Area Specification

To develop the Digital Competence Framework for Health Professionals, we needed to specify the digital competences required of health professionals to manage digital health effectively, critically, and responsibly. Among the various initiatives led by the European Commission to improve people's digital literacy is DigComp, which is "an umbrella or meta-framework for current frameworks, initiatives, curricula, and certifications" [28]. Using DigComp as a reference, we mapped the 6 selected frameworks, projects, and studies to establish relationships and connections between the identified keywords and the most relevant competences. We ordered the competences by similarity to reveal thematic areas and common content (Multimedia Appendix 2).

Axial coding was then applied to this content distribution to define areas, competences, and indicators [35]. Coding was performed using the ATLAS.ti software (version 22; ATLAS.ti Scientific Software Development GmbH; Multimedia Appendix 3).

These areas and competences were validated by a panel of 12 experts using a web-based questionnaire developed by the researchers. Considering the validation criteria (wording, consistency, applicability, and relevance), the experts assessed the clarity and precision of the labeling and the description of the competence areas, validated them or suggested changes, and answered open-ended questions on each item. The experts' feedback was used to refine some of the definitions (Multimedia Appendix 4).

Indicators were then defined for each of the competences to determine which aspects should be assessed for all health professionals. Indicators are characteristics that can be observed through specific tests by either predefined measures or other qualitative information. Finally, 21 professionals of various profiles from the working group of challenge 4 of the Professional Dialogue Forum validated the framework of competence areas and indicators through a web-based questionnaire (Multimedia Appendix 5).

Digital Competence Assessment and Accreditation Model for Health Professionals

Test Creation and Administration

Having developed the Digital Competence Framework for

Health Professionals, the next step was to create an assessment and accreditation model. Given the variation in health professionals' roles, we could not reduce this process to a one-size-fits-all test. So, to ensure that it would be relevant to each health professional's activities and duties, 4 professional profiles were defined to account for most cases (Table 1).

Table 1. Professional profiles and their descriptions.

Profile code	Profile	Description
P1	Direct patient care	Professionals who spend >70% of their workday providing direct patient care or services (eg, physicians, nurses, occupational therapists, speech therapists, optometrists, opticians, dental hygienists, and pharmacists)
P2	Indirect patient care	Professionals who spend >70% of their workday providing health care support services (eg, physicians working in biological diagnostic and pathological anatomy services, specialist biologists, specialist physicists, specialist chemists, pharmacists, and dental prosthetists)
P3	Innovation, research, and teaching	Professionals who spend >70% of their workday providing innovation, research, or teaching services (eg, researchers and innovation specialists)
P4	Management	Professionals who spend >70% of their workday managing centers, organizations, departments, services, or teams (eg, executives and middle managers)

The test questions in our assessment and accreditation model had to be linked to definitions of observable behaviors that could be put into practice in different professional settings within the Catalan health care environment. Observable behaviors are understood as practices or actions performed by health professionals as part of their work (eg, finding clinical information in databases, communicating and collaborating remotely with teams or patients, using information management tools, and creating content). As the point of the assessment was to determine respondents' level of digital competence, we considered it appropriate to use assessment scenarios that would present them with challenges that they would need to overcome. Their attempts to deal with situations similar to those in the real world and provide the best possible digital response to the proposed challenges would provide greater insights into their competence level for each indicator. It would also allow respondents to put into practice other skills, such as problem-solving, critical thinking, and the analysis and responsible use of information and communications technology [23].

The test for the 4 professional profiles included a set of 2 cases (scenarios) with a total of 28 questions to be answered within 60 minutes. The test was contextualized for each of the 4 profiles: P1, P2, P3, and P4. The maximum score was 30 points (26 questions counted for a maximum of 1 point each, and 2 questions counted for a maximum of 2 points each). Wrong answers on the multiple-choice questions were scored negatively (-0.2 points). A minimum score of 70% (21/30) was required to pass the test. Participants who scored <21 points were categorized as "suggested level not achieved," and those who scored between 21 and 30 points were categorized as "suggested level achieved."

Implementation and Analysis of the Assessment and Accreditation Model

To analyze the proposed assessment and accreditation model for our competence framework and identify areas for improvement (eg, time allotted, number of test questions, types of test questions, professional profiles, real-life situational approach by profile, assessment scenarios, and suitability of the cases and challenges presented) and validate the proposed level test (ie, to determine whether the proposed level was appropriate), we conducted a pilot study involving a web-based test with legally recognized health professionals [36] and health care social workers employed in Catalonia who reported an intermediate or advanced self-perceived digital competence level.

The web-based test consisted of 3 activities: a level test based on the exam required to obtain the ACTIC 2—intermediate level certificate [23] (activity 1); the test developed for our proposed assessment and accreditation model, as described in the previous section (activity 2); and a feedback questionnaire to understand participants' opinions on the proposed assessment and accreditation model and other aspects of the pilot test (activity 3). The estimated time to complete the 3 activities was 90 minutes. The activities were to be done consecutively and in the specified order.

The ACTIC 2—intermediate level test (activity 1) was used to determine the participants' baseline digital competence level and compare their scores with the results of the proposed assessment and accreditation test. Participants were categorized into 1 of the following 3 groups based on their scores: beginner (0-9.9), basic (10-24.9), and intermediate (25-35).

In relation to the test developed for our proposed assessment and accreditation model (activity 2), Table 2 shows all the variables involved in the pilot study.

Table 2. Variables for which data were collected from participants during the study.

Descriptor	Collection method
Name and surname	Forms (Microsoft Corp) questionnaire
Email address	Microsoft Forms questionnaire
Health profession	Microsoft Forms questionnaire
Self-perceived digital competence level	Microsoft Forms questionnaire
Experience related to digital competence training	Microsoft Forms questionnaire
Official certification in digital competences	Microsoft Forms questionnaire
Professional profile (P1, P2, P3, or P4)	Microsoft Forms questionnaire
Score achieved in activity 1	Moodle (Moodle HQ) questionnaire
Score achieved in activity 2	Moodle (Moodle HQ) questionnaire
Feedback questionnaire	Moodle (Moodle HQ) questionnaire

The feedback questionnaire (activity 3) consisted of 9 questions, 3 (33%) of which were open-ended and 1 (11%) of which asked for the participants' self-perceived level in each of the digital competences defined for health professionals.

Data Collection

To focus the scope of the study, the Catalan Ministry of Health asked relevant professional associations to invite members whom they felt could meet the study's inclusion criteria to volunteer as participants. Volunteer participants were recruited using a Microsoft Forms (Microsoft Corp) questionnaire ([Multimedia Appendix 6](#)). After informing them of the purpose of the study, their personal and professional details were collected. If they met the inclusion criteria, they were enrolled in the study and given credentials to access Moodle (Moodle HQ) for the web-based test.

Although the study was scheduled to remain open for 30 days, from March 3 to 31, 2022, it was ultimately extended to April 14, 2022, to increase the response rate. During this period, 2 emails were sent to all candidates to remind them of the study's end date (or to inform them of the extension) and the remaining activities to be completed.

After this period, the test results were reported in accordance with "Good practice in the conduct and reporting of survey research" [31] and the General Data Protection Regulation, where applicable.

Statistical Analysis

When designing the study, we calculated the minimum sample size to ensure significant results with a 10% error rate, the maximum allowed in research studies [37]. On the basis of the results of an exploratory study [23] and the latest available report on the population of health professionals in Catalonia [22], the minimum sample size for the study was set at 168.

Descriptive statistics were performed for professionals who had correctly completed activities 1 and 2, with results presented as absolute and relative frequencies. Arithmetic means and SDs were used for comparative analysis of subgroups according to sociodemographic and professional characteristics, and *P* values were used for hypothesis testing.

The reliability of activity 2 was analyzed by measuring the consistency of its items. In addition, the level of discrimination of the items in relation to the advanced level was evaluated. The arithmetic mean and SD were used in descriptive statistics; *P* values, Bonferroni-adjusted *P* values, and Holm-adjusted *P* values were used in hypothesis testing and subgroup comparisons; and the greatest lower bound (GLB) was chosen to diagnose the test given the lack of homogeneity of the scoring scale, as was done in the exploratory study [23].

The study instrument was analyzed using the participants' scores and the discrimination index (DI) [38]. The DI measures how well an item could discriminate between high-scoring participants (ie, those with strong digital competences) and low-scoring participants in activity 2. DI values between 0 and 0.2 indicate that the item is not discriminating, and negative values imply an inverse relationship between the score on that item and the total score.

Finally, for activity 3, the numerical variables were presented as arithmetic means and SDs, whereas the categorical variables were presented as absolute and relative frequencies.

All responses were analyzed using the R statistical software (version 4.2.0; R Foundation for Statistical Computing). Responses to the open-ended questions (questions 5 and 7) in the feedback questionnaire (activity 3) were analyzed using quantitative content analysis to group them into limited categories [39].

Ethical Considerations

No ethics approval was required due to the type and nature of the study as the Catalan Department of Health is responsible for formulating the general criteria for health planning, setting the objectives, and the levels to be achieved in the topics that are included in the *Health Plan for Catalonia* [40]. All participants were informed about the study's purposes and that their participation was voluntary. Data protection treatment was informed to the participant and before accessing the survey, participants had to provide acceptance.

Results

Specific Map of Digital Competences for Health Professionals

[Multimedia Appendix 7](#) shows the specific map of digital competences for health professionals validated by the 21 individuals (of different profiles) in the working group of challenge 4 of the Professional Dialogue Forum.

Implementation and Analysis of the Digital Competence Assessment and Accreditation Model for Health Professionals

Recruitment

During the study period, we recorded a total of 398 visits to the Microsoft Forms recruitment questionnaire. Of the 398 visitors, 377 (94.7%) agreed to participate and gave their consent for the TIC Salut Social Foundation to process their personal data.

After excluding participants who did not meet the inclusion criteria and removing repeated registrations, the total recruited sample comprised 372 participants, who were given access to Moodle to start the 3 programmed activities. A total of 49.5% (184/372) of the participants logged into Moodle and started the designed activities. In the end, 176 professionals completed activity 1 correctly, of whom 122 (69.3%) also completed activity 2 correctly.

For the purposes of this study, we considered a result as valid when the test was completed, allowing for a maximum of 3 consecutive questions with no blank answers.

Sample Description

The sample consisted mainly of health professionals with a direct patient care profile (P1; 95/122, 77.9%), followed by those with a management profile (P4; 13/122, 10.7%); an innovation, research, and teaching profile (P3; 8/122, 6.6%); and an indirect patient care profile (P2; 6/122, 4.9%; [Table 3](#)).

Table 3. Descriptive statistics for participants who correctly completed activities 1 and 2 (N=122).

Descriptor	Participants, n (%)
Profile	
P1—direct patient care	95 (77.9)
P2—indirect patient care	6 (4.9)
P3—innovation, research, and teaching	8 (6.6)
P4—management	13 (10.7)
Health profession	
Specialist biologist	1 (0.8)
Dietician or nutritionist	1 (0.8)
Pharmacist	21 (17.2)
Specialist physical chemist	0 (0)
Physical therapist	17 (13.9)
Dental hygienist	7 (5.7)
Nurse	37 (30.3)
Speech therapist	7 (5.7)
Physician	4 (3.3)
Dentist	0 (0)
Optometrist/optician	6 (4.9)
Podiatrist	5 (4.1)
Dental prosthetist	1 (0.8)
Clinical or general psychologist	4 (3.3)
Occupational therapist	9 (7.4)

ACTIC 3	6 (4.9)
Experience at digital health events	
No experience	107 (87.7)
Speaker or trainer	11 (9)
Organizer	2 (1.6)
Both	2 (1.6)

^aACTIC: Accreditation of Competence in Information and Communication Technologies.

Responses were received from professionals in all health professions, with the exception of specialist physical chemists and dentists. Nurses represented the largest proportion of the sample (37/122, 30.3%), followed by pharmacists (21/122, 17.2%) and physical therapists (17/122, 13.9%). According to the distribution of health care professions in Catalonia, a

representative sample of nurses was obtained; however, this was not the case for physicians [41].

The vast majority of the sample (110/122, 90.2%) reported an intermediate self-perceived digital competence level, with only 9.8% (12/122) of participants considering themselves advanced. Overall, 82.8% (101/122) had no ACTIC certification, 11.5% (14/122) had an ACTIC 2 (intermediate) certification, 4.9%

(6/122) had an ACTIC 3 (advanced) certification, and 0.8% (1/122) had an ACTIC 1 (basic) certification.

Activity 1: ACTIC 2—Intermediate Level Test (Baseline Level)

The mean total score for activity 1 was 24.3 (SD 4.1) points, which was significantly lower ($P=.03$) than the cutoff score for

“Intermediate” (25 points). Of the 122 participants, 59 (48.4%) scored between 10 and 24.9 points (basic), and 63 (51.6%) scored ≥ 25 points (intermediate). On average, the sample took 12.2 (SD 3.8) minutes to complete the baseline level test. There were no outliers in the times recorded (Table 4).

Table 4. Summary of activity 1 results (N=122).

Descriptor	Values
Score, mean (SD)	24.3 ^a (4.1)
Score range (points), n (%)	
<10 (beginner)	0 (0)
10-24.9 (basic)	59 (48.4)
≥ 25 (intermediate)	63 (51.6)
Minutes taken to complete the activity, mean (SD)	12.2 (3.8)

^aScores significantly below 25 points ($P=.03$).

The scores followed a normal distribution, with a mode of 25 points. Only 0.8% (1/122) of the participants obtained the maximum possible score on the level test (Multimedia Appendix 8).

Subgroups were compared to determine whether there were any significant differences in the overall scores. It was found that participants who had experience at digital health events scored significantly higher than those who did not ($P=.03$).

The scores for each subgroup were also compared to determine which subgroups scored significantly below 25 points in activity 1 (ie, did not reach intermediate level) and which scored significantly above 25 points (ie, did reach intermediate level).

Several subgroups were found to have scored significantly below 25 points, including P1 (direct patient care; $P=.04$), Dental hygienist ($P=.01$), Intermediate level self-perception ($P=.03$), no ACTIC certification or ACTIC 1 ($P=.02$), no experience in digital health events ($P=.02$). Some subgroups scored significantly above 25 points, particularly the group of participants who reported ACTIC 3 certification ($P=.40$). P2 (indirect patient care) professionals and professionals with experience at digital health events scored significantly above 25 points, but this difference did not remain significant after correcting for multiple testing using the Bonferroni and Holm methods (Table 5).

Table 5. Overall scores and subgroup comparisons according to participant characteristics for activity 1.

Subgroup	Overall score, mean (SD)	Group comparison ^a			Intermediate level check						
		Unadjusted <i>P</i> value	Bonferroni-adjusted <i>P</i> value	Holm-adjusted <i>P</i> value	<25 points ^b			≥25 points ^c			
					Unadjusted <i>P</i> value	Bonferroni-adjusted <i>P</i> value	Holm-adjusted <i>P</i> value	Unadjusted <i>P</i> value	Bonferroni-adjusted <i>P</i> value	Holm-adjusted <i>P</i> value	
Profile		.23	>.99	.52							
P1—direct patient care (n=95)	24.1 (4.0)				.01 ^d	.04	.04	.99	>.99	>.99

Activity 2: Proposed Assessment and Accreditation Test for the Map of Digital Competences for Health Professionals

Overview

The mean score for activity 2 was 18.5 (SD 3.7) points, which was very significantly lower (*P*<.001) than the cutoff score for

passing the test (21 points). Of the 122 participants, 89 (73%) scored <21 points (did not pass), and 33 (27%) scored ≥21 points (passed). On average, the sample took 34.4 (SD 11.4) minutes to complete the test. There were no outliers in the times recorded (Table 6).

Table 6. Summary of activity 2 results (N=122).

Descriptor	Values
Score, mean (SD)	18.5 ^a (3.7)
Score range (points), n (%)	
<21 (did not pass)	89 (73)
≥21 (passed)	33 (27)
Minutes taken to complete the activity, mean (SD)	34.4 (11.4)

^aScores significantly below 21 points (*P*<.001).

An internal consistency analysis of activity 2 for P1 showed excellent internal consistency overall (GLB=0.91). The internal consistency of activity 2 could not be determined for the remaining profiles because there were not enough participants in them (Multimedia Appendix 9).

For activity 2, subgroup comparisons revealed significant differences between health professions and between professionals with intermediate and advanced self-perceived competence levels. However, the comparisons did not remain

significant after applying the Bonferroni and Holm adjustments for multiple comparisons.

Some subgroups did not score significantly below 21 points, including P2 professionals ($P=.83$), nurses ($P=.01$), physical therapists ($P=.22$), speech therapists ($P=.18$), physicians

($P>.99$), podiatrists ($P=.37$), occupational therapists ($P=.78$), professionals with an advanced self-perceived competence level ($P=.16$), professionals with ACTIC 3 certification ($P>.99$), and professionals with experience at digital health events ($P=.23$). In some cases, the lack of significant level determination was likely due to the small size of the subgroup (Table 7).

Item Dimension (Instrument Diagnosis)

It should be noted that we performed this analysis only for activity 2 and P1 (direct patient care) as this subgroup was large enough for this type of analysis (n>40; [Multimedia Appendix 10](#)).

Correlation Between Participants' Performance in Activity 1 and Activity 2

Regarding the correlation between participants' performance in activity 1 and activity 2, there were 2 main groups: those who did not pass either activity 1 or activity 2 (49/122, 40.2%) and those who passed activity 1 but did not pass activity 2 (40/122, 32.8%) ([Table 8](#)).

Table 8. Participant classification according to performance in activity 1 and activity 2 (N=122).

Descriptor	Participants, n (%)
Passed activity 1 and passed activity 2	23 (18.9)
Passed activity 1 and did not pass activity 2	40 (32.8)
Did not pass activity 1 and passed activity 2	10 (8.2)
Did not pass activity 1 and did not pass activity 2	49 (40.2)

Of the 33 participants who passed activity 2, a total of 10 (30%) did not pass activity 1. Although these are isolated cases, they call into question the validity of the advanced level of activity 2 and need to be investigated further. No significant differences were found between this subgroup and the remaining professionals in the time taken to complete or in the number of blank answers in activity 1.

Activity 3: Feedback Questionnaire

A total of 94.3% (115/122) of the participants completed activity 3, although not all of them answered every question.

There were no significant differences in the ratings by profile (P1, P2, P3, and P4) or by health profession that would allow for robust conclusions to be drawn (Table 9).

Table 9. Results of the feedback questionnaire (N=115).

Question number and topic	Result
Question 1—level of difficulty of activity 2, mean (SD)	3.6 (0.7)
Question 2—self-perceived level in activity 2, n (%)	
Basic	7 (6.1)
Intermediate	49 (42.6)
Advanced	59 (51.3)
Question 3—wording of the questions, mean (SD)	3.8 (0.9)
Question 4—appropriateness of the challenges, mean (SD)	3.2 (1.2)
Question 5—feedback on the challenges and scenarios	Open-ended question
Question 6—appropriateness of the profiles, mean (SD)	4.2 (0.8)
Question 7—feedback on the profiles	Open-ended question
Question 8—self-perceived level in each of the digital competences defined for health professionals	Multiple-choice question
Question 9—general feedback on the pilot study and the initiative	Open-ended question

When asked whether they would change any of the challenges or scenarios presented in activity 2 as part of our assessment and accreditation model (question 5), a considerable number of professionals (45/94, 48%) indicated that they did not fully identify with them (Multimedia Appendix 11).

When the responses were analyzed by health profession, we found that nurses and physicians generally identified with the challenges more than their counterparts in other health professions did (Multimedia Appendix 12). While 48% (11/23) of nurses and physicians gave positive feedback in this regard, only 31% (15/48) of respondents from other professions said that they adequately identified with the challenges and scenarios.

When asked whether they would change any of the profiles in our model (question 7), most participants (49/79, 62%) agreed that the profiles were accurately defined. Of the participants who did not fully agree, some questioned the workday

percentage defined for categorization (eg, 70% direct patient care for P1). Others felt that there were hybrid profiles halfway between P1 and P4 or other profiles altogether or indeed that some profiles should be included in others (Multimedia Appendix 13).

It should be noted that the participants who indicated that they did not fully agree with the profiles were either from the private sector or working in pharmaceutical companies.

Regarding the participants' self-perceived level in each of the 10 digital competences defined for health professionals in our framework (question 8), most reported having a basic competence level of data analysis and digital transformation (71/111, 64% and 64/111, 58%, respectively). The competence for which most professionals reported an advanced level was ethics and civic-mindedness (44/111, 40%; Figure 2).

Figure 2. Participants' self-perceived level in each of the digital competences defined for health professionals.

Discussion

Frameworks and Competence Assessment Challenges

Digital health offers a valuable opportunity to make strides toward attaining the United Nations' Sustainable Development Goal of universal health coverage by 2030 [42]. To that end, and given the gradual digitization of the health care sector, health professionals must have the appropriate competences regardless of their specific disciplines [2,5,16,17,43].

Furthermore, the constant evolution of new technologies requires the continuous updating of digital health competence. This entails reviewing both the relevant competences and the methods for properly assessing them [2]. Some discrepancies and overlap still exist among available frameworks, the methods used to conceptualize such frameworks, and the competences they include [2] and also among the health professionals at whom they are aimed [44,45]. The lack of a comprehensive framework applicable to all health professionals warrants the development of frameworks that include different health professionals.

Among the most recent frameworks is the Health Information Technology Competencies. Developed using an iterative method, it is the most complete framework aimed at a broad range of health professionals and medical specialties [30]. In Spain, and more specifically in the Basque Country (northern Spain), the Ikanos project was developed (2020) based on the European DigComp framework as a benchmark for the description of digital competences. Drawing on interviews with

experts, the Ikanos framework focuses on profiles based initially on primary care professionals (medical and nursing staff) [29].

The COMPDIG-Salut project was launched for the purposes of designing a specific map of digital competences for health professionals and creating a specific digital competence assessment and accreditation model to enable health professionals to obtain a specific accreditation certificate. Taking an iterative approach, which included a review of the gray literature and consultation with local experts [2], we designed a map of digital competences, consisting of 10 competences under 4 competence areas: data access, management, and analysis; communication and collaboration; digital awareness; and professional development. The second and fourth of these areas have the highest number of competences (3 each). In short, the map includes competences related to essential skills for the digital management and analysis of health and social data and information and includes emerging technological innovation (ie, health apps, artificial intelligence, and autonomous decision support systems) [2,46]. Moreover, and given that digital health entails new methods of communication (teleconsultations and email), it is imperative for health professionals to know how to convey information in a precise, effective, and timely manner to patients, health professionals, and any collaborating parties [47-49]. Effective communication, collaboration, and teamwork are crucial in a health setting, so health professionals must also possess the ability to work effectively as members of interdisciplinary teams [2,50]. The creation and publication of health-related digital content is another basic competence that health professionals should have to ensure high-quality health

care provision and help improve the communities they serve [31,51]. Finally, emphasis is placed on the importance of health professionals complying with the ethical principles and security criteria associated with the appropriate use of digital technologies [52] and also keeping abreast of the regulations on health and social data and information privacy, confidentiality, and protection [2,53,54]. However, we should bear in mind that the evolving nature of digital health and professional practice in the health field—which often outpaces research—requires constant, flexible development of professional competences [55]. Hence, some of the competences in the competence framework defined in the COMPDIG-Salut project may need to be adjusted to incorporate future digital trends, such as addressing challenges in the areas of cybersecurity and the use of artificial intelligence and robotics in professional practice. This implies that the methods for accurately assessing such competences may need to be updated.

Digital Competence Assessment Model

Meanwhile, given the need to assess health professionals' digital competence levels for the purposes of narrowing the digital gap and, by so doing, maintaining health service quality [11,45], a digital competence assessment model for health professionals was developed as part of the COMPDIG-Salut project. Drawing on the competence content defined in the project, the model was designed in accordance with ACTIC's new scenario-based assessment model [23]. In this sense, the assessment model was adapted to the 4 distinct health sector profiles: professionals providing direct patient care; professionals providing indirect patient care; professionals providing innovation, research, or teaching services; and professionals who manage. This not only reflects the impact of the professional role on digital competence [56] but also, with the differentiation of the 4 profiles, facilitates the design of a specific training pathway for each role (Multimedia Appendix 14).

While the focus was on the type of health professional profile (P1, P2, P3, or P4), the most frequent professional categories into which participants fell were nurses, pharmacists, and physiotherapists. The internal consistency of the digital competence assessment model for health professionals in P1 was excellent overall, bearing in mind that it was a proposed assessment model (GLB=0.91). We found that 54% (15/28) of the questions discriminated between health professionals with an advanced level of digital competence and those with a lower level ($DI \geq 0.20$) and that 11% (3/28) of the questions were highly discriminating ($DI > 0.4$). However, 7% (2/28) of the items had a negative DI, so these would need to be reviewed because a negative DI implies an inverse relationship between the level and the correct answer, meaning that the wording of the question may not have been sufficiently precise. However, as these values were close to 0, they could be regrouped with the nondifferentiating questions ($DI = 0-0.2$). As the assessment model for the remaining profiles assessed the same competences as those in the P1 test, we expected the internal consistency and the degree of discrimination of the questions to be similar among the profiles. However, it was not possible to directly extrapolate the P1 results.

Most of the questions in the feedback questionnaire (activity 3) could not be robustly interpreted because they did not constitute a standard instrument that had been validated by another study. The values obtained in the Likert-type questions could not be robustly interpreted either because the values were not near the ends of the scale. Many health professionals felt that their roles and challenges were not adequately represented in the assessment model despite the professional profiles being well defined. This was especially the case among health professionals who made up the smallest groups (mostly nonmedical and nonnursing staff and those working in the private or pharmaceutical sectors). This result underscores the necessity of refining the assessment model to meet the diverse digital competence needs of health care professionals, emphasizing the potential requirement for more targeted measures tailored to specific groups, and acknowledging their potential cultural dependencies. Therefore, it would be necessary to either review the profile proposal for the competence assessment model or add scenarios and challenges to it for health professionals who were not reflected in the proposed situations. The sample size of some subgroups (physicians, health professionals with advanced digital competence, P2, P3, and P4) may have been too small to represent the population.

Self-Perceived Digital Competence and Certification

Although most study participants (110/122, 90.2%) reported an intermediate self-perceived digital competence level and only 9.8% (12/122) of participants considered themselves advanced, we found that the vast majority would not attain ACTIC 2 (intermediate) certification [34]. This situation was similar to the one found in an exploratory study conducted in 2021 [23]. Consistent with the low score for the ACTIC 2 certification (activity 1), the total mean score for activity 2, which assessed the defined competence framework, was significantly lower than the defined threshold. In fact, 73% (89/122) of the sample did not pass the tests. Participants with ACTIC 3 certification significantly passed activity 1 but not activity 2. In fact, none of the subgroups studied showed a significant increase in activity 2. This shows that the assessment model is a useful tool as an approach to assessing the competence framework for health professionals, and the results strengthen those obtained in the exploratory study [23]. This also shows that health professionals still need training, that such training goes beyond that required for the main tools currently used, and that merely being exposed to digital media as consumers is insufficient in terms of acquiring the necessary digital skills. More and more faculties of medicine are incorporating digital health training into their programs of study [57,58], and there is an ever-increasing number of initiatives to meet that need [2], such as the Digital Capability Framework developed by Health Education England [59] or the free introduction to eHealth web-based course offered by the EU*US eHealth Work project [60]. The designed map of digital competences could serve as the basis of the knowledge and skills for digital literacy specific to health professionals, to which other competences or areas could be added in accordance with the particularities of the various health professions and medical specialties. This map of digital competences could also inform and contribute to the development of future digital health

training programs for health workers at different stages of their professional careers.

Strengths and Limitations

Our study provides a competence framework and a tool for assessing the digital competences of health professionals that is consistent with the certification available to citizens (ACTIC). It also yields results that strengthen those obtained in the previous exploratory study [23]. However, this study has several limitations. First, several weaknesses in the interpretation of findings from the review should be considered. While narrative reviews are often used in social science research for educational purposes, they may be biased and lack objectivity. That said, they can provide a unique perspective and identify knowledge gaps in the literature [61]. Although a considerable number of reference frameworks from gray literature were included, some may have been overlooked. Moreover, while performing thematic analysis, we found that some frameworks had either vague competence categories or overlaps among categories, which engendered differences of opinion during the classification process. However, the 4 reviewers drew on their experience to develop and clearly define the competence areas and assign the corresponding competences to them, first independently and then jointly through discussion-based agreement to reduce bias and classify the information in the most appropriate way possible. Although the reviewers tried to make the classification process as transparent and replicable as possible, it should be borne in mind that there could be other ways of interpreting and classifying the information and that the categorization might differ in the future with new advances in digital health. Second, while valid results were obtained for 122 participants, the minimum sample size set for the study was not reached ($N=168$). The platform used for the test (Moodle), the number of activities (3), and the time allotted (estimated at 1.5 hours) were almost certainly the reasons for poor participation in the study, especially given the high workload of the professional group in question. A study assessing both perceived and demonstrated eHealth literacy through a computer simulation of health-related internet tasks also revealed that evaluating demonstrated eHealth literacy via simulations is a challenging endeavor in terms of time [62]. When comparing the results of this study (using Moodle for the test) to those of the previous exploratory study (using Microsoft Forms for the test), it could be said that Moodle might have had an influence on a health professional's decision not to take part in the study [23]. Third, the most highly represented health professionals in this study were those providing direct patient care (P1). Thus, many of the conclusions drawn from the study are limited to that profile. The poor participation of physicians (4/122, 3.3%) meant that they were underrepresented if compared to the 2017 professional population data for Catalonia [22]. As it fell to professional associations to inform their members about this study, the dissemination mechanisms they used are not precisely known. However, their impact was seemingly greater in the associations of nurses, pharmacists, and physiotherapists than in the associations of other health professions. Fourth, the absence of a detailed demographic analysis of the participant population limits our ability to provide a comprehensive understanding of sample characteristics. While demographic

characterization could aid in contextualizing the results and their relationship to the simulation performance, such data were not collected in this study in accordance with the General Data Protection Regulation principle of “data minimization” [63]. Consequently, the lack of this analysis may restrict our ability to generalize findings to broader populations and fully comprehend the influence of demographic variables on study outcomes. Fifth, our findings enable us to estimate the prevalence of P1 as the most common profile; however, they do not provide a basis for drawing more specific conclusions. The 2022 report on health care professionals in Catalonia lacks profession categorization [22], and acquiring accurate and current data poses challenges attributable to factors such as professional mobility (eg, change of workplace, the coexistence of public and private sectors, and mobility between various institutions) and liberal professions. Subsequent research endeavors should prioritize the inclusion of all 4 profiles for a more comprehensive understanding. Sixth, the overrepresentation of health professionals with an intermediate self-perceived competence level compared to those considering themselves advanced also limited some of the study conclusions. We will probably need to review our definitions of the different self-perception levels because, perhaps due to the wording used, there was a greater perception of exigency than there really was (eg, advanced user: “I have attained the most advanced digital competences for transforming and innovating in today's digital society.”). Moreover, the evaluation of digital health competences should take into account that, despite being notable, there is a moderate correlation between perceived and actual digital competences, as other studies looking at simulation scenarios in health care have shown [62,64]. Despite the considerable similarity between the latter simulation scenarios and those used in this study, previous research has focused on distinct demographic groups within the general population, such as individuals aged ≥ 50 years [62], or specific cohorts, such as patients with chronic illnesses [64], rather than health care professionals.

Conclusions

Assessing the digital competence level of health professionals based on a defined competence framework should enable such professionals to be trained and updated to meet real needs in their specific professional contexts and, consequently, take full advantage of the potential of digital technologies [65]. The information and data gathered, together with the results of an exploratory study on competence levels conducted in 2021 [23], should be taken as the starting point for promoting relevant strategic policies and actions to ensure that the right resources and conditions are in place for good professional performance [15,66-69]. Faced with the need to improve the digital competence of health professionals working in Catalonia, these results have informed the *Health Plan for Catalonia 2021-2025* [40] and lay the foundations for designing and delivering specific training to first assess and then certify the digital competence of such professionals. Thus, the assessment model presented in this paper—designed in accordance with the competence content defined in the map of digital competences and based on scenarios—has the potential to be applied in diverse countries and languages with appropriate modifications

to meet the specific needs and contexts of health care professionals in different health systems, although further evidence is needed to fully support this claim. This might provide a preliminary perspective for assessing the competence levels and needs of health
