Abstract

Background: The emergence of the COVID-19 pandemic has posed a significant ethical dilemma in the allocation of scarce, life-saving medical equipment to critically ill patients. It remains uncertain whether medical students are equipped to navigate this complex ethical process.

Objective: This study aimed to assess the ability and confidence of medical students to apply principles of medical ethics in allocating critical medical devices through the scenario of virtual patients.

Methods: The study recruited third- and fourth-year medical students during clinical rotation. We facilitated interactions between medical students and virtual patients experiencing respiratory failure due to COVID-19 infection. We assessed the students' ability to ethically allocate life-saving resources. Subsequently, we analyzed their written reports using thematic analysis to identify the ethical principles guiding their decision-making.

Results: We enrolled a cohort of 67 out of 71 medical students with a mean age of 34 (SD 4.7) years, 60% (n=40) of whom were female students. The principle of justice was cited by 73% (n=49) of students while analyzing this scenario. A majority of them expressed hesitancy in determining which patient should receive life-saving resources, with 46% (n=31) citing the principle of nonmaleficence, 31% (n=21) advocating for a first-come-first-served approach, and 25% (n=17) emphasizing respect for patient autonomy as key influencers in their decisions. Notably, medical students exhibited a lack of confidence in making ethical decisions concerning the distribution of medical resources. A minority, comprising 12% (n=8), proposed the exploration of legal alternatives, while 4% (n=3) suggested medical guidelines and collective decision-making as potential substitutes for individual ethical choices to alleviate the stress associated with personal decision-making.

Conclusions: This study highlights the importance of improving ethical reasoning under time constraints using virtual platforms. More than 70% of medical students identified justice as the predominant principle in allocating limited medical resources to critically ill patients. However, they exhibited a lack of confidence in making ethical determinations and leaned toward principles such as nonmaleficence, patient autonomy, adherence to legal and medical standards, and collective decision-making to mitigate the pressure associated with such decisions.

Introduction

The COVID-19 pandemic has caused millions of deaths and countless hospitalizations worldwide owing to critical conditions caused by the virus [1]. This has raised the ethical dilemma of allocating scarce life-saving devices to critically ill patients [2-5].

Physicians often make clinical decisions based on scientific evidence to avoid moral distress [3,6,7]. However, clinical decisions may have to be made under time constraints. Preparing physicians to apply appropriate ethical principles, have self-confidence in making choices, and prevent moral trauma has become essential during the pandemic [8].

The principles of autonomy, justice, beneficence, and nonmaleficence commonly serve as guiding references for allocating scarce medical resources [9]. However, these principles have multiple interpretations when facing limited resources and can be based on utilitarianism, egalitarianism, or deontology [10]. Utilitarianism believes that the primary obligation is not to treat people equally, but to maximize the greatest amount of happiness for the greatest number of people; the best actions would be based on what brings the best benefit. By contrast, egalitarianism upholds the rights and interests of individuals, which should be equally protected [10]. Deontology judges the morality of choices by its conformity with a moral norm [11], regardless of its consequences. Persad et al [12] present a comprehensive framework for the allocation of scarce medical resources grounded in the core principles of autonomy, justice, beneficence, and nonmaleficence. Their framework encompasses 4 distinct ethical value categories, including equal treatment, prioritization of the most vulnerable, maximizing overall benefits, and recognition of social usefulness. Within each category, 2 competing ethical principles emerge, yielding a total of 8 subprinciples that provide detailed guidance aligned with the overarching ethical values [12]. The core values or principles that medical students prefer or overlook when facing ethical dilemmas are unclear and require further study.

The School of Medicine for International Students at I-Shou University has a 4-year Doctor of Medicine program that collaborates with the Ministry of Foreign Affairs and enrolls college graduates from countries with official diplomatic ties to Taiwan. Due to the limited medical resources in such students' home countries, they may face the challenge of a shortage of life-saving medical facilities in clinical practice. Therefore, equipping them with the knowledge and skills to allocate life-saving medical devices to critically ill patients, based on reasonable principles of medical ethics, is crucial. The use of virtual patients for teaching medical humanities may strengthen the effectiveness of medical ethics education [13,14]. Considering the challenges imposed by the COVID-19

pandemic, this solution aims to offer a secure and personalized training environment, transcending the boundaries of time and space. By doing so, students can become fully engrossed in virtual scenarios, enriching their learning experiences.

The objective of this study was to assess the ability and confidence of medical students to apply principles of medical ethics in allocating critical medical devices through the scenario of virtual patients.

Methods

Study Design

We designed a virtual scenario and asked medical students to allocate lifesaving medical devices to only 1 patient. In this scenario, a 62-year-old COVID-19-infected patient with respiratory failure was admitted to the intensive care unit. Medical students were instructed to interview a virtual patient and review the patient's laboratory and imaging findings. They then were asked to make clinical diagnoses and adopt appropriate ethical principles to determine whether to remove the extracorporeal membrane oxygenation (ECMO) device from an 80-year-old patient currently using it and reallocate it to the new younger patient. After making their decision, the students were requested to write a short essay addressing the ethical conflicts they encountered in making the choice.

Ethical Considerations

We explained the rationale for this qualitative study and recruited third- and fourth-year medical students from the School of Medicine for International Students Program when they undertook clinical rotation at the hospital. All participants completed the virtual clinical scenarios within 4 hours in May 2021, during the COVID-19 pandemic in Taiwan, after signing an informed consent form. This study was approved by the E-Da Hospital Institutional Review Board (no. EMRP05109N and EMRP04111N), and the data were not identifiable. The teaching and evaluation of students were not affected by whether they participated in the research.

Case Scenario

Leona is a 62-year-old retired woman. She had been well without any underlying disease until recently being diagnosed with COVID-19 pneumonitis. Her lung condition continuously deteriorated, and ECMO was the last resort to support her tissue oxygenation. However, the only available ECMO machine was currently being used by an 80-year-old patient with multiple chronic illnesses who remained unstable after receiving ECMO treatment, with minimal chances of recovery.

The students were given the above scenario to assess and answer relevant questions. One of the questions was "Will you continue to let the 80-year-old patient use the ECMO, or let Leona use

the ECMO instead? Please explain your decision and your reasons to support it.”

The medical students could use the 4 principles of medical ethics or base their responses on their individual analytical perspectives and reasoning for the allocation of limited medical resources.

Data Analysis

Age (>25 vs ≤25 years) and sex (male vs female) served as basic demographic variables, with the age of 25 years as a threshold of maturity. Grade (third vs fourth year) represented differences in clinical exposure experiences [15]. Textual content analysis was performed by 2 of the authors to search for keywords and summarize the students' responses independently. The keywords were encoded and categorized for both quantitative and qualitative analyses. We used the principles of summative content analysis, which combines the quantitative counting of specific content or words or terms with latent content analysis to identify and categorize their meanings. In brief, we created a new coding category for any newly introduced terms in the assignment, and then assessed conceptual similarities to determine whether to further organize these codes into additional categories with appropriate names.

The qualitative analysis consisted of the following steps:

1. The coding items included the final decision of the students (for whom to use), which core medical ethical principles were applied with various degrees in their choices, and whether viewpoints other than ethics, such as medical guidelines or legislation, were mentioned.
2. The reasons for the students' final decisions were classified according to the patient they selected, either the 62-year-old younger patient or the 80-year-old patient with multiple comorbidities. Our analysis focused on encoding the ethical justifications provided by the medical students to support their final decisions. We omitted considerations related to their alternative choices during the decision-making process.
3. The classification of reasoning for those who made a decision was primarily based on the students' understanding and interpretations in their essays, which Persad et al [12]

mentioned were equality, vulnerability, maximizing the quality of life, and contribution to society. The original resource allocation principles were designed for the distribution of medical supplies among a group of individuals. However, the present case pertains to the treatment decision for an individual patient, further complicated by the fact that one patient had already been put on a ventilator. By contextualizing the principles within the framework of the present case, we eliminated the applicability of 4 subprinciples: lottery, saving the most lives, reciprocity, and giving priority to the worst off (ie, sickest first).

4. If students displayed reluctance in making a choice, we also coded their explanations for the perception that ethical decision-making might not be suitable, categorizing these explanations as “undetermined” or “both unqualified.”
5. The main reasons for the students' final decisions were classified into medical, legal, and ethical perspectives.
6. The coding process was independently judged by 2 researchers with expertise in qualitative research. Any inconsistencies in coding were resolved by reviewing the classification descriptions to refine the precision of category definitions and revisiting the context to ensure accurate coding.

Results

Student Demographics

From 2021 to 2022, a total of 71 international third- and fourth-year clinical medical students who were facing the COVID-19 pandemic most significantly were enrolled. Of these, 67 students (33 third-year and 34 fourth-year students) from 12 countries participated in the study. Because 4 fourth-year medical students did not participate, the response rate was 94%. Overall, 40 (60%) participants were female and 61 (91%) were older than 25 years. Most medical students were from the Kingdom of Eswatini, accounting for 48% (n=32) of the total group (Table 1 and Multimedia Appendix 1).

Table 1. Basic information of the students.

Demographic	Medical students (n=67), n (%)
Sex	
Male	27 (40)
Female	40 (60)
Age (years)	
>25	61 (91)
≤25	6 (9)
Seniority year	
Third	33 (49)
Fourth	34 (51)
Country of origin	
The Kingdom of Eswatini	32 (48)
Saint Lucia	7 (10)
Belize	7 (10)
Kiribati	5 (7)
Honduras	3 (4)
The Marshall Islands	3 (4)
Saint Kitts and Nevis	3 (4)
Paraguay	2 (3)
Saint Vincent & The Grenadines	2 (3)
Palau	1 (1)
Haiti	1 (1)
Solomon Islands	1 (1)

Choosing the Best Candidate for ECMO Allocation

Of the 67 participating students, age group (<25 vs ≥25 years old), sex (male vs female), and seniority year (third vs fourth year) did not affect patient selection preferences, and a larger proportion of students from Eswatini (21/32, 66%) selected the 80-year-old patient for ECMO compared to the rest of the students (39/67, 58%). The majority of students decided to continue treating the 80-year-old patient with ECMO (Table 2).

Additionally, 5 (8%) students argued that the medical information provided was not sufficient to make decisions that were highly dependent on factors such as the patient's condition, the course of the disease, and legal requirements. One student

(1%) suggested that, in accordance with medical guidelines, neither patient met the conditions to be a candidate for ECMO. A possible reason for them to abstain from decision-making could be the pressure they experienced while facing an ethical dilemma. As one student (no. 16) stated:

Doctors should not take the treatment away of one person and give it to another, regardless of the odds of survival rate of these two patients, because it means that we are taking the role of God, deciding who lives and who dies.

Another student (no. 20) stated:

I don't believe I have the right to decide who is more deserving or who needs this equipment more.

Table 2. Choosing the most suitable patient for extracorporeal membrane oxygenation treatment.

Patient selected	Students (n=67), n (%)
80-year-old	39 (58)
62-year-old	22 (33)
Undetermined	5 (8)
Both unqualified	1 (1)

Students' Perspective of Allocating Limited Resources

Building upon the framework proposed by Persad et al [12], this study identified 4 coding categories after excluding subprinciples that were deemed inapplicable to the current case. In accordance with the students' final decisions regarding the most suitable recipient for ECMO, we categorized the reasons endorsed by the students (Table 3). The primary justifications for selecting an 80-year-old patient included nonmaleficence (n=31, 46%), first-come-first-served (n=21, 31%), and patient autonomy (n=17, 25%). Students grounded their decisions in 3 of the 4 ethical principles, arguing that in this particular scenario, those advocating for the principle of nonmaleficence contended that physicians lacked the authority to withdraw a life-saving device in active use. "First-come-first-served" represents 1 of the 4 interpretive angles of the justice principle from Persad's framework. Students believed that the life of each patient held equal value, and those who received treatment first should be allowed to continue treatment. Students who mentioned patient autonomy were particularly concerned about the absence of informed consent and its potential legal implications for health care providers.

The reasons for selecting the 62-year-old patient primarily revolved around the principle of justice. The utilitarian principle

of maximum benefit was the most popular: 31% (n=21) of students mentioned that medical resources should be reserved for patients who can survive the longest and have the best quality of life. When comparing who had better survival probabilities, some students suggested that medical guidelines should serve as the basis for the final decision. Overall, 10% (n=7) of students made decisions depending on who had contributed more to society as a whole, and 4% (n=3) prioritized the disadvantaged, where the disadvantaged can be interpreted as the younger patient.

Students who expressed an "undetermined" stance believed that decision-making authority should be entrusted to guidelines, which could be either principles collectively established by physicians within the hospital (n=4, 6%), hospital policies (n=4, 6%), local laws (n=4, 6%), or decisions made by the hospital's ethics committee (n=3, 4%). Alternatively, some advocated for decisions to be made collectively by physicians within the hospital (n=1, 1%), by the patients' families (n=1, 1%), or based on other information relevant to the patient's condition (n=1, 1%). One student expressed a "both unqualified" position and approached the issue from a medical rather than an ethical perspective. The student asserted that, based on the guidelines, neither of the 2 patients met the criteria for usage.

Table 3. Multiple-choice analysis of the reasoning for case selection among students.

Reasoning for selected patient	Students (n=67), n (%)
80-year-old	
Nonmaleficence (physician has no right to withdraw)	31 (46)
Treat patients equally (first come, first served)	21 (31)
Patient's autonomy (law issue)	17 (25)
Withdraw can't prove 62-year-old patient's survival	2 (3)
62-year-old	
Higher survival rate, save the maximum quality of life (medical issue)	21 (31)
Rewarding social usefulness	7 (10)
Giving priority to the worst off; youngest first	3 (4)
Undetermined	
Decided by medical guidelines, collective decision	4 (6)
Decided by hospital	4 (6)
Depend on law	4 (6)
Decided by the ethics committee	3 (4)
Decided by 80-years-old patient's family member	1 (1)
Depend on other medical information	1 (1)
Both unqualified	
Both are unqualified for ECMO ^a per guidelines	1 (1)

^aECMO: extracorporeal membrane oxygenation.

Adequacy of Using Medical Ethical Principles

In total, 73% (n=49) of students cited the principle of justice while analyzing this case. When ethical principles were in conflict, the principle of justice was most commonly cited. The frequencies of ethical principles considered by medical students

in making final decisions (coding as simple choice) were as follows: 48% (n=32) used the principle of justice, 25% (n=18) used the principle of nonmaleficence, 12% (n=8) used the principle of patient autonomy, and 9% (n=6) were unable to provide a definitive response.

Confidence in Ethical Decision-Making

Overall, 75% (n=50) of the participants analyzed the case from other perspectives, such as medicine and law, and 25% (n=18) made their final decision based on the principles mentioned in the clinical guidelines. These students were more inclined toward the scientific mode of thinking, believing that evidence-based medicine is objective and may provide clear standards that can give them a sense of security. Students no. 23 and 31, respectively, indicated the following:

I can respond to this situation based on scientific evidence.

A comprehensive assessment of the pathology of the patient's current condition and the state of illness is a major consideration in decision-making.

For 12% (n=8) of the medical students, their final decisions were made from a legal perspective; that is, they stated that the decision should be made in accordance with the law of the state. They emphasized that physicians should protect themselves from being sued and provide decision-making authority to the patient or family. The patients or their family members should sign the emergency consent form, allowing the patient or family to participate in decision-making. As stated by student no. 40:

Medical care providers must consider medical laws, including those for removing the machine from the patient and withholding services from patients.

Additionally, 6% (n=4) of the medical students believed that medical institutions should provide clear guidelines or set up ethics committees to make collective decisions, thus preventing individual doctors from facing the pressure of decision-making. Student no. 18 stated:

I will follow the organization's code of ethics. The handling rules approved by a specific organization that will guide you in such situations so that you do not face a violation of the law.

Discussion

Principal Findings

ECMO is recommended for severe COVID-19-related acute respiratory distress syndrome to reduce mortality [16]. Currently, there is no evidence-based ethical guidance for prioritizing ECMO when resources are limited during the COVID-19 pandemic [17]. Justice is the preferred principle in virtual settings, although students have diverse interpretations. Nearly half of the students used additional principles, such as nonmaleficence and respect for patient autonomy, to prevent further harm while making ethical decisions. Multiple perspectives were adopted by three-fourths of the students.

The context of clinical situations is important for making clinical decisions based on ethical dilemmas [18]. The use of virtual patients for medical education may strengthen the effectiveness of medical ethics education [13,14]. Using virtual patients for clinical decision-making training among international medical students offers several advantages [19-21]. It provides a safe training environment amidst the COVID-19 pandemic and allows for diverse case presentations from multiple countries

and cultures [22]. The application of virtual care has flourished internationally during the post-COVID era. The Cleveland Medical Center in the United States has also explored the integration of remote and virtual health care. Medical institutions in the southern United States have proved that virtual diagnosis and treatment can alleviate caregiver burden and promote patient care [23]. Our study has provided evidence that combining virtual training with ethical reasoning in solving ethical dilemmas may present a safe environment for learning clinical decision-making and offer opportunities for improvement.

Students were asked to think about and answer questions according to the situation of the virtual patient. More than half of the students chose the oldest or the sickest patient to be the best candidate. The clinical scenario that was tested involved ex-post triage, which entails discontinuing ongoing treatment in favor of a newly arrived patient. Particularly in the context of a pandemic with limited resources (eg, ventilators), the primary objective is to maximize overall benefits for all individuals. While challenging, medical physicians may need to make the difficult decision of reallocating life-saving facilities from the most critically ill patients to those who have a higher probability of survival [5]. During a pandemic, rationing may require the withdrawal of care in order to provide ventilators to patients who are given higher priority, a reason foreign to many front-line clinicians [24]. Sharing and leveraging the diverse responses of medical students themselves can serve as a valuable reference for fostering innovative approaches in medical ethics education and facilitating ethical deliberation on challenging medical issues.

Medical students must define problems, identify potential solutions, and also inform patients about the current treatment options. The students' understanding of patient autonomy and informed consent was superficial and formalistic; they were more concerned about obtaining consent or documents to avoid legal proceedings. Recent discussions on the principles of patient autonomy have concluded that superficial autonomy cannot guarantee patient autonomy [25-27]. Moreover, physicians should make more efforts to meet the best interests of patients [28,29]. Considering students' diverse backgrounds, it is important to take into account their various learning styles to enhance and personalize educational materials [30].

The inability to establish a definitive ethical guideline capable of resolving issues stemming from the scarcity of medical resources underscores the complexity of the situation. Furthermore, factors such as patients possessing varying medical needs, financial capabilities to cover medical expenses, and the policies of health care institutions can all impact the ethical judgments of students [31,32]. Therefore, teachers can take the opportunity to emphasize to students that the premise of patient autonomy and informed consent is to uphold the patient's right to live, and promoting the well-being of the patient is the core value of the principle of patient autonomy. To ensure the patient's autonomy is respected, physicians should make decisions that benefit the patient's overall health and care.

Students were unfamiliar with philosophical and ethical reasoning and were under pressure to make ethical decisions about allocating life-saving medical modalities. They tended to

analyze ethical issues from both medical and legal perspectives [33,34]. Most medical students relied on objective medical guidelines, legal documents, or hospital management systems to help them make decisions while lacking life-saving medical modalities. Experts might erroneously assume that by dutifully adhering to the code's regulations they fulfill all pertinent ethical obligations. Similarly, many people hold the belief that by fulfilling all applicable legal prerequisites, they have fulfilled their moral duties. It is important to note that what may be deemed ethically correct does not always find support within the confines of the law. Legal education places emphasis on the introduction of statutes and their applicability, while ethical education delves into the reasoning process underlying diverse ethical decisions. Within medical ethics education, an exploration of students' abilities to discern the implications of various ethical decisions and make informed value judgments is paramount [35]. Some students believe that developing medical guidelines can serve as a substitute for individual ethical decision-making. Use of the specification method to solve ethical dilemma questions has limitations. If a specification eliminates contingent conflict, it may be arbitrary, lack impartiality, or fail for other reasons. We cannot avoid judgements that balance different principles or rules in the very act of specifying them. It also seems pointless or unduly complicated to engage in specification in many circumstances [35].

To foster the development of medical students' ethical thinking, it becomes crucial to provide them with opportunities to analyze cases using established ethical frameworks with proper guidance [5]. Furthermore, facilitating the sharing of diverse perspectives on case analysis can also prove valuable in nurturing community-specific morality, which draws its foundations from culture, religion, and institutional systems [35]. Based on our study, we proposed that the necessity of strengthening medical ethics education stems from the following: acknowledging physicians' needs for independent ethical decisions during a pandemic, recognizing the irreplaceability of clinical ethical judgment over legal rules and medical guidelines, elevating students' ethical reasoning abilities, and elucidating the core value and application scope of patient autonomy.

This study explored the current status of critical ethical decision-making from the diverse perspectives of international

medical students and provided information using a virtual patient scenario. Heist et al [36], using case summaries, found that 5 sessions of virtual patient case scenarios significantly improved students' clinical reasoning abilities. In light of the rapid advancement of virtual medical education platforms amidst the COVID-19 pandemic, it is suggested that medical schools proactively integrate a series of diverse virtual patient ethics decision-making exercises. This strategic inclusion aims to foster robust and well-rounded ethical education training for medical students, equipping them with the necessary skills to navigate complex ethical dilemmas in their future medical practice.

Through incorporating the survey in the formal class activity, we received a robust 94% response rate from a diverse group of medical students [37]. However, this study has some limitations. First, the interface and language processing technique of the virtual system could be more user-friendly in mimicking the true clinical interaction with patients. The responses of virtual patients were based on a predetermined script derived from a limited database design, making it difficult to respond to students' more in-depth or spontaneous questions. Second, owing to the limited number of participants (n=67) and the fixed setting of a single virtual patient, students' responses may not have been extrapolated. If the current medical resources and institutional policy differ, students might make various decisions.

Conclusion

This study addressed the need for practical clinical ethics training in medical education by using virtual patients to offer students simulated scenarios for cultivating decision-making experiences. It compiled diverse perspectives from students of various cultural backgrounds, enhancing their capacity for comprehensive ethical considerations. The research suggests a more effective curriculum development approach by combining individual case studies with a collective analysis of answers. As future physicians, these students will benefit from this training when making time-sensitive ethical decisions based on all stakeholders' viewpoints. This study also identifies a lack of student confidence in making ethical decisions related to patients' lives. It highlights the need to foster the independent ethical decision-making competency of medical students.

Acknowledgments

We thank the School for International Medical Students, College of Medicine of I-Shou University for offering the teaching material and facilities; the library of the E-Da Hospital for research resources and space; and the National Science and Technology Council for their support. This project was funded by the National Science and Technology Council, Taiwan (grants MOST-109-2511-H-650-002-MY2 and MOST 111-2410-H-650-002).

Authors' Contributions

H-YH contributed to the conception of this work, data analysis and interpretation, and writing of manuscript. RYH contributed to the conception of work, data acquisition, writing of the manuscript. G-CL contributed to data analysis and interpretation. J-YL and CA contributed to the substantial revision of the manuscript with English editing. C-HL contributed to the conception of this work, oversaw the quality, and contributed to substantial revisions. The authors have read and approved the final manuscript.

Abstract

Background: Communication is a core competency of medical professionals and of utmost importance for patient safety. Although medical curricula emphasize communication training, traditional formats, such as real or simulated patient interactions, can present psychological stress and are limited in repetition. The recent emergence of large language models (LLMs), such as generative pretrained transformer (GPT), offers an opportunity to overcome these restrictions

Objective: The aim of this study was to explore the feasibility of a GPT-driven chatbot to practice history taking, one of the core competencies of communication.

Methods: We developed an interactive chatbot interface using GPT-3.5 and a specific prompt including a chatbot-optimized illness script and a behavioral component. Following a mixed methods approach, we invited medical students to voluntarily practice history taking. To determine whether GPT provides suitable answers as a simulated patient, the conversations were recorded and analyzed using quantitative and qualitative approaches. We analyzed the extent to which the questions and answers aligned with the provided script, as well as the medical plausibility of the answers. Finally, the students filled out the Chatbot Usability Questionnaire (CUQ).

Results: A total of 28 students practiced with our chatbot (mean age 23.4, SD 2.9 years). We recorded a total of 826 question-answer pairs (QAPs), with a median of 27.5 QAPs per conversation and 94.7% (n=782) pertaining to history taking. When questions were explicitly covered by the script (n=502, 60.3%), the GPT-provided answers were mostly based on explicit script information (n=471, 94.4%). For questions not covered by the script (n=195, 23.4%), the GPT answers used 56.4% (n=110) fictitious information. Regarding plausibility, 842 (97.9%) of 860 QAPs were rated as plausible. Of the 14 (2.1%) implausible answers, GPT provided answers rated as socially desirable, leaving role identity, ignoring script information, illogical reasoning, and calculation error. Despite these results, the CUQ revealed an overall positive user experience (77/100 points).

Conclusions: Our data showed that LLMs, such as GPT, can provide a simulated patient experience and yield a good user experience and a majority of plausible answers. Our analysis revealed that GPT-provided answers use either explicit script information or are based on available information, which can be understood as abductive reasoning. Although rare, the GPT-based chatbot provides implausible information in some instances, with the major tendency being socially desirable instead of medically plausible information.

Introduction

Communication is one of the core competencies of health care professionals [1,2]. In the medical context, communication serves multiple functions, including relationship building, information gathering, and decision-making [3]. The ability to communicate with patients is crucial for their health outcomes [4,5]. Furthermore, inadequate communication can result in missed diagnostic opportunities and thus poses a hazard to patient safety [6,7]. Consequently, medical curricula worldwide incorporate either dedicated communication courses or a communication curriculum, depending on the level of curricular integration [8-10]. Formats that allow for the acquisition of communication competencies include theoretical lessons, peer-assisted learning, learning with simulation patients, and learning with real patients [11,12].

In this study, we assessed the potential of large language models (LLMs), such as generative pretrained transformer (GPT), in enhancing communication training. One key skill in medical communication is history taking, which is required in almost all medical fields to make a correct diagnosis and initiate treatment [13]. This learning objective typically starts with taking a systematic history (ie, assessing the history regarding all relevant body functions and organ systems). To practice history taking, the learner is required to have an interactive encounter [14], and courses frequently rely on simulated or real patients [15]. These formats are associated with high costs and a high organizational effort, however, which shortens the time available to acquire these skills. These restrictions often do not allow all students to interactively practice a skill or practice for more than 1 repetition [16]. Furthermore, learning in these settings often occurs supervised by the patient and peer group, thereby impacting performance and possibly inhibiting rather shy students from using the learning opportunity [17,18].

Chatbots offer a significant potential to overcome these restrictions, thereby enhancing the utility thereof in health care and medical education settings. Chatbots have thus become valuable tools in health care; their nonjudgmental and easily accessible nature makes them particularly well suited for responding to patient inquiries and concerns [19,20]. The use of chatbots in medical education offers equally promising opportunities. In particular, chatbots are of interest tool-wise in the area of virtual patients [21,22].

The advance of chatbots is significantly supported by the developments of LLMs, such as GPT, which progressed considerably in 2022 [23]. This progress in artificial intelligence (AI) technology opens up new horizons for innovative, cost-effective, and accessible learning methods [24,25]. GPT has performed surprisingly well regarding medical knowledge,

including board exams [26-28]. The combination of excellent language skills and medical knowledge predispose GPT to perform as a chatbot. Moreover, LLMs allow for unsupervised and repeated learning, thereby enabling all students to learn for as long as it is needed. However, LLMs, such as GPT, are language models using a next-word prediction paradigm [29] and are thus prone to “hallucinations” (ie. producing nonsensical content) [30]. Moreover, LLMs are also known to occasionally escape prompts.

Chatbots have been used in medical education before the broader application of LLMs [31]. However, these virtual simulated patients did not reach human performance in terms of language expression and dynamics [31]. Although chatbots to practice history taking have been developed based on pre-LLM technology [32], it is unknown whether and how LLMs, such as GPT, can be used as a simulated patient to acquire communication skills. To investigate the previously uncharted potential of GPT as a simulated patient, we conducted a mixed methods study. Here, we present our analysis of GPT capabilities, as a chatbot as well as an improved version of an AI-optimized illness script.

Methods

Study Outline

First, we developed an illness script [33] that contained relevant medical information from a fictitious patient and a prompt to make GPT-3.5 (OpenAI) act as a simulated patient. We introduced the chatbot to medical students through a web interface, allowing them to voluntarily practice their history-taking skills. The conversations were recorded and systematically analyzed to explore the conversations with the GPT-powered chatbot. We focused on feasibility and usability and performed a quality assessment of GPT’s text output.

Setting and Participants

During a large-scale skill-refreshing event with participants from all our faculty, students were invited to voluntarily participate in our investigation. After they provided informed consent, students were provided with a laptop on which the interface was ready to use. After entering demographic information, students could chat for as long as they felt necessary.

Since our participants were native German speakers, we conducted all interactions with GPT in German and later translated the data and screenshots into English for this paper.

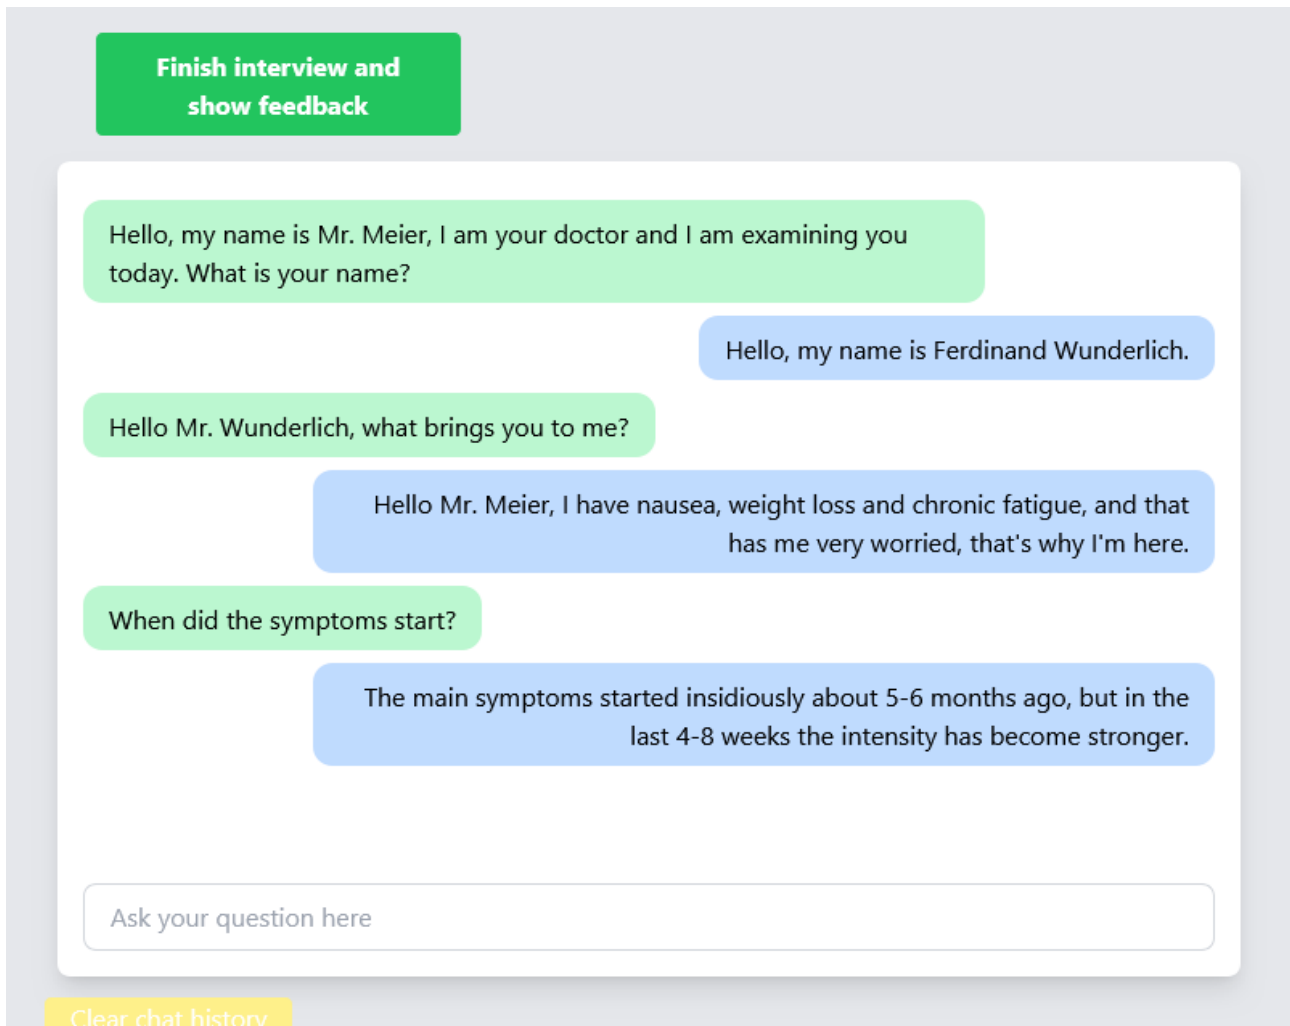

Chat Platform

To enable the interaction between students and GPT, we created a chat interface through which the students could post written

questions to a virtual patient and receive written answers (Figure 1). This interface enabled us to guide user input and send system messages to GPT. The system was developed as a local HTML file. It used JavaScript code for processing and *tailwindcss* for layout. We called the OpenAI application programming interface (API) using the JavaScript Fetch API and making calls to

OpenAI's chat/completions endpoint using *gpt-3.5-turbo*. Model parameters were left at default settings. The complete chat history for each user input up to that point was sent to the model. At the conclusion of the conversation, the full chat history was saved to a text file for further processing.

Figure 1. Screenshot of self-developed web interface.

Prompt Development

Next, we developed prompts that were needed to make GPT act as a simulated patient. The prompts were designed to guide GPT's behavior and ensure it provided medically accurate and relevant responses. Presented in detail next, our prompt included a chatbot-optimized illness script as well as a behavioral instruction prompt.

Chatbot-Optimized Illness Script With a Medical Case

We developed a fictitious medical case in a format that could be posted to GPT. As our learning objective was to take a systematic history, we intended to provide all required details. A short version with some information about the case is presented in Table 1, and the full case is provided as Multimedia Appendix 1.

Table 1. Illness script “Nausea, weight loss, and chronic fatigue” (shortened version).

Variable	Details
Patient details	<ul style="list-style-type: none"> • Ferdinand Wunderlich, 48 years of age • Occupation: administrative employee in the finance department of a municipal hospital • Personal life: overweight, previously tried diets unsuccessfully; enjoys family time, has two sons aged 8 and 6 years; not physically active • Initial consultation with a new general practitioner
Medical concerns	<ul style="list-style-type: none"> • Presenting with nausea (especially after large meals), significant weight loss (10 kg in 6 weeks), and chronic fatigue • Muscle cramps mainly in the legs and frequent at night • Mental fatigue, with forgetfulness at work • Has felt run down and tired for about 5-6 months, with symptoms intensifying in the past 4-8 weeks • Feels severely limited by his current condition
Accompanying symptoms	<ul style="list-style-type: none"> • Multiple minor infections recently • Episodes of dizziness (ie, light-headedness) occurring 1-2 times daily • Dry skin • Increased thirst (drinks about 4-5 L of water daily) and frequent urination day and night
Medical history	<ul style="list-style-type: none"> • Known hypertension, currently on blood pressure medication (Hygroton 50 mg and ramipril 5 mg) • Shortness of breath during exertion • Fatty liver diagnosed 3 years ago • Right inguinal hernia treated surgically 3 years ago • Mild constipation • Allergic to penicillin since childhood • Previously smoked for 4 years in his twenties • Consumes beer occasionally (1-2 times a week)
Family history	<ul style="list-style-type: none"> • Father died of a heart attack • Mother died at 79 years of age and had diabetes later in life • Brother diagnosed with colon cancer

Behavioral Prompt

In addition to the required medical information, it was necessary to instruct GPT to behave as a simulated patient, which is why we developed a behavioral prompt. To achieve this, we used our custom interface to test the answers provided by GPT by conducting the interviews ourselves. Where we noticed a failure to stick to the provided medical information, we tried to improve the manner in which the information was presented. For improvements to the prompt, we relied on our experience as well as the advice and model explanation provided by OpenAI [34].

During the iterative process of prompt development, 2 areas of improvement were evident: the role-play aspect (ie, that GPT sticks to the role as a patient) and the medical aspect (ie, that GPT provides answers as close as possible to the given information, while sounding human).

Regarding role-play, the model often struggled to maintain its assigned role, especially during discussions of potentially serious medical issues. We had little success with providing details of the role or simply reinforcing that the goal was to impersonate a patient. Instead, we found the most helpful tweak was adding “patient name:” at the end of any user input, where “patient name” would be replaced by the name specific to each case. This resulted in GPT generating a continuation of “patient name:,” making it more probable that the LLM would actually produce a sensible utterance by the patient. Other tweaks were to begin the initial system message with the patient’s name and

continue to use this name to “address” GPT in this manner. We also instructed the model to not assist the user in this setting but to impersonate the patient, although we found this to have a much smaller effect than the other changes. Notably, the model was instructed to provide short answers to reduce reading times.

We provided GPT with the case description, preceded by instructions to use this information for answering medical questions. We also provided a list of all categories the student should ask about in the interview. The list contained possible answers and information for each category; for this list, we also included a statement about its format (ie, we explicitly stated that “[the list] will have the form ‘category’: ‘information or possible answer if asked’”). In general, surrounding factual information with an explicit description of its content and format increased the reliability of using that information.

It is important to note that formatting was also important, as the model sometimes picked up patterns in formatting in its own answers. Since the medical information was first produced with common text editing software, a simple copy and paste into our system also copied large amounts of formatting, such as indents, bullet points, or whitespace. Cleaning this formatting from the prompt helped the model avoid repeating these patterns in the output.

In a similar way, we tried to give more structure to the prompt by using special delimiter statements, such as “===DIALOGUESTART.” These were intended to help the model switch from reading in medical information to

impersonating a patient. However, our approach was not successful, as the model started to repeat such patterns in its output, sometimes even initiating further switches, for example, by inserting “===DIALOGUEEND” itself. We had more

success in achieving the desired behavior using structuring with explicit descriptions in natural language, as described before.

Full Prompt

The full prompt including both aforementioned parts is presented in [Textbox 1](#).

Textbox 1. Prompt sent to the generative pretrained transformer (GPT) application programming interface (API) in JavaScript Object Notation (JSON) format. The prompt consists of a behavioral instruction prompt and the first user message. Further dialogue was appended during the interview.

```
{
  "role": "system",
  "content": "Hello Mr. Wunderlich, in the following you will assume the role of an acting patient. You will not assist the user, but answer questions based on the following information: Your name is Ferdinand Wunderlich,
  [... Further Case Information ...]
  Here is some more information on your complaints, Mr. Wunderlich. These are in the form of 'Category': 'Information or possible answer on request'
  Chief complaint, if applicable, with: Nausea and weight loss (most recently 10 kg in 6 weeks) Chronic fatigue, exhaustion and lack of drive
  Localization and spread: The muscle cramps occur mainly in the legs.
  [... Further details (see illness script) ...]
  In the following, you will take the role of Ferdinand Wunderlich, [...], that is, you will answer as Ferdinand Wunderlich. Try to keep your answers rather short."
},
{
  "role": "user",
  "content": "[USER INPUT]
  "Ferdinand Wunderlich:"
}
```

Qualitative Analysis

To gain a more profound understanding of the conversation between chatbot and participant, we conducted a qualitative analysis (ie, the Braun-Clarke inductive approach [35]) of the question-answer pairs (QAPs). All QAPs were thus aggregated

and stored in a Microsoft Excel (version 16.0.10394.20022) sheet. For each question and answer, the word count was automatically analyzed using an Excel formula. Each QAP was assessed by 1 rater (author FH) for the aspects listed in [Table 2](#). In equivocal cases, the items were discussed with another rater (author MM) until consensus was reached.

Table 2. Aspects, categories, and text examples used for rating.

Aspect and categories	Example(s)
Conversation part	
Greeting/introduction	<ul style="list-style-type: none"> Student: "Good day, my name is Mrs Müller, and I am your attending physician. What brings you to me today?" GPT^a: "Good day, Mrs Müller. I have been experiencing nausea, weight loss, chronic fatigue, and lethargy for some time and would like to find out what could be causing it."
Medical history	<ul style="list-style-type: none"> Student: "How much are you limited in your daily life?" GPT: "I am now severely restricted. After a long day at work, I am incapable of doing anything in the evening, and I also notice that I keep forgetting things at work. This way, I cannot manage either my work or the tasks at home in the family." Student: "I will ask you briefly about a few other points that could be relevant. Do you have headaches?" GPT: "No, I do not have headaches."
Goodbye/outlook	<ul style="list-style-type: none"> Student: "Okay. We will now conduct some examinations. Thank you for your responses." GPT: "Thank you for the questions and your attention. I hope we can find the cause of my complaints and a suitable treatment option."
Interactive exchange	<ul style="list-style-type: none"> Student: "I will discuss this with my boss and let you know tomorrow." GPT: "Okay, that sounds good. Thank you for your help. I look forward to your feedback tomorrow."
Student's question covered by the illness script	
Question not covered by the script	<ul style="list-style-type: none"> Student: "Have you been on vacation recently?" Student: "I imagine you sit a lot at your work. Do you have any back pain?"
Question indirectly/partially covered by the script	<ul style="list-style-type: none"> Student: "Are your lymph nodes enlarged?" Student: "Do you have a history of thyroid disease?"
Question explicitly covered by the script	<ul style="list-style-type: none"> Student: "What medications are you taking and at what dosage?"
Statement (no question)	<ul style="list-style-type: none"> Student: "Thank you for the conversation! I would now like to conduct a physical examination and initiate further diagnostics."
GPT's answer uses the illness script	
Answer based on explicit script information	<ul style="list-style-type: none"> GPT: "For several months, I have been increasingly struggling with chronic fatigue and a lack of drive. The weight loss of 10 kg in the past 6 weeks has additionally worried me."
Answer based on implicit script information	<ul style="list-style-type: none"> GPT: "No, no laboratory diagnostics have been carried out so far."
Answer based on fictitious information	<ul style="list-style-type: none"> GPT: "No, due to the current situation around the COVID-19 pandemic, I have not traveled recently."
Answer medically plausible (regarding case and illness script)	
+2: Answer plausible, highly specific for case	<ul style="list-style-type: none"> Student: "Okay, how much do you drink in a day?" GPT: "I currently drink about 4-5 L a day, I have a noticeably increased thirst." Student: "All right, you also mentioned weight loss. How many kilograms are we talking about?" GPT: "I have lost about 10 kg in the past 6 weeks."
+1: Answer plausible, relevant for case	<ul style="list-style-type: none"> Student: "Do you have any accompanying pain?" GPT: "So far, I have not noticed any particular pains, except maybe occasional muscle cramps in my legs."
0: Answer plausible, not case specific	<ul style="list-style-type: none"> Student: "Have you ever had surgery?" GPT: "Yes, I had laparoscopic surgery for a right inguinal hernia 3 years ago."

Aspect and categories	Example(s)
-1: Answer rather implausible	<ul style="list-style-type: none"> GPT: "I do not follow any specific diet or way of eating. In principle, I eat quite balanced." GPT: "I used to exercise regularly, but in the past few months, I have been unable to do any sports due to my complaints." <p><i>Comment: Both statements do not fully align with the predefined role of a patient with long-standing obesity, but they show aspects of social desirability.</i></p>
-2: Answer very implausible	<ul style="list-style-type: none"> GPT: "On average, I drink about 10-12 L of fluids per week. This includes water, tea, and occasionally other drinks, such as juice spritzers." <p><i>Comment: Here, ChatGPT fails to convert the specified daily fluid intake into a weekly intake. Since polydipsia is an important symptom of hyperglycemia, this statement was rated as very implausible.</i></p>
Not applicable	<p><i>Comment: For QAPs^b with empty answers due to technical reasons.</i></p>

^aGPT: generative pretrained transformer.

^bQAP: question-answer pair.

Chatbot Usability Questionnaire

To assess how our participants perceived the simulated patient, we used the Chatbot Usability Questionnaire (CUQ) [36]. This 16-item questionnaire measures the personality, user experience, error management, and onboarding of a chatbot and has recently been validated [37]. After ending the chatbot sessions, our participants were asked to fill out a written version of the CUQ, and the CUQ score was calculated using the tool provided by the authors [38].

Quantitative Analysis

Statistical analysis and figure generation were performed with R statistical software (version 4.3.1; R Foundation for Statistical Computing) [39]. For the CUQ, we provided relative numbers of Likert categories. For counts, we reported the total (n) as well as percentages. Numerical data were inspected for normal distribution and provided as the mean and SD. If a Gaussian distribution could not be assumed, median and 25%-75% quartiles (Q25-Q75) were provided. We used the Spearman correlation coefficient to check for correlations, considering $P < .05$ as statistically significant.

Ethical Considerations

The study was approved by the Ethics Committee of the Faculty of Medicine at University Hospital Tübingen (385/2023A). Data were kept anonymous and were not associated with students. Although the participant got an opportunity to use the chatbot without providing consent that the data could be used for our study, all students consented that their data could be used.

Results

Demographic Data of Participants

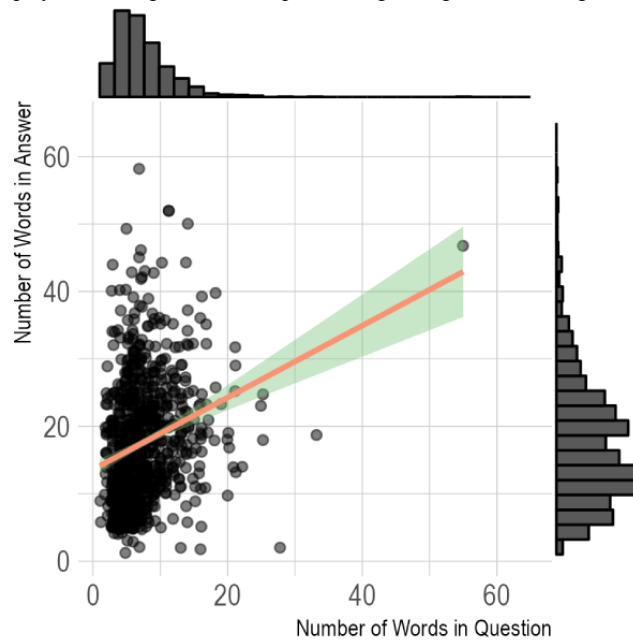

A total of 28 students participated in the experiment, 24 (85.7%) of whom identified as female and 4 (14.3%) as male; no participants identified as nonbinary. Their ages ranged from 19 to 31 years (mean 23.4, SD 2.9 years). Of the 28 participants, 26 (92.9%) studied human medicine and 2 (7.1%) studied midwifery. The semesters varied from the second to the tenth semester, and 1 (3.6%) participant was in their final year. No participant was excluded from the analysis.

Conversation Length and Part of Conversation

A total of 28 conversations yielded 826 QAPs. Each conversation consisted of a median of 27.5 QAPs (Q25-Q75: 19.8-36.5 QAPs). The questions asked by participants yielded a median of 6 words (Q25-Q75: 6-9 words). The answers provided by GPT had a median of 16 words (Q25-Q75: 11-23 words). The Spearman correlation coefficient between the word count of the question and the word count of the answer was significant ($P < .01$), with $\rho = 0.29$, indicating a positive but mild correlation. A scatter plot is displayed in Figure 2.

Of the 826 QAPs, most were related to history taking (n=782, 94.7%). A minority reflected interactive exchange (n=17, 2.1%), greeting/introduction (n=15, 1.8%), and goodbye/outlook (n=12, 1.6%).

Figure 2. Scatter plot including the trend line for the number of words in the student's question (x axis) and the number of words in the GPT answer (y axis). Representative variables are displayed as histograms at the top and along the right side. GPT: generative pretrained transformer.

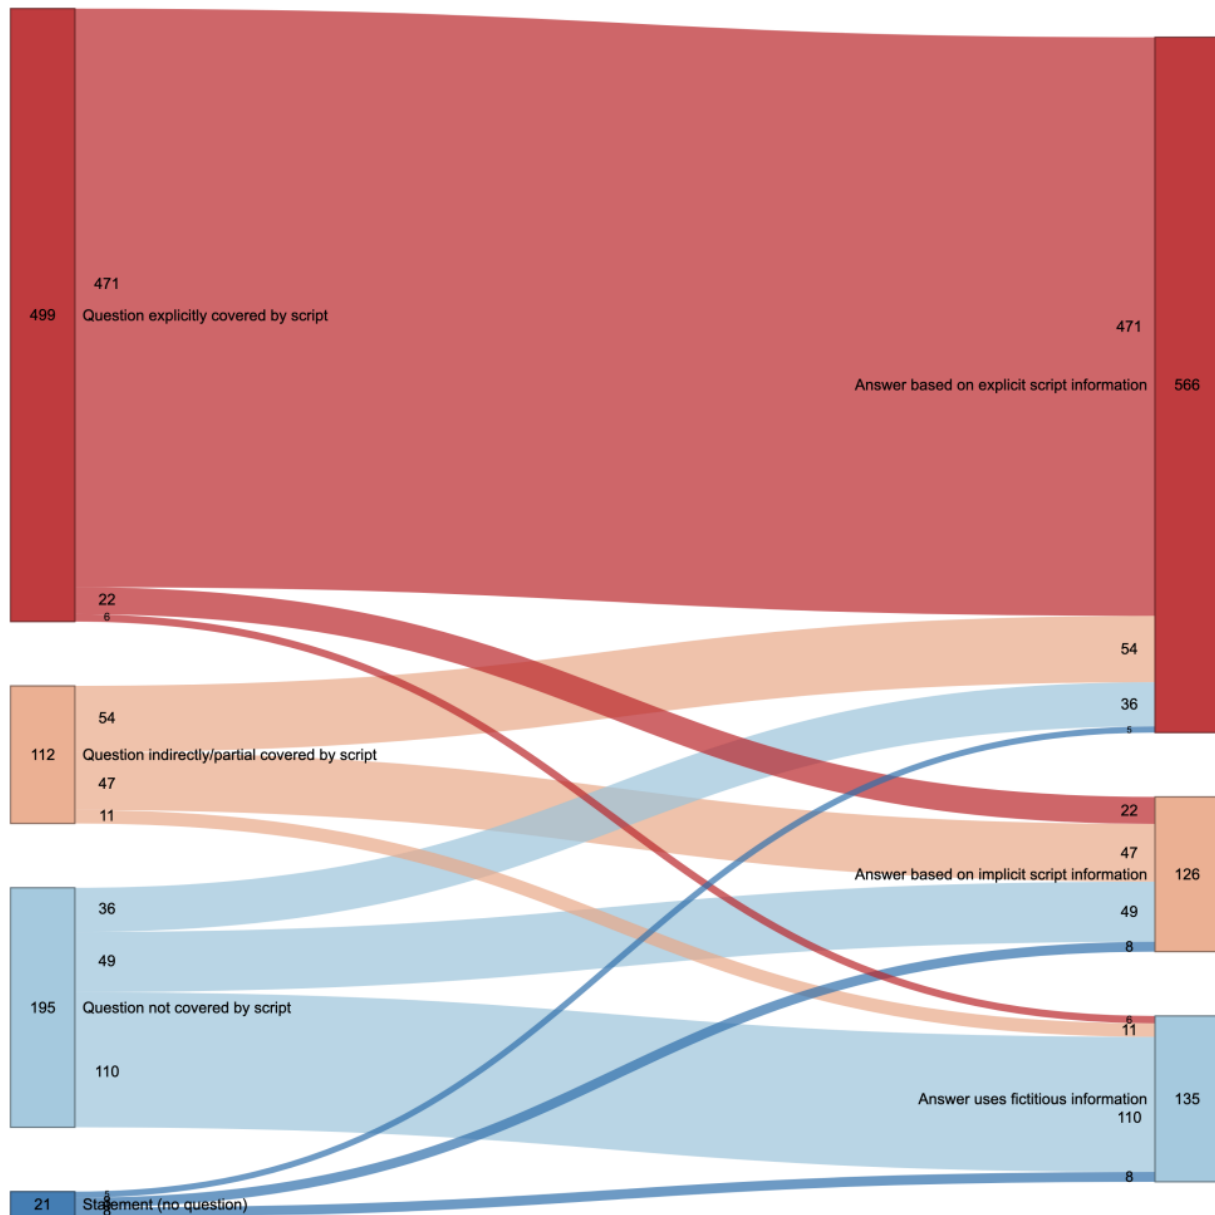

Content Analysis of Conversations

How Do Questions and Answers Relate in the Context of the Script?

In the subsequent assessment, we examined whether the questions posed by the students were covered by the script. We

then analyzed how the GPT responses were based on the information provided in the script (Figure 3).

Figure 3. Sankey plot for “Student’s question covered by the illness script” and “GPT’s answer uses the illness script” categories in relationship to one another. Numbers indicate the total QAPs per group or connection, and connections without numbers are 0. GPT: generative pretrained transformer; QAP: question-answer pair.

For questions explicitly covered by the script ($n=502$, 60.3%), 471 (94.4%) of GPT’s answers were based on explicit script information, 22 (4.4%) on implicit script information, and 6 (1.2%) on fictitious information. When the questions were indirectly or partially covered by the script ($n=112$, 13.4%), 54 (48.2%) of GPT’s responses were based on explicit information, 47 (42%) on implicit information, and 11 (9.8%) on fictitious information. For questions not covered by the script ($n=195$, 23.4%), 36 (18.5%) of GPT’s answers used explicit script information, 49 (25.1%) used implicit script information, and 110 (56.4%) used fictitious information. In instances where students provided statements without posing questions ($n=24$, 2.9%), 5 (23.8%) of GPT’s responses were based on the explicit script, 8 (38.1%) on the implicit script, and 8 (38.1%) on fictitious information. A total of 33 (3.8%) QAPs were excluded,

because they could not be assessed in 1 of the 2 evaluated categories.

Are the GPT Answers Plausible?

When analyzing the answers in detail, 33 (4%) of the 826 QAPs concerned multiple aspects (ie, related to different questions or multiple parts of the illness script). We consequently further divided 32 (97%) QAPs into 2 QAPs and 1 (3%) QAP into 3 QAPs. In total, this resulted in 860 QAPs that were used for the subsequent qualitative plausibility analysis.

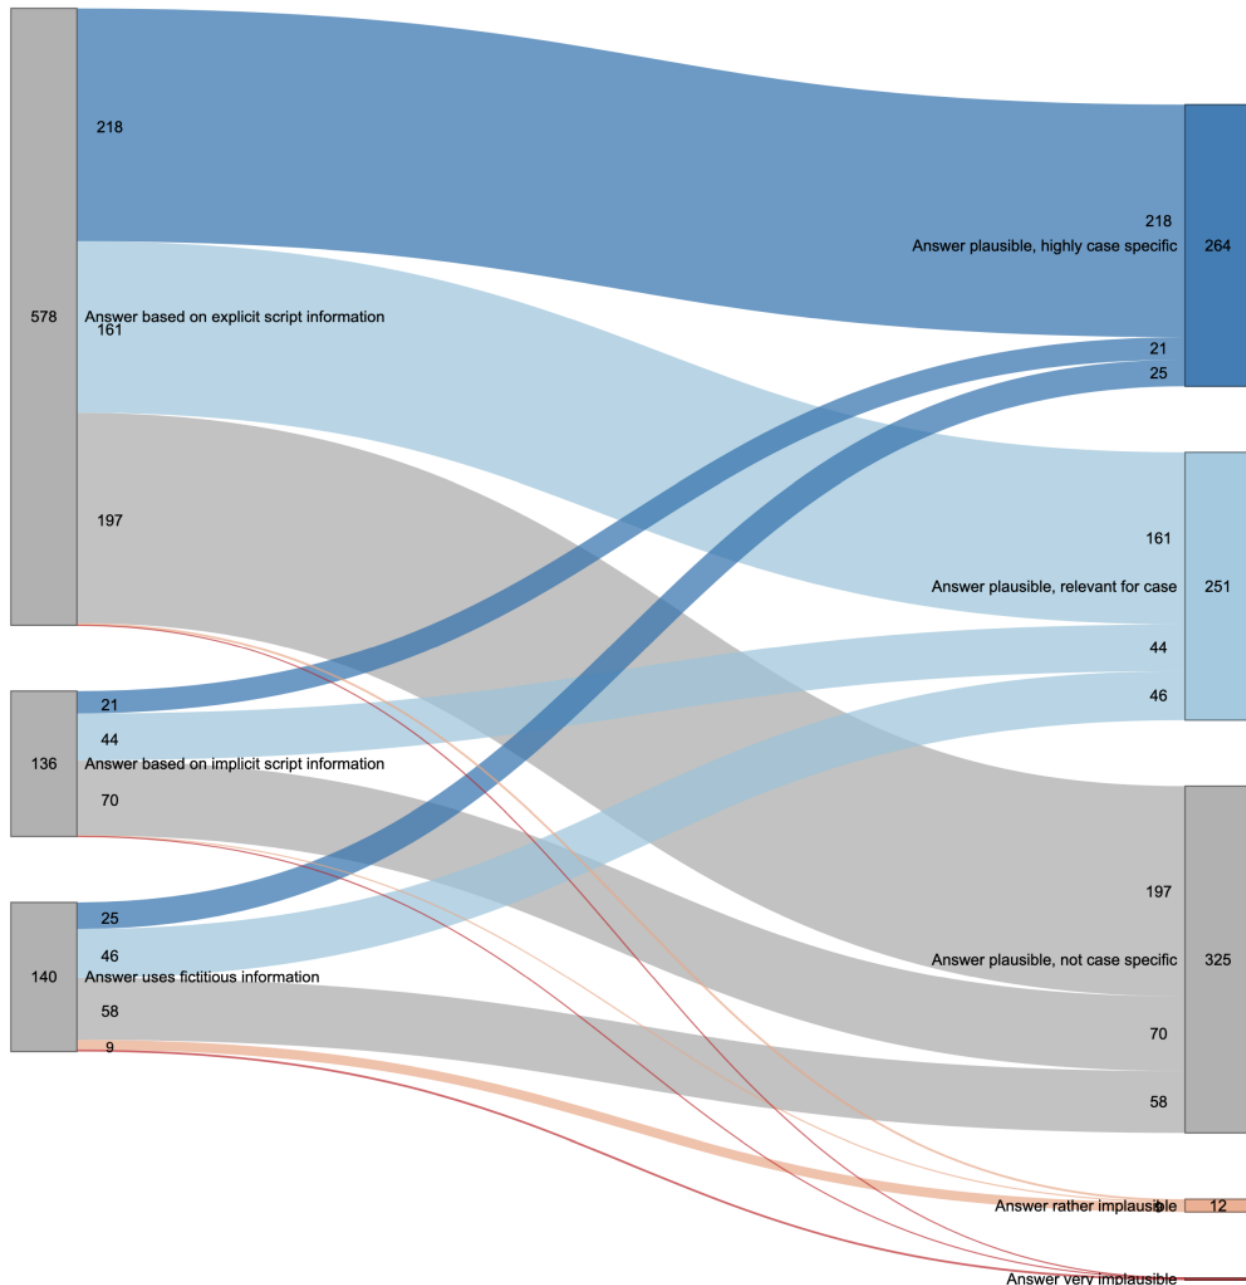

We further analyzed whether the GPT-provided responses were medically plausible. Of the 860 QAPs, 842 (97.9%) were rated as plausible. Specifically, 264 (30.7%) were rated as “answer plausible, highly specific for case,” 252 (29.3%) as “answer plausible, relevant for case,” and 326 (37.9%) as “answer

plausible, not case specific.” A smaller proportion (n=14, 1.6%) were rated as rather implausible, while 2 (0.2%) were found to be very implausible. This rating could not be applied to 2 (0.2%) QAPs.

Correlation Between Reliance on the Illness Script and Plausibility

We further analyzed whether the answers used explicit or implicit information from the illness script or fictitious information (Figure 4).

Figure 4. Sankey plot for “GPT’s answer uses the illness script” and answer plausibility categories in relationship to one another. Numbers indicate the total QAPs per group or connection, and connections without numbers are 0. GPT: generative pretrained transformer; QAP: question-answer pair.

Among answers that used explicit script information (n=578, 67.7%), 218 (37.7%) were “plausible, highly specific for the case,” 161 (27.9%) were “plausible, relevant for the case,” and 197 (34.1%) were “plausible, not case specific,” with a mere 2 (0.3%) answers being rather implausible and none very implausible.

Among answers stemming from implicit script information (n=136, 15.9%), 21 (15.4%) were “plausible, highly specific for the case,” 44 (32.4%) were “plausible, relevant for the case,”

and the majority (n=70, 51.5%) were “plausible, not case specific.” Only 1 (0.7%) answer was deemed rather implausible, and none were rated as very implausible.

In the context of fictitious information (n=140, 16.4%), the answers were varied: 25 (17.9%) were “plausible, highly specific for the case,” 46 (32.9%) were “plausible, relevant for the case,” and 58 (41.4%) were “plausible, not case specific.” Additionally, 9 (6.4%) answers rated as were rather implausible, and 2 (1.4%) were viewed as very implausible.

Furthermore, 6 (0.7%) answers could not be categorized.

Analysis of Implausible Answers

Finally, we analyzed all answers rated as rather or very implausible. Of the 14 (2.1%) answers that were rated as rather implausible, 7 (50%) were rated as socially desirable. A recurrent example for this category could be observed when the GPT-powered chatbot was asked for its eating habits; in these cases, the answers contained popular eating recommendations, instead of eating habits that were plausible for our case. For another 2 (14.3%) answers, the model did not stick to its role as a simulated patient but tried to assist the user (ie, when greeted, the simulated patient asked the doctor, “How can I help you?”). For 1 (7.1%) other QAP, the model referred to the doctor by the name of the patient, which thus rated this QAP as “GPT leaving its role identity.” In another case, information clearly evident from the script (ie, vertigo) was not used and the simulated patient stated that he did not suffer from vertigo. One

more rather implausible QAP was illogical in itself (ie, “But due to my weight loss, I have had a reduced appetite lately.”).

Among the 2 (0.2%) QAPs rated as very implausible, GPT escaped its role in 1 (50%) case. Herein, the participant asked about what can be seen in the physical exam, and the GPT-provided answer was, “Sorry, I am a language AI and do not have access to visual information. I can only provide information that is given to me through text input. Please consult a doctor for a complete clinical examination.” The second QAP was rated as very implausible due to a calculation error by GPT: When our chatbot was asked how much he drinks during 1 week, the answer was 10-12 L. Our script indicated 4-5 L per day, however, which would be an average of 28-35 L per week.

Chatbot Usability Questionnaire

The results of the CUQ are displayed in [Figure 5](#) (also see [Multimedia Appendix 2](#) for numeric results).

Figure 5. Results of the CUQ, grouped by category, as proposed by Holmes et al. 2023. Neutral responses are indicated on the right side of the figure. CUQ: Chatbot Usability Questionnaire.

Personality

User Experience

Error Handling

Onboarding

Other

Within the personality category, the majority of respondents (n=16, 57%) felt the chatbot’s personality was realistic and engaging and 9 (32%) strongly agreed. When considering whether the chatbot seemed too robotic, a large proportion (n=13, 46%) disagreed and 2 (7%) strongly disagreed. The chatbot was perceived as welcoming during the initial setup by 12 (43%) of respondents, and 8 (29%) respondents strongly agreed. A significant portion (n=15, 54%) strongly disagreed,

and 12 (43%) disagreed with the notion that the chatbot seemed unfriendly. In terms of understanding, 12 (43%) respondents agreed and 16 (57%) strongly agreed that the chatbot understood them well.

For the user experience category, the chatbot was seen as easy to navigate by 10 (36%) respondents, with a notable 18 (64%) strongly agreeing. In contrast, when asked whether it would be easy to get confused when using the chatbot, 17 (61%) disagreed

and 8 (29%) strongly disagreed. The chatbot's ease of use was highlighted by 11 (39%) respondents agreeing and 16 (57%) strongly agreeing. Most respondents disagreed with the perception that the chatbot was complex: 12 (43%) disagreed and 13 (46%) strongly disagreed.

In the error handling category, a majority (n=16, 57%) of the respondents remained neutral about the chatbot coping well with errors. Of the remainder, most respondents were positive about the error handling, with 6 (21%) agreeing and 4 (14%) strongly agreeing. Conversely, 6 (21%) respondents strongly disagreed and 10 (36%) disagreed that the chatbot seemed unable to handle errors, with only a minority (n=3, 11%) agreeing.

For the onboarding category, 12 (43%) respondents agreed and another 12 (43%) strongly agreed that the chatbot explained its scope and purpose well. Accordingly, 8 (29%) respondents agreed, 7 (25%) disagreed, and 5 (18%) strongly disagreed with the statement that the chatbot gave no indication as to its purpose.

For questions not related to a factor, 18 (64%) respondents agreed and 8 (29%) strongly agreed that chatbot responses were useful, appropriate, and informative. Accordingly, 14 (50%) respondents strongly disagreed and 12 (43%) disagreed that chatbot responses were irrelevant. Additionally, 18 (64%) respondents strongly disagreed and 7 (25%) disagreed with the statement that the chatbot failed to recognize many inputs.

Overall, the CUQ score was 77 (Q25-Q75: 71-83) out of a maximum score of 100, which indicated a positive user experience with the chatbot.

Improved AI-Capable Illness Script

Finally, we analyzed the QAPs for aspects on how to improve the illness script. Of 302 QAPs where the student's question was either not covered or only indirectly/partially covered by the script, we were able to further classify 301 (99.7%) QAPs as to whether the script needs to be updated. The 1 (0.3%) unclassified QAP consisted of an uncontextual exchange and was thus discarded.

QAPs Implicating an Update of the Illness Script

For the majority of the QAPs (n=141, 46.8%), no update was required, as the information was not relevant for the case, although it was medically relevant. A further 14 (4.7%) QAPs were neither medically relevant nor relevant for the case, also not implicating an update. For 86 (28.6%) QAPs, however, we determined that an already existing criterion in our illness script needed further details. Moreover, for 60 (19.9%) of the analyzed QAPs, we judged that our illness script needed additional criteria.

Detailed Additions to Existing Criteria

More detailed specifications were recommended for some of the already existing criteria. These encompassed the specification of vomiting, nausea, stress, daily symptom progression, timing of individual symptoms throughout the day, attempts at relief, prior investigations, urine output, bedding/nightclothes, and stool.

Specific New Criteria Required

A closer examination of the content revealed several specific criteria that were absent but found to be relevant. These included dietary habits, activity/sports, pain, travel abroad, urine, and potential autoimmune diseases.

Improved Script Version

Based on the aforementioned information, we generated an updated version of our illness script ([Multimedia Appendix 3](#)).

Discussion

Principal Findings

In this study, we investigated the capabilities of GPT used as a chatbot to practice history taking, a core competency of medical professionals [1,2]. Using a mixed methods approach, we provided a comprehensive overview of the performance of GPT, as well as the perception of our participants about the chatbot. Our main findings can be divided into 2 areas: the performance of GPT as a simulated patient and how medical students perceive this chatbot as a conversational agent.

Performance of GPT as a Simulated Patient

When developing our chatbot, our focus was the feasibility of using an LLM model as a simulated patient. Before incorporation of our chatbot, we developed a prompt consisting of behavioral instructions and a chatbot-optimized illness script. Our analysis revealed that GPT was capable of providing most of the answers that were medically plausible and in line with the illness script. When questions were covered by the script, GPT was capable of referring to them, even when the information was only present in an implicit form ([Figure 3](#)). Even if questions were not covered by the script, GPT used the information from our medical case to generate answers that were mostly medically plausible. However, our analysis revealed that the degree of plausibility decreased when less information was present in the script ([Figure 4](#)).

The ability of GPT to act as a simulated patient requires reasoning capabilities (ie, thinking about something in a logical and systematic way) [40-45]. There are different types of scientifically recognized reasoning, such as deductive reasoning that applies a general rule to a specific case, inductive reasoning that uses specific observations to draw a general rule, and abductive reasoning that finds the best conclusion for some observations [40]. Although LLMs, such as GPT, have been successful in various reasoning areas [46], our investigation revealed some caveats.

As most of the GPT answers were based on explicit script information, providing the user with these details did not necessitate the generation of new ideas and was thus a mere task of reformulating the given information for the context of a conversation. As a LLM [29], it was not surprising that GPT mastered this task. Regarding information that is not or only indirectly evident from the script, however, we postulated that both abductive and commonsense reasoning capabilities would be required; for these answers, we observed more implausible answers when compared to answers that were based on explicit script information.

Indeed, GPT-3.5 is known to perform reasonably well in both abductive and commonsense reasoning tasks [46,47]; our data confirmed these observations. There were a few instances when GPT provided implausible responses, however, and our content analysis revealed a tendency toward socially desirable answers. These errors could be interpreted as “escaping” abductive reasoning and applying deductive reasoning instead, thereby using general principles (eg, about a healthy diet) for a specific case. A similar observation was made by Espejel et al [46], when GPT “ignored” provided information and instead “relies on its general knowledge and understanding of the world.”

Regarding our illness script, these examples highlight that the illness script must include details about the patient role, especially when the patient displays traits that do not match popular or socially accepted norms. Although our script was capable of providing most information required for history taking either explicitly or implicitly, some criteria missed important details, while other criteria were completely missing. With the intention of keeping the illness script as short as possible and thereby reduce the work for teachers, we used the data from our study to amend our illness script.

Of note, we found a positive correlation between the word count of the question and the word count of the answer of GPT. Although the correlation was rather mild, possible interpretations for this behavior include GPT mimicking the language style (and length) of the interview, as well as inputs containing multiple questions, thus provoking longer answers. Although our analysis does not provide insight into this question, our data imply that future prompts should focus more on specifying the conversation style of GPT to achieve a standardized patient experience.

Perception of Medical Students

After exploring the performance of GPT as a simulated patient, we interviewed our participants about their perceptions of our chatbot using the CUQ. Confirming the qualitative analysis we performed, the students rated our chatbot as realistic and engaging. Again, in line with our qualitative data, the chatbot was rated as useful, appropriate, and relevant, with only a negligible number of students stating that the chatbot did not recognize their inputs; notably, some issues were detected with our chatbot being robotic. These data largely confirm the linguistic capabilities of GPT-3.5, with its output even showing personality traits [48-51]. Given the importance of the chatbot’s authenticity to provide students with a plausible conversation partner to practice their skills, the results of the CUQ are reassuring that GPT is capable of providing this experience.

Comparison With Prior Work

Owing to the costs and potential disturbances associated with the use of real or simulated patients in communication training [52,53], there has been great interest in the use of virtual simulated patients as chatbots for communication training [21,31]. In the past years, studies were published using chatbots to cover a wide range of conditions and domains [52,53]. In addition to physician-patient communication skills, chatbots have been used for interprofessional communication [54] and for skill assessments [55]. However, in contrast to our study,

most of these studies were performed before the broad accessibility of LLMs, such as GPT. These chatbots have thus been restricted in their authentic skills, capability of adoption (ie, in terms of personality, cases, etc), and ability to be transferred to different health care domains [31]. Although we also focused on 1 patient case, the ability of LLMs makes them theoretically capable of adapting to a given situation. Furthermore, our assessment using the CUQ revealed that our chatbot was perceived as realistic. This indicates that LLMs, such as GPT, when investigated rigorously, might be able to overcome the aforementioned restrictions.

As is the case with the technology used to process and generate language, previous studies have used various interfaces [52,53]. Similar to our study, many rely on web-based chat-like interfaces, and good usability seems to be of importance for acceptance by the learners [56]. Indeed, the CUQ used in our study also revealed that our user interface yields a good user experience. However, even with good acceptance, chat-like interfaces are limited to written language, thus restricting communication to the verbal domain. Therefore, newer approaches integrate chatbots in virtual reality environments [54], paving the way for a more integrated learning experience.

Limitations

Our study has some noteworthy limitations. As this was the first study using GPT as a simulated patient, we focused on 1 language model (ie, GPT-3.5, which we chose for its free availability and fast response time) and 1 patient case. Although we perceived our case as representative for history taking, our data did not allow for generalization to more specialized medical fields, and further studies are required to verify scalability to other medical specialties. Moreover, we focused on history taking, and although our chatbot performed well in general communication skills, it remains unclear how it will perform in other areas. Additionally, history taking is usually performed with spoken language, in contrast to the written language we used in our investigation. As this was a feasibility study, we only interviewed our participants about their perceptions but did not perform any objective skill measurements. We therefore cannot conclude that our participants improved in history taking, which should be addressed in future studies. Furthermore, the majority of our participants were female, which may have reduced the generalizability of our results. Due to the fact that we designed our study as an exploratory feasibility study, we did not perform a sample size calculation and therefore used descriptive statistics almost exclusively. Moreover, our participants were volunteers and thus probably motivated toward AI technology [22], possibly indicating a selection bias.

Conclusion

This study showed that a GPT-powered simulated patient chatbot works well and is perceived favorably among medical students. Although real patients remain the cornerstone of clinical teaching, technology-based education, as shown in this study, could be particularly beneficial for novice learners during their initial learning phases. It is important to note that we did not investigate skill acquisition, which is an important next step when evaluating GPT-based chatbots. Furthermore, our chatbot could be combined with other new technologies, such as speech

recognition and virtual/augmented reality, and thus could offer an even more integrated learning environment. Despite limitations, our study has implications for the field of medical education. Most importantly, we could show that GPT is capable of providing a simulated patient experience using an illness

script, paving the way toward technology-assisted acquisition of communication skills. Moreover, by showing the capabilities of GPT-3.5 in history taking, the technology of LLMs might be capable of assisting learners in other areas as well.

Acknowledgments

We acknowledge the support of the Open Access Publishing Fund of the University of Tübingen. We thank Eric Nazareus for his assistance in performing the analysis.

Data Availability

The data sets used and analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

AHW, FH, and MM were responsible for designing and conducting the study, as well as the acquisition, analysis, and interpretation of data. CSP developed the web interface and the prompts. MM drafted the first version of the manuscript. TFW and LH were involved in the data analysis and interpretation. AN, JAM, JG, LH, and MH made substantial contributions to the study design and interpretation. All authors critically revised the manuscript, and all authors approved the final version of the manuscript and agreed to be accountable for all aspects of the work.

Conflicts of Interest

None declared.

Abstract

Background: Medical interviewing is a critical skill in clinical practice, yet opportunities for practical training are limited in Japanese medical schools, necessitating urgent measures. Given advancements in artificial intelligence (AI) technology, its application in the medical field is expanding. However, reports on its application in medical interviews in medical education are scarce.

Objective: This study aimed to investigate whether medical students' interview skills could be improved by engaging with AI-simulated patients using large language models, including the provision of feedback.

Methods: This nonrandomized controlled trial was conducted with fourth-year medical students in Japan. A simulation program using large language models was provided to 35 students in the intervention group in 2023, while 110 students from 2022 who did not participate in the intervention were selected as the control group. The primary outcome was the score on the Pre-Clinical Clerkship Objective Structured Clinical Examination (pre-CC OSCE), a national standardized clinical skills examination, in medical interviewing. Secondary outcomes included surveys such as the Simulation-Based Training Quality Assurance Tool (SBT-QA10), administered at the start and end of the study.

Results: The AI intervention group showed significantly higher scores on medical interviews than the control group (AI group vs control group: mean 28.1, SD 1.6 vs 27.1, SD 2.2; $P=.01$). There was a trend of inverse correlation between the SBT-QA10 and pre-CC OSCE scores (regression coefficient -2.0 to -2.1). No significant safety concerns were observed.

Conclusions: Education through medical interviews using AI-simulated patients has demonstrated safety and a certain level of educational effectiveness. However, at present, the educational effects of this platform on nonverbal communication skills are limited, suggesting that it should be used as a supplementary tool to traditional simulation education.

Introduction

Medical interviews play a crucial role not only in the diagnostic process with patients but also in building trust and rapport [1]. Medical interviewing skills are necessary in medical practice and are categorized in the Japanese Model Core Curriculum for Medical Education under the categories of “Comprehensive Patient and Community Perspective” and “Clinical Competencies for Patient Care” [2]. In Japan, the Pre-Clinical Clerkship Objective Structured Clinical Examination (pre-CC OSCE), provided by the Public Interest Incorporated Association, Common Achievement Tests Organization, assesses fourth-year medical students for their competence and aptitude to participate in clinical clerkships [3]. This examination evaluates basic clinical skills, including medical interviewing. It is a nationwide standardized test with very limited flexibility in terms of feedback and the examination itself. Upon passing, medical students are expected to acquire the skills to conduct medical interviews through proper communication and gather necessary information before graduation through participatory clinical clerkships. The standard practice method involves learning medical interviewing in lectures, followed by practice sessions under the supervision of instructors and simulated patients [4].

However, opportunities for Japanese medical students to practice medical interviewing within the medical education curriculum are limited [5]. Japanese medical education has evolved by following the German model since the mid-19th century and the American model since the mid-20th century. As a unique development in Japan, standard curricula and nationwide common exams, including the pre-CC OSCE, have been introduced in medical schools across Japan, aiming to standardize medical education over the past quarter century. However, this has also restricted the autonomy of each university. The learning methods remain predominantly lecture-based and more flexible. In contrast, clinical-based learning methods such as problem-based learning and team-based learning have not yet been widely adopted in Western countries. Even after clinical clerkships, there are many restrictions on medical practice involving patients. This can be attributed to the fact that mandatory clinical training after graduation was implemented much later in Japan than in Western countries, and the integration between undergraduate medical education and postgraduate education is still underdeveloped. Furthermore, simulation education is effective across many fields for learners, not just medical interviewing, but the opportunities to use such education are limited in terms of both location and time [6]. Additionally, from educators’ perspective, introducing medical interview education through simulation faces numerous barriers, including a lack of tutors, staff, simulated patients (including mannequins), and budget constraints [7].

Since the release of ChatGPT by OpenAI in the fall of 2022 [8], generative artificial intelligence (AI) technologies such as large language models (LLMs) have undergone rapid evolution and have been applied across various fields. In the medical domain, their integration is being considered in both clinical and research contexts [9]. One study demonstrated that LLMs

can accurately answer questions of the United States Medical Licensing Examination (USMLE), demonstrating their use in medical education and assessment [10]. The COVID-19 pandemic accelerated the digital transformation from traditional bedside teaching to simulation education, including research into remote education models using chatbots [11,12]. However, research integrating LLMs into simulation education remains in its developmental phase [13].

In the field of medical interviewing, a survey of 3018 medical students revealed mixed feelings regarding the integration of LLMs. While some expressed concerns that it might deteriorate the patient-physician relationship, others were hopeful about the potential of AI technology in education, recognizing its dual value [14]. LLMs, which are distinct from previous deep learning-based algorithms, can predict the likelihood of a sequence of words based on the context of the preceding words. Natural and meaningful language sequences can be generated by learning from sufficient textual data. This capability led us to consider their application in practicing medical interviews.

In response to new advances in AI technology and the ongoing digital transformation and to alleviate the lack of educational resources for medical interview training, our team designed a simulation program to improve students’ medical interview skills. This program uses GPT-4 Turbo to fulfill 2 roles: simulated patients and instructors providing feedback. To assess the educational impact of AI-assisted medical interview training on novice learners, specifically fourth-year medical students, we compared the scores from the clinical skills examination, pre-CC OSCE, between the control group, which practiced medical interviews only through traditional methods under the supervision of simulated patients and instructors, and the AI group, which received additional training through AI-simulated patient interviews. Since the medical students were preclinical clerkships, it was not possible to directly measure clinical competence. However, the pre-CC OSCE has shown a significant correlation with performance during clinical clerkships in Japanese medical student cohorts [15]. Notably, the scores of medical interviews have been identified as crucial predictors of performance during clinical clerkships. Therefore, in this study, the analysis was conducted using the scores from medical interviews.

Methods

Ethical Considerations

This educational research was approved by the institutional review board of Okayama University (2312-006). In this study, all data were anonymized and deidentified to ensure the privacy and confidentiality of the participants. No personally identifiable information was retained, and appropriate measures were taken to safeguard the participants’ information. Furthermore, no compensation was provided to the participants for their involvement in the research.

Recruitment

As of November 2023, 35 fourth-year medical students at Okayama University, a national university in Japan, who consented to participate and had completed medical interview

practices at least once using our developed AI-simulated patient were designated as the intervention group (AI group, $n=35$). Fourth-year medical students from Okayama University as of November 2022 who had only a traditional educational program and did not participate in the intervention were selected as the control group (control group, $n=110$). The practice period was set to 1 month, and the students were provided with an educational environment that allowed them to practice at any time using their laptops or smartphones. After this 1-month training period, the students underwent the pre-CC OSCE, which served as the primary evaluation metric.

Educational Platforms

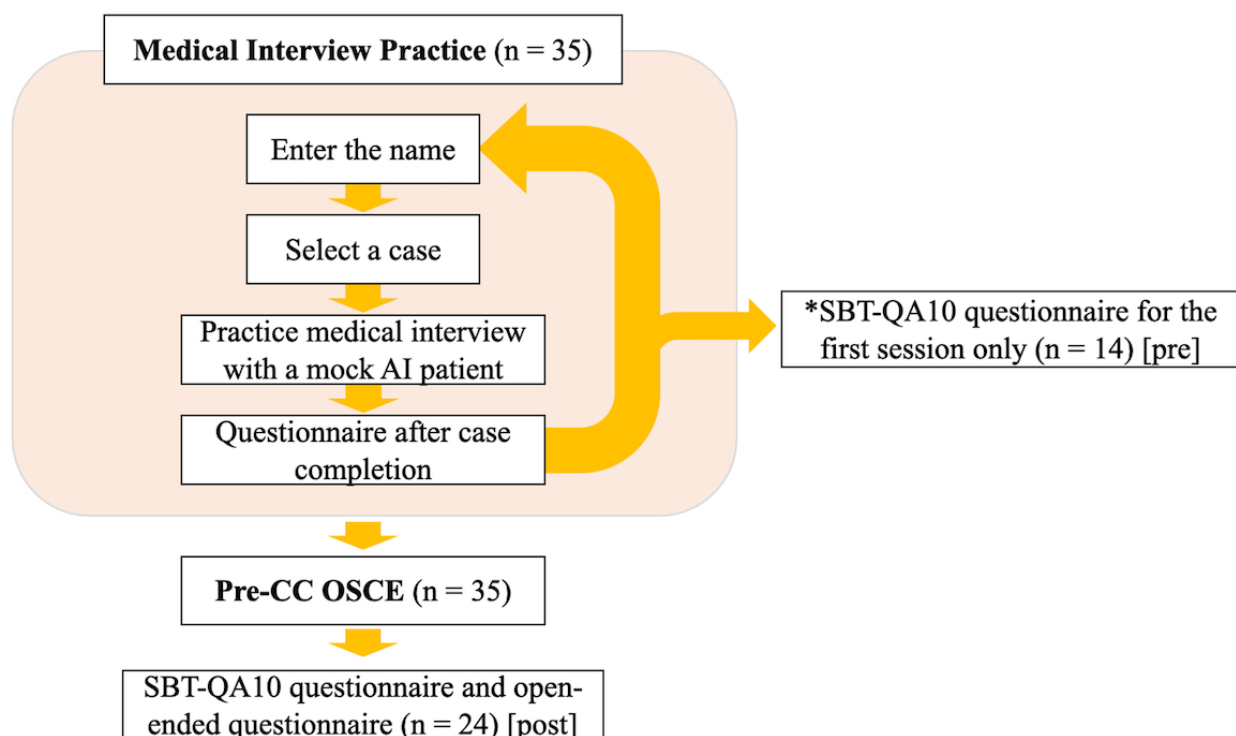

The responses of the AI-simulated patients were powered by GPT-4 Turbo, released in November 2023. We integrated it with the service “miibo” (miibo Corporation) through an application programming interface, which allows conversations with specified generative AI in a chat format. In this service, learners cannot see the prompts but can interact with fixed texts, such as case selections and questionnaires that do not involve AI, and choose from options and branch scenarios. While miibo is accessible via a web browser, it was also linked with LINE (LINE Corporation), which is widely used among students in Japan, for enhanced usability and to allow them to practice medical interviews via LINE as well. Learners could conduct interviews in chat format on either platform.

The GPT prompts were primarily composed of 3 elements: basic structure, case information, and feedback. The basic structure designated GPT-4 to act as the simulated patient and the learner as the physician practicing medical interviewing, with the emotional parameters fluctuating in response to the physician’s statements. All outputs were in Japanese. The emotional parameters were set from 1 to 10 for 8 emotions—joy, sadness,

anticipation, surprise, fear, disgust, trust, and anger—based on Ekman et al’s [16] theory and Plutchik’s [17] work. Initially, we loaded the case information into ChatGPT-4, ran a common prompt 3 times to estimate the initial emotional parameters, and set the average values. Case information included basic patient details, such as name, age, date of birth, and sex, along with relevant medical history. We prepared cases based on 8 primary symptoms, namely chest pain, abdominal pain, cough, heartburn, fatigue, fever, dizziness, and shortness of breath, which were developed and revised by multiple specialists. The feedback prompt was designed to provide feedback on general communication skills, elicitation of medically important information, and changes in patient emotions based on the conversation logs after the start of the medical interview. An example of a GPT prompt set on miibo is shown in [Multimedia Appendix 1](#).

Consenting students could access the miibo platform page or a dedicated LINE account via a specified URL, where they could enter their name and select a case. After case selection, they were presented with a scenario starting with the patient entering the consultation room and initiating a greeting, marking the beginning of the medical interview. The conversations were primarily text-based, although voice input was also possible. After completing the medical interview practice, the session could be ended by clicking a button on the screen labeled “End medical interview” or by declaring it, followed by a transition to feedback within the miibo scenario. After the feedback, the conversation log was deleted, and the session proceeded to a questionnaire. After completing the questionnaire, participants were redirected to the case selection section, allowing them to repeat the practice of medical interviews as many times as they desired ([Figure 1](#)).

Figure 1. Research overview diagram. Pre-CC OSCE: Pre-Clinical Clerkship Objective Structured Clinical Examination.

Questionnaire

After completing the case, the questionnaire asked participants to rate the difficulty of the case on a 5-point scale and assess the realism of the AI-simulated patient, the sense of presence (interaction through emotions with the AI-simulated patient), and their levels of tension and anxiety on a 10-point scale. Participants were also asked to provide open-ended feedback on what they found good and bad about the experience. After completing the first practice session, students were asked to complete a questionnaire based on the Simulation-Based Training Quality Assurance Tool (SBT-QA10, prequestionnaire) [18] to evaluate the quality of the simulation training program. The SBT-QA10, a conventional evaluation tool for simulation training, was not used directly in this study but was partially modified to meet our specific needs. The item "I felt part of the team" was revised to reflect the sense of inclusion within a medical team comprising faculty members.

Additionally, while the medical interview practice solely involved conversations with AI, without direct visibility of faculty, all interaction logs were meticulously reviewed, and responses to questions were managed by faculty. Therefore, items related to support and interaction from faculties were retained. This questionnaire was administered again at the end of the study (postquestionnaire) by gathering open-ended feedback on the overall positive and negative experiences throughout the study.

Statistical Analysis

The primary outcome measure was the scores related to medical interviewing in the pre-CC OSCE. The pre-CC OSCE consisted of 2 evaluation formats: an overall performance evaluation (summary evaluation, scored from 1 to 6 points) and a score assessment based on individual skills according to a checklist (total score evaluation, scored from 1 to 31 points), both of which were targeted for assessment. As secondary outcome measures, we evaluated the SBT-QA10 and postcase practice questionnaires, specifically assessing the difficulty of the case, the realism of the simulated patient, interaction through emotions, and levels of anxiety and tension. The conversation logs from each practice session were also reviewed. At the start of practice, a unique ID was generated for each device and

browser. This ID allowed for the accurate tracking of individual activity records when cross-referenced with the participant's initial name entry.

Statistical analysis was performed using Prism 9 for macOS (Version 9.5.1). The scores from the pre-CC OSCE were treated as interval data. In addition to the open-ended responses, the questionnaire used a Likert scale. The Mann-Whitney *U* test was used to compare 2 unrelated groups. Fisher exact test was applied to compare sex ratios, and Student *t* tests were used to compare backgrounds between groups based on grade point average (GPA; scored from 0.5 to 4.5). Multiple regression analysis was conducted with the pre-CC OSCE scores as the dependent variable and the questionnaire items as independent variables. The interpretation of correlation coefficients in this study follows the guidelines established by Hinkle et al [19]. According to their criteria, the strength of the correlation is categorized as follows: negligible (0.00-0.30), low (0.30-0.50), moderate (0.50-0.70), high (0.70-0.90), and very high (0.90-1.00). Missing values in the questionnaire items were excluded from the analysis. Additionally, only responses from participants who completed both the pre- and post-SBT-QA10 questionnaires were included in the analysis. The study was conducted with a feasible number of cases, and the effect size was evaluated by calculating Cohen *d* effect size using the pre-CC OSCE scores [19,20].

Results

Finally, the AI group that received LLM-based simulation education consisted of 35 of 87 students who had consented to participate in this study. In contrast, the control group comprised 110 students who had an opportunity to decline participation, but none chose to refuse. The effect size was calculated using the actual sample size and pre-CC OSCE scores, which revealed 0.48.

No significant differences were observed in the AI and control groups in the age, sex, or GPA of medically related subjects (Table 1). Regarding the medical interview practice, Multimedia Appendix 2 shows an abbreviated version of a representative conversation log and AI feedback, translated from Japanese to English.

Table 1. Background.

	AI ^a group	Control group	<i>P</i> value
Sex (female:male), n	15:20	34:76	.11 ^b
Age (years), median (IQR)	22 (1)	23 (1)	.37 ^c
GPA ^d , mean (SD)	2.9 (0.5)	2.7 (0.6)	.10 ^e

^aAI: artificial intelligence.

^bFisher exact test was used for the sex ratio.

^cThe Mann-Whitney *U* test was used for the age.

^dGPA: grade point average.

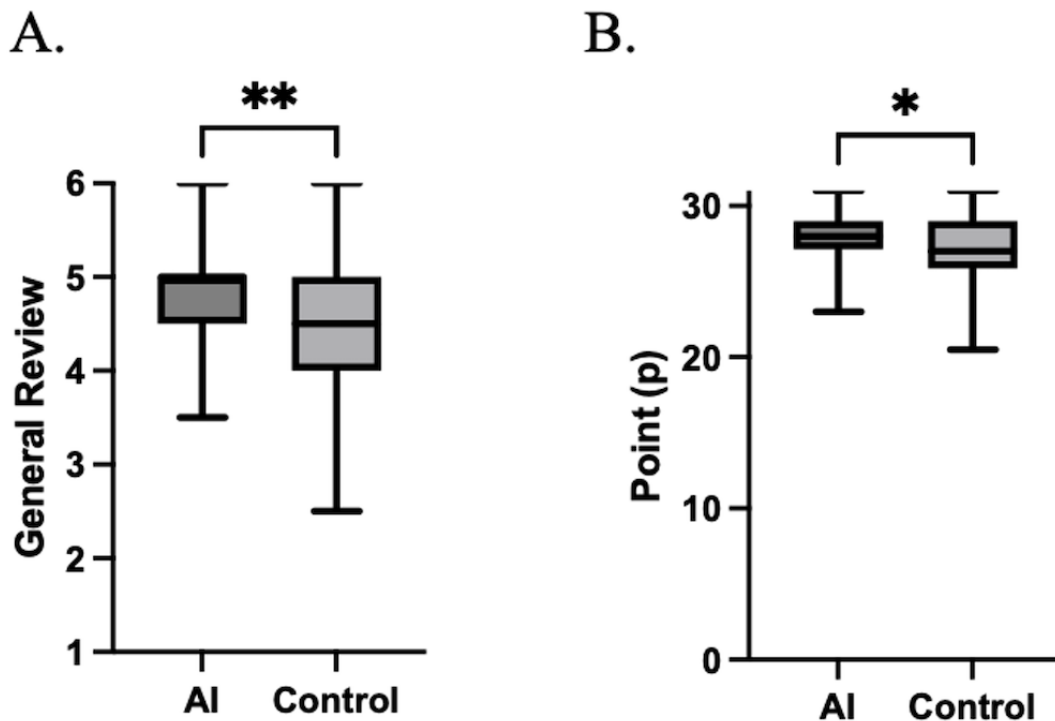

^eThe Student *t* test was used for the GPA (scored from 0.5 to 4.5) analysis.

Regarding the evaluation of educational effects, when comparing the scores for medical interviews in the pre-CC OSCE, the AI group scored significantly higher than the control group in both

summary evaluations (AI vs control: 4.8, SD 0.7 vs 4.5, SD 0.7; 2-tailed; *P*=.007; maximum of 6 points, minimum of 1 point on a scale of 1-6) and total score evaluation (AI vs control: 28.1,

SD 1.6 vs 27.1, SD 2.2; 2-tailed; $P=.01$; maximum 31 points, minimum 0 points graded; Figure 2). Additionally, the passing score for the pre-CC OSCE has not been disclosed.

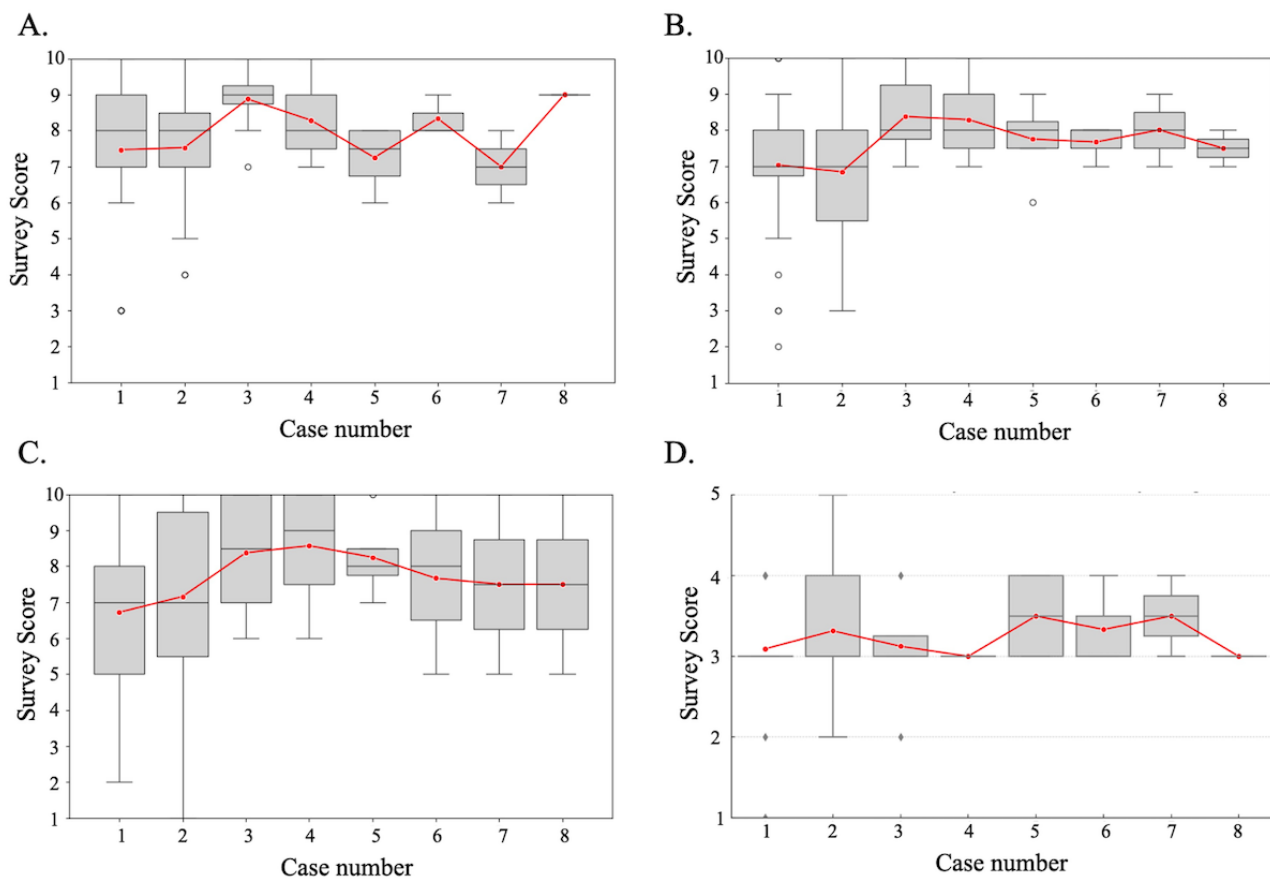

Figure 2. Pre-CC OSCE and LLMs-educational interventions. (A) Summary evaluation (maximum of 6 points, minimum of 1 point on a scale of 1-6). (B) Total score evaluation (maximum 31 points, minimum 0 points graded). Data were analyzed using the Mann-Whitney U test. LLM: large language model; pre-CC OSCE: Pre-Clinical Clerkship Objective Structured Clinical Examination. * $P<.05$, ** $P<.001$.

The questionnaire results for each case regarding the realism of the AI-simulated patient, interaction through emotions, levels of anxiety and tension, and difficulty of the case are shown in Figure 3. The responses regarding the AI-simulated patients' reproducibility and interaction through emotions remained stable throughout, with median scores ranging from 7 to 9 for reproducibility and 7 to 8 for emotional interaction. Regarding the levels of anxiety and tension, it was observed that

participants experienced them to some degree but without significant stress. Lastly, for the case difficulty, 75% (n=24) of the responses indicated it was "appropriate," 19% (n=6) found it "difficult," 3% (n=2) each considered it "easy" and "very easy," and 0% (n=0) found it "very difficult" in the first instance of the case (n=32). The response "appropriate" was the most common throughout the entire training period, ranging from 50% to 100%.

Figure 3. Questionnaire to be taken at the end of each case. (A) Artificial intelligence–simulated patient reproducibility is rated on a scale of 1–10, with 10 indicating “Very High Accuracy” and 1 indicating “no reproduction.” (B) Interaction through emotions is rated on a scale from 1 to 10, where 10 signifies “Very Effective” and 1 signifies “Not Effective at All.” (C) Anxiety and nervousness are rated on a scale from 1 to 10, with 10 indicating “Not Felt at All” and 1 meaning “Felt Very Strongly.” (D) The difficulty of the case is rated on a scale from 1 to 5, where 1 represents “Very Easy” and 5 represents “Very Difficult.”

The scores for the SBT-QA10 in both the pre- and postquestionnaires were relatively high across all items, with the median scores ranging between 4 and 5 (Table 2). No significant changes were observed across all items from pre-questionnaire to postquestionnaire. Additionally, this

analysis focused on the group (n=10) that responded to both the pre- and postsurveys. The results from separate analyses for the groups that only responded to the presurvey (n=14) and the postsurvey (n=24) are presented in Multimedia Appendix 3. No significant changes in trends were observed among these groups.

Table 2. Evaluation of the simulation program by SBT-QA10^a.

	SBT-QA10 questionnaire after the first session (pre), median (IQR)	SBT-QA10 questionnaire after pre-CC OSCE ^b (post), median (IQR)	P value (Wilcoxon test)
I felt part of the team (medical staff team, including faculty)	4.0 (1.3)	4.0 (1.0)	.13
The faculty member(s) interacted well with me	4.5 (1.0)	4.0 (1.0)	.50
Being observed did not intimidate me	4.0 (2.3)	5.0 (2.0)	.50
I felt I was able to act as independently as I wanted to	4.0 (1.0)	4.0 (1.0)	>.99
I felt adequately supported by the faculty member(s)	4.0 (1.0)	4.0 (0.3)	.63
I felt that the scenario was realistic	5.0 (1.0)	4.5 (1.0)	>.99
I understood the purpose of the scenario	4.0 (1.3)	4.5 (1.0)	.38
It did not require a lot of mental effort to play my role in the scenario	4.0 (2.3)	4.0 (2.3)	>.99
I was not distracted by non-relevant objects and events during the scenario	4.0 (1.3)	4.0 (1.5)	>.99
I was focused on being involved in the scenario	4.5 (1.0)	4.5 (1.0)	>.99

^aSBT-QA10: Simulation-Based Training Quality Assurance Tool. The results of the SBT-QA10 administered after the first session (pre) and pre-CC OSCE (post) for a sample size of 10 are presented for each item. Before-and-after comparisons were analyzed using the Wilcoxon test.

^bPre-CC OSCE: Pre-Clinical Clerkship Objective Structured Clinical Examination.

Next, we evaluated the group that received AI education to determine which subgroup achieved higher scores on the pre-CC OSCE. Given the high correlation coefficient of 0.75 between the total score evaluation and summary evaluation of the pre-CC OSCE and considering multicollinearity, we focused solely on the total score evaluation for further analysis, incorporating various questionnaire items, GPA and age in a multiple regression analysis. Among these, a consistent trend was observed with the SBT-QA10, where many items showed a negative correlation with the pre-CC OSCE scores. Specifically, the item “I felt part of the team” showed this trend statistically significant in both pre- (coefficients -1.8 , SE 0.77 ; $P=.047$; $R^2=0.41$) and postevaluations (coefficients -3.2 , SE 0.54 ;

$P<.001$; $R^2=0.81$; **Figure 4**). When analyzing the total scores of each item in relation to the pre-CC OSCE scores to illustrate the overall trend, a negative correlation was observed; however, none were statistically significant. The analysis results of the combined pre- and post-SBT-QA10 scores are presented in **Table 2**, including the items of “I felt part of the team” (**Table 3**). In addition, the results from separate analyses for the groups that only responded to the presurvey ($n=14$) and the postsurvey ($n=24$) are presented in **Multimedia Appendix 4**. The multiple regression analysis revealed consistent negative trends across both the excluded groups and the entire dataset. No significant differences in all the items were observed, including the item ‘I felt part of the team’ in the pre-and postsurveys.

Figure 4. Multiple regression analysis of pre-CC OSCE and SBT-QA10. Multiple regression analysis of the “I felt part of the team (medical staff team, including faculty)” item in the SBT-QA10 questionnaire. (A) Pre. (B) Post. Pre-CC OSCE: Pre-Clinical Clerkship Objective Structured Clinical Examination; SBT-QA10: Simulation-Based Training Quality Assurance Tool.

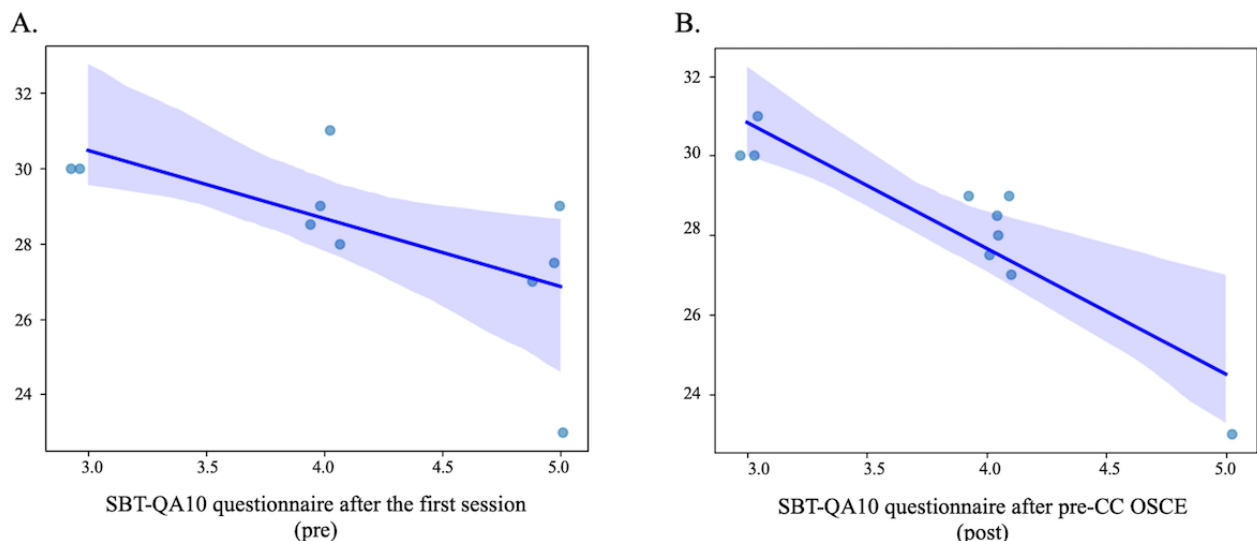

Table 3. Multiple regression analysis for analyzing pre-CC OSCE^a scores and SBT-QA10^b.

Item	Const			Independent variable			R^2	Adjusted R^2
	β (SE)	<i>t</i> test (<i>df</i>)	<i>P</i> value	β (SE)	<i>t</i> test (<i>df</i>)	<i>P</i> value		
Pre-1: "I felt like part of the team"	35.9 (3.3)	11.0	<.001	-1.8 (0.8)	-2.4	.047	0.41	0.33
Post-1: "I felt like part of the team"	40.3 (2.1)	19.3	<.001	-3.2 (0.5)	-5.8	<.001	0.81	0.79
Total scores of pre-SBT-QA10	36.7 (6.9)	5.3	<.001	-2.0 (1.6)	-1.2	.25	0.16	0.05
Total scores of post-SBT-QA10	37.1 (7.1)	5.3	<.001	-2.1 (1.7)	-1.3	.25	0.16	0.06

^apre-CC OSCE: Pre-Clinical Clerkship Objective Structured Clinical Examination.

^bSBT-QA10: Simulation-Based Training Quality Assurance Tool. Scores showed an overall inverse correlation with pre-CC OSCE scores, whereas the other items did not show a consistent trend. To illustrate the overall trend, the combined total scores of the SBT-QA10 from both pre and post are presented, including the item of "I felt part of the team" (pre 1 and post 1), in terms of which a significant difference was observed.

The AI group provided detailed feedback on both the advantages and disadvantages of the simulation system, summarized as follows:

- Positive aspects Practicality of training with AI: Participants could practice realistically with an emotional AI, akin to interacting with an actual patient. Convenience and accessibility: Training was available on an easy-to-use platform such as LINE, allowing participants to practice alone without a supervisor and offering flexibility in time and frequency of practice. Increased confidence through practice: Participants gained an understanding of the flow of a medical interview and learned essential questions relevant to clinical settings. Educational value and skill improvement: The training provided practical experience in medical interviewing and valuable feedback that helped improve skills, teaching participants how to inquire in various clinical situations.
- Negative aspects Dialogue and communication with AI: Participants encountered unnatural responses, such as repetitive expressions like "I'm worried" and instability in feedback. Technical and functional aspects: Issues included typing and response time delays, system errors, and operational inconveniences like incorrectly sent messages. Participants suggested that incorporating voice input might improve the experience. Comparison of medical interviews with pre-CC OSCE: Differences were noted in the information provided to simulated patients compared to pre-CC OSCE settings. Some participants appreciated the AI's superior conversational abilities, whereas others found the AI's casual speaking manner distracting.

Discussion

This study is the first to quantitatively verify the effectiveness of entrusting all aspects of medical interview education to AI, from acting as simulated patients to providing feedback as evaluators. It was found that the AI group, for which medical interview practice by LLM-based simulated patients was added to traditional medical interview education when practicing with simulated human patients, scored higher in the pre-CC OSCE

medical interviews compared to the control group that only practiced with simulated human patients [4].

As previously reported, medical students do not resist the use of AI in medical education [21], which was evident in this study. The educational style of this study, which allowed students to practice using their smartphones and PCs, enabled them to practice repeatedly at their convenience, as mentioned in the open-ended feedback. This measure not only improved medical interview skills but also reduced anxiety due to a lack of practice and enhanced self-efficacy, suggesting a positive impact on the examination results. Although the 2 groups were from different academic years and might have confounding background factors, basic information such as GPA remained consistent between the groups. This educational method supported by LLMs has the potential to reduce financial and time costs for instructors and simulated patients. This study demonstrates that incorporating this method can effectively supplement the existing shortcomings in medical interview education, thus proving beneficial. However, there are limitations as outlined below. While improvements and applications are anticipated in the future, currently, platforms like this LLM-based medical interview practice should be cautiously used as supplementary tools to traditional simulation education.

Evaluating Clinical Significance

To verify the statistical significance of this study, the effect size was examined and found to be a moderate effect size [20,22]. Additionally, the minimal clinically significant difference (MCID), an indicator that represents the slightest change of clinical relevance to patients and health care providers, was used to evaluate the meaningfulness of the pre-CC OSCE scores. Unfortunately, there are limited references available that provide specific scores for setting MCID based on pre-CC OSCE scores. We considered the average score minus one standard deviation of the Match group from the study by Horita et al [23] as a reference value for MCID, which was calculated to be 26.9. Initially presented in percentage form in the source study, this value was converted to a point scale to align with the metrics used in our research. In this study, while the Control group's average score was approximately equal to the MCID, the

Intervention group significantly exceeded this benchmark. This suggests that the intervention could have led to clinically meaningful improvements in pre-CC OSCE scores. However, it is important to note that there are various methods for setting an MCID, and given the limited studies, this should be regarded as only one reference point.

Association Between Pre-CC OSCE Scores and AI Educational Interventions

When exploring which subgroups within the AI group tended to score higher on the pre-CC OSCE, there was an inverse correlation with the SBT-QA10 scores. Educators used the SBT-QA10 to understand the various perceptions experienced by learners during simulation education. High SBT-QA10 scores are generally thought to reflect positive experiences during simulations, leading to subsequent learning. The overall trend of high scores in this study suggests that the training had a positive impact on learners. However, subgroup analysis revealed results that contradict this implication. Unlike traditional simulation education with human-simulated patients, simulations conducted on one's smartphone or laptop allow for learning in a mentally safe state, potentially resulting in effortless learning within the comfort zone of students, thereby diminishing its effectiveness [24]. Conversely, for students who felt challenged, this may have created a learning zone that enhanced the learning effect.

Additionally, the SBT-QA10 is based on research in Western cultures, and this study, targeting learners in a Japanese cultural context, may require a different interpretation. People from Asian cultures have been reported to be stricter in self-evaluations. This cultural difference may have influenced the results significantly [25,26]. It is, therefore, considered important to adjust the learning environment, such as the difficulty level of cases, while constantly checking feedback from learners and educational outcomes because a good learning environment can vary among learners. However, there is a possibility that some extreme values are influencing the overall trend, as shown in [Figure 4](#). Furthermore, as demonstrated in [Multimedia Appendix 4](#), changing the comparison group eliminates the statistical significance previously observed, although a consistent negative trend is still evident. This suggests that the reliability of the data may be weak. Therefore, the interpretation of this trend should be approached with caution.

Fabrications by LLMs

Although concerns about fabrication by LLMs have been raised in various contexts [27], their occurrence in this study was limited, and no expressions deviating from the case settings were observed. During the alpha-testing phase with GPT-3.5 Turbo, fabrications were somewhat common, especially in instances where the AI began playing the role of the doctor instead of the simulated patient early in the conversation. Although modifications to the prompts somewhat mitigated this issue with GPT-3.5 Turbo, the change to GPT-4 and GPT-4 Turbo significantly reduced fabrications to a practical level of improvement [28].

The behavioral anomalies of AI in this study can be summarized as follows: The first concern is violations related to public order and morals based on OpenAI's guidelines. Upon analyzing the conversation logs, it was evident that the students' inputs did not contain any issues, indicating that the observed discrepancies were due to inaccuracies in the AI output. As the students were preinformed about the possibility of such errors, they could continue with their medical interviews by starting another consultation, preventing it from becoming a significant issue. The second point is related to fabrication in the feedback. For instance, despite confirming the patient's date of birth and name, there were a few cases in which the feedback suggested that these were not confirmed. This issue was thought to be caused by the prompts treating "confirming the patient's date of birth and name" as a continuous stream of information, and it was resolved by breaking down the information into separate elements. While prompt adjustments could improve some aspects, the specifications of GPT, which only allow reference to a certain amount of context window and have a limit on the amount of conversation that can be stored, are also considered to be contributing factors [29].

Safety

No excessive tension or anxiety associated with learning was observed during the simulations. Furthermore, responses from the GPT throughout the study period did not contain any statements that could harm learners' safety, and no students reported such concerns.

Limitations

This study was conducted with voluntary participation in educational research without using more desirable intervention methods, such as randomized controlled trials. The emphasis was on equality of educational opportunities, keeping the opportunities of traditional practice with simulated patients. Although consent was obtained from many students, only some of them actually participated in the medical interview practice sessions. This phenomenon can be attributed to unique cultural factors in Japan. Specifically, Japanese medical students often feel a strong inclination to meet others' expectations when explaining the research, leading them to provide consent [30]. However, this consent might not always reflect their genuine willingness, resulting in a lower actual participation rate. Consequently, the sample size was limited.

In addition, this study employed LLM-simulated patients' interventions and evaluated their effectiveness through a simulation-based assessment such as the pre-CC OSCE. However, reports suggest that qualitative improvements in simulators do not directly cause clinical skill enhancement, underscoring the importance of conducting clinical skill assessments in real-world settings as much as possible [31]. As this study focused on pre-clinical clerkship medical students, the assessment was limited to an indirect and short-term evaluation of clinical skills using medical interview scores from the pre-CC OSCE [15]. Therefore, we plan to conduct long-term evaluations of this program for clinical clerkship students and early-career physicians in actual clinical settings in future studies. Moreover, since this platform is text-based, its capacity to handle non-verbal communication is restricted. For instance,

similar to how GPT-4 can partially recognize visual and voice information, further advancements in LLM technologies that could better recognize and process human emotions and sensory inputs may help overcome this limitation. Currently, LLM-based medical interview simulation training should serve as a supplemental tool to existing medical interview education and is not yet capable of fully replacing traditional methods. Nonverbal communication skills, which are crucial, are still best developed through instructor-led training involving human-simulated patients. This study was conducted as a pilot project for the future application of LLMs in medical interview training.

Plan

This study suggests the potential for a significant reduction in the workload of instructors and simulated patients in medical interview practice while maintaining educational effects for medical students. Furthermore, the introduction of LLM-simulated patients to clinical skill examinations such as the pre-CC OSCE is conceivable. It holds promise not only for educating young doctors but also for the lifelong education of doctors, including simulations for handling complex cases in clinical settings. However, when introducing LLM simulations into medical education, caution is necessary regarding ethical considerations and accuracy, as previously pointed out.

Completely replacing traditional instructor-led training with AI carries risks, and further studies thereon are required [13,21].

Improvements in prompts and the evolution of AI technology suggest that more realistic and accurate simulation education can be expected in the future. The integration of AI into medical education is inevitable; however, it has the potential to disrupt traditional medical education practices. Educators must remain vigilant regarding the potential positive and negative impacts of this integration [32]. Concurrently, it is essential to continue research on AI-mediated medical education to explore its applicability and limitations.

Conclusions

Education on medical interviewing using LLM-simulated patients demonstrated superior educational effectiveness while maintaining safety. This platform holds promise for multifaceted applications in the field of medical education in the future. It should be noted that this study only assessed short-term impacts and did not directly evaluate clinical skills. Additionally, due to the extremely limited educational effects on nonverbal communication skills, it is currently advisable to use this platform as a supplementary tool in medical interview training. Given the occurrence of fabrications and the opaque nature of LLM technology across various companies, caution and intense monitoring by tutors are essential when incorporating LLM-based educational platforms into medical education.

Acknowledgments

We extend our sincere thanks to Noriyuki Yamashita of the Center for Education in Medicine and Health Sciences, Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama, Japan, for expertly managing our budget and meetings and ensuring the smooth progression of our project. We also thank Kana Nishikawa of the Instruction and Student Section, School of Medicine, Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama University, for her pivotal role in compiling performance data and liaising with the Public Interest Incorporated Association, Common Achievement Tests Organization, which was crucial for our funding and data integrity. Their contributions were invaluable to our work. This research was supported by Nishikawa Medical Foundation, Japan Medical Education Foundation, and donations to the Department of Primary Care and Medical Education, Dentistry and Pharmaceutical Sciences, Okayama University Graduate School of Medicine, Okayama, Japan.

Abstract

Background: Since the release of ChatGPT in November 2022, this emerging technology has garnered a lot of attention in various fields, and nursing is no exception. However, to date, no study has comprehensively summarized the status and opinions of using ChatGPT across different nursing fields.

Objective: We aim to synthesize the status and opinions of using ChatGPT according to different nursing fields, as well as assess ChatGPT's strengths, weaknesses, and the potential impacts it may cause.

Methods: This scoping review was conducted following the framework of Arksey and O'Malley and guided by the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews). A comprehensive literature research was conducted in 4 web-based databases (PubMed, Embase, Web of Science, and CINHALL) to identify studies reporting the opinions of using ChatGPT in nursing fields from 2022 to September 3, 2023. The references of the included studies were screened manually to further identify relevant studies. Two authors conducted studies screening, eligibility assessments, and data extraction independently.

Results: A total of 30 studies were included. The United States (7 studies), Canada (5 studies), and China (4 studies) were countries with the most publications. In terms of fields of concern, studies mainly focused on "ChatGPT and nursing education" (20 studies), "ChatGPT and nursing practice" (10 studies), and "ChatGPT and nursing research, writing, and examination" (6 studies). Six studies addressed the use of ChatGPT in multiple nursing fields.

Conclusions: As an emerging artificial intelligence technology, ChatGPT has great potential to revolutionize nursing education, nursing practice, and nursing research. However, researchers, institutions, and administrations still need to critically examine its accuracy, safety, and privacy, as well as academic misconduct and potential ethical issues that it may lead to before applying ChatGPT to practice.

KEYWORDS

ChatGPT; large language model; nursing; artificial intelligence; scoping review; generative AI; nursing education

Introduction

Artificial intelligence (AI) was defined as a machine system that can make predictions, recommendations, and decisions influencing real or virtual environments based on a human-defined objective [1]. In recent years, with the rapid development of computer science, AI technology represented by machine learning, deep learning, and natural language processing has made amazing progress and achievements in the field of health care and been widely used in clinical practice, and has demonstrated a diagnostic performance that is not inferior to, or even better than human beings in some cases [2,3]. In the fields of nursing, AI is also playing an important role, including optimizing nursing processes [4], providing more personalized care [5], making health care more accessible [6], etc.

ChatGPT is an AI chatbot developed by OpenAI based on the third generation of the generative pretrained transformer architecture [7]. Since its release in November 2022, ChatGPT has attracted widespread attention and interest across the academic and scientific communities. Based on deep learning algorithms and natural language processing techniques, and trained with massive amounts of data from the internet, books, and articles, ChatGPT can automatically identify users' inputs and generate appropriate responses to simulate the interactive dialogue and feedback process between humans [8]. In the field of clinical medicine, ChatGPT has exhibited its ability to assist in disease diagnosis, and it was reported the correct diagnosis rate of ChatGPT-3 was about 93.3% in 10 differential diagnoses [9]. At the same time, ChatGPT has also shown great potential in assisting nursing. For example, ChatGPT could help nurses to improve documentation by standardizing the terms and concepts, thus reducing nurses' workload [10].

However, there are also widespread concerns about using ChatGPT in health care.

First, since ChatGPT's training data came from the internet and lacked transparency, researchers have expressed concerns about its accuracy, usability, and safety in clinical practice [11]. Second, during clinical application, considering the potential inconsistency between the training data and the clinical application scenarios, ChatGPT may endure implicit bias and data-shift problems, as well as artificial hallucinations caused by them, which may lead to insecurity issues and care inequity [12,13]. Overreliance on ChatGPT can also weaken nurses' judgment and lead to workforce deskilling. Third, in the academic publishing world, ChatGPT has caused broader discussions about academic integrity due to the difficulty of reviewers and available technologies in distinguishing content written by AI and a human [14]. In addition, especially in the field of education, although ChatGPT can help simplify administrative work, more educators expressed concerns that overdependence and complete trust in ChatGPT may cause and reinforce automation bias, and prevent students from developing abilities of critical thinking [15].

There have been extensive discussions about the application of ChatGPT in nursing. However, to date, no study has comprehensively summarized the perceptions on using ChatGPT in different nursing domains. Therefore, the aim of this study was to synthesize the opinions and acceptance of using ChatGPT from different application scenarios in nursing, as well as the strengths and weaknesses of ChatGPT and its possible impacts, to provide a reference for the future development of a large language model (LLM) that is more appropriate for nursing education and practice.

Methods

Study Design

This scoping review was conducted according to the 5-step methodological framework proposed by Arksey and O'Malley [16] (identifying the research question, identifying relevant studies, study selection, charting the data, and collating, summarizing, and reporting the results). The reporting of the review was guided by the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines [17].

Identifying the Research Questions

1. How is ChatGPT used in different nursing fields, and what are the opinions and acceptance of this technology?
2. What are the strengths, weaknesses, ethical considerations, and potential impacts of the application of ChatGPT in nursing?

Identifying Relevant Studies

A comprehensive literature search was conducted in 4 web-based databases (PubMed, Embase, Web of Science, and CINHAL) from 2022 to September 3, 2023, to identify studies reporting the opinions and acceptance of using ChatGPT in nursing fields. Two reviewers (YCH and XYT) screened the

references of the included articles to further identify relevant studies.

To include as many studies as possible, the search terms were not limited strictly. The search terms in PubMed included two key topic areas: ("ChatGPT" OR "Chatbot*" OR "Large language model" OR "LLM" OR "LLMs") AND ("Nursing" OR "Nurse*"). The search, using a combination of keywords and Boolean operators, was designed to comprehensively cover the intersection of ChatGPT and nursing.

Study Selection

The inclusion criteria were as follows: (1) articles associated with the application or opinions of ChatGPT in nursing fields, such as nursing education, nursing practice, nursing academic writing, etc; (2) any types of articles including original articles, review articles, preprints, protocols, editorials, letters to editor, correspondence, and case reports; and (3) English publications. We excluded studies without available full-text and nonhuman studies.

All identified articles were first imported into the EndNote X9 (Clarivate Analytics) software to manually remove duplicates. Then, two reviewers (YZ and SJL) independently screened the titles and abstracts through the Rayyan application according to the inclusion and exclusion criteria to include studies for further full-text assessment. Any disagreements were resolved through consensus by consulting another reviewer (MHP).

Charting the Data

According to the research question, two reviewers (XYT and YCH) independently extracted and synthesized pertinent information using an Excel sheet, including authors, year of publication, country, study design, objective of study, study results (opinions or findings of using ChatGPT in nursing), fields of concern, and suggestions or recommendations for future studies. Any disagreements were resolved through consulting another reviewer (MHP).

Collating, Summarizing, and Reporting the Results

The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram showed the process of study selection. Two researchers (YZ and SJL) independently used an inductive approach to analyze and thematically summarize the contents of the included studies to identify the opinions and acceptance of similarities and differences about using ChatGPT in nursing. On this basis, the opinions extracted from studies were further synthesized and categorized according to different nursing fields in which ChatGPT was applied (such as nursing education, nursing practice, nursing research, nursing writing, etc). A table of supplement material in [Multimedia Appendix 1](#) were also created to demonstrate the status and opinions of using ChatGPT in nursing.

Results

Search Results

[Figure 1](#) showed the process of literature selection. A total of 320 studies were identified from the initial literature search. After removing the duplicates (n=135), 185 studies were

identified for titles and abstracts screening, of which 47 studies meeting the inclusion criteria were allowed for full-text evaluation. Finally, 17 studies were excluded, and 30 studies were included in this review.

Figure 1. PRISMA flow diagram of study selection. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

Study Characteristics

Table 1 summarized the characteristics of the included studies. All 30 studies were published in 2023. The United States (7/30), Canada (5/30), and China (4/30) were countries with the most publications, accounting for more than 50% of all publications. In terms of study design, more than half of the studies were editorials (12/30) as well as letters to the editor (6/30), only 3

were original articles, and this study's design was unclear in 7 studies. **Table 2** presented the fields of concern of the included studies. Most studies focused on the application of ChatGPT in nursing education (n=20). Other fields of concern included using ChatGPT in nursing practice (n=10), nursing research (n=2), nursing academic writing (n=2), nursing examination (n=2), and nursing future (n=1). Six studies addressed the use of ChatGPT in multiple fields of nursing [15,18-22].

ChatGPT and Nursing Education

Existing research has shown that ChatGPT has great potential in the field of nursing education. For educators, ChatGPT can be used for curriculum development, drafting course materials, and generating practice tests, which can simplify teachers' course preparation and assessment tasks [15,42,43]. Teachers can use ChatGPT to simulate patient encounters, providing students with an interactive learning experience to practice skills such as communication and assessment to enhance education [21,36,42]. For students, since ChatGPT has the function of instant feedback, it can be used as a tool to quickly acquire knowledge and skills, helping to improve learning efficiency and time management [19,27,40]. Students can also create individualized learning plans and obtain personalized feedback from ChatGPT, and use it to develop their writing skills, which will help motivate students to carry out independent learning and improve the efficiency and accuracy of the writing process [21,35,36,42-44]. In addition, ChatGPT has been believed to improve students' digital literacy [26,42].

However, opposition exists at the same time. The researchers argue that using ChatGPT in nursing education may lead to plagiarism in assignments and academic dishonesty, given its superior ability to generate textual content [21,28,31,36]. It is also for this reason that, ChatGPT may undermine the nursing education assessment system that is now based on essays and assignments [24,36]. Students' excessive use of ChatGPT may lead to reduced course participation [15]. Moreover, due to the nature of passive acceptance, over-reliance on ChatGPT will be detrimental to students' ability to transform information into knowledge, as well as critical thinking, literature retrieval, and evidence synthesis [15,20,28,31,32,42].

ChatGPT and Nursing Practice

The current view is that nurses can provide an unprecedented personalized care to patients based on ChatGPT; at the same time, patients can use it for health consultations, information about the status of their diseases and symptoms, and about their treatments [23]. In addition, due to the advantages of rapid assistance and rapid resource accessibility, ChatGPT can be

used as a tool for nurses to quickly access information, helping nurses to keep up to date with information about patients' illnesses, treatments, and medications, which is conducive to optimizing time management and providing high-quality care for patients [37,38,40].

However, despite the promising applications, there are still some problems and limitations in applying ChatGPT to nursing practice. First, ChatGPT cannot guarantee the security and confidentiality of the information uploaded to the servers. Therefore, inputting detailed and private information of patients to it may lead to a leakage of patients' privacy [18-20,23,38]. Second, unlike search engines, ChatGPT does not search the internet to find the best answer to a question, but rather analyzes a large amount of data and then predicts the next most likely word in the answer, and therefore may output incorrect or biased information [19,20,37,38,45]. What's more, nursing is a human-centered discipline, and a major disadvantage of chatbots is that they do not have the unique emotions and empathy of humans. Communication based on ChatGPT may make communication between nurses and patients impersonal and lacking in empathy, which may have a negative impact on the nurse-patient relationship [18,19,23,27,37,38].

ChatGPT and Nursing Research, Writing, and Examination

There are also widespread concerns about using ChatGPT in academia and publishing. As ChatGPT is not an individual nor can it be held responsible for the content it generates, scholars argued that the decision to list ChatGPT as a coauthor was wrong and undesirable [39]. In addition, researchers had attempted to complete the nursing examinations using ChatGPT. Taira et al [41] found that ChatGPT demonstrated a stable, very close passing level in the 2019 - 2023 Japanese National Nurse Examinations, however, ChatGPT showed some limitations in dealing with questions in complex situations. Zong et al [46] tested ChatGPT's performance on the 2017 - 2021 Chinese National Nurse Licensing Examination. The results showed that ChatGPT did not pass the examination in any of the years but scored equally close to the passing score [46].

Discussion

Principal Findings

This scoping review aimed to summarize the opinions and acceptance of published studies on the use of ChatGPT in nursing fields. The results of our study indicated that, nursing research on ChatGPT is still in its infancy and few original research has been conducted. ChatGPT has the potential to provide nursing students with personalized study guides, provide patients with high-level personalized care plans, and greatly facilitate research and academic writing efforts, but at the same time, it can also lead to automation bias, nurse-patient mistrust, and potential ethical issues caused by misinformation, and academic misconduct issues. Discussion about using ChatGPT in nursing education, nursing practice, and nursing research and academic writing remains heated and the researchers have not yet reached a unanimous opinion.

Considering the global nursing shortage, the cultivation of exceptional nurses has become an important issue in the field of nursing education. Therefore, when new technologies are available, what role they can play in nursing education is of particular interest. First, ChatGPT can assist teaching. For example, ChatGPT's superior generative and analytical capabilities can help teachers reduce their workload by converting complex learning materials into easy-to-understand classroom content and assisting in grading students' work [47]. Second, ChatGPT can facilitate changes in learning methods. ChatGPT can generate outlines to assist with literature reviews; create realistic clinical cases and scenarios to help medical students improve their diagnostic skills; and act as a personal tutor to create personalized learning plans and materials based on students' abilities and learning feedback to improve learning efficiency [47,48]. In addition, ChatGPT was found to improve information skills in nursing students. In a study by Rahman and Watanobe [49], ChatGPT was found to assist students in generating code, checking code errors, and debugging and optimizing code. This is very important. With the advent of the digital age, programming will likely become a required course for nursing education and an essential skill for nurses in the future. ChatGPT's significant help in programming learning is very meaningful to the learning of nursing informatics and cultivation of digital literacy for nursing students.

Although ChatGPT has demonstrated potential benefits in nursing education, opposition emerges from researchers. Academic writing is crucial for students' success, yet crafting a research paper is a daunting task, even for experienced writers. ChatGPT plays a vital role in assisting with the writing process, but also raises issues about academic dishonesty, particularly when students become overly dependent on it [50]. In addition, students can also exploit ChatGPT for cheating during examinations, thus undermining the integrity of these assessments [51,52]. Furthermore, the use of ChatGPT in nursing education also brings ethical considerations such as data privacy and security. Students may share personal thoughts, feelings, and experiences while using ChatGPT, posing potential risks associated with the collection of this sensitive information [53].

Therefore, when integrating nursing education and the emerging technology, educators should comprehensively consider the strengths and limitations of ChatGPT. Educators and educational institutions should embrace this technology with an open mind and avoid simply banning its use. In practice, educators should teach students to critically evaluate and properly use ChatGPT to avoid overreliance; and use diverse teaching methods to encourage them to acquire skills of critical and independent thinking, and clinical reasoning. It is also critical to address and resolve ethical concerns, such as finding a balance between data privacy and correctly using ChatGPT. Moreover, educational institutions or educational administrations ought to establish guidelines and consensus or systems regarding the proper use of ChatGPT in nursing education.

In addition to nursing education, researchers also showed great interest in how ChatGPT can be applied to and improve nursing practice. ChatGPT empowers patients with health consultations and can help nurses to give personalized patient care by acting as an information tool. In a study by Kuroiwa et al [54], patients achieved accurate self-diagnosis of carpal tunnel syndrome and lumbar spinal stenosis by ChatGPT. ChatGPT seems to have the potential to become a patient self-management and condition monitoring tool outside the hospital. Therefore, future research could attempt to develop a ChatGPT-based chatbot and integrate it into existing mobile health (mHealth) intervention programs and platforms, exploring the role of mHealth interventions integrated with a LLM on symptom control and lifestyle change in patients with chronic diseases.

However, ethical concerns (ie, security and confidentiality, accuracy and bias in information output, and the lack of human empathy) also exist, and some issues are inevitable due to the nature of AI. For instance, the disclosure of patients' privacy and provision of incorrect information may damage the trusting relationship between patients and nurses. Additionally, compassion emerges from interpersonal relationships and social interactions with persons, thus chatbots were considered to lack the capacity for compassion [55]. However, some consumer informatics studies found that chatbots seemed to be better at projecting the impression of empathy. In the study by Chen et al [56], a chatbot provided high-quality, empathetic, and easy-to-read answers to cancer-related questions on social media that were comparable to those provided by doctors. While the issue of empathy seems to be resolved, it is worth pondering whether chatbots will still be able to balance empathy and ethics to provide reliable answers to patients' questions in the face of complex and varied real-life clinical environments and problems.

Given these concerns, implementing risk management strategies to control these risks is crucial. First, data confidentiality is essential when applying ChatGPT in nursing practice, and patients should be provided with informed consent and told not to disclose private personal information. Second, information provided by ChatGPT may be inaccurate and biased, thus professionals' interventions such as reviewing the information developed by ChatGPT, and addressing bias in decision-making processes are necessary. Third, although ChatGPT can greatly improve nurses' efficiency, it still cannot replace the important role of nurses. Future nurses should emphasize the human touch and ethical considerations in nursing processes and conduct

more research to determine the support resources needed to effectively use this technology [19].

The concerns regarding using ChatGPT in other nursing fields also exist. As far as research and academic writing is concerned, several studies have now listed ChatGPT as a coauthor [36,57,58]. However, Palagani et al [59] found that although ChatGPT can generate article content as well as references as requested by the author, most of the references were incorrect or nonexistent. As a supportive tool for academic writing, ChatGPT can assist researchers in conducting a literature review and correcting grammatical errors to improve writing quality [60]. However, the abuse of ChatGPT may carry a great risk of leading to academic misconduct. In a study by Gao et al [14], reviewers indicated that it was difficult to distinguish between content generated by AI and human. Although recognition tools such as GPTZero and GPT-2 Output Detector (OpenAI) are already available, accurately identifying AI-generated content in submitted manuscripts will still be a daunting task as chatbot algorithms are iterated and optimized. Therefore, future research should focus on the development of recognition tools for AI-generated content and try to optimize the language style of different languages to improve the detection performance.

Scholars also explored ChatGPT's capability to pass nursing licensing examinations and found that although it approached the passing threshold, it failed to meet the required passing standards. Considering that ChatGPT was developed primarily based on English-language data, and that there are differences in health care policies, regulations, languages, and cultures in various countries, this may partly explain why ChatGPT could not pass the examinations. This emphasizes an important ethical concern about the applicability and fairness of using AI in different health care settings. To address this issue, incorporating a wider range of languages and cultural contexts may be the future aim of AI technologies' development.

Future Directions

First, from the perspective of nursing education, educators should instruct students on the proper use of ChatGPT. Teachers should inform students to consciously consider LLMs such as ChatGPT as information search engines and learning assistants to avoid overreliance. Further, the most important thing is to cultivate students' critical thinking and information discernment skills so that they can recognize artificial hallucination and extract useful information provided by ChatGPT while discarding untrue and false contents. Additionally, educational institutions could establish guidelines and consensus about the proper use of ChatGPT in nursing education to standardize the current state of using LLMs in the educational profession.

Second, in the context of nursing practice, given the potential of applying ChatGPT into symptom management and lifestyle change in patients with chronic diseases, a ChatGPT-based chatbot could be developed and integrated into mHealth intervention programs, and patients' private data can be secured by setting access rights and encrypting private data. In addition, more research and multiple efforts are required to identify the support resources needed to apply ChatGPT into nursing practice. Specifically, laws and regulations, and ethical standards for using LLMs in clinical practice are still to be introduced by the government and health care management agency; in terms of health care organizations, use guidelines and training curricula should be developed according to local application scenarios, patients' needs, and nurses' qualifications in the future; for researchers and developers, there is still a need for further diagnostic accuracy evaluation and usability testing to enhance the reliability of ChatGPT in complex clinical environments. Third, regarding nursing research, future research should concentrate on developing advanced tools to identify AI-generated content. To enhance the applicability and fairness of using ChatGPT, incorporating a broader spectrum of languages and cultural contexts may be the future aim of AI technologies' advancement.

Limitations

This study also had some limitations. First, this study only included publications in English, which may lead to a certain publication bias. Second, the search deadline for this study was September 3, 2023, considering the rapidly growing publication volume of studies on the application of ChatGPT in nursing, further reviews are still needed in the future to include more studies to enrich our findings. In addition, given the small number of original studies available about ChatGPT and nursing, this review included a wide range of types and quality of studies, and some of the low-quality studies may compromise the generalizability of the results of this study.

Conclusions

As an emerging AI technology, ChatGPT has received a lot of attention and generated intense discussion in various nursing fields. Although at present, there is still a lack of original studies about its practical application in nursing, ChatGPT has showed great potential to revolutionize nursing education, nursing practice, and nursing research. However, before it can be applied to practice, researchers, institutions, and administrations still need to critically examine the privacy, safety, and accuracy as well as academic misconduct and potential ethical issues it may lead to.

Acknowledgments

The author thanked all authors of this study. This study was funded by the nonprofit central research institute fund of Chinese Academy of Medical Sciences (grant 2023-RC320-01).

Data Availability

The datasets used or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

YZ and MHP designed this study. YZ and SJL conducted literature searching. YZ and SJL screened and reviewed the articles. XYT and YCH extracted the data from included studies. YZ drafted the manuscript. MHP provided guidance and approved the final draft. All authors contributed to the development of the manuscript.

Conflicts of Interest

None declared.

Multimedia Appendix 1

Details on the study content of the included studies.

Abstract

Background: In recent years, virtual reality (VR) has gained significant importance in medical education. Radiology education also has seen the induction of VR technology. However, there is no comprehensive review in this specific area. This review aims to fill this knowledge gap.

Objective: This systematic literature review aims to explore the scope of VR use in radiology education.

Methods: A literature search was carried out using PubMed, Scopus, ScienceDirect, and Google Scholar for articles relating to the use of VR in radiology education, published from database inception to September 1, 2023. The identified articles were then subjected to a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses)-defined study selection process.

Results: The database search identified 2503 nonduplicate articles. After PRISMA screening, 17 were included in the review for analysis, of which 3 (18%) were randomized controlled trials, 7 (41%) were randomized experimental trials, and 7 (41%) were cross-sectional studies. Of the 10 randomized trials, 3 (30%) had a low risk of bias, 5 (50%) showed some concerns, and 2 (20%) had a high risk of bias. Among the 7 cross-sectional studies, 2 (29%) scored “good” in the overall quality and the remaining 5 (71%) scored “fair.” VR was found to be significantly more effective than traditional methods of teaching in improving the radiographic and radiologic skills of students. The use of VR systems was found to improve the students’ skills in overall proficiency, patient positioning, equipment knowledge, equipment handling, and radiographic techniques. Student feedback was also reported in the included studies. The students generally provided positive feedback about the utility, ease of use, and satisfaction of VR systems, as well as their perceived positive impact on skill and knowledge acquisition.

Conclusions: The evidence from this review shows that the use of VR had significant benefit for students in various aspects of radiology education. However, the variable nature of the studies included in the review reduces the scope for a comprehensive recommendation of VR use in radiology education.

Introduction

The use of technology in education helps students achieve improved acquisition of professional knowledge and practical skills [1-3]. Virtual reality (VR) is a modern technology that simulates experience by producing 3D interactive situations and presenting objects in a virtual world with spatial dimensions [4,5]. VR technology can be classified as nonimmersive or

immersive [6]. In a nonimmersive VR, the simulated 3D environment is experienced through a computer monitor [6]. On the other hand, an immersive VR provides a sense of presence in a computer-generated environment, created by producing realistic sights, sounds, and other sensations that replicate a user’s physical presence in a virtual environment [6,7]. Using VR technology, a person can look about the artificial world, navigate around in it, and interact with simulated objects or items [5,8]. Due to the broad nature of VR technology,

it has many applications, some of which are in the field of medicine [9,10].

The use of VR in medicine started in the 1990s when medical researchers were trying to create 3D models of patients' internal organs [11-13]. Since then, VR use in the field of medicine and general health care has increased substantially to cover many areas including medical education. Radiology education has also come to see the use of VR technology in the recent past [14]. The use of VR in radiology education enables students to practice radiography in a virtual environment, which is radiation free [15]. Additionally, the use of VR enables effective and repeatable training. This allows trainees to recognize and correct errors as they occur [16,17]. The aim of this review is to explore the scope of VR in radiology education.

Methods

This systematic review has been performed using the PRISMA (Preferred Reporting Items for Systematic Review and Meta-Analysis) guidelines [18] [Checklist 1]).

Information Sources and Study Selection

The bibliographic databases used were PubMed, Scopus, ScienceDirect, and Google Scholar. A systematic literature search was conducted for articles published from database inception to September 1, 2023. Topic keywords were used to generate search strings. The search strings that were used are provided in Table 1. Only the first 10 pages of Google Scholar results were exported. The identified studies were then subjected to a study selection process. The search string for ScienceDirect was shorter because the database only allows a maximum of 8 Boolean operators, hence the sting had to be shortened. The search in PubMed was limited to the title and abstract. The searches in Scopus and ScienceDirect were limited to title, abstract, and keywords.

Table 1. Search strings used in the systematic review.

Database	Search string
PubMed and Scopus	("virtual reality" OR "immersive reality" OR "simulated reality" OR simulator OR simulate) AND (radiology OR radiography OR imaging OR radiologist) AND (education OR teaching)
ScienceDirect and Google Scholar	("virtual reality" OR "immersive reality" OR "simulated reality" OR simulator) AND (radiology OR radiography OR imaging) AND (education OR teaching)

Inclusion and Exclusion Criteria

Original research articles written in the English language were included in the review. Studies conducted on medical, dental, and allied health sciences students (undergraduate and postgraduate) from any part of the world were included in the review. Studies exploring the use of VR learning in radiology education were included.

Narrative reviews, scoping reviews, systematic reviews, meta-analyses, editorials, and commentaries were excluded. Studies that did not align with the required study objective were excluded.

Method of Quality Assessment

Randomized controlled trials (RCTs) and randomized experimental studies were appraised using the RoB 2 tool from

the Cochrane Collaboration [19]. A visualization of the risk-of-bias assessment was done using the web-based *robvis* tool [20]. Cross-sectional studies were appraised using the appraisal checklist for analytical cross-sectional studies from the Joanna Briggs Institute [21].

Data Extraction

Each article included in the review was summarized in a table, including basic study characteristics. The extracted attributes were study author(s), publication year, study design, type and number of participants, type of radiology education under study, and the outcome being assessed. The extracted data are provided in Table 2.

Table . Data extraction table of the studies included in the systematic review.

Study	Study design	Participants	Aspect of radiology	Study outcome
Ahlqvist et al [22]	RCT ^a	31 first-year radiologic technology student	Diagnostic radiology	Assessing radiographic image quality
Bridge et al [23]	Randomized experimental trial	48 medical imaging students	General radiology	Student satisfaction and technical skills (ie, patient positioning, equipment positioning, and mean proficiency)
Gunn et al [24]	Randomized experimental trial	45 medical imaging student	Diagnostic radiology	Technical radiographic skills
Gunn et al [25]	Cross-sectional study	28 medical imaging students and 38 radiation therapy students	Interventional radiology	Students' perceived confidence in performing diagnostic and planning CT ^b scans
Jensen et al [26]	Cross-sectional study	10 radiography students	General radiology	Self-perceived clinical readiness of radiography students regarding the acquisition of wrist radiographs
Kato et al [27]	Randomized experimental trial	30 first-year radiologic technology student	General radiology	Radiographic skills proficiency
Nilsson et al [28]	Randomized experimental trial	57 dental students	Oral radiology	Interpretation of spatial relations in radiographs using parallax
Nilsson et al [29]	Randomized experimental trial	45 dental students	Oral radiology	Interpretation of spatial relations in radiographs using parallax
O'Connor and Rainford [30]	Randomized experimental trial	191 radiography students	General radiology	Patient preparation, room preparation, patient care, radiographic technique, and image appraisal
O'Connor et al [15]	Cross-sectional study	105 first-year radiography students	General radiology	Reporting student experience
Rainford et al [31]	Cross-sectional study	35 radiography students and 100 medical students	Interventional radiology	Reporting student experience
Rowe et al [32]	Randomized experimental trial	188 radiography students	General radiology	Technical skills (ie, duration of the exam, frequency of machinery movement, frequency of incorrect machinery movement, frequency of radiographic exposure errors, and frequency of patient positioning errors)
Sapkaroski et al [33]	Cross-sectional study	92 medical radiation science students	General radiology	Reporting student experience
Sapkaroski et al [34]	RCT	76 first-year radiography students	Radiation technology	Patient positioning
Sapkaroski et al [35]	RCT	76 radiography students	General radiology	Students' perception about developing radiographic hand positioning skills.
Shanahan [36]	Cross-sectional study	86 first-year radiography students	General radiology	Reporting student perception
Wu et al [37]	Cross-sectional study	18 medical students	General radiology	Reporting student perception

^bCT: computed tomography.

Results

Search Results

The database search identified a total of 2877 studies; 374 (13%) studies were from PubMed, 2169 (75.4%) were from Scopus, 234 (8.1%) were from ScienceDirect, and 100 (3.5%) were from Google Scholar. Before the screening procedure, 37 duplicates

were removed. During title and abstract screening, 2808 articles were excluded since they did not align with the eligibility criteria. The remaining 32 articles were then subjected to a full-text review, and 15 were excluded for reasons provided in [Figure 1](#), which shows the study selection process [38]. At the end of the process, 17 studies were found eligible for inclusion in the review.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart showing the study selection process.

Characteristics of Included Studies

Among the 17 studies, 3 (18%) RCTs, 7 (41%) randomized experimental trials, and 7 (41%) cross-sectional studies were included. The studies encompassed various aspects of radiology

education, including dental radiology [28,29], diagnostic radiology [22,24], and interventional radiology [25,31].

Results of Quality Assessment

Among the 7 cross-sectional studies, 2 (29%) scored “good” in overall quality and the remaining 5 (71%) scored “fair.” The

results for the quality appraisal of cross-sectional studies are shown in Table 3. Studies were appraised using the checklist for analytical cross-sectional studies from the Joanna Briggs Institute [21].

Among the 10 randomized trials, 3 (30%) had a low risk of bias, 5 (50%) showed some concerns, and 2 (20%) had a high risk of bias. These results are shown in Table 4. RCTs were appraised using the RoB 2 tool from the Cochrane Collaboration [19]. A risk-of-bias graph (Figure 2) and a risk-of-bias summary (Figure 3) are also provided.

Table . Appraisal for cross-sectional studies included in the systematic review.

Study	Item 1 ^a	Item 2 ^b	Item 3 ^c	Item 4 ^d	Item 5 ^e	Item 6 ^f	Item 7 ^g	Item 8 ^h	Overall quality
Gunn et al [25]	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Good
Jensen et al [26]	Yes	Yes	Yes	No	No	N/A ⁱ	Yes	Yes	Fair

^aD1: risk of bias arising from the randomization process.

^bD2: risk of bias due to deviations from the intended interventions (effect of assignment to intervention).

^cD3: risk of bias due to missing outcome data.

^dD4: risk of bias in measurement of the outcome.

^eD5: risk of bias in selection of the reported result.

Figure 2. Risk-of-bias graph using a traffic light plot for different domains (D1 to D5) [22-24,27-30,32,34,35].

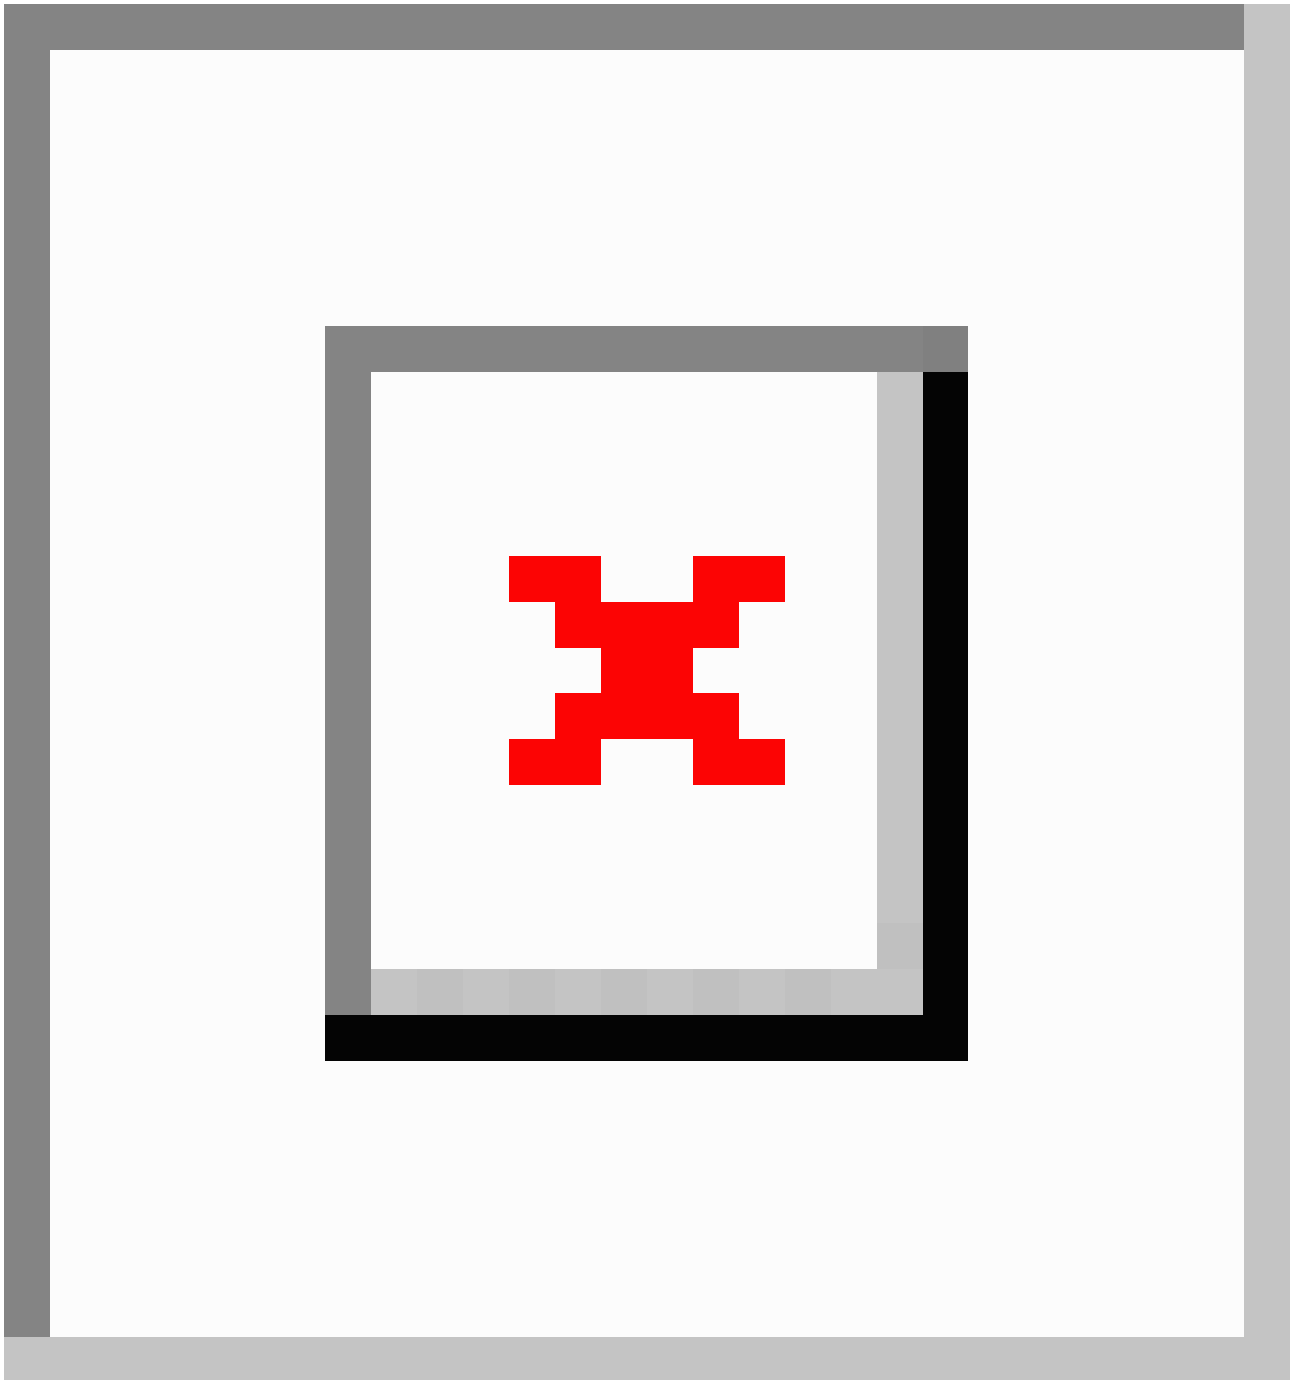

Figure 3. Weighted bar plots displaying the distribution of risk-of-bias judgments within each bias domain.

Type of VR Hardware and Software Used in the Studies

The studies used a wide range of VR software and hardware. Some of the studies used 3D simulation software packages displayed on 2D desktop computers [22,24,25,36], whereas others used headsets for an immersive VR environment [15,23,26,35,37]. The most used VR teaching software were the CETSOL VR Clinic software [33,35], Virtual Medical Coaching VR software [15,30,32], Projection VR (Shaderware) software [36], SieVRt VR system (Luxsonic Technologies) [37], medical imaging training immersive environment software [23], VR CT Sim software [25], VitaSim ApS software [26], VR X-Ray (Skilitics and Virtual Medical Coaching) software

[27], and radiation dosimetry VR software (Virtual Medical Coaching Ltd) [31].

Effect of VR Teaching on Skill Acquisition

Ahlqvist et al [22] looked at how virtual simulation can be used as an effective tool to teach quality assessment of radiographic images. They also compared how it fared in comparison to traditional teaching. The study reported a statistically significant improvement in proficiency from before training to after training. Additionally, the study reported that the proficiency score improvement for the VR-trained students was higher than that for the students trained using conventional method.

In the study conducted by Sapkaroski et al [34], students in the VR group demonstrated significantly better patient positioning

skills compared to those in the conventional role-play group. The positioning parameters that were assessed were digit separation and palm flatness (the VR group scored 11% better), central ray positioning onto the third metacarpophalangeal joint (the VR group scored 23% better), and a control position projection of an oblique hand. The results for the control position projection indicated no significant difference in positioning between the 2 groups [34].

Bridge et al [23] also performed a performance comparison between students trained by VR and traditional methods. They assessed skills about patient positioning, equipment positioning, and time taken to complete a performative role-play. Students in the VR group performed better than those in the control group, with 91% of them receiving an overall score of above average (>3). The difference in mean group performance was statistically significant ($P=.0366$). Similarly, Gunn et al [24] reported improved and higher role-play skill scores for students trained using VR software simulation compared to those trained on traditional laboratory simulation. The mean role-play score for the VR group was 30.67 and that for the control group was 28.8 [24].

Another study reported that students trained using VR performed significantly better (ranked as “very good” or “excellent”) than the control group (conventional learning) in skills such as patient positioning, selecting exposure factors, centering and collimating the x-ray beam, placing the anatomical marker, appraisal of image quality, equipment positioning, and procedure explanation to the patient [30]. Another recently conducted study found that the VR-taught group achieved better test duration and fewer errors in moving equipment and positioning a patient. There was no significant difference in the frequency of errors in the radiographic exposure setting such as source-to-image distance between the VR and the physical simulation groups [32].

Nilsson et al [28] developed a test to evaluate the student’s ability to interpret 3D information in radiographs using parallax. This test was applied to students before and after training. There was a significantly larger ($P<.01$) pre-post intervention mean score for the VR group (3.11 to 4.18) compared to the control group (3.24 to 3.72). A subgroup analysis was also performed, and students with low visuospatial ability in the VR group had a significantly higher improvement in the proficiency test compared to those in the control group. The same authors conducted another follow-up study to test skill retention [29]. Net skill improvement was calculated as the difference in test scores after 8 months. The results from the proficiency test showed that the ability to interpret spatial relations in radiographs 8 months after the completion of VR training was significantly better than before VR training. The students who trained conventionally showed almost the same positive trend in improvement. The group difference was smaller and not statistically significant. This meant that, 8 months after training, the VR group and the traditionally trained group had the same skill level [29].

Among the included studies, only 1 reported that the VR group had lower performance in proficiency tests and radiographic skill tests, compared to a conventionally trained group. The study, conducted in 2022, showed that the proficiency of the

VR group was significantly lower than that of the conventional technique group in performing lateral elbow and posterior-anterior chest radiography [27]. An itemized rubric evaluation used in the study revealed that the VR group also had lower performance in most of the radiographic skills, such as locating and centering of the x-ray beam, side marker placement, positioning the x-ray image detector, patient interaction, and process control and safety [27]. The study concluded that VR simulation can be less effective than real-world training in radiographic techniques, which requires palpation and patient interaction. These results may be different from those of other studies due to different outcome evaluation methods and since they used head-mounted display VR coaching, whereas the other studies, except O’Connor et al [15], used VR on a PC monitor.

All of the studies except Kato et al [27] agreed that VR use was more effective for students in developing radiographic and radiologic skills. Despite this general agreement, there were slight in-study variations in learning outcomes, which made some of the studies look at factors that may influence skill and knowledge acquisition during VR use. In studies such as Bridge et al [23], it was noted that the arrangement of equipment had the greatest influence on the overall score. After performing a multivariable analysis, Gunn et al [24] reported that there was no effect of age, gender, and gaming skills or activity on the outcome of VR learning. In the study by Shanahan [36], a few students (19/84, 23%) had previously used VR simulation software. This had no bearing on the learning outcomes. Another observation in the same study was that student age was found to significantly affected the student’s confidence about skill acquisition after VR training [36].

Students’ Perception of VR Uses for Learning

The findings from the study by Gunn et al [25] revealed that 68% of students agreed or strongly agreed that VR simulation was significantly helpful in learning about computed tomography (CT) scanning. In another study by Jensen et al [26], 90% of the students strongly agreed that VR simulators could contribute to learning radiography, with 90% reporting that the x-ray equipment in the VR simulation was realistic. In the study by Wu et al [37], most of the students (55.6%) agreed or somewhat agreed that VR use was useful in radiology education. Similarly, 83% of the students in Shanahan’s [36] study regarded VR learning with an ease of use. In the same study, students also reported that one of the major benefits of VR learning include using the simulation to repeat activities until being satisfied with the results (95% of respondents). Students also stated that VR enabled them to quickly see images and understand if changes needed to be made (94%) [36]. In the study by Gunn et al [25], 75% of medical imaging students agreed on the ease of use and software enjoyment in VR simulated learning. In the same study, 57% of the students reported a positive perceived usefulness of VR. Most respondents (80%) in the study by Rainford et al [31] favored the in-person VR experience over web-based VR. Similarly, 58% of the respondents in the study conducted by O’Connor et al [15] reported enjoying learning using VR simulation. In the study by Wu et al [37], 83.3% of students agreed or strongly agreed that they enjoyed using VR for learning. Similarly, the

studies by Rainford et al [31] and O'Connor et al [15] reported student recommendation of 87% and 94%, respectively, for VR as a learning tool.

Students' Perceived Skill and Knowledge Acquisition

In the study by Bridge et al [23], students who trained using VR reported an increase in perceived skill acquisition and high levels of satisfaction. The study authors attributed this feedback to the availability of "gold standards" that showed correct positioning techniques, as well as instant feedback provided by the VR simulators. Gunn et al [25] examined students' confidence in performing a CT scan in a real clinical environment after using VR simulations as a learning tool. The study reported an increase (from before to after training) in the students' perceived confidence in performing diagnostic CT scans. Similarly, the study by Jensen et al [26] reported that the use of VR had influenced students' self-perceived readiness to perform wrist x-ray radiographs. The study, however, found no significant difference in pre- and posttraining (perceived preparedness) scores. The pre- and posttraining scores were 75 (95% CI 54-96) and 77 (95% CI 59-95), respectively. The study by O'Connor et al [15] looked at the effect of VR on perceived skill adoption. Most of the students in the study reported high levels of perceived knowledge acquisition in the areas of beam collimation, anatomical marker placement, centering of the x-ray tube, image evaluation, anatomical knowledge, patient positioning, and exposure parameter selection to their VR practice. However, most students felt that VR did not contribute to their knowledge of patient dose tracking and radiation safety [15]. In the study by Rainford et al [31], 73% of radiography and medical students felt that VR learning increased their confidence across all relevant learning outcomes. The biggest increase in confidence level was regarding their understanding of radiation safety matters [31]. Sapkaroski et al [33] performed a self-perception test to see how students viewed their clinical and technical skills after using VR for learning. In their study, students reported a perceived improvement in their hand and patient positioning skills. Their study also compared 2 software, CETSOL VR Clinic and Shaderware. The cohort who used CETSOL VR Clinic had higher scores on perceived improvement [33]. Sapkaroski et al [35] compared the student's perception scores on the educational enhancement of their radiographic hand positioning skills, after VR or clinical role-play scenario training. Although the VR group scored higher, there was no significant difference between the scores for the 2 groups [35]. In the study by Shanahan [36], when the perception of skill development was evaluated, most of the students reported that the simulation positively developed their technical (78%), radiographic image evaluation (85%), problem-solving (85%), and self-evaluation (88%) abilities. However, in the study by Kato et al [27], there was no difference in the perceived acquisition of knowledge among students using traditional teaching and VR-based teaching.

Discussion

Principal Findings

The results presented in this review reveal strong evidence for the effectiveness of VR teaching in radiology education,

particularly in the context of skill acquisition and development [22,24,27,30,32,34].

In this review, quality appraisal of the cross-sectional studies revealed that the strategies for deal with confounding factors was one of the factors directly affecting the reliability of the results. Similarly, the appraisal of the randomized trials revealed that the bias arising due to missing outcome data was one of the factors directly affecting the reliability of the results.

All the studies found that VR-based teaching had a positive impact on various areas of radiographic and radiologic skill development. In comparison to the traditional way of teaching, only 1 study by Kato et al [27] reported VR teaching as inferior to traditional teaching. The studies consistently reported better improvements in proficiency, patient positioning outcomes, equipment handling, and radiographic techniques among students trained using VR. According to Nilsson et al [29], O'Connor et al [15], and Wu et al [37], the improvements were due to the immersive and interactive nature of VR simulations, which allowed learners to engage with radiological scenarios in a dynamic and hands-on manner. The studies also revealed that VR learning has the ability to easily and effectively introduce students to new skills. It was also found that existing skills could be improved, mainly through simulation feedback that happens in real time during training [22,24,28,30,36].

The improvement of skills after VR training have been noted in different domains, including patient positioning, equipment positioning, equipment knowledge, assessment of radiographic image quality, and patient interaction. Improvement was also observed in other skills such as as central ray positioning, source-to-image distance, image receptor placement, and side marker placement [22,24,30,32,34]. Two studies, Nilsson et al [28] and Nilsson et al [29], looked at how VR affected the students' ability to interpret 3D information in radiographs using parallax. They both reported a positive effect. Nilsson et al [29] also gave insights into the long-term benefits of VR training in radiology. Eight months after training, the control (traditionally taught) group in Nilsson et al [29] showed a slight increase in skills, but the VR-trained group still maintained a significantly higher skill level. This finding shows the enduring impact of VR-based education on skill acquisition in radiology. Although most studies supported the effectiveness of VR in radiology education, 1 study reported contrasting results [27]. VR-trained students were found to perform worse than traditionally trained students in conducting lateral elbow and posterior-anterior chest radiography in Kato et al [27]. This difference in results was, according to the authors, attributed to the use of a different rubric evaluation method and the use of a head-mounted display-based immersive VR system, which was not used in other studies. These 2 reasons may be the reason for the variation in study findings.

A wide range of VR software with different functions were used in the studies. In addition to acquiring radiographic images, the CETSOL VR Clinic software facilitated students to interact with their learning environment [33,35]. Students using the Virtual Medical Coaching VR software performed imaging exercise on a virtual patient with VR headsets and hand controllers [15,30,32]. The SieVRt VR system displayed Digital

Imaging and Communications in Medicine format images in a virtual environment, thus facilitating teaching [37]. The medical imaging training immersive environment simulation software provided automated feedback to the learners including a rerun of procedures, thus highlighting procedural errors [23]. The VR CT Sim software allowed the student virtually to perform the complete CT workflow [25]. Students could manipulate patient positioning and get feedback from the VitaSim ApS software [26]. The VR X-Ray software allowed students to manipulate radiographic equipment and patient's position with a high level of immersive experience [27]. Radiation dosimetry VR software facilitated virtual movement of the staff and equipment to radiation-free areas, thus optimizing radiation protection [31].

The included studies also looked at factors that could influence skill acquisition when VR is used in radiology education. Bridge et al [23], Gunn et al [24], Kato et al [27], and Shanahan [36] investigated factors such as age, gender, prior gaming experience, and familiarity with VR technology. However, these factors were shown to have no significant effect on VR learning outcomes. This shows that VR education can equally accommodate a wide range of learners, regardless of experience or existing attributes.

Across several studies, positive feedback emerged regarding the utility, ease of use, enjoyment, and perceived impact on skill and knowledge acquisition. The included studies consistently reported positive perceptions of VR use among students [25,26,37]. Gunn et al [25] reported that a significant proportion of medical imaging and radiation therapy students found the use of VR simulation to be significantly helpful in learning about CT scanning. Similarly, Jensen et al [26] and Wu et al [37] reported that a majority of students agreed on the usefulness of VR in radiology education. Another aspect that received positive feedback was the ease of use. Students liked the ability to repeat tasks until they were satisfied with the results and the ability to quickly visualize radiographs to determine the need for revisions [36]. Rainford et al [31] and O'Connor and Rainford [30] found that most students would recommend VR as a learning tool to other students.

Several studies investigated student's perceptions of skill and knowledge acquisition when using VR for radiology education. Bridge et al [15] and O'Connor et al [23] discovered an increase in students' perceived acquisition of radiographic skills. Gunn

et al [25] reported an increase in students' perceived confidence to perform CT scans after learning using VR simulations. According to Rainford et al [31], a large percentage of radiography and medical students felt that VR learning boosted their confidence across all relevant learning outcomes, with the highest levels of confidence recorded in radiation safety. Sapkaroski et al [33] discovered that after using VR for learning, students experienced an improvement in their hand and patient placement skills. In summary, the positive feedback from the students shows that VR use in radiology education is a useful, engaging, and effective teaching tool. This perceived acquisition of skills is backed by the results from the proficiency tests.

The VR modalities used in some of the studies allowed remote assistance from an external agent (teacher), as the VR training is conducted in front of a screen while being part of a team, with the teacher making constant corrections and indications [22,24,27]. However, researchers are looking into VR systems with artificial intelligence-supported tutoring, which includes the assessment of learners, generation of learning content, and automated feedback [39].

Conclusion

Findings from the included studies show that VR-based teaching offers substantial benefits in various aspects of radiographic and radiologic skill development. The studies consistently reported that students educated using VR systems improved significantly in overall proficiency, patient positioning, equipment knowledge, equipment handling, and radiographic techniques. However, the variable nature of the studies included in the review reduces the scope for a comprehensive recommendation of VR use in radiology education. A key contributing factor to relatively better learning outcomes was the immersive and interactive nature of VR systems, which provided real-time feedback and dynamic learning experiences to students. Factors such as age, gender, gaming experience, and familiarity with VR systems did not significantly influence learning outcomes. This shows that VR can be used for diverse groups of students when teaching radiology. Students generally provided positive feedback about the utility, ease of use, and satisfaction of VR, as well as its perceived impact on skill and knowledge acquisition. These students' reports show the value of VR as an important, interesting, and effective tool in radiology education.

Abstract

Background: Over the last decade, there has been growing interest in inverted classroom teaching (ICT) and its various forms within the education sector. Physiology is a core course that bridges basic and clinical medicine, and ICT in physiology has been sporadically practiced to different extents globally. However, students' and teachers' responses and feedback to ICT in physiology are diverse, and the effectiveness of a modified ICT model integrated into regular teaching practice in physiology courses is difficult to assess objectively and quantitatively.

Objective: This study aimed to explore the current status and development direction of ICT in physiology in basic medical education using bibliometric visual analysis of the related literature.

Methods: A bibliometric analysis of the ICT-related literature in physiology published between 2000 and 2023 was performed using CiteSpace, a bibliometric visualization tool, based on the Web of Science database. Moreover, an in-depth review was performed to summarize the application of ICT in physiology courses worldwide, along with identification of research hot spots and development trends.

Results: A total of 42 studies were included for this bibliometric analysis, with the year 2013 marking the commencement of the field. University staff and doctors working at affiliated hospitals represent the core authors of this field, with several research teams forming cooperative relationships and developing research networks. The development of ICT in physiology could be divided into several stages: the introduction stage (2013 - 2014), extensive practice stage (2015 - 2019), and modification and growth stage (2020 - 2023). Gopalan C is the author with the highest citation count of 5 cited publications and has published 14 relevant papers since 2016, with a significant surge from 2019 to 2022. Author collaboration is generally limited in this field, and most academic work has been conducted in independent teams, with minimal cross-team communication. Authors from the United States published the highest number of papers related to ICT in physiology (18 in total, accounting for over 43% of the total papers), and their intermediary centrality was 0.24, indicating strong connections both within the country and internationally. Chinese authors ranked second, publishing 8 papers in the field, although their intermediary centrality was only 0.02, suggesting limited international influence and lower overall research quality. The topics of ICT in physiology research have been multifaceted, covering active learning, autonomous learning, student performance, teaching effect, blended teaching, and others.

Conclusions: This bibliometric analysis and literature review provides a comprehensive overview of the history, development process, and future direction of the field of ICT in physiology. These findings can help to strengthen academic exchange and cooperation internationally, while promoting the diversification and effectiveness of ICT in physiology through building academic communities to jointly train emerging medical talents.

Introduction

In recent decades, student-centered active learning strategies have been implemented in numerous educational institutions worldwide as an alternative to traditional passive learning strategies such as didactic lecturing [1]. As a novel teaching mode, inverted classroom teaching (ICT), first proposed by Lage et al [2] in 2020, is now widely used to enhance the engagement of students in the active learning process. ICT, also known as “flipped classroom teaching,” promotes student participation, engagement, and identification of necessary resources and needs to meet learning objectives by repurposing classroom time for student-centered learning activities [3,4]. The teaching materials are made available for self-study outside of the classroom, while ICT also emphasizes active learning by assigning preclass tasks to students with clear learning objectives. ICT represents a significant advancement in modern classroom design, and its potential for promoting student-centered learning is particularly noteworthy.

Medical institutions were among the first to shift away from traditional didactic methods toward student-centered learning, which has been shown to motivate and empower students to be life-long learners, foster self-growth, and encourage receiving and applying up-to-date information and techniques in various medical fields [5,6]. Since it was first proposed as a teaching model [2], ICT has been used in almost all fields of education, especially in basic medicine and clinical medicine, and has become a focus of educational research. A recent bibliometric analysis on ICT revealed its ability to reallocate the teaching content taught in traditional classrooms outside the classroom for students to study on their own before the class. The resulting saved classroom time is then used for various student-centered learning activities such as problem-based and inquiry-based learning [4,7,8]. With the COVID-19 pandemic wreaking havoc around the globe, ICT has been increasingly incorporated into online teaching and is regarded as a promising and flexible approach for securing high-quality teaching via different forms of teaching media [9]. Despite the overwhelming benefits and compelling cases, researchers have also reported negative examples and disadvantages of using active-learning strategies, such as students lacking learning motivation [10,11], increased workload for both faculty and students [12], longer preparation time [12], and reluctance to discuss the teaching content with peers [13]. Moreover, a systematic theoretical and practical system of ICT in medical education has not yet been established.

Physiology is a bridging course between basic and clinical medicine, which is a core course for students in medicine and related subjects. Physiology is typically scheduled in the first semester of the second year of medical school. This course is often considered challenging for students in the early stages of their medical education owing to its highly conceptual nature, the significant cognitive effort required to acquire academic information, and the combined laboratory experiments associated with theoretical knowledge [9,14,15]. To a certain extent, the history and development of inverted teaching in physiology may serve as a window to probe into the general picture of the use of ICT in basic medical education. However, there is still a vast knowledge gap in the development and

application of ICT in physiology courses; for example, it remains unclear how ICT in physiology evolved from the information era to the digital and artificial intelligence era. With the development of CiteSpace, a powerful visualization and analysis software, it has now become feasible to depict and visualize science knowledge graphs [16], including the outline and timeline of ICT in physiology, which can help to address these knowledge gaps in a more quantitative manner than possible with traditional qualitative methods such as a scoping review.

Therefore, in this study, we performed a visual analysis of the ICT in physiology literature from the Web of Science (WoS) database with CiteSpace. The aim was to explore the temporal evolution context and spatial distribution networks of ICT in physiology; investigate the cooperation network among authors, institutions, and countries publishing research in this field using co-occurrence analysis; and uncover hot research topics and development trends through cocitation analysis of references, authors, and journals, along with keyword co-occurrence and clustering analyses.

Methods

Search Strategy

We selected the WoS Core Collection as the data source for this study. To capture a broad range of potentially eligible articles, we used the following search terms with Boolean operators: (“flipped classroom” OR “flipped classroom teaching” OR “flipped study” OR “flipped learning” OR “flipped teaching” OR “flipped instruction” OR “inverted teaching” OR “inverted learning” OR “inverted study” or “inverted classroom” OR “inverted instruction”) in all fields AND (“Physiology”) in all fields. The time span was set from January 2000 to April 2023, and the data were collected on December 11, 2023. Only journal articles indexed in the WoS Core Collection were used to gather data. This database was selected because it is the longest-established citation tracking database, which includes quality indices such as Journal Citation Reports [17], provides a well-recognized subject classification for research journals, and permits the easy download of a considerable number of stored references [18].

Study Selection Criteria

The search was performed in English to obtain the largest number of documents in the WoS data set on the use of ICT in physiology education. The following inclusion criteria were applied: (1) document type=articles, (2) language=English, (3) years of publication=2000-2023 (November). The exclusion criteria were (1) studies in a field not related to medicine or pedagogy; (2) not published in English; (3) categorized as books, chapters, theses, protocols, study outlines, government publications, posters, editorial materials, duplicates, or nonpeer-reviewed articles; and (4) published outside of the time frame of 2000-2023.

Upon applying the above search strategy, 632 indices were retrieved in the WoS data set and 295 records were screened after removing 237 studies using automation tools from the database. Before further screening and retrieval of the full texts

of the references, all 294 indices with detailed citation records and bibliometric information were exported in both record and reference formats, saved as plain-text files, and stored in the .txt format. The stored records were then input into the CiteSpace software for visualization, as indicated by the user manual [19], which generated clustered plots of bibliometric references and differentiated various topics. The relevant articles pertaining to inverted classroom pedagogy were identified by examining the visualized clusters and topics, and irrelevant literature was excluded by adhering to the guidelines in the CiteSpace manual. In brief, in the cluster plots, irrelevant topics are presented in isolated clusters without citation networks; hence, these dots, representing the irrelevant literature, were removed from the eligible references after reviewing the titles and abstracts.

The full text of the included articles was downloaded and reviewed by two authors independently (YW and ZH), and a consensus was reached through discussion between the two reviewers in the case of any disagreements. In total, 253 studies were excluded after title and abstract screening and a total of 42 articles were included for the final analysis. The flowchart of study selection is provided in [Multimedia Appendix 1](#) and the details of the excluded studies with reasons for exclusion are provided in [Multimedia Appendix 2](#).

Data Analysis Process

CiteSpace 6.1.R6 software was used to visually analyze the literature related to ICT in physiology published up to November 2023. CiteSpace is a knowledge visualization software developed by Chaomei Chen at Drexel University and is now a widely used knowledge mapping tool in various fields of education and teaching [20]. CiteSpace can measure and visualize literature collections in broad fields of the natural and social sciences using cocitations of references, authors, and journals; the co-occurrence of authors, keywords, institutes, and countries; and cluster analysis to create a scientific knowledge network map, explore the critical path of the evolution of the discipline, and analyze the hot spot research topics and frontier trends clearly and scientifically.

In this study, we analyzed the overall national and regional distributions and cooperation of the authors of ICT in physiology research papers through the constructed network cooperation map, and then determined the knowledge base and the core authors of ICT in physiology research through analysis of the literature and author cocitation networks. We further identified the “star” journals publishing research in this field through a cocitation analysis of the source journals. Finally, the hot spot keywords were determined through keyword co-occurrence and clustering analysis based on the frequency and centrality of the keywords, which were used to further explore the hot topics of worldwide research on ICT in physiology. Overall, the methodology used in this study involved cooperative network analysis and cocitation analysis.

Cooperative network analysis was used to identify core authors, leading research institutions, and national/regional cooperation in ICT in physiology research. The nodes in the graph are represented by circles, with larger circles indicating a greater number of items represented, such as papers, authors,

institutions, references, and countries. In CiteSpace, intermediary or between centrality is used as a critical indicator of node importance, which is characterized by the shortest number of paths passing through a node. Nodes with a centrality value above 0.1 are considered to be important. In this study, the circle size represents the cited frequency of an article, with purple circles indicating high centrality; thus, larger and deeper-purple circles suggest greater importance of the study in ICT in physiology research.

Cocitation analysis was used to identify relationships between cited articles, authors, and journals in the field of ICT in physiology research. For example, if two articles (or authors or journals) A and B are cited simultaneously by a third article, then a cocitation relationship exists between them. Frequent citation of articles (or authors or journals) together suggests that their research topics, including concepts, theories, or methods, are likely related. Cocitation analysis ranks key papers according to their citation frequency and explains the correlation between their contents and directions through the centrality value. This analysis can also infer literature clusters from various papers that are published during the same period, indicating hot spots in the field. The frequency and relevance of citations represent hot spots in scientific research over time, and these core documents form the knowledge base for the hot spots. In turn, the knowledge base clarifies the cutting-edge nature of the research, as frequently cited papers constitute the corresponding knowledge base [21].

Results

Publication Trends in ICT in Physiology

The year 2013 marks the commencement of the field, in which Tune et al [22] were the first to publish a research paper related to ICT in physiology. The research volume then increased yearly, reaching its peak in 2022. According to the number of publications, different stages of ICT in physiology development can be defined. Before 2017, there were only a small number of papers related to ICT in physiology, marking 2013 - 2017 as the gradual upward stage. In 2018, there was a slight decrease in the number of published papers on the topic, which may be due to the conflicts between conventional teaching and incorporating ICT into physiology teaching, indicating the need for more modification and reflection in practice. Hence, 2018 - 2019 can be considered as the adaptation period. The second gradual upward period appeared during the COVID-19 outbreak in 2021 and then peaked in 2022, indicating a boom period for this field of study.

Authors' Cooperative Network

An author's contribution to the area of ICT in physiology can be identified by their significant publications and cooperative connections with other authors, which facilitates understanding the progress in ICT in physiology [23]. Author collaboration appears to be generally limited, and most academic work in this field is conducted in independent teams with minimal cross-team communication.

As shown in [Figure 1A](#), the research author cooperation map highlights various research partnership teams, particularly those

surrounding the authors Gopalan C, Gillam-Krakauer M, and multiple researchers with cooperative connections. Gopalan C has the highest citation count with 5 publications, followed by authors Carbajal MM, Falck AJ, Johnston LC, Feng D, Luo Z, French H, Dadiz R, Vasquez MM, and Gray MM who collaborated on three records with a citation count of 3 each, as depicted in [Multimedia Appendix 3](#).

Since 2016, Gopalan C has published 14 relevant papers, with a significant surge from 2019 to 2022, as illustrated in [Figure 1A](#). Gopalan C, Bingen H, Tveit B, Steindal S, and Krumsvik R have jointly published three papers centered on nursing education [24-26], indicating a stable partnership among these authors who conducted a series of studies on ICT in nursing education. Additionally, some other authors, including Feng D and Luo Z from Central South University in China, have coauthored two papers [27,28].

Figure 1. Network analysis map. The collaboration networks for (A) authors and national/regional collaboration (N=145, E=400) and (B) institutions (N=85, E=216) in the field of inverted teaching in physiology. Node size (N) corresponds to the frequency of inverted teaching in physiology publications from each author/institution. The connecting lines (E) represent collaborative connections between authors/institutions, with thicker lines indicating more frequent collaboration.

National/Regional and Institutional Cooperative Networks

Overall, the extent of collaboration between nations and research institutions is relatively weak, with very low centrality, and the research power of countries is uneven. As seen in [Figure 1](#) and [Multimedia Appendix 4](#), US-based authors published the highest number of inverted teaching in physiology-related papers (18 in total, accounting for over 43% of the total papers). Moreover, their intermediary centrality is 0.24, indicating that they have strong connections and are highly engaged in international cooperation. Chinese authors ranked second, publishing 8 papers; however, their intermediary centrality is only 0.02, suggesting that their papers have limited international influence and lower overall quality, providing little influential power in the field of ICT in physiology. Australia ranked third, with a centrality of 0.01 covered by 3 papers on ICT in physiology.

As shown in [Figure 1B](#) and [Multimedia Appendix 5](#), universities and affiliated hospitals are the primary institutions that have published ICT in physiology-related papers. Southern Illinois University Edwardsville and Duke University in the United States have published the most papers in this field since 2018 and have significantly contributed to ICT in physiology research.

Other institutions, including the University of Washington, University of Texas, Vanderbilt University, Central South University, University of Rochester, University of Pennsylvania, Yale University, University of Washington, and Baylor College of Medicine, contributed 3 research papers each. As seen from the year color bar on the left bottom corner of [Figure 1B](#), most nodes are labeled in orange, indicating that most institutions published these articles in 2021 and 2022. Specifically, most of the studies performed in the United States are labeled in green and yellow, corresponding to earlier years, indicating the pioneering role of universities in the United States for ICT in physiology research; in particular, authors from Southern Illinois University published an ICT in physiology paper in 2017, which is earlier than most institutions contributing to this field.

Cocitation Analysis of References

The highly cited literature on ICT in physiology is summarized in [Table 1](#), which shows the top 15 most influential articles in this field of research ranked by citation frequency and mediation centrality published between 2013 and 2020. The top-ranked item by citation counts is by Chen et al [21], which was published in 2017 with a citation count of 8 and a centrality of 0.26, followed by the paper published by McLaughlin et al [29] in 2014, also with a citation count of 8.

Table 1. Top 12 influential papers on inverted teaching in physiology published in the last decade (2013 - 2023).

Cited reference	Citation count	Centrality	Publication year
Chen et al [21]	8	0.26	2017
McLaughlin et al [29]	8	0	2014
Tune et al [22]	5	0	2013
Gilboy et al [30]	4	0.12	2015
Pierce and Fox [31]	4	0.15	2012
Betihavas et al [1]	4	0.5	2016
Xiao et al [32]	4	0.17	2018
Hew and Lo [33]	4	0.2	2018
Day [34]	3	0.07	2018
French et al [35]	3	0.04	2018
Blair et al [36]	3	0.06	2020
Freeman et al [37]	3	0.08	2014
Akçayır and Akçayır [38]	3	0.3	2018
Foldnes [39]	3	0.03	2016
Gross et al [40]	3	0.03	2015

Cocitation Analysis

As shown in [Multimedia Appendix 6](#) and [Multimedia Appendix 7](#), Gopalan C was found to be the most cited author with a count of 5 and a centrality of 0.02.

[Multimedia Appendix 8](#) summarizes the top 10 journals that published ICT in physiology papers. *Advances in Physiology Education* was the first journal to publish ICT in physiology research papers and has maintained the highest frequency of citations from 2013 to 2022 (also see [Multimedia Appendix 6](#)). Additionally, journals such as *Computers & Education* and *The*

Internet and Higher Education have also provided considerable attention to this topic, implying that modern educational technologies such as information science and the internet play a crucial role in facilitating the inverted classroom mode.

Research Hot Spots Suggested by Keyword Co-Occurrence Analysis

[Figure 2](#) presents the coexistence diagram of ICT in physiology keywords, with each node representing a keyword and the font size indicating the node's size; that is, a larger font indicates that the keyword appears more frequently. The cluster labels

obtained from the keyword cluster analysis can indirectly reflect the leading research topics, while the timeline map of the keyword clusters can demonstrate the leading research topics by time. Table 2 lists the top keyword clusters in ICT in physiology research according to the number of occurrences and centrality of each keyword, demonstrating that the top keywords are “flipped classroom,” “active learning,” “student

performance,” “performance,” and “medical education.” Figure 2A shows that from 2013 to 2022, research on ICT in physiology focused on medical education, performance, engagement, active learning, online teaching, and other aspects. According to the intermediary centrality, “flipped classroom” (0.69) is the most influential keyword, followed by “medical education” (0.2) and “education” (0.14).

Figure 2. Co-occurrence map and appearance history of keywords in literature related to inverted teaching in physiology. (A) The map of keyword clusters and the timeline map (N=131, E=459). (B) The co-occurrence map of keywords (N=233, E=795). The node size, N, corresponds to the frequency of publications from each journal. The connecting lines, E, represent collaborative connections between journals, with thicker lines indicating more frequent collaboration.

Table . Main keywords in research related to inverted teaching in physiology.

Keywords	Co-occurrence number	Mediator centrality	First year of appearance
flipped classroom	22	0.69	2013
medical education	8	0.2	2016
education	7	0.14	2020
performance	6	0.14	2014
engagement	6	0.26	2015
flipped teaching	5	0.19	2018
student performance	4	0.04	2013
medical students	4	0.19	2016
active learning	4	0.05	2016
online teaching	3	0.06	2021
instruction	3	0.11	2015
classroom	3	0.09	2015
modified team-based learning	2	0.02	2017
dental education	2	0	2017
classroom model	2	0.05	2017
science	2	0.03	2017
faculty	2	0	2021
covid-19 pandemic	2	0	2022
physiology education	2	0.04	2016
bioscience	2	0.01	2019
perceptions	2	0.04	2022
higher education	2	0.01	2019
medical student	2	0.01	2018
students	2	0.01	2015
efficacy	2	0.09	2020
physiology	2	0.02	2015
learning preference	2	0.01	2021
student perceptions	2	0.02	2016
too	2	0	2022
blended learning	2	0.03	2020
online flipped classroom	2	0	2022
intrinsic motivation	2	0.03	2014
self-determination theory	2	0	2021
learning style	2	0.15	2016

The keyword co-occurrence analysis showed that in addition to the retrieved topic term “flipped classroom,” “medical education” ranked the highest in terms of word frequency and ranked the third highest according to mediator centrality, reflecting that active learning is a hot topic in ICT in physiology research. The keywords “education,” “performance,” and “engagement” followed closely behind, with the centrality being 0.14, 0.14, and 0.26, respectively (Table 2). This indicates that researchers in the field of ICT in physiology have been paying relatively more attention to performance aspects, which could

reflect the effectiveness and satisfaction of ICT in physiology. The keywords “engagement” and “perceptions” also had high co-occurrence numbers and mediator centrality.

Research Hot Spots and Frontier Topics Suggested by Keyword Cluster Analysis

Based on other keywords in the same cluster and the popular words obtained by the latent semantic analysis/indexing algorithm, it was found that many popular words in each cluster reflected the current hot spots of ICT in physiology and had

good consistency with the hot spot topics obtained by the co-occurrence analysis of keywords (see [Multimedia Appendix 9](#)), such as active learning, self-directed learning, student characteristics, learning preferences, learning styles, modified team-based learning, learning environment, flipped design, student engagement, and undergraduate medical education, among others.

Discussion

Principal Findings

In this study, we used CiteSpace software to visually analyze the literature related to the use of ICT in physiology published between 2000 and 2023 retrieved from the WoS database. The results of this bibliometric analysis showed that the core authors publishing in the field of ICT in physiology include staff from universities and affiliated hospitals. Some research teams have also formed cooperative relationships. Research in ICT in physiology mainly focuses on active learning, autonomous learning, student performance, teaching effectiveness, blended teaching, personalized flipped teaching, and other related topics.

Overall, studies on the ICT model in the context of physiology remain scarce, with limited collaboration among authors and a consequent lack of a cohesive research network. Regional growth in this field is uneven and international disparities are evident. Despite the many established benefits of ICT, it is not widely used in various nations and regions. This may be attributable to the fact that the development of the ICT model is still in its infancy, and a mature theoretical structure is needed and must be tested over a wide range of professional specialties. In this sense, relevant researchers must increase interaction and collaboration, investigate systematic teaching techniques appropriate for various disciplines, and perform practical testing and assessment of the model. In the future, research power can be integrated to form a cohesive unit through cooperation among research institutions to promote further breakthroughs in ICT research in the context of physiology.

Development of ICT in Physiology

The ICT model has undergone three stages of development, including the introduction stage (2013 - 2014), extensive practice stage (2015 - 2019), and modification and growth stage (2020 - 2022).

Several studies have confirmed that an active-learning strategy is associated with improved student performance, a reduced failure rate, and better learning achievements in basic and clinical medical education [37,41]. Shaffer [42] reported that anatomy course objectives were achieved at a much higher rate after incorporating an active teaching style compared to the achievement rate following traditional teaching. Furthermore, in the clinical discipline, Qutub [43] reported the considerable effectiveness of ICT as an active learning style in a hematology course, enabling students to obtain desirable knowledge and improve their academic performance; moreover, students recognized that ICT as an active learning style was more beneficial than the traditional teaching approach. In 2016, Bethavas et al [1] performed a systematic review of 9 studies on the use of ICT in nursing education and reported that nursing

students achieved similar or higher academic outcomes with ICT than with a conventional teaching strategy; however, the students indicated a mixed sense of satisfaction.

Other researchers in medical education and health science programs have reported similar results. For example, in an analysis of 274 papers, Barranquero-Herbosa et al [44] found that ICT in nursing education improves performance and is well-received by both students and instructors. O'Connor et al [45] concluded that reversing the flow of classroom teaching improves academic performance, develops self-directed learning skills, and consolidates acquired knowledge through active learning strategies. Sultan [46] found that flipping the classroom gives students more time for active learning, peer collaboration, and applying and analyzing theoretical knowledge. Moreover, McLean et al [47] showed that ICT could improve students' preparation, attendance, and participation in the course Medical Sciences 4200, an elective nonthesis-based course that covers content related to physiology, biochemistry, and immunology.

With COVID-19 wreaking havoc worldwide in early 2020, the strict and rapid public health measures put forward led to the suspension of face-to-face education and the transfer of the classroom to online meetings, which also corresponds to the application of blended learning as a pedagogical approach based on a combination of online and face-to-face education processes [48]. This necessary shift during the pandemic greatly facilitated the implementation of ICT in various subjects and expanded the use of other types of education tools. For instance, Bawazeer et al [49] reported the use of polls in virtual sessions on physiology, pharmacology, and pathology courses to assess students' engagement, understanding, performance, and attendance, and found improvements in understanding and performance. Feng et al [28] reported that incorporating the inverted classroom and a team-based learning strategy in the online setting can enhance the learning outcomes for students in a clinical immunology laboratory course. Although the pandemic and the availability of novel technologies have made blended learning a "new normal" in medical education, the successful adaptation of blended learning requires sufficient teacher training as well as the adoption of appropriate technologies by educational institutions [50].

The Role of ICT in Medical Education

In 2018, Chung et al [51] performed a systematic review on the use of ICT in nursing education, which showed that the basic flipped classroom mode has been frequently used in nursing education; nevertheless, the effects of ICT on learning behavior in physiology courses were not clearly investigated and only a few studies included in the review reported the use of after-class activities to engage students in facilitating the applications of the knowledge learned. Moreover, Lin and Hwang [52] reviewed studies on ICT papers published up to 2017 based on the technology-enhanced learning model, and noted that little attention was paid to the assessment of learners' higher-order thinking skills and their degree of preparation or cognitive load. Similar findings have also been reported in relation to the application of ICT in subjects other than medicine, including mathematics [53].

Nevertheless, there is no doubt that ICT can efficiently engage students in learning sessions, even during the pandemic [54]. Research investigating students' perceptions and performance revealed that students have high levels of acceptance for a virtual flipped teaching approach, which was already evident prior to the COVID-19 pandemic [9,55-57].

Lack of a Cohesive Research Network in ICT in Physiology Research

Acknowledging the importance of international cooperation and the role of different countries contributing to research on ICT in physiology may facilitate communication and collaboration among countries. With the highest number of published papers, authors from the United States have been the primary contributors to research on the applications of ICT in physiology courses since 2013.

The positive effects of ICT largely depend on an effective classroom design [58]. Designing an effective inverted classroom, guiding students to engage in inverted classroom learning, and personalizing the ICT to enhance teaching effectiveness and student learning outcomes have increasingly become the main topics of ICT research. These are common challenges encountered by teachers and students in ICT. Since a layered teaching approach adapted to the learning, teaching, and classroom conditions can maximize the expected benefits, various ICT approaches have been developed to date, such as partially inverted classrooms [59], Small Private Online Courses-based inverted classrooms [60], and lecture-based inverted classrooms [61].

Current Hot Spots of ICT in Physiology Research

There are currently three main topics generally discussed in the field of ICT: preparation before class, classroom activities, and consolidation after class [23]. The current hot spots of research in ICT for physiology worldwide focus on active learning, inverted classroom design, student perception and engagement, teaching effectiveness, and teaching evaluation, among others, while the scope of the research includes students, teachers, school teaching management, and national educational guidelines and policies. Moreover, our results are consistent with previous bibliometric studies related to the research on ICT in other fields [62]. For instance, a recent review by Cheng et al [62] on the top 100 highly cited ICT papers similarly showed that researchers in this field have largely focused on students' learning achievements and learning behaviors rather than directly comparing the benefits of inverted and traditional learning. Similarly, Meral et al [63] reported that motivation, perception, and academic achievement/performance were the most common topics in the ICT studies published between 2010 and 2019.

Regarding the research hot spots suggested by the analysis of keywords, we identified the following main areas of focus of

research on ICT in physiology at present: (1) ICT theories, including active learning and independent learning; (2) ICT strategies, including inverted design, student characteristics, learning style, learning preference, learning environment, educational technology, and student participation; and (3) ICT evaluations, including academic performance, student performance, and student satisfaction. Specific to disciplines and programs, the field of research on ICT in physiology covers clinical medicine, stomatology, nursing, pharmacy, and veterinary medicine, among others. With respect to the courses, ICT approaches can be applied to general physiology, gastrointestinal and renal physiology, exercise physiology, physiology lab courses, and introductory biology. The applicable levels of education include graduate, undergraduate, professional training, and adult continuing education.

Study Strengths and Limitations

This study has both strengths and limitations. To our knowledge, this is the first study to map the current ICT studies in physiology specifically rather than considering the whole field of ICT. Moreover, the visualization of the quantitative results provides a convenient and comprehensible understanding of the current publication status of studies, research hot spots, and development trends in the field of ICT for physiology.

Although all attempts were made to include relevant nouns and terms in the literature retrieval process, some relevant papers may have nevertheless been missed. Additionally, the search only incorporated "physiology" as the keyword for the teaching subject, which may have led to evidence selection bias in which research that covers all medical courses rather than physiology alone may have been missed and could not be incorporated into the study for analysis. In addition, the search was limited to the WoS database, which may have excluded some important non-English publications. Moreover, each subject has unique characteristics in the application of an inverted teaching model, and the results and conclusions reached based on the analysis of this study may not necessarily be generalized to other subjects; thus, these results should be interpreted with caution.

Conclusion

This study analyzes literature on ICT in physiology, identifying core authors, research topics, and development stages. To date, research in this field has focused on active and autonomous learning, student performance, the teaching effect, blended teaching, and personalized flipping teaching models. The development of ICT is linked to modern information technology, the COVID-19 pandemic, educational teaching concepts, and related teaching reform policies. Based on these findings, further academic exchanges and cooperation in applications of ICT in physiology are encouraged, which can highlight the potential of this teaching model to train the next generation of excellent medical talents.

Abstract

Background: The integration of chatbots in nursing education is a rapidly evolving area with potential transformative impacts. This narrative review aims to synthesize and analyze the existing literature on chatbots in nursing education.

Objective: This study aims to comprehensively examine the temporal trends, international distribution, study designs, and implications of chatbots in nursing education.

Methods: A comprehensive search was conducted across 3 databases (PubMed, Web of Science, and Embase) following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.

Results: A total of 40 articles met the eligibility criteria, with a notable increase of publications in 2023 (n=28, 70%). Temporal analysis revealed a notable surge in publications from 2021 to 2023, emphasizing the growing scholarly interest. Geographically, Taiwan province made substantial contributions (n=8, 20%), followed by the United States (n=6, 15%) and South Korea (n=4, 10%). Study designs varied, with reviews (n=8, 20%) and editorials (n=7, 18%) being predominant, showcasing the richness of research in this domain.

Conclusions: Integrating chatbots into nursing education presents a promising yet relatively unexplored avenue. This review highlights the urgent need for original research, emphasizing the importance of ethical considerations.

KEYWORDS

nursing education; chatbots; artificial intelligence; narrative review; ChatGPT

Introduction

Nursing education, crucial for positive patient-professional relationships [1,2] and continuous professional development [3], holds a pivotal position in global health care systems [4], driving progress [5] and integrating technological advancements to enhance patient-centered care [6,7]. A study on oncology nursing provided compelling evidence for nurses, addressing challenges and advocating for specialized education and safety measures in the escalating global cancer burden [8]. A recent meta-analysis of 12 studies with 821 participants evaluated the role of virtual reality in nursing education, which revealed substantial enhancements in knowledge but identified no distinguishable disparities in skills, satisfaction, confidence, and performance time, underscoring the imperative for additional investigations in these domains [9]. Another study explored the usability and feasibility of extended reality smart glasses in core nursing skill training for undergraduate students, uncovering positive effects on engagement, learning satisfaction, and competency improvement and highlighting the potential of smart glasses as an impactful educational strategy in nursing training [10]. However, nursing education encounters obstacles

such as a worldwide scarcity of nursing expertise [11], uneven distribution of resources [12], potential disparities between theoretical and practical aspects [9], restricted interdisciplinary collaboration [13], insufficient opportunities for professional development [14], and the ramifications of the global COVID-19 pandemic [15].

In the swiftly evolving landscape of artificial intelligence (AI) and smartphone proliferation, the integration of large language models such as ChatGPT into chatbots is emerging as a trend, with chatbots progressively showcasing the potential to revolutionize mental health [16], behavior [17], and knowledge [18] within the dynamic and advancing field of deep learning. Recent studies on education have accentuated the use of chatbots to deliver personalized learning experiences [19,20] by tailoring content delivery to the unique needs of individual students, thereby augmenting comprehension and retention. Concurrently, chatbots provide an easily accessible platform for continuous learning [21], affording students the opportunity to retrieve information at their convenience and cultivating a culture of self-directed learning. Moreover, the interactive attributes of chatbots facilitate real-time feedback, permitting the prompt rectification of misconceptions and fostering a more profound

grasp of intricate health care concepts [22]. The adaptability of chatbots caters to diverse learning styles, ensuring inclusivity in education [23]. Despite these advantages, few studies investigate the integration, development, and feasibility of chatbots within nursing education.

Our aim is to meticulously investigate and amalgamate the existing literature pertaining to the integration of chatbots in nursing education by reviewing selected articles. By scrutinizing studies sourced from 3 prominent databases (PubMed, Embase, and Web of Science), we highlight insightful perspectives on the evolving role of chatbots in nursing education. Approaching this investigation with the perspective of a reviewer, we seek to contribute a nuanced and well-supported analysis of the existing literature on this topic.

Methods

Search Strategy

We devised pertinent search queries concerning nursing education and chatbots, with the designated search terms detailed in Section 1 in [Multimedia Appendix 1](#). A thorough investigation encompassing 3 databases—PubMed, Embase, and Web of Science—was carried out from their individual inception dates to November 16, 2023.

Eligibility Criteria for Study Inclusion

The eligibility criteria were devised in accordance with the PICOS (Population, Intervention, Comparison, Outcome, and Study Design) framework [24]. The study inclusion criteria were meticulously outlined to ensure the accuracy and relevance of the selected research. The specified population comprised nurses or nursing students, including managers and clinical nurses, with a deliberate exclusion of doctors and other professional personnel. The intervention criteria encompassed any chatbot intervention, including chatbot apps, messaging, and web-based interventions, while excluding interventions not specifically focused on chatbots or lacking communication with them. The comparator conditions involved conventional education methods, such as face-to-face or drug interventions, excluding the integration of chatbot interventions. The exclusion criteria also considered comparators that included chatbot interventions at comparable rates but with differing frequencies. The outcomes of interest included results relevant to nursing education, covering levels of medical knowledge, nurses' engagement with chatbots, and the improvement of practical skills. The study design inclusion criteria accepted any design. Detailed eligibility criteria are shown in Section 2 in [Multimedia Appendix 1](#).

Selection Process and Outcomes of Interest

The search findings were imported into Covidence (Veritas Health Innovation) while adhering to established protocols. The screening process involved 2 stages. Initially, titles and abstracts were screened, followed by a thorough review of full-text articles. Duplicated papers were removed using Covidence prior to the screening stages to ensure the integrity of the selection process. Three authors (SZ, XL, and WW) independently and in duplicate executed all screening stages and data extraction, resolving any discrepancies through consultation with the senior author (FZ). To ensure precision and uniformity in data, we formulated a comprehensive data extraction form (SZ and WW) that underwent subsequent refinement (SZ and FZ), in alignment with guidelines from the *Cochrane Handbook for Systematic Reviews of Interventions* [25]. Before full extraction, the form underwent a pilot test on a subset of included studies. Extracted details from all included studies (SZ, XL, and WW) included elements such as publication details (study ID, title, and year), author particulars (lead author contact information), study specifics (country, study design, and objectives), and conclusions.

Study Design and Statistical Analysis

This was a narrative review. After the screening process, we successfully gathered comprehensive data, encompassing publication details (study ID, title, and year), author particulars (contact information for the lead author), study specifics (country, study design, and objectives), and conclusions. Subsequently, we categorized this data based on the respective year, country, and study design. To provide a visual representation of the trends observed, we conducted percentage calculations for each category. These percentages were then used to illustrate the trend over time and to convey the distribution of studies across various categories.

Results

In total, 38,412 distinct records were identified. Subsequently, an eligibility assessment was conducted on 77 full-text articles, with 3 articles not retrieved, as depicted in [Figure 1](#). Out of these, 37 were subsequently excluded, resulting in the inclusion of 40 articles that met the eligibility criteria for synthesis [26-65].

Between 2010 and 2020, on average, 1 article was published every 3 - 4 years, culminating in a total of 3 articles, contributing to 8% of the 40 publications. However, a noticeable upswing occurred in 2021, with the publication of 3 (8%) articles. In 2022, the count increased to 6 (15%) articles. The most notable surge transpired in 2023, with the publication of 28 articles, accounting for a substantial 70% of the total publications ([Figure 2](#)).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram showing the study selection process.

Figure 2. Temporal fluctuations in articles published from 2010 to 2023.

Taiwan province contributed 20% (8/40) of the total articles [31,32,34,35,37,42-44]. Following closely was the United States, contributing 15% (6/40) of the articles [39,40,46,52,55,59]. South Korea secured the third position, representing 10% (4/40) of the articles [41,47,48,63]. Canada [26,28,30], Mainland China [33,50,64], and Singapore [57,58,60] each contributed 8% (3/40) of the articles. Turkey [29,62] contributed 5% (2/40) of the articles. Other countries such as Australia [45], France [38], Germany [49], Hong Kong [36], India [56], Iraq [27], Italy [51], Japan [61], Malta [54], the United Kingdom [53], and Ukraine [65] each contributed 3% (1/40) of the articles.

In our review, the predominant study design was reviews, constituting 20% (8/40) of the total articles [36,46,49,50,56,59,60]. Reviews exemplify a meticulous

synthesis of existing literature, providing comprehensive insights and analyses on specific topics. Editorials, comprising 18% (7/40) of the articles [28,39,45,47,52-54], serve as platforms for commentary, opinions, or perspectives on current issues and developments in the field. Commentaries constituted 10% (4/40) of the articles [26,30,35,64], offering critical reflections, analyses, or perspectives on specific subjects. Letters to the editor, making up 8% (3/40) of the articles [27,29,61], provide readers with a platform to express opinions, raise concerns, or offer feedback on published content. Quasi-experimental studies comprised 8% (3/40) of the articles [41,48,58], employing experimental methods without random assignment. Constituting 5% (2/40) of the articles, teaching tips offer valuable insights into effective educational strategies [34,55]. Randomized

controlled trials (RCTs), considered the gold standard in experimental design, constituted 5% (2/40) of the articles [42,62]. Experimental design, symbolizing systematic investigation, was embodied in 3% (1/40) of the articles [31]. Empirical articles, grounded in observations and experiences, constituted 3% (1/40) of the articles [32]. Phenomenological studies, delving into lived experiences and perceptions, comprised 3% (1/40) of the articles [33]. Proof-of-concept studies, showcasing the feasibility of an idea or approach, constituted 3% (1/40) of the articles [38]. Mini reviews, furnishing concise overviews, comprised 3% (1/40) of the articles [65]. Descriptive qualitative studies, concentrating on

detailed exploration, accounted for 3% (1/40) of the articles [40]. Experimental studies, engaging in controlled testing, made up 3% (1/40) of the articles [43]. Systematic reviews, characterized by methodical literature synthesis, represented 3% (1/40) of the articles [44]. Articles centering on experimentation methodology represented 3% (1/40) of the articles [51]. Development studies, exploring the creation of new methodologies or tools, constituted 3% (1/40) of the articles [57]. Lastly, articles classified as communications, conveying crucial information or updates, represented 3% (1/40) of the articles (Table 1) [63].

Discussion

Principal Findings

In this paper, we comprehensively examined the temporal trends, international distribution, study designs, and implications of chatbots in nursing education to map the challenges and issues to address in the future. Our analysis highlights significant findings, including a marked increase in research publications in 2023, reflecting growing interest in this field. Contributions from Taiwan province, the United States, and South Korea illustrate the global scope of chatbot integration in nursing education. The diverse study designs reviewed, ranging from reviews and editorials to quasi-experimental studies, indicate the extensive research exploring chatbots' role in enhancing personalized instruction, patient-care simulations, and critical thinking. Despite these advancements, challenges such as the need for rigorous original research, funding, ethical considerations, and resource distribution disparities remain. Furthermore, addressing these issues through international collaboration and targeted research will be crucial for fully realizing the potential of chatbots in nursing education.

AI language models such as chatbots have caused a revolution in nursing education through the provision of personalized and interactive learning activities. Chatbots are implemented in nursing education for personalized instruction, patients-care simulation, and critical thinking enhancement. Chatbots in health care are used for teleconsultation to improve communication skills, support clinical judgment, and enable remote patient monitoring. Chatbots are a key component in addressing the global shortages of knowledge and resources in nursing training. They bridge theoretical and practical aspects, thereby illustrating the potential of this technology to revolutionize learning processes and change the face of health care services and education.

This study aims to shed light on the evolution of chatbots in nursing education through data analysis of temporal trends. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram facilitates a systematic search procedure, which guarantees a transparent and strict methodology. Indeed, articles published in 2023 accounted for 70% (28/40) of the included articles, which might be due to either increased scholarly interest or intensified effort. This study tries to delve into the technological education aspect of health care, which is a rapidly expanding area. Consequently, it will provide a comprehensive reflection of the dynamic and developing educational sector.

This study provides a new approach about how AI and mobile communication can be applied in and influence nursing education. Chatbots and AI integration can be seen as a technical invention with thrilling effects on mental health, behavior, and knowledge in relation to the field of deep learning. The analysis stresses the sole benefits of chatbots in education, that is, chatbots provide the capacity for individualized learning [27,31,32,39,43,44,47,48,50,51,53,56,60]. The studies focus on problems in nursing education that involve the shortage of global knowledge, condition differences, and lack of relationship

between theory and practice [29,35,45,49,58] and illustrate the ways chatbots can cope with these issues.

A detailed study of the worldwide distribution and categorization of chatbot research on nursing education is carried out with reference to international contexts, highlighting major contributions. The participation of United States and South Korea is notable, and Taiwan province has the largest share, accounting for 20% (8/40) of all articles. This regional perspective highlights the universal nature of adding chatbots to nursing education. As the research methodology analysis reveals, reviews cover 20% (8/40) of the articles, providing exhaustive summaries of the present literature. A diverse range of designs that includes commentaries, quasi-experimental studies, teaching tips, and RCTs explains the extensive and varied research on chatbots in nursing education.

In spite of the huge benefits, there are some barriers that nursing education will face as they try to incorporate chatbots. Original research such as RCTs or cohort studies is the most important part of confirming the efficiency of conversational bots. Funding research about advanced techniques and the application of rigorous process need high levels both of staff and finance. The integrity and the security problems of chatbots that provide wrong advice are highlighted, demonstrating the need for correcting the technical problems in order to ensure ethical and secure operations. Funding should be set aside to close resource distribution disparities [39,40,47,57-59], so that students from disadvantaged backgrounds can also have an opportunity to have access to technologically advanced educational resources. Collaboration among those in the academic, technical, and health care disciplines is indispensable as an effort to develop supportive surroundings for the application of chatbots to nursing education globally.

This study demonstrates the substantial changes that chatbots bring into nursing education to make nursing practice more enjoyable. This integration aims at resolving several issues, including the lack of competitiveness from a global perspective and economic disparity, in essence to establish an integrated and dynamic learning environment. Analyzing the small components of chatbots and conducting research on the feasibility, pros, and cons are necessary aims for the future of education [44]. The lack of original research forces us to rely more on the already existing qualitative studies such as commentaries and editorials. Above all, great attention should be given to privacy and ethics when integrating current technologies into the health care education system.

There are some limitations. First, the study only provides a description of the changes over time in articles related to chatbots in nursing education, as well as the distribution of regions and types of articles. Due to the lack of original studies, it does not show the characteristics of papers included in the final analysis. Second, there is uncertainty about whether the specific research topics related to chatbots in nursing education are consistent between countries. Third, there is a lack of in-depth quantitative exploration and discussion regarding the specific application directions of chatbots in nursing education, preventing the formulation of more constructive recommendations.

Conclusion

Integrating chatbots into nursing education presents a promising yet relatively unexplored avenue. This review highlights the urgent need for original research, emphasizing the importance

of ethical considerations. This exploration contributes to the evolving landscape of technology in health care education, bridging gaps and fostering a learner-centric approach aligned with contemporary health care demands.

Authors' Contributions

SZ contributed to conceptualization, methodology, data curation, formal analysis, writing—original draft preparation, and writing—review and editing. XL contributed to methodology, data curation, and writing—original draft preparation. WW contributed to methodology, data curation, and writing—original draft preparation. FZ contributed to conceptualization, methodology, project administration, and supervision.

Abstract

Background: Digital competence is listed as one of the key competences for lifelong learning and is increasing in importance not only in private life but also in professional life. There is consensus within the health care sector that digital competence (or digital literacy) is needed in various professional fields. However, it is still unclear what exactly the digital competence of health professionals should include and how it can be measured.

Objective: This scoping review aims to provide an overview of the common definitions of digital literacy in scientific literature in the field of health care and the existing measurement instruments.

Methods: Peer-reviewed scientific papers from the last 10 years (2013-2023) in English or German that deal with the digital competence of health care workers in both outpatient and inpatient care were included. The databases ScienceDirect, Scopus, PubMed, EBSCOhost, MEDLINE, OpenAIRE, ERIC, OAster, Cochrane Library, CAMbase, APA PsycNet, and Psynindex were searched for literature. The review follows the JBI methodology for scoping reviews, and the description of the results is based on the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist.

Results: The initial search identified 1682 papers, of which 46 (2.73%) were included in the synthesis. The review results show that there is a strong focus on technical skills and knowledge with regard to both the definitions of *digital competence* and the measurement tools. A wide range of competences were identified within the analyzed works and integrated into a validated competence model in the areas of technical, methodological, social, and personal competences. The measurement instruments mainly used self-assessment of skills and knowledge as an indicator of competence and differed greatly in their statistical quality.

Conclusions: The identified multitude of subcompetences illustrates the complexity of digital competence in health care, and existing measuring instruments are not yet able to reflect this complexity.

KEYWORDS

digital competence; digital literacy; digital health; health care; health care professional; health care professionals; scoping review

Introduction

Background

The 2006 European Parliament recommendation on key competences for lifelong learning lists digital competences as 1 of the 8 key competences for every citizen to enable personal fulfillment, active citizenship, social cohesion, and employability in our modern society [1]. Therefore, it is no surprise that the digital transformation within the health care sector, involving new processes and technologies [2], has completely changed the demands on people working in health care professions. Digital competence in health care is needed [3,4]. According to Vitello et al [5], competence is “the ability to integrate and apply contextually-appropriate knowledge, skills and psychosocial factors (e.g., beliefs, attitudes, values and motivations) to consistently perform successfully within a specified domain.” Salman et al [6] divide competence into 2 aspects: hard and soft. The hard aspects of competence include knowledge, skill, and behavior, whereas the soft aspects include character traits, motives, attitudes, values, and self-image. Together, all these aspects determine the performance or output—both visible and invisible—of an individual in a particular job. *Competence*, in contrast to *competency*, is attached to the person rather than to a task or activity [5], which fits better within this work because we are focusing not on specific digital activities but on how professionals deal with digital technologies when working in the health care domain. This is why we concentrate on competence in this work.

The updated version of the digital competence framework for citizens (DigComp 2.2) [7] divides digital competences for private individuals into 5 main dimensions: information and data literacy, communication and collaboration, digital content and creation, safety, and problem-solving. Specific knowledge, skills, and attitudes are assigned to each of these dimensions. Along with the requirements for digital competence in private life, there are certain requirements to be met before one can be considered digitally competent in professional life in the health care sector.

Unfortunately, to date, there is no standard definition for the construct *digital competence* within the health care domain. Although the topic of interest is *digital competence*, the term *digital literacy* was also considered because this term is more common in English-speaking countries, and both concepts are often used synonymously [8]. Currently, for both terms, different understandings exist [9]. In this review, the semantic meaning of the terms is important, that is, *the skills and characteristics required to navigate the (professional) digital world*.

The lack of a uniform definition also leads to problems in determining digital competence for health professionals: authors criticize the lack of validated and up-to-date instruments to measure digital literacy or digital competence in this field [10,11]. With existing measurement tools, the focus is solely on technical skills; the related aspects that also affect the use of digital technologies are neglected [10].

Therefore, the objective of this research was to create an overview of how digital competence is defined and measured

among health care professionals and thus to provide a holistic picture.

Research Questions

Primarily, the following questions will be answered with the help of the literature review:

- What definitions exist of the digital competence of health care professionals?
 - What are the similarities and differences among the various definitions?
 - On which basic models are the different definitions based?
- What possibilities exist for measuring the digital competence of health care professionals?
 - Which dimensions of digital competence are measured?
 - How are the dimensions measured (self-assessment, performance tasks, etc)?
 - Have the assessment tools been validated? What quality criteria have been applied?

Methods

Overview

To provide a systematic overview of existing research literature on digital literacy in health professions, we conducted a scoping review [12]. The review follows the JBI methodology for scoping reviews [13] (based on the works of Arksey and O'Malley [14] and Levac et al [15]), which follows these steps: (1) defining and aligning the objectives and questions; (2) developing and aligning the inclusion criteria with the objectives and questions; (3) describing the planned approach to evidence searching, selection, data extraction, and presentation of the evidence; (4) searching for the evidence; (5) selecting the evidence; (6) analysis of the evidence; (7) presentation of the results; and (8) summarizing the evidence in relation to the purpose of the review, making conclusions, and noting any implications of the findings.

The review was planned beforehand by AM and SM, including choosing the review method, formulating the research questions, selecting the databases, phrasing the search terms, and determining the eligibility criteria. AM screened the search results, during which process there was regular professional exchange with another author, VW. The results were reviewed by SM, VW, and JN. AM, SM, VW, and JN all have experience in conducting scoping reviews.

To ensure the high quality and informative value of the results report, the description of the results is based on the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist [12,16] (Multimedia Appendix 1). In addition, an evaluation protocol was prepared in advance of the review and made publicly available on OSF [17].

Search Strategy

The literature search took place in April 2023 and used the databases ScienceDirect, Scopus, PubMed, EBSCOhost (which provides results from MEDLINE, OpenAIRE, ERIC, and

OAIster), Cochrane Library, CAMbase, APA PsycNet, and Psynex. The search term used was as follows: (“digital competence” OR “digital literacy”) AND (“medical professional” OR “healthcare professional” OR “healthcare worker” OR “physician assistant” OR “health professional”).

Fixed combinations of terms (such as digital literacy) are placed in quotation marks. Parentheses are used to force the right evaluation order of the expression. No adjacent terms were added so as not to make assumptions about the nature of the terms of interest. These were combined with various health

worker designations. Neutral terms were chosen for the designation of nonmedical personnel to achieve a neutral and comprehensive understanding for different health professions. The keywords were linked with the Boolean operator “OR” to show results with at least one of the given terms. The operator “AND” ensures that all search results contain both “digital competence” or “digital literacy” and a health worker designation. The search term was developed through several trial cycles of a combination of terms. These were entered into the different databases and, based on the search results, terms were added or removed. The results are shown in [Table 1](#).

Table 1. Results of the database search. The search term (“digital competence” OR “digital literacy”) AND (“medical professional” OR “healthcare professional” OR “healthcare worker” OR “physician assistant” OR “health professional”) was used for each database (N=1682).

Database	Results, n (%)
ScienceDirect	594 (35.31)
Scopus	361 (21.46)
PubMed	15 (0.89)
EBSCOhost (MEDLINE, OpenAIRE, ERIC, and OAIster)	706 (41.97)
Cochrane Library	6 (0.36)
CAMbase	0 (0)
APA PsycNet	0 (0)
Psynex	0 (0)

Eligibility Criteria

This scoping review considered peer-reviewed publications that were research articles, book chapters, review articles, or conference papers published within the last 10 years (2013-2023). Papers in either English or German were included.

The articles address the digital competence of health care workers in both outpatient and inpatient care. They come from

medical, technical, or educational research fields. Papers from the patient’s perspective or those that address eHealth literacy or digital health literacy, defined as the “skills, knowledge and resources to search for, find, understand, evaluate and apply health information [from the internet]” [18], were excluded because the concept of interest is more concerned with the understanding of information rather than with the professional use of digital technologies. The overall eligibility criteria for this scoping review are presented in [Textbox 1](#).

Textbox 1. Inclusion and exclusion criteria for the scoping review.

<p>Inclusion criteria</p> <ul style="list-style-type: none"> • Peer-reviewed publications • Research articles, book chapters, review articles, or conference papers • Research field: medical, technical, or educational • Subject: articles addressing digital competence or digital literacy • Population: health care workers in both outpatient and inpatient care and students and graduates of health care professions • Period: articles published from 2013 to 2023 • Language: English or German <p>Exclusion criteria</p> <ul style="list-style-type: none"> • Not peer-reviewed publications • Research field: any research field other than medical, technical, or educational • Subject: articles addressing eHealth literacy or digital health literacy • Population: patients • Period: articles published before 2013 • Language: other than English or German

Article Screening and Data Extraction

According to the recommendations of Moher et al [19], these steps are followed in the study selection process: first, duplicates are removed from the initial search results, after which the remaining publications are evaluated based on their titles, keywords, and abstracts and, subsequently, checked for suitability based on the full texts. The eligible papers are included in the review [19]. We followed the recommended process and, from the eligible papers, extracted and listed the following data in a Microsoft Excel sheet that was developed a priori but refined iteratively: authors, year of publication, country of origin, type of survey, and target group.

Synthesis of Results

We present the characteristics of the selected studies, with a comparison of the drafted definitions of digital competence. In addition, we report the fundamental frameworks, models, and research papers that originally specified these definitions. We have collected and clustered all competences mentioned in the eligible papers. The structuring of the competences identified in the works was based on the competence categories according to the competence model developed by Hecklau et al [20], who

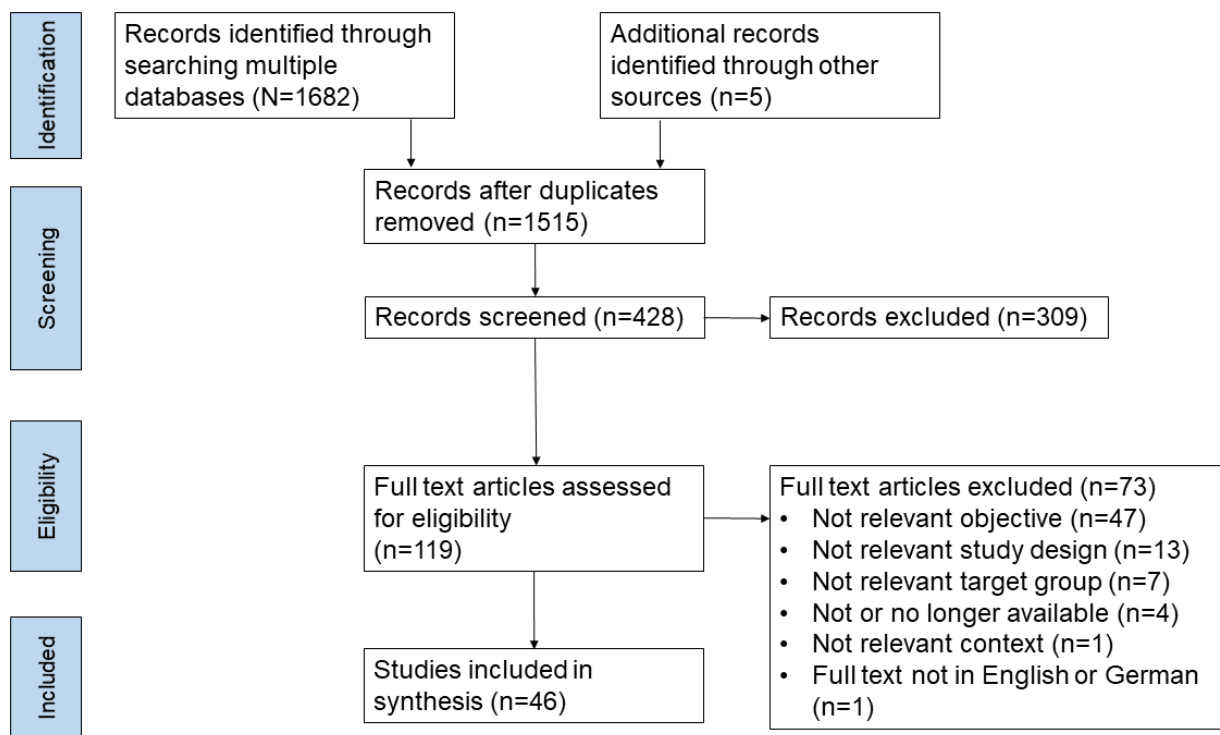

cluster competences into technical, methodological, social, and personal competences to achieve clarity and transparency of the competence model. This clustering was adopted within our work to organize the determined competences. Finally, we explicitly examine the papers in which digital literacy assessment tools are used, with a consideration of the origin of the questionnaires, the form of measurement, and an assessment of their statistical quality.

Results

Selection of Sources of Evidence

The initial search identified 1682 papers (Table 1), of which 1510 (89.77%) remained after duplicates were removed. After applying the inclusion criteria (time period, type, and language) and screening the titles, of the 1510 papers, 428 (28.34%) were available for preselection, which, after the screening of the abstracts, reduced to 119 (27.8%) titles. Finally, after consideration of the full texts, of the 1682 papers identified through the initial search, 46 (2.73%) were included in this scoping review (Figure 1).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart showing the number of articles identified, screened, assessed for eligibility, and included in the final analysis.

Characteristics of Sources of Evidence

The selected papers were largely published from 2020 onward (35/46, 76%), indicating an increase in the perceived relevance of digital literacy among health professionals in the scientific world. In the years prior (2013-2019), only 11 (24%) of the 46 papers were published, with a slightly perceptible increase from

1 (9%) paper in 2014 to 4 (36%) in 2019. Of the 46 papers, the maximum number was published in 2020 (n=15, 33%); in subsequent years, the number of papers decreased to 8 (17%) in 2021 and 6 (13%) in 2022, and in 2023, a total of 6 (13%) papers had been published until May of that year. Table 2 shows the key data of the included papers.

Table 2. Key data of the included papers.

Authors	Year	Country	Type of study	Target group

^aSWOT: strengths, weaknesses, opportunities, and threats.

The majority of the articles were published in Australia (7/46, 15%), Finland (7/46, 15%), and the United Kingdom (6/46, 13%). The remaining papers were distributed worldwide: Ethiopia (3/46, 7%); Denmark, Germany, Singapore, Spain, and the United States (2/46, 4% each); and Chile, Indonesia, Italy, Lebanon, Libya, Malta, Myanmar, New Zealand, Poland, South Korea, Switzerland, 13 countries in Europe (Austria, Belgium, Croatia, Denmark, Finland, France, Italy, Malta, Netherlands, Norway, Poland, Portugal, and the United Kingdom), and the rest of the world (1/46, 2% each).

The types of papers were mainly distributed between quantitative studies (23/46, 50%) and reviews (scoping reviews, systematic reviews, and meta-analyses; 11/46, 24%). Less represented were qualitative interviews (5/46, 11%) and framework development (3/46, 7%), as well as questionnaire development; mixed methods study; strengths, weaknesses, opportunities, and threats analysis; and historical development report (1/46, 2% each).

The papers' target group was largely unspecific, with most of them addressing *health care professionals* (25/46, 54%). Other papers addressed specifically *nurses* (4/46, 9%), *pharmacists* (3/46, 7%), *health graduates* (2/46, 4%), *health science lecturers* (1/46, 2%), *physicians* (1/46, 2%), and *radiotherapists* (1/46, 2%). Some of the papers were aimed at students: students of health professions in general (3/46, 7%), medical students and nursing students (2/46, 4% each), and optometry students and physiotherapy students (1/46, 2% each).

Definition of Data Literacy

The main difficulty concerning the literature analysis was that some of the papers used the term *digital literacy* but actually referred to a different concept (especially *eHealth literacy*). When selecting the papers for review, articles that dealt, in terms of semantics, with concepts other than *data literacy* were sorted out.

Most of the papers provided definitions in which digital competence is composed of various dimensions of competence. There was a strong focus on skills in the formulated definitions of digital competence [9,21,22,25-33,35,36,39,40,42,43,45,47,48,50-55,59,60,62]. Many papers (27/46, 59%) also stated in their definitions that certain kinds of knowledge are necessary for competence [4,10,22,23,25-28,30-33,36,39,40,42,47,

49-55,59,60,62]. Some of the papers (17/46, 37%) proposed that the attitude toward technical issues should be considered a component of competence [4,10,11,21,24,27,28,30-33,36,42,47,49,54,59]. Other papers (6/46, 13%) added that former experiences with digital topics play a crucial role in forming competence [28,31,40,42,43,46]. According to Konttila et al [42], experiences are the base for the emergence of attitudes. Other works mentioned motivation (7/46, 15%) [31,35,36,40,42,57,59], practices (2/46, 4%) [9,31], consciousness (2/46, 4%) [9,54], fears (2/46, 4%) [11,43], goals (1/46, 2%) [25], identity (1/46, 2%) [9], self-awareness (1/46, 2%) [28], and strategies (1/46, 2%) [54] as part of competence. These competence dimensions provide a framework for the required competence areas, which are described in the *Identified Competence Areas and Competences* subsection.

The definitions used are either the results of scoping reviews or frameworks where many individual results have been merged (15/46, 33%) [4,10,23,26,28,33,37,42,44,46,48,51,52,59,61]. Alternatively, they are based on other, explicitly named works, such as DigComp 2.2 [7] (4/46, 9%) [22,29,54,56]; the European framework for the digital competence of educators [63] (1/46, 2%) [27]; the technology acceptance model [64] and the unified theory of acceptance and use of technology [65] (1/46, 2%) [11]; the accreditation of competence in information and communication technologies by the government of Catalonia [66] (1/46, 2%) [53]; the Educause Center for Analysis and Research [67] (1/46, 2%) [60]; the General Confidence with Computer Use Scale [68] (1/46, 2%) [32]; the eHealth literacy questionnaire [69] (1/46, 2%) [40]; the eHealth literacy assessment toolkit [70] (1/46, 2%) [34]; the Self-Assessment of Nursing Informatics Competencies Scale [71] (1/46, 2%) [24]; a scale assessing the informatics competencies for nurses [72] (1/46, 2%) [39]; a scale assessing digital literacy with regard to information and communication technology [73] (1/46, 2%) [41]; the definition by Konttila et al [42] (1/46, 2%) [31]; the definition by Ferrari [74] (1/46, 2%) [21]; the definition by Bawden [75] (1/46, 2%) [25]; the definition by Sharpe and Beetham [76] (1/46, 2%) [9]; the definition by Hecklau et al [20] (1/46, 2%) [38]; the definition by Gretton and Honeyman [77] (2/46, 4%) [43,44]; the Health Education England definition [78] (1/46, 2%) [45]; the Jisc 7 elements of digital literacies (1/46, 2%) [47]; the World Health Organization's *Electronic Health Records: A Manual For Developing Countries* [79]

(1/46, 2%) [49]; and the definition by Skiba et al [80] (1/46, 2%) [57]. No information was provided in 4 (9%) of the 46 studies [30,50,58,62] about the basis of the definition used. Montebello et al [47] refers to the Jisc 7 elements of digital literacies as basis for their digital literacy definition but the original source is not available anymore.

Identified Competence Areas and Competences

Overview

Within the included papers, competences in the 4 main competence areas according to the model developed by Hecklau et al [20] were identified: multiple competences could be grouped into technical, methodological, social, and personal competences. All these competences, classified into 4 competence areas, are described in the following paragraphs and depicted in [Textbox 2](#).

Textbox 2. The identified competences grouped into different competence areas.

Competence areas and competences

- Technical competences
- Basic computer competence [4,9,11,21-25,27-29,32,33,35-39,41,43-45,47-49,51-54,56,57,62]
- Basic competence to use wireless devices [21,23-25,37,49]
- Applied digital health skills [4,10,22,24,26,29,30,33,35,37,39,40,42,43,46,48,50-53,55,57,58,61,62]
- Anticipation of advanced and future digital competences [30,37,38,41,48,50,57]
- Administration of technology [4,23,45]
- Ethical aspects of digitalization [4,36,37,48,50,57,58]
- Legal aspects of digitalization [4,37,48,50,52]
- Methodological competences
- Data and information processing competence [4,9,21,22,24-26,29-31,35,37,38,40,41,44,45,47,48,50-57,62]
- Continuous learning [4,9,23,25,28-30,32,38,41,45-47,49,54,55,57,62]
- Project management [4,57,61]
- Research competence [4,37,45,47,57]
- Problem-solving [22,35,38,41,54,56,62]
- Social competences
- Working in teams [9,23,29,35,38,41,42,45,47,50,51,53-55,62]
- Communication competence [4,9,22,29-31,35,36,38,42,43,45,47,49-51,54-57,59,62]
- Networking skills [38,47,50]
- Teaching [27,45]
- Focus on patients [4,10,35-37,48,50,55,57]
- Personal competences
- Innovative behavior [23,38,45,50]
- Self-reflection [35,53,54]
- Critical thinking [22,25,54]
- Creativity [38,54]
- Professionalism [23]

Technical Competences

Multiple subcompetences of technical competences were identified: the ones mentioned most often were *basic computer competence*, meaning knowledge of different computer components and basic computer concepts [21,32,43]; and skills in using hardware (eg, switching equipment on and off and operating input and output devices) [49,62]. Internet use, consisting of navigating the internet, knowledge of various internet sources, and finding and downloading articles, is part

of basic computer competence [24,25,28,37,43,52,62]. The users should be able to use and install software [24,28,32,33,37,49,52,62] and especially be able to use information and communication technology, including understanding the basic concepts and components of information and communication technology and designing, creating, integrating, publishing, and revising content [4,9,22,23,27,35-38,41,43-45,47-49,53,54,56,57,62]. Another part of basic computer competence is file management and

comprehensive knowledge of file formats, the creation of documents and folder structure [37,49], and IT security (eg, using passwords and antivirus tools) [22,29,37,38,45,52,54,56,62].

Another subcompetence mentioned was *basic competence to use wireless devices*, consisting of operating hardware [49], using the internet [21,37], managing files [21,37], and using applications [21,37].

Existing competences can be transferred to eHealth contexts to achieve the foundation for *applied digital health skills* [46]. Here, one of the largest areas is the use of health applications, meaning the use of various digital health solutions for treatment planning, diagnostics, treatment, processing imaging data, and so on [22,24,33,35,40,42,48,57,58]. This includes the management of electronic patient records [22,24,37,43,49,51,57,58,62], the use of wearables and mobile health apps [30,57], the administration of electronic documentation [4,37], and the use of health information systems [37,52,55,57]. In addition, health professionals need skills and knowledge about specific data protection and security requirements of their profession [4,30,48,53]. Furthermore, digitally competent health care workers need to be able to establish new technologies in their work environments and participate in the design, implementation, and evaluation of systems, as well as seek available resources, formulate ethical decisions technical wise, and promote the use of IT in health environments [4,24,42,48,50,57].

A further subcompetence is the *anticipation of advanced and future digital competences*, where users stay informed about the current state of the art of digital technologies and the competences that are necessary to use these [38,41], as well as how certain technologies will develop in the future, which play a role in the future of health care (eg, big data, artificial intelligence, robotics, and genomics) [30,37,48,50].

One crucial aspect of technical competence is the *administration of technology*, which encompasses planning, implementation, optimization, and operation or management, as well as the control of technological products or tools, processes, and services [4,23,45].

Knowledge about *ethical aspects* [4,36,37,48,50,57,58], such as freedom of choice, privacy, autonomy, and fairness [36], as well as the *legal aspects of digitalization* [4,37,48,50,52,62], in particular regarding the regulation of medical practice and medical devices [50] and the protection of patient data as well as confidentiality when processing data [52], is equally important when handling new technologies to enable data protection and data security.

Methodological Competences

The competence to *process data and information* consists of finding [4,23,24,26,37,44,47,52,53,62], evaluating [21,23,25,37,43,47,50-53,57,62], creating [23,24,44,49,51], managing [4,23,24,26,29,30,47-49,52,53,57], sharing or communicating [4,23,26,31,44,47,53,57], analyzing [4,26,37,50,53], visualizing [4], and interpreting [24,26,47,49] information or data; deriving actions or decisions [50]; being

well versed in data protection and security [50,51]; and knowing the difference among data, information, and knowledge [48].

In addition, the ability to *continuously learn* is a fundamental component of digital competence. Learning is described as using educational methods such as teaching, training, storytelling, discussion, and targeted research to acquire knowledge, skills, values, beliefs, and habits [23]. It includes the anticipation of service and training needs and, for future digital literacy skills [57], learning how to use new technologies [29,49,62] and acquiring new concepts, methods, and tools [23], especially by using digital teaching and learning resources [4,29,41,47].

Digitally competent health professionals should also be proficient in *project management* to be able to introduce new operating models and lead IT-based change in their field [4,57,61].

They should be able to use IT for research support and innovations [4] as well as for assessment and continuous improvement of their own skills, their work community skills development, and the development of electronic services [57] through *research competence*.

Problem-solving competence can be interpreted as both dealing with digital problems [22,35,38,54,56] and solving problems through digital means [41,54,56,62].

Social Competences

To engage digitally in the social work environment, digitally competent health professionals must be able to *work in teams*, meaning they should be able to work cooperatively or collaboratively [9,23,38,41,45,47,50,53,62]; take a leadership role [38]; deal with diverse teams consisting of members with different demographics, from different professions, and with different personality traits [38,51]; be willing to compromise for the sake of group harmony [38]; and establish collegial support to create positive digital experiences [35,42].

Another basic requirement to work in (digital) teams is *communication competence* using a wide range of communication methods [50], including digital communication [4,9,30,38,57,62] (eg, web-based meetings and consultations and the use of social media [57] within the team [36,57] and with patients [35,36]). Digitally competent health professionals need to know the correct vocabulary [57] and, with this knowledge, the ability to share knowledge [38].

Networking skills are evident in the use of knowledge networks, where health professionals participate in digital networks for learning and research and develop an open-access mentality [38,47,50].

Health professionals should not only be able to gain knowledge but also to pass it on: *teaching* is an important part of digital literacy. Health professionals could impart their knowledge using digital resources and provide these resources to learners, assess their learning success, and increase not only their own but also the learners' digital literacy [27,45].

Another important part of digital literacy is keeping the *focus on patients* by considering the patients' digital needs and evaluating their digital skills, as well as considering their

willingness to use digital services to provide services that they feel safe to use and capable of using [35,57]. In addition, health professionals should promote the use of IT among patients through support and empowerment for self-management, IT guidance (eg, guides and web-based materials), and support in finding information [4,57].

Personal Competences

To be digitally competent, health professionals need *innovative behavior* as a personality trait, meaning they should have the spirit of invention and lifelong determination [23,38,45,50]. The initiative to conceive, consider, try out, or apply new ideas, products, processes, and procedures to their individual work role or their work unit without fear of change [23] is essential to drive the transformation process of health care forward [50].

Another relevant ability for health professionals is *self-reflection* with regard to their own digital competence [35,53,54] and the identification of personal and professional needs to apply technical solutions [53].

Other personal traits mentioned as relevant for digital competence are *critical thinking* [22,25,54] and *creativity* [38,54]. Critical thinking is mentioned in connection with information evaluation [25] or gaining new information within a professional context [22,54]. Creativity is of use when knowledge is built up [54] or a task has to be approached with an innovative mindset [38].

Professionalism is defined as the behavior, demeanor, and attitude of a person in a work environment and is considered a

useful quality rather than a requirement of a role [23], but it is a characteristic that is beneficial to health professionals wishing to be digitally competent.

Measurement Instruments

Of the 46 included papers, 25 (54%) used different questionnaires to evaluate the digital literacy of health professionals. The majority of the questionnaires used (15/25, 60%) [21,22,25,28,30-32,36,49,50,52,53,58,61,62] were developed originally for these papers. Others used existing questionnaires or frameworks (Textbox 3) such as the Self-Assessment of Nursing Informatics Competencies Scale [71] in the study by Brown et al [24]; a scale assessing the informatics competencies for nurses [72] in the study by Kaihlanen et al [39]; the eHealth literacy assessment toolkit [70] in the study by Holt et al [34]; the eHealth literacy questionnaire [69] in the study by Kayser et al [40]; the General Confidence with Computer Use Scale [68] in the study by Hallit et al [32]; the attitudes and digital literacy toward information and communication technology scale [73] in the study by Kim and Yeon [41]; the Educause Center for Analysis and Research [67] in the study by Vissers et al [60]; the technology acceptance model [64] and the unified theory of acceptance and use of technology [65] in the study by Kuek and Hakkennes [11]; DigComp 2.2 [7] in the studies by Barbosa et al [22], Shiferaw et al [54], and Tegegne et al [56]; the European framework for the digital competence of educators [63] in the study by Cabero-Almenara et al [27]; and the accreditation of competence in information and communication technologies by the government of Catalonia [66] in the study by Reixach et al [53].

Textbox 3. Underlying work for the questionnaires used in the studies.

Underlying work and corresponding studies

- Accreditation of competence in information and communication technologies by the government of Catalonia [66]
- Reixach et al [53]

Digital literacy was measured in various forms, and some questionnaires used different combinations of measurement forms (Textbox 4). The specific items of the questionnaires considered in the review are categorized thematically herein. In many surveys, participants provided a self-assessment of specific skills and knowledge. Often, they had to assign certain abilities or confidence levels to themselves [11,22,24,25,27,28,30-32,34,36,39-41,49,52-54,56,58,61,62]. Other questionnaires collected participants' attitudes toward technical topics [11,21,24,30,31,36,40,41,50,62]. Some items dealt with the experiences or needs of participants with regard to (further) training in digital topics [21,25,30,49,50,53,56,62]. Another way of measuring digital literacy involved requesting

access to different technologies, such as smartphones, laptop computers, or tablet devices, for private or professional use [28,32,49,60,62] or the frequency of use of these technologies [11,25,28,40,60]. Other items addressed user behavior: what the devices were used for [24,49,60], and which applications were used [21,24].

The questionnaires differed greatly in their statistical quality. Some have not been validated in any statistical form [21,25,28,39,50,58,60-62], whereas others were only tested on internal consistency [41,49,53], and several were verified with different reliability and validity tests [11,22,24,27,30-32,34,36,40,52,54,56].

Textbox 4. Different measurement forms of digital literacy with item examples.

Measurement form and item examples

- Self-assessment [11,22,24,25,27,28,30-32,34,36,39-41,49,52-54,56,58,61,62]
- “I can use the most common computer programs and services (e.g. email, intranet) in my work.” [36]
- “How well do you feel you master the following skills required to use information systems?” [58]
- Attitudes [11,21,24,30,31,36,40,41,50,62]
- “I believe that new digital technologies will fundamentally change medicine in the next few years.” [30]
- “The transfer to digital services is a positive change.” [36]
- Experiences, needs of education, or training [21,25,30,49,50,53,56,62]
- “I would benefit from additional trainings/courses in the field of shaping digital competences.” [25]
- “On a personal level, would you like to have specific training in any of the following areas? eg. Digital culture, participation and citizenship using digital tools.” [53]
- Access to technology [28,32,49,60,62]
- “Do you think you have internet access in your office?” [62]
- “Owning a computer.” [32]
- Frequency of use [11,25,28,40,60]
- “Please state how often you use the following in your work and in your personal life: computers, Microsoft Office applications, smartphones, tablets, email, the internet, and social media (i.e. Facebook, Twitter and Instagram).” [11]
- “How often do you use the internet?” [60]
- User behavior [21,24,49,60]
- “I use MS Excel for work.” [21]
- “What is the purpose of [sic] you use a computer?: work, education, communication, entertainment, and playing games” [49]

Discussion

Principal Findings

The selected literature sources show the increasing scientific interest in digital literacy in health care and the worldwide spread of this development. There is a focus on quantitative research, although, because the available survey instruments were considered insufficient to determine digital literacy, researchers often developed their own. The underlying definitions are based on a variety of approaches and sources, which highlights the need for a structured overview. Most of the definitions focused on skills and knowledge as indicators of competence. *Soft aspects*, as described by Salman et al [6], were also mentioned by authors but less frequently and in many different forms. Attitude, experience, and motivation were mentioned most often. Behavior, which is a *hard aspect* according to Salman et al [6], was not addressed explicitly in the definitions provided in the included papers.

The identified competences have been categorized according to the competence categories formulated by Hecklau et al [20]. The determined technical competences include basic computer competence, basic competence to use wireless devices, applied digital health skills, anticipation of advanced and future digital competences, administration of technology, ethical aspects of digitalization, and legal aspects of digitalization. Data and information processing competence, continuous learning, project management, research competence, and problem-solving were mentioned in the literature as methodological competences. The

following were classified as social competences: working in teams, communication competence, networking skills, teaching, and focus on patients. Personal competences include innovative behavior, self-reflection, critical thinking, creativity, and professionalism.

The results confirm that existing measurement tools focus solely on technical areas [10], and other related aspects, such as the identified competences from the methodological, social, and personal areas in other nonquantitative works, have not been taken into account. Unlike what Longhini et al [10] and Kuek and Hakkennes [11] stated, many of the questionnaires used had high statistical quality and were verified with different reliability and validity tests. The questionnaires largely measure digital literacy via self-assessment. Some also use items relating to attitudes, experiences, access to technology, frequency of use, and use behavior.

The allocation of competences to the categories was sometimes not trivial and not clearly distinguishable; for example, *teaching* could be categorized as both a social and a methodological competence. How the partial competence areas are connected also remains unanswered in these works. Hurst [81] describes 3 possible dependency relationships: a general factor model where basic competence is composed of equally important subspects, an additive model where the individual subspects have a juxtaposed relationship, or a hierarchical model where basic subcompetences and higher-level competences exist that build on each other [81]. A more complex consideration of the relationships among the individual competences, for example,

through a factor analysis, would also be conceivable and should be investigated in subsequent research work. Some of the skills identified are specifically linked to digital topics, but others are more general and *analog* in nature, especially in the social and personal categories. Therefore, mutual influences among the competences are not only conceivable but also probable.

Limitations

One limitation of this literature review is that, because of the very nature of scoping reviews, the quality of the included works was not considered in the review process, and all papers were included in the synthesis, irrespective of quality [14]. This may have led to inferior works being included in the results and being placed on an equal footing with high-quality works. When constructing the search term, no wildcards were used, which limited the search of potential fitting literature, which must be specified as a further limitation. In addition, more variants of the job title *medical professional* could have been used to maximize the search results. Another limitation could be the practical implementation of the selection of papers and their evaluation by just 1 author. Although the procedure was planned as a team, and the results were discussed extensively, the process was carried out by only 1 person.

Future Directions

This literature review focuses solely on the terms *digital competence* and *digital literacy* and provides an overview of the use of these closely related terms. A larger literature review that includes other adjacent topics, such as *informatics competences*, or refers to specific digital activities in the health

care sector, such as *telemedicine competences*, would heighten the credibility in terms of an overall semantic understanding of the concept of competence when dealing with all sorts of digital technologies. Within this work, which aimed at an understanding of the specifically named term *digital competence*, the addition of related concepts would not be possible without the development of an initial understanding of this concept, which the authors have developed in the course of this work.

A further enrichment of an in-depth analysis would be the addition of specific medical specialties. The aim of this work was the nonspecific and generalizable consideration of required digital skills in health care, but, of course, every profession has its individual (digital) requirements that are worth considering.

Conclusions

The review shows that the interest in digital literacy as a research topic in health care is currently on the rise but that the understanding of this rather abstract term is widely divergent. A uniform definition and use of terms is needed. The existence of hard and soft aspects of competence, as described by Salman et al [6], was confirmed by many of the used definitions, but which of the identified aspects contribute to what extent needs to be investigated further. Furthermore, the multitude of subcompetences illustrates the complexity of digital competence that needs to be taken into account when developing a measurement instrument. Well-validated questionnaires exist, these focus solely on technical aspects. The competency model identified in this work can be used as a starting point for factor analysis of the identified competences or questionnaire development.

Abstract

Background: During health crises such as the COVID-19 pandemic, shortages of health care workers often occur. Recruiting students as volunteers could be an option, but it is uncertain whether the idea is well-accepted.

Objective: This study aims to estimate the global rate of willingness to volunteer among medical and health students in response to the COVID-19 pandemic.

Methods: A systematic search was conducted on PubMed, Embase, Scopus, and Google Scholar for studies reporting the number of health students willing to volunteer during COVID-19 from 2019 to November 17, 2023. The meta-analysis was performed using a restricted maximum-likelihood model with logit transformation.

Results: A total of 21 studies involving 26,056 health students were included in the meta-analysis. The pooled estimate of the willingness-to-volunteer rate among health students across multiple countries was 66.13%, with an I² of 98.99% and *P* value of heterogeneity (*P*-Het) $<$.001. Removing a study with the highest influence led to the rate being 64.34%. Our stratified analyses indicated that those with older age, being first-year students, and being female were more willing to volunteer (*P* $<$.001). From highest to lowest, the rates were 77.38%, 77.03%, 65.48%, 64.11%, 62.71%, and 55.23% in Africa, Western Europe, East and Southeast Asia, Middle East, and Eastern Europe, respectively. Because of the high heterogeneity, the evidence from this study has moderate strength.

Conclusions: The majority of students are willing to volunteer during COVID-19, suggesting that volunteer recruitment is well-accepted.

KEYWORDS

COVID-19; education; health crisis; human resource management; volunteer

Introduction

The initial outbreak of COVID-19, an emerging and highly infectious respiratory illness, which originated in Wuhan City, Hubei Province, China, occurred in early December 2019 [1]. Subsequently, the situation escalated swiftly, leading to its declaration as a Public Health Emergency of International Concern by the World Health Organization (WHO) [1]. Some of its clinical presentations are fever, cough, dryness, fatigue, dyspnea, and myalgia [2]. The disease also induces prolonged anxiety, chest pain, persistent depression, dizziness, and other lingering symptoms after recovery [3]. In 2020, the WHO reported the rapid spread of the disease to various parts of the world, marking it as a global pandemic, with the number of confirmed cases and deaths escalating worldwide [4]. The pandemic not only affects health but also disrupts various aspects of life, including emotional stability, environmental quality, and the economy [5-7].

The high incidence of COVID-19 has led to an increased demand for health care services and workers [8]. Unlike many other sectors, jobs in health care were not temporarily halted during the COVID-19 pandemic, as health care professionals are essential in combating and preventing viral transmission [9]. However, infections among medical personnel have resulted in an acute shortage of workforce in this sector. Coupled with the increased workload of health care workers, this has led to inadequate patient management [8,10]. A previous study found that nearly half of health care workers exposed to COVID-19 experienced burnout and compassion fatigue, stemming from factors such as excessive workload, emotional exhaustion, personal infection risk, and fear of transmitting the virus to their families [5,11]. Consequently, hospitals faced the challenge of addressing staffing deficits [12].

During health emergencies, it is crucial to bolster the human resource capacity within the health care system. Among the various approaches available, recruiting volunteers is an option worthy of consideration [13]. Volunteering entails participating in activities where individuals dedicate their time to providing services to vulnerable populations without coercion [14,15]. Medical and health students can actively participate in volunteering activities to help manage the COVID-19 crisis. In certain countries and health care institutions, it is suggested that medical and health students voluntarily contribute to crisis management based on their competencies [13,16,17]. Collaborating with volunteers to provide community services could help bridge gaps in human resource capacity and decrease instances of burnout among health care workers during the COVID-19 crisis [18].

Volunteering among health care students has emerged as a valuable resource during outbreaks. A previous study has evaluated the willingness of medical students to volunteer during pandemics and disasters [19]. Furthermore, a previously published systematic review on the willingness of health students to volunteer for COVID-19 reported willingness-to-volunteer rates ranging from 19.5% to 91.5% [20]. Unfortunately, a meta-analysis was not conducted in that systematic review [20]. Data on the global rate of willingness

to volunteer are necessary as a basis for evaluating the feasibility of recommending volunteering for health students. Moreover, it is crucial to observe feasibility across different populations, economies, and regions. Therefore, our aim is to conduct a new systematic review with a meta-analysis on the willingness-to-volunteer rate among medical and health students in response to the COVID-19 pandemic.

Methods

Study Design

The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement was used as the guidance for this study (see Tables S1 and S2 in [Multimedia Appendix 1](#)) [21]. The research questions were formulated as follows: (1) What is the percentage of COVID-19 volunteer willingness among health care students? (2) What are the demographic factors associated with the willingness of health care students to volunteer? This review was not registered because it did not evaluate direct effects on human health.

Search Strategy

A systematic review search was carried out on PubMed, Scopus, and Embase up to December 10, 2023. Google Scholar was also included as a gray literature source in the search. The keywords used were “health students,” “willingness,” “volunteer OR volunteering OR volunteerism OR voluntary,” AND “COVID-19 OR covid-19 OR SARS-CoV-2 OR COVID-19 pandemic.” The complete search technique is outlined in Table S3 in [Multimedia Appendix 2](#) and searches for the other databases were developed using the Embase search strategy.

Eligibility Criteria, Articles Selection, and Data Extraction

The inclusion criteria were cross-sectional studies aimed at evaluating the rate of willingness to volunteer among medical and health students (encompassing disciplines such as medical, nursing, pharmacy, dentistry, midwifery, public health, and other relevant fields) in response to the COVID-19 situation from December 2019 to December 2023. Willingness to volunteer was defined as a “yes” response to the question “Are you willing to volunteer?” or “Do you want to volunteer?” We only included studies involving undergraduate or diploma students; studies involving other levels of education were excluded. Medical and health students were defined as individuals pursuing higher education degrees (undergraduate or diploma) in medicine, nursing, dentistry, pharmacy, midwifery, public health, and related fields. Exclusion criteria were applied to studies meeting any of the following conditions: (1) qualitative analysis, (2) focused on postgraduate or professional students, (3) non-English language articles, (4) review articles, (5) case reports, (6) randomized controlled trials, (7) clinical trial proposals, and (8) case-control studies.

GT and MI independently screened all duplicate topics, titles, abstracts, and full texts using Zotero version 6.0.30 (Corporation for Digital Scholarship). Duplicate entries were removed, and title and abstract screening were conducted on the remaining records. Subsequently, the selected records were searched for full-text access, and further comprehensive screening was

conducted on the obtained full texts by applying the eligibility criteria. Data extraction was conducted using the tabulation method, covering details such as author and year of publication, country, student population, sample size, gender distribution, academic year of the students, health status, marital status, living arrangements, volunteer experience, and the proportion indicating willingness. GT and MI independently carried out the data extraction process. Continuous data were presented as mean (SD), with conversion from median performed when necessary using an online calculator [22]. Any discrepancies were resolved through consensus.

Quality Appraisal

The quality of individual studies was assessed by one reviewer (MM) and independently reviewed for agreement by a second reviewer (SH). In instances of disagreement, a third review author (NN) was consulted. The standardized Quality Assessment Checklist for Survey Studies in Psychology (Q-SSP) tool, consisting of 20 checklist items, was used for the quality assessment of the included studies [23]. High-quality articles were defined as those scoring 70% or higher. The score was determined by the percentage of “yes” responses on the checklist. The utilization of this tool aligns with a previous study [24].

Statistical Analysis

The proportion was initially transformed using the logit function ($y = \text{logit}[x]$) before being pooled for meta-analysis with a restricted maximum-likelihood model. The rate was then obtained by multiplying the pooled proportion, following the back transformation from the logit function ($y = 1/(1 + \exp[-x])$), with 100%. A rate exceeding 50% was considered the threshold for determining the majority's willingness to volunteer during the pandemic. The CI was set at 95% (ie, 95% CI), with a P value of total effect ($P\text{-tot}$) $< .05$ indicating statistical significance. A value of I^2 greater than 50% or a P value of heterogeneity ($P\text{-Het}$) $< .1$ was used as the cutoff for determining data heterogeneity in the pooled analysis. Begg's funnel plot was used to assess the presence of publication bias. The meta-analysis was conducted using jamovi 2.3.21. A moderator analysis was conducted to examine the effects of sample size,

age, gender (indicated as male-to-female ratio), academic year (indicated as the ratio of students in second to first year, third to first year, and so on), volunteer experience (indicated as the ratio of students with to without volunteer experience), type of academic program (indicated as the ratio of medical to nursing students and the ratio of medical to dentistry students), country income category, and continent. Country income was categorized based on the World Bank classifications (high income, upper middle income, lower middle income, and low income). The variables used in the moderator effect analysis were also used in the stratification analysis, with the following cutoffs: 22 years old for age, 1 for the male-to-female ratio, 15% for the proportion of first-year students, 1 for the ratio of students with to without volunteer experience, and 5 for the ratio of medical to nursing students. Statistical significance in the stratification analysis was determined using Z-statistics. The statistical analysis adhered to recommendations from previous studies [24-26].

Results

Search Findings

Collectively, 283 records were identified from PubMed, Scopus, Embase, and Google Scholar in the initial stage. A total of 89 duplicates were automatically detected and subsequently removed. The remaining 194 records underwent screening for relevance based on the title and abstract. Forty records were then selected for full-text access and further thorough screening. During this stage, we identified 1 commentary [27], 1 correspondence [28], and 2 non-English articles [29,30], which were subsequently excluded. One study was excluded because the participants were not specified as medical or health students [31]. Seven studies were found to be qualitative, and therefore data extraction was not feasible; these studies were subsequently removed [32-38]. Additionally, 1 study was excluded because the participants were not pursuing undergraduate degrees [39]. Ten studies were deemed irrelevant to the objective of this review [40-49]. Finally, 21 studies were included in the systematic review and meta-analysis [50-70]. The screening and selection processes are depicted in Figure 1.

Figure 1. Schematic diagram for screening and selection of eligible studies following PRISMA guideline. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

Characteristics and Quality of the Included Studies

Characteristics of the included studies along with their quality are presented in [Table 1](#). A total of 21 studies were included, with a combined sample size of 26,024 students [50-70]. The studies were conducted in various countries, including Nigeria (n=3), Pakistan (n=2), Saudi Arabia (n=2), Serbia (n=1), India (n=1), Bulgaria (n=1), Vietnam (n=1), Poland (n=1), Brunei Darussalam (n=1), Australia (n=1), Nepal (n=1), Indonesia (n=1), Romania (n=1), the United Kingdom (n=1), China (n=1), Syria (n=1), and Sudan (n=1). Eligible studies from South and North Americas (including the United States, Canada, and Mexico) were not identified in this systematic review. The

average ages of the participants ranged from 22 to 24 years, whereas the proportion of female students varied considerably across studies. Nine studies exclusively recruited medical students [50-54,61,62,67,69], 3 focused on nursing students [55,60,65], and others included a mix of students from different departments. Thirteen studies were categorized as “high quality” based on the Q-SSP [50-62], while others had scores below 70% [63-67], and some even scored 50% or below [68-70]. Detailed assessment results based on the Q-SSP tool are presented in Table S4 in [Multimedia Appendix 2](#) [50-70]. A total of 9/21 (43%) studies did not provide sufficient justification for the sample size. See Table S5 in [Multimedia Appendix 2](#) for the 20 checklist items of Q-SSP and their respective code.

^aQ-SSP: Quality Assessment Checklist for Survey Studies in Psychology.

Willingness-to-Volunteer Rate

The forest plot of the pooled analysis on the rate of willingness to volunteer is presented in [Figure 2](#). After being transformed

back from the logit function, the pooled proportion of willingness to volunteer was 66.13% (95% CI 56%-72%). The heterogeneity for this pooled estimate was high, with $I^2=98.99\%$ and $P\text{-Het}<.001$.

Figure 2. Forest plot for the pooled proportion of willingness to volunteer among health students. RE: random effect.

Sensitivity Analysis

To observe if a single study affects the entire pooled estimate, a sensitivity test based on a one-leave-out analysis was conducted. The pooled estimates for each study removed are presented in Table 2. The lowest logit proportion was obtained when Adejimi et al [58] was removed (0.59, 95% CI 0.35-0.82),

with the I^2 value becoming relatively lower (72.06%), although the P -Het remained $<.001$. The overall rate of willingness to volunteer after the removal of Adejimi et al [58] was 64.34% (95% CI 59%-69%). It is noteworthy that the rate of willingness to volunteer reported by Adejimi et al [58] was the highest among all included studies, at 90.97%.

Table 2. Results from the one-leave-out analysis for the pooled willingness to volunteer among health students.

Study removed	Logit proportion	95% CI	<i>P</i> value of total effect	<i>I</i> ² , %	<i>P</i> value of heterogeneity

Elsheikh et al [52]	0.63	0.35-0.90	<.001	98.97	<.001

Moderator Effect

The effects of moderators were analyzed, and the results are presented in Table 3. The ratio of third- to first-year students significantly affects the overall rate of willingness to volunteer

with $P=.02$. Furthermore, the higher statistical significance of the moderator effect was observed on the ratios of fourth-, fifth-, or sixth- to first-year students ($P<.001$, respectively). However, other variables did not moderate the pooled estimate of the willingness-to-volunteer rate (P value ranged from .22 to .70).

Table 3. Moderator effect on the pooled estimates of willingness-to-volunteer proportion (N=21).

Moderator	Data type	Study, n (%)	Z	P value
Sample size	Continuous	21 (100)	-0.61	.54
Age	Continuous	14 (67)	0.79	.43
Male-to-female ratio	Continuous	20 (95)	-1.23	.22
Second-to-first-year students ratio	Continuous	7 (33)	-2.93	.003 ^a
Third-to-first-year students ratio	Continuous	7 (33)	-2.28	.02 ^b
Fourth-to-first-year students ratio	Continuous	7 (33)	-3.33	<.001 ^a

Continent	Category	21 (100)	-1.16	.24

^aSignificant at $P<.01$.

^bSignificant at $P<.05$.

Stratification Analysis

We further stratified the pooled estimate of the willingness-to-volunteer rate based on several variables, and the results are presented in [Table 4](#). According to Z-statistics, groups with older mean age, a higher number of male participants, and a higher number of first-year students had a significantly higher rate of willingness to volunteer ($P<.001$). Conversely, a higher number of participants from medical school contributed to a lower rate of willingness to volunteer ($P<.001$). As compared with the pooled rates of willingness to volunteer in high-income countries, those in upper-middle-income

($P<.001$) and low-income countries ($P=.04$) tend to be significantly lower, except for lower-middle-income countries (66.37% vs 69.42%; $P<.001$). Based on regions, rates of willingness to volunteer were the highest among African and Western European countries (77.38% and 77.03%, respectively). It is worth noting that the heterogeneity of a pooled estimate of studies from Eastern European countries was negligible ($I^2=0.05%$, $P=.30$), where the rate was 55.23%—the lowest among all regions. The number of samples recruited in studies according to regions and their corresponding rate of willingness to volunteer are presented in [Multimedia Appendix 3](#).

Table 4. Stratification analysis based on the characteristics of participants.

Variable	Study, n (%)	Sample, n	Logit proportion	95% CI	Rate, %	P-Z	I ² , %	P value of heterogeneity

Publication Bias

Begg's funnel plot for the overall pooled estimate is presented in [Figure 3](#). The symmetrical shape of the funnel plot suggests that publication bias was not detected, with P -Begg=.14.

Figure 3. Begg's funnel plot for studies reporting willingness to volunteer during pandemic among health students. The shape is symmetrical with P -Begg's=.14.

Discussion

Rate of Willingness to Volunteer During the Pandemic

The pooled estimate herein revealed that the overall rate of willingness to volunteer was 66.13%, with the rate being over 50% in almost every individual study. When stratified based on regions, the highest rate of willingness to volunteer was found among students from African countries (77.38%), followed by Western European countries (77.03%). Furthermore, the stratified analyses indicate that being older or female was associated with a higher rate of willingness to volunteer ($P < .001$, respectively). In addition, students in the first academic years were more willing to volunteer compared with those in more senior years ($P < .001$). According to individual studies, students were willing to volunteer due to various motivations, particularly internal factors [50-70]. Studies reported that students are driven by altruistic and duty-driven reasons, where individuals, particularly those aspiring to become future health professionals, feel a sense of responsibility in assisting during the pandemic [35]. They also perceive volunteering activity as an opportunity to learn, gain clinical skills, and enhance personal growth [34]. Research suggests that medical students exhibiting high prosocial motivation are more likely to engage in volunteer activities and persist in such endeavors, even in the absence of prior experience [49]. Moreover, external motivations contribute to such willingness in various forms, notably compensation-related factors. These external motivations include the recognition of academic credit, achievements, receipt of scholarships, and provision of material compensation [49].

Importantly, the willingness of students to volunteer is heightened when such engagement aligns with governmental needs and is endorsed by universities. Students are more likely to engage in volunteering if it is needed by the government and recommended by universities [71].

Despite the positive aspects of volunteering, attention should also be given to the mental health of students. A previous study by Tempiski and colleagues [16] revealed a negative association between the mental health problems of medical students (including stress, anxiety, and depression) and their participation as volunteers during the COVID-19 pandemic. Furthermore, many volunteer students express fear of getting infected and spreading the virus to their relatives or friends during their volunteer tasks [72,73]. Students also reported feeling unprepared to deal with the pandemic, citing issues such as personal protective equipment shortages, lack of training and knowledge, role confusion, insufficient information, and a lack of support from social or family networks [71]. As highlighted in a qualitative study, the well-being of volunteers was neglected due to a lack of access to psychological support [36]. Moreover, these challenges are further perpetuated by the academic workload and responsibilities as undergraduate students [74].

In this study, we found that the willingness-to-volunteer rate among first-year students was higher compared with students in the second to sixth year of education. As suggested by a previous study, most first-year students have not yet commenced their involvement in extracurricular activities and are still in the process of selecting the type of activities they wish to pursue

[75]. This further poses a challenge in using student volunteers to overcome the health care workforce shortage, as first-year students lack skills and experience, making them unsuitable for direct clinical assistance. For first-year students, community-based work is more suitable, including but not limited to childcare for health care workers, delivery of medicines to vulnerable populations, mental health checks on children, and other similar tasks. However, aiming to reduce the workload and burnout incidence among health care workers still necessitates recruiting students in higher academic years. Students in higher academic years are more involved in extracurricular activities and more occupied with lecture schedules, making them less willing to volunteer. Moreover, as students are exposed to more medical and health knowledge, they become more considerate of preventive measures. A previous study reported that students were more willing to volunteer if they were assured their grades would not suffer and be compensated, guaranteed coverage of treatment costs if they got infected while volunteering, offered separate accommodation during the duration of their volunteer work, and provided with psychological support [53]. Therefore, addressing these barriers is crucial to encourage students in higher academic years to volunteer during the pandemic.

Herein, we found that female students are more likely to volunteer than male students. This aligns with previous findings, showing a willingness proportion of 60.2% for females compared with 52.3% for males [20]. Consistent with a previous study, women were reported to be more willing to volunteer due to a nurturing inclination to help people in need and their empathetic nature, driven by personal and thoughtful motivations in the long term [76]. However, a study by Lazarus et al [54] stated that being male was one of the significant demographic factors influencing willingness to volunteer in Indonesia. The differing findings among these studies are indicative of the influence of sociocultural factors on students' willingness to volunteer during the pandemic.

Our findings indicate that the highest rate of willingness to volunteer is observed in Africa and Western Europe, while the lowest is in Eastern Europe. This aligns with a study revealing significantly lower volunteer rates in Eastern Europe compared with Western Europe, except for the trade union [77]. One of the primary factors contributing to the lower willingness-to-volunteer rate in Eastern Europe is the historical context—having been under communist rule for half a century, memories of mandatory volunteering have imbued the concept of volunteer work with a distinctly negative connotation. This negative perception is further compounded by a postcommunist lack of trust in any public activity [78]. Nowadays, Eastern European countries have progressed beyond acknowledging volunteering to establish a legal framework that actively promotes volunteering [78]. This indicates that certain countries might have to put extra effort into encouraging students to volunteer.

In pandemic settings such as COVID-19, health students play essential roles in addressing the shortage of health care workers and responding to health problems [71]. The students' activities can be placed into various categories, such as hospital works (triage, admission wards, and emergency rooms), call centers,

administrative epidemiological aspects (contact tracing, testing), online or remote consultation (regarding COVID-19 or non-COVID-19 cases, using the phone or internet), laboratory-related works, food or personal protective equipment supply, mentoring juniors, providing childcare for health workers, public education (such as countering hoaxes), and research programs [20,45,71]. With the help of volunteers, health care providers express appreciation for their valuable contributions. There are many significant advantages to volunteering, including helping provide more services and clinical care, reducing the workload for local staff, improving the quality of care, and shortening waiting times for patients. In return, it enhances how the community views and uses health care services [79].

Recommendations and Considerations

Based on the findings of this study, we propose several recommendations to increase the willingness-to-volunteer rate among medical and health students during the pandemic. First, we suggest implementing a robust encouragement program that integrates volunteering activities into curricula and offers psychological and accommodation support. Second, schools should prioritize the provision of high-quality training, promote knowledge, ensure clear role distribution, and effectively disseminate information to enhance the overall volunteering experience. Third, it is imperative for schools to ensure the complete safety of health care students by implementing measures such as preventing shortages of personal protective equipment, facilitating grade conversion, and guaranteeing coverage of treatment costs in case of infections incurred during volunteering.

Last but not least, although deploying students as volunteers could help overcome the health care worker shortage during the pandemic, it is important to consider potential drawbacks. The risks of contracting the disease and consequently experiencing death or long COVID-19 symptoms are high, especially during the early stages of the pandemic when managing the disease is significantly challenging. This further implicates liability issues for universities, colleges, or academic health centers. Therefore, it is crucial to actively inform students who are willing to volunteer regarding the aforementioned risks. Moreover, during volunteering, students might not be able to study optimally. The additional burden on health care workers to supervise volunteers should also be considered, implying the necessity to prepare students with volunteering skills beforehand and to establish a specific body tasked with managing the volunteers.

Limitations

Our study is the first to calculate the global rate of willingness to volunteer during the pandemic among medical and health students. We obtained data from countries across different regions, namely, Africa, Eastern Europe, Western Europe, East and Southeast Asia, South Asia, and the Middle East. However, the study has several limitations, including being unable to retrieve data from sources other than scientific publications. We did not collect data from reports published by government or nongovernmental organizations. Additionally, we did not contact experts who might have unpublished data regarding the willingness-to-volunteer rate. The rate was calculated from

heterogeneous data, which indicates the moderate strength of evidence. More than 40% of the included studies did not sufficiently justify the sample size, raising caution about the representativeness of the data. Moreover, moderator effects might be influenced by confounding factors that could not be controlled in this study. For example, as the effect of gender was observed based on the male-to-female ratio, the numbers might be influenced by differences in baseline demographics across countries and the composition of medical and other health professional schools. It is, therefore, important to confirm the findings through primary research.

Conclusions

The overall rate of willingness to volunteer among medical and health students during COVID-19 was 66.13%. This number

indicates that the recommendation for medical and health students to volunteer can be pursued, as the majority of students are willing to volunteer, although efforts to increase willingness remain necessary. Higher rates of willingness to volunteer were observed among studies with more first-year students and female participants. According to the region, students from African and Western European countries were more willing to volunteer during the pandemic. Unfortunately, the interpretation of the pooled estimate is limited by high heterogeneity, which is expected due to the variability in different countries, settings, and populations. However, this study can serve as a basis for managing medical and health students in volunteering during health crises.

Abstract

Background: The successful integration of artificial intelligence (AI) into clinical practice is contingent upon physicians' comprehension of AI principles and its applications. Therefore, it is essential for medical education curricula to incorporate AI topics and concepts, providing future physicians with the foundational knowledge and skills needed. However, there is a knowledge gap in the current understanding and availability of structured AI curriculum frameworks tailored for medical education, which serve as vital guides for instructing and facilitating the learning process.

Objective: The overall aim of this study is to synthesize knowledge from the literature on curriculum frameworks and current educational programs that focus on the teaching and learning of AI for medical students, residents, and practicing physicians.

Methods: We followed a validated framework and the Joanna Briggs Institute methodological guidance for scoping reviews. An information specialist performed a comprehensive search from 2000 to May 2023 in the following bibliographic databases: MEDLINE (Ovid), Embase (Ovid), CENTRAL (Cochrane Library), CINAHL (EBSCOhost), and Scopus as well as the gray literature. Papers were limited to English and French languages. This review included papers that describe curriculum frameworks for teaching and learning AI in medicine, irrespective of country. All types of papers and study designs were included, except conference abstracts and protocols. Two reviewers independently screened the titles and abstracts, read the full texts, and extracted data using a validated data extraction form. Disagreements were resolved by consensus, and if this was not possible, the opinion of a third reviewer was sought. We adhered to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist for reporting the results.

Results: Of the 5104 papers screened, 21 papers relevant to our eligibility criteria were identified. In total, 90% (19/21) of the papers altogether described 30 current or previously offered educational programs, and 10% (2/21) of the papers described elements of a curriculum framework. One framework describes a general approach to integrating AI curricula throughout the medical learning continuum and another describes a core curriculum for AI in ophthalmology. No papers described a theory, pedagogy, or framework that guided the educational programs.

Conclusions: This review synthesizes recent advancements in AI curriculum frameworks and educational programs within the domain of medical education. To build on this foundation, future researchers are encouraged to engage in a multidisciplinary

approach to curriculum redesign. In addition, it is encouraged to initiate dialogues on the integration of AI into medical curriculum planning and to investigate the development, deployment, and appraisal of these innovative educational programs.

Introduction

The field of medicine is constantly evolving with new technologies and discoveries [1]. One of the emerging technologies is artificial intelligence (AI), a simulation of human intelligence powered by machines, specifically computer systems that use machine learning and deep learning [2]. AI allows for complex decision-making and the ability for human capabilities such as tasks done by physicians and other health care providers [2]. Through recent advancements, AI has begun to become an innovation to be adopted in the field of medicine [3]. Current fields using this type of technology are radiology [4], pathology [5], dermatology [6], primary care [7], and surgery [8], among other fields of medicine [9]. These AI-related medical innovations can be seen through different ways, including robot-assisted surgical procedures, diagnosis and risk assessments, as well as the development and customization of drugs [3,10]. However, to move forward with the implementation of AI in clinical practice, physicians need to have a better understanding of AI and how to use it in clinical practice [11].

Although medicine has seen major changes over the last decades, medical education is still largely based on traditional curricula [12]. It often lacks fundamental concepts and even basic familiarization with AI and other emerging technologies [13]. A recent survey by Stanford Medicine found that 44% (230/523) of physicians and 23% (48/210) of medical students and residents reported that their education had not been helpful in preparing for new technologies in health care [14]. Currently, there are no accreditation requirements related to AI [15]. The knowledge gap between engineers, clinicians, and scientists continue to grow as health care moves to a more digital environment, which will ill-prepare young physicians who will work with AI-enabled tools and technologies [16,17].

At the moment, AI is beginning to enter the field of medical education through its uses in learning support, assessments of students' learning, and curriculum review [2]; however, there are several publications urging institutes and clinical educators to begin integrating AI educational concepts into their medical curricula [12,13,15-20]. There have been efforts to include AI education globally within each level of medical training. These efforts are led by national medical associations such as the UK National Health Service [21], the US American Medical Association [22], and Canada's Royal College of Physicians and Surgeons [23]. They have released documents recommending policies for integrating AI within their respective medical educational institutions [21-23]. This highlights the importance of the work on the intersection of medical education and AI around the world. Surveys of medical trainees have also

supported the need to incorporate the teaching of AI in the undergraduate medical curriculum [24]. To our knowledge, there are no medical schools with formal required courses on AI in health care. While still uncommon, the importance of AI medical education has been identified and acted on at some institutions, such as Duke University, which offers a training course called *Machine Learning School for the School of Medicine* [12]. Other institutions have also developed elective courses to teach AI to residents, such as in radiology [25]. As AI is being used in a variety of fields within medicine [9], it is important to have a structured and validated curriculum framework because future medical providers will be exposed to these types of technologies depending on their chosen fields.

A curriculum framework is a document which describes “the educational environment in which syllabuses (or subject-specific outlines of objectives, outcomes, content and appropriate assessment and teaching methodologies) can be developed” [26]. Curriculum frameworks can be described as educational road maps to teaching and learning. For example, a curriculum framework was created for global health concepts in family medicine education [27]. Medical educators work regularly with frameworks to inform the appropriate learning, assessment, and performance of the health care workforce [28]. Frameworks are tools that can inform the delivery of teaching and curricula development as well as inspire innovation in health care education. There are various aspects that can be included in curriculum frameworks and how they may be used for other disciplines. Obadeji [29] clearly describes the common elements of curriculum frameworks for health professional education, which include (1) the need and the purpose of a curriculum or a program, (2) learning objectives and outcomes, (3) course content that will facilitate the accomplishment of the objectives or learning outcomes, (4) organization of the content, and (5) implementation of curriculum—educational strategies and methods of assessment.

Due to the broad nature of this topic and its prospective limited data, a scoping review is the most appropriate method. Previous reviews exploring topics surrounding AI and medical education have focused on the application of AI in medical education [2,30], attitudes of medical students toward AI [31], and gaps of AI learning within medical education [32]. A recent review of AI educational programs and competencies for health care professionals was published [33]; however, due to the increase in attention on this topic, further reviews must be conducted. Furthermore, the previous reviews had some limitations, such as the exclusion of continuing professional education and the lack of investigating learning theories, pedagogies, and frameworks of their identified AI educational programs. Our review will cover these limitations by focusing on the medical

education continuum as the developed AI educational programs for medical students, residents, and practicing physicians can help medical educators navigate the learning pathway for current and future physicians. Moreover, no review has focused on examining curriculum frameworks that guide AI concepts within medical education.

Thus, we conducted a scoping review of published literature on AI curricula being used in medical education. Overall, the main aim of this scoping review is to synthesize knowledge from the literature on curriculum frameworks and current educational programs that focus on the teaching and learning of AI for medical students, residents, and practicing physicians. More specifically, we aim to investigate the details of the current educational programs including (1) the framework, pedagogy, or theory used; (2) the delivery of the educational program; (3) the curricular content; and (4) the evaluation of the program, to inform future research on developing or adopting AI curriculum frameworks for use in medical educational institutions.

Methods

Protocol and Registration

The protocol for this review was developed in accordance with the Joanna Briggs Institute (JBI) Reviewers Manual for Evidence Synthesis [34] and guided by the methodological framework developed by Arksey and O'Malley [35], supplemented by Levac et al [36]. The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [37] was used when reporting results, and is reported in [Multimedia Appendix 1](#). The protocol was registered on Open Science Framework Registries and published on JBI Evidence Synthesis [38].

Eligibility Criteria

Participants

To be eligible for inclusion, the participants of the studies had to fall under the population that provided medical education or received medical education, which includes medical students. This includes undergraduate medical education (UME), residents or postgraduate medical education (PGME), and practicing physicians (continuing medical education [CME]) at any health care setting (ie, primary, secondary, and tertiary care).

Exposure

Included studies must describe either a curriculum framework or programs for AI education within medicine. The frameworks and programs must focus on learning about AI and how to use AI-specific tools for the medical profession.

Outcome

For the purpose of this review, all elements of a curriculum framework described by Obadeji [29], either in part or as a whole, were considered and reported. Included papers may also describe current and developed educational programs for AI training in medicine. These educational programs have already been developed or evaluated, and papers describing recommendations of what to teach or programs not yet developed were not considered. This review focused on any

framework, theory, or pedagogy mentioned within the program; the delivery of the educational program (eg, course and workshop); and curricular content (eg, learning topics and learning objectives); if the educational program was evaluated, it was described according to the model of training evaluation developed by Kirkpatrick et al [39].

Information Sources

All types of studies were included, such as theoretical work, program descriptions, and empirical studies. Commentaries, reviews, perspectives, opinions, as well as position papers and any companion papers associated were also included. All study designs for empirical studies using qualitative, quantitative, or mixed methods studies were eligible for inclusion. These include experimental and quasi-experimental studies (such as randomized controlled trials, quasi-randomized controlled trials, nonrandomized clinical trials, interrupted time series, and controlled before-and-after studies), observational studies (such as cohort, case control, cross-sectional, and case series studies), qualitative studies (such as ethnography, narrative, phenomenological, grounded theory, and case studies), and mixed methods studies. Conference abstracts and protocols were excluded. Conference abstracts often contain preliminary findings that may not be as comprehensive or validated as full-text articles. As they are brief summaries of studies, they may lack the detailed methodology and results needed for a thorough understanding and synthesis in our scoping review. Furthermore, as protocols are plans of how to conduct the research, they do not provide findings or results that are necessary for a scoping review's goal to map the extent, range, and nature of research activity in a given field. Therefore, considering the provided justifications, we decided to exclude conference abstracts and protocols.

Search Strategy

The following search strategy has been developed by a specialized librarian. The text words contained in the titles and abstracts of relevant papers and the index terms used to describe the papers were used to develop a full search strategy. The search strategy took an iterative approach, initially using general terms such as "artificial intelligence," with the later addition of variations and synonyms such as "deep learning" and "machine learning." In addition, terms for the concepts of medical education and curriculum were added. An initial limited search of MEDLINE (PubMed) was conducted to identify relevant papers on this topic. An information specialist (GG) performed a comprehensive search in the following bibliographic databases: Ovid MEDLINE, Ovid Embase, CENTRAL (Cochrane Library), CINAHL, and Scopus. To identify any unpublished frameworks, web searches of Google, New York Academy of Medicine Grey Literature Report, and medical learning institutional websites were searched. Reference lists of all included research papers and all relevant reviews were back searched, and Google Scholar was used for forward citation tracking to identify further studies.

Papers were restricted to English and French due to the constraints of the research team. Papers were also restricted by date beginning in the year of 2000, as during the 1950s to the late 1990s AI was in its early phase with reduced funding and

interest of AI in medicine [40]. The initial search was conducted in November 2021 and later updated in May 2023.

Selection of Sources of Evidence

Following the search, all identified records were collated and uploaded into a reference management system, EndNote (version 20.3; Clarivate Analytics), where duplicates were removed. Following a pilot test with 2 reviewers (RT and AB) using 10% (510/5104) of the studies, titles and abstracts were then screened using Rayaan, a web-based research platform, by 2 independent reviewers (RT and AB) for assessment against the inclusion criteria for the review. The full text of selected citations was assessed in detail against the inclusion criteria by 2 independent reviewers (RT and AB). Any disagreements that arose between the 2 reviewers were resolved by a third reviewer (SAR).

Data Extraction

Data were extracted by 2 reviewers (RT and AB) using a data extraction tool on an Excel (Microsoft Corp) sheet developed and validated by the team. The data extraction tool was created and validated using previously validated data extraction tools [32-34] and input from experts in the field. It focuses on key characteristics related to curriculum framework elements and educational program details. Any disagreements that arose between the 2 reviewers were resolved by a third reviewer (SAR). Data on paper characteristics (eg, authors, title, country of origin, type of study, and year of publication), curriculum framework elements, and educational program details were extracted.

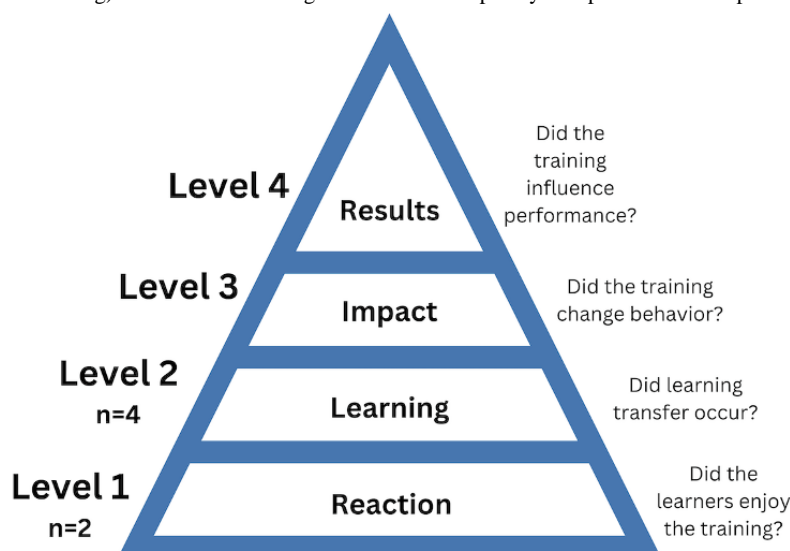

Synthesis of Results

The results of the review are presented as a table of the data extracted from the included literature to highlight the key

findings with respect to the aims of this scoping review. Descriptive statistics (eg, frequency) was used when reporting paper characteristics and education program details. For curriculum frameworks described, reviewers presented main elements, including (1) the need and purpose of curriculum, (2) the learning objectives and outcomes, (3) course content that will facilitate the accomplishment of the objectives or learning outcomes, (4) the organization of the content, and (5) implementation of curriculum. For current educational programs described, reviewers independently recorded and presented data on the framework, theory, or pedagogy that may have been used; the delivery of the educational program; and curricular content; and if the educational program was evaluated, it was described according to the model of training evaluation developed by Kirkpatrick et al [39].

The model of training evaluation developed by Kirkpatrick et al [39] was used to categorize educational outcomes evaluations (Figure 1 [39]). Level 1 describes the degree to which learners find the training favorable, engaging, and relevant; level 2 describes the degree to which learners acquire the intended knowledge, skills, confidence, and commitment based on their participation in the training; level 3 describes the degree to which learners apply what they learned during training when they are back to work; and level 4 describes the degree in whether the targeted outcomes resulted from the training program at an organizational level [39]. A narrative summary accompanied [41] the charted results and described what and how AI curriculum content is being delivered to trainees of various medical education stages.

Figure 1. Outcomes (and their meaning) of the 4-level training evaluation developed by Kirkpatrick and Kirkpatrick [39].

Quality Appraisal of Included Studies

Due to the nature of this review, the methodological quality or risk of bias of the included papers was not appraised, which is consistent with scoping reviews guidelines [34,37].

Results

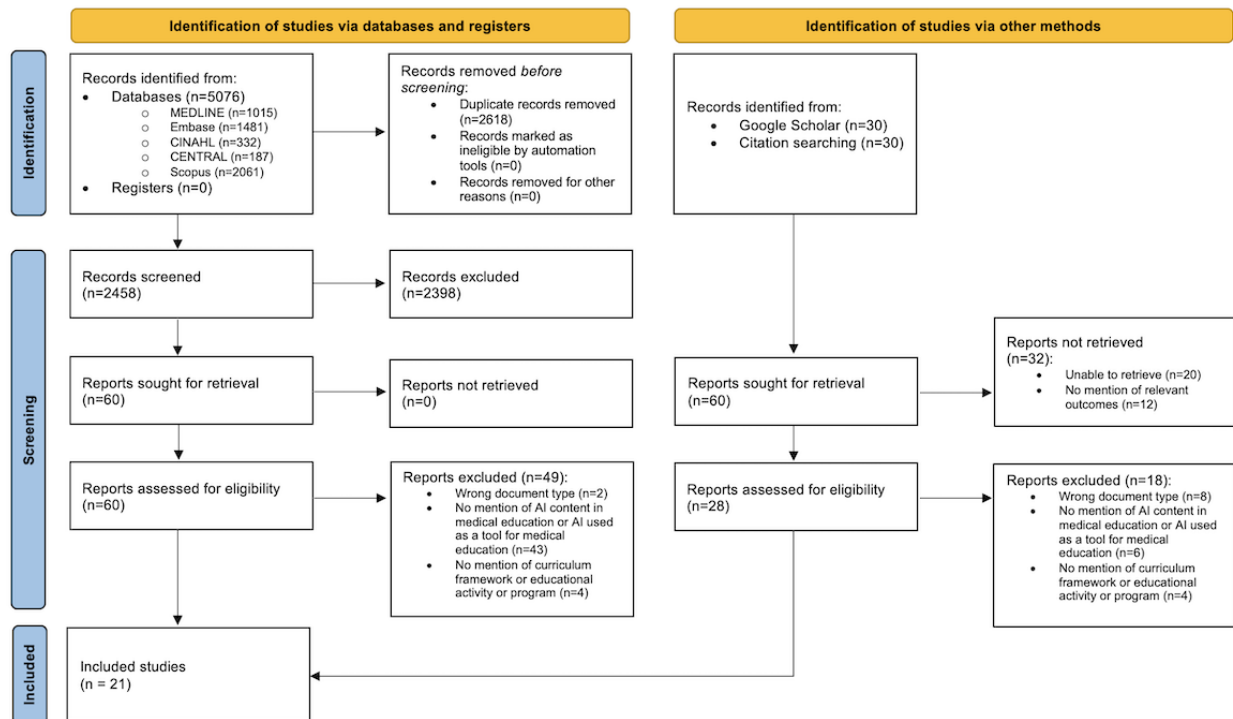

Search Results

From the systematic search, 5076 total papers were identified. These papers were extracted from web-based databases, and the computer software EndNote was used to manage these

references. Following removal of duplicates on EndNote, 2458 papers were uploaded to Rayyan software and screened by title and abstract. After abstract and title screening, 60 papers remained for full-text screening. A gray literature search identified 60 papers from Google Scholar and reference lists, from which 28 (47%) papers were retrieved for full-text

screening, and 32 (53%) papers were not retrieved or were irrelevant. Following full-text screening of databases and gray literature, 21 papers were included for further analysis [12,25,31-33,42-57]. Refer to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram (Figure 2) [58].

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart.

Characteristics of the Included Studies

Data was collected from 21 included studies and summarized in [Multimedia Appendix 2](#) [12,25,31-33,42-57]. A total of 12 studies were published in the United States [12,31,32,42-45,48,51,52,54,57]; 6 in Canada [33,46,47,49,50,55]; and 1 each in Germany [25], Korea [53], and Oman [56] ([Multimedia Appendix 3](#)). The earliest publication retrieved was from 2016, with 77% (15/21) of the papers [25,31-33,42,43,45,47,49-51,54-57] published in the last 3 years since the pandemic began ([Multimedia Appendix 3](#)). From the 21 studies, 6 (29%) were reviews [31-33,45,53,54], 4 (19%) were commentaries [44,47,50,51], 4 (19%) were opinions [12,48,52,56], 3 (14%) were perspectives [43,55,57], 3 (14%) were empirical studies using a cross-sectional survey design [25,42,49], and 1 (5%) was a position paper [46].

In terms of setting, 43% (9/21) of the papers mentioned multiple levels of education ranging from UME, PGME, to CME [12,31-33,46,50,51,54,56], while 24% (5/21) of the papers specified on UME [42,44,47,53,55], 19% (4/21) of the papers

specified on PGME [48,49,52,57], and 14% (3/21) of the papers were focused on CME [25,43,45]. Across the 21 included studies, 19 (90%) altogether described 30 current or previously offered educational programs [12,25,31-33,42-55] and 2 (10%) described elements of a curriculum framework [56,57].

Curriculum Framework Elements

Two papers described the main elements of a curriculum framework ([Table 1](#)) [56,57]. The first paper was an opinion paper by Masters [56], which mentions 3 of the 5 elements of a curriculum framework. The paper describes the need and purpose of a curriculum, course content, and brief descriptions in terms of organization of content. The second paper to describe elements of a curriculum framework was the study by Valikodath et al [57], which provides information for all 5 elements. This includes the main purpose of an ophthalmology AI curriculum, the learning objectives, course content topics, a 4-year resident organization plan, and implementation of the curriculum, as outlined in [Table 1](#). We noticed similarities in relation to what medical trainees should learn, as emphasized in [Figure 3](#) [56,57].

Table 1. Curriculum framework studies' characteristics (n=2).

Masters [56]	Valikodath et al [57]
Organization of content —	<ul style="list-style-type: none"> Year 1 and 2: understand basic statistics and mathematics Year 1-3: become familiar with components and functions of AI Year 1-4: use web-based learning tools (articles, lectures, modules, and case-based learning) Year 2-4: assess primary literature on current AI systems in ophthalmology Year 3 and 4: understand integration of AI into clinical practice
Implementation of content —	<ul style="list-style-type: none"> Teaching tools (curriculum delivery and assessment methods) background reading: articles on concepts in AI case studies web-based lecture series from experts in the field (regularly updated) interactive webinars and modules surgical simulation-based training standardized tests

^aPGME: postgraduate medical education.

^bAI: artificial intelligence.

^cNot applicable.

Figure 3. The comparison between the course content described by Masters [56] and Valikodath et al [57].

From our comparisons, we found that the main curricular topics presented by Masters [56] appropriately corresponded to the curricular topics presented by Valikodath et al [57], for example, a main curricular topic of “AI in Medical Systems,” which describes the way in which students should learn the structures and processes of AI systems that they will be using in the future. This corresponds to “Clinical Applications” and “Surgical Applications” in which the content is targeted into learning how to use AI applications for ophthalmology. It appears that

Masters’ [56] framework on course content can work as the foundation on what curricular concepts a program should include. This is because previous reviews have detailed similar curricular topics currently being taught.

Current Educational Programs

From the 19 papers that describe an educational program, 30 current or previously offered educational programs were identified (Table 2) [12,25,31-33,42-55]. A total of 13 papers

described, mentioned, or presented 24 educational programs [12,31-33,43,45-47,50-54], while 6 papers described and assessed 6 educational programs using evaluation methods (eg,

survey and test scores) [25,42,44,48,49,55]. No papers described a theory, pedagogy, or framework that guided the educational program.

Table 2. Educational program characteristics (n=30 educational programs described in 19 papers).

Characteristic	Frequency, n (%)
Type of educational program	
Course	15 (50)
Project	4 (13)
Lecture (dedicated to artificial intelligence)	4 (13)
Webinar	3 (10)
Educational summit or conference	2 (7)
Workshop	2 (7)
Pathway of education and program audience	
Undergraduate medical education	
General topics	16 (94)
Radiology	1 (6)
Postgraduate medical education	
Radiology	5 (100)
Continuing medical education, n (%)	
General topics	4 (50)
Radiology	3 (34)
Cardiology	1 (13)
Delivery setting	
Medical school	23 (77)
National or international medical association	7 (23)

Educational Program Delivery

Of the 30 educational programs described collectively in the 19 remaining papers, 15 (50%) programs were courses, 4 (13%) were project-related initiatives, 4 (13%) were didactic lectures dedicated to AI, 3 (10%) were webinars, 2 (7%) were an educational summit or conference, and 2 (7%) were 1-day workshops. "AI courses were defined as elective courses focused on AI-based education. Didactic lectures dedicated to AI are 1 or 2 lectures that mention AI education but not a full course. There were 77% (23/30) educational programs delivered from a medical school, while 23% (7/30) were delivered from recognized national or international medical associations. Furthermore, it is important to clarify that some papers used multiple educational program delivery approaches. For example, an included paper explained their educational intervention was a course, but this course included didactic lectures, mentorship, and a final project. However, the reporting of this educational program's delivery is classified as only a course and not counted as another delivery approach to minimize confusion.

Of the 30 educational programs described collectively in the 19 remaining papers, 17 (57%) UME educational programs were targeted toward medical students. Of these 17 programs, 16 (94%) were UME educational programs focused on general

topics of AI in medicine and 1 (6%) was an UME educational program focused on radiology concepts. In total, 17% (5/30) of the postgraduate educational programs were for residents who were in the radiology specialty. Of the 30 educational programs, 8 (26%) were specified for practicing physicians (n=4, 50% were CME educational programs focused on general topics of AI in medicine, n=3, 37% were radiology for CME education, and n=1, 13% was in cardiology for CME). The educational program characteristics are provided in [Table 2](#).

Curricular Content

The following curricular concepts were adapted and framed from previous similar reviews [32,33]. The curricular content and concepts were divided into 2 types: theoretical curricular concepts and application-based curricular concepts. The subcategories and their descriptions are outlined in [Table 3](#). The following describe the theoretical curricular concepts: fundamental of AI for using AI systems (15/19, 79%) [12,25,31-33,42-47,49,51-53]; fundamentals of health care data science for using AI systems (10/19, 53%) [12,25,31-33,45,47,49-51]; strengths and limitations of AI (9/19, 47%) [31-33,45-49]; and ethical, legal, and economic considerations of AI systems (11/19, 58%) [12,25,31-33,42,45-48,52]. The following describe the application-based curricular concepts: applications of AI systems

(19/19, 100%) [12,25,31-33,42-55], operating AI systems in health care settings (10/19, 53%) [12,25,31-33,43,46,47,52,55], impact of AI on clinical reasoning and medical decision-making (7/19, 37%) [12,25,31-33,43,55], communication of AI results to patients (4/19, 21%) [12,31-33], and critical appraisal of AI systems (7/19, 37%) [12,31-33,50,53,54].

Table 3. Curricular concepts mentioned in the educational program papers (n=19).

AI ^a curricular concept	Description of curricular concept	Reference
Theoretical curricular concepts (learning what is AI in medicine)^b		
Fundamental of AI for using AI systems	Providing an overview of AI definitions and concepts, including machine learning; natural language processing; and the basics of data acquisition, cleaning, analysis, and visualization	[12,25,31-33,42-47,49,51-53]
Fundamentals of health care data science for using AI systems	Providing an overview of the environment supporting AI, which includes biostatistics, big data, and the use and processing of data by algorithms and machine learning	[12,25,31-33,45,47,49-51]
Strengths and limitations of AI	Promoting learners' comprehension of the advantages and limitations of various AI systems, such as factors that affect AI accuracy (eg, sources of error and bias)	[31-33,45-49]
Ethical, legal, and economic considerations of AI systems	Developing a comprehensive understanding of ethics, equity, inclusion, patient rights, and confidentiality, alongside regulatory frameworks, policy considerations, liability, and intellectual property issues related to using AI systems as well as grasping the potential alterations to business or clinical processes resulting from the integration of AI technologies	[12,25,31-33,42,45-48,52]
Application-based curricular concepts (learning how to use AI for clinical practice)^c		
Applications of AI systems	Familiarizing with clinical application of AI systems in clinical practice to understand how they are used	[12,25,31-33,42-55]
Operating AI systems in health care settings	Understanding how to embed and engage with AI tools into clinical settings and workflows (eg, learning to engage in data mining tools or how to properly communicate with AI systems to receive meaningful results)	[12,25,31-33,43,46,47,52,55]
Impact of AI on clinical reasoning and medical decision-making	Having the ability to understand, interpret, and apply results of AI systems in clinical practice	[12,25,31-33,43,55]
Communication of AI results to patients	Communicate findings to patients in a personalized and meaningful manner and engage in discussions regarding the use of AI in the medical decision-making process	[12,31-33]
Critical appraisal of AI systems	Acquiring proficiency in assessing diagnostic and therapeutic algorithms powered by AI to ensure safe and effective integration and use in clinical practice	[12,31-33,50,53,54]

^aAI: artificial intelligence.

^bThe mentioned concepts encompass foundational learning that serves as the basis of medical artificial intelligence educational philosophy and clinical practice.

^cThe mentioned concepts prioritize the practical applications of artificial intelligence knowledge and skills in a clinical context.

Assessment of Educational Outcomes

Of the 19 papers, 6 (32%) presented the results of their evaluation of an educational program (Table 4) [25,42,44,48,49,55]. Two papers described only level 1 evaluation outcomes (eg, learner reaction and satisfaction with the educational program) in which participants were overall very satisfied with the AI content learned [42,48]. Four papers described level 2 evaluation outcomes (eg, change in attitude,

knowledge, or skill) in which learners demonstrated acquisition of a variety of competencies (linear algebra pertaining to AI and basics of AI) and skills (eg, incorporate medical decisions given by an algorithm and implementing AI in clinical practice) [25,44,49,55] where two of these papers also evaluated level 1 outcomes [25,49]. There were no outcomes that could be categorized as level 3 or level 4; thus, the program evaluations did not comment on the change in behavior or affect at the organizational level or on patient outcomes.

Table 4. Studies describing evaluation outcomes (n=6).

Study	Educational program	Levels and outcomes of the model of training evaluation developed by Kirkpatrick and Kirkpatrick [39]
Alderson et al [42], 2021	Course	<ul style="list-style-type: none"> Level 1: "...satisfaction scores of 4.4/5.0 (n=13) [...]"
Barbour et al [44], 2019	Educational summit	<ul style="list-style-type: none"> Level 2: "...there was a general belief [about 70% from the figures] that AI would make health care less humanistic." Level 2: "...did not observe a meaningful shift in attitudes regarding the desire to take a leadership role in developing or implementing AI [...]" Level 2: "Attendees arrived believing they had a poor baseline understanding of AI's role in health care, and left the summit with an enhanced understanding of the topic [...]"
Hedderich et al [25], 2021	Course	<ul style="list-style-type: none"> Level 1: "The participants were overall very satisfied with the study material and the organization of the course, and deemed the content of the course important for their work as a clinician or scientist." Level 2: "...self-perceived skills improved in all areas, for understanding Python code as well as for understanding concepts of linear algebra pertaining to AI." Level 2: "...participants felt more confident to analyze a research paper in the field, to implement an AI algorithm in a clinical environment, and to incorporate the decisions given by an algorithm into their clinical decision making." Level 2: "Most of the participants felt more competent at dealing with AI in medical imaging after the course."
Kang et al [48], 2017	Workshop	<ul style="list-style-type: none"> Level 1: "Ninety percent of the residents... reported that the course was helpful or very helpful [...]" Level 1: "...94% of the participants...felt that the lectures were of high or very high quality." Level 1: "Eighty-two percent...reported that they planned to pursue additional educational or research training in CER or big data analytics after the course [...]" Level 1: "[...] 98% of the respondents felt that health services and big data research are important or very important for the future of radiology."
Lindqwister et al [49], 2021	Course	<ul style="list-style-type: none"> Level 1: "Exit surveys demonstrated a high degree of learner satisfaction, with an aggregate rating of 9.8/10." Level 2: "There is a statistically significant difference between all pre- and postlecture question results ($P<.04$) by Wilcoxon Sign-rank test."
Tschirhart et al [55], 2022	Workshop	<ul style="list-style-type: none"> Level 2: "...considerable improvement in the first independent dataset, with further improvement in subsequent datasets [...]"

Discussion

Principal Findings

The development and implementation of AI in medical education has greatly increased within the last decade, specifically since the COVID-19 pandemic where there was a global shift into the digital world accelerating the development of AI technology [59]. This can be seen as the majority (15/21, 77%) of included papers within this review were published since COVID-19 pandemic. Although there is a growing field within research and practice, AI medical education, specifically within curricula development, is still limited. We found that the current curriculum frameworks for AI medical education are limited, indicating a need for further research. We also found that the current state of AI educational programs lack the use of a theory, framework, or pedagogy. In addition, we uncovered alternative methods and different levels of in-depth curriculum planning for AI in medical education.

Current State of Curriculum Frameworks for AI Medical Education

This is the first review to identify curriculum frameworks for AI medical education, and our findings demonstrate that they

are very limited. Although the literature is abundant in terms of recommendations and potential plans of actions for integrating AI education within medical education, there is an inadequate amount of formal curricula or frameworks [20,60,61]. For example, curricular recommendations lack specific learning outcomes and are not based on a particular education theory, as they usually focus solely on the content or competencies that should be taught [32,56]. Although understanding what concepts should be taught in AI is important, curriculum frameworks must be as comprehensive as possible.

From the identified frameworks, Masters [56] outlines a broad framework for any level of education, while Valikodath et al [57] outlines a complete framework for ophthalmology residency education. Their frameworks remain dissimilar in all aspects, except in how their course content was described. As seen with these 2 papers, the lack of curriculum frameworks in the literature is staggering. Further studies should focus on the development of these frameworks and start thinking on how to plan for the impending changes in medical education. As Valikodath et al [57] demonstrated their AI curriculum framework for ophthalmology, other specialties should follow suit, as AI affects each specialty differently [9]. Overall, the current state of curriculum framework in medical education

appears to be far from sufficient in the existing literature, and further research is needed.

Current State of AI Medical Educational Programs

Overview

In comparison to curriculum frameworks, educational programs in this field have been reviewed recently, specifically in the past 3 years [31-33]. However, research in AI medical education evolves quickly, and thus, a further identification of programs was carried out. We specifically looked at the framework, pedagogy, or learning theory described; the content and its audience; and if the program was evaluated for outcomes, which were used to assess its effectiveness, according to the model developed by Kirkpatrick et al [39].

The Lack of Learning Theories and Pedagogies

There were no papers that referenced a framework, pedagogy, or learning theory that guided the existence of the educational program. However, the use of frameworks, pedagogies, or learning theories is important for informing the development of valid, accurate, and competent educational programs [62-64]. By using frameworks, pedagogies, or learning theories, educators can choose the most effective instructional tactics, learning objectives, assessment, and evaluation approaches that can best help their students to learn [65]. A recent paper that fell outside the scope of our search date describes the use of constructivist theory and backward design learning principles that guided the development of their AI course [66]. Further papers should implement and report on a learning theory, framework, or pedagogy, as they have a role in medical education [65].

The Generalized AI Medical Content

The integration of AI concepts and topics within medical education remains generalized throughout the different levels of medical education, as seen with the educational programs described in our review. A total of 20 educational programs were described as focusing on general topics such as introductions to AI or information on AI and its application to medicine. The only postgraduate and continuing educational programs that had an AI-specific educational material were radiology, ophthalmology, and cardiology. This can be attributed to various reasons, including the constant evolution and novelty of AI technology, which may describe why generalized educational programs for AI appear across the medical educational continuum [67]. Radiology had the highest number of educational programs and was seen in all levels of medical education because AI in medicine was first applied in the field of radiology as it detected microcalcifications in a mammography during the year of 1992, or it could be due to the field being highly technological [68]. It is encouraging to see that specialties such as ophthalmology and cardiology have increased interest in AI education; other specialties and medical institutions should begin to follow suit. This is encouraging as it demonstrates that other specialties besides the highly technological field of radiology have been learning AI within medical education. This is especially important as more fields of medicine besides radiology are integrating AI within their practice, such as cardiology, pathology, and ophthalmology [3].

Furthermore, most of the educational programs were found in UME and within medical schools, which is ideal as it introduces a large audience of medical students to the concept of AI and its applications early in their careers.

The Success of Current AI Educational Programs

The included literature demonstrates that current efforts are being made to evaluate the outcomes of AI-related educational initiatives. According to the model developed by Kirkpatrick et al [39], an internationally recognized tool for evaluating and analyzing the results of educational, training, and learning programs, current AI programs have overall been positively received by medical learners. This was represented by the positive reactions, opinions, and attitudes toward AI after completing an educational program (level 1) as well as the acquisition of AI-related knowledge, skills, and confidence (level 2). These findings were also presented in a similar review in which the AI educational programs they identified also had positive outcomes, which were categorized as level 1 or level 2 [33]. However, further studies must assess educational programs for outcomes in relation to behavioral changes (level 3), specifically if there has been a transfer of AI-related knowledge, skills, and abilities into their daily work.

Further studies should also assess how the acquisition and application of these AI-related knowledge, skills, and abilities has affected the organization as a whole (eg, Has the increase in AI-educated physicians improved overall efficiency at the hospital?) or on patient outcomes (eg, Has there been an improvement in the patient's functional status or safety because of AI-educated physicians? [level 4]). By assessing for these additional outcomes, educators and medical organizations can understand how current AI educational programs have affected physician performance with AI technology. Increased research on the evaluations of educational programs can help further validate current educational tools and be used as inspiration for other institutions to create their own educational material. As seen in the review [33], there is a lack of consistency in the measures of these outcomes, as self-constructed and nonvalidated instruments were also used. Future studies should develop a validated tool to evaluate educational outcomes for a comprehensive synthesis.

Curriculum Planning and Framework Development of AI Medical Education

Curriculum planning of AI educational initiatives within medical education is insufficient. Although limited studies of curriculum frameworks were published, other forms of curriculum planning can be seen in the literature. Some medical institutions have conducted AI perception surveys [69,70], curriculum needs assessment surveys [71-73], and an interview [74] to understand what should be integrated into the AI medical curriculum. These studies are promising and contribute to the overall efforts to understanding how current educators, medical students, residents, and physicians consider AI within their educational system.

The absence of curriculum frameworks is staggering, especially given that AI competence is likely to become a required skill for medical graduates [75]. The development of AI curricula

and frameworks have already been gaining traction across other fields of education and levels. This can be seen as early as childhood education; for example, Su and Zhong [76] present their own curriculum framework, which outlines their concepts, teaching methods, teaching activities, projects, and assessment suggestions for AI education.

From a global perspective, the United Nations Educational, Scientific, and Cultural Organization, a specialized agency of the United Nations, released a document outlining the current practices of developing and implementing AI curricula in primary and secondary school education (K-12) [77]. From their report, several types of frameworks for AI literacy have been suggested, such as the AI Literacy Competency Framework, the AI4K12: 5 Big Ideas Framework, and the Machine Learning Education Framework. These recent reports and papers suggest increased efforts to integrate AI education before postsecondary school, which further stresses the importance of developing AI curricula and frameworks in medical education. Although there are current educational frameworks for AI education, each target audience must have their own specialized curricula to tailor the educational needs of the learners.

Medical educators can develop their curriculum through several different methodologies, such as the 10 key questions to be addressed while developing a curriculum [78] and the 6-step approach for curricular design [79]. However, curriculum frameworks allow a visual and detailed road map to implement a curriculum. Through this detailed format, educators are able to easily navigate the curriculum and its implementation, especially for new concepts in medicine, such as AI. To develop curriculum frameworks for AI in medicine, there must be an interdisciplinary team consisting of medical educators, AI experts and users, researchers, and curriculum designers due to the multiple fields incorporated.

The introduction of AI in medicine must be properly structured and organized within UME, PGME, and CME. Therefore, curriculum frameworks should be properly established through different levels of education and specialties. This has been emphasized by other reviews that call for integration of AI education in all levels and, thus, all specialties of medicine [17,33]. For example, a curriculum framework for UME will be different than a curriculum framework for PGME in dermatology. Curriculum frameworks can be adapted and they most likely will be, especially since AI education in medical education is still in its infancy. This is where leaders in UME, PGME, and CME organizations (eg, policy makers, medical educators, and researchers) must communicate effectively to eliminate any crossover education and repeated information. New technology and innovations in relation to AI and medicine will inevitably occur; however, it is important to be cognizant of the fundamentals of AI and how it will affect a physician's practice at the time. Sufficient planning of an AI curricula will deliver effective education for physicians who will increasingly be using AI technology in the near future; therefore, medical educators and institutions must begin to consider curriculum planning.

Incorporating and Advocating for AI Into the Medical Curriculum

The literature emphasizes the need to introduce AI in the medical education curriculum [12,13,15-20]; however, there are several challenges that have been discussed in terms of implementing this type of education. This includes insufficient time, insufficient resources (eg, lack of teaching staff or knowledge), and variable aptitude and interest in AI [80-82]. However, this review details several approaches to implementation as well as 6 studies that have evaluated their educational program. These successful educational programs can provide medical schools and national and international medical organizations with examples of current AI content topics and implementation methods that have worked for others. These medical education institutions can view how AI-based medical education is currently being offered around the world and understand any challenges, opportunities, and strengths about these programs. Although the content and provision of AI education is heterogenous, this heterogeneity can allow educators and students to view the many types of programs that were offered. As AI education for medicine is still in its infancy, educators should explore these programs where they can then potentially modify an educational program that best suits their needs. As seen in this review, there are several ways to incorporate AI material into the current curriculum seamlessly, such as an AI fundamentals lecture or module, an AI elective, or a research project.

Medical students, residents, and practicing physicians also have the opportunity to advocate for the inclusion of AI education at their respective institutions [46]. For example, there are several North American university chapters of the Artificial Intelligence in Medicine Student Society, such as the University of Toronto and University of Alberta, which organizes workshops, conferences, and multiple speaker sessions throughout the year [46]. These student interest groups demonstrate the increased interest for AI and can potentially build momentum and advocate for AI education at their respective institutions. As some of the offerings at these student interest groups include brief educational material for AI, medical institutions can work with these students as a starting point.

Strengths and Limitations

The strengths of this review include the comprehensive search strategies, the inclusion of a variety of information sources, and rigorous methodological approaches that are replicable. For example, study selection was completed by 2 reviewers, and disagreements were resolved by discussion or consensus involving a third investigator. Furthermore, a scoping review protocol was registered and published to improve transparency of the methodological process.

Although this study was conducted in a structured and systematic manner, there are some limitations that are important to consider. A limited number of papers were retrieved during the search and selection process. Only 2 papers reported having a curriculum framework, with 1 reporting a full curricula plan related to AI in medicine. This can be because AI technology is emerging and continuing to change within medicine and it has been limiting in terms of educational advances. Because of

the nature of the scoping review, the quality of each identified study was not assessed.

Conclusions

Medicine is rapidly evolving from the information age to the age of AI, where machines will become an integral part of medical practice. Thus, medical education needs to keep pace with changes in medical practice. This review synthesized knowledge from the literature on curriculum frameworks and current educational programs that focus on the teaching and learning of AI for medical students, residents, and practicing physicians. To better integrate AI curricula into the continuum of medical education, discussions surrounding curriculum

planning of AI should begin where institutions are recommended to work collaboratively with teams of curriculum designers, data scientists, and medical educators to develop AI curricula and educational programs. There is a need to (1) develop a general AI education curriculum framework for UME; (2) develop a specific AI education curriculum framework for each specialty within PGME and CME; and (3) design, implement, and evaluate current educational programs. Overall, institutions must begin equipping current and future physicians with the knowledge, skills, and confidence to effectively use AI applications as it will continue to grow within the field of health care.

Acknowledgments

SAR is Canada Research Chair (Tier II) in Advanced Digital Primary Health Care, received salary support from a Research Scholar Junior 1 Career Development Award from the Fonds de Recherche du Québec-Santé (FRQS) during a portion of this study, and her research program is supported by the Natural Sciences Research Council (NSERC) Discovery (grant 2020-05246). The study was also supported by the *Fonds de recherche du Québec–Société et Culture* team grant to the McGill Family Medicine Education Research Group.

Authors' Contributions

RT, SAR, and PP conceived the idea, developed the research protocol and methods, and drafted and edited the final manuscript. GG helped develop and run the search strategy. AB, PP, and SAR helped to refine and develop the research question and study methods and helped with drafting and editing of the manuscript. All authors except PP approved the final manuscript submitted; however, the authors would like to acknowledge that the late PP provided many meaningful contributions to this work before his passing.

Abstract

Background: Learning and teaching interdisciplinary health data science (HDS) is highly challenging, and despite the growing interest in HDS education, little is known about the learning experiences and preferences of HDS students.

Objective: We conducted a systematic review to identify learning preferences and strategies in the HDS discipline.

Methods: We searched 10 bibliographic databases (PubMed, ACM Digital Library, Web of Science, Cochrane Library, Wiley Online Library, ScienceDirect, SpringerLink, EBSCOhost, ERIC, and IEEE Xplore) from the date of inception until June 2023. We followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines and included primary studies written in English that investigated the learning preferences or strategies of students in HDS-related disciplines, such as bioinformatics, at any academic level. Risk of bias was independently assessed by 2 screeners using the Mixed Methods Appraisal Tool, and we used narrative data synthesis to present the study results.

Results: After abstract screening and full-text reviewing of the 849 papers retrieved from the databases, 8 (0.9%) studies, published between 2009 and 2021, were selected for narrative synthesis. The majority of these papers (7/8, 88%) investigated learning preferences, while only 1 (12%) paper studied learning strategies in HDS courses. The systematic review revealed that most HDS learners prefer visual presentations as their primary learning input. In terms of learning process and organization, they mostly tend to follow logical, linear, and sequential steps. Moreover, they focus more on abstract information, rather than detailed and concrete information. Regarding collaboration, HDS students sometimes prefer teamwork, and sometimes they prefer to work alone.

Conclusions: The studies' quality, assessed using the Mixed Methods Appraisal Tool, ranged between 73% and 100%, indicating excellent quality overall. However, the number of studies in this area is small, and the results of all studies are based on self-reported data. Therefore, more research needs to be conducted to provide insight into HDS education. We provide some suggestions, such as using learning analytics and educational data mining methods, for conducting future research to address gaps in the literature. We also discuss implications for HDS educators, and we make recommendations for HDS course design; for example, we recommend including visual materials, such as diagrams and videos, and offering step-by-step instructions for students.

Introduction

Background

In the era of artificial intelligence, big data, and digitalization of health care, there is a growing demand for educating specialists in analyzing health data [1-3]. The integration of IT into health care has undergone significant evolution in recent decades that has led to a change in the definition of health informatics. The current definition of health informatics encompasses the interdisciplinary study of designing, developing, adopting, and applying IT-based innovations in health care service delivery, management, and planning. By contrast, health care data analytics, a nascent subfield within health informatics, specifically addresses methods and techniques for analyzing, integrating, and interpreting health care data. Health data analytics, or health data science (HDS), as it can also be understood, involves data manipulation, mining, and statistical analysis to gain valuable insights from health, medical, or biological data. In other words, while health informatics encompasses noncomputational aspects, such as system development and maintenance, health data analytics or HDS concentrates only on using computational tools and methods for analyzing data [4].

However, given the novel and interdisciplinary nature of HDS, learning and teaching HDS is highly challenging [1,5,6]. Students and teachers are often faced with a lack of common language and prior knowledge in health or computational sciences, thus making it hard to learn and teach HDS concepts effectively [1,7]. In postgraduate study, in particular, students who enroll in HDS courses have diverse academic backgrounds, including computational and medical backgrounds (but rarely a combination of the two); therefore, traditional learning and teaching approaches in biology, medicine, or computer sciences may not be effective for HDS training [1,8].

Shedding light on HDS students' learning preferences and strategies is particularly important in this context and can help address some of these challenges [7,9-12]. There is heterogeneous literature around the definitions of *learning strategy*, *learning tactic*, *learning approach*, *learning style*, and other related terms [10,13,14,15]. In this paper, we view learning strategy as the approach that students use to manage their learning processes.

Similar to recent studies [16-19], we also understand learning preference as the perceived tendency of learners regarding the presentation of learning materials, types of learning activities, and the organization of their learning process, while learning strategy or learning approach is the actual way in which students manage their learning process [19].

We also recognize that the learning preferences that students exhibit within the HDS field inform the strategies they use to support their learning [20,21]. We decided to focus on learning preferences and strategies from the aforementioned perspectives because these field-specific preferences and strategies can offer insights into HDS education, which are useful for personalized learning [17,22-24].

Given the aforementioned definition of learning preference, research studies about learning styles in HDS-related fields touch upon HDS-specific learning preferences and can thus be used to identify students' tendencies in the field regarding information presentation, learning activities, and learning organization. However, it should be mentioned that the term *learning style* has been consistently misinterpreted [18] and defined variably across numerous studies in the literature [18,25]. In recent years, several research studies [26,27] have criticized the claim that each individual student has a dominant learning style, which is a stable neurological, psychological, or innate learning preference. Nonetheless, these and other studies [10,12,16,18,26,27] have also acknowledged that students in each field of study, specific to the nature of the discipline, might exhibit some preferences regarding course materials and activities and the way in which they approach these materials and activities [10,12,16,18,26]. As mentioned in a previous study [26], while the concept of stable learning styles for students is considered a myth, there are preferences that students exhibit within each field that informs the strategies they use to support their learning, which can in turn support personalized learning [10,11,16,18,20,26,28-30].

Given this context, gaining knowledge about learners' preferences and strategies in HDS courses can help course designers create optimized courses or redesign existing courses [10,31,32], creating a positive impact on student interest, engagement, and performance [16,32]. In addition, informing teachers about students' learning preferences and strategies in HDS courses can assist them not only in selecting appropriate teaching methods but also in providing personalized feedback to students [10,30,33,34].

Although several systematic reviews have been conducted to investigate the learning preferences of nurses [35,36] and physiotherapists [37], none of them are related to interdisciplinary programs in the realm of HDS. To fill this gap, and following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [38], we conducted a systematic review to present the current state of knowledge on learning strategies and preferences in HDS.

There are important aspects of learning strategies and preferences that are of interest in this systematic review because they are useful for implementing personalized learning in the HDS field [11,21]. The types of multimedia resources in a course are important because they significantly influence engagement, understanding, and the overall learning experience of students [39,40]. Each discipline has its unique nature [10,26], and presenting concepts in an effective way that is aligned with students' preferences in the discipline can improve students' satisfaction [41]. Therefore, insight into preference regarding the types of multimedia resources used for information delivery can enhance course design and student satisfaction.

Collaborative learning is one of the popular strategies in education, but it is not always easy to implement it successfully because engaging all students in teamwork is challenging [42-44]. Therefore, understanding students' collaboration preferences in HDS can facilitate the integration of both peer learning and independent study within a course to improve

collaborative skills, support diverse perspectives, and help students to develop self-directed learning skills [42-44].

In addition, understanding whether HDS students prefer a global or sequential approach when studying topics can inform both teachers and students about effective learning strategies to enhance the student educational journey; for example, course designers can arrange topics in more effective sequences that align better with students' preferences, thereby improving the overall learning experience [45].

Moreover, understanding the preferred focus granularity of students, such as their inclination toward details or abstract concepts, assists in prioritizing topics for teaching and determining effective teaching strategies [46,47]; for example, identifying whether HDS students prefer applied topics or theoretical aspects helps educators decide the level of details to include in the course materials [47]. These are all important topics related to learning strategies and preferences, which are worth shedding light on in the context of HDS education.

Research Questions

Therefore, this systematic review focuses on the following research questions (RQs), which were selected based on available literature and their potential benefits for personalized learning [20,21]:

- RQ1: What types of information presentation do students prefer in HDS?
- RQ2: Do students prefer team-based learning over independent learning in HDS?
- RQ3: How do students organize their learning process (global vs sequential) in HDS?
- RQ4: Do students in HDS prefer abstract concepts over factual concepts?

Our goal with this systematic review is not only to present and analyze research findings on learning strategies and preferences in HDS but also to discuss their implications for future course design in HDS. This way, we can help HDS educators make informed decisions about teaching methods and assist them with developing effective courses. To the best of our knowledge, this is the first systematic review that discusses learning strategies and preferences in HDS-related disciplines. The contributions of this study are as follows:

- It consolidates the heterogeneous knowledge available in the literature and presents it in 4 categories, that is, information presentation (RQ1), collaboration preference (RQ2), organization strategy (RQ3), and focus granularity (RQ4).

- It provides suggestions to assist course designers and teachers in delivering more effective HDS-related courses.
- It provides suggestions for future research in HDS education, which can help researchers conduct better informed investigations in this area.

Methods

Overview

This systematic review was conducted to understand what learning strategies and preferences are used by students in HDS-related fields. To this end, we followed all steps outlined in the PRISMA guidelines [38] except for the meta-analysis step because, given the diversity of the included papers, the narrative data synthesis approach [48] was deemed more appropriate for combining the findings from the different studies. Therefore, we used narrative data synthesis to report our findings. The PRISMA checklists for abstracts and articles are available in Tables S1 and S2 in [Multimedia Appendix 1](#), respectively. We also used the Mixed Methods Appraisal Tool (MMAT) [49] to assess the quality of the included articles. The MMAT allows the assessment of the quality of studies with different methodological designs, such as quantitative, qualitative, and mixed designs. The protocol used in this study is available in [Multimedia Appendix 2](#) [38,48-51], and the PICO (Population, Intervention, Comparison, and Outcomes) components of the review question are presented in Table S1 in [Multimedia Appendix 2](#).

Types of Studies and Participants

In this systematic review, we considered various types of primary studies, including both quantitative and qualitative journal or conference papers, all of which focused on exploring learning preferences or strategies in HDS-related courses. We did not apply any restrictions regarding participants' academic degrees; therefore, all high school, undergraduate, and postgraduate students as well as nontraditional learners (eg, health care professionals) were included.

Study Eligibility

This systematic review focuses on courses and programs falling within the scope of HDS (using data analytics methods to analyze biological, medical, and health data) [4,7]. Studies focusing on non-data analytics aspects of health informatics were not considered in this systematic review.

The inclusion criteria are presented in [Textbox 1](#) (for more study eligibility details, refer to Table S2 in [Multimedia Appendix 2](#)).

Textbox 1. Criteria used to select the studies.

Inclusion criteria

- Language of publication: English
- Year of publication: no restriction applied regarding the year of publication
- Participants: students in fields highly relevant to health data science (HDS; using computational methods for medical, biological, or health data analysis), such as bioinformatics, biostatistics, computational biology, neuroinformatics, biomedical science, precision medicine, HDS, and HDS courses
- Participants' academic level: high school, undergraduate, and postgraduate students in any relevant course; nontraditional learners, such as health care professionals, also included
- Type of publication: conference and journal papers; primary research articles
- Subject: papers discussing learning preferences, strategies, tactics practices, or styles of the aforementioned learners
- Analysis type: both quantitative and qualitative methods included

Study Identification

The literature search was carried out on June 15, 2023. The PubMed, ACM Digital Library, Web of Science, Cochrane Library, Wiley Online Library, ScienceDirect, SpringerLink, EBSCOhost, ERIC, and IEEE Xplore databases were searched independently. We supplemented the literature search by using Google Scholar manually to find potentially missed articles. Given the interdisciplinary nature of HDS, these databases were selected to cover literature across computer science, education, and medicine. We used a combination of terms to identify papers about students' learning preferences and strategies in a variety of courses and programs related to HDS. The keywords used for searching the literature are presented in Table S3 in [Multimedia Appendix 2](#), and the queries used for each database are presented in Table S4 in [Multimedia Appendix 2](#).

Study Selection

The title, abstract, and full-text screening were carried out independently by 2 reviewers: NR, who has an academic background in HDS; and SS, who has a background in education. They screened the titles and abstracts of all extracted articles, followed by a full-text review of eligible studies (Cohen κ agreement index=0.95). In cases of disagreement, a third screener, AM, was involved to resolve conflicts. The screening questions are presented in Table S5 in [Multimedia Appendix 2](#).

Data Extraction

Both NR and SS used a standardized Microsoft Word form for extracting and documenting data (for details, refer to [Multimedia](#)

[Appendix 2](#)). The data they extracted included the following categories: publication characteristics (this included details such as the publication title, journal or conference, authors, and publication year); methodological features (the reviewers recorded various methodological aspects, such as the participants' field and course name, the number of participants, the method of analysis used, the type of input data used, the students' degree level, the study subject, and any learning inventory used); and learning preference or learning strategy (information regarding reported learning preferences or strategies was collected, along with the corresponding percentage of students exhibiting each learning preference or strategy).

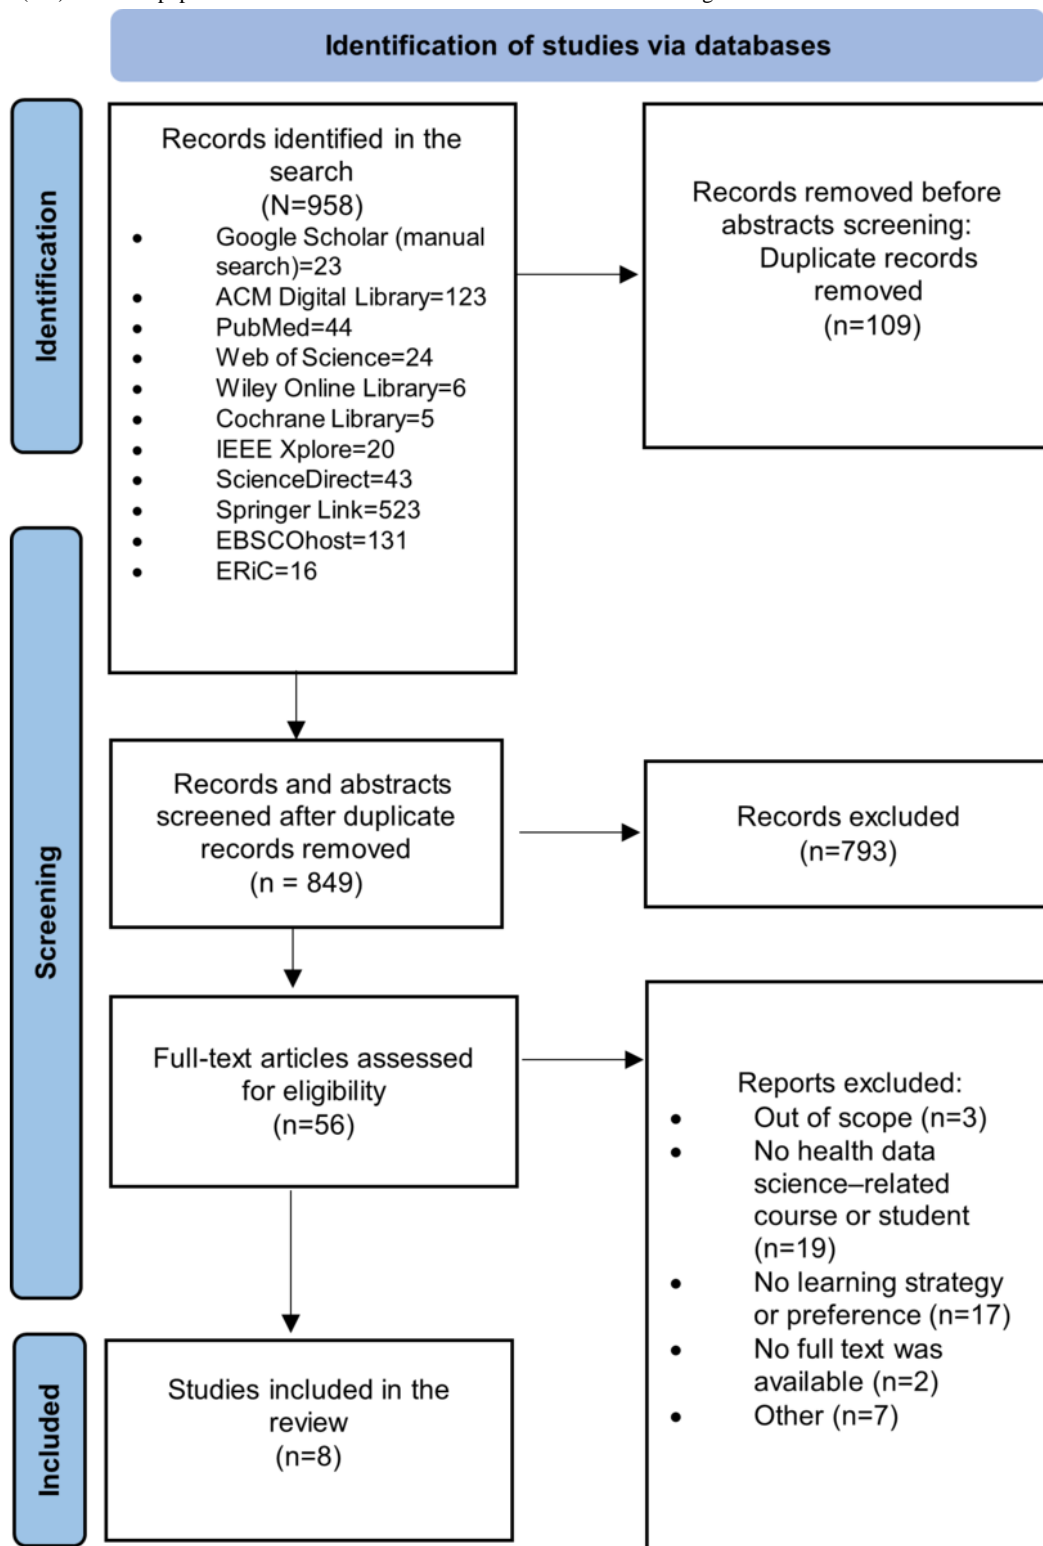

After the initial extraction, both reviewers cross-checked the extracted data to ensure accuracy. In addition, both reviewers assessed the quality of the included articles independently by using the MMAT [49]. Finally, any discrepancies or inconsistencies were independently resolved by the third reviewer, AM.

Results

Search Results

The literature search resulted in 958 articles, which were reduced to 849 (88.6%) studies after removing 109 (11.4%) duplicates (for details, refer to [Figure 1](#)). Of these 849 articles, after full-text review, 8 (0.9%) studies that were published between 2005 and 2021 were included in the synthesis. The reasons for excluding papers during full-text screening are presented in Table S6 in [Multimedia Appendix 2](#).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart of the study selection process. Full texts could not be found for 2 (4%) of the 56 papers considered for full-text review after abstract screening.

Characteristics of the Included Studies

As shown in [Table 1](#), most of the articles (7/8, 88%) were published between 2017 and 2021. Of the 8 studies, 2 (25%) were conducted in the United States; 2 (25%) in Malaysia (2/8, 25%); and 1 (12%) each in Denmark, India, Sweden, and Israel.

Of the 8 studies, 3 (38%) [[45,46,52](#)] focused on undergraduate students, and 3 (38%) focused on postgraduate students [[53-55](#)], while high school learners were investigated by 1 (12%) study [[56](#)], and health care professionals were the focus of 1 (12%) study [[41](#)].

Table 1. Summary of the included studies.

Study, year; country	Sample size, n	Participants' field	Course	Course delivery type	Participants' academic level	Study subject	Learning inventory	Results
Holtzclaw et al [45], 2017; United States	28	Genetics	Bioinformatics	Face-to-face with web-based materials	Undergraduate student	Learning style	FSILS ^a	Procession: active=54% ^b , reflective=46%; input: visual=82%, verbal=18%; perception: sensing=67%, intuitive=33%; understanding: sequential=79%, global=21%
Micheel et al [41], 2017; United States	751	Oncology	Precision medicine	Web based	HCP ^c	Learning style	Custom survey with 1 question	Multimodal (80%): watching, listening, and reading=39%, watching and reading=19%, listening and reading=12%, watching and listening=10%; unimodal (20%): reading=15%, watching=3%, listening=2%
Nielsen and Kreiner [53], 2017; Denmark	57	Public health	Advanced statistics	Face-to-face	Postgraduate student	Learning style	D-SA-LSI ^d and qualitative analysis	Function: executive=5.42 ^e (strong), legislative=4.59 (strong), judicial=4.41 (medium); form: democratic=4.62 (strong), anarchic=4.34 (medium), monarchic=3.68 (medium), hierarchic=4.12 (medium), oligarchic=2.65 (weak); learning: conservative=4.54 (strong), progressive=4.83 (strong); level: global=3.97 (medium), local=3.59 (medium); scope: external=5.43 (strong), internal=3.53 (medium)
Diwakar et al [54], 2018; India	84	Biotechnology, microbiology, and bioinformatics	Bioinformatics and biotechnology	Web based	Postgraduate student	Learning style	Kolb learning style inventory	Assimilators=60%, divergers=20%, convergers=16%, accommodators=4%
Sani Ibrahim [46], 2020; Malaysia and Nigeria	2 data sets were used: procession data set=95, perception data set=2168	Bioinformatics	Genomics technology	Web based	Undergraduate student	Learning style	FSILS and data mining	Procession: active=70%, reflective=30%; perception: intuitive=94%, sensing=6%
Abrahams-son and Dávila Lopez [55], 2021; Sweden	65	Bioinformatics	Bioinformatics	Web based and face-to-face	Postgraduate student	Learning style	Custom survey and qualitative analysis	Lecture format: real-time Zoom sessions=64%, offline as a video=27%, offline as reading=9%; synchronize work preference: alone=50%, alone and then in group=12%, same group=19%, different group=19%
Gelbart et al [56], 2009; Israel	4	Biology	Bioinformatics	Face-to-face with web-based materials	High school student	Learning strategy or approach	Custom survey and qualitative analysis	1 pair research oriented and 1 pair task oriented

Study, year; country	Sample size, n	Participants' field	Course	Course delivery type	Participants' academic level	Study subject	Learning inventory	Results
Li and Abdul Rahman [52], 2018; Malaysia	46	Bioinformatics	Genomics technology	Web based	Undergraduate student	Learning style	FSILS and data mining	Procession: active=55%, reflective=24%, neutral=21%; input: visual=66%, verbal=18%, neutral=16%; perception: sensing=31%, intuitive=48%, neutral=21%; understanding: sequential=62%, global=12%, neutral=26%

^aFSILS: Felder and Soloman Index of Learning Styles.

^bThe numbers denoted by a percentage sign in the Results column represent the percentage of learners who have declared the corresponding learning preference among all learners.

^cHCP: health care professional.

^dD-SA-LSI: Danish Self-Assessment Learning Styles Inventory.

^eThe scores indicate the strength of students' inclination toward the corresponding preference and were calculated based on the D-SA-LSI (range 0-7).

Of the 8 included studies, 6 (75%) [45,46,52,54-56] explored the learning strategies and preferences of bioinformatics students or courses, 1 (12%) investigated a precision medicine course [41], and 1 (12%) investigated an advanced statistics [53] course. It is worth noting that none of the included studies focused on courses specifically labeled as "health data science" courses.

Of the 8 included studies, 7 (88%) explored learning preferences, while 1 (12%) [56] analyzed students' learning strategies. Slightly more than one-third of the studies (3/8, 38%) [41,55,56] used a custom survey to measure students' learning preferences or strategies, while the rest (5/8, 62%) [45,46,52-54] used learning inventories, which are questionnaires that categorize students into different groups based on various learning dimensions (for a detailed description, refer to [Multimedia Appendix 3](#) [57-63]). Of the 8 included studies, 3 (38%) [45,46,52] used the Felder and Soloman Index of Learning Styles (FSILS) [58,59], 1 (12%) [54] used the Kolb learning style inventory [57], and 1 (12%) [53] used the Danish Self-Assessment Learning Styles Inventory based on the theory propounded by Sternberg [60,64,65].

Regarding the analysis approach and data, most of the articles (6/8, 75%) performed only a qualitative analysis using a questionnaire and simple quantitative methods, such as statistical descriptive techniques applied to questionnaires (3/6, 50%) [53,55,56]. Three of them also supplemented their studies with a qualitative method. However, 2 (25%) of the 8 papers [46,52] used advanced data mining methods, such as k-means, and analyzed log data alongside self-reported data. Nevertheless, these studies [46,52] did not use log data to identify students'

learning preferences; instead, they relied on self-reported inventories to train their models. Furthermore, all included studies except that by Micheel et al [41] had sample sizes of <100 (average 65) participants. The characteristics of the included articles are illustrated using various visualizations in Figures S1 and S2 in [Multimedia Appendix 2](#).

The studies' quality, assessed using the MMAT, ranged between 73% and 100%, indicating excellent quality overall. None of the studies were excluded based on the MMAT score. Further details regarding the quality of the included articles and the MMAT checklists can be found in [Multimedia Appendix 4](#) [41,45,46,52-56].

We used the narrative data synthesis approach [48] to combine the included studies to identify the learning preferences and strategies used in HDS. The studies were synthesized and narrated across different aspects, including information presentation preference (RQ1), collaboration preference (RQ2), preferred organization of learning process (RQ3), and preferred focus granularity (RQ4).

Proxies Used for Synthesis

Due to the heterogeneity among the included studies in terms of the measurements used to determine learning preferences and strategies in HDS courses, we found it necessary to define specific proxies for each learning preference. These proxies help in making connections between the results presented in the different studies. [Table 2](#) displays the proxies associated with each RQ in this systematic review. More information about the learning inventories discussed in the included studies is available in [Multimedia Appendix 3](#).

Table 2. Proxies used to connect the included studies' results to the research questions (RQs). The supporting evidence column provides available evidence in the literature about the association between the learning preference, style, or strategy and the proxies used.

Learning preference or strategy	Proxy	Source of the learning preference or strategy	Supporting evidence	RQ
Watching	Visual	Customized survey designed by Micheel et al [41]	Tendency toward watching lectures can be equivalent to a preference for visuals [41]	RQ1
Lecture	Visual	Customized survey designed by Abrahamsson and Dávila Lopez [55]	Tendency toward watching lectures can be equivalent to a preference for visuals [55]	RQ1
Assimilator	Visual	Kolb learning style inventory [57]	Assimilators are interested in learning through visual materials, such as videos and figures [57]	RQ1
Active	Teamwork	Felder and Soloman Index of Learning Styles [58,59]	Active students tend to work as a group and discuss learning materials with others [58,59]	RQ2
External	Teamwork	Danish Self-Assessment Learning Styles Inventory based on the theory propounded by Sternberg [60,65]	External students tend to work in a team and collaborate with others to solve problems [60,65]	RQ2
Internal	Independent work	Danish Self-Assessment Learning Styles Inventory based on the theory propounded by Sternberg [60,65]	Internal students prefer to work alone without communication with others [60,65]	RQ2
Reflective	Independent work	Felder and Soloman Index of Learning Styles [58,59]	Reflective learners are inclined to work alone or communicate with a close friend instead of a large group [58,59]	RQ2
Sequential	Sequential	Felder and Soloman Index of Learning Styles [58,59]	Sequential students have a linear learning process, which means they prefer to gain knowledge by following incremental and logical steps [58,59]	RQ3
Assimilator	Sequential	Kolb learning style inventory [57]	Assimilator students can organize the gained knowledge in a logical and clear format [57]	RQ3
Sensing	Factual information	Felder and Soloman Index of Learning Styles [58,59]	Sensing learners are interested in facts and concrete concepts, and they prefer exploring detailed information and intend to solve problems with standard approaches rather than innovative ones [58,59]	RQ4
Intuitive	Abstract information	Felder and Soloman Index of Learning Styles [58,59]	Intuitive learners are enthusiastic about abstract information, such as theories, and the deep meaning of learning materials [58,59]	RQ4
Global	Abstract information	Danish Self-Assessment Learning Styles Inventory based on the theory propounded by Sternberg [60,65]	Global students have the desire to solve abstract and huge problems [60,65]	RQ4
Local	Factual information	Danish Self-Assessment Learning Styles Inventory based on the theory propounded by Sternberg [60,65]	Local students prefer problems that need detailed and realistic solutions [60,65]	RQ4
Assimilator	Abstract information	Kolb learning style inventory [57]	Assimilators tend to prefer abstract ideas and concepts and are capable of perceiving a diverse range of information [57,66]	RQ4

Learning preference or strategy	Proxy	Source of the learning preference or strategy	Supporting evidence	RQ
Task oriented	Factual information	Customized survey designed by Gelbart et al [56]	The task-oriented student pair preferred specific tasks, and they did not always stay involved in all research steps; therefore, they only got a basic idea of what the research was about. They concentrated more on learning the details [56]	RQ4
Research oriented	Abstract information	Customized survey designed by Gelbart et al [56]	Research-oriented students are high achievers who are highly motivated to learn concepts with a deep understanding. They focus on generating abstract ideas and explanations that are connected to theoretical concepts [56]	RQ4

Information Presentation Preference (RQ1): Multimodal With Higher Tendency Toward Visual Presentation

Of the 8 studies included in this systematic review, 5 (62%) explored the preference of students regarding the type of presentation [41,45,52,54,55]. All these studies reported that students in HDS-related courses prefer visual presentations and benefit more from visualizations than from audio or reading types of presentations. However, all articles also acknowledge that students are multimodal learners and do not have only 1 preference regarding information presentation. In other words, if students prefer visual presentations, such as watching videos, it does not necessarily mean that they do not have any tendency toward reading or other types of presentations; for instance, Micheel et al [41] investigated the learning styles of oncology health care professionals learning precision medicine from web-based educational materials, and their research study showed that 80% of the learners had multimodal learning styles: the majority of the learners (39%) preferred watching, listening, and reading, while the next largest group (19%) preferred watching and reading. Abrahamsson and Dávila Lopez [55] analyzed the learning preferences of graduate students in 5 web-based bioinformatics-related courses and found that 91% of the students preferred synchronous and asynchronous lectures, which include visual presentations, while only 9% favored reading materials. Li and Abdul Rahman [52] analyzed the learning styles of bioinformatics students using the FSILS and found that the majority of the students were visual learners (66%). Holtzclaw et al [45] investigated the learning styles of undergraduate genetics students in a bioinformatics module and reported that the most dominant learning style among the students was visual (82%) compared to verbal (18%). The results from these studies are consistent with other research [41,52,55] highlighting that the majority of students prefer visual presentations. Finally, the study by Diwakar et al [54] also found that HDS students prefer visual presentations. The authors used the Kolb learning style inventory to classify bioinformatics students into multiple learning preferences and found that the majority of learners were classified as assimilators (60%) [54]. Assimilators tend to learn visually and prefer to observe a clear explanation [57]. A summary of the results of the studies is presented in Table 1.

Collaboration Preference (RQ2): Inconclusive Evidence

Of the 8 included studies, 5 (62%) [45,46,52,53,55] focused on the collaboration preferences of HDS students, and the results were inconclusive (Table 1). Most of these studies (3/5, 60%) [45,52,55] demonstrated that approximately half of the students preferred teamwork, while the other half preferred to work individually. Conversely, 2 (40%) of these 5 studies [46,53] indicated that HDS students had a preference for working in groups.

The study by Holtzclaw et al [45] is 1 (33%) of the 3 studies that show no clear student preference regarding collaboration in HDS. In particular, the authors reported that 54% of the bioinformatics students were found to be active learners, who typically prefer collaborating with peers, and 46% were found to be reflective learners, who have a tendency to work independently [45]. The difference between the 2 groups was not significant enough to conclude that there was a clear preference for collaboration or individual work. Similarly, Li and Abdul Rahman [52] found that more than half (55%) of the undergraduate bioinformatics students in their study were categorized as active learners (a tendency to collaborate with others), with the rest being categorized as reflective learners (a preference to work alone) or neutral. Abrahamsson and Dávila Lopez [55] reported that approximately 50% of the bioinformatics students in their study preferred to work alone on course assignments, while the other half preferred to work in groups (19% preferred to study with the same group for all sessions, 19% preferred to study with different groups, and 12% preferred to work individually in the first sessions and then study in groups).

The study by Sani Ibrahim [46] is 1 (50%) of the 2 studies indicating HDS students' preference for working in groups. The author reported that 70% of the bioinformatics students participating in the study were active learners who performed better in groups. In addition, the findings from the study by Nielsen and Kreiner [53], who used the Danish Self-Assessment Learning Styles Inventory, demonstrated that students enrolled in an advanced health statistics course had a strong tendency to be external, which shows their preference toward teamwork, with 89.3% of the students scoring as strong or very strong in this dimension (Table 1). This strong preference for external scope style suggests that students are willing to work as a team and communicate with others.

Overall, no consistent conclusion can be drawn based on the studies regarding HDS students' preference for working individually or in a group. Abrahamsson and Dávila Lopez [55] discuss several possible reasons for this inconsistency: first, the academic level of students may influence their preferences—postgraduate students have a higher research workload and are busier, which may lead to a higher tendency to work alone. Second, the type of assignment can influence students' working preferences; for example, the authors encouraged students to adopt paired programming for their programming assignments, and this optional approach was adopted by 85% of the bioinformatics students in their study, highlighting the effect of including activities in course design to promote student interactions. Finally, according to the authors, another possible reason could be the course platform because collaboration can be difficult in web-based courses.

Learning Process Organization Preference (RQ3): Sequential Learning Is More Popular

According to 3 (38%) of the 8 studies [45,52,54], the majority of HDS learners tend to have a sequential learning preference for organizing their learning process. Li and Abdul Rahman [52] found that 62% of their study participants had a sequential learning preference, while Holtzclaw et al [45] reported an even higher percentage of 75% (Table 1). Diwakar et al [54] also supported this conclusion, with 60% of their student population being assimilators, who tend to organize information logically and with clear order [57]. However, we should note that the number of studies that explored this dimension of preference is low, and further research is required to draw strong conclusions.

Focus Granularity Preference (RQ4): Higher Preference Toward Abstract Information

Of the 8 papers included in this systematic review, 5 (62%) provide evidence regarding the focus of students on abstract versus detailed information [45,46,52-54], with the majority of these papers (4/5, 80%) [46,52-54] agreeing that HDS students prefer main and abstract ideas (refer to Table 1 for further details).

The evidence regarding students' preferences for detailed or abstract information can be identified from the different learning styles reported (eg, intuitive or sensing, global or local, assimilator, executive, and research or task oriented) in the learning inventories used by these 5 studies. The study by Li and Abdul Rahman [52] found that the percentage of intuitive students (48%) was higher than that of sensing students (approximately 30%), while approximately 20% of the students were neutral in this dimension. Intuitive students prefer to focus on abstract ideas rather than detailed and factual knowledge, and they use a creative approach to problem-solving [58]. Similarly, Sani Ibrahim [46] expanded on the findings of Li and Abdul Rahman [52] and after using their data in addition to Moodle data, concluded that 94% of the bioinformatics students were intuitive. In the study by Diwakar et al [54], students were mostly assimilators (60%), who typically focus on abstract ideas and concepts. In addition, Nielsen and Kreiner [53] showed that HDS students tend to be slightly more global (ie, have the intention to solve abstract problems) rather than local (ie, have

the desire to address detailed and realistic problems). Although the difference in the average scores for the 2 groups is small (Table 1), a much higher percentage of students (approximately 30%) scored strongly or very strongly as global compared to local (approximately 11%).

In contrast to the aforementioned studies that indicate a preference for abstract information, Holtzclaw et al [45] found that most students (67%) had a preference for sensing learning, preferring to focus on factual and detailed information.

In addition to the aforementioned 5 studies, Gelbart et al [56] identified 2 learning approaches among high school biology students in a bioinformatics-related course: research oriented (where abstract ideas are valued more highly) and task oriented (where there is attention to detail and focus on factual knowledge). However, this study included only 4 participants (research oriented: 2 and task oriented: 2), with insufficient evidence for addressing the particular RQ.

In conclusion, there is some evidence supporting the inference that HDS students prefer abstract information. However, it should be noted that there are also contradictory findings, and further research is needed to arrive at a more solid conclusion.

Discussion

Overview

A total of 8 articles that were published between 2005 and 2021 were included in the synthesis step. The synthesized results show that most HDS learners prefer visual presentations as their learning input. Regarding learning process and organization, they mostly prefer to follow logical, linear, and sequential steps. In addition, they focus more on abstract information, rather than detailed information. In terms of collaboration, HDS students prefer a mix of teamwork and independent work. On the basis of the findings of this systematic review, we provide herein some suggestions for future research and some recommendations for improving the design of HDS courses.

Recommendations for Course Design

It is known that student preferences can guide course instructors in designing more effective courses [10,22,24]. On the basis of HDS students' preference for visual presentation of information, it would be beneficial to include more attractive plots, flowcharts, and visual graphics within the course materials to make them more visually impressive.

Given HDS students' inclination toward sequential learning, where they organize their learning process in logical and clear steps, it would be advantageous to consider a stepwise approach in course design. Including step-by-step instructions for practical implementations or dividing concepts into meaningful sequential parts, may also benefit students; for example, Holtzclaw et al [45] designed a bioinformatics module based on students' learning styles, containing highly visual components and facilitating sequential learning. On the basis of postcourse feedback, students rated this module as valuable for their educational goals.

In terms of collaboration preferences, there is no consistent conclusion based on existing studies. Therefore, we recommend

designing HDS courses in such a way that students can choose freely between individual work and teamwork. This includes coursework where both types of assignments are offered.

Our final suggestion is that, given the evidence regarding the higher focus of HDS students on main and abstract ideas (as opposed to detailed information) and their tendency to apply a creative approach to problem-solving, it would be advantageous to reduce the details in the main course materials and instead include them in an appendix. In addition, creating challenging assignments that prompt reflection on abstract concepts and encourage the use of intuitive approaches for problem-solving can be beneficial for HDS students.

Although the aforementioned recommendations are based on the preferences of the majority of students in the reviewed studies, it is essential for educators to be aware of the heterogeneity of students' learning preferences and diversify HDS course design accordingly [53]. As the suggestions presented in this systematic review are based on a limited number of available studies, it is essential for educators to carefully consider the context of their specific course and student population when integrating these suggestions into their course design.

Guidelines for Future Studies

Additional research is needed to explore learning preferences and strategies in HDS courses, especially considering the conflicting findings in certain learning preferences (eg, collaboration preference and preferred focus granularity). In this subsection, we provide some suggestions for future studies.

First, we recommend the use of log data and data mining methods to analyze learning preferences and strategies in HDS courses. The majority of the included studies (6/8, 75%) entirely relied on self-reporting questionnaires or think-aloud protocols [41,53,56]. However, several studies have shown that self-reported inventories may not accurately reflect the actual behavior of learners because the learners may over- or underestimate their learning preferences or learning strategies [10,67]. To avoid this bias, we suggest using log data from learning platforms and data mining methods to accurately analyze the actual behaviors of students and uncover their learning preferences and strategies [10,68,69]. Applying data mining tools on log data can also help to analyze the temporal and dynamic behavior of students over time [70]. Recent studies [10,71] have demonstrated that using data mining tools uncovers students' preferences or strategies, which are dynamic and highly correlated with their performance [72]. As students may change their learning preferences and strategies throughout their interaction with a course [10,73], it is important to shed light on such changes. In this review, data-driven methods were used only by 2 (25%) of the 8 studies [46,52], which, however, were not well designed because they did not identify students' learning preferences based on the log data. Instead, they applied the FSILS to identify students' learning styles and then used the identified learning styles based on self-reported data as labels to train a model using log data; for example, Li and Abdul Rahman [52] only trained a computational model based on self-reported data instead of finding students' learning preferences using an unsupervised approach.

Second, it is necessary to analyze larger samples to strengthen the results and increase the generalizability of the findings. As mentioned earlier, all included studies except for that by Micheel et al [41] analyzed courses with <100 learners, which can be a limitation depending on the type of analysis conducted. The study by Gelbart et al [56] had a sample size of only 2 pairs of students. Although the study used qualitative analysis, the number of students considered and the information reported about them seem insufficient to support the authors' conclusion regarding the learning approaches of students [56]. Therefore, researchers, depending on the type of analysis (quantitative or qualitative), should be aware of the importance of having a suitable sample size to minimize the risk of bias in their conclusions [74,75].

Third, most of the included studies (5/8, 62%) did not report the demographic information of students. This is an important omission because students' nationality, race, and culture may affect their learning preferences [52]. To minimize the impact of other factors on the students' preferences and capture the preferences related solely to the HDS discipline, future research needs to include a diverse range of learners in terms of nationality, race, and other demographic characteristics. It is worth mentioning that in this systematic review, we examined the learning strategies and preferences of students across different academic levels, but no statistically significant differences were found between the different levels. Nevertheless, it is important to note that students' academic levels may influence their learning strategies and preferences. This aspect requires further investigation in future studies.

Finally, future studies should focus on students' learning strategies rather than learning styles because learning strategies are known to provide more useful information about a field in comparison with learning styles [10,13,76]. In addition, previous research has shown that learning strategies are highly associated with students' academic performance [77,78], while the association between learning styles and performance is controversial [76,79]. Among the 8 included studies, only 1 (12%) [56] discussed the learning strategies of HDS students, which was limited to self-reported data and had a very small sample size. Overall, much more needs to be done to gain comprehensive knowledge about HDS students. We encourage researchers to explore learning strategies in HDS courses using both log data and self-reported data.

Limitations

A limitation of this systematic review concerns the small number of studies included (n=8). Although we were systematic in our review and synthesis of these 8 studies, we acknowledge that it is a small number of studies, and therefore the results should be interpreted with caution.

Second, the heterogeneity among the included studies required the use of proxies to synthesize the results, and using meta-analysis was impossible due to the diverse measurements used across the studies. Although this systematic review defined meaningful and valid proxies to connect the heterogeneous pieces of evidence in the included studies, the use of different inventories in the studies to measure learning preferences and strategies can affect the accuracy of our findings.

It is worth mentioning that none of the included studies labeled their courses as “health data science” courses; the majority (6/8, 75%) referred to them as bioinformatics courses. It is important to note that in this systematic review, HDS is defined as a discipline in which students use computational methods and tools to analyze biological, health, or medical data. We did not include courses that focus on non-data analytics aspects, such as mobile health or electronic health records. Therefore, the findings of this systematic review may not apply to non-data analytics courses in health informatics.

Regarding the search queries and inclusion criteria, our study only included primary research studies in English published in journal and conference formats. In addition, due to the wide range of terminologies used in the literature to describe learning preferences and strategies, some relevant studies might have been overlooked given the search keywords used in this review; for example, we did not use the keyword “learning approach” in our search query, which could have resulted in additional studies for inclusion.

Moreover, due to the high occurrence of false positives in the search results obtained through SpringerLink and Wiley Online Library, our query for these 2 databases was restricted to studies that included the keyword “student” in their abstracts, which could have led to studies involving health care professionals being overlooked.

Regarding the quality of the included studies, while the MMAT serves as a powerful tool with low bias in assessment [80], it should be acknowledged that the assessment of the quality of included papers can be subjective. However, the 3 reviewers who assessed the quality of the included articles have different academic backgrounds and levels of expertise, which can potentially mitigate the associated bias.

Finally, students’ learning preferences and strategies can be influenced by the mode of course delivery (eg, web based or face-to-face) and course design [11]; therefore, teachers and course designers should not solely rely on the findings of this study without considering other factors that might influence

students’ learning strategies and preferences. In addition, some suggestions within this review may specifically apply to web-based courses; for instance, the recommendation to use learning analytics to analyze students’ learning behavior to identify dynamic learning strategies is not feasible for face-to-face courses.

Conclusions

We reviewed the literature to identify student learning preferences and strategies in HDS courses. The PRISMA guidelines were used, and, as a result, 8 papers were included for narrative synthesis. The synthesis of these studies provided evidence that most HDS students are visual and prefer learning through visual materials, such as videos, diagrams, plots, and so on, as part of their learning process. They also tend to follow logical and sequential steps in their learning process, and they are inclined to focus more on abstract information than on factual and detailed information. Moreover, there is no agreement among existing studies regarding students’ collaboration preferences (teamwork vs independent work). HDS students might prefer to work alone on some assignments, while sometimes they prefer to work as part of a team.

On the basis of the reviewed studies, we recommend including more visual and less detailed materials in HDS courses, accompanied by stepwise instructions.

Furthermore, to address the limitations of existing studies, future research should consider using log data instead of self-reported questionnaires to capture the actual HDS learning experience. Including a large sample of students from different backgrounds and races can also strengthen research results and reduce the impact of other cofactors unrelated to the HDS discipline.

In addition, analyzing the learning strategies of students, rather than their learning preferences, has the potential to yield deep insights into HDS education because learning strategies are more associated with student performance. Overall, because a small number of studies have investigated learning preferences and strategies in HDS courses, further research is needed to draw definitive conclusions.

Acknowledgments

This work was supported by the Medical Research Council (grant MR/N013166/1). The authors would like to thank the funder and the Precision Medicine Doctoral Training Programme of the University of Edinburgh for their support for this research study. The authors also thank Dr Michael Gallagher and Dr Kobi Gal for their support and constructive discussions about students’ learning strategies.

Data Availability

All data generated or analyzed during this study are included in this published article and its supplementary information files.

Authors' Contributions

NR and AM conceptualized and designed the project. NR and SS screened and reviewed the papers, while AM served as the third screener to resolve any conflicts between the 2 screeners. NR synthesized and wrote the first draft of the paper, and AM and SS assisted in enhancing the written work. AM supervised this project. All authors have read and approved the final version of the paper.

Conflicts of Interest

None declared.

Abstract

For more than 50 years, digital technologies have been employed for the creation and distribution of knowledge in health services. In the last decade, digital social media have been developed for applications in clinical decision support and population health monitoring. Recently, these technologies have also been used for knowledge translation, such as in the process where research findings created in academic settings are established as evidence and distributed for use in clinical practice, policy making, and health self-management. To date, it has been common for medical and public health institutions to have social media accounts for the dissemination of novel research findings and to facilitate conversations about these findings. However, recent events such as the transformation of the microblog Twitter to platform X have brought to light the need for the social media industry to exploit user data to generate revenue. In this viewpoint, it is argued that a redirection of social media use is required in the translation of knowledge to action in the fields of medicine and public health. A new kind of social internet is currently forming, known as the “fediverse,” which denotes an ensemble of open social media that can communicate with each other while remaining independent platforms. In several countries, government institutions, universities, and newspapers use open social media to distribute information and enable discussions. These organizations control their own channels while being able to communicate with other platforms through open standards. Examples of medical knowledge translation via such open social media platforms, where users are less exposed to disinformation than in general platforms, are also beginning to appear. The current status of the social media industry calls for a broad discussion about the use of social technologies by health institutions involving researchers and health service practitioners, academic leaders, scientific publishers, social technology providers, policy makers, and the public. This debate should not primarily take place on social media platforms but rather at universities, in scientific journals, at public seminars, and other venues, allowing for the transparent and undisturbed communication and formation of opinions.

Introduction

Digital technologies have been used for the creation and distribution of knowledge in medicine and public health for more than 50 years. In addition to their applications for clinical decision support and population health monitoring [1-5], in the last decade, digital social media have been used for knowledge translation [6] such as in the process of establishing research findings as scientific evidence and distributing these findings for use in clinical practice, policy making, and health self-management. However, in May 2023, an editorial in *Lancet Digital Health*, a leading digital health journal, stated that the social media industry serves as “a commercial determinant of health due to the indirect health consequences of its business practices and actions” [7]. Eight months earlier, the entrepreneur Elon Musk had taken control of the microblog Twitter with a US \$44 billion deal. At the time, Twitter was the social media platform most frequently used for knowledge translation and

opinion formulation in the fields of medicine and public health. In one of his first actions as Chief Operating Officer, Musk laid off approximately 80% of the company’s employees [8] and phased out most of the content moderation work that countered disinformation and misbehavior [9]. In addition, Musk allowed previously suspended users such as Russian state actors to reactivate their accounts [10]. Changes to the platform also made it essentially impossible for researchers to study the activities occurring on Twitter [11]. Users with verified (paid) accounts were only allowed to read 6000 posts per day, those with unverified accounts could read 600 posts, and new users with unverified accounts could read 300 posts per day. This action exposed that the rationale for the verification and dissemination procedures on the platform is based on financial rather than social capital; consequently, the possibilities for external observers to inspect interactions had been made almost nonexistent. The dismantling of Twitter was manifested by renaming the service X in July 2023, thereby completing the transformation of the platform.

To date, it has been considered standard practice for academic and health service institutions as well as for individual researchers and practitioners to have social media accounts for the dissemination of research findings, access to topical information, and participation in debates about novel discoveries. However, the transformation of Twitter to platform X highlights new threats to the presence of health institutions on social media platforms; in particular, the rational translation of scientific knowledge to health action is currently at stake. In this viewpoint, it is argued that a redirection of social media use is needed with respect to the translation of knowledge to action in medicine and public health.

Social Media Platforms as Transformative Technologies

More than 60 years ago, mass communication researchers pointed out that the introduction of any novel information technology has the potential to change the shape and character of the affected community [12,13]. Without much forethought or debate, in many countries, social media platforms have become organic components of the information infrastructure. For instance, in Sweden, the proportion of the population regularly following national news broadcasts on the radio and television remained constant between 2009 and 2020, while the proportion of social media users increased from 33% to 78% and the proportion subscribing to printed morning newspaper decreased from 70% to 24% during this same time period [14].

Public institutions active on social media typically choose a platform that they consider generally agrees with the content they want to disseminate; universities and scientific journals share research findings on microblogs such as platform X, whereas cultural authorities tend to use TikTok to share visual content and elementary schools share information in Facebook groups. Even before Twitter was rebranded as platform X, the microblog was associated with several problems and challenges that could have a potential impact on knowledge translation, especially concerning the verification of posted and shared information [15]. The decision made by Elon Musk and his managerial team to reduce the possibility for researchers to analyze the content and interactions occurring on the platform brings to light the fact that a large share of these issues can be traced back to the need for the social media industry to exploit user data to generate revenue.

The logic underpinning such user and customer misuse can be explained by the “life cycle” model of social media platforms [16]. Initially, while financed by seeding financial capital, the platforms produce value for their primary users; the platforms then exploit the users to produce value for business customers and then finally also exploit their business customers to maximize the value for the owners, which eventually leads to death of the platform. The life cycle model thus highlights that small efforts needed to change the operation of social media platforms can serve to rapidly redistribute value between stakeholders in a “two-sided market,” where the platforms sit between users and producers of information. For example, user value is downplayed to produce value for business customers when platform algorithms are tuned to reward conflict-making

and fragmentation with the goal of generating more views of posts, which, by extension, increases the display of ads paid for by business customers [17]. A recent study of news dissemination on Facebook [18] reported the greater circulation of conservative than liberal news domains, and indicated that a larger share of the news content was labeled as “false” in the conservative domains than in the liberal domains. The explanation provided by the authors for the faster propagation of conservative content, which has also been observed in other studies [19,20], was that false news stories disseminate faster on social media than true stories because false news items have more “novelty” and tend to arouse more emotions such as fear, disgust, and surprise than true news [21]. The authors argued that the Facebook functions Pages and Groups constitute a news curation and dissemination machine [22], which could then be available to any interest group for manipulation of public opinion [19] or intentionally fracturing an information ecosystem [23].

The Fediverse and Open Social Media

The problems associated with current social media platforms indicate that if social technologies are to be used for knowledge translation in medicine and public health, this translation should only take place on digital platforms where users are not exploited to create value for the platform’s business partners and investors. The fediverse concept denotes an ensemble of open social media that can communicate with each other while remaining independent platforms [24]. With the emergence of open microblogs such as Mastodon [25] and Bluesky [26], the photo-sharing service Pixelfed [27], and the video service PeerTube [28], users can choose how they want to participate and own their data. Users sign up to specific instances in the fediverse and these instances host their data. The instances are operated by various actors, ranging from the Mastodon project to public institutions, for-profit corporations, nonprofit organizations, and groups of individual users. Technically, the fediverse consists of interconnected network servers running software applications that can read and write the same content.

The open architecture of the fediverse can be compared to that used for email messaging. The email user does not have to compose, organize, and read messages in the same software application, and two users do not have to use the same tools to communicate. The underlying idea is that email simply represents a source of data, and thus many software applications should be able to understand and manipulate these data. In other words, although email applications can have different interfaces, privacy policies, and purposes, every email application can interpret the meaning of an email address and every email address can send messages to every other email address, regardless of the application used. Similarly, if a user posts on Mastodon in the fediverse, another user can see the post in their Pixelfed feed.

The key enabler of the fediverse has been ActivityPub, a communication protocol overseen by the World Wide Web Consortium. More recently, other similar protocols have appeared, including AT managed by Bluesky. In Germany, government institutions, universities, and newspapers have

already begun using such forms of open social media [29]. This enables these organizations to control their own channels while still being able to communicate with other platforms through the open standards. In several other countries, many institutions, ranging from public service organizations such as the BBC in England to civil society organizations, have chosen to establish themselves with official accounts at alternative digital platforms. However, reliable data on the magnitude of the migration to alternative digital platforms remain scarce. One early study estimated that approximately 2% of Twitter users deleted their accounts and left the platform for the Mastodon project within the first weeks following the Musk takeover [30]. Approximately 15% of the followers of these users migrated to the exact same Mastodon instance as that of the users they follow. While the larger Mastodon instances attracted more users (the 25% largest instances on Mastodon attract 96% of users), the smaller instances, directed toward specific topics, attracted the more active users.

Translation of Health Knowledge on Social Media

Based on their responsibility for the peer review, verification, and distribution of research findings, scientific journals play a central role in knowledge translation. Medical and public health journals currently use social media platforms for the promotion and dissemination of content, branding, and facilitating conversation [31,32]. Although the number of social media posts shows a positive correlation with journal Altmetric scores and impact factors [33,34], there is no evidence for causal associations between social media activity and improved knowledge translation. Typically, approximately 40% of all scientific literature is posted on social media [35]; however, half of these posts draw no clicks to the underlying research, whereas an additional 20% of the posts receive only one or two clicks [36]. Moreover, the citation of articles by other researchers will not benefit from social media posting [37]. Instead, the social media presence of scientific journals may indirectly impede rational knowledge translation by luring potential users of new health knowledge to digital environments where research evidence is not necessarily discriminated from unrestrained streams of disinformation. Therefore, medical and public health journals have multiple motivations for reevaluating their social media presence and considering movement to open platforms or even leaving social media altogether. Reconsidering their social media presence is also relevant for the academic and health service institutions that produce and use the knowledge managed by scientific publishers. Establishing accounts and developing the ability to communicate on open microblogs such as Mastodon and Bluesky have become a technically viable alternative along with the use of open

standards and protocols such as ActivityPub and AT. By moving to open social media platforms, health institutions can create a digital community that owns and operates their own channels for communication with each other, policy makers, and the public. Open platforms are not susceptible to the capriciousness of private companies and can also provide channels for the dissemination of unaltered health knowledge required during contingencies such as a pandemic. However, moving only one or a few health institutions from platform X to open platforms will not suffice in creating such digital environments.

Toward a Social Internet for Medicine and Public Health

A new kind of social internet is currently forming. As of February 2024, approximately one-fifth of daily Twitter/X users had left the platform since the Musk takeover in 2022 [38,39]. Considering the status of the social media industry, a short-term goal of medical and public health institutions should begin with contemplating the purpose of their social media presence and explaining how they protect health science beneficiaries from being misled by disinformation (eg, whether and how they promote science literacy [40]) among their followers.

In parallel, a broad discussion is needed about the use of social technologies for knowledge translation in medicine and public health. Examples of translation of medical knowledge in social media platforms where users are less exposed to disinformation are beginning to appear [41]. However, the new social internet also offers possibilities for novel, innovative forms of knowledge translation (eg, in demanding settings such as global health contingencies). For instance, as grounding for a synchronized response to a future pandemic, social media instances with purposive interaction rules [42] can proactively be created in interpandemic periods. Here, instances can be created for separate professional disciplines (from virologists to modelers) and policy-maker categories (from public health officers to politicians) [43]. In parallel, a set of orthogonal instances, organized as multidisciplinary networks, can be created where the professionals and policy makers can collaborate in local and regional response programs [44].

Continued discussion about the use of social media for knowledge translation in medicine and public health should involve researchers and health service practitioners, academic leaders, scientific publishers, social technology providers, policy makers, and the public. This debate should not primarily take place on social media platforms but also at universities, in scientific journals, at public seminars, and other venues, enabling the transparent and undisturbed communication and formation of opinions.

Acknowledgments

The preparation of this viewpoint article was supported by grants from the Swedish Research Council (VR 2021–05608, VR 2022-05608), Region Östergötland (ALF–936190), and the Research Council of Southeast Sweden (FORSS–940915).

Abstract

Large language models (LLMs), like ChatGPT, are transforming the landscape of medical education. They offer a vast range of applications, such as tutoring (personalized learning), patient simulation, generation of examination questions, and streamlined access to information. The rapid advancement of medical knowledge and the need for personalized learning underscore the relevance and timeliness of exploring innovative strategies for integrating artificial intelligence (AI) into medical education. In this paper, we propose coupling evidence-based learning strategies, such as active recall and memory cues, with AI to optimize learning. These strategies include the generation of tests, mnemonics, and visual cues.

KEYWORDS

artificial intelligence; large language models; ChatGPT; active recall; memory cues; LLMs; evidence-based; learning strategy; medicine; AI; medical education; knowledge; relevance

Introduction

e-Learning has revolutionized the way medicine is taught and learned through the use of different internet-based technologies that enhance education [1]. Among these technologies, artificial intelligence (AI) tools, especially large language models (LLMs), have notably garnered significant attention in recent years, given their promising implications for medical education. LLMs are algorithmic models that are trained by extensive data sets, and they have the capability to comprehend text and generate natural-language text in response to a given prompt (input). This allows for interactive engagement with these technologies in a conversational format akin to a “chat” [2,3]. One of the most known LLMs is ChatGPT (owned by OpenAI), and its latest version, ChatGPT-4, was recently released to the public.

Recent studies have demonstrated the great achievements of LLMs in relation to medical knowledge and reasoning, such as ChatGPT-4 scoring 90% when answering USMLE (United States Medical Licensing Examination)–type questions [4], ChatGPT-4 passing a neurosurgery written board examination [5], and ChatGPT outperforming physicians in terms of providing empathic responses [6]. The educational potential of this technology is immense, encompassing a wide variety of applications. These include but are not limited to tutoring (personalized learning), patient simulation, generation of examination questions, and streamlined access to information

[7-9]. The revolutionary potential of LLMs has resulted in researchers and medical students exploring the integration of AI into medical school curricula [10,11]. The rapid advancement of medical knowledge and the need for personalized learning underscore the relevance and timeliness of exploring innovative strategies for integrating AI into medical education [12].

Although numerous publications have examined the implications of LLMs for medicine and medical education, few have explored, in detail, specific strategies whereby LLMs can be used to optimize learning. In this paper, we propose strategies based on active recall, mnemonics, and the use of ChatGPT-4 [13] and DALL·E 3 (through ChatGPT-4) for enhancing learning outcomes regarding factual knowledge and thus help fill this gap of information. These strategies include the creation of pretests and posttest quizzes, the development of mnemonics, and the use of visual cues and mnemonics. Pretests and posttests serve as effective tools for active recall—a proven method for improving memory retention. Mnemonics simplify complex information into more digestible and memorable formats. Visual cues provide a graphical representation of information, aiding in better understanding and recall.

Active Recall–Based Strategies

Medical school requires a significant amount of time spent on reading. Research indicates that medical students typically dedicate an average of 1.5 to 6 hours per day to reading [14,15]. Moreover, teacher-centered lectures, which predominantly focus

on passive learning, persist as one of the most used strategies despite challenges in the medical education community with regard to encouraging integration with active learning methods that enhance the retention and application of knowledge [16-18]. This may be because medical school students might prefer classic didactic lectures over demonstrations, small group discussions, feedback activities, group work (generating test questions and coming up with solutions to a problem), and other active learning methods that have been reported to better enhance memory and retention [19].

It is essential to adopt evidence-based strategies to enhance learning efficiency, especially considering the substantial academic workload and the ongoing reliance on passive learning methods. One such strategy is active recall, which involves actively retrieving information that was initially acquired passively through lectures, articles, or videos. This strategy is known to enhance learning significantly in comparison with passive learning strategies [20,21]. In this context, it is beneficial for readers to approach their reading proactively. This can be achieved by prefacing their reading with self-directed inquiries, understanding the main topics of the material, consistently formulating questions, and recognizing key concepts of high

significance. Some related techniques include elaborative interrogation, which consists of answering “why” questions about a given concept to enhance medium- to long-term associative memory; self-explanation to relate new information to known information or explain steps taken for solving a problem to improve memory, comprehension, and transfer; and practice testing, which can improve memory, is not as time consuming, and can be applied at different times of the learning process [20].

One application of an active recall-based strategy involving the use of AI is illustrated in [Figure 1](#), which shows ChatGPT being instructed to generate questions about cellulitis, as an example. Students are encouraged to attempt such questions before starting lectures or reading text. Answering questions before attending a lecture or reading a text (pretesting) is a strategy that enhances the learning process [22]. Interestingly, making mistakes during the study process can enhance learning by improving later memory; generating correct feedback; facilitating active learning; and stimulating the learner to redirect attention appropriately, especially when a mistake is followed by corrective feedback [23,24].

Figure 1. Example of the use of ChatGPT for pretesting.

Taking tests has been proven to enhance learning in various studies [25-28]. Repeated test-taking increases the transfer of learning [25] and improves long-term recall [28], and it even outperformed concept mapping for long-term retention in a previous study [26]. This strategy can be integrated with AI, as shown in Figure 2, which depicts our attempt to extract information from a *StatPearls* article on cellulitis [29] and request ChatGPT to generate relevant questions. The AI system can produce various question formats, such as multiple-choice, true-false, and fill-in-the-blank questions, when given the appropriate prompts. These questions may be stored and reviewed days or weeks after the initial review to successfully

apply spaced repetition, which has been demonstrated to improve learning and the consolidation of knowledge [21].

By using this method, one can input answers to questions and prompt ChatGPT to evaluate the answers' accuracy against the provided text. For instance, using questions from Figure 2, we tested ChatGPT's response by answering a query about common causative bacteria of cellulitis. We intentionally incorporated broad, correct concepts (gram-positive bacteria) and specific yet erroneous details (emphasizing staphylococci, particularly *Staphylococcus aureus*, as primary causatives instead of the correct streptococci) (Figure 3). ChatGPT feedback was tested again to contrast it with the feedback on a completely wrong answer (Figure 4).

Figure 2. Example of the use of ChatGPT for creating a posttest.

Figure 3. Feedback from ChatGPT on a partially correct answer to a question provided by ChatGPT.

Figure 4. Feedback from ChatGPT on a wrong answer to a question provided by ChatGPT.

Memory Cues

Memory cues are learning strategies in which a process of metacognition transforms information in a way that makes the information easier to recall or understand. Cues can be self-generated or generated by external agents, other people, or AI. Evidence has long suggested that self-generated cues are superior to cues generated by other people [30,31]. Nonetheless, there is available evidence that indicates that memory cues generated by others can still enhance recall [32].

Memory cues are effective because they make difficult-to-remember information into something simpler or meaningful, which facilitates recall [32,33]. For example, a

classic memory cue in medical school for remembering descriptors of pain is the use of the mnemonic “SOCRATES” (site, onset, character, radiation, associations, time course, exacerbating factors, and severity). In this context, the name of the great philosopher is repurposed to recall how to properly assess pain in a patient, with the name becoming an acronym. In a recent meta-analysis, a statistically significant effect was found for cueing decreasing the learners’ perceived cognitive load and promoting learning outcomes, namely retention, and the transfer of knowledge [34].

Other modalities of memory cues that are commonly used include pictures, short stories, songs, and rhymes [32]. Evidence indicates conflicting conclusions regarding the superiority of a specific modality of cues over another. For instance, in a study

conducted by Pearson and Wilbiks [35], the authors attempted to evaluate the effect of the number of self-generated memory cues and aimed to test the findings of previous research that showed that the use of multisensory memory cues (ie, audiovisual cues) had a greater effect on recall than the use of one modality (ie, either visual cues [written words] or auditory cues [spoken words]). Their findings were that a greater number of cues led to higher recall, with statistical significance, but the modality of the cues did not have an effect on recall.

As previously indicated, one way to enhance the creation of an effective mnemonic is by using a common word as a cue to recall information [33]. This is one of the various ways that learners attempt to encode new vocabulary, abstract concepts, and master knowledge.

Figure 5 is an example of ChatGPT generating a mnemonic, using the word “brains” to recall the absolute contraindications of thrombolysis. Other examples are shown in Figure 6, in which ChatGPT creates a short story, and in Figure 7, in which ChatGPT creates a poem.

Figure 5. Acronym created by ChatGPT.

Figure 6. Short story created by ChatGPT.

Figure 7. Poem created by ChatGPT.

Visual Mnemonics

A visual mnemonic or cue is a tool that uses visual imagery to improve the recall of information. This differs from verbal mnemonics, which use words, phrases, or songs, as visual mnemonics use pictorial cues to forge memorable links. Their effectiveness stems from the incorporation of visual representations, analogies, or symbolism, which fortifies the associations and makes them more distinct. Visual mnemonics aid in recalling abstract or intricate information and facilitate both the sequential and the immediate retrieval of memorized material [36,37]. The use of mnemonics can be highly useful for learning difficult or abstract information [30], which is often found in the field of medicine [38]. Multiple studies have

demonstrated that using visual or pictorial mnemonics can enhance learning outcomes [35,39].

DALL·E 3 is an AI system created by OpenAI that generates images based on prompts provided by the user and can be used for the creation of visual mnemonics. An example is given in Figure 8; a prompt was given to DALL·E 3 to create an image. For this example, which we created via DALL·E 3, the prompt “Fat purple man with long hair falling into a trap in a dry desert” was used to help recall some important features of hairy cell leukemia. “Fat” was used to recall the massive splenomegaly seen in patients with this condition; “purple” was used to make an association with lymphocytes, which are commonly seen as purple cells via hematoxylin and eosin staining and are involved in the pathogenesis of this neoplasm; “long hair” helps with

recalling the filamentous projections of cells in hairy cell leukemia; “trap” was used to remember that this disease stains positively in tartrate-resistant acid phosphatase staining; and

“dry desert” was used to recall that bone marrow fibrosis leads to dry tap on aspiration.

Figure 8. DALL-E 3 creation with the prompt “Fat purple man with long hair falling into a trap in a dry desert.”

Discussion

Active Recall

Active recall is a highly effective learning strategy and significantly outperforms passive restudying when it comes to certain learning outcomes, such as conceptualization and long-term retention [21]. It has yielded better evaluation testing performance than traditional studying or rereading. Kornell et al [22] reviewed recall when participants were presented with fictional and nonfictional information, modifying the time for

pretesting and read-only strategies. The testing strategy yielded a greater amount of correct answers than the read-only strategy, with statistical significance when equal or more time was allocated to the testing condition when the final test was performed more than 24 hours after the learning exercise, as well as in the fictional topic scenarios ($P < .01$). Other studies supporting the use of pretesting have been reported [22,40,41]. This highlights the role of pretesting in learning new information.

The benefits of active learning through testing have also been supported by other authors. Butler [25] tested students' recall ability when they were either passively restudying or studying via repeated testing. Butler [25] found that repeated testing resulted in better performance on a recall test than passive learning strategies and concluded that repeated test-taking increases the transfer of learning. In another study performed by Karpicke and Blunt [26], when retrieval practice (testing) was evaluated against passive learning strategies and even concept mapping, it proved to be better for verbatim and inference question answering, resulting in an improvement of about 50% in long-term retention scores ($d=1.50$; $F_{1,38}=21.63$; $\eta_p^2=0.36$). Additionally, the superiority of retesting over passive restudying for long-term retention has even been proven in a randomized controlled trial, wherein pediatric and emergency medicine residents were randomized to study the same text passages either via testing or repeated studying (ie, rereading). They were then tested on day 1, week 2, week 4, and month 6. The test results showed that the scores of participants who studied via testing were, on average, 13% higher than the scores of participants who performed repeated studying ($P<.001$), with an effect size of 0.91 [28]. Spaced testing (taking tests on different days between study sessions) has an even better effect on retention, long-term memory, and evaluation performance than repeated test-taking [27]. On the other hand, research indicates that spaced repetition (regardless of whether studying is done actively or passively) promotes more efficient and effective learning [42].

The previously mentioned studies highlight the importance of leveraging evidence-based techniques for studying rather than passive learning strategies. As we exemplified, these strategies can be coupled with AI. This approach addresses the limitation of relying solely on teacher-provided tests or textbook tests [20]. Moreover, ChatGPT is available on different platforms (web application and mobile app), and it can save chats (interactions) across these platforms. Therefore, students can easily access ChatGPT wherever it is needed and space their study sessions. Further, self-testing with AI reduces the pressure of graded assessments and leverages errors as learning opportunities [23,24], which research has shown to be particularly effective when the learner is confident in their incorrect answers [23]. This could be related to the effect of feedback.

Several articles on active recall and learning emphasize the role of feedback in enhancing learning processes, which is a characteristic that passive studying lacks. Roediger and Butler [27] compared traditional studying with test-taking studying without feedback and test-taking studying with differently timed feedback to determine whether test-taking studying results in better retention and whether retention is enhanced by feedback. They tested participants at different times and highlighted the efficiency of test-taking as a studying strategy, which was superior to that of traditional reading and restudying (22%, 32%, and up to a 43% difference between traditional studying and test-taking studying without feedback, test-taking studying with immediate feedback, and test-taking studying with delayed feedback, respectively). Since feedback has a clear impact on learning, especially when coupled with active recall strategies,

non-AI-mediated active learning strategies could be limited by the lack of opportunities to offer feedback. Feedback generally comes from a reliable source, such as a teacher or an expert, or is obtained through an appropriate literature search, which can be time consuming. Sometimes, it is not possible to have the timely intervention of a teacher or an expert if there is a lot to study, and it may not be possible for a student to conduct a proper literature search if the student is new to a given topic. Furthermore, there are different types of feedback; some feedback is self-directed (ie, obtained through an introspective process). Feedback in the learning process can be used to enhance or develop skills for setting goals, monitoring one's own learning process, and assimilating input (feedback) toward enhancing performance [43]. All of these are important skills to have when one attempts to obtain feedback on their own, such as when using LLMs for feedback.

AI can enhance medical education by offering feedback and explanations to clarify incorrect responses, thereby increasing study efficiency. By using AI tools like ChatGPT, students can receive detailed feedback on their answers, including the identification of errors and the provision of correct information, as we have shown. ChatGPT presents promising implications in providing technically accurate medical feedback, given the exceptional knowledge it has exhibited, as we previously described. This process, however, should not replace thorough literature research or foundational knowledge acquisition. AI models can also serve as tutors to facilitate discussions on specific knowledge areas, similar to existing models in other fields, such as Khan Academy's Khanmigo, which serves as a fully personalized tutor [44]. One limitation of AI systems like ChatGPT is their character limit for inputs, which can be managed by breaking text into sections or using multiple prompts. Additionally, web searching is only available with ChatGPT's paid subscription; for the free version, one should provide ChatGPT with the reference text by copying and pasting it. Further research is needed to explore the potential of AI-assisted tutors in medical education, especially in education on basic subjects.

Memory Cues

Memory cues can be used as effective learning tools that ease the studying experience for a student attempting not only memorization but also mastery of complex concepts and new vocabulary. Evidence has described the superiority of self-generated memory cues over cues created by others [30,31]. The explanations behind the superiority of self-generated memory cues are (1) the generation effect of creating such cues, that is, the act of generation requires significant cognitive effort, which boosts memory, and (2) the cue selection process itself and the consequential metamnemonic effect. This means that students who identify the learning formats that work best for them are able to create their own memory cues by using a modality that is tailored to their needs [31]. For example, if a student prefers to have a visual representation of the ideas that they are attempting to memorize, they might lean toward the creation of mnemonics that create a mental picture to integrate information. Tullis and Fraundorf [31] proposed evidence that the benefits of self-generated cues come in great part from the correct selection of a cue from a list of candidates. If students

can create multiple cues, they can, with greater effectiveness, select the cue that best benefits retrieval. Tullis and Fraundorf [31] further suggested that allowing a learner to select from multiple options of cues requires less cognitive work, takes less time, and may not hinder memorization.

As we described, the act of generation is effortful and may be time consuming. AI tools like ChatGPT can help students as a result of their seemingly tireless and effortless generative capacity. In addition, these tools can create multiple cues with different modalities (textual-based cues and pictorial cues) when prompted to do so, thereby allowing learners to focus on understanding the material and selecting the most appropriate cue that fits their educational needs. The downside to the use of this method is that multiple attempts may be required for ChatGPT to produce a mnemonic that is subjectively good or fitting enough for a particular student. In addition, it is our opinion that these tools are best used when the user has an idea of what they should learn or memorize, and the user should prompt the AI tool to create a mnemonic device that facilitates the recall of the information they wish to encode. This is because there is abundant evidence of ChatGPT not only making errors but also blatantly providing false information [45], which is known as “artificial hallucination.”

Visual Mnemonics

Previous research has explored the effectiveness of visual mnemonics in improving learning outcomes. An experimental study that compared pictorial mnemonic use to traditional study methods found that pictorial mnemonics aid in learning from text passages by improving the recall of factual knowledge and long-term memory retention in college students [46]. Additionally, a randomized trial compared audiovisual mnemonics against traditional text-based learning for retaining medical knowledge; participants who used mnemonics demonstrated significant improvements in free-recall tests, with scores improving by 65%, 161%, and 208% immediately, after 1 week, and after 1 month, respectively, when compared to those who used text materials ($P < .001$). Moreover, the group that used mnemonics outperformed the group that used text materials by 55% in a 1-week–delayed multiple-choice test that focused on higher-order thinking ($P < .001$) [47]. In a comparative study of visual mnemonics versus traditional lectures for learning the porphyrin pathway, there was no significant difference in quiz scores immediately or 1 week after the intervention; however, the mnemonic group exhibited a 20% higher score 3 weeks later ($P = .02$) [48]. In another randomized trial that compared story-based audiovisual mnemonics with traditional text reading for memory retention among medical students, the audiovisual mnemonics group demonstrated significantly better performance in multiple-choice tests immediately after the intervention ($P = .04$), as well as at 1 week, 2 weeks, and 4 weeks after the intervention [49]. These results underscore story-based mnemonics’ superior effectiveness in enhancing immediate and long-term memory retention in medical education. Although there is some variation in the visual mnemonic techniques across studies (eg, the studies by Yang et al [47] and Abdalla et al [49] used some audiovisual mnemonics), they consistently demonstrated that factual

knowledge can be represented visually and that the use of this type of mnemonic enhances both the recall and long-term retention of knowledge, with large effect sizes.

The visual mnemonic proposed in our study highly resembles the strategy used in the experiment by Rummel et al [46], in which visual mnemonics were created from texts about psychologists, incorporating elements for recalling both the psychologists’ names and the key aspects of their theories. In our mnemonic, “long hair” aids in recalling the name of the disease (hairy cell leukemia), and the other elements in the image are used to help recall the disease’s main features. The Picmonic System, which uses mnemonics from a web-based educational platform [50] that was used in the studies by Yang et al [47] and Abdalla et al [49], also adopts the visual mnemonic approach by combining visual elements and storytelling to enhance the recall of information; this is also highly similar to our approach. Thus, using DALL·E 3 for mnemonic generation shows promise for improving different learning outcomes, such as test performance, long-term retention, and free recall. Future studies should experimentally investigate the effectiveness of visual mnemonics generated by text-to-image models in learning processes. A significant limitation of using DALL·E 3 for medical mnemonic generation is its restriction on explicit content, prohibiting prompts with terms like “blood.” By recognizing this limitation, knowledge area–specific text-to-image models can be developed to more accurately describe the information needed and enable the use of words that are commonly used in a knowledge area but are censored in current models. Another limitation is that creating stories that accurately reflect the intended factual knowledge for mnemonic cues can be complex, particularly for certain subjects. Effective prompt engineering techniques could help in creating more relevant and coherent visual mnemonics.

Conclusions

LLMs, as a form of AI, are transforming the landscape of medical education. They offer a vast range of applications, and their potential has sparked discussions about integrating them into medical school curricula. Active recall–based learning strategies can be integrated with AI and can promisingly improve the recall and retention of information. This integration can be effectively applied by using AI to generate pretests and posttest quizzes. Memory cues, including self-generated mnemonics and mnemonics created by AI, can effectively simplify and transform complex information, thereby enhancing recall and optimizing learning. ChatGPT can create multiple types of memory cues, such as acronyms, short stories, and even poems. Moreover, AI tools, like DALL·E 3, can create images based on text and thus can be used to create visual mnemonics. However, crafting the right prompts can be challenging and time consuming, and results may vary. Thus, we believe that the use of new AI-based technologies, such as ChatGPT and DALL·E 3, is a highly useful strategy for learning, especially when these technologies are used with evidence-based principles. Further research is warranted to elucidate the impact of these strategies within the context of medical education.

Acknowledgments

JPAI designed and conceptualized the work. JPAI, JAPN, JPDS, and GCS gathered the data and performed the interpretation. JPAI, JAPN, and JPDS drafted the manuscript. JPAI, JAPN, JPDS, and GCS reviewed and corrected the final version of the manuscript. All authors have read and approved the final version of the paper.

Abstract

A significant component of Canadian medical education is the development of clinical skills. The medical educational curriculum assesses these skills through an objective structured clinical examination (OSCE). This OSCE assesses skills imperative to good clinical practice, such as patient communication, clinical decision-making, and medical knowledge. Despite the widespread implementation of this examination across all academic settings, few preparatory resources exist that cater specifically to Canadian medical students. MonkeyJacket is a novel, open-access, web-based application, built with the goal of providing medical students with an accessible and representative tool for clinical skill development for the OSCE and clinical settings. This viewpoint paper presents the development of the MonkeyJacket application and its potential to assist medical students in preparation for clinical examinations and practical settings. Limited resources exist that are web-based; accessible in terms of cost; specific to the Medical Council of Canada (MCC); and, most importantly, scalable in nature. The goal of this research study was to thoroughly describe the potential utility of the application, particularly its capacity to provide practice and scalable formative feedback to medical students. MonkeyJacket was developed to provide Canadian medical students with the opportunity to practice their clinical examination skills and receive peer feedback by using a centralized platform. The OSCE cases included in the application were developed by using the MCC guidelines to ensure their applicability to a Canadian setting. There are currently 75 cases covering 5 specialties, including cardiology, respiratory, gastroenterology, neurology, and psychiatry. The MonkeyJacket application is a web-based platform that allows medical students to practice clinical decision-making skills in real time with their peers through a synchronous platform. Through this application, students can practice patient interviewing, clinical reasoning, developing differential diagnoses, and formulating a management plan, and they can receive both qualitative feedback and quantitative feedback. Each clinical case is associated with an assessment checklist that is accessible to students after practice sessions are complete; the checklist promotes personal improvement through peer feedback. This tool provides students with relevant case stems, follow-up questions that probe for differential diagnoses and management plans, assessment checklists, and the ability to review the trend in their performance. The MonkeyJacket application provides medical students with a valuable tool that promotes clinical skill development for OSCEs and clinical settings. MonkeyJacket introduces a way for medical learners to receive feedback regarding patient interviewing and clinical reasoning skills that is both formative and scalable in nature, in addition to promoting interinstitutional learning. The widespread use of this application can increase the practice of and feedback on clinical skills among medical learners. This will not only benefit the learner; more importantly, it can provide downstream benefits for the most valuable stakeholder in medicine—the patient.

Introduction

In 2020 and 2021, over 5000 final-year medical students graduated from a Canadian medical program and were matched

to a residency program [1]. For these cohorts, portions of in-person clinical learning were limited due to the COVID-19 pandemic. Alongside clinical learning, the COVID-19 pandemic also caused numerous academic and health care institutions to

adopt more web-based learning platforms [2], thus emphasizing the importance of remote learning in the current day.

Prior to 2021, final-year Canadian medical students were required to pass an objective structured clinical examination (OSCE) held by the Medical Council of Canada (MCC) in order to progress to a residency training program [3]. Although this requirement has ceased for Canadian medical graduates, OSCEs remain integral within the medical education curriculum by serving as assessment tools for clinical skills. The goal of these OSCEs is to assess the candidate's clinical judgment, reasoning, knowledge, and skills. The examination is typically divided into twelve 11-minute-long stations, with a 2-minute break between each station. Stations can include clinical problems within the following fields: internal medicine, surgery, pediatrics, obstetrics and gynecology, psychiatry, and preventative medicine and public health [3].

The resources available to medical students for OSCE preparation and the real-world clinical setting are few and far between. Although such resources exist, they are limited by one or more factors. One of the biggest limitations for existing OSCE resources is that they are not specific to the MCC objectives, thus restricting their use in a Canadian medical education setting. Another major limitation is that they are often not directed at medical students but rather at students in other health care disciplines, such as pharmacy students and nursing students. Although these resources are beneficial for practice purposes, other professions have different scopes of practice, and the OSCE feedback generated for students via such resources may not always be translatable. Additionally, many of the existing OSCE preparation tools require user setup with platforms such as Zoom or Microsoft Teams; there are few that exist as stand-alone applications through which students can access feedback, clinical prompts, and OSCE assessments within a single centralized platform.

Another important limitation of existing resources is the inability to provide users with feedback regarding their clinical performance, specifically through formative learning experiences. Clinical educators often utilize quantitative scores and feedback in the form of checklists in order to provide students with assessments of their performance. However, this may not always be possible, given the time constraints of clinicians and staff. A possible solution to this is the utilization of peer feedback through formative learning experiences [4]. Unlike summative assessments and examinations, formative learning experiences provide students with opportunities in which they are able to focus on skill development as opposed to percentages and grades. Several studies have demonstrated the benefits of formative experiences, such as encouraging reflective review, reducing test anxiety, and advancing the learners' self-regulation skills [5,6]. Moreover, the remote nature of web-based platforms for formative learning can contribute to interinstructional learning, in which peers who have additional knowledge or exposure within certain medical fields can enhance the clinical skills of those whose training lacks in these areas.

Given the emphasis on web-based learning and the fact that few formative learning experiences exist for students, it is evident

that there is a need for an electronic OSCE (e-OSCE) preparation tool that fills the aforementioned gaps in the medical education system. Thus, the beta version of the MonkeyJacket application for OSCE practice was developed with these gaps in mind [7]. The e-OSCE tool was piloted among a group of 6 medical students and resident physicians at Western University and McMaster University, with the goal of providing direct feedback to the software development team to refine the utility of the application. The primary research objective of this study was to describe the approach to the development and dissemination of the MonkeyJacket e-OSCE application tool. This paper also aims to describe the platform itself, the potential utility of the application as a tool that provides scalable formative feedback for learners, and how the application serves as a valuable tool in Canadian undergraduate medical education.

Development

Purpose of Development

The MonkeyJacket platform was built for the purpose of developing a formative learning experience (ie, rather than a summative one) in which the goals are to practice with various clinical cases and receive feedback through peer evaluations.

Tool Development

The backend of the MonkeyJacket platform was developed by a team of software engineers, project managers, and data scientists. The platform, including the video chat functionality, was custom coded by using a combination of Jitsi (8x8 Inc) and JavaScript Node.js (OpenJS Foundation). Through numerous rounds of user testing and quality control, the application was consistently reviewed and improved by the development team to ensure a smooth experience for users.

Development and Testing of the Application

The cases for the MonkeyJacket application were created by medical students and resident physicians. The trialing and testing of the application were conducted by a group of 6 medical students and resident physicians over a span of 3 months. Group members were encouraged to practice with everyone in the group to allow for diversity in perspectives and promote intragroup learning during the testing period. In addition to seeking group feedback regarding the practice cases and feedback checklists, the user study group was encouraged to provide feedback regarding functionality and ease of use. Comments were then relayed to the development team, and appropriate changes to the application were made.

Inclusion of Cases

The goal was to build practice cases that address CanMED (communicator, collaborator, leader, health advocate, scholar, professional, and medical expert) roles and provide formative feedback in the following disciplines: cardiology, respiratory, gastroenterology, neurology, and psychiatry [8-10]. Within each discipline, cases were developed based on common and vital red-flag clinical presentations across patient demographics. Additionally, some uncommon and highly fatal conditions were also included within the data set to represent the diversity of cases seen in clinical settings. There are a total of 75 cases in

the data set, with no repeated diagnoses. All aspects of OSCEs, except the physical examination, were assessed. The cases were based on a composite of patient cases, of which some were created based on real-life deidentified scenarios, and others

were adapted from an existing repertoire of cases from resources geared toward medical students, such as *OSCE and Clinical Skills Handbook* and other web-based resources [11-13]. Table 1 presents the number of cases per discipline.

Table 1. Breakdown of cases within the data set by medical discipline.

Medical discipline	Cases, n
Cardiology	14
Respirology	15
Gastroenterology	16
Neurology	15
Psychiatry	15

Building the Physician Candidate Prompts

The next step was developing the clinical prompt and task for each case, for both the student presenting as the “patient” and the student practicing as the “physician.” We followed the MCC guidelines in ensuring that prompts were written in a clear and unambiguous manner and tasks could be completed in real time. For example, we avoided prompts such as “explore this further with the patient” and instead replaced them with prompts such as “take a thorough history, with a focus on GI symptoms and summarize your findings.” We also avoided time-defining phrases, such as “the symptoms started at 9am,” and instead replaced them with more definite timelines, such as “2 hours ago.” All clinical stems included the patient’s name, age, gender, and presenting symptoms and the task(s) that must be completed by the physician. The cases were framed such that it was the candidate’s first time assessing the patient, rather than assuming that they had a pre-existing relationship with the patient.

Compiling Information for the Standardized Patient and Trainers

All patient case stems included the following demographic data: the patient’s name; age; occupation; opening statement or history of the presenting illness, including symptoms with qualifications (onset, duration, quality, severity, timeline, alleviating factors, etc); associated symptoms; past medical history; medication history; family history; and social history. For the latter items, only positive histories (eg, if the patient has a history of past illnesses or a family history) were given. Nonverbal cues were also indicated on the patient’s prompt so that they could be communicated to the physician, especially in psychiatry stations (eg, “I avoid eye contact, either looking at the ground or focusing on my hands. I give limited information making it obvious that I’m holding something back.”).

Developing the Feedback Checklists

In deciding the number of checklist items for each clinical prompt, we included items that were relevant to assessing the candidate’s abilities and ensured that the checklists were not exhaustive. The number of items on each checklist depended on the complexity of the case, but most checklists consisted of 30 to 40 items. The checklist items all began with an action verb to guide the standardized patient, who is also the examiner, on what was expected from the physician.

Using the MCC guidelines, we ensured that the items were discrete, observable, and dichotomous. Toward ensuring that items were discrete, each checklist item assessed for 1 concept or grouped concepts together; the candidate could get the full score even if they asked about 1 concept within the group. For example, a checklist item for qualifying pain was “Elicits character of pain – sharp, dull.” For this checklist item, the candidate would get full marks for asking about any character of pain. In ensuring that items were observable, we avoided terminology including “understands” and “appreciates” and instead used terms like “asks about” and “gives reasonable differential diagnoses.” Toward ensuring that items were dichotomous, the candidate either received the full mark for the item or did not; the checklist did not have any rating scales or instructions regarding part marks.

Review, Revise, and Pilot

The MCC states that case development is an iterative process requiring thought, review, and revision, and thus one should be open to feedback. The first step of the review involved the medical development team, which consisted of medical students and resident doctors, piloting the application in an iterative process to continue to refine the platform. This allowed us to identify missing information from the patient script and review the checklist to reduce ambiguity. Additionally, the cases were also reviewed by attending physicians in order to increase the validity of the clinical situations.

Ethical Considerations

This study did not contain or capture any human information or data. Therefore, as per Article 2.4 from the Tri-Council Policy Statement Research Ethics Board, this study was exempt from research and ethics review and did not require research ethics board approval [14].

Application Interface and Features

Description of the Application

Upon entry into the platform, students land on a home page in which they are able to enter their email and password credentials (Figure 1). Prior to the start of an OSCE station, the student completing the station as the acting physician receives a brief prompt that introduces the patient’s name, age, and chief complaint (Figure 2).

Once both students press “Begin station,” the practice OSCE station starts, and the session begins. In this example, student A is practicing their skills as the “physician,” and student B is providing feedback as the “patient.” During this time, student A is only able to see the brief clinical prompt entailing the chief complaint. However, student B is able to view a more extensive patient history, along with behavioral cues, and the feedback checklist for items that student A should inquire about during

the patient interview. While student A takes the history, student B is responsible for completing the checklist along with answering clinical questions, which are asked by student A, based on the history provided (Figure 3). At the end of the practice OSCE station, student B is responsible for completing the assessment checklist for student A in order to successfully save and submit the practice session.

Figure 1. Main log-in screen of the MonkeyJacket platform. OSCE: objective structured clinical examination.

Figure 2. Example screen of the student in the role of the physician. The student physician is able to see the student patient on the left side of the screen and a blank clinical note that may be filled during the encounter.

Figure 3. Example of the MonkeyJacket platform screen as seen by the student in the role of the standardized patient. The case details are shown on the left, and the checklist assessment is shown on the right.

Feedback Checklists

Checklist items can be divided into two categories: (1) generic items and (2) items relevant to the presenting concern. Examples of general checklist items can be found in [Textbox 1](#).

Relevant checklist items are those that are pertinent to the primary presenting concerns of the patient. For example, if the patient presents with shortness of breath, some relevant checklist items could include those listed in [Table 2](#).

At the end of all assessment checklists, the student is also asked to state the top 2 or 3 differential diagnoses based on the history presented. After stating the differential diagnoses, the student is asked for their top diagnosis. There are also other pertinent

clinical questions that the student must answer. Examples of other clinical questions include questions about deciding on the most appropriate imaging modality, other diagnostic tests, and the initial management of the clinical presentation.

After assessment checklists are completed and submitted on the platform, a percentage score is calculated based on the total number of check marks received. The score is recorded and stored within the MonkeyJacket platform. Students are able to review all personal case attempts that they have completed within the platform. Additionally, audio files are also captured so that students can later review the session and reflect on not just their medical expert knowledge but also the soft skills of

communication and rapport building that they must demonstrate (Figure 4).

Textbox 1. Examples of general objective structured clinical examination checklist items.

- Introducing self
- Confirming patient's name and age
- Explaining reason for consult
- Building initial rapport
- Gaining consent
- Asking open-ended questions
- Asking about medications and allergies
- Exploring social history (including cigarettes, alcohol, recreational drugs, diet, occupation, and physical activity)
- Exploring and responding to ideas, concerns, and expectations
- Showing empathy
- Avoiding jargon
- Summarizing issues back to patient
- Global score
- Answering follow-up questions correctly

Table . Examples of relevant objective structured clinical examination checklist items, with the primary presenting concern being shortness of breath.

Assessment checklist items	Examples of what should be asked about
Asking qualifying questions about presenting symptoms	Onset, duration, site, character, severity, duration, and timeline of pain
Asking about relevant associated symptoms	Coughing, recent calf pain, palpitations, fever, and chest pain
Asking about recent illnesses and past medical history	Heart disease, stroke, diabetes, hypertension, etc
Asking about relevant family history	Heart disease among family members aged younger than 55 y, diabetes, high cholesterol, autoimmune disease, history of atopy, etc

Figure 4. Example of the review screen, through which students may access their scores, their clinical notes, comments from their peers, and an audio file of the encounter. SOAP: Subjective, Objective, Assessment, Plan.

Discussion

Overview

The MonkeyJacket application is a novel, innovative, and unique tool for medical students seeking additional practice regarding the development of clinical skills. The overarching goal of the MonkeyJacket application is to fill the gap that exists within medical education—a lack of scalable formative feedback for clinical skill development for learners. The MonkeyJacket application addresses this gap through the focus on peer feedback and the technological features built within the platform. Additionally, the application keeps track of participants' scores

so that individuals may review the trend in and learn from their performance after practice sessions.

The biggest advantage of this platform is the potential for scalability it provides for medical learners. According to Medical Education Statistics 2020, there were 14,967 faculty members and 11,865 medical learners across Canadian medical schools by the beginning of 2020 [15]. On top of the clinical responsibilities of faculty members, they are also responsible for fulfilling teaching and academic requirements. As such, it is not feasible for faculty members to provide additional feedback to learners outside of the designated OSCE preparation time. The MonkeyJacket platform allows students to receive an abundance of feedback from peers, should they wish for

additional practice. The scalability of the platform also decreases the administrative load on medical schools, as students would have simple access to additional clinical skills feedback that does not require constant faculty supervision.

Another significant advantage of the MonkeyJacket application is the remote nature of the web-based platform. Traditionally, practice OSCE examinations have been conducted in person, often with a student's peer or friend. The utilization of the MonkeyJacket application is simple, in that it allows a student to share the link with anyone that has access to a computer and internet connection, thus allowing students to practice regardless of their geographical location. Moreover, medical students would be able to practice with students from other schools, thus promoting interinstitutional learning. A medical student residing in British Columbia could easily practice history-taking skills with a fellow student in Ontario, thus allowing both students to learn from each other and teach each other strategies that they have learned within their respective curricula. It is known that medical education institutions across Canada place emphasis on different areas of focus. For example, it was found that preclerkship pediatric clinical skills training greatly varied across the 17 Canadian medical schools, with 6 schools dedicating less than 7 hours and 8 schools dedicating over 10 hours—a total difference of 30% [16]. The development of a remote-based platform allows medical students to learn from their peers, who may have had more exposure within certain areas when compared to students' own training, thus enhancing their knowledge.

In addition to the remote nature of the application, it also poses a great advantage in terms of its accessibility with respect to cost. A significant barrier to finding accessible practice resources for medical students is the cost associated with purchasing resources. It was found that, on average, osteopathic medical students spend US \$4129 on resources exclusively in preparation for their board examinations [17]. Although this finding is specific to medical students in the United States, where there are different board examinations, Canadian medical students are not exempt from such costs. Canadian medical graduates, on average, finish medical school with CAD \$164,688 (US \$846,612 as of the time of writing) of debt, including education-related and non-education-related expenses [18]. Although numerous companies offer preparation courses, these can vary in cost from a few hundred dollars to several thousands of dollars. Thus, costs associated with expensive preparation courses and resources can be a significant barrier for students seeking resources. The MonkeyJacket platform is completely open access and free of charge. For medical students looking to gain extra practice, the MonkeyJacket platform provides a simple and accessible option, with multiple opportunities for peer evaluation and progress tracking.

Limitations

To ensure that the MonkeyJacket web application was serving its intended population, relevant feedback from medical students and residents was taken into consideration when developing the functions and design of the web application. Nonetheless, there were some limitations to this study.

One limitation of this study is the sample size of students included in the feedback process. In this study, there were 5 medical students and 1 medical resident involved throughout the testing process. At the time of writing, the 6 participants have completed over 200 practice case scenarios via the MonkeyJacket platform. Future studies should include a larger sample size of participants in order to obtain more diverse feedback regarding the functionality and usability of the application.

Another limitation of this study is that all participants were from either Western University or McMaster University. This application originated from researchers based in Western University, and thus all students were recruited from the same institution for ease of organization and planning. Although this was advantageous, as the knowledge and OSCE skills were standardized among study participants, this can also reflect a lack of diversity in perspectives with respect to OSCE skills.

Lastly, traditional OSCE examinations are extensive, in that they also evaluate a candidate's ability to perform relevant physical examination and procedural skills in response to a primary patient concern. Given the web-based nature of the MonkeyJacket platform, it was not possible to integrate such assessments. However, one way to assess a candidate's knowledge regarding relevant physical examination skills is to add it to the checklist and ensure that the candidate knows the rationale for why certain physical examination components would be used.

Future Directions

In the future, the MonkeyJacket application will be preparing for extensive nationwide deployment across Canadian medical institutions. Through partnership with major Canadian medical student groups, the application will be disseminated for widespread use. This will allow us to collect a vast amount of quality improvement feedback. Ideally, we will be able to test if the use of the application leads to improved medical examination scores.

At the time of writing, the cases included within the platform are tailored toward scenarios that can help medical learners, who will become competent resident physicians, develop clinical skills. The expansion of the application in the future can include more specialized cases for specific residency subspecialties. In addition, MonkeyJacket is useful not only for Canadian medical students but also for medical trainees globally, as clinical skills examinations are part of many international medical education programs. This can be explored in the future, once the application is successfully deployed in Canada.

Conclusions

The MonkeyJacket OSCE tool is a comprehensive and accessible learning resource for medical learners. This innovative tool offers medical learners a solution that addresses the lack of practice tools and formative feedback within the realm of clinical skill development. As medical students proceed through their training, OSCEs remain an integral component of assessments ensuring that learners are demonstrating required competencies for safely practicing medicine upon graduation. The development of comprehensive and accessible OSCE

practice tools with built-in evaluations eases the stress associated with preparation for clinical examinations and promotes a more competent medical workforce, with the latter benefiting the most important stakeholders in medicine—the patients.

Acknowledgments

We are grateful for funding through Canada's Department of National Defence Innovation for Defence Excellence and Security (IDEaS) COVID-19 Challenge. No staff from the Department of National Defence participated directly in this research.

Authors' Contributions

CS oversaw the direction of the publication and was the senior author and organizer of the project. AA and FF wrote the manuscript. AA created the figures. EA provided a summary of Medical Council of Canada (MCC) objectives. AA, FF, EA, TB, AK, and EW conducted the practice OSCE sessions. All authors reviewed the final manuscript.

Conflicts of Interest

The MonkeyJacket application is owned by GoodLabs Studio. CS and TL are part of the GoodLabs Studio development team; however, there is no conflict of interest that affected this work.

Abstract

Higher education institutions, including medical schools, increasingly rely on fundraising to bridge funding gaps and support their missions. This paper presents a viewpoint on data-driven strategies in fundraising, outlining a 4-step approach for effective planning while considering ethical implications. It outlines a 4-step approach to creating an effective, end-to-end, data-driven fundraising plan, emphasizing the crucial stages of data collection, data analysis, goal establishment, and targeted strategy formulation. By leveraging internal and external data, schools can create tailored outreach initiatives that resonate with potential donors. However, the fundraising process must be grounded in ethical considerations. Ethical challenges, particularly in fundraising with grateful medical patients, necessitate transparent and honest practices prioritizing donors' and beneficiaries' rights and safeguarding public trust. This paper presents a viewpoint on the critical role of data-driven strategies in fundraising for medical education. It emphasizes integrating comprehensive data analysis with ethical considerations to enhance fundraising efforts in medical schools. By integrating data analytics with fundraising best practices and ensuring ethical practice, medical institutions can ensure financial support and foster enduring, trust-based relationships with their donor communities.

Introduction

Higher education institutions play a crucial role in shaping society's future by developing new ideas, advancing knowledge, and preparing future leaders. However, to fulfill this role, institutions need financial resources. Digital medicine, a rapidly evolving field of technology and health care, is revolutionizing how fundraising is conducted toward funding medical research and public health initiatives. Data, in conjunction with artificial intelligence, are transforming health care and paving the way for personalized medicine. By leveraging cutting-edge digital tools in data analysis, organizations can now gather, process, and interpret vast amounts of health-related data more efficiently [1]. This data-driven approach enables a deeper understanding of disease patterns, patient needs, and effective treatment strategies, facilitating more targeted and impactful fundraising efforts (by segmenting fundraising strategies in keeping with these new patient data streams). Furthermore, innovative fundraising platforms are emerging, harnessing the power of artificial intelligence and algorithmic data analysis that draws from and informs social media, mobile technology, and web-based crowdfunding [2]. These platforms expand the reach of fundraising campaigns and allow for real-time engagement with donors, aimed at enhancing transparency and trust. By

integrating these digital advancements, fundraising with digital medicine is becoming more efficient and more personalized, aligning donor interests with specific health care projects and research endeavors.

Fundraising is vital to higher education because it helps organizations acquire some of the financial resources needed to achieve their mission, vision, and strategic goals. Fundraising can help institutions fund new academic programs, foster research and student learning, advance knowledge, and build links with the community [3,4]. Higher education and medical schools, in particular, are expensive [5], and many students require financial assistance to attend college or university. Fundraising can help institutions provide financial support for scholarships, grants, and other forms of financial aid to students who need it most. The paper is aimed at a novice audience, providing a basic framework for data-driven fundraising. It is set in a Canadian context, where resources such as wealth indicators are less prevalent than those in the United States.

Proceeds generated from fundraising endeavors can enhance and modernize campus infrastructure, encompassing vital domains such as classrooms, laboratories, libraries, dormitories, and athletic amenities. Increased financial resources from fundraising activities can be strategically allocated to recruiting and retaining distinguished faculty and researchers, establishing

scholarships and awards for students, and supporting community outreach activities.

To provide a broader context on fund development terminology, it is crucial to differentiate and link fund development, fundraising, and advancement:

- **Fund development:** This term encompasses the overarching process of creating and nurturing relationships that foster an organization's growth. It includes strategic planning, donor engagement, and stewardship, going beyond mere transactional activities to build a sustainable funding base.
- **Fundraising:** This is a subset of fund development focused on securing funds. It may involve direct or web-based solicitation, single-purpose or multiyear comprehensive campaigns, events, grant writing, and sponsorships. Fundraising is the operational action that stems from the broader fund development strategy.
- **Advancement:** In academic and nonprofit sectors, advancement refers to efforts that advance the institution's mission through fundraising, stakeholder or alumni relations, public affairs, and marketing.

Advancement offices play a pivotal role in the ecosystem of fundraising and donor engagement within institutions. They are responsible for leading an ongoing dialogue between the faculty and the prospective or current donors. Key to advancement work is seeking to understand the impact that the donors want to make through their philanthropic activities and connecting those goals with approved fundraising priorities when possible. Furthermore, advancement offices are instrumental in identifying and capitalizing on various funding opportunities, ensuring that the institution's projects and initiatives are adequately supported. They also provide crucial support for single-purpose campaigns, offering strategic guidance and resources to shape success. By doing so, these offices foster immediate financial support and build long-term relationships between the institution and its benefactors.

Universities increasingly establish "advancement" units integrating fund development, fundraising, alumni, and community outreach activities. The term "fund development" is preferred, as it emphasizes cultivating and maintaining long-term relationships and support. This approach is integral to fostering enduring commitments rather than transactional contributions. Within universities, fundraising can occur at various levels, including within smaller units, departments, or faculties, as well as at the university-wide level. However, consulting and collaborating with advancement or fund development professionals are crucial before initiating fundraising efforts. This ensures that fundraising activities are in harmony with the broader institutional plans and goals, as well as coordinated among the different units and subunits to ensure maximum impact.

Professionals in advancement offices play a pivotal role in managing potential donor relationships, understanding their interests, and aiding units in crafting strategic fundraising plans and proposals. They are skilled in identifying donor interests in the institution and its programs, often starting with smaller initiatives to support donor engagement. These experts often keep a comprehensive list of funding opportunities, including

scholarships, bursaries, and specific project or equipment funding. They may support small-scale or single-purpose campaigns for various university needs, such as funding a simulation center or a theater. Advancement professionals also know about the institution's approach to endowment funds versus expendable or "flow-through" funds. Endowments are typically maintained in perpetuity, providing a unit with a percentage of the total endowed principal plus investment, whereas expendable funds are designated for use over a predetermined period until depleted. Advancement professionals' expertise is vital in aligning donor intentions with the vision, strategic plan, and priorities of the university. Furthermore, these fundraising professionals are known to play the role of networker, negotiator, and knowledge broker [6].

The aim of this paper is to explore a data-driven approach to fundraising in medical education, integrating comprehensive data analysis with ethical considerations.

A Fundraising Road Map

A fundraising plan or road map is aligned with an institution's strategic plan and is an essential component of a successful fundraising effort. It is a written document that sets Specific, Measurable, Achievable, Relevant, and Time-bound (SMART) goals [7] for the fundraising campaign and communicates these goals and objectives to internal and external stakeholders, including faculty, staff, donors, prospective donors, and the general public. The road map helps determine the resources (human, financial, material, etc) needed to successfully implement the campaign, including academic leadership, advancement staff, volunteers, campaign materials, and so on, as well as how best to allocate these resources to maximize the return on investment (ROI).

Establishing SMART objectives is crucial for the success of fundraising campaigns. These objectives provide a clear road map, ensuring that every aspect of the fundraising effort is intentional and efficient. A well-structured fundraising plan, guided by these SMART objectives, allows for a strategic approach, setting clear milestones and measurable goals. This approach facilitates focused efforts, efficient resource allocation, and the ability to track progress effectively. Such meticulous planning is essential for aligning the fundraising activities with the institution's overarching goals and ensuring the optimal use of resources for maximum impact. Although setting SMART objectives is foundational, the consistent application of workflows, standards, and daily execution ultimately determines the campaign's success.

The plan also aims to recognize the organization's most generous philanthropic contributors. In particular, it helps ensure that prospective supporters with the necessary financial capacity are engaged, including alumni and friends, corporations, foundations, and government agencies, and that they share an interest in furthering the organization's mission, strategic goals, and fundraising priorities. The road map often includes targeted cultivation, solicitation, and stewardship strategies by fundraising program, unit, geographic region, and source of funds (eg, cash, gifts of publicly traded securities) to ensure maximum ROI [6].

By establishing a framework that includes timelines for evaluating the campaign's success, the fundraising plan helps keep the campaign on track by checking the progress made against goals set on a monthly, quarterly, and annual basis. The plan also includes key performance indicators to measure each fundraising program and solicitor's success. Some key performance indicators may consist of the number and quality of meetings undertaken with potential donors, gift proposals submitted, gifts received, total funds raised, number of new donors, and gift size; ultimately, they impact the organization.

Fundraising activities should align strategically with an institution's broader goals and plans. This alignment ensures that fundraising efforts secure the necessary funds and support and advance the institution's mission and objectives. The fundraising plan is closely aligned with the institution's strategic priorities, ensuring that fundraising supports key teaching, learning, and research goals, establishing a long-term focus instead of a short-term financial solution. Collaborating with advancement and fund development professionals is crucial in this process. These experts bring invaluable insights and strategies that help identify and engage with potential donors whose interests and values resonate with the institution's goals. Such collaboration ensures that fundraising activities are not only successful in the short term but also contribute to the long-term growth and success of the institution.

Using Data in Fundraising

Data play a critical role in developing a successful fundraising plan. Data provide valuable insights into the past, current, and future donor areas of philanthropic interest and a measurement of the effectiveness of past fundraising campaigns, strategies, programs, and methods. Once analyzed, data can guide the fundraising efforts toward opportunities for growth and help offer the indicators of potential risks or barriers to success. Publicly available data can help drive donor strategies in keeping with their consumption interests. Algorithms are used to make sense of these masses of data and to help predict the greatest potential fundraising strategies and potential donors.

Medical schools (or any faculty) can develop a data-driven fundraising plan based on information and insights aligned with achieving their mission and fundraising goals. Using data to inform strategy and decision-making, medical schools can develop more effective and targeted fundraising plans that deliver better results and build stronger relationships with donors, prospective donors, and the intended beneficiaries [8].

Establishing a data-centered culture in fundraising involves a strategic shift toward using data analytics to guide decision-making processes. This approach emphasizes collecting, analyzing, and leveraging data to understand donor behaviors, preferences, and trends. By adopting a data-centered culture, institutions can make informed decisions about whom to approach, when, and how, thereby increasing the effectiveness and efficiency of their fundraising efforts. Guidance on this aspect includes investing in the right tools and training for data analysis, cultivating a mindset among staff that values data-driven insights, and continuously refining strategies based on data feedback.

Making the data actionable is crucial; it should directly inform and shape your fundraising strategies. MacLaughlin [9] highlights the importance of using data strategically in fundraising. Key points include prioritizing data quality, using data for effective segmentation and personalized communication, and fostering a culture of experimentation. Data should inform strategies, help identify potential donors, and predict giving patterns. Investment in data skills and tools is crucial for effective analysis. Data-driven storytelling can demonstrate donation impact, while good data governance ensures responsible data management. A growth mindset encourages learning from successes and failures. Understanding the difference between business intelligence (analyzing historical data) and predictive analysis (using data to predict future outcomes) can also enhance fundraising strategies. While this paper focuses on business intelligence, which involves diagnostic analytics, predictive analysis involves forecasting future outcomes and represents a more advanced stage of data-driven fundraising.

The 4 Pillars of Data-Driven Fundraising

There are four key steps to developing an end-to-end data-driven fundraising plan: (1) data collection; (2) data analysis; (3) establishing fundraising goals and objectives; and (4) formulating targeted fundraising strategies.

Data Collection

The first step for medical schools in developing a data-driven fundraising plan is collecting quantitative and qualitative data. External and internal research, both from primary and secondary sources, are critical. External information about current and potential donors is often publicly available, including secondary data sets such as demographic and career information, professional networks, and affiliations; giving history; and philanthropic interests. Institutional primary donor data can be analyzed to determine linkages to the medical school; affinity; and giving patterns, including gift amounts, giving frequency, past gift designations, and retention rates. These primary data sets can often be used in algorithmic analysis (in combination with secondary data available in the marketplace) to deepen our understanding of the donor landscape.

Additional information about donor experience, potential future giving interests, and preferred methods of communication can be gleaned from various data collection tools, such as surveys, focus groups, personal meetings, and social media. Internal and external data sets, as well as primary and secondary data sets, can be used together and separately to help organizations better understand donors' and prospective donors' interests, as well as the financial capacity and emotional links to the organization, thereby enabling medical schools to develop targeted outreach strategies that better meet donors' needs and preferences.

In addition to collecting data on donors, it is also important to have access to information about an institution's past fundraising campaigns, comparative data about other professional schools and peer organizations, and industry trends. These data provide benchmarks and guideposts for planning, measurement, and evaluation.

Data Analysis

Once data on donors, past campaigns, and industry trends have been collected, they can be analyzed to uncover patterns and trends that provide insights for future fundraising goals, objectives, strategies, and resource allocation. For example, by examining the giving patterns of alumni, friends, retirees, corporations, and foundations, analysts can pinpoint the organization's foremost donors in terms of total contributions. Data analysis can reveal which donors have made the most substantial gifts, including those with deep ties to the organization, based on their motivations, giving history, donation frequency, level of involvement, and satisfaction. Based on these data points, predictive analysis can help guide donor stewardship and retention strategies, as well as determine which donors are most likely to increase their contributions, both in terms of their capability and willingness to give more. Analysis allows fundraising campaign planners to highlight individuals and organizations currently not donating but with significant potential to support crucial future initiatives.

Data from past fundraising campaigns can be analyzed to determine what programs (annual, major, principal, and planned gifts) and strategies were the most successful against their respective goals. Analysis helps us understand performance trends (high and low) and which areas have the most potential for future growth. Similarly, fundraising tactics, such as direct mail, call centers, electronic solicitations, personal approach, social media, events, and so on, can be evaluated to see which methods have the greatest ROI and growth potential. Understanding that donor-acquisition methods are generally costlier than those used to upgrade existing donors, steps in donor acquisition, retention, and upgrading can be further analyzed to understand and guide the fundraiser's strategic planning and resource deployment. Data can also help determine whether some geographical regions, sources of revenue, fund designations, cohorts, and programs will provide the most predictable ROI for scarce faculty resources.

An analysis of data on current and prospective donors; past campaign successes and failures; peer organizations; and industry, socioeconomic, and technological trends are some of the factors to consider when determining where to allocate future resources for maximizing fundraising success. A thoughtful fundraising strategy can also further equity, diversity, and inclusion initiatives, inviting a broad range of Canadians and international citizens to invest in specific educational missions.

Establishing Fundraising Goals and Objectives

To establish an overall fundraising campaign with SMART goals, medical schools should start by determining the cost of delivering programs and services as per their strategic plan and expected revenue from nonfundraising sources. Once the revenue gap is determined, fundraising campaign planners can then examine the following: (1) past fundraising campaign results; (2) financial capacity and affinity as well as inclination of the faculty's donor pool, notably high-net worth individuals with the greatest capacity to give; (3) opportunities for growth based on institutional, industry, technological, and global trends; (4) social, economic, and political climate; (5) organizational reputation; and (6) potential risks. These can be used to discover

a realistic overall fundraising goal depending on the time frame established.

However, of utmost importance is establishing a compelling case in support of a given program or project (gift designation). Donors give because they are deeply interested in supporting a given cause and because of the impact their gift will have on the beneficiaries. Research on high-net worth donors has concluded that donors give because they want to make transformational change, have a societal impact, and leave a personal legacy [10]. So, as we analyze the data to focus on our most promising potential donors and the most efficient fundraising strategies, a compelling case for support remains crucial to the success of any fundraising program.

In addition to the overarching fundraising goal, there are other subgoals that organizations can establish to align with the overarching goal. For example, the subgoals may be to increase the total number of donors to a medical school by a specific percentage (ie, the percentage of alumni who give back to their alma mater), as well as increase the average gift size per donor, the number of annual campaign donors upgraded to major gifts, the number of new monthly donors, and the number of new multiyear pledges. Subgoals are chosen from the data analysis as these data points align with increasing overarching fundraising success.

Subgoals can also be established by year or decade of graduation; region; fundraising program (eg, an annual campaign, major gifts, principal gifts, and planned giving); source (eg, alumni, friends, foundations, corporations, and other organizations); gift designation (eg, case for supporting students, research, infrastructure, and community engagement); and individual fundraiser or solicitor, team, and unit. Donor communication, engagement, and stewardship subgoals can also be set. Aligning subgoals and measurements with overarching goals associated with success metrics supports an integrated strategy.

Developing Targeted Fundraising Strategies

Once SMART fundraising goals have been established, medical schools can use data to develop targeted strategies and related activities, budgets, and timelines to reach their organizational goals and objectives.

For example, if the goal is to increase revenue to a specific fund designation or case for support, and the data reveal specific donor groups to be most supportive of these, then targeted communications, outreach, and solicitation strategies can be developed to better reach these donor groups, thereby increasing the chances of fundraising success.

For example, suppose past giving trends indicate that alumni are most likely to support scholarship funds. In that case, medical schools may focus their fundraising efforts and activities on reaching out to their alumni via various means of communication, highlighting the impact that scholarships have on student access and achievement, and inviting alumni to make or upgrade their commitment to scholarship funds. In other words, the fundraising ROI becomes greater by reinforcing the compelling case for support with donor groups most likely to respond.

In another example, if the data show that a certain percentage of a medical school's donors is in the 60+ years age range, the faculty can develop focused, planned giving strategies, communicating how legacy gifts (eg, deferred giving in the form of a bequest or life insurance) contribute to the long-term sustainability of the medical school's vision. If the data show that a significant number of high-net worth donors live in a particular geographical area, regional engagement, cultivation, and solicitation strategies can be developed accordingly better to meet the needs and interests of this group. This list of examples shows how targeted approaches can be developed through data analysis and planning.

Ethical Practice in Fundraising

Ethics in higher education fundraising are about conducting fundraising efforts in a manner that is consistent with ethical values and principles and that fosters trust and accountability. In a normative context, it can be said that "fundraising is ethical when it promotes and protects trust in fundraising and unethical when it harms trust." [11] Medical schools must ensure that fundraising practices are transparent, honest, and responsible, and that all parties involved in the fundraising process are treated with respect.

Ethical practices in fundraising are of utmost importance, particularly in maintaining trust and integrity in the relationship between institutions and donors. A critical aspect of this is developing and adhering to clear gift acceptance policies. These policies help ensure that all donations are aligned with the institution's mission and ethical standards. In addition, it is crucial to manage the extent of donor influence. While donor engagement is important, institutions must maintain autonomy and ensure that donations do not compromise their values or objectives. Upholding these ethical standards fosters a transparent and trustworthy environment and protects the institution's reputation and long-term sustainability.

Many fundraisers in Canada are guided by the Association of Fundraising Professionals Code of Ethical Principles, which encourages them to practice their profession with integrity, honesty, and truthfulness, as well as safeguard public trust [12]. The Association of Fundraising Professionals Donor Bill of Rights highlights the principle of philanthropy rooted in voluntary action for communal benefit, emphasizing transparency, trust, and responsible stewardship in nonprofit engagements. It outlines donors' rights, including being informed of the organization's mission, usage of donations, board identity, access to financial statements, assurance of gift use as intended, respectful and confidential handling of donation information, professional interactions, clarity on the status of solicitors (volunteers or employees), option to opt out from mailing lists, and the freedom to inquire and receive honest responses when donating [13].

The authors make the case that "fundraisers are unlike commercial marketers in that they arguably have two key constituencies—their donors and their beneficiaries through a transfer rather than an exchange" [11]; therefore, there must be balance in protecting both donors and beneficiaries and not applying ethics to one at the expense of another.

Fundraisers should be transparent about the intended purpose of the funds being raised, how the funds will be used, and any potential benefits or risks associated with donating. Furthermore, they should treat all potential donors and beneficiaries fairly and equitably, without discrimination or favoritism. Donors' data, including personal information and donation history, should be confidential and not shared with third parties without consent [8]. Moreover, fundraisers should avoid situations that could create conflicts of interest for themselves, their organizations, the donors, and the beneficiaries.

One area of importance is grateful patient fundraising (GPFR), a unique approach to charitable giving where patients, often touched deeply by the care they have received, choose to support their health care institutions financially. Although GPFR is widespread, it raises ethical issues for patients, physicians, development professionals, and institutions. In 2004, the American Medical Association Council on Ethical and Judicial Affairs acknowledged that philanthropic donations are essential to maintaining state-of-the-art medical facilities and conducting research. However, they discouraged physicians from directly soliciting from their patients, especially during a clinical encounter [14]. More recently, Collins et al [13] made a list of recommendations and stated, among others, that GPFR discussions must be avoided when patients are clinically vulnerable. Philanthropy does not justify a level of medical care not available to other patients, and institutions should recognize and take measures to mitigate the ethical risks inherent in wealth screening [15].

Educational institutions are also responsible for using donated funds wisely and effectively and ensuring that the intended purposes of the donations are fulfilled. Institutions are urged to have a fundraising committee of educators, physicians, and fundraisers to reduce safety concerns and prevent fraudulent behavior. It is crucial to establish clear gift acceptance policies and set limitations on donor influence to maintain transparency and ethical fundraising practices. Fundraisers are required to abide by the established rules of their fundraising organization [16].

Conclusions

Developing a fundraising plan or road map is crucial for medical education institutions to achieve their institutional vision and goals; allocate resources effectively; and raise the funds they need to make up for budget shortfalls, remain competitive, and transform their institutions. This is a partnership among the advancement office, practitioner fundraisers, and academic leadership.

A fundraising plan with clear goals, objectives, strategies, action plans, and timelines helps build stronger relationships with existing and prospective donors and volunteers by providing them with a clear understanding of the institution's needs and goals, the institution's plan to achieve these goals, and how their gifts can make a difference.

Data collection and analysis are essential for establishing SMART fundraising goals and developing strategies to yield the greatest results. By having a well-designed and data-driven

fund development plan, medical schools can ensure that they have the resources to support their students, research, and mission in the short and long term.

Abstract

The COVID-19 pandemic has had a significant impact on the mental health of college students worldwide. As colleges shifted to online instruction, students faced disruptions and increased stressors, leading to a decline in mental health that appears to continue in the postpandemic era. To alleviate this problem, academic institutions have implemented various interventions to address mental health issues; however, many of these interventions focus on a single approach and lack diverse delivery methods. This viewpoint introduces the concept of a multimodal self-care online course, *Life101: Mental and Physical Self-Care*, and discusses the potential effectiveness of such an intervention in improving students' well-being. The course combines evidence-based interventions and incorporates interactive lectures, workshops, and guest speakers. Pre- and postcourse surveys were conducted over a span of 4 academic terms to evaluate the impact of this course on the well-being and self-care practices of students. The survey data suggest positive outcomes in students taking *Life101*, including the adoption of healthier habits, reduced stress levels, and increased knowledge and practice of self-care techniques. *Life101* represents a novel multimodality intervention to address the epidemic of mental health issues faced by students today. By implementing similar evidence-based multimodal didactic curricula across campuses, academic institutions may be able to better equip students to navigate challenges and promote their overall well-being.

KEYWORDS

self-care course; stress management; student mental health; multimodal online course; mental health interventions

Background

The COVID-19 pandemic has presented numerous challenges for college students worldwide [1]. As universities transitioned to online instruction in response to the pandemic, students faced significant disruptions in their lives [2]. These changes have tested students' ability to adapt to unforeseen circumstances and underscored the importance of robust mental health resources within academic institutions [3,4]. Surveys conducted within 2 months of the pandemic indicated a substantial decline in college students' mental health [1,4]. New stressors emerged, creating uncertainty about students' academic futures. Unfamiliar learning environments, loss of access to academic resources, limited social interaction, and sudden lifestyle changes led to increased rates of mental disorders, including anxiety, alcohol/substance abuse, depression, attention-deficit hyperactivity disorder, eating disorders, self-injury, and even suicidal ideation [5]. Marginalized communities such as first-generation college students, ethnic minorities, and LGBTQ+ communities were disproportionately affected [4]. Consequently, it is crucial for academic institutions to develop evidence-based resources that address the mental and physical health needs of their students.

While the impact of COVID-19 on physical health may diminish over time, its effects on mental health may lead to a new concern: an epidemic of mental illnesses [6]. To combat the rising prevalence of mental health issues and psychological stress among students, academic institutions have adopted various solutions. Many campuses have introduced mindfulness-based interventions to assist students in managing stress, while others have implemented positive psychology practices aimed at enhancing self-confidence and happiness [3,7]. However, institutional approaches often focus on a single intervention rather than equipping students with a range of evidence-based stress management techniques. A study that exposed college students to a combination of evidence-based multimodal strategies demonstrated enhanced mental well-being compared to that observed in studies testing a single intervention [8]. Moreover, institutional approaches are often delivered through a singular mode that may not cater to students' diverse learning styles. Therefore, evidence-based multimodal approaches, incorporating multiple stress management techniques and healthy lifestyle habits, may hold greater potential for addressing the complex and diverse demands of college students. This viewpoint describes the impact of one such approach, a course titled *Life101: Mental and Physical Self-Care* (hereafter referred to as *Life101*), on students' lives during the COVID-19 pandemic, and explores strategies for

further improving this course and similar modalities to help students manage stress.

Course History, Structure, Content, and Assessment

Life101 is a 10-week course that uses a combination of asynchronous and synchronous components to fulfill various learning outcomes related to self-care. The first online version of *Life101* was offered in 2013. Students watched a 1-hour video lecture on their own and then took a quiz at the end of the lecture. During the summer of 2020, with the help of a grant from the University of California Office of the President, an updated version of *Life101* was developed with new lectures and new educational modalities. This new multimodal course incorporated interactive video lectures with evidence-based content, online group discussions, workshops, quizzes, and practical exercises to facilitate student learning and encourage lifestyle changes. This version was adopted by the University of California system to be offered to students on all 10 University of California campuses. The course also became available to the general public through Coursera and has garnered significant popularity, with current enrollment

exceeding 16,500 students and an impressive rating of 4.9 stars out of 5 (as of January 1, 2024) [9]. The primary objective of *Life101* is to enhance college students' academic and personal successes by equipping them with the necessary lifestyle skills to navigate the numerous stressors typical of college life. While the specific content of self-care courses may vary across institutions, they have consistently demonstrated a significant influence on retention rates and other measures of academic success [10].

The course is divided into 10 modules, each focusing on a distinct self-care topic (outlined in Table 1). Every module includes 3-4 short lecture videos ranging from 10 to 15 minutes in length, and reflective questions and exercises are interspersed throughout the videos to encourage student introspection and active learning. After watching the videos, students participate in an online discussion forum in small groups and share what they have learned in the lectures and how they have practiced what they have learned. For each module, supplemental online resources are also made available, such as reading lists of the relevant scientific literature and motivational videos. At the end of each module, students take an online quiz to assess their understanding of the content presented in the module.

Table . *Life101* module topics and their content summaries.

Week	Module topic	Content summary
1	The Science of Adopting Good Habits for Self-care	Importance of developing healthy lifestyle habits, how to develop and maintain healthy habits, developing SMART ^a habits
2	The Etiology, Physiology, Symptoms, and Health Outcomes of Stress	Stress response and relaxation response, how to identify symptoms of stress, impact of stress on health, how to manage stress
3	Nutrition & Wellness	How to read food labels, physiological effects of sugar consumption on health, strategies to avoid harmful foods, the importance of cooking your own meals
4	Mindfulness & Emotional Intelligence	Importance of mindfulness for optimal self-care, practicing mindfulness and relaxation through breathing exercises, definition of emotional intelligence (EI) and how to use it to manage stress
5	The Many Mental and Physical Health Benefits of Exercise	Role of exercise in chronic disease prevention, mental and physical health outcomes of exercise, developing an exercise plan
6	The Impact of Sleep on Mental & Physical Wellness	Importance of sleep for mental and physical health, cognitive impairments caused by sleep deprivation, how to implement good sleep hygiene habits
7	The Health Benefits of Volunteering & Gratitude	Health benefits of volunteering and gratitude, definition of “helper’s high,” how to develop a habit for a gratitude journal
8	Bad Drugs on College Campus	Commonly used substances with high abuse potential, negative health effects of substances of abuse, impact of energy drink consumption on health outcomes
9	Managing Personal Finances	Importance of managing personal finances, how to develop a monthly budget and pay attention to personal finances, 5 money principles to manage personal finances
10	The Impact of Nature Therapy on Stress Management	Definition of nature therapy and its role in stress management, methods to practice nature therapy

^aSMART: specific, measurable, achievable, realistic, and time-bound.

Survey Project

Survey Design

At the beginning and following the conclusion of the course, a self-assessment survey was conducted to evaluate students’ understanding of the topics presented and their own self-care practices, as well as to gain qualitative insight into the impact of *Life101* on these parameters. Together with some requests for narrative answers, the survey posed 67 statements with responses provided on a 7-point Likert scale ranging from 1 (eg, “never” or “strongly disagree”) to 7 (eg, “always” or “strongly agree”). As an aggregate measure of the impact of the course on student beliefs and practices across different self-care areas, the proportion of students who responded positively (ie, selected responses 5 - 7) to questions with a scalar answer was compared between the precourse and postcourse surveys. Because the responses of individual students on the two surveys were not tracked for reasons of confidentiality, formal statistical analysis of the results was not possible.

Ethical Considerations

As outlined by the guidelines of its Office of Research [11], the Institutional Review Board of the University of California, Irvine did not require a formal review of this survey project since the research was conducted in an educational setting, involving normal educational practices.

Impact of *Life101* on Self-Care Knowledge and Practices

The impact of the original version of the *Life101* course (offered from 2013 to 2020) on the self-care knowledge and practices of prehealth care undergraduate students has been reported previously in a descriptive fashion [12]. Given the context of the pandemic, an objective evaluation of the revised course appeared to be necessary. Pre- and postcourse surveys were conducted over 4 academic quarters (summer 2020, winter 2021, spring 2021, and summer 2021). Out of 1548 students surveyed, 71% (n=1099) reported a negative impact of the pandemic on their mental health.

As presented in [Table 2](#), upon completing the course, the proportion of students who were able to replace unhealthy habits with healthier habits increased by 14% when compared to the precourse responses. Those who took the course during the winter 2021 quarter reported an even greater impact, with an increase of 27%. Many students with high baseline stress levels (68% of respondents) experienced a decrease in their stress levels after completing *Life101*. The survey also provided deeper insights into students' success in learning and practicing new self-care techniques. For example, as students' overall knowledge about mindfulness increased by 12%, their practice of mindfulness also increased by 18%. Similarly, as students learned about stress management techniques, they not only

demonstrated an increase (+27%) in knowledge of these strategies but also reported substantial changes in their practice of specific stress management techniques. There were decreases in the proportion of students who relied on alcohol consumption (-3%) or on the use of various types of media (eg, social media and TV) as means of destressing. Conversely, there were increases in the practice of the destressing techniques emphasized by *Life101*, such as exercise (+10%), nature therapy (+25%), and meditation (+5%). While self-reporting does not necessarily translate directly into an actual change of behavior, the collected data nevertheless depict an overall beneficial outcome of *Life101* on the self-care practices of students.

Table . Impact of *Life101* on the knowledge and practice of selected self-care topics over a span of 4 academic terms.

Survey question	Positive answers in precourse survey, n	Positive answers in postcourse survey, n	Change to positive, % ^a	Mean change % ^b

^aPercent of students changing to a positive response to this statement between the pre- and postcourse surveys, normalized based on the total number of students per semester.

^bCalculated as sum of normalized percent changes of students changing to a positive response to this statement between the pre- and postcourse surveys for each semester/number of semesters.

^cn values represent the total number of students responding to both pre-and postcourse surveys for that term.

^dThis measure was not collected for the summer 2020 course offering.

Life101 as a Model to Address Mental Health Challenges in College Students

Life101 was developed and launched a decade ago to attempt to address the plethora of challenges college students face with regard to personal and mental health, which have only increased since the COVID-19 pandemic. The course has been modified and refined every year based on student feedback. The data from pre- and postcourse surveys conducted during the COVID-29 pandemic suggest that the current version of *Life101* has the potential to improve the mental and physical well-being of college students. Two studies examining similar approaches to *Life101* have also reported positive outcomes [8,13]. Morton et al [8] found that students participating in a 10-week multimodal program with multiple strategies to improve their mental health experienced greater improvements in mental health compared to those focusing solely on a single strategy. Similarly, a recent study evaluating an 8-week multimodal stress management program demonstrated positive effects of the program on college students' psychological distress during the pandemic [13]. Although the published literature regarding programs and courses similar to *Life101* is limited, the favorable outcomes obtained are likely attributed to the multimodal nature and multi-interventional design of the course, which equip students with a repertoire of stress-coping strategies for different situations. Similarly, the overall positive impact of *Life101* might in part be attributed to its incorporation of multiple pedagogical methods, including interactive video lectures, embedded reflective questions and activities in the videos, assigned scientific readings, workshops, discussion forums,

practical exercises, and quizzes. By using various modes of content delivery and assessment, the course can enhance student comprehension and retention while accommodating diverse learning styles. In addition, the comprehensive range of topics covered in *Life101* empowers students to address the typical stressors of college life. Definitive proof of the superiority of multimodality approaches to addressing student mental health and well-being will require larger comparative studies of different teaching approaches.

Future Directions

While self-care courses such as *Life101* have the potential to benefit students' psychological and physical health, it is important to continually improve these courses to meet the evolving mental health needs of students. In addition to the typical stressors faced by college students, such as academic pressure and financial burdens, research has highlighted the link between psychological stress and excessive use of social media platforms [14-17]. Excessive use of social media has been associated with declining mental health [15,16]. Today's college students, often referred to as "digital natives," heavily rely on their mobile devices for various purposes, including accessing health information, entertainment, and maintaining social connections [18]. To take advantage of this fact, the practice of mindfulness, as introduced in *Life101*, should be expanded to include its application during the use of social media apps. Studies have shown that mindful use of social media can lead to reduced stress and increased well-being compared to passive scrolling [16,19,20]. By incorporating mindfulness into social media use, self-care courses can promote intentional engagement

with digital platforms and address the mental health issues associated with excessive social media use and exposure.

Another area of opportunity for institutions developing self-care programs is the prevention of online misinformation among college students. The COVID-19 pandemic highlighted the role of social media in the dissemination of health-related information [21], resulting in a flood of both reliable and unreliable content online. Since college students often rely on online sources for obtaining and sharing health-related information, it is crucial for them to be able to differentiate between reliable and unreliable sources [18,21,22]. A study on the information-seeking behavior of college students found that nearly half of the students (50%) found it challenging to evaluate the credibility of information [23]. Recognizing the importance of addressing this issue, the Department of Health and Human Services released an advisory on “Confronting Health Misinformation” in 2021, emphasizing the need for individuals to develop skills in assessing the credibility of online sources [24]. In addition, according to a systematic review conducted in 2021 on the prevalence of health misinformation on social media, misinformation in various social media platforms had a high prevalence, especially for vaccines and diseases [25]. Although the importance of evidence-based health information is discussed in all of the *Life101* modules, we are considering incorporating a module in this course that covers the basics of evaluating source credibility. This new module can empower students to make informed choices and safeguard their mental and physical well-being.

In addition to the aforementioned recommendations, delivering self-care programs such as *Life101* through mobile apps can be beneficial. Given that most college students own a mobile phone,

rely on online resources for support, and spend a significant amount of time using apps, delivering a self-care course through a smartphone-based app aligns with their preferences [26,27]. A systematic literature review conducted in 2021 demonstrated the effectiveness of mental health apps in preventing stress, anxiety, and depression, and recommended that universities adopt mobile apps designed to benefit student mental health [28]. By delivering self-care courses through a mobile app, institutions can increase accessibility among a wider student population and gather real-time data on students’ stress levels, sleep patterns, mood changes, and physical activity levels. These data can be used to track and analyze students’ well-being and provide tailored and personalized recommendations through in-app notifications. Delivering self-care courses such as *Life101* via a mobile app can be a transformative step in empowering students to actively engage in their own health.

Conclusion

Given the individual needs and diverse challenges students face, the incorporation of diverse evidence-based educational strategies in *Life101* provides students with opportunities to practice self-care and take greater personal responsibility, which are essential aspects of early adulthood [3]. If colleges adopt a multimodal approach in self-care courses across all campuses nationwide, students would be better equipped to navigate challenges, both during and outside of a pandemic period. Furthermore, colleges can develop targeted resources that focus on the mindful use of social media, identification of accurate health misinformation, and the creation of mobile phone apps that deliver self-care content tailored specifically to students’ needs.

Acknowledgments

The author would like to acknowledge an Innovation Learning Technology (ILTI) University of California Online grant from the University of California, Office of The President, that supported the design of the revised online *Life101* course.

Abstract

China's secondary vocational medical education is essential for training primary health care personnel and enhancing public health responses. This education system currently faces challenges, primarily due to its emphasis on knowledge acquisition that overshadows the development and application of skills, especially in the context of emerging artificial intelligence (AI) technologies. This article delves into the impact of AI on medical practices and uses this analysis to suggest reforms for the vocational medical education system in China. AI is found to significantly enhance diagnostic capabilities, therapeutic decision-making, and patient management. However, it also brings about concerns such as potential job losses and necessitates the adaptation of medical professionals to new technologies. Proposed reforms include a greater focus on critical thinking, hands-on experiences, skill development, medical ethics, and integrating humanities and AI into the curriculum. These reforms require ongoing evaluation and sustained research to effectively prepare medical students for future challenges in the field.

KEYWORDS

secondary vocational medical education; artificial intelligence; practical skills; critical thinking; AI

Introduction

A well-established medical education system is pivotal in training a sufficient number of high-quality professionals to meet societal health needs and tackle challenges. China's medical education structure encompasses secondary vocational medical education, undergraduate, master's, and doctoral degrees [1]. Specifically, secondary vocational medical education is a 3-year program for junior high school graduates [2]. Its origin traces back to the "barefoot doctors" of the 1960s. While not all were formal doctors, they underwent fundamental medical and health training, primarily serving rural areas. To address the medical service shortage in rural areas, the Chinese government trained a group of farmers with basic medical skills in the 1960s [3,4]. These barefoot doctors played a pivotal role in China's health care system, significantly alleviating rural medical service shortages and improving overall health standards. However, as the medical system and the economy evolved in the late 1970s and early 1980s, the barefoot doctor model gradually phased out [3]. Despite its development, China

still exhibits a dual nature due to uneven progress. On one side, in economically developed coastal and major urban areas, medical resources are comparable with those in economically developed regions such as Europe and America. On the other side, similar to some regions in Asia or Africa, areas such as Qinghai, Tibet in the west of China and many rural locales experience a severe lack of medical resources. In some of these areas, the standards for practicing qualifications have even been lowered to meet basic health care needs. This stark contrast underscores the challenge of achieving equitable health care access across diverse geographic and economic landscapes [5-8].

Secondary vocational medical education can be seen as an evolved version of the barefoot doctor model, aiming to address medical resource shortages and service imbalances due to regional disparities [1]. The core objectives of this educational system are to enhance grassroots medical levels, nurture qualified medical personnel, and reinforce grassroots medical institution infrastructure, thus bolstering public health response capabilities [9]. Nevertheless, this system heavily relies on

traditional teaching methods, leading to a significant disconnect between theory and practice for students [10].

Artificial intelligence (AI) is profoundly reshaping the medical sector, but the current secondary vocational medical education system has not fully integrated AI technology into its teaching. To ensure that students can fully harness and address these technological revolutions, educators need to reconsider curriculum design, integrating these cutting-edge technologies and preparing students for future medical innovations [11-13]. Based on the long-term experience accumulated by the team in secondary vocational medical education and existing research, this study will delve into the challenges faced by secondary vocational medical education in the era of AI and potential strategies to address them, and this analysis will provide valuable insights and lessons that can be applied to similar countries and regions at various levels of economic development.

Opportunities and Challenges Faced by Secondary Vocational Education in the Era of AI

Over the past 70 years, the grassroots medical standard in China has been improving. However, constrained by economic development and population growth, the distribution of medical resources across the country remains limited and severely imbalanced. A small amount of high-quality medical resources is concentrated in economically developed areas (Figure 1), and medical staff generally bear a high workload. Research indicates that in rural grassroots areas, medical personnel work an average of about 8.9 hours daily, working at least 6 days a week [14]. Another study shows that in 2010, 2015, and 2016, health care workers had monthly workloads exceeding 30 days for 6, 5, and 9 months, respectively [15]. The massive patient flow due to the large number of patients places a heavy burden on doctors.

Figure 1. Distribution of the top 100 hospitals in China. Data were sourced from Fudan University [16]. Data from Taiwan, Hong Kong, and Macau are excluded from this analysis.

Concurrently, the 3-year fast-track training provided by secondary vocational medical education does not endow medical students with the plethora of skills they should ideally possess. Many doctors who enter grassroots work lack systematic and in-depth professional training. They might rely merely on basic medical knowledge and experience to diagnose and treat patients. While this may suffice for the majority of primary diagnoses and treatments, it still falls short when dealing with complex cases [17,18]. Combined with the heavy workload, this could potentially lead to misdiagnoses or overtreatment.

It is noteworthy that the overwhelming workload also results in doctors having little desire to communicate adequately with patients [19]. In many instances, the root cause of doctor-patient

disputes is not merely the misdiagnosis itself but rather the lack of effective communication between the doctor and the patient.

In recent years, the rapid development of AI has demonstrated its potential impact on China's health care landscape. In the realm of direct patient care, the application of AI not only has the potential to enhance the efficiency of medical services [20-26] but also opens new opportunities for medical equity across different regions [27].

Before the widespread application of generative AI, scientists had already been using AI imaging systems and other technologies to address the disparities in medical standards between regions. In primary health care settings, AI is

progressively gaining prominence and is perceived as an auxiliary tool with immense potential [28-30]. Numerous studies have highlighted that particularly in areas lacking experienced radiologists, AI plays a pivotal role in medical imaging analysis, such as in x-rays or basic scans [31,32]. Furthermore, AI offers data-driven therapeutic suggestions not only to physicians, enhancing the accuracy and efficiency of treatments, but also in health care resource management, such as bed allocation. Its predictive models proficiently optimize resource allocation, ensuring that patients receive timely and appropriate care [12]. In the context of telemedicine, the integration of AI with wearable devices undoubtedly delivers more precise health information to medical practitioners, leading to more efficient health management. This would substantially alleviate the workload of health care providers, laying the groundwork for a more harmonious doctor-patient relationship [33].

Building on this foundation, generative AI technologies such as ChatGPT have opened up new possibilities for enhancing primary health care. Multiple studies have confirmed the significant potential and reliability of generative AI in the medical field, enhancing the decision-making capabilities of primary care physicians [20-24]. Notably, these technologies have also shown significant potential in improving doctors' communication skills.

Communication is one of the core skills for physicians, especially when dealing with a large number of patients. Effective communication skills can aid in better patient recovery and provide a harmonious practice environment [34,35]. Studies have demonstrated that ChatGPT exhibits a high level of empathy when addressing common queries [22,36]. In addition, research has explored the potential of generative AI to enhance the communication skills of emergency medical doctors, particularly in delivering bad news, by simulating patient reactions and dialogues during the disclosure of a cancer diagnosis [37]. With the aid of AI, we can better simulate clinical environments, thus improving the training of medical students in patient communication [38].

Furthermore, the future of medical practice will become more complex, requiring doctors to not only possess professional knowledge but also have a basic understanding of technologies related to health care, such as blockchain, cloud services, data quality, machine learning, electronic health records, and mobile health. Some of these technologies are straightforward, while others are complex; AI can help beginners simplify concepts and accelerate their learning [39].

However, despite the conveniences and advantages that AI brings to the training of medical students in primary care, we must still face several inherent challenges: the threat to employment, the necessity of skill updates, and the ongoing need for training. The automation capabilities of AI may gradually replace some basic and repetitive tasks, such as preliminary diagnosis and data entry, which could impact the job stability of medical personnel [12,13].

Moreover, the rapid development of AI technology may increase the obsolescence of certain traditional medical practices and skills. To keep pace with technological progress, health care workers may face more frequent training demands. Although

the concept of lifelong learning is inherently positive, it could impose additional psychological stress on doctors [40,41].

Advancements in technology, while opening new treatment possibilities, also raise new ethical issues, such as data privacy and machine bias, which need to be addressed and resolved in medical education [42]. In addition, while problem-based learning (PBL) approaches attempt to bridge the gap between theory and practice, a lack of practical opportunities and the disconnection between theory and practice might leave students feeling unprepared when facing real medical challenges. These challenges need to be carefully considered and overcome in the AI-integrated educational process to ensure the quality of education and the professional development of students.

At this stage, AI primarily acts as an auxiliary tool [43], helping medical personnel solve problems more effectively and optimize services to patients. As educators, we have a responsibility to directly address any fears students may have [44] and to start popularizing and applying AI knowledge from the educational phase. This will help them more effectively use these technologies in their future practice and reduce resistance to new technologies.

The reform of AI in education will not happen overnight, as school reforms often depend on policy support and tend to lag [45]. Furthermore, the development of AI requires the integration of technology, which in turn necessitates significant resource investment, such as in hardware, software, and professional talent. Unequal resource distribution could make achieving this goal difficult. The rapidly changing technological environment also demands frequent updates to educational content, presenting ongoing challenges for educational institutions.

Recommendations for the Reform of Medical Education in Chinese Secondary Vocational Schools

Integration With Technology

In recent years, AI has taken a central role amidst the technological revolution in the medical field, particularly given its significant impact on enhancing diagnosis and treatment efficiencies. To adapt to this trend, secondary vocational medical education must adjust to ensure that students not just grasp traditional medical techniques but also intertwine with AI technology and applications. This encompasses understanding the significance of machine learning algorithms and data analysis techniques, as well as how to effectively use AI in real-world medical settings [46].

The preclinical teaching phase serves as an ideal starting point. Strengthening courses on health data management, integration, and governance and emphasizing foundational AI, ethics, and legal issues are paramount [46,47]. These courses can be offered independently, ensuring that students maintain foundational knowledge even if certain technologies or applications become obsolete [48].

In addition, students should comprehend the computer and software engineering principles behind AI applications. Insights

into hardware and software development and foundational knowledge of user experience design could be invaluable for their future medical careers [49-51]. Furthermore, during clinical rotations and residencies, students should focus on the practical application of AI, such as the widespread use of AI-based technologies for digital biomarkers and therapies in home settings, which offer large-scale diagnostic and therapeutic solutions [52,53]. In essence, tightly weaving AI into secondary vocational medical education will equip students to serve patients better, ensuring efficiency and accuracy in medical services.

Lifelong Learning

Given the constantly evolving nature of medicine, it is imperative for practitioners to adapt continually to its changing landscape. To ensure that medical students thrive in this dynamic environment, there should be a heightened emphasis on cultivating a growth mindset and fostering lifelong learning capabilities. This mindset encourages viewing challenges and failures as opportunities for learning and growth rather than end points [54,55]. With rapid advancements in medical technology and treatments, students need the awareness and ability to continually refresh their knowledge and skills, keeping them current [56,57]. Offering students exposure and hands-on experience with AI tools not only aligns them with current medical technology trends but also instills a strong adaptive and continuous learning culture—a key to success in a fast-evolving medical field [58,59].

Nurturing Ethical and Critical Thinking

There is a growing global focus on how medical curriculum design balances traditional medical education with the integration of emerging technologies [60-62]. Enhancing the medical curriculum should include not just traditional medical knowledge but also medical ethics and humanities [63,64]. Such a structure not just cultivates students' grasp of medical concepts but also strengthens their ethical foundations, critical thinking, and decision-making abilities [65]. With advancements in medical technology, especially the widespread adoption of AI, students must learn to balance technology use and ethics. Despite the unparalleled conveniences AI offers in health care, it has evident limitations. Students need sound judgment to ensure optimal treatment choices for patients [66-68]. Furthermore, as AI's role in medicine expands, solidifying foundational medical knowledge becomes even more crucial. Students require a robust medical foundation, providing them with a framework to make accurate judgments about AI technologies and ensuring their correct clinical application [69].

Emphasizing Practical Experience

Modern medical education is at a pivotal juncture, necessitating a closer alignment of profound theoretical knowledge with actual medical practice. To achieve this, there is a need to revisit and optimize the curriculum, placing hands-on experience and skill cultivation at its core. PBL offers a direction for this educational transformation. PBL not only stimulates students' proactivity, enabling them to devise solutions for real medical scenarios, but also nurtures their critical thinking abilities [70,71]. At the same time, the advent of AI will compel

educators to abandon traditional teacher-centered instructional methods. With the assistance of AI, educators can facilitate active participation and personalized education for students. They can generate learning materials tailored to each student's learning status and needs, such as by simulating standard patients, providing diverse case studies, and offering brainstorming activities and practice exercises [72,73], thereby increasing clinical internship opportunities that allow students to delve deeper into and comprehend medical practice. Specific practical activities, such as internships and simulated diagnostics, not only deepen students' understanding of medical environments but also aid them in making wiser decisions when faced with intricate medical issues [74]. More crucially, such authentic clinical experiences bridge the gap between theoretical knowledge and practical operation, helping students foster a more professional demeanor, boosting their confidence, and ensuring superior performance in real medical settings [75].

Resource Allocation

To ensure the successful implementation of medical education reform, it is essential to focus on optimizing resource distribution [76]. Specifically, financial investments should be concentrated on upgrading educational infrastructure, acquiring and maintaining new technologies, and establishing a dedicated fund to support the technologization of medical education. In addition, the professional development of teachers is crucial. Systematic training must be provided on AI and related technologies to ensure that teachers possess the most advanced knowledge and skills. Schools should also be equipped with the necessary technical resources to access the latest medical databases and AI tools, such as high-speed internet, updated computer hardware, and software.

Policy Support

In terms of policy support, reforms in medical education should be facilitated through the development of policies that specifically support technology integration and lifelong learning. This includes establishing standards for educational quality and teacher evaluations while encouraging cross-sector collaboration between education departments and health, technology, and private sectors. Importantly, a comprehensive regulatory framework needs to be established to monitor the application of AI technology in medical education, ensuring that all activities comply with ethical and legal standards to protect the rights of students and patients.

Infrastructure Development

Modernizing educational infrastructure is key to enhancing teaching quality [77,78]. Relevant authorities should invest in upgrading traditional classrooms and laboratories to support applications such as virtual reality and augmented reality. Combined with AI, these technologies can be used to simulate complex medical scenarios and surgical procedures [79]. Developing or adopting advanced learning management systems to support web-based teaching and resource sharing, as well as constructing more modern clinical training facilities, can significantly enhance students' practical skills and lay a solid foundation for their future careers.

Discussion

As noted in earlier sections of this paper, China's secondary vocational medical education system, while comprehensive, still relies heavily on traditional teaching methods that emphasize rote memorization over practical application and critical thinking skills [80]. As we move further into the era of AI, these educational frameworks are becoming increasingly outdated. Technologies such as ChatGPT offer the potential to radically reform these traditional systems. By using AI tools and methods, we can address many of the current issues in our educational system, such as the disconnect between theoretical knowledge and practical application.

In the AI era, medical students are presented with unique opportunities to access a wealth of medical curricula previously unimaginable. For instance, AI integrated with augmented reality and virtual reality can greatly enhance interactivity, creating more engaging learning environments that allow students to practice skills in a risk-free setting [79]. Moreover, AI can facilitate personalized education, adjusting learning materials and pacing to meet individual student needs [72,73]. By leveraging these technologies, educational institutions can cultivate more skilled and versatile medical professionals who are well prepared to tackle the challenges of the modern medical environment.

Within the context of China's secondary vocational medical education, practical applications of AI should include the introduction of AI-driven diagnostic tools during clinical rotations, allowing students firsthand experience with their use. This exposure not only enhances their diagnostic capabilities but also enables them to critically understand the advantages and limitations of AI-assisted decision-making [81,82].

To effectively integrate AI into medical education, educational departments must revise curricula to include specialized courses in data science, machine learning, and the ethical considerations of using AI [63,64]. These courses should be designed to ensure students comprehend both the capabilities and limitations of AI technology. In addition, training for educators must also be undertaken to ensure that they possess the requisite up-to-date knowledge and concepts to teach these new modules.

While the benefits of integrating AI into medical education are clear, significant challenges and potential resistance exist. These challenges include transforming traditional educational paradigms, the high costs of technological integration, and the need for continual curriculum updates to keep pace with technological advancements. A crucial step in addressing these challenges involves engaging all stakeholders—including educators, students, and policy makers—in the educational reform process. Demonstrating the specific benefits of AI in enhancing student learning outcomes and patient care can help garner broader support to realize these changes.

Conclusions

The future of medical education in China, particularly at secondary vocational schools, will largely depend on the ability of educators, policy makers, and society to adapt and respond to technological advances. By embracing AI and incorporating it into curriculum design, we can train the next generation of health care professionals, equipping them not only with traditional medical knowledge but also with the skills to use technology to improve patient outcomes. Although challenges exist in the reform process, it is vital to ensure that medical students are well prepared for future medical practices.

Acknowledgments

This research was supported by the Scientific Research Project of Traditional Chinese Medicine Bureau of Guangdong Province (project number: 20221086).

Disclaimer

During the writing process of this study, we used ChatGPT for language polishing and editing, not for generating scientific content or data. We ensure that all content refined through ChatGPT fully aligns with the original authors' intent and expression, maintaining the accuracy and consistency of the information. The accuracy and originality of all scientific assertions, data analyses, and conclusions were independently carried out by our team. This disclosure is intended to maintain complete transparency in the research process.

Authors' Contributions

WT and H Zhang spearheaded the study, managing design, literature review, and manuscript drafting. XZ offered pivotal suggestions and comprehensive revisions, enriching the article's quality. H Zeng analyzed challenges in China's vocational medical education and proposed solutions. JP evaluated the influence of AI on medical education. CG discussed interdisciplinary collaboration and adaptability, while XZ assessed implementation challenges and resolutions. H Zhang supervised the project and refined the manuscript's intellectual content. All authors contributed to data interpretation and manuscript revision and approved the final submission.

Abstract

Health care delivery is undergoing an accelerated period of digital transformation, spurred in part by the COVID-19 pandemic and the use of “virtual-first” care delivery models such as telemedicine. Medical education has responded to this shift with calls for improved digital health training, but there is as yet no universal understanding of the needed competencies, domains, and best practices for teaching these skills. In this paper, we argue that a “digital determinants of health” (DDoH) framework for understanding the intersections of health outcomes, technology, and training is critical to the development of comprehensive digital health competencies in medical education. Much like current social determinants of health models, the DDoH framework can be integrated into undergraduate, graduate, and professional education to guide training interventions as well as competency development and evaluation. We provide possible approaches to integrating this framework into training programs and explore priorities for future research in digitally-competent medical education.

KEYWORDS

digital health; digital determinants of health; digital health competencies; medical education curriculum; competency development; digital health education; training competencies; digital health skills; digital care delivery; health professions training

Introduction

The COVID-19 pandemic heralded a transformation in care delivery to virtual services and digital technologies such as telemedicine, remote patient monitoring, and asynchronous patient portal communications. This transition, coupled with the growing field of “Big Data” informatics and generative artificial intelligence (“GenAI”), has reinvigorated enthusiasm in the “digital transformation” of health care [1] and the use of novel digital technologies to provide personalized, convenient, and comprehensive care for all. It has also resulted in calls to improve the “digital health competencies” of clinicians, to help both current health care providers and trainees meet this transformative moment in care delivery [2-4].

Digital health tools—which include a wide range of “virtual” technologies such as telemedicine, remote sensors, and wearables, as well as medical “apps” and eHealth and mobile health tools, digitized health record and communications platforms (electronic health records [EHRs] and patient portals), clinical decision support systems, and personalized and predictive modeling technologies [5]—have been progressively integrated into mechanisms of care delivery over the last decade, with growing support from both patients and clinicians [3,6,7]. Patient empowerment and self-management are factors that contribute to patient use of digital health [8]. In the United States, 93% of physicians believe digital health tools are an

advantage for patient care, with the majority citing a desire to provide competent remote care to patients as a significant motivator to adopt digital tools [6].

Among medical trainees, sentiments around use of digital health technologies are similar, with these technologies increasingly becoming inseparable from medical training [9,10]. This trend accelerated during the COVID-19 pandemic, as resident clinics pivoted to telemedicine and training shifted to virtual conferences, e-learning modules, and telesimulation [11,12]; nursing and other allied health professions saw similar shifts in their own education and care delivery experiences [13,14]. This dramatically shifted environment has created an appetite for both learning and teaching digital health skills among medical trainees, while also exposing gaps in current approaches to curricular development, implementation, and evaluation [3,4,15-17]. At the same time, there is growing recognition of the equity risks associated with digital health technology [18,19], particularly as the use of these tools was expanded during the pandemic and disparities in access and proficiency widened existing health care inequalities [18,20-22]. This reality underscores the need to cultivate a health care workforce that is both technically *and* culturally competent, as well as to better integrate health equity efforts in clinical training.

This paper explores the current state of digital health education and training competencies among medical and allied health

professions through a brief narrative review and identifies key limitations in these approaches. We then offer a novel framework—the digital determinants of health (DDoH)—that can help unify and direct ongoing competency development and evaluation efforts. The DDoH framework can also ensure that key equity considerations of digital health are incorporated into trainee competencies, thereby helping reduce disparities associated with these technologies' use.

Current Digital Health Education and Training

At its core, the challenge of teaching digital health competencies to medical trainees lies in the lack of consensus regarding *what* those competencies are and *how* they should be taught. While several major medical organizations in the United States and internationally have released statements [23-25] regarding some

element of digital health competencies at undergraduate, graduate, and professional continuing medical education levels, significant heterogeneity exists in these organizations' definitions, areas of focus, and evaluation tools and metrics (Table 1). A brief narrative review of the current medical literature on the topic of “digital health training” reveals both vagueness and variability in the definition of “digital health,” with overrepresentation of language from biomedical informatics, health information technology, and telemedicine. Often, only general recommendations for training competency domains (eg, patient safety and medical knowledge) are offered, rather than any specific competencies. Existing instruments to measure competencies often focus on specific use cases (eg, EHR proficiency) rather than the broad-scope digital health tools and services that exist today [2]. Many instruments are not validated, being either adapted from previously developed tools or newly designed to meet the changing technological landscape and educational needs [2].

Table . Brief narrative review of digital health technology definitions, domains, competencies, and skills.

Source	Digital health definition	Main domains or technologies	Competencies and skills
Accreditation Council for Graduate Medical Education	Not defined: reviewed competencies relevant to digital health but not explicitly digital health specific	Specific domains and technologies are not recognized in core competencies	<ul style="list-style-type: none"> Broad competencies encapsulate patient care, medical knowledge, practice-based learning and improvement, systems-based practice, interpersonal and communication, and professionalism. None are specific digital health competencies [26].
American Medical Association (AMA) [27]	Definition: “Digital health encompasses a broad scope of tools that can improve health care, enable lifestyle change and create operational efficiencies” [27]	Digital solutions: telemedicine and telehealth, mHealth ^a , wearables, remote monitoring, and apps	<ul style="list-style-type: none"> While specific competencies are not outlined, the AMA has been studying, since 2016, physicians’ motivations for using digital clinical tools.
Association of American Medical Colleges (AAMC) [23]	Not defined	Telehealth competencies across 6 domains and 3 tiers	<ul style="list-style-type: none"> Domains: “Patient safety and appropriate use of telehealth, access and equity in telehealth, communication via telehealth, data collection and assessment via telehealth, technology for telehealth, ethical practices and legal requirements for telehealth.” Competency tiers: “entry to residency or recent medical school graduate, entry to practice or recent residency graduate, experienced faculty physician or three to five years post-residency” [23].
Centers for Disease Control and Prevention (CDC)	Definition: “the systematic application of information and communications technologies, computer science, and data to support informed decision-making by individuals, the health workforce, and health systems, to strengthen resilience to disease and improve health and wellness” [28]	Outlines key competencies for public health professionals [29]	<ul style="list-style-type: none"> The CDC uses the 10 essential public health services to guide its competencies. These 10 services do not include digital health-specific competencies [30].
The Standing Committee of European Doctors (CPME) [25]	Not defined: digital competency web page focuses on digital health literacy of health professionals	Calls on members to support investing in eHealth solutions to improve patient care and expand digital health literacy	<ul style="list-style-type: none"> The CPME does not list specific digital competencies in this statement but outlines the importance of digital competencies, given the way digital health is transforming medicine and health care.
Royal Australasian College of Physicians (RACP); Scott et al [4]	Definition: digital health encompasses digital systems integrated in health care and “extends beyond electronic storage, retrieval or transmission of data to the active use of these data in quality improvement, service redesign and knowledge development” [4]	Digital systems: EMRs ^b , e-ordering, e-prescribing, virtual care, e-messaging, e-consults, clinical decision support, mHealth, remote patient monitoring, and artificial intelligence	<ul style="list-style-type: none"> 11 foundational digital competencies in knowledge and understanding outlined over 3 digital health capability horizons: <ul style="list-style-type: none"> “Horizon 1: Embedding safe, ethical, and effective use of systems if electronic records Horizon 2: Integrating new technologies and ways of working Horizon 3: Digital health transformation” [4].

Source	Digital health definition	Main domains or technologies	Competencies and skills
World Health Organization (WHO)	Definition: within global strategies for digital health, the WHO defines digital health as “the field of knowledge and practice associated with the development and use of digital technologies to improve health” [31]	Domains encompassed: eHealth, advanced computing, big data, and artificial intelligence	<ul style="list-style-type: none"> The WHO proposes in their global strategy on digital health (2020 - 2025) to identify core digital health literacy competencies in short term for training of health professionals and ensure that digital health competencies are integrated into education [31].
Longhini et al [17]	Not defined: uses the WHO definition of digital health interventions, “discrete function of digital technology to achieve health care sector objectives” [32]	Digital health competencies including terms related to digital literacy, health informatics, and eHealth	<ul style="list-style-type: none"> Four main categories of digital health competencies identified (with subcategories): <ul style="list-style-type: none"> Category 1: “self-rated competencies” <ul style="list-style-type: none"> Subcategories: “digital literacy,” “eHealth literacy,” “patient-oriented competencies,” and “process of care-oriented competencies.” Category 2: “psychological and emotional aspects towards digital technologies” <ul style="list-style-type: none"> Subcategories: “attitudes and beliefs,” “confidence,” and “awareness” Category 3: “use of digital technologies” <ul style="list-style-type: none"> Subcategory: “general use of digital technologies” Category 4: “knowledge about digital technologies”
Khurana et al [3]	Definition: “an umbrella term broadly defined as the use of digital technologies for health” and “a means by which to increase the delivery of and access to healthcare” [3]	Domains include EHRs ^c , telehealth, mobile and wearable health technology, and artificial intelligence	<ul style="list-style-type: none"> A total of 40 topics across 3 subcategories (digital health knowledge, digital health skills, and digital health attitudes) were identified.
Jimenez et al [33]	Definition: “digital health refers to a broad umbrella term encompassing eHealth...broadly defined as “the use of information and communications technology in support of health and health-related fields” as well as emerging areas of advance computing sciences” [33]	Domains include eHealth, genomics, and artificial intelligence	<ul style="list-style-type: none"> Identified competency domains rather than competencies. Most prevalent digital health competency domains identified: electronic health/medical records, computer/tablet/app use and internet skills, practice administration/management, health information systems, and information literacy.
van Houwelingen et al [34]	Not defined: presents examples of telehealth and digital care: e-visits, devices for self-measurement, activity monitors, and personal alarms	52 competencies included for consideration: competencies focused on nursing curricula to adequately prepare nurses for the world of telehealth	<ul style="list-style-type: none"> 32 competencies were specifically needed for telehealth provision. Competencies were identified and selected for each of the 14 nursing activities the authors included in the study.

Source	Digital health definition	Main domains or technologies	Competencies and skills
Health Information Technology Competencies (HITComp) database [17,35]	Not defined: HITComp does not define digital health but outlines technology competencies for health care professionals	5 competency domains: administration, direct patient care, engineering/information systems/ICT ^d , informatics, and research/biomedicine	<ul style="list-style-type: none"> 33 areas of competency are listed in the HITComp database, allowing users to select relevant areas. Competencies are defined for each domain. A total of 1025 competencies are included in the database [35].
Kinnuen et al [13]	Definition: authors quote digital health definition, “the field of knowledge and practice associated with the development and use of digital health technologies to improve health” [13,31]	Main competency domains: working in digital environment, nursing documentation, and ethics and data protection. Domains capture technologies for documenting nursing diagnosis, planned care, basic IT skills, and eHealth services	<ul style="list-style-type: none"> 3 informatics competencies identified: ethics and data protection, nursing documentation, and digital environment.
Hübner et al [36]	Definition: defines informatics as focusing on data, information, knowledge, and user applications and defines information technology as addressing systems development and life cycle management. Health informatics described as comprised of informatics from multiple disciplines	TIGER ^e core competencies for nursing informatics: 24 core competency areas in nursing and nursing management in health informatics clustered in 6 domains. Questionnaire used by authors included 10 technological items, including eHealth, telematics, and telehealth	<ul style="list-style-type: none"> The 6 domains for the TIGER competencies include “data, information, knowledge,” “information exchange and information sharing,” “ethical and legal issues,” “systems life cycle management,” “management,” and “biostatistics and medical technology.” Results showed the top 10 core competency areas for 5 different roles: clinical nursing, quality management, coordination of interprofessional care, nursing management, and IT management in nursing.

This state of ambiguity has resulted in an uneven and ad hoc approach to digital health education programming in undergraduate and graduate training institutions. Since the pandemic, a growing number of medical schools have implemented digital health courses, consisting mostly of electives focused on biomedical informatics or (more recently) telemedicine [3,37]. Few of these programs are integrated into the larger medicine curriculum, however [38], in part because considerable knowledge gaps remain regarding the most effective ways to integrate them [33]. Even less work has been done at the graduate level, although several novel Objective Structured Clinical Examinations (OSCEs) have been developed to provide “hands-on” training to residents [26,38-40]. Overall, systematized approaches to understanding, defining, and building digital health curriculum for medical trainees are lacking, as are those for faculty development and practicing clinicians [41].

DDoH: A Novel Framework to Advance Digital Health Training and Competency Development

We argue that a comprehensive, multilevel approach to understanding, defining, and evaluating digital health skills for trainees is needed in order to properly prepare health professions students to meet the needs of patients in this new health care landscape. To accomplish this, we offer a model based on our growing understanding of “digital determinants of health”—the novel technological contexts and constructs that mediate an individual or community’s interactions with the health care system—and their intersections with care delivery, innovations, education, and equity.

DDoH refer to antecedents within the digital environment that impact a patient’s ability to access, use, and satisfactorily experience the health care system. DDoH exist at individual, community, and structural levels [18] and include a patient’s personal experiences with digital health technology (eg, use patterns, preferences, and digital skills), communal attitudes (eg, perceptions of usefulness, trust, privacy, and surveillance),

cultural beliefs and social conditions (eg, the digital environments a community experiences, including “digital deserts”), and structural factors (eg, national technology policies, bias, and discrimination; [Figure 1](#)). DDoH can act as barriers or facilitators to effective health care and may disproportionately affect certain individuals or communities [[18](#)].

Figure 1. Mapping digital determinants of health to social determinants of health.

The DDoH framework is modeled on the well-established social determinants of health (SDoH) framework [[42](#)]. The SDoH framework consists of conditions that shape the lived experiences of individuals and environments that impact health [[43](#)]. SDoH include both place-based conditions and “political, socioeconomic, and cultural constructs” [[43](#)]. Some examples include income level, availability of transportation, and social support and community inclusivity [[43](#)]. SDoH affect populations in negative and positive ways and can both protect health and contribute to disparities [[44](#)]. Given the developments made in understanding SDoH in the last 2 decades and

integrating them in health and medicine, a large body of literature now exists exploring socioeconomic factors and the ways they shape health outcomes [[45,46](#)]. As knowledge of SDoH has expanded to health care, it has been integrated into medical curricula, and SDoH training is now considered to be a core piece in medical education [[47,48](#)]. The success of SDoH competencies and curricula development can serve as a model for integrating DDoH into medical education. The DDoH model effectively transposes SDoH thinking into digital spaces and challenges us to think beyond individual characteristics (eg, digital health literacy) when considering a person, community,

or population's interactions with digital health tools (Figure 1) [19]. DDoH are valuable to effectively conduct virtual care delivery, which is becoming more prominent in health care today [49].

Why Teach DDoH?

Overall, we argue that digital care delivery cannot be successful or equitable without more attention to the DDoH that define it. Critical to this is the inclusion of DDoH thinking into training paradigms, programs, and resources at all levels.

Specifically, the DDoH framework can help improve digital health competency development through the following:

- *Ensures a standardized and comprehensive approach to curricular design* that would address digital health skill needs at individual, interpersonal, social, and structural levels: for example, when developing training tools to teach and evaluate a learner's ability to assess patient "readiness" for a telemedicine appointment, educators can use the DDoH framework to include not only screening for individual digital health literacy but also an evaluation of community and social factors such as access (eg, the "digital divide"). This approach allows for a better understanding of the specific barriers to an individual patient's use of health technologies, which can then be tailored to better meet that patient's needs. Systematically applying these layers across learning programs creates a shared mental model for digital health training that can unify language, competency domains, and evaluation tools.
- *Can be both technology specific and technology agnostic*: this means that the DDoH framework can be useful when developing both specific technical skills as well as universal competencies such as patient communication, education, and shared decision-making—all of which facilitate a patient's broader ability to successfully engage with the digital health ecosystem across devices and services. This can help avoid the ongoing challenge when developing digital health competencies, which is the tendency for technical skills to become outdated as the technologies themselves evolve (eg, computer-based web browsers vs smartphone apps vs smartwatches). For example, in teaching students EHR proficiency, using the DDoH layers can ensure that specific technical competence (eg, being able to log onto and successfully navigate the platform) is matched with interpersonal communication skills (eg, talking to the patient and *not* the EHR) and shared decision-making (eg, EHR screensharing with patients) that will serve learners regardless of the EHR platform they use.
- *Can build on existing successful SDOH-based curriculum and pedagogy*, allowing for more efficient program development and quick adaptation and validation of learning tools, rather than starting from scratch: existing SDOH programming that has been shown to be effective can quickly be adapted to DDoH contexts and tested in similar environments to assess for fidelity and effectiveness. There are now a variety of existing instructional frameworks for SDOH teaching [50] and curricula that are experiential, longitudinal, interprofessional, and community based that

can be adapted [50,51]. This can also apply to preexisting SDOH evaluation tools, as well as common program requirements and other educational standards. For example, an undergraduate medical education OSCE designed to teach SDOH related to hypertension management can be quickly adapted to a case involving remote blood pressure monitoring, thereby exposing learners not only to well-known social factors related to hypertension control (eg, regular access to medications) but also unique technology-mediated factors such as access to reliable Wi-Fi for sending home values.

- *Supports digital health equity*: crucially, a DDoH-informed approach incorporates an equity-sensitive perspective into digital health training, by placing drivers of digital health disparities at the center of skills and competency development. Teaching trainees about the potential social biases of a piece of technology alongside the technology itself can help reduce the likelihood of producing clinicians that reinforce technology bias in their practice. This is particularly relevant given the growing literature exposing the relationships between digital health technology and health disparities, as well as the need for a workforce that is trained to address this even as the field expands and these tools become normalized as part of care delivery.

Applying DDoH to Health Professions Training

Overall, health professions educators should use the DDoH framework as a guide in creating robust educational programming and evaluation tools aimed at developing health professionals who understand and can competently use digital health tools to deliver care for diverse patients. Practically, the integration of DDoH in educational programming should leverage a mixed-pedagogical approach that extends beyond passive learning and includes applied learning strategies such as OSCEs and "flipped" classrooms and innovative technologies such as virtual reality. To accomplish this effort, educators can first identify existing spaces in didactic curriculum to infuse DDoH, including adding it to SDOH training. However, a DDoH-based approach can also be taught through problem-based learning, experiential and workplace-based learning, performance assessment, and continuing medical education. Experiential "hands-on training" within community-based and service-learning opportunities (eg, homeless shelters and community advocacy organizations) can imbue technical facility while also educating on social and structural contexts of care using these technologies. In particular, connecting trainees with lay community members such as community health workers or digital navigators can expose them to the common technical skills needed to support patients as well as the social and cultural nuances of a digital health technology's use in the real world. Incorporating trainees into health system IT efforts is another example that can provide unique administrative and regulatory contexts for learners. DDoH-sensitive learning can also complement quality improvement curricula, particularly as those programs increasingly involve EHRs, clinical decision support, informatics, and other digital health tools.

In keeping with a multilevel approach, digital health competency assessments should evaluate skills at technical, interpersonal, and structural levels, and educators applying the DDoH framework should consider stratifying their assessment domains based on these levels. For example, when developing a learning program on remote blood pressure monitoring in hypertension management, consider the following:

1. What *individual technical skills* are needed for both clinicians and patients to successfully install, set up, and transmit remote blood pressure data using currently available technologies?
2. What *immediate individual and/or community social contexts and barriers* might be relevant for patients being considered for a remote blood pressure monitoring program, and how would a clinician evaluate and address those?
3. What *larger national or structural social factors*—including scope of practice and device regulations—might impact a patient's ability to access and use a remote blood pressure monitor, or a clinician's ability to interpret and make medical decisions based on that data?

In this case, depending on the level of learner and training goals, while a teaching session dedicated purely to technical skill building (eg, training clinicians on the variety of remote blood pressure monitors and how to successfully take a home blood pressure measurement) may be the focus, using a DDoH-guided approach would allow educators to increase the value of the training by teaching clinicians to also address individual DDoH needs (eg, language preferences and physical or cognitive accessibility needs) and social layers (eg, local library Wi-Fi access) that may contribute to a blood pressure device's ultimately successful use.

There are some challenges to creating an educational system based on the DDoH framework. Designing robust experiences is time-consuming and often labor-intensive. Consequently, it is important to identify already developed programs that can be

quickly adapted and evaluated; this can include existing SDoH programs, but it can also include the myriad of ad hoc telemedicine training tools that proliferated during the COVID-19 pandemic that can now be reworked to be more robust and structured. In general, flexible learning approaches that can respond to the short technology life cycles of many of these products are critical to ensure that skills remain relevant or can be quickly updated; this is challenging to keep on top of and may favor a longitudinal approach that offers multiple teaching touch points throughout a training program. Finding competent faculty to teach these skills may also be difficult, as practicing clinicians and educators are often learning about novel technologies alongside trainees. Finally, convincing health care stakeholders that DDoH are worth studying, learning, and evaluating in their own right take efforts, particularly given the other demands and competing priorities of health training. However, we strongly believe these technologies will only continue to proliferate and become further embedded in health care delivery, and ignoring their outsized and disruptive role in clinical care in critical training periods is ultimately a disservice to the health care workforce and patients.

Summary

There is growing need to develop unified digital health education and training competencies for health professions students. Efforts to cultivate a workforce adept in digital health tools must prioritize understanding and mitigating the digital determinants of health that shape individuals' interactions with health care technology. Using a DDoH framework in medical education—including not only didactic training but also hands-on skill building, as well as continuing education opportunities—can help guide robust educational programming and evaluation tools aimed at developing health professionals who understand and can competently use digital health tools to deliver care for diverse patients.

Abstract

Instructional and clinical technologies have been transforming dental education. With the emergence of artificial intelligence (AI), the opportunities of using AI in education has increased. With the recent advancement of generative AI, large language models (LLMs) and foundation models gained attention with their capabilities in natural language understanding and generation as well as combining multiple types of data, such as text, images, and audio. A common example has been ChatGPT, which is based on a powerful LLM—the GPT model. This paper discusses the potential benefits and challenges of incorporating LLMs in dental education, focusing on periodontal charting with a use case to outline capabilities of LLMs. LLMs can provide personalized feedback, generate case scenarios, and create educational content to contribute to the quality of dental education. However, challenges, limitations, and risks exist, including bias and inaccuracy in the content created, privacy and security concerns, and the risk of overreliance. With guidance and oversight, and by effectively and ethically integrating LLMs, dental education can incorporate engaging and personalized learning experiences for students toward readiness for real-life clinical practice.

Introduction

In recent years, dental education has experienced a significant transformation, driven by the rapid evolution of technology [1-3]. Dentistry faculties and educators have recognized the potential of these advancements to enhance the learning experience and guide patient care and have actively integrated them into their curricula [4]. Therefore, this has led to a change in the state of dental education in dental schools, focusing on the incorporation of technology to foster a more effective, engaging, and innovative learning environment. Specifically, the emergence of artificial intelligence (AI) has created a broader impact [1].

Dentistry has always been a highly specialized field, requiring a combination of theoretical knowledge, practical skills, and clinical acumen. Dental faculty have traditionally employed a combination of lectures, seminars, laboratory work, and supervised clinical practice to deliver a comprehensive educational experience to dental students. However, the advent of cutting-edge technology and AI has created new possibilities for improving the quality of education as well as the practice

to better prepare future dental professionals [1,5,6]. By leveraging these technological advancements, dental educators are able to create more interactive and personalized learning experiences. Virtual reality, for instance, allows students to immerse themselves in realistic clinical scenarios, enhancing their understanding of complex dental procedures and techniques [7]. Similarly, haptic devices and 3D printing enable the development of accurate dental models, facilitating hands-on practice and improving students' dexterity and confidence in performing intricate procedures [8]. Finally, the addition of advanced medical charting (eg, integrated electronic medical records or voice-activated periodontal charting) to clinical practice has required the dental school faculty to instruct on how best to use technology to provide safe clinical care when in practice [9-11]. Beyond all, AI has been perceived to improve operations, innovation, and practices in dental education at multiple levels [1].

Transformation in Education and Technology With Large Language Models

As dentistry continues to evolve with the integration of advanced technologies, AI has emerged as a powerful tool with new potentials to improve dental education. One such innovation, which has been highly communicated recently, is large language models (LLMs). An LLM is a type of AI model designed to conceptualize and generate human-like text based on large amounts of data [12]. These models are trained on vast amounts of text from various sources online, enabling them to generate contextually relevant responses, summaries, translations, and more. LLMs have been argued to potentially transform various domains, including education, by providing personalized learning experiences and assisting in content creation [13]. Further ahead, multimodal foundation models (FM) are similar large-scale AI models which are pretrained on extensive data, enabling them to conceptualize and generate image and audio, in addition to the text [14].

Currently well-known LLMs and FMs, such as GPT (OpenAI) [15], LaMDA and PaLM (Google) [16], and LLaMA (Meta) [17], have shown potential in medical education and practice, including problem-solving, question and answering, summarization, and content creation [13,18,19]. Especially in dental education, it may provide innovative methods to enhance the learning experience for dental students. Personalized learning could be one, as these models can be used to create unique experiences for students by generating custom learning materials based on their individual needs, preferences, and learning styles [20,21]. In addition, LLMs and FMs can be used for content creation, where it can create educational content such as quizzes, assessments, and lesson plans which in turn can help educators save time and improve the quality of their teaching materials [20]. Therefore, it is important to explore the application of LLMs and FMs in dental education. In this perspective, to take a glimpse at applications in dental education, we share a use case of periodontal charting, and highlight major opportunities and challenges associated with AI implementation.

Use Case: Periodontal Charting

Overview

Periodontal charting, an important component of dental practice and clinical care, involves the systematic recording of information related to a patient's periodontal health, such as probing depths, gingival recession, clinical attachment levels, and the presence of bleeding or suppuration. Accurate periodontal charting is essential for diagnosis, treatment planning, and monitoring the progress of periodontal therapy. Periodontal health is an important part of the dental school curriculum, and ultimately a significant component of clinical practice. Dental students are asked to complete numerous

competency examinations on the assessment and treatment of periodontal disease. Additionally, periodontal assessment and treatment is a critical component of dental licensure examinations. Integrating generative models (eg, LLMs and FMs) into the teaching and learning process of periodontal charting offers several opportunities to improve students' understanding and mastery of this important clinical skill [22].

One major opportunity is to provide personalized feedback and guidance. By inputting the students' charting data and observations, a model can analyze the information, compare it with established guidelines and best practices [23], and generate tailored feedback. This feedback can highlight errors, suggest improvements, and reinforce correct techniques, supporting students in refining their charting skills and enhancing their clinical decision-making capabilities. Another opportunity is the creation of realistic case scenarios and simulations. LLMs and FMs can generate a wide range of patient cases with varying periodontal conditions, enabling students to practice periodontal charting in diverse clinical contexts. This exposure to a multitude of cases can foster deeper comprehension of the underlying principles and techniques, and better prepare students for real-life clinical practice.

However, there are also challenges associated with the integration of these models into dental education. One primary concern is the potential for biases or inaccuracies in the AI-generated content. As these models rely on the data they have been trained on, they may inadvertently reproduce erroneous information or reflect biases present in their training data [18]. To mitigate this issue, it is crucial for educators to carefully review and validate the content generated, ensuring that it aligns with current evidence-based practices and professional standards. Yet, validation might be challenging with tools such as ChatGPT, which do not provide the reference to the source of the information presented. Another challenge is the potential overreliance on AI by students, which may lead to a decreased emphasis on critical thinking and problem-solving skills [24]. To address this concern, educators must keep a balance between leveraging the benefits of AI and fostering independent learning. Encouraging students to critically evaluate the feedback and suggestions provided by AI can promote the development of essential clinical reasoning skills [24,25].

To demonstrate the capability of these generative AI (LLM or FM) models in dental education, we present a series of examples of LLM or FM applications as a periodontal charting educational support mechanism.

Example 1: Periodontal Charting Feedback

In this example, a student enters a prompt to obtain feedback about performed periodontal charting. The prompt and response are presented in [Textbox 1](#). We used the GPT-4 model (via ChatGPT application) [26] to generate this example in March 2023.

Textbox 1. Periodontal charting prompt and response by GPT-4.

<p>Prompt:</p> <p><i>I performed periodontal charting on a patient and recorded the following data for tooth #3:</i></p> <ul style="list-style-type: none"> • <i>Probing depths: 2 mm (mesial), 3 mm (buccal), 2 mm (distal)</i> • <i>Gingival recession: 0 mm (mesial), 1 mm (buccal), 0 mm (distal)</i> • <i>Bleeding on probing: absent (mesial), present (buccal), absent (distal)</i> • <i>Suppuration: absent</i> <p>Response:</p> <p><i>Based on the information provided, it seems that the periodontal charting for tooth #3 is fairly comprehensive. The probing depths, gingival recession, bleeding on probing, and suppuration have all been recorded, which are important aspects of periodontal charting.</i></p> <p><i>However, there are a few aspects that could be improved or clarified for a more complete assessment:</i></p> <ol style="list-style-type: none"> 1. <i>Six-point probing: To provide a comprehensive picture of the periodontal health around tooth #3, it's important to record probing depths for all six points (mesial-buccal, mid-buccal, distal-buccal, mesial-lingual, mid-lingual, and distal-lingual) rather than just three points (mesial, buccal, and distal). Consider adding the missing data for the lingual side of the tooth.</i> 2. <i>Consistency in recording: Ensure that all aspects of the charting (probing depths, gingival recession, bleeding on probing, and suppuration) are documented for each of the six points, if applicable. This will provide a more accurate representation of the periodontal health of tooth #3.</i> 3. <i>Mobility and furcation involvement: While not mentioned in the provided data, it is also essential to assess and record tooth mobility and furcation involvement, if present. These factors can have a significant impact on the periodontal prognosis and treatment planning.</i> 4. <i>Use of standard notation: Make sure to use standard notation when recording periodontal charting data. This will help to ensure that the information is clear and easily understood by other dental professionals who may be involved in the patient's care.</i> <p><i>Overall, the charting seems to be accurate for the data provided, but additional details are necessary for a complete periodontal assessment of tooth #3.</i></p>

Example 2: Periodontal Disease Classification

In this example, a student enters a prompt to obtain feedback about periodontal disease assessment. The prompt and response are presented in [Textbox 2](#) (AI-based periodontal health

assessment from [Figure 1](#) [27]). The image was captioned as “Upper jaw acute gingivitis in a non-smoker 26-year-old male patient. Abundant plaque deposit is visible on the surfaces of the teeth” [27]. We used the GPT-4 model (via ChatGPT application) [26] to generate this example in January 2024.

Textbox 2. Artificial intelligence–based periodontal health assessment.

<p>Prompt:</p> <p><i>What can you say about the periodontal health of these teeth?</i></p> <p>Response:</p> <p><i>Based on the provided image, there are several clinical signs indicative of periodontal health issues:</i></p> <p><i>Gingival Inflammation: The gums appear to be red and swollen, particularly around the necks of the teeth. This is suggestive of gingival inflammation, which could be due to gingivitis or the initial stages of periodontitis.</i></p> <p><i>Gingival Recession: There seems to be some recession of the gums, especially noticeable around the left central incisor. This could indicate a loss of periodontal attachment.</i></p> <p><i>Plaque Accumulation: There are visible yellowish deposits near the gum line of the teeth, which likely represent plaque. Plaque accumulation is a primary factor in the development of both gingivitis and periodontitis.</i></p> <p><i>Tooth Discoloration: There is also evidence of tooth discoloration, which may be related to dietary habits, oral hygiene practices, or possibly the presence of calculus (tartar), which is hardened plaque that can form both above and below the gum line.</i></p> <p><i>Gingival Margin Contours: The contour of the gingival margin appears to be irregular, which can be a sign of periodontal disease progression.</i></p> <p><i>It's important to note that a definitive diagnosis would require a full periodontal examination, including periodontal probing to measure pocket depths, assessment of bleeding on probing, mobility testing, and possibly radiographs to evaluate bone levels. This image provides a snapshot that suggests the presence of periodontal issues, but a comprehensive evaluation by a dental professional is necessary for an accurate diagnosis and to formulate an appropriate treatment plan.</i></p>
--

Figure 1. Image of upper jaw acute gingivitis (reproduced from Cafiero et al [27], which is published under Creative Commons Attribution 4.0 International License [28])

Example 3: Estimating Periodontal Pocket Depth

In this example, a student enters a prompt to obtain feedback about the periodontal pocket depth (PPD) estimations. The prompt and response are presented in [Textbox 3](#) (AI-based PPD assessment from [Figure 2](#) [27]). The image was captioned as “A periodontal probe is inserted into the sulcus and in a parallel position with respect to the long axis of the tooth. The physiological value of PPD is considered to be ≤ 3 mm. PPD allows an immediate evaluation of diseased sites” ([Textbox 3](#)

and [Figure 2](#)) [27]. We used the GPT-4 model (via ChatGPT application) [26] to generate this example in January 2024.

The response provided by GPT-4 (as a multimodal FM) demonstrates a natural language understanding and image recognition for periodontal charting and questions. The readers should note that these examples do not provide the validity or accuracy of the model but rather a demonstration of its capability. However, in terms of the accuracy of exemplified cases, the response by GPT-4 is in line with general dental knowledge and practices.

Textbox 3. Artificial intelligence–based periodontal pocket depth (PPD) assessment.

Prompt:

Here is the probe for your reference ([Figure 2A](#)). Now estimate the PPD in the next image ([Figure 2B](#)).

Response:

Now, with the reference image of the periodontal probe provided, I can give an estimate of the periodontal pocket depth (PPD) in this image. The probe's tip appears to be between the 3 mm and 4 mm marks, as it does not reach the first black band (which I assume, based on common probe designs, indicates 5 mm). It is not clear how much of the probe is within the sulcus due to the angle of the photo and the overlap of the tooth. However, it seems that the probe may be inserted approximately 3 mm into the sulcus. Therefore, the estimated PPD in this image appears to be about 3 mm, which is within the normal physiological range. It's important to note that this is an estimation and that in clinical practice, measurements should be taken from multiple angles and at several points around each tooth for accuracy.

Figure 2. (A) Image of a periodontal probe; (B) image of a periodontal probe inserted into the sulcus (reproduced from Cafiero et al [27] which is published under Creative Commons Attribution 4.0 International License [28]).

In example 1, GPT-4 offers a critique of the data entered by the student. The response identifies areas where the charting is accurate and comprehensive and suggests areas where the charting could be improved or clarified. The feedback highlights the importance of 6-point probing, consistency in recording, mobility and furcation involvement, and the use of standard notation. These aspects are essential for dental students to learn and incorporate into their practice, as they will help to document an accurate and comprehensive periodontal assessment that will be used to enhance patient care. The suggestions for improvement, such as including readings from the lingual aspect of the tooth and ensuring consistency in recording, are valid. From an educational standpoint, the response offers a structured and informative critique that could be beneficial for dental students. The feedback emphasizes the importance of thorough periodontal assessments, which is essential for optimal patient care and treatment planning. Additionally, the response encourages the use of standard notation, which ensures clear communication among dental professionals.

In example 2, GPT-4 offers an evaluation of the given clinical image. The response evaluates the image, providing clinical details present on the image. The feedback highlights the presence of inflammation, plaque accumulation around the gingival margin, and discoloration of the teeth. This evaluation can be helpful in guiding dental students on what to clinically evaluate for periodontal and dental health and can demonstrate examples with analysis of healthy and unhealthy gingiva and dentition. There is a tendency for the model to extrapolate clinical findings from a simple image evaluation; however, the model does caution that a clinical examination should be completed to properly diagnose and evaluate. This response, generally, can be helpful in guiding dental students to properly evaluate and examine patients in the clinical setting.

In example 3, GPT-4 offers an evaluation of the depth indicated on the periodontal probing instrument. The feedback indicates the correct reading, and the appropriate justification for this analysis, while also providing information about common probes and how the probe indicators are arranged. This is helpful for dental students to understand common instrumentation and how

to properly read these instruments in the clinical setting. From an educational standpoint, the response offers information on instrumentation from which students can learn. The feedback appropriately evaluates the information, gives context, and indicates the need for a full examination to corroborate findings.

Challenges and Considerations

While the LLM and FM responses provide valuable feedback and highlight areas for improvement within the given use case on periodontal charting, it is essential to consider the potential challenges, risks and limitations associated with this approach on a broader scale.

Publicly available generative AI tools (such as GPT, LaMDA, and LLaMA) are not trained specifically on the dental domain. As probabilistic models, they predict how likely a particular sequence is to occur in the language based on a training data set and they reflect this. Therefore, they may generate different contents for very similar questions depending on the structure of the questions (Textbox 4). This inconsistency could also be the case with repetition of the same prompts with the same model [29]. This may not be ideal for standardization of the educational contents. In some occasions, it may create misleading, biased, or incorrect results, such as responses irrelevant to the question or prompt or responses note based on existing data for the prompt [18]. It is important to be aware that the information generated by the AI may contain such inaccuracies or biases, necessitating a thorough review, experiments, and creation of safeguards or operational guidelines by educators or clinicians to ensure alignment with evidence-based practices and ethical principles [30]. In addition, fine-tuning and advanced prompt engineering (eg, chain-of-thought or in-context learning) could be adopted to mitigate risks [31,32]. Unlike LLMs, FMs are multimodal and more versatile but may require significant fine-tuning with complex domain-specific data to mitigate the risk of generating generalized content that may not align with specialized dental knowledge or practice standards. This adjustment is crucial to tailor the outputs of FMs to reflect up-to-date clinical guidelines and diagnostic criteria specific to dentistry.

Textbox 4. Differences in basic question answering (created by GPT-4 in March 2023). Authors asked GPT-4 to explain periodontal charting in 2 different question forms. The explanations in both responses are slightly different. Whereas response 1 defines periodontal charting as a dental diagnostic and monitoring tool, response 2 defines this as a procedure. Similarly, response 1 addresses the measuring tool as a “specialized probe,” whereas response 2 addresses this as a “periodontal probe.”

Prompt 1: *What is periodontal charting?*

Response 1: *Periodontal charting is a dental diagnostic and monitoring tool used by dentists and dental hygienists to evaluate the health of a patient's gums and teeth. During periodontal charting, the dental professional measures the depth of the space between the gum line and the tooth root, known as the periodontal pocket, using a specialized probe...*

Prompt 2: *Tell me about periodontal charting.*

Response 2: *Periodontal charting is a procedure performed by dental professionals to evaluate the health of a patient's gums and teeth. It involves measuring the depth of the spaces between the gum line and the tooth root, known as periodontal pockets, using a periodontal probe...*

Regardless of the level of accuracy achieved by technical improvement, while adopting these tools, educators and students must be encouraged to critically assess the feedback provided by the AI to develop their clinical reasoning and problem-solving skills, rather than solely relying on the model's

output. Otherwise, there is a risk that students might become overly reliant on AI for decision-making, potentially undermining the development of their independent clinical judgment and manual skills. Similarly, the limitation of the models on detailed tasks, such as critical appraisal of literature,

may further contribute to adverse outcomes, where educators consider adapting teaching and assessment methods to leverage AI's benefits while mitigating risks such as academic dishonesty [21].

It is crucial to design educational programs that balance the use of AI with traditional hands-on and problem-solving training to ensure that students remain adept at both using technology and performing without it. This practice may further necessitate cultural and contextual specific considerations for dental practices in diverse environments, regarding regional differences in dental conditions, treatment preferences, and public health guidelines.

Furthermore, privacy and security of personal health information (PHI) are important to consider. Dental education often involves the use of patient data, including medical histories, diagnostic images, and clinical findings. When using LLMs and FMs in this setting, it is essential to ensure that PHI is not included and that the use of AI has been discussed and approved by the institutions in which they are being used. The entered information (including text and image) should be stripped of any identifying information (and images should be checked for not violating copyright laws) before being input into the AI

model to prevent potential privacy breaches, especially with publicly accessible LLM and FMs, which are loosely governed or regulated. These models, as a dental education tool, ideally should be hosted on secure platforms with robust encryption and access controls to prevent unauthorized access and data breaches. Some institutions may provide secure cloud services via compliant service providers (eg, Microsoft Azure, Amazon Web Services, and Google), which may ensure a more private ecosystem for AI use. Various regulations govern the handling of PHI and the use in health care, such as the Health Insurance Portability and Accountability Act in the United States and the General Data Protection Regulation in the European Union [33]. These regulations set forth strict requirements for the management of PHI, including data privacy, security, and patient rights. In addition, dental education institutions using such AI models must ensure compliance with the relevant regulations in their jurisdiction to avoid legal repercussions and maintain the trust of patients and the dental community (eg, the recently proposed California AI accountability act necessitates transparency by requiring agencies to disclose interaction with AI and to conduct risk assessment before AI adoption) [34]. [Table 1](#) outlines current challenges and strategies to address them in dental education.

Table . Strategies to address challenges with LLMs^a and FMs^b in dental education.

Category and strategy	Details
Bias and inaccuracy mitigation	
Specialized training data sets and knowledge base	Use data sets compiled from a diverse range of dental texts, research papers, and case studies to train the LLM or FM or for use as part of the knowledge base, ensuring they cover various dental specialties and scenarios.
Continuous clinical validation	Regularly validate LLM or FM outputs against current dental practices and standards by engaging with dental boards or professional groups.
Domain-specific fine-tuning and guided prompt engineering	Work with dental faculty and practicing dentists to tailor the LLM or FM outputs to reflect up-to-date clinical guidelines and diagnostic criteria. In addition, use guided prompt engineering and alternative approaches (eg, chain-of-thought) to improve outputs.
Operational guidelines	
Curriculum integration guidelines	Develop specific guidelines on how LLM or FM integrates into different parts of the dental curriculum, such as diagnostics, treatment planning, and patient communication.
Professional oversight	Set up a committee of dental professionals to oversee the implementation and use of LLM or FM, ensuring alignment with educational outcomes and clinical accuracy.
Enhancing student interaction	
Simulation-based learning	Incorporate LLM or FM into simulation settings where students can interact with AI ^c to diagnose and treat virtual patients, enhancing their practical skills without risk.
Reflective practice sessions	Facilitate sessions where students reflect on the AI's suggestions compared to standard treatment protocols, promoting critical thinking and decision-making skills.
Privacy and security	
Scenario-based training	Train students and staff on handling personal health information through scenario-based exercises, ensuring they understand how to manage data securely when using LLM or FM in dental settings.
Enhanced encryption for dental data	Implement higher levels of encryption and security measures for platforms hosting dental data to ensure compliance and safeguard against breaches.
Regulatory compliance	
Tailored compliance workshops	Hold workshops focused on the specific legal requirements related to using LLM or FM with PHI in the dental field, such as Health Insurance Portability and Accountability Act in the United States and General Data Protection Regulation in Europe.
Ethical use guidelines	Develop ethical guidelines that address the nuances of using AI in dental training and practice, including issues of patient consent and AI transparency.
Feedback and continuous improvement	

Category and strategy	Details
Feedback system for clinical use	Establish a structured feedback system where dental students and professionals can report inaccuracies or ethical concerns with AI outputs, facilitating continuous improvement.

^aLLM: large language model.

^bFM: foundation model.

^cAI: artificial intelligence.

Conclusions

The integration of LLMs and FMs into dental education holds promising opportunities for improving the quality of education and better preparing future dental professionals. By navigating the challenges and leveraging the potential benefits, dental educators can create more interactive, personalized, and innovative learning experiences that effectively prepare students for the complex and evolving world of dental practice. These

considerations are also applicable for patient education and self-care practices as well. Considering the accessibility of these models to the public, educational considerations could be further expanded for patient education. Future works are suggested on gathering empirical evidence for the feasibility and utility of LLMs or FMs, including alternative prompt engineering approaches, fine-tuned custom model testing, user testing, cost-benefit analysis, and expanding AI guidelines for including generative AI use in dental education.

Acknowledgments

We used the generative AI tool, ChatGPT by OpenAI [35], to draft example cases (Textbox 1-Textbox 4).

Authors' Contributions

ES conceived the idea. ES and DC contributed to ideation and planning, contributed equally in drafting and finalizing this paper, and reviewed and approved the final paper.

Conflicts of Interest

ES is an associate editor in the editorial board of *Journal of Medical Internet Research* at the time of this publication.

Abstract

Digital transformation has disrupted many industries but is yet to revolutionize health care. Educational programs must be aligned with the reality that goes beyond developing individuals in their own professions, professionals wishing to make an impact in digital health will need a multidisciplinary understanding of how business models, organizational processes, stakeholder relationships, and workforce dynamics across the health care ecosystem may be disrupted by digital health technology. This paper describes the redesign of an existing postgraduate program, ensuring that core digital health content is relevant, pedagogically sound, and evidence-based, and that the program provides learning and practical application of concepts of the digital transformation of health. Existing subjects were mapped to the American Medical Informatics Association Clinical Informatics Core Competencies, followed by consultation with leadership to further identify gaps or opportunities to revise the course structure. New additions of core and elective subjects were proposed to align with the competencies. Suitable electives were chosen based on stakeholder feedback and a review of subjects in fields relevant to digital transformation of health. The program was revised with a new title, course overview, course intended learning outcomes, reorganizing of core subjects, and approval of new electives, adding to a suite of professional development offerings and forming a structured pathway to further qualification. Programs in digital health must move beyond purely informatics-based competencies toward enabling transformational change. Postgraduate program development in this field is possible within a short time frame with the use of established competency frameworks and expert and student consultation.

KEYWORDS

digital health; digital transformation; health care; clinical informatics; competencies; graduate education

Introduction

In contrast to simple digitization of processes, digital transformation describes the “comprehensive reorientation of an industry, including its business models, due to the coming of age of digital technologies” [1]. In health care, digital technologies have attracted considerable investment for their potential to reduce costs, improve patient experience, and clinician and system efficiency [2]. However, potential digital health interventions can experience “pilotitis” as innovators and health systems can lack the reciprocal clarity of roles and processes to be able to successfully design, launch, and scale a robust product [3]. This fragmentation explains the observation that while diverse innovative digital health interventions have proliferated in the last 50 years [4], the hope for transformational change and increased value-add of health systems has not yet been delivered [5].

Alongside global recognition of the importance of digital health [6], the domains of digital health and health informatics have become areas of increasing focus for education and workforce

development. In Australia, the newly published National Digital Health Capability Action Plan (CAP) and institutional education strategies have a significant role to play in building digital health capability across the health workforce [7-9]. Across a 7-year roadmap, the CAP has outlined priority actions including the development of specialist digital health career pathways, specialist digital health courses, and continuing professional development opportunities for clinicians, informaticians, service management, and related roles in the health sector.

However, the digital transformation of health care cannot be driven by 1 sector alone. For this reason, innovation centers have been established globally in recent years to facilitate collaboration between all stakeholders involved in digital health [3]. In Australia, the University of Melbourne runs multidisciplinary digital health programs through The Center for Digital Transformation of Health, established in 2019 with the vision of “connecting digital innovation to health” [10]. The center sits within the Faculty of Medicine, Dentistry and Health Sciences and operates in conjunction with the School of Computing and Information Systems, Faculty of Engineering

and IT. In 2023, the authors of this paper were commissioned for 3 months to redesign and adapt the existing Graduate Certificate in Health Informatics and Digital Health to meet contemporary national and international digital health standards and align with key center vision and mission objectives.

This viewpoint describes the realignment of the existing Graduate Certificate in Health Informatics and Digital Health with the philosophy of “digital transformation,” building on the internationally recognized American Medical Informatics

Association (AMIA) clinical informatics competency framework [11,12]. The methodology may be used as a blueprint to aid the development of future digital health programs.

Methods

Market Context

The market needs analyses and student feedback informed subsequent stages of competency mapping and course structure review (Figure 1).

Figure 1. Process for evaluation and redesign of the digital health postgraduate program. AMIA: American Medical Informatics Association; HEIMS: Higher Education Information Management System.

A market scan was conducted using data from the Higher Education Information Management System, from the University of Melbourne Department of Education and Training. Over the

past 5 years, universities across Australia have seen increased interest in students pursuing higher professional certification in digital health. Many new postgraduate offerings in digital

health, eHealth, health information management, and health and clinical informatics have been created, with 60 - 70 new enrollments in graduate certificates offered in Queensland and Victoria in 2023 alone [13].

Several commissioned needs assessments, market analysis reports, and student reflections within course evaluations were undertaken by the center between 2021 and 2023 to assess future directions for offering digital health professional development, degree, or award programs. The analyses confirmed the challenges of the changing clinical landscape and increased enrollment trends in national graduate certificates in digital health, as well as the presence of an emerging market for people entering or transitioning into the field of digital health. In October 2020, some students (n=14, 20% response rate) enrolled in the University of Melbourne Master of Information Systems Health specialization and the graduate certificate indicated that they were looking for new digital health work opportunities (10 of 14, 71.4% response rate). The survey respondents recommended stronger education in key entry-to-practice degrees and incentives for continued professional development programs.

A recurring theme indicated current clinical career pathways in digital health are not dependent on formal professional certification. Of the 699 advertised digital health-related jobs found over a 3-month period, between October 12, 2020, and January 18, 2021, of which 130 positions were advertised in the state of Victoria, there was significant variation in the range of qualifications, as well as the specialized knowledge and skills relevant to digital health. Short course participant data also highlighted that clinicians are more inclined to consider a graduate certificate if it helped progress their career, with top subjects of interest in domains of data science and artificial intelligence (“machine learning, artificial intelligence and big data” and “data analytics, data linkage, power BI and R”), and the development, implementation, or evaluation of digital health interventions.

Key quotes from participants included “I think you need some ability to put skills learnt into practice in a guided way to really make an impact” and “Theory is just more theory and many of us are way beyond that. Those wanting to do this course would be wanting to make a change, not theorise about it.”

In summary, and with consideration to the accelerating pace of digital health technology development, it was anticipated that the observations heralded ongoing and increasing interest in this field.

Competency Mapping

The University of Melbourne’s Graduate Certificate in Health Informatics and Digital Health, offered at the postgraduate level, or Australia Qualifications Framework level 8, sits above the professional certificate, and upon completion can be streamlined into a relevant master’s degree. The existing certificate consisted of 3 core subjects in biostatistics, health informatics methods, and critical thinking with analytics, alongside limited elective subject options.

To ensure the certificate had core alignment with international informatics standards, SC and MM examined the learning

outcomes in subjects in the existing certificate and compared them to the AMIA Core Clinical Informatics Competencies. The Australian Health Informatics Competency Framework (AHICF), developed by the national peak body for informatics, the Australasian Institute of Digital Health (AIDH) [14] was also examined, and syllabi of comparable national and international graduate certificates, sourced from institutional websites, were considered for completeness. The initial mapping phase consisted of a direct comparison of subject-level learning outcomes with statement-level competencies in the AMIA framework. Subsequently, the results were summarized and presented to an expert panel of subject coordinators and center leadership to confirm the accuracy of the mapping and identify further gaps and opportunities.

Results from the competency mapping and the panel interview were used to inform the decision about whether there were existing University of Melbourne subjects that could be used to complement missing competencies, or if there was an opportunity to develop a new subject in digital health, or both. Subjects in the certificate should also be included if they could be accredited toward a relevant master’s degree, should the certificate student choose to continue with a higher qualification.

Course Learning Outcomes and Course Structure Redesign

Course-level learning outcomes were developed with consideration to (1) core clinical informatics competencies and (2) desired skills and knowledge beyond clinical informatics, that could equip a graduate to navigate the digital transformation of health care. The latter was derived from course participant feedback, as outlined, as well as key concepts from digital transformation literature:

- “A multi-stakeholders perspective (which) is critical to understanding properly how, in practice, the various players of a (healthcare) ecosystem (patients, pharmaceutical companies, hospitals, public agencies, and many more) exploit (digital transformation) technologies and means to quality of care, value creation, and many more managerial issues” [15]
- Reducing roadblocks that may slow innovation in health systems, including “aligning cross-departmental stakeholders (information technology, security, risk, legal, etc)” [3]
- Introducing the concept of learning health systems, in which “science, informatics, incentives, and culture are aligned for continuous improvement and innovation, with best practices seamlessly embedded in the care process, patients and families as active participants in all elements, and new knowledge is captured as an integral by-product of the care experience [16].”

Core subjects were selected from the results of the competency mapping, and their subject-level learning outcomes were reviewed to ensure accordance with the course-level learning outcomes.

Electives for Digital Transformation of Health

The University Handbook, an online catalog of courses and programs, was searched for subjects that could be suitable for

inclusion in the certificate as elective subjects. Inclusion criteria included subjects in domains relevant to data science and statistics, product development, business, leadership and change management, consumer participation in health care, research methods, sustainability, or ethics or legal subjects. A total of 79 subjects were identified. Upon closer consideration, 50 were excluded for the reasons of limited relevance to digital health; required pre-requisite subjects that could not be taken within the constraints of the graduate certificate; discontinued subject; or timing or delivery of the subject not suitable (eg, not semester-long or on-campus only, whereas the certificate required hybrid or online subjects).

As it was intended that the graduate certificate could be used to build a career pathway in digital health, the remaining subjects were assessed for their suitability to scaffold toward a master's pathway. Coordinators of eligible subjects were contacted to determine their availability and interest to be part of the new graduate certificate. After approvals were received, subjects were chosen for their eligibility to form a pathway from professional certificate, graduate certificate, to master's pathways in public health, information systems, and clinical Research.

Results

The mapping and interview phases revealed that many core informatics competencies were already covered within the existing certificate, but there were opportunities to include advanced content about data science, machine learning, and artificial intelligence; the development, implementation, and evaluation of digital health interventions, digital transformation of health care systems, and indigenous data governance. These topics have become increasing areas of interest and debate in recent years, and their need for inclusion in the certificate was evident if the certificate was to both align with recognized standards and be relevant to the modern digital health landscape.

Additionally, the mapping process highlighted the need for a more structured approach to the certificate design, which the center was in a position to provide given the depth and diversity of expertise available.

The new certificate consists of 2 core subjects that were previously electives, that had been identified as achieving the most comprehensive range of AMIA Core Clinical Informatics Competencies ([Multimedia Appendix 1](#)). Further mapping to AHICF competencies confirmed alignment with national clinical informatics competencies ([Multimedia Appendix 2](#)). The Applied Learning Health Systems subject additionally had a strong focus on practical multidisciplinary learning for the digital transformation of health. The certificate title, course overview, and course-level learning outcomes were updated to align with the skills and competency requirements of the changing market ([Textbox 1](#)).

The proposed course-level learning outcomes could now map upstream to the 5 AMIA Clinical Informatics domains ([Textbox 2](#), [Table 1](#)) and downstream to subject-level intended learning outcomes of the 2 core subjects ([Table 2](#)). Considering the close alignment of the AMIA and AHICF frameworks, for simplicity, the table shows mapping to AMIA competencies only.

A total of 13 electives were identified that would complement the core subjects and allow participants the flexibility to build knowledge and skills in 1 of the self-identified areas of data science and statistics, product development, business, leadership and change management, consumer participation in health care, research methods, sustainability, or ethico-legal contexts in digital health ([Table 3](#)). Students would be able to choose 2 elective subjects to complement the core subjects.

To reflect the center's vision of translating digital health innovations into clinical practice, the final metamorphosis of the course included a strategic title change from Graduate Certificate of Health Informatics and Digital Health to Graduate Certificate in Digital Transformation of Health.

Textbox 1. Comparison of previous and newly developed course-intended learning outcomes.

<p>Previous course-level intended learning outcomes</p> <p>On completion of this course, graduates will be able to:</p> <ul style="list-style-type: none"> Communicate knowledgeably about core health and biomedical informatics concepts, tools and methods, and methods. Critically evaluate approaches to information systems and information technology in contemporary health care in Australia and internationally. Develop an integrated understanding of how digital data, information, and knowledge are generated and managed for clinical care, biomedical research, public health, and health policy and planning. <p>New course-level intended learning outcomes</p> <p>On completion of this course, graduates will be able to:</p> <ul style="list-style-type: none"> Describe how contemporary digital health technologies can be integrated into health care practice in terms of their effect on safety and quality, access and equity, continuity of care, effectiveness, and consumer empowerment. Critically evaluate the generation, governance and use of digital data, information and knowledge, including legal and ethical considerations, in the context of electronic health records, clinical decision support systems, virtual care, mobile health, and machine learning and artificial intelligence applications in health. Apply the concept of a learning health system and processes of problem assessment, data analysis, design thinking, implementation science, and evaluation frameworks to digital health initiatives in specific contexts. Apply principles of governance, leadership, change management, and strategic planning to integrate digital health initiatives and innovation within organizations, across communities and health care systems.

Textbox 2. The American Medical Informatics Association clinical informatics competency domains.

- Fundamentals
- Improving care delivery and outcomes
- Enterprise information systems
- Data governance and data analytics
- Leadership and professionalism

Table . Relationship of clinical informatics competencies and new course-level intended learning outcomes.

Course-level intended learning outcomes (CILO)	Relevance to AMIA ^a domains
CILO1: Describe how contemporary digital health technologies can be integrated into health care practice in terms of their effect on safety and quality, access and equity, continuity of care, effectiveness, and consumer empowerment.	AMIA1, AMIA2, and AMIA3
CILO2: Critically evaluate the generation, governance, and use of digital data, information, and knowledge, including legal and ethical considerations, in the context of electronic health records, clinical decision support systems, virtual care, mobile health, and machine learning and artificial intelligence applications in health.	AMIA2, AMIA3, and AMIA4
CILO3: Apply the concept of a learning health system and processes of problem assessment, data analysis, design thinking, implementation science, and evaluation frameworks to digital health initiatives in specific contexts.	AMIA1 and AMIA2
CILO4: Apply the principles of governance, leadership, change management, and strategic planning to integrate digital health initiatives and innovation within organizations, across communities, and health care systems.	AMIA5

^aAMIA: American Medical Informatics Association.

Table . Relationship of new course-level and subject-level intended learning outcomes.

Core subject title and subject-level intended learning outcomes (SILO)	Relevance to course-level intended learning outcomes (CILO)
Digital transformation of health	
SILO1: Explain complex aspects of the structure of health care, including the roles of patients, various professionals, insurance companies and governments.	CILO1
SILO2: Describe the implications of the generation and the use of biomedical data, information, and knowledge within a variety of relevant systems and settings.	CILO2
SILO3: Demonstrate the understanding of how core digital health technologies work, through practical activities with simulations of tools such as electronic health records, clinical decision support systems, patient portals, and mobile apps and wearable sensors.	CILO1 and CILO2
SILO4: Critically analyze how various digital technologies can optimize information use within health care and summarize the potential risks associated with these solutions.	CILO1
SILO5: Apply ethical frameworks and conceptual models to critique contemporary digital health practices and trends.	CILO1
Applied learning health systems	
SILO1: Appraise emerging trends and approaches in digital health and informatics.	CILO1 and CILO2
SILO2: Illustrate how concepts of the learning health system can be applied to your current workplace and role.	CILO3
SILO3: Outline potential activities in a learning health system project starting with data access and analysis—through designing a virtual care model—and ending with evaluation, implementation, and transformation.	CILO1, CILO3, and CILO4
SILO4: Create a proposal for a learning health systems (LHS) project that could be implemented at your current or future workplace, which applies digitally enabled LHS concepts.	CILO3 and CILO4

Table . Elective subjects for digital transformation of health.

Elective title	Elective overview
Digital health informatics methods	Overview of major health informatics research areas and methods that contribute to quality improvement, scientific research, and technological innovation in health care and biomedicine.
Biostatistics	Introduction to the fundamental concepts of statistics and the essential methods required to equip students to perform basic statistical analyses and interpret research findings in the public health setting.
Digital health for consumers	Explores wise use of consumer health technologies through dimensions of consumer digital health literacy, global consumer health technology marketplace, lived experiences of active users, and scenarios where consumers are partners in designing and using digitally enabled learning health systems.
Leading health care change for impact	Examines strategies for leading change in clinical settings and health care organizations.
Technology and aging	Examines ways in which recent technological advancements can revolutionize the experience, management, and future of aging.
Health care environment evaluation	Explores the complex, dynamic, interdisciplinary, and multipurpose nature of health care environments focusing on key dimensions of physical workspaces design, virtual work-spaces, and leadership and management practices.
Introduction to programming	Introduction to the fundamental concepts of computer programming and how to solve simple problems using high-level procedural language, with a specific emphasis on data manipulation, transformation, and visualization of data.
Law and emerging health technologies	Examine ways in which law is affecting, and being affected by, the latest advances in medical technology, including genetic, big data analytics, regenerative, therapeutic, artificial intelligence, and reproductive technologies.
Innovation and emerging technologies	Introduction to innovative and contemporary technology that has been recently developed and is currently used in clinical practice and research for the purposes of measurement, diagnosis, and prescription.
Sustainability and health care	Explores the need to urgently formulate adaptation and mitigation strategies, thereby addressing the global climate change emergency, through the lens of sustainable health care.
Natural language processing	Learn computational methods for working with text, in the form of natural language understanding and language generation to develop an understanding of the main algorithms used in natural language processing.
Machine learning applications for health	Introduction to different artificial intelligence applications in health, using different clinical data sources and computational techniques.
Indigenous data governance in health	Provides an overview of the scope of Indigenous data including governance, ethical health research, knowledge translation and evaluation, institutions, and data collections.

Discussion

Principal Results

The redesigned Graduate Certificate in Digital Transformation of Health occurs in the context of increasing awareness of the need to develop a digitally capable health workforce [7-9]. However, broader industry trends show that the digital health sector also contains diverse careers in data analysis, informatics, and application development, with early and mid-career professionals from clinical care, health management, and technology sectors keen for interactive, practical, and interdisciplinary learning [17]. Although the certificate was redesigned with clinical informatics competencies in mind, a high proportion of its students are likely to be from nonclinical

backgrounds or nonphysician careers, based on the demographics of previous enrollments.

It was, therefore, the aim of the certificate to align with industry trends and provide flexibility for any professional interested in digital health transformation, not just clinicians, to tailor their learning. This was achieved by mapping the competency frameworks, which revealed 2 subjects that could be used as core subjects, allowing the certificate to be condensed from 3 to 2 cores and creating room for 2 elective subjects. The new “2 core plus 2 elective” structure allows the professional certificate to form a path to a graduate certificate and also allows a range of elective choices that are unique to the certificate. The newly identified electives were not only chosen based on participant feedback and framework gaps but also are aimed to

empower health professionals to lead change within our complex adaptive health system. Newly identified electives with a focus on innovation and emerging technologies, indigenous data governance, sustainable health care, and machine learning applications will facilitate the next transformative phase within the industry.

The new title aligns with existing course offerings including the Professional Certificate of Digital Transformation of Health and organizational strategic vision. The program's content also aligns with new industry trends strengthening management and leadership skills in the core Applied Learning Health Systems subject to allow for a spectrum of digital health pathways. This is critical as although many traditional degrees have set curricula and linear career pathways, learners in digital health come with vast differences in career backgrounds, qualification levels, expertise, amount of work experience, and intrinsic motivations for joining digital health. Consequently, they may end up applying their knowledge and skills to any part of the digital health ecosystem.

Limitations

The multitude of certifications and career pathways in digital health reflects the demand from professionals to enter this pathway. However, the complexity of developing a program in this rapidly progressing field cannot be overstated. This viewpoint describes the practical needs assessment and redevelopment of a graduate program within the time constraints of an institutional schedule. Consultation for this project was informed by reports that included student evaluations but mainly occurred at the faculty educators and executive level. Given the diverse demographics of digital health learners, there is scope to continue co-design the program with past and potential future

certificate students, as well as other major stakeholders in digital health such as consumer advocates.

Future work will focus on evaluating the acceptability and effectiveness of the structure and content of the certificate to these stakeholders. A robust evaluation process, modeled on the Kirkpatrick framework, is already in place within 1 core subject [18] and forms the model for evaluation for other subjects in the certificate. In addition, all University subjects undergo continuous evaluation using Student Learning Surveys, in accordance with University standards and processes [19]. As comprehensive program evaluation is critical for its long-term success, assessment of further approaches such as the creation of logic models [20] is underway.

Mapping the previous program to clinical informatics competencies and student feedback was efficient in reaching this point. Challenges ahead lie in maintaining the currency of the learning content and ongoing evaluation and improvement of the effectiveness of its curriculum, learning activities, and assessments. The program will continue to be reviewed against the progress of the CAP, the evolution of the digital health landscape in Australia, and insights from international colleagues and organizations. The next steps will include the development of a decision matrix to aid the prioritization and co-design of new subjects.

Conclusions

A systematic refinement of this postgraduate program has been conducted to align with the center's vision of digital innovation and transformation of health care. Through strategic alignment, competency mapping, and a pedagogical ethos, the transformed graduate certificate aspires to make a substantial impact on the evolving health care ecosystem.

Acknowledgments

The authors sincerely thank Wendy Chapman, Meredith Layton, Daniel Capurro, Brian Chapman, Sathana Dushyanthen, Elizabeth Dent, and Gouri Ligam for their input and assistance in progressing this project.

Abstract

In the field of medicine, uncertainty is inherent. Physicians are asked to make decisions on a daily basis without complete certainty, whether it is in understanding the patient's problem, performing the physical examination, interpreting the findings of diagnostic tests, or proposing a management plan. The reasons for this uncertainty are widespread, including the lack of knowledge about the patient, individual physician limitations, and the limited predictive power of objective diagnostic tools. This uncertainty poses significant problems in providing competent patient care. Research efforts and teaching are attempts to reduce uncertainty that have now become inherent to medicine. Despite this, uncertainty is rampant. Artificial intelligence (AI) tools, which are being rapidly developed and integrated into practice, may change the way we navigate uncertainty. In their strongest forms, AI tools may have the ability to improve data collection on diseases, patient beliefs, values, and preferences, thereby allowing more time for physician-patient communication. By using methods not previously considered, these tools hold the potential to reduce the uncertainty in medicine, such as those arising due to the lack of clinical information and provider skill and bias. Despite this possibility, there has been considerable resistance to the implementation of AI tools in medical practice. In this viewpoint article, we discuss the impact of AI on medical uncertainty and discuss practical approaches to teaching the use of AI tools in medical schools and residency training programs, including AI ethics, real-world skills, and technological aptitude.

KEYWORDS

artificial intelligence; machine learning; uncertainty; clinical decision-making; medical education; generative AI; generative artificial intelligence

Introduction

In clinical practice, uncertainty refers to a physician's perceived inability to accurately explain or advise on a patient's medical problem [1] and may arise at any stage of the patient encounter, be it assessment, investigation, diagnosis, or treatment [2]. Physicians have both a professional and instinctive desire to be as certain as possible when diagnosing or treating patients [3]. While teaching physicians to tolerate uncertainty is important, there is also a need to overcome problems in medicine that contribute to uncertainty in the physician's mind. Several models of uncertainty have been proposed, but for the ease of our discussion, the distinction between reducible and irreducible uncertainty is most relevant.

Simply put, uncertainties associated with unknowable things are irreducible, and uncertainties associated with knowable things that are currently unknown are reducible [4]. Reducible

forms of uncertainty in medicine may stem from the lack of information about the effects of treatment; information overload or complexity; vagueness of terms; or differing beliefs, values, and preferences among providers [5]. Reducible uncertainty can be overcome by obtaining new knowledge. For example, an 85-year-old woman with a headache and a pulsatile temporal artery with a normal erythrocyte sedimentation rate and normal C-reactive protein (CRP) levels may be treated for giant cell arteritis (GCA) with pulse steroids in the emergency department by one provider, but might be deemed unlikely to have the same diagnosis by another. The uncertainty may arise, in this case, from any number of factors, including the lack of a consensus definition of GCA, differing tolerances of risk among providers, and the overall clinical appearance of the patient.

Irreducible forms of uncertainty in medicine, on the other hand, stem from statistical limitations (eg, random error due to natural variation), epistemic problems (such as measurement error,

systematic error, model uncertainty, and uncertainty about inducing case probability from class probability), or numerical vagueness [5]. For example, again considering the diagnosis of GCA, both an elevated erythrocyte sedimentation rate and elevated CRP level (eg, CRP level >10 mg/dL) may help to confirm the diagnosis. However, even a CRP level of 12 mg/dL may not be considered elevated for older age, obesity, and smoking (all of which are factors that may raise the CRP level). The uncertainty in this case is due to the difficulty in applying the broader diagnostic criteria to the specific patient being assessed, and natural variation in numerical criteria used to make the diagnosis. Even with the development of more specific numerical cutoffs for CRP levels, patients with levels slightly above the threshold may not truly have an increased risk of the disease. These are foundational problems of knowledge creation and not specific to medicine. As such, irreducible forms of uncertainty cannot be eliminated by obtaining new knowledge.

Artificial intelligence (AI) tools are being increasingly used as adjuncts to improve diagnosis, medical decision-making, and treatment. Here, the distinction between reducible and irreducible uncertainty becomes important; the forms of uncertainty that can be improved by obtaining knowledge (namely, the reducible forms) may see a benefit with the introduction of AI tools in medical practice. AI tools that have been developed can assist physicians with documenting encounters [6], diagnosing skin cancer [7], providing patient information on medical conditions [8], and teaching surgical skills to medical trainees [9].

Despite the promise AI tools may hold to overcome the sources of uncertainty in medicine, the relationship between AI and medical uncertainty has not been explored in the literature. In this viewpoint article, we consider the potential of AI tools to reduce uncertainty in medical practice, when used as adjuncts to clinical reasoning. In addition, we offer practical approaches to teaching the use of AI in medical schools and residency programs to increase the uptake of these tools in practice.

Impact of AI on Reducible Uncertainty

The potential impact of AI tools on reducible uncertainty in medical practice is vast. We will, however, focus our discussion on three sources of reducible uncertainty: (1) lack of clinical information, (2) provider competence, and (3) provider bias.

Clinical Information

A significant source of uncertainty in medical practice is the lack of availability of relevant information to make a decision. This may include the lack of studies about the disease process or the lack of information about the particular patient. AI tools are currently being employed to gather scientific data, through large database management and integration with biobanks [10], and integrate these biological and clinical variables in prediction outputs [11]. This accelerated pace of data gathering may substantially advance our understanding of disease. In addition to the limited understanding of disease in the scientific community, the lack of information about the particular patient can also create uncertainty. Consider a patient who presents for psychiatric assessment with suicidal ideation. A detailed history

is required to arrive at the underlying cause of distress, but it is time-consuming to elicit this information and is affected greatly by patient rapport. AI tools, including scribes [12], can help to address such time constraints, by reducing time spent on documentation and administrative tasks. AI may also provide feedback on a physician's skills in providing patient-centered care, facilitating improvement in this domain [13]. In addition, patients may be more willing to provide socially negative information to AI programs than to physicians, assisting with the collection of data used in clinical decision-making [14].

Provider Competence

Provider skill, knowledge, and experience may also lead to diagnostic uncertainty. AI tools are currently being developed as clinical decision support aids. For example, deep neural networks have been able to classify skin cancer from dermoscopic images at similar levels of accuracy to board-certified dermatologists [15]. Similarly, AI tools have been developed to support the triage process in emergency departments with a 27% greater accuracy than that of the average nurse [16]. These tools have the tremendous potential of reducing human error and contributing to personal learning and process improvement.

Provider Bias

Differing beliefs, values, and preferences among physicians also contribute to reducible uncertainty in diagnosis and treatment. Medical decision-making is ideally a balance of the best available evidence and clinical gestalt, the latter being influenced by unconscious biases. For example, in cases where the incidence of disease is lower in a particular population, a reliance on heuristics may result in underdiagnosis. Take for example, the diagnosis of cutaneous malignant melanoma, which has a lower incidence rate in people with darker skin color compared to non-Hispanic individuals with lighter skin color [17]. Research has shown that patients with darker skin types are more likely to present with later stage cancers [18], resulting in higher mortality rates [19]. AI could assist with addressing disagreements by providing recommendations, irrespective of the decision-making agent's personal perspectives, beliefs, or biases. In fact, a recent study demonstrated that ChatGPT could predict dermatoses in people with lighter and darker skin color with similar levels of accuracy [20], despite established clinical disparities in the diagnosis of skin conditions between these groups [21].

Impact of AI on Irreducible Uncertainty

Despite the potential of AI tools to affect the reducible forms of uncertainty, there are irreducible forms of uncertainty in medicine that these tools will not resolve. Here, we will discuss two irreducible forms of uncertainty, (1) the application of class-to-case probability and (2) model uncertainty, and how AI tools will impact them.

Class-to-Case Probability

The distinction between class probability and case probability as a source of uncertainty was first described by Austrian economist and philosopher, Ludwig von Mises [22]; he described class probability as a general understanding of risk

for a particular group of people, and case probability as the specific understanding of risk for an individual. For example, based on large population studies, we understand that by the age of 80 years, 14% of smokers will develop lung cancer [23]. However, for a particular 65-year-old smoker who comes into the office, whether they will develop lung cancer remains uncertain. Their risk is based on several immeasurable factors, including their comorbidities, environmental exposures, and genetic profile. Regardless, medical decision-making routinely involves an abstraction of class probability to case probability, and we reasonably accept this patient's risk of lung cancer to be 14%.

What is the impact of AI on this problem? AI tools are capable of analyzing large datasets and identifying patterns that may improve the overall accuracy in estimating the risk for groups of patients (class probabilities). Additionally, these tools are being increasingly used to advance the field of precision medicine [24]. For example, genotype-guided treatment is an area of active research in precision medicine. Genomic profiling can be used to provide targeted therapy for patients with lung or breast cancer [25]. By integrating massive amounts of individual data (genetics, lifestyle, and environmental exposure), AI may be able to better predict how a specific patient might respond to treatment, improving our understanding of case probability. Additionally, these tools are also able to learn continuously and may be able to refine their predictions regarding disease risk and prognosis as more information becomes available. Wearable devices, for example, which collect continuous, multidimensional data during daily activities, have captured subtle changes in cognition and functional capacity long before the onset of dementia [26]. Despite these advances, decision-making in medicine will continue to rely on the abstraction of class probability to case probability, as the future outcome of a particular case can never be predicted with complete certainty. This is an epistemological source of uncertainty that AI may be able to mitigate, but never eliminate.

Model Uncertainty

Model uncertainty is another reducible form of uncertainty in medicine. This form of uncertainty arises from the fact that models of disease are approximations of complex systems and involve simplifications of reality and assumptions. As a result, these models may not explain all presentations of a disease. For example, we understand a depletion in serotonin as being a cause of depression [27]; however, this model is imperfect and does not explain why some people who meet the criteria for depression do not respond to selective serotonin reuptake inhibitors. One advantage AI tools offer is that they are data-driven rather than assumption-driven. Deep learning techniques can allow AI tools to learn from raw data rather than predefined model parameters. For example, AI tools used in the COVID-19 pandemic were able to identify unusual cases of pneumonia before public health authorities recognized the threat [28]. Unlike traditional models that are fixed once developed, AI models can also learn and adapt over time as new data becomes available. This means that AI tools can develop models that change over time, at rates much faster than traditional scientific models were developed.

While these tools may reduce model uncertainty, one limitation of AI tools when used to develop models of disease is the lack of explainability or algorithmic transparency. It is not always easy or possible to understand how and why an AI system arrives at its decision [29]. Currently, the tools, methods, policies, and frameworks required for explainable AI have not been well developed [11]. This lack of transparency may increase model uncertainty, due to a lack of physician trust in the model's decision. While explainable AI is foreseeable with time and technological advances, on an epistemological level, AI cannot overcome the fundamental limitation that models are approximations of reality with inherent error. Therefore, model uncertainty will persist as a challenge to medical decision-making despite advances in AI.

Teaching AI to Medical Learners

Overview

Despite the promise AI tools hold in reducing uncertainty, there has been considerable resistance to the implementation of AI tools in medical practice. Several reasons for this reluctance exist, including a lack of transparency, cost, privacy issues, reputation concerns, and legal liability [30]. Some medical professionals also perceive AI systems as threats to medical professional identity (recognition and capability) [31]. In addition, patients worry that these tools may not be able to account for their unique preferences the way a physician might [32]. These concerns are valid and will need to be addressed before AI tools reach widespread implementation. Indeed, our understanding of AI ethics and privacy issues has greatly improved in the last 5 years [33]. Despite these barriers, AI tools have already made their way into medical practice. In fact, learners are increasingly voicing an interest in training on how to use AI technologies in medical practice [34]. Consequently, a shift in perspective is required in medical education to teach learners how to practically use these tools and to understand their benefits and limitations.

Novel teaching approaches are needed to train medical learners to use AI tools practically and responsibly. For educators involved in designing medical curricula, three objectives should be considered: (1) improving students' understanding of capabilities, limitations, and ethics of AI use; (2) increasing practical skills in the use of AI; and (3) increasing technological aptitude needed for producing AI systems.

Teaching the Capabilities, Limitations, and Ethics of AI Use

Students should receive formal education on the capabilities and limitations of AI tools. This includes the scope of technologies presently available in various fields of medicine, in addition to those that are newly emerging, including AI scribes, triage assistants, and patient-facing chatbots. Learners should also be made aware of the limitations of these technologies, including the potential for error due to assumptions of class-to-case probability and model uncertainty. Generative forms of AI, including ChatGPT, experience the lack of context and generalizability and are consequently at risk of spreading misinformation [35]. This phenomenon, known as

“hallucination,” refers to the generation of information that appears statically plausible but may not be accurate [36]. Students must be made aware of these limitations. In addition, students should be educated about the ethical and legal risks and issues, misinformation, and hallucinations. This includes social discrimination and racial bias in datasets used to develop these tools, which may be further perpetuated by these tools [37]. The legal implications of AI use should also be discussed. While the legalities around AI use are currently being debated, there is a possibility of medical negligence and liability to both physicians and medical institutions if undue harm to the patient is caused by these tools [38]. Students should also be informed about the privacy and security considerations of sharing personal health information with AI tools, including generative forms of AI, such as ChatGPT [39,40]. The capacity of AI tools to “hallucinate” or provide misinformation, and the efforts needed to improve the technical abilities of present forms of AI should also be taught. Teachers and institutions should find ways to develop and enhance students’ critical thinking and analytical skills first, as these technologies are first introduced and refined for practice.

Teaching Practical Skills in AI Use

At present, there is very little teaching on how to practically use AI tools for medical students and residents. This includes the use of these tools for personal, academic, and medical purposes. Perhaps the first step in medical education reform is to normalize the use of AI as a teaching and learning aid. AI has been shown, for example, to ameliorate teaching through helping with teaching concepts; creating and improving scenario modeling, courses, and content; and traditional curriculum and coursework [14]. Technologies that rely on large language models can help with developing curricula and teaching plans [40], generating teaching aids [41], simplifying complex medical concepts [42], and pretesting examination questions [43]. AI can also enhance self-directed learning for medical students. ChatGPT is being used by medical students to practice clinical scenarios, access medical literature, and study for examinations [44]. AI applications are currently being developed, for example, to improve case-based learning and decision-making skills [45,46]. In addition, they can analyze students’ responses in real time and provide immediate feedback and insights into students’ comprehension and learning progress [47]. As large language models become increasingly integrated, skills in prompt engineering and the development and refinement of appropriate inputs for generative AI are also needed to maximize the efficacy of these tools [48].

In addition to openness around the use of AI as a teaching and learning aid, training is needed on how to practically use AI tools as adjuncts to traditional clinical decision-making tools. The integration of AI into medical practice will require professionals to learn how to adapt workflows and communicate effectively with these tools. For example, AI scribes used to

assist with documentation in patient encounters may require providers to learn to explicitly describe physical examination findings or to edit initial documentation effectively [49]. Surgical residents should be taught the use of AI tools used for surgical planning early in training [50]. Additionally, learners should be trained on how to communicate the process, risks, benefits, and alternatives of AI use to patients [34].

While it is encouraged that AI is used in medical education, safeguards will equally be necessary to address issues with academic integrity [14] while using ChatGPT and other such technologies for examinations, assignments, and assessments [44]. Guidelines encompassing accountability systems, ethical considerations, privacy, and moral and integrity issues can be used to help address academic integrity issues [40]. In addition, educating students on how to avoid plagiarism in conjunction with plagiarism detection and language analysis software can promote responsible use of these tools [51].

Increasing Technological Aptitude

In addition to training medical learners on the use of existing AI technologies, a possible long-term goal to improve medical education on AI is to develop the technological aptitude. This includes skills in coding, Python language, mechanisms of data leakage, and an overview of how AI tools are developed [34]. The combination of clinical aptitude and understanding of the practical problems these tools need to solve make physicians uniquely positioned to assist with the production of these technologies. At present, however, many physicians lack the technical skills to help with AI development. Down the line, medical schools will need to consider how they can train physicians to do both.

Conclusion

As AI tools become increasingly integrated into medical practice, they will offer powerful solutions to problems of uncertainty in medicine. These tools have the potential to address reducible forms of uncertainty, including the lack of available clinical information and scientific studies, limits to physician ability, and provider personal bias in decision-making. These tools may also improve the irreducible forms of uncertainty to some extent, increasing our ability to make case predictions from class probabilities and develop models of disease. Despite these capabilities, these tools will never be able to overcome foundational knowledge problems in medicine and pose ethical concerns that must be addressed. Nonetheless, AI tools are being used in practice, and trainees must learn the scope of these technologies, the ethical and legal challenges they pose, and how to use them practically. In the future, trainees should also be taught technical skills of how to develop these technologies. AI has reached medicine, and the medical profession is being asked time and time again to adapt; medical education reform is crucial in this transformation.

Authors' Contributions

SRA and SQH contributed equally to the preparation of this manuscript. All authors were involved in the conception and design of the work. SRA and SQH performed the literature search, conducted the analysis, and created the initial draft. SD and RU

substantively revised the work. All authors approve the final manuscript and assume accountability for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved.

Conflicts of Interest

SD is a member of the advisory board of the Subcortical Surgery Group. He is a member of the speakers bureau for the Congress of Neurological Surgeons and American Association of Neurological Surgeons. He receives research funding from Synaptive and VPIX. He receives royalty payments from Oxford University Press. He serves as the provincial lead for CNS Cancers, Ontario Health (Cancer Care Ontario). RU has received research funding from the Canadian Institutes of Health Research, Health Canada and Wellcome Trust. He serves on advisory boards for the World Health Organization, Doctors Without Borders, the College of Family Physicians of Canada, the Royal College of Physicians and Surgeons of Canada, and the Canadian Medical Association.

Abstract

The use of artificial intelligence (AI) in medicine, potentially leading to substantial advancements such as improved diagnostics, has been of increasing scientific and societal interest in recent years. However, the use of AI raises new ethical challenges, such as an increased risk of bias and potential discrimination against patients, as well as misdiagnoses potentially leading to over- or underdiagnosis with substantial consequences for patients. Recognizing these challenges, current research underscores the importance of integrating AI ethics into medical education. This viewpoint paper aims to introduce a comprehensive set of ethical principles for teaching AI ethics in medical education. This dynamic and principle-based approach is designed to be adaptive and comprehensive, addressing not only the current but also emerging ethical challenges associated with the use of AI in medicine. This study conducts a theoretical analysis of the current academic discourse on AI ethics in medical education, identifying potential gaps and limitations. The inherent interconnectivity and interdisciplinary nature of these anticipated challenges are illustrated through a focused discussion on “informed consent” in the context of AI in medicine and medical education. This paper proposes a principle-based approach to AI ethics education, building on the 4 principles of medical ethics—autonomy, beneficence, nonmaleficence, and justice—and extending them by integrating 3 public health ethics principles—efficiency, common good orientation, and proportionality. The principle-based approach to teaching AI ethics in medical education proposed in this study offers a foundational framework for addressing the anticipated ethical challenges of using AI in medicine, recommended in the current academic discourse. By incorporating the 3 principles of public health ethics, this principle-based approach ensures that medical ethics education remains relevant and responsive to the dynamic landscape of AI integration in medicine. As the advancement of AI technologies in medicine is expected to increase, medical ethics education must adapt and evolve accordingly. The proposed principle-based approach for teaching AI ethics in medical education provides an important foundation to ensure that future medical professionals are not only aware of the ethical dimensions of AI in medicine but also equipped to make informed ethical decisions in their practice. Future research is required to develop problem-based and competency-oriented learning objectives and educational content for the proposed principle-based approach to teaching AI ethics in medical education.

artificial intelligence; AI; ethics; artificial intelligence ethics; AI ethics; medical education; medicine; medical artificial intelligence ethics; medical AI ethics; medical ethics; public health ethics

Introduction

Background

Artificial intelligence (AI) and its applications have been of interest in both the scientific and societal domain for many years. AI has the potential to improve medical care through more accurate diagnosis and to reduce the burden on the health

care system by reducing costs and workload [1,2]. Although AI in medicine has the potential to reduce the burden on medical staff, uncertainty about its capabilities raises concerns regarding job displacement [3]. The use of AI is expected to pose significant ethical challenges. AI algorithms are often trained on unrepresentative data, leading to potential discrimination and disadvantages for certain patient groups. Bias on the part of developers can also result in inequitable treatment [4]. The

use of AI in medicine can also lead to erroneous diagnoses such as unnecessary treatment, which violates the basic principles of medical ethics [5].

Research recommends teaching AI ethics early in medical education to prepare for its potential impacts and challenges [6-8]. In addition to the technical and legal aspects of the use of AI in medicine, recent publications emphasize the importance of teaching AI ethics in medical education [9-11]. Recent studies have indicated that medical students anticipate significant ethical challenges from the use of AI in medicine [12,13]. Furthermore, research suggests limited knowledge and understanding of AI among medical students [14]. Despite the need for early teaching of AI ethics, there is a lack of guidance on specific content and methods for integrating AI ethics into medical curricula [10].

Definitions of AI

Although the term *artificial intelligence* dates to the 1950s, there is inconsistency regarding its definition within the scientific community and the public [15]. On the basis of current scientific definitions, AI can be subdivided into “artificial general intelligence,” referred to as “strong AI” and “artificial narrow intelligence,” commonly referred to as “weak AI” [16]. Artificial general intelligence refers to the development of systems with “general intelligence,” capable of performing intellectual tasks comparable with humans. The term “artificial narrow intelligence” refers to an AI that has the capability to perform specific intellectual tasks comparable with humans without possessing general intelligence [17]. Artificial narrow intelligence can be subdivided into 2 main fields of current research: “symbolic AI” and “statistical AI.” On the basis of the idea of representing knowledge or certain intelligent behaviors using symbols and rules, “symbolic AI” commonly refers to rule-guided expert systems [16,18]. The term “statistical AI” refers to the development of systems that can find correlations and patterns within the analyzed data sets using statistical methods, without being explicitly programmed to do so or following predefined rules. Examples of “statistical AI” include “machine learning” (ML) with its subfield, “deep learning,” or “natural language processing” (NLP) [18]. While the ability to learn from data independently and increase their capabilities lies at the heart of ML, the subfield of deep learning focuses on the development of artificial neural networks that mimic the human central nervous system to process information. The subfield of NLP focuses on the analysis and processing of human language-based information by computer systems to enable improved human-computer interactions [16]. Advanced NLP techniques are, for example, used in large language models such as the AI-based chat applications available to the public, for example, ChatGPT (OpenAI, LLC) or Bard (Google LLC).

In medicine, AI and its respective subfields and specializations have attracted increased scientific interest in recent years [19]. For example, “symbolic AI” is used to develop rule-based expert systems such as “clinical decision support systems” (CDSSs) [20]. CDSSs aim to assist with diagnosis and selection of the best treatment for patients by providing information based on the current guidelines and information provided by experts. CDSSs follow rules and instructions predefined by experts and are therefore susceptible to ethical challenges such as the transfer

of bias by experts or developers [21]. Because of their ability to analyze large amounts of data, systems based on ML are used to identify and process image-based data in medical specializations such as radiology or dermatology. An extensive study published in *Nature* in 2017 showed that systems based on ML are capable of detecting certain types of skin cancer (eg, malignant melanomas) with an accuracy comparable to that of dermatologists using image-based data [22].

As the data used to train ML-based systems and applications represent the basis of any subsequent analysis and therefore significantly influence accuracy, the data need to be representative of the target population [23]. This is especially important in the medical context, where demographic disparities in data can lead to systematic misdiagnoses or treatment recommendations that are less effective for underrepresented groups [24]. Unrepresentative data can potentially lead to bias and discrimination, with significant effects on patients [21,24]. To avoid any discrimination or negative effects for patients, the sources and composition of data sets used for AI development are of paramount importance. Ensuring the representation of the data is crucial, as the diversity and comprehensiveness of the data determine the system’s ability to generate reliable and valid outputs across different patient demographics [23]. Furthermore, acknowledging and addressing potential limitations and errors in AI products is essential for maintaining the validity of AI outputs, which directly affect the scope of their applicability in clinical settings [21]. AI systems trained on narrow or biased data sets may not only perform inadequately in diverse real-world scenarios but also misinform clinical decision-making, undermining the trust and credibility essential in medical practice [25]. The low accuracy and validity of AI, potentially leading to a lack of trust and credibility, could severely impact the utility of AI in the medical context. Utility refers to not only the performance of AI on a technological level but also how it translates into meaningful and practical advantages in health care settings. Therefore, the utility of AI in medicine is intrinsically linked to its ability to provide actionable, accurate insights that directly inform and enhance clinical decision-making [26]. It is therefore imperative to rigorously evaluate and validate AI systems against a variety of data sets that reflect the full spectrum of clinical cases and patient populations to ensure the utility, generalizability, and accuracy of AI tools in a broad range of health care contexts.

Although becoming broadly available rather recently, AI-based chat applications such as ChatGPT have rapidly emerged as significant tools with the potential to revolutionize various aspects of medicine, including the education and training of future physicians [27,28]. For example, these applications could be deployed for simulated patient-physician interactions, providing medical students with a low-risk environment to practice diagnostic skills and ethical decision-making [28]. The potential and broad availability of AI-based chat applications raise new ethical questions that necessitate comprehensive teaching in medical education.

AI Ethics

The field of AI ethics was an area of interest for both scientific and governmental communities, even before the emergence of

AI applications such as ChatGPT, which has gained widespread public attention [29,30]. However, there remains a lack of consensus on the definition of AI ethics, which can be attributed to several factors, including the novelty and interdisciplinary nature of the field as well as the absence of a widely accepted definition of AI [31].

Despite the current lack of consensus on the definition of AI ethics, some definitions are available. For example, AI ethics can be defined as “the emerging field of practical AI ethics, which focuses on developing frameworks and guidelines to ensure the ethical use of AI in society (analogous to the field of biomedical ethics, which provides practical frameworks for ethical practice in medicine)” [32]. This definition emphasizes the novelty of the field, further highlighting the importance of biomedical ethics.

The emphasis on biomedical principles is consistent with current scientific and governmental efforts aimed at developing AI ethics frameworks and guidelines to ensure the ethical development, deployment, and use of AI technologies [29,33]. The biomedical principles mentioned in the definition of AI ethics refer to the well-known and established principles of medical ethics initially proposed by Beauchamp and Childress [34]. The 4 principles of autonomy, beneficence, nonmaleficence, and justice are considered fundamental to medical ethics, while most guidelines and frameworks on AI ethics do not specifically focus on ethical considerations regarding the development, implementation, or use of AI in medicine; the emphasis on these principles further reinforces their importance [30,35].

Although existing guidelines and frameworks aim to address various ethical concerns related to AI, such as privacy, bias, accountability, and transparency, it should be noted that they fail to provide a clear definition of AI ethics [30]. Given the rapid pace of advancements in AI technology and its increasing impact on society, the need for clear and consistent definitions of AI and AI ethics is becoming increasingly urgent [30]. To specifically address ethical considerations related to AI in medicine and medical practice, a definition of “medical AI ethics” has been proposed, which “is an interdisciplinary subfield of AI ethics concerned with the application of ethical principles and standards to the research, development, implementation, and use of AI technologies within the practice

of medicine” [10]. This definition emphasizes the importance of principles regarding the use of AI in medicine, which is fundamental to this study.

AI Ethics in Medical Education

Although the need for teaching AI ethics in medical education is emphasized in scholarly literature, there is a lack of specification on relevant teaching content for AI ethics. In a recent scoping review, only a limited number of publications specifically focusing on the teaching of AI ethics as part of medical education were identified [10]. Although other publications acknowledge the importance of ethics in AI education, they do not provide specific content or guidance [36-39].

In one of the 2 identified publications specifically addressing AI ethics teaching content for medical education, 6 potential topics were defined: informed consent, bias, safety, transparency, patient privacy, and allocation [9]. The 6 teaching subjects were proposed to address the potential challenges related to the application of AI in medicine. For example, the anticipated challenge of *informed consent* highlights the importance of patient autonomy, potentially impeded by the lack of transparency or explainability in the decision-making of AI-based applications. Besides these 6 potential teaching subjects, the importance of teaching fairness and responsibility is emphasized by another publication that focuses on AI ethics education [11]. Furthermore, the importance of empathy has been emphasized in relation to the use of AI in medicine and the associated need to teach AI ethics [6].

A recurrent theme related to the teaching of AI ethics as part of medical education focuses on the principles of medical ethics according to Beauchamp and Childress (autonomy, beneficence, nonmaleficence, and justice) [10]. This emphasis is also echoed by existing guidelines and frameworks regarding AI ethics [30]. Additional recommendations on AI ethics teaching content include “explainability,” “liability,” and “accountability,” which are also considered important by available guidelines [30,40]. On the basis of the analysis of existing publications on teaching AI ethics in medical education, 12 potential subjects were considered for teaching AI ethics. The 12 identified potential teaching subjects for AI ethics in medical education are listed in [Textbox 1](#).

Textbox 1. Recommended artificial intelligence (AI) ethics teaching content with specific descriptions.

Informed consent

Informed consent in the context of AI in medicine requires that patients be fully informed about treatment options and risks, necessitating a comprehensive understanding and explanation of AI technologies by physicians.

Bias

The use of AI in medicine may exhibit biases stemming from nonrepresentative data or structural conditions, leading to potential discrimination based on sex, age, or socioeconomic status.

Safety

The use of AI in medicine can have potentially harmful consequences for patients, necessitating a critical examination of the accuracy of AI-based applications and clear communication of their limitations.

Transparency

Transparency in AI-based medical applications is essential for understanding decision-making processes, influencing the quality and ethics of patient care, and maintaining trust, particularly in critical scenarios.

Privacy

Privacy not only refers to implementing technical data protection measures but also comprehensively understanding the ethical implications of handling sensitive patient data.

Allocation

In the context of AI in medicine, allocation refers to equitable access to technology and the impact of AI on equitable access to care.

Fairness

Fairness in AI ethics within medicine refers to ensuring equitable treatment for all patients regardless of their background. This encompasses the need for AI systems to be free from biases that may affect diagnosis, treatment recommendations, or patient outcomes.

Responsibility

Responsibility in the context of AI ethics in medicine emphasizes the importance of health care professionals and AI developers to using AI tools responsibly. This includes ensuring that these tools are safe, reliable, and used in a manner that benefits the patients.

Empathy

Empathy in the context of AI underscores the importance of maintaining the human aspect of health care, especially as AI technologies become more prevalent.

Explainability

Explainability in AI in medicine is closely linked to transparency and is important for understanding the AI-based decision-making process, affecting physician-patient relationships, and shared decision-making.

Liability

Liability in medical AI ethics concerns the potential for treatment errors related to the use of AI in the medical context. Questions on liability extend from potential users to health care institutions and AI developers.

Accountability

Accountability in medical AI involves understanding the associated limitations and competent oversight by medical professionals. This includes critically assessing AI errors and biases and ensuring accurate, informed, and ethical applications within medical decision-making. In addition, this accountability extends to continuously monitoring AI performance and adapting to evolving ethical and clinical standards in medical practice.

Objective

On the basis of a discussion and reflection theoretical analysis of the recommended teaching subjects on AI ethics informed by existing literature (as specified in the AI Ethics in Medical Education section), this study aims to introduce a set of ethical principles for “medical AI ethics.” As the proposed AI ethics teaching subjects for medical education in the existing scientific literature primarily focus on the challenges associated with the use of AI in medicine, they fail to acknowledge the broader implications of foundational ethical principles. By concentrating on a principle-based approach to AI ethics, this paper aims to address the gap in the existing scientific literature, serving as a

foundational framework for AI ethics teaching content in medical education.

Theoretical Analysis of Recommended AI Ethics Teaching Subjects in Medical Education

Overview

Ethics commonly relies on principles as foundational guidelines for decision-making and behavior. The 4 foundational principles of medical ethics—autonomy, beneficence, nonmaleficence, and justice—are highly relevant in the context of teaching ethics in medical education [41].

While these 4 principles have been an integral part of current scientific publications on AI ethics in medical education, the

recommended teaching subjects are mainly derived from the anticipated challenges associated with the use of AI in medicine [10]. Addressing these challenges is important for fostering a comprehensive understanding regarding the use of AI in medicine. However, this approach does not fully capture the multidisciplinary and interdisciplinary nature of this field. The complexity of AI ethics in medicine extends beyond these anticipated challenges, encompassing a wide range of disciplines such as law, medicine, ethics, and computer science. For example, the proposed teaching subject of “informed consent” warrants a detailed analysis to exemplify the high level of interdisciplinarity present in AI ethics, intersecting with each of the other proposed teaching subjects. This interconnection results in a substantial overlap, which can challenge the establishment of clear distinctions between the different areas of AI ethics.

The methodology of this study is anchored in a theoretical approach, building upon a previous comprehensive scoping review of the existing literature on teaching AI ethics in medical education [10]. This also includes the consideration of relevant guidelines and frameworks regarding the ethics of AI, resulting in the identification of 12 potential teaching subjects for AI ethics as detailed in [Textbox 1](#). To exemplify the high level of interdisciplinarity present in AI ethics by focusing on the subject of “informed consent,” the publications included in the scoping review, including the proposed challenges associated with the use of AI in medicine, were re-evaluated. This theoretical analysis provides the foundation for the development of the principles of medical AI ethics presented in the Medical AI Ethics section. The theoretical basis of the proposed principle-based approach to AI ethics is further strengthened by our expertise as we specialize in the ethical use of AI in medical and public health contexts. This background informs the depth and rigor of the analysis, ensuring that the developed framework is both relevant and grounded in practical ethical considerations in these fields. The theoretical methodology we used is characterized by a focus on conceptual development and theoretical insights rather than empirical testing or data collection.

Informed Consent

Overview

Informed consent represents an important development in medical ethics and patient rights, representing a departure from the historically paternalistic nature of medical practice [42]. In earlier medical paradigms, decision-making was predominantly physician driven, with minimal patient involvement. This approach, often paternalistic, assumes the primacy of the physician’s judgment, potentially leading to interventions conducted without comprehensive patient understanding or consent [42].

The development and integration of informed consent into medical practice represents a substantial cultural and ethical transition toward acknowledging and upholding patient autonomy. Central to this evolution is the concept of shared decision-making (SDM), a collaborative process that involves physicians and patients jointly making treatment decisions. SDM encompasses a thorough discussion of available treatment

options, including their benefits and risks, and considers patient values, preferences, and circumstances [42,43]. This method positions patients as active participants in their health care journey rather than as passive recipients of medical decisions.

In this context, informed consent is pivotal in facilitating SDM, as it ensures that patients are not only informed of their medical choices but also engaged in selecting options that resonate with their personal health goals and values. This approach transforms the traditional physician-patient relationship into a partnership, where decisions are mutually agreed upon, thereby honoring the patient’s right to self-determination. It also fosters a deeper level of trust and respect within the physician-patient relationship.

As a result, informed consent serves more than just a legal requirement to minimize liabilities; it is a crucial aspect of patient-centered care and a fundamental element of ethical medical practice. This signifies the transition from a paternalistic approach to one that emphasizes patient autonomy and upholds the principles of SDM.

Informed Consent in the Context of AI in Medicine

Regarding the development, implementation, and use of AI in medicine, the concept of informed consent warrants a comprehensive introduction owing to the technical complexities inherent to AI. AI systems, particularly those used in diagnostics and treatment recommendations such as ML, often involve algorithms that might be nontransparent to both patients and health care professionals. This lack of transparency presents a substantial challenge to the conventional process of informed consent, complicating the task of understanding and communicating how an AI-based application formulates recommendations [44].

Moreover, the development of AI-based applications involves extensive data sets, raising concerns regarding data privacy and the potential for expropriation of personal health data [9]. These issues necessitate clear communication with patients throughout the physician-patient relationship and during the process of ensuring informed consent. It is imperative that patients are adequately informed about not only the advantages and risks associated with AI-assisted treatments but also the manner in which their data are used, protected, and stored [45]. With the increasing integration of AI in medicine and health care, the process of obtaining informed consent must be adapted to meet these challenges, thereby ensuring that patients retain control over their health care decisions in an environment increasingly influenced by AI.

Intersections of Informed Consent With Key AI Ethics Teaching Subjects

Overview

This section aims to underscore interdisciplinarity and intersectionality among the recommended teaching subjects in AI ethics, as outlined in the Informed Consent section, with informed consent serving as a representative example. Focusing on these intersections, this section highlights the importance of an integrated educational approach in the context of medical AI ethics. Such an approach acknowledges that topics such as

bias, privacy, and transparency, among others, are not merely isolated subjects but instead require a comprehensive, holistic evaluation. Embracing this integrated perspective is important for a comprehensive understanding of AI ethics in medical practice and education, underscoring the need to re-evaluate and potentially refine current teaching recommendations. To effectively illustrate the interdisciplinarity and interconnectedness of frequently recommended teaching subjects for AI ethics in medical education, “informed consent” should be discussed in the context of 5 frequently proposed teaching subjects: bias, safety, transparency, privacy, and liability.

Bias

To enable patients to make informed decisions when AI-based applications are used in their treatment, it is important to address the possibility of bias inherent in these technologies. Informed consent in this context requires the awareness and understanding of potential biases in AI decision-making processes [46]. For instance, a diagnostic AI-based application might exhibit varying levels of accuracy across different demographic groups, potentially owing to data representation issues [21]. Patients must be informed of such disparities in accuracy as this information is vital for them to consent to the use of AI in their treatment.

Safety

The safety of AI-based applications in medicine is a critical component of informed consent for medical treatment recommendations involving AI. Patients must be clearly informed about the potential risks associated with AI-driven medical decisions, including the possibility of erroneous outcomes such as false positives or negatives [47]. This comprehensive understanding of the safety profile of AI-assisted treatments is essential for patients to make informed decisions about their care. Being informed and knowledgeable about the limitations and risks of AI technologies ensures that patients can weigh these factors against potential benefits when consenting to AI use in their treatment.

Transparency

Transparency in AI systems is important not only for patients but also for physicians, who serve as the primary receivers and communicators of AI-driven medical information. A clear understanding of how AI-based applications work, particularly how decision-making processes are performed, is required for physicians to effectively communicate with their patients [48]. Such informed communication is a fundamental aspect of the informed consent process, fostering a deeper understanding and trust within the physician-patient relationship [49]. When patients receive comprehensive and transparent information from their trusted health care providers, they enhance their engagement and participation in decision-making. Therefore, transparency in AI goes beyond technical clarity and is crucial for fostering a strong physician-patient relationship, ensuring that informed consent is based on a shared understanding of the potential risks and benefits associated with AI-assisted treatments [50].

Privacy

The process of obtaining informed consent for AI-based medical treatment recommendations should include data privacy. It is important for patients to be informed about the use, access, and protection of their data. Ensuring that patients understand how their personal health data are used, who has access to it, and the measures in place to protect it is a key component of the informed consent process [51]. This comprehensive disclosure and transparency regarding data handling are vital for maintaining the integrity of the physician-patient relationship and for upholding the ethical standards of medical practice in the era of AI.

Liability

Regarding the use of AI in medicine, it is imperative to address the concept of liability in the informed consent process. Patients should be clearly informed of the potential for errors and liability issues associated with AI-driven medical decisions [52]. This conversation should entail a discussion on who bears responsibility, including the liability of physicians, if an AI system malfunctions or leads to incorrect medical outcomes such as misdiagnoses or inappropriate treatment plans. The explicit clarification of liability, particularly the role and responsibility of health care providers in conjunction with AI, is important for helping patients understand the potential risks involved [53]. This understanding is a key component of a comprehensive informed consent process that directly affects the patients' trust in AI and their treating physicians. By transparently addressing these liability concerns, including the physicians' responsibilities, health care providers can reinforce the integrity of the physician-patient relationship and uphold the ethical standards of medical practice in an AI-integrated health care environment [53].

Medical AI Ethics

Overview

The high degree of interdisciplinarity and intersectionality in AI ethics, as detailed in the previous section, highlights potential conflicts in teaching AI ethics based solely on the anticipated challenges associated with the implementation and use of AI in medicine. This complexity underscores the necessity of adopting a principle-based approach to AI ethics education, mirroring established pedagogical frameworks in medical ethics education [41].

In the context of traditional medical ethics education, the emphasis on foundational principles provides a broad and adaptable framework that is essential for understanding and addressing complex ethical dilemmas. This approach facilitates the holistic comprehension of ethical issues, offering the flexibility to accommodate the diverse and evolving nature of medical scenarios. Similarly, when considering AI in medicine, a focus on core ethical principles rather than solely on specific challenges lays the groundwork for a robust and comprehensive educational strategy. Future medical professionals should be equipped with a deeper and more nuanced understanding of ethical decision-making by emphasizing ethical principles in the context of implementing and using AI in medicine. This principle-based approach ensures that medical ethics education

remains relevant and responsive to the dynamic landscape of AI integration in medicine. The goal is for medical students to be able to effectively navigate the ethical complexities associated with AI technologies in medicine, not just focusing on potential challenges but also emphasizing the ethical values that are essential to medical practice.

Owing to the paramount importance and relevance of the 4 principles of medical ethics formulated by Beauchamp and Childress [34], the principles of autonomy, beneficence, nonmaleficence, and justice should provide the essential foundation for medical AI ethics. These 4 principles are subsequently introduced based on existing scholarly discourse, focusing on the use of AI in medicine, with an emphasis on medical education.

Traditional medical practices have predominantly focused on individual relationships between physicians and patients. However, modern health care increasingly necessitates considering broader aspects such as cost-effectiveness, resource allocation, and proportionality, especially in light of financial constraints. A prominent illustration of these evolving dynamics in medical practice is the COVID-19 pandemic. This global health crisis underscored the critical importance of public health considerations and highlighted extensive interdisciplinarity and interconnectivity within the field of medicine. The COVID-19 pandemic has highlighted the importance of balancing individual patient care with broader public health measures [54]. It demonstrated how medical decisions are not made in isolation but are profoundly influenced by factors such as resource availability, health care infrastructure, and broader societal

implications. This scenario emphasizes the crucial role of public health principles in informing medical practices, particularly in crises. The pandemic also illustrates the necessity of integrating insights from various disciplines, including epidemiology, health economics, and ethics into medical decision-making.

Given the anticipated impact of AI on the field of medicine, which extends beyond the traditional concept of medical practice owing to its inherent interdisciplinarity and complexity, ethical considerations must be adapted accordingly. The scope of AI in medicine introduces novel ethical dimensions that require a broader framework for ethical analysis. Therefore, the integration of 3 principles of public health ethics—efficiency, common good orientation, and proportionality—is proposed along with the established principles of medical ethics to form a comprehensive foundation for medical AI ethics [55-58].

Similar to the principles of medical ethics outlined by Beauchamp and Childress [34], each principle of public health ethics is examined in subsequent sections with a specific focus on its relevance to AI in medical practice and education. While the principles of public health ethics may not be as established or universally agreed upon as those of medical ethics, their inclusion provides a suitable framework to address the unique challenges posed by AI in medicine and health care. This extended ethical framework aims to provide a more comprehensive understanding of the role and implications of AI in medicine, ensuring that future medical professionals are equipped to make ethically sound decisions in increasingly AI-integrated medical practice. The proposed principles of AI ethics for medical education are presented in Figure 1.

Figure 1. The principles of medical artificial intelligence (AI) ethics for medical education.

Autonomy

The principle of autonomy in medical ethics emphasizes the right to make independent decisions regarding health care [34]. This principle recognizes an individual's capacity for self-determination and personal choice, affirming that patients have the authority to provide or withhold consent for medical

treatment. Respecting autonomy in medical practice involves providing patients with sufficient information, ensuring comprehension, and facilitating independent decision-making [59]. This respect for autonomy is closely tied to the principle of informed consent, which ensures that patients actively participate in decisions regarding their care and treatment.

In the context of using AI in medicine, particularly in diagnostics and treatment recommendations, technology introduces new challenges and opportunities to maintain patient autonomy [60]. For example, when using AI-based diagnostic applications, it is crucial to inform patients about how these tools impact their health care decisions, ensuring that informed consent is comprehensive. Equally important is equipping physicians with the knowledge to balance AI-generated insights with their clinical expertise, thus upholding both patient and physician autonomy in decision-making processes. The incorporation of AI into health care decision-making can affect the presentation and comprehension of options by patients. Ensuring that patients retain their autonomous decision-making power in an AI-driven environment requires the careful consideration of how the information is communicated and understood [60]. Autonomy in this context extends to ensuring that patients have a clear understanding of AI interventions and their capabilities, limitations, and impact on personal health decisions. Moreover, the principle of autonomy extends to physicians. If AI increasingly assists in medical decision-making, it is imperative that physicians remain empowered to make independent professional judgments, balancing AI insights with their clinical expertise and ethical considerations.

The principle of autonomy addresses several anticipated challenges and recommends teaching subjects on AI ethics in medical education. For example, in the context of informed consent, autonomy ensures that patients are fully aware of the role and limitations of AI in their treatment, including potential bias and safety concerns. Autonomy also involves clear communication regarding data privacy, ensuring that patients understand how their data are used in AI systems. In the context of using AI in medicine, autonomy is not limited to the patient's understanding and decision-making; it also encompasses the physician's ability to make independent judgments informed by, but not solely reliant on, AI-driven data. This dual focus preserves the integrity of clinical decision-making and respects both the patient's and the physician's autonomous roles. Furthermore, transparency and explainability in AI systems are fundamental to ensure that patients autonomously understand and evaluate AI-driven health care choices. Autonomy acts as a guiding principle that addresses these challenges, ensuring that patient rights and self-governance remain central to the increasingly AI-integrated landscape of medical practice. This principle also extends to the equitable allocation of medical resources and fairness in treatment decisions, where an autonomous choice must be informed by unbiased AI recommendations. This comprehensive approach to autonomy in AI ethics education underscores the need for a balanced consideration of both patient and physician perspectives to ensure ethical integrity in the application of AI in medicine.

Beneficence

The principle of beneficence, a fundamental aspect of medical ethics, underscores the responsibility of health care providers, including physicians, to act in the best interests of patients [61]. This principle is the basis of the ethical framework guiding health care delivery and promoting actions that enhance patient well-being and welfare [34]. In medical practice, beneficence guides physicians to consider the actual benefits of medical

interventions, extending from the sole minimization of potential harm. Therefore, this principle encompasses a broader responsibility toward enhancing the overall quality of life of the patient, affirming that every medical decision should contribute positively to the holistic well-being of the patient [50].

The principle of beneficence is paramount in the application of AI in medicine, such as through predictive analytics and personalized medicine. Although promising, AI-based applications must be critically evaluated for their efficacy and safety to ensure alignment with the overarching goal of promoting patient well-being, which reflects the true essence of beneficence in medical practice [62]. In addition, it is crucial to ensure that AI-based applications align with the broader goals of patient care, emphasizing not only clinical outcomes but also patient quality of life and overall well-being. Such an approach should consider individual social backgrounds and personal circumstances, ensuring that AI-driven health care focuses on the diverse needs of each patient [50].

In the context of AI ethics and medical education, beneficence emphasizes the importance of developing, implementing, and using AI applications designed with the primary aim of improving patient outcomes. This includes addressing potential biases in AI algorithms that could negatively impact patient care, ensure patient safety, and maintain transparency in the AI decision-making processes. Therefore, the principle of beneficence guides the ethical application of AI in medicine, ensuring that these advancements aim to maximize patient benefits and well-being, consistent with the overarching goals of medical practice.

Nonmaleficence

Although the principle of nonmaleficence also focuses on ensuring the best possible treatment for patients and aligning all actions accordingly, it emphasizes that health care professionals should do no harm [34]. This principle is complementary to the principle of beneficence, and it aims not only to prevent harm but also to proactively avoid and reduce risks associated with medical care. Nonmaleficence requires that the risks of any medical intervention are carefully weighed against their potential benefits and actions that could cause harm are avoided. This principle underlines the responsibility of health care providers to ensure that any treatment or medical advice does not adversely affect a patient's health.

The potential risks of using AI in medicine, such as misdiagnosis, algorithmic biases, and data security breaches, reinforce the relevance of the principle of nonmaleficence. To ensure nonmaleficence, the rigorous testing and validation of AI systems, ongoing monitoring for adverse outcomes, and commitment to addressing any safety concerns are crucial [62]. Moreover, this commitment extends to the ethical development and deployment of AI technology. It involves actively working to mitigate risks, such as biases in training data, that could lead to unequal or unfair treatment outcomes [50].

To raise the awareness of potential conflicts with the principle of nonmaleficence regarding the use of AI in medicine, medical education should focus on the ethical design, development, and

deployment of AI applications in medicine. Therefore, nonmaleficence is an important part of medical AI ethics, emphasizing the need to ensure the accuracy and reliability of treatment recommendations originating from the use of AI-based applications in medicine. Teaching content on nonmaleficence addresses various anticipated challenges regarding the use of AI in medicine, such as safety, privacy, bias, and transparency. By adhering to the overarching principle of nonmaleficence, physicians can navigate the ethical challenges posed by AI in medicine, ensuring that the technology is used in ways that prioritize patient safety and harm reduction.

Justice

The principle of justice in medical ethics, as outlined by Beauchamp and Childress [34], is concerned with ensuring fair and equal treatment for all patients regardless of their socioeconomic status, background, or circumstances. This principle emphasizes the importance of fairness in the distribution of resources and access to health care services. In practical medical settings, justice can be translated into unbiased decision-making, equal opportunity for treatment, and eradication of any form of discrimination.

Justice is an important aspect regarding the use of AI in medicine. Owing to the risk of bias due to unrepresentative training data, for example, treatment recommendations from the use of AI in medicine could lead to disadvantages for different groups or individuals, directly conflicting with the principle of justice [50]. Furthermore, access to the technology itself could be limited, for example, by economic means, thereby potentially perpetuating existing inequalities in access to advanced medical technologies [35]. This potential for injustice can be further exacerbated if an increasing prevalence of AI in medical practice is anticipated.

Owing to the substantial risk of injustice with the use of AI in medicine, medical education should include teaching the principle of justice in the context of AI. Focusing on the equitable availability and use of AI technologies, future physicians should be trained to recognize and address the potential inequities that AI might introduce or perpetuate. Therefore, teaching the principle of justice, extending from traditional medical ethics education, can serve as a foundation to address anticipated challenges such as allocation, bias, fairness, liability, and accountability. For instance, when considering liability and accountability, justice refers to ensuring that patients are not disproportionately affected by errors or failures in AI systems. It involves advocating for systems that hold developers and health care providers responsible for potential technological malfunctions, ensuring that accountability measures are in place to protect all patients from potential harm or injustice, especially those in vulnerable or marginalized groups [53].

Efficiency

Efficiency within public health ethics underscores the strategic use of resources to maximize health benefits for the population [57]. This principle is not only solely an economic concern but also a moral imperative to ensure the equitable and judicious use of medical technologies and services. Ethical considerations

regarding the principle of efficiency are especially relevant in health care settings where resources are limited and demand is high, as exemplified in the context of the COVID-19 pandemic.

Owing to the capabilities of AI in medicine with the potential to enhance the efficiency of medical services through faster and more accurate diagnostics, it is crucial to consider the ethical implications of these developments [19]. The ability of AI to rapidly analyze large data sets can greatly enhance the speed of diagnostic procedures, which could result in more timely patient care and improved treatment choices that are more precise. However, this benefit is contingent on the data quality. Poor-quality data can result in AI models that incorrectly predict outcomes based on artifacts in the data rather than actual clinical results [21]. Therefore, the ethical use of AI in health care must include rigorous validation of the data quality to ensure accurate and reliable outcomes. For example, physicians must balance the efficiency gains offered by AI with the need for clinical judgment and personalized patient care and upholding and maintaining the quality of physician-patient relationships [63].

Teaching the principle of efficiency in the context of AI ethics education should focus on the balance between technology-driven efficiency and patient-centered care. Future physicians need to understand how to leverage AI to optimize health care delivery without compromising quality of care. Therefore, teaching the principle of efficiency highlights the anticipated challenges related to a lack of empathy. It is imperative to ensure that the pursuit of efficiency through AI does not lead to the depersonalization of patient care. Empathy remains a crucial aspect of health care, and AI systems should be used to enhance, rather than replace, the human elements of patient interaction and care.

Common Good Orientation

Common good orientation is a guiding principle of public health ethics, aiming to improve the collective well-being and health of the community or population as a whole [58]. This principle extends the focus of individual patients, emphasizing the interconnectedness between individual and public health. This involves considering the wider impacts of health care interventions and prioritizing actions that promote the health and welfare of the public.

The principle of common good orientation in the context of AI, crucial in guiding the integration of technology into medical practice, calls for a delicate balance between individual patient benefits and the collective well-being of the community. It is essential to recognize how AI in medicine can address or potentially exacerbate health disparities [64]. The ability of AI to process and analyze data can be harnessed to identify and address gaps in health care delivery, offering insights into underserved populations and tailoring interventions to meet their specific needs. Conversely, if not carefully managed, AI could unintentionally increase these disparities by favoring populations with better access to the technology. This duality underscores the need for AI advancements in health care to contribute positively and equitably to public health, promoting fairness in health care access and outcomes. It is important to note that the selective application of AI not only undermines the principle of common good orientation but also risks creating

a perception of elitism in the medical profession. Such a scenario could harm the reputation of the medical field, rendering it as unevenly benefiting certain populations. Furthermore, using AI in medical practice could potentially lead to events where patients are harmed, for example, through biased decision-making or errors made by users. This could potentially lead to a negative perception of AI within the broader population, which in turn may result in a general unwillingness or resistance to adopting AI technologies. This hesitance could directly conflict with the principle of common good orientation, as it hinders the widespread and equitable implementation of AI that could benefit the entire community [25].

Teaching the principle of common good orientation in the context of AI ethics in medical education underscores the importance of developing, implementing, and using AI technologies in ways that serve a wider community not just the individual patient. This includes understanding the potential of AI in managing public health crises such as pandemics. Medical education based on the principle of common good orientation emphasizes aspects of safety, transparency, allocation, and responsibility, which are important to best prepare for potential challenges through AI in medicine and associated ethical considerations.

Proportionality

The principle of proportionality in public health ethics necessitates a balanced approach to medical interventions that weighs benefits against risks [57]. Therefore, this principle can be applied to ensure that the measures taken, such as medical interventions, are proportional to the health risks that they aim to mitigate. In medicine, proportionality is important in decision-making, ensuring that the intervention aligns with the expected health outcomes.

In medical practice, the principle of proportionality is important when considering the integration of AI technology to balance benefits against potential risks for individual patients and the broader population. This principle necessitates a careful assessment of the role of AI, particularly in ensuring equitable resource distribution and maintaining public trust [25]. For instance, when using AI for diagnostics, it is necessary to evaluate the accuracy and effectiveness of the technology against risks, such as misdiagnosis or overreliance on AI. This evaluation should consider not only the immediate impact on individual patients but also the broader implications for health care resources and community trust. In the critical area of resource allocation within health care, the use of AI holds substantial promise in enhancing the efficiency and effectiveness of distributing limited medical resources [63]. However, it is essential to guard against the risk of AI systems inadvertently perpetuating existing biases or failing to address the diverse needs of different patient groups. This calls for a transparent, community-engaged approach to the development and deployment of AI in health care, ensuring that AI recommendations do not unfairly disadvantage any patient group [24]. By adhering to the principle of proportionality, health care providers can better navigate the ethical complexities of using AI, ensuring that its application is not only technologically

sound but also ethically responsible, both at the individual patient level and in the wider context of public health.

The principle of proportionality can be helpful for future physicians to comprehend the anticipated challenges of AI in medicine, particularly regarding the aspects of allocation. This principle also addresses other anticipated challenges such as transparency and explainability to understand how decisions are made and whether the overall population is considered, ensuring that recommendations are reasonable.

Discussion

Overview

The integration of AI in medicine necessitates a nuanced approach to ethics education that addresses the unique challenges and opportunities introduced by this technology. By exploring public health and medical ethics principles, medical AI ethics offers a comprehensive framework for guiding future physicians in this complex landscape. The proposed teaching of medical AI ethics in medical education emphasizes the importance of ethical principles rather than focusing solely on anticipated challenges, aiming to foster a deeper understanding of potential ethical considerations and enable adaptation in the light of rapid technological advancements.

Given the dynamic nature of AI and the associated rapid technological advancements, for example, as demonstrated by AI-based chat applications such as ChatGPT, ethical considerations need to be continually adapted [65]. The need for timely adaptation challenges traditional ethics education in medicine, which may not account for the current use of AI in medicine. Traditional ethics education primarily focuses on the 4 principles of medical ethics as formulated by Beauchamp and Childress [41]. While these principles can provide valuable guidance in the age of AI in medicine and are therefore foundational to the proposed medical AI ethics education, adaptation is needed to reflect the complexities and challenges introduced by the implementation and use of AI in medicine and medical practice.

The high level of intersectionality and interdisciplinarity inherited by the implementation and use of AI in medicine highlights the importance of a principle-based approach rather than solely focusing on anticipated challenges. While the proposed ethical principles also show a high level of interconnectivity, the chosen educational approach aims to encourage a more nuanced understanding, not limited to specific anticipated challenges but rather to enable future physicians to adapt to the changing landscape associated with the use of AI in medicine, facilitating the consideration of multiple ethical dimensions simultaneously. In addition to the proposed principles, medical education should incorporate practical case studies and simulations to reflect real-world scenarios. For example, applying AI to patient triage during health emergencies such as the COVID-19 pandemic can offer practical contexts for students. This approach would not only enhance their understanding of ethical principles but also prepare them for decision-making in complex, real-life medical situations influenced by AI. It is important for future physicians to

understand the balance between the potential benefits of AI and the ethical implications of its use, particularly in scenarios in which biased algorithms could lead to unequal treatment of diverse patient groups. Therefore, a comprehensive curriculum that includes both theoretical knowledge and practical applications is essential to cultivate ethically informed medical professionals.

An in-depth and interdisciplinary understanding of ethics is important in the dynamic field of medical AI. This importance is underscored by the fact that the integration of AI into medical education may not always keep pace with rapid advancements in medical practice. A focus on ethical principles rather than solely on specific challenges of AI use in medicine aims to prepare medical students for various scenarios in the medical context. This approach maintains relevance even if the AI applications used in education are not representative of the latest state-of-the-art developments in medical AI. The principle-based approach to AI ethics offers broader applicability and reduces dependence on the most recent AI technologies, potentially benefiting medical schools with limited financial resources. In addition, AI products for teaching, often sourced from third parties and guided by cost considerations, may pose unique challenges such as the risk of bias or rapid obsolescence [66,67]. This necessitates awareness, among medical students, of the potential ethical issues associated with these tools. By emphasizing a principle-based approach to AI ethics, educators can equip students with the necessary understanding to navigate the evolving landscape of AI in medicine, fostering adaptability and ethical sensitivity in future medical professionals. This adaptability is crucial to ensure that future physicians are prepared for the ethical dilemmas they may encounter in a rapidly evolving AI landscape.

In the applicability of the principle-based approach to AI ethics, the paramount importance of AI-based chat applications such as ChatGPT must be assumed [68]. As ChatGPT demonstrated extensive medical knowledge, as exemplified by its ability to pass the written part of the United States Medical Licensing Exam, AI-based chat applications offer new opportunities for medical education and medical students, such as in simulated patient interactions and case study analysis [69,70]. However, as ChatGPT was not explicitly developed for use in the medical context and, for example, does not adhere to stringent medical device regulations, it raises new ethical challenges. This becomes particularly evident, as AI-based chat applications can hallucinate and might not provide correct medical information due to improper “prompting” [70]. The limitations of ChatGPT, such as inaccurate or misleading medical information, necessitate an awareness of not only the technical limitations but also the associated ethical considerations. This reinforces the importance of a principle-based approach to AI ethics in medical education, emphasizing the importance of critically reflecting on and evaluating any use of AI in medicine. Awareness of potential ethical considerations regarding AI-based chat applications also extends from the provision of medical knowledge to a broader medical context, such as scientific research [71]. For example, if AI-based chat applications such as ChatGPT are used for medical research, medical education should facilitate an understanding of how

this could impact research integrity or potentially interfere with the existing ethical standards [71]. Medical education should prepare students to navigate through these complexities, ensuring the ethical integration of AI in practice and research.

Although the integration of public health ethics principles as part of medical AI ethics offers a comprehensive approach for teaching AI ethics in the medical setting, it is important to recognize that the field of public health ethics is still evolving [72]. Unlike the well-established principles of medical ethics proposed by Beauchamp and Childress [34], public health ethics principles such as efficiency, common good orientation, and proportionality are not universally agreed upon or applied consistently across different contexts. This lack of standardization presents a challenge for formulating a universally applicable ethical framework for AI in medicine. Furthermore, the interdisciplinary nature of public health ethics, encompassing the aspects of sociology, economics, and political science, adds to the complexity of integrating these principles into medical AI ethics education. This complexity requires careful consideration during curriculum development to ensure that these principles are taught in a manner that is both relevant and applicable to medical students. Moreover, the rapidly changing landscape of AI technology necessitates a dynamic approach to ethics education in which principles and guidelines are continuously revisited and updated. This need for adaptability may challenge the traditional formats of medical education, calling for innovative pedagogical approaches to ensure that future physicians are adequately prepared for the ethical complexities of AI-integrated medical practice.

Limitations

This study and the proposed theoretical foundation to medical AI ethics is subject to several limitations that need to be considered. Continuous evolution in the field of AI presents substantial challenges for the development of static ethical guidelines and frameworks for medical education. The dynamic nature of AI technology underscores the need for an adaptable and responsive ethical framework in medical education, particularly in the context of public health ethics, where principles are still developing and gaining consensus. Given that new advancements, for example, as exemplified by AI-based chat applications such as ChatGPT, cannot be foreseen and that the capabilities of AI and AI-based applications in medicine are anticipated to expand, continuous updates of existing educational frameworks and content are required.

Furthermore, the applicability and relevance of ethical principles as a part of medical AI ethics education may vary across cultural and health care settings. Different regions may have varying access to AI technologies, and cultural values may influence the perceptions of integrating and using AI in the medical setting. This variability could impact the universality of the proposed ethical framework and limit the applicability of teaching medical AI ethics as a part of medical education.

Moreover, integrating new teaching content into medical curricula is challenging due to the need for time-intensive accreditation processes and extensive teaching content. The integration of new teaching content such as medical AI ethics education requires careful planning to ensure that future

physicians are adequately prepared and not overwhelmed by information. In addition, limited access to instructors knowledgeable in ethics, medicine, and AI may pose a challenge to implementing the proposed teaching of medical AI ethics, as these experts may not be available in most institutions.

Conclusions

This study highlights the imperative need for medical AI ethics education and the integration of a comprehensive set of ethical principles into medical education to prepare physicians for the ethical challenges posed by AI in medicine. As the advancement of AI technologies in medicine is expected to increase, it is essential for medical ethics education to adapt and evolve accordingly to keep pace with these developments. Educational institutions should take proactive steps to update their curricula, ensuring that future medical professionals are not only aware

of the ethical dimensions of AI in medicine but also equipped to make informed ethical decisions in their practice. The principles discussed, drawn from both traditional medical and public health ethics, provide a multidimensional framework for understanding and navigating the ethical landscape associated with the use of AI in medicine.

Given the rapid advancements in the field of AI, it is essential that these ethical guidelines be regularly revisited and updated to remain relevant in the context of medical education. The proposed dynamic approach, with an emphasis on ethical principles, aims to ensure that medical professionals not only are equipped to use AI in ways that enhance patient care but also uphold the highest ethical standards. Future research is needed to develop problem-based and competency-oriented learning objectives and educational content for medical AI ethics and implementation and validation.

Abstract

Despite the increasing relevance of statistics in health sciences, teaching styles in higher education are remarkably similar across disciplines: lectures covering the theory and methods, followed by application and computer exercises in given data sets. This often leads to challenges for students in comprehending fundamental statistical concepts essential for medical research. To address these challenges, we propose an engaging learning approach—DICE (design, interpret, compute, estimate)—aimed at enhancing the learning experience of statistics in public health and epidemiology. In introducing DICE, we guide readers through a practical example. Students will work in small groups to plan, generate, analyze, interpret, and communicate their own scientific investigation with simulations. With a focus on fundamental statistical concepts such as sampling variability, error probabilities, and the construction of statistical models, DICE offers a promising approach to learning how to combine substantive medical knowledge and statistical concepts. The materials in this paper, including the computer code, can be readily used as a hands-on tool for both teachers and students.

KEYWORDS

learning statistics; Monte Carlo simulation; simulation-based learning; survival analysis; Weibull

Introduction

The correct use and application of statistics plays a fundamental role in the health sciences, in turn providing objective and quantitative evidence to support decision-making in public health [1]. Despite the increasing relevance of statistics in health research, it is often taught in isolation, usually through standard lectures covering the theory and methods followed by computer exercises with given data sets. This can lead to a disconnect between statistical and epidemiological methods such as study design, as well as insufficient awareness of important statistical concepts such as sampling variability [2]. Therefore, teaching methods that deliver statistical concepts in conjunction with epidemiology for students in the health sciences are crucial for educational development [3].

Simulation-based learning has previously been proposed as a tool to support engaging learning [4] and has been shown to be

an effective learning method to develop critical thinking and reflective skills [5-7]. In the context of public health and epidemiology, 2 articles in particular highlight Monte Carlo simulations [8] (hereafter simulations) as a method to illustrate, learn, and understand statistical and epidemiological concepts. First, Rudolph et al [3] demonstrate how to use simulations to teach and learn nondifferential misclassification and understand the concept of the *P* value. Second, Fox et al [9] illustrate how to design simple simulations from directed acyclic graphs and use them to explain epidemiological concepts. Both papers provide helpful resources for students to familiarize themselves with the basics of setting up a simulation.

However, despite a broad acceptance of simulations as a helpful tool to learn statistical and epidemiological concepts [5], in our experience, they are rarely implemented as the main teaching and learning method for students in health sciences. Rather than using simulations to learn a stand-alone element of statistics,

we propose a learning method that uses simulations to explore and understand the major steps involved in conducting a scientific investigation. In expanding upon the current foundations of simulation-based learning in health sciences, we introduce DICE (design, interpret, compute, estimate), an engaging, problem- and simulation-based learning method. The overall aim is to promote statistical reasoning in the health sciences by combining medical and statistical knowledge in designing epidemiological studies. The purpose of this viewpoint paper is therefore to describe the concept of DICE and discuss its potential strengths and limitations in learning statistics in the health sciences. The statements expressed in this paper are based on the experiences and opinions of the authors.

The remaining part is structured as follows: we will first describe the proposed method—DICE—and explain the intended learning objectives and outcomes. We will then illustrate the use of DICE with an example of a time-to-event outcome. Finally, we will discuss some potential strengths and limitations of applying the method in a classroom setting.

The DICE Approach

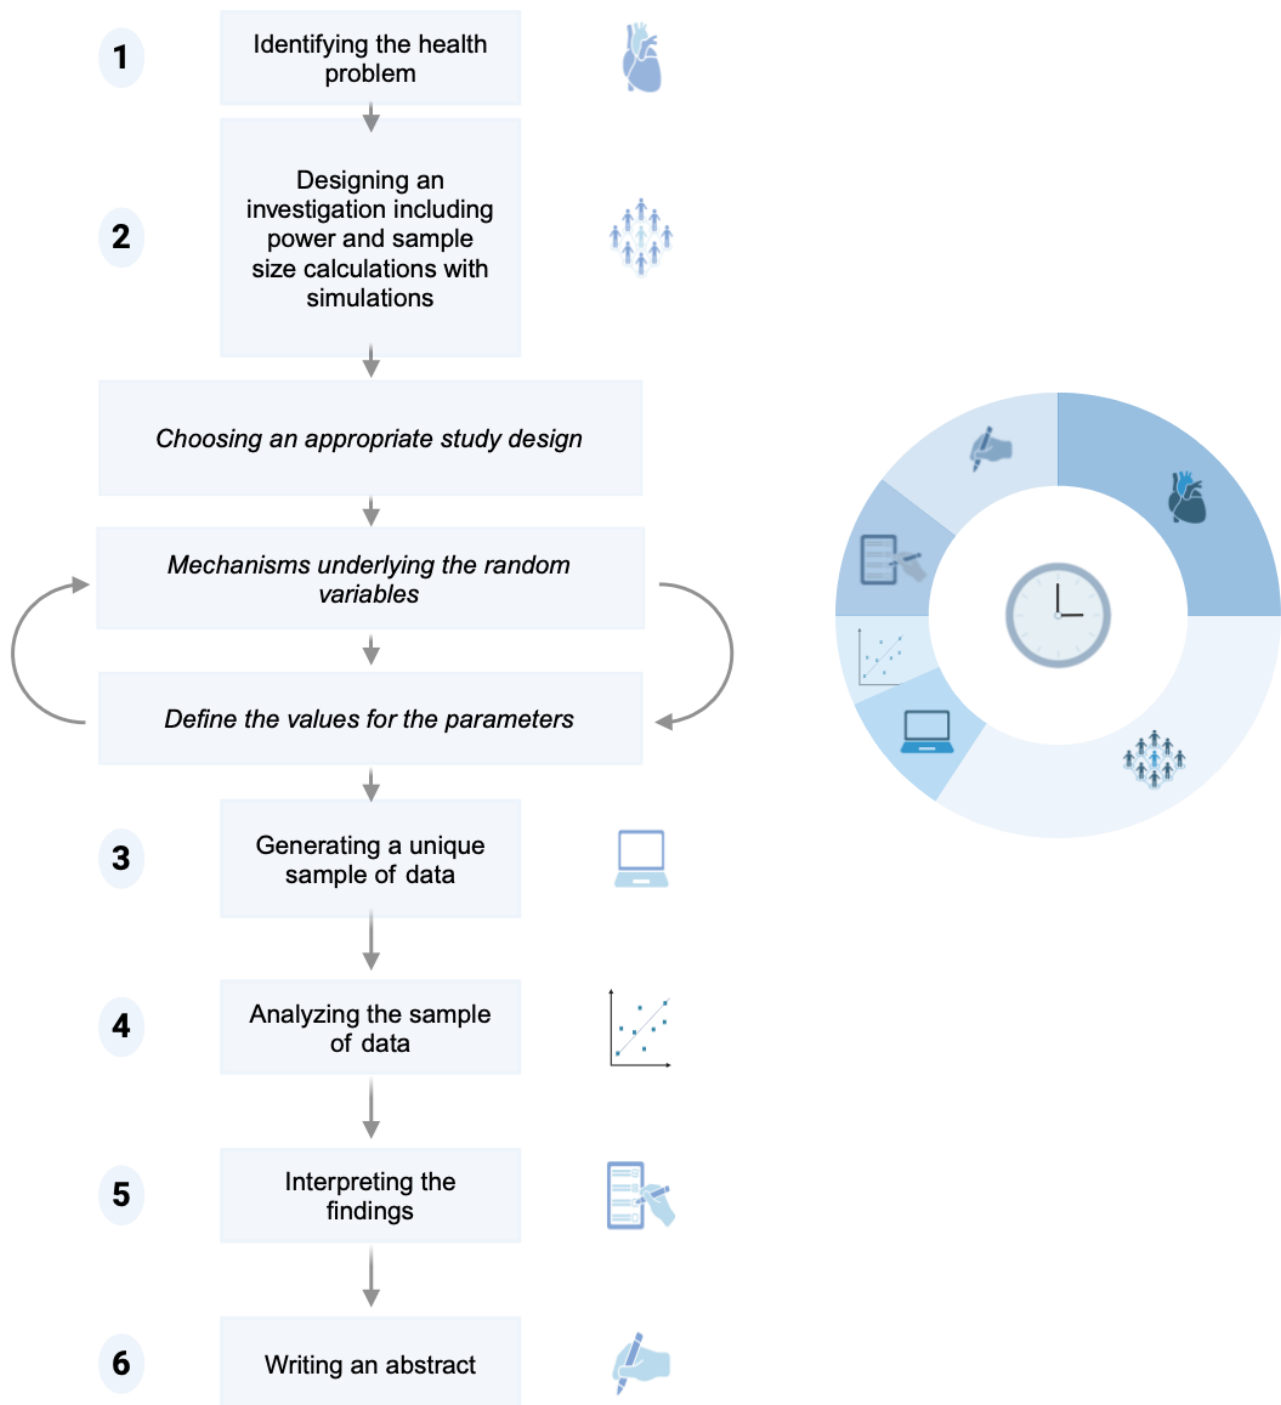

DICE is an engaging learning method that enables students to use simple simulations to design, analyze, and interpret a realistic epidemiological study (note that the acronym DICE represents the learning steps involved, but not in order). The

use of DICE as a learning tool combines problem-oriented learning [10,11] with simulations [12]. A detailed description of Monte Carlo methods can be found elsewhere [13]. While there are numerous ways to simulate artificial data, we focus on the approach presented by Fox et al [9] due to its simplicity to implement in statistical software and its easy-to-follow translation from a causal framework. In brief, simulations enable us to study a mechanism empirically by sampling from a statistical model that governs the mechanism. Data are then sampled from a predefined probability distribution (eg, Bernoulli, normal, or Weibull) that defines the mechanism, commonly referred to as the inverse transformation sampling method [14]. Further, the data are analyzed with an appropriate statistical model (preferably the same model that generated the data). These steps can be repeated a large number of times to empirically observe the variability of the sampling process [13].

Steps and Learning Objectives

DICE includes 6 major steps that cover the major stages of a scientific investigation. Figure 1 visualizes the chronological order of these steps and highlights the approximate amount of time that one step requires. The second step—designing an investigation including power and sample size calculations with simulations—is further divided into 3 parts, which can be repeated to calibrate the power and sample size of a study before moving on to step 3.

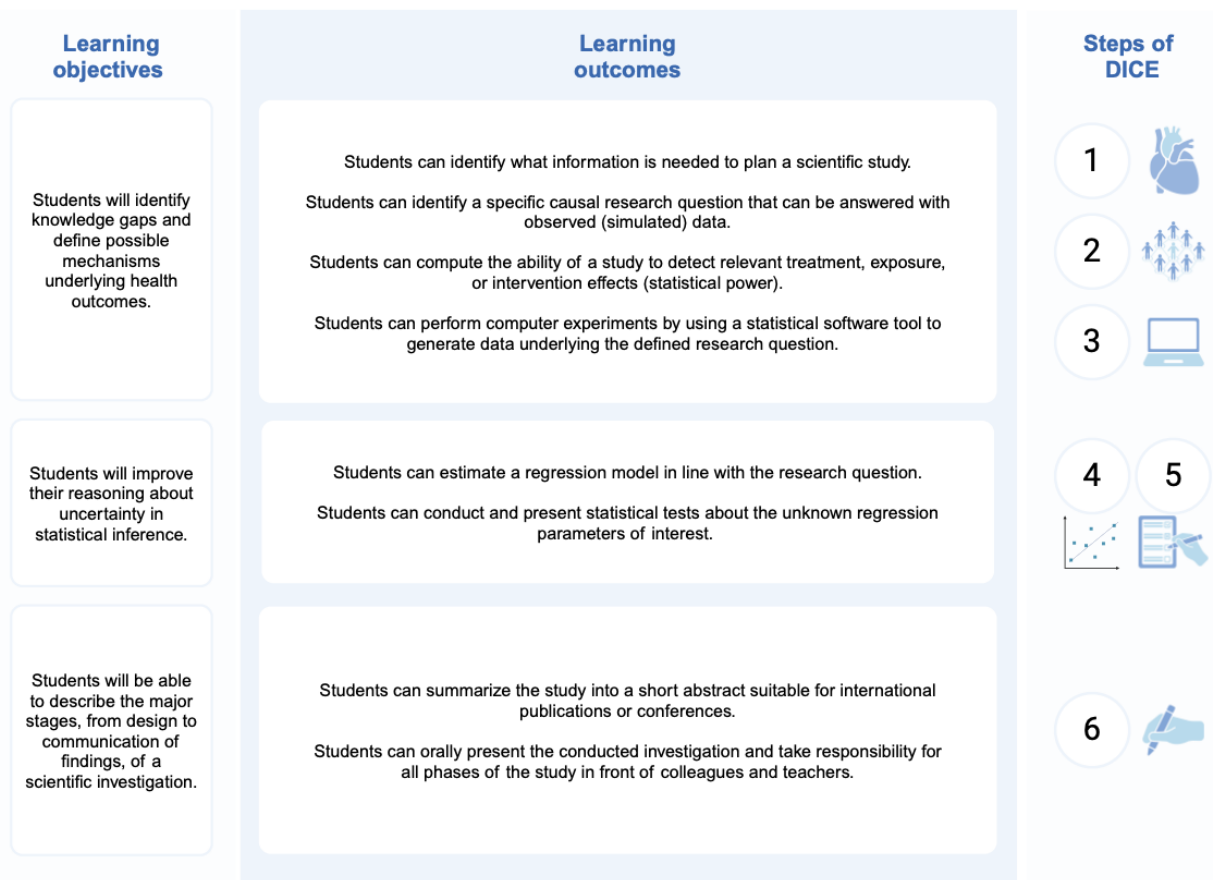

Figure 1. Flowchart of the 6 steps involved in DICE (design, interpret, compute, estimate) with an illustrative pie chart showing the approximate time dedicated to each step. The curved arrows in step 2 indicate that these activities can be completed multiple times to calibrate the sample size and power of a study before moving on to the next step.

The key learning objectives and outcomes of DICE, as highlighted in Figure 2, target experiential learning [15] and active learning styles [16] according to Bloom's taxonomy of educational objectives, including applying recently learned concepts and theories, making informed judgements and evaluations, and generating new knowledge [17]. DICE is a flexible method that accommodates different learning styles that have been shown to play an important role in medical

education [18]. As such, each student can work according to their strengths (eg, taking a leading role in the group to cover a specific aspect of the design of a simulated study, like computer coding or result interpretation). Due to the heterogeneity in the working groups, it can be expected that students will use their own learning styles and strengths to learn from other students with different skills [18].

Figure 2. The main learning objectives and outcomes across the steps of DICE (design, interpret, compute, estimate). The steps of DICE include (1) identifying the health problem, (2) designing an investigation including power and sample size calculations with simulations, (3) generating a unique sample of data, (4) analyzing the sample according to the plan, (5) interpreting the findings carefully, and (6) writing a short abstract to be presented in class.

A Guide Through an Example

Each step is now practically explained with an example. The following example is inspired by 2 recent epidemiological studies [19,20]. All information and data are simulated and only serve educational purposes. The computer code in Stata (StataCorp) and R (R Core Team) can be readily used to replicate the example (the code is provided in [Multimedia Appendix 1](#)).

Step 1: Identifying the Health Problem

During the first step of DICE, students should think about a particular problem, population, and area that they would like to investigate. This can be somewhat time-consuming and requires a decision about the nature of the research question (ie, causal, descriptive, or predictive) [21]. As we focus on simulating data according to a causal framework explained by Fox et al [9], the research questions are intended to answer a causal question. Other forms of research questions can, of course, be incorporated and simulated; however, they are not the focus of this example. In our example, the aim is to examine the effect of physical activity on the 10-year mortality rate in a large cohort of older people.

Step 2: Designing an Investigation Including Power and Sample Size Calculations With Simulations

The second step addresses the overall design of the study, including the assessment methods for the specified variables. The step is further divided into three specific parts: (1) students should reflect on the appropriate study design (eg, experimental or observational), (2) put forward the possible mechanisms (confounding, interaction, etc) underlying all the random variables involved in the study, and (3) discuss plausible values for all of the parameters. These are discussed in more detail below.

Part 1: Choosing an Appropriate Study Design

Designing an investigation that includes power and sample size calculations with simulations requires careful consideration of available literature and substantive knowledge about the underlying health problem. We recommend allocating sufficient time for this step of planning a realistic simulation study.

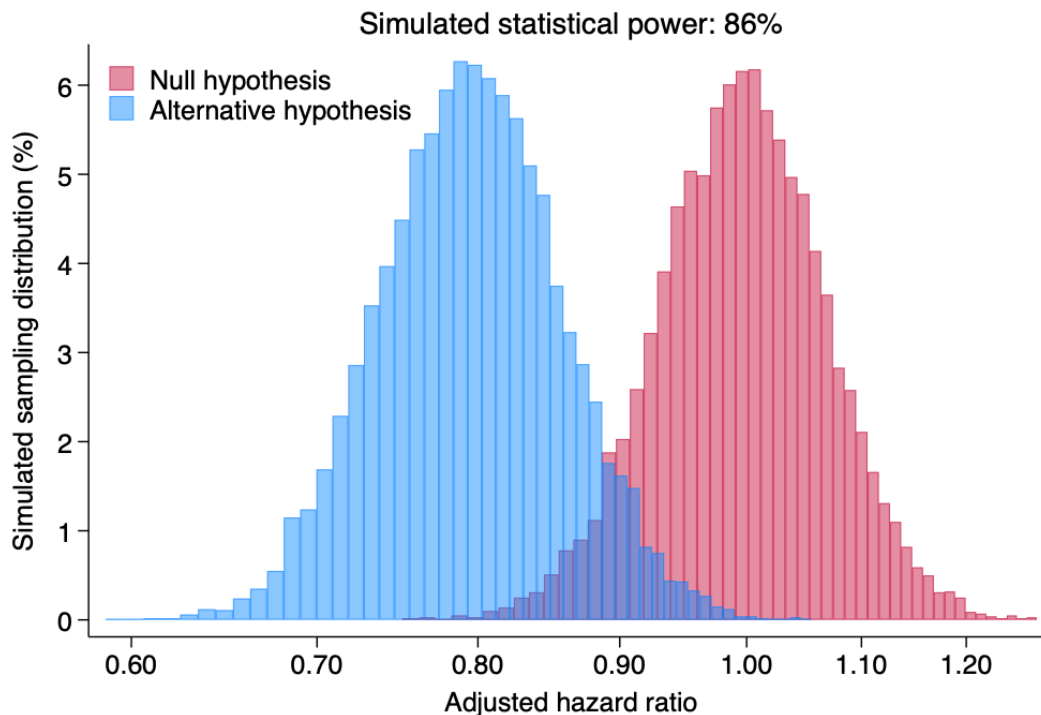

In our example, we design a large, observational cohort study with a confounding effect by age. Information on physical activity (3.5 hours per week of moderate to vigorous physical activity [MVPA] vs less), together with age (≥ 80 years vs < 80 years), is assessed at baseline in a short questionnaire. The mortality rate in a cohort of older people is likely to increase over time due to aging, among both physically active and inactive populations. Assuming a baseline mortality rate in the

younger and physically inactive population of 7 deaths per 1000 person-years, we determined that 5000 individuals (about 1005 deaths during 10-year follow-up) would provide a statistical power of about 86% to detect at least a 20% lower mortality rate (age-adjusted hazard ratio 0.8) in the physically active population relative to the inactive population. A 2-sided Wald-type test for the age-adjusted hazard ratio conferred by

physical activity equal to 1 with a type II error of 5% is conducted based on a multivariable Weibull survival model including physical activity and age as covariates.

Figure 3 shows the sampling distribution of the age-adjusted hazard ratio comparing physically active versus inactive individuals under the null and alternative hypotheses.

Figure 3. Simulated sample distribution of the age-adjusted mortality hazard ratio comparing active versus inactive individuals under the null and alternative hypotheses (hazard ratio 0.8). The simulated statistical power was obtained by counting the number of studies that correctly rejected the null hypothesis with a 2-sided Wald-type test at a significance level of 5% based on a multivariable Weibull survival model. The number of simulations is 10,000, the sample size of each study is 5000, and the average number of deaths within each study is 1005.

Part 2: Mechanisms Underlying the Random Variables

Parameters and their distributions can be inspired by previous studies, textbooks, or substantive knowledge from group members. For example, if the exposure is defined as systolic blood pressure (mmHg), students can assume an approximately symmetric and bell-shaped distribution with a given mean and SD and derive the parameter from a normal distribution function. For this study, we need the following variables: (1) z , an indicator variable for the older population (1 “>80” vs 0 “≤80 years”); (2) x , an indicator variable for the physically active population (1 “>3.5 h/w of MVPA” vs 0 “≤3.5 h/w MVPA”); and (3) t , the time from baseline to death (in years) or the end of follow-up (10 years), whichever came first.

Part 3: Define the Values for the Parameters

During this step, students should write a few lines of code or a function capable of generating data according to the desired study and mechanism. Simulations can be used to calibrate the sample size and statistical power of the study. To achieve the desired statistical power (eg, 80%), the sample size can be changed accordingly during this step. This requires some time, and we recommend students try to adapt certain values for the parameters or underlying mechanisms from the previous step

(Figure 1). This process is commonly referred to as the data generating mechanism (DGM). We understand DGM as the mechanism underlying the causal structure, including the uncertainty governing the observed data. The simulated power of the statistical test to detect an effect is simply given by the sum of studies that reject the null hypothesis of no effect divided by the total number of simulated studies.

In our example, the first variable to be generated is baseline age (about 60% are older than 80 years of age), which is a confounding variable in the relationship between physical activity and mortality:

For the exposure model, the second variable to be generated is baseline physical activity as a function of age. People aged ≤80 years have a probability of being physically active of 50%, whereas the odds of being physically active among older people are 1/3 (67% lower odds) relative to younger people:

Of note, Bernoulli is a statistical function, whereas logit and ln are mathematical functions.

For the outcome model, individual time-to-death (in years) conditional on the variables physical activity and age is obtained under the Weibull survival model, as follows:

where γ is the parameter defining the departure from a simpler exponential (constant mortality rate) survival model. The value of γ is set to 1.1, indicating a slight increase in the mortality rate over the follow-up period in all the covariate patterns.

The natural logarithm of the baseline mortality rate (per 1 year) among young and inactive people is assumed to be 7 deaths per 1000 person-years, so the intercept is $\beta_0 = \ln(7/1000) = -4.962$

The age-adjusted mortality hazard ratio comparing physically active versus inactive people is set to 0.80, as determined by $\beta_1 = \ln(0.80) = -0.2231$.

The physical activity-adjusted mortality hazard ratio comparing older versus younger people is set to 4, computed as $\beta_2 = \ln(4) = 1.386$.

Given a random value for the survival probability S ranging over the 0 to 1 interval, a random value of individual time-to-death (in years) conditionally on the variables physical activity and age is obtained as follows:

In addition, any randomly generated time-to-death beyond the follow-up time of 10 years is set to 10 and considered censored (ie, still alive at the end of the follow-up). An indicator variable for death or censored status is also created to inform any survival analysis.

Step 3: Generating a Unique Sample of Data

Once the study has been designed with sufficient statistical power to detect the relevant effect, the next step is to draw one unique sample. Students will analyze and present only this sample in class. The uniqueness and reproducibility of the simulated data are guaranteed by setting a numerical sequence, called a seed, before obtaining realizations of the random variables. This is important for the exact replication of the study. Every group of students is asked to use a common seed in generating the analytical sample of data so that all groups replicate the study under the same conditions. Each group will have a different research question and an underlying health problem with varying parameters. The reason for choosing a seed in the beginning is to highlight the uniqueness of a single study generated under a known DGM. The easiest choice is to specify the seed according to the date of the DICE activity. In our example, we use the seed 20230413 (based on the year, month, and date: “YYYYMMDD”). However, for specific tasks such as power calculations or simulating a distribution of effects, the seed must be deleted to ensure variability in the simulations.

Step 4: Analyzing the Sample of Data

The outcome model is specified according to the process underlying the data, and it is estimated based on the only sample available. Students estimate the statistical model whose performance was evaluated in the initial step of the study design. In our example, we estimate a multivariable Weibull regression model including physical activity and age as covariates.

Step 5: Interpreting the Findings

Students carefully interpret the estimated model and write about the inferential results. In our example, during the 10-year follow-up period, a total of 974 people died out of 5000. Compared with inactive people, the age-adjusted hazard ratio for active people was 11% lower (hazard ratio=0.89; 95% CI 0.78-1.03). A Wald-type 2-sided test indicates some compatibility between this sample of data and the hypothesis of a null age-adjusted mortality hazard ratio for physical activity ($z = -1.52$; $P = .13$). This unique sample of data is an example of type II error (failing to reject the null hypothesis, which is indeed incorrect). Nonetheless, the magnitude and direction of the hazard ratio indicate a beneficial effect of physical activity on the 10-year mortality rate. This provides an example of correctly differentiating statistical and scientific inference.

Step 6: Writing an Abstract

Each group of students should then write a structured scientific abstract (200-250 words) summarizing all the previous steps suitable for an epidemiological conference. The findings and interpretation are then presented in class. Each group of students briefly presents their findings and reasoning behind the study design. Teachers and peers have the possibility of asking questions. The presentations of each group should not exceed 10 minutes per group.

What Have we Learned?

Based on our experiences teaching with DICE and to conclude the steps of DICE shown in the practical example, we hope the key learning lessons for students will include the following: First, students should realize that the most challenging and time-consuming step is the design of the study and identifying a plausible distribution of the random variables involved, the mechanisms underlying the data, and all the parameters included. Second, students should understand that error probabilities (type I, type II, and power) in conducting a test of hypothesis can be easily evaluated by replicating the study many times under similar conditions (Figure 3) using a simulation. Third, students should appreciate the fundamental distinction between the analysis of a single study and the analysis of a collection of estimates obtained from its replication (Figure 4). Fourth, students should understand that the ability of a study to find a relevant exposure or intervention effect (statistical power) can be achieved only with respect to one parameter of interest. Fifth, students should learn that the correct use of statistics plays a key role in all stages of a scientific investigation.

Figure 4. Sampling variability of the estimated survival probability comparing physically active and physically inactive young participants based on 900 simulated studies. The thick dashed lines for both physically active and inactive groups show the functions that were set under the original data-generating mechanism.

Strengths and Limitations of DICE

We proposed an engaging learning method, DICE, to stimulate experimental, active, and enjoyable learning of statistical concepts, fostering key scientific skills in designing and conducting experiments. While the main strengths of this approach lie in its interactivity and group-based nature, we acknowledge several limitations.

First, the proposed simulation method is practically limited to only a few numbers of parameters that can be included in the design of a study. Each additional variable increases the complexity of the DGM exponentially. Thus, this approach is best suited for illustrative, simplified examples of realistic health problems. More sophisticated data derived from multivariate distributions would exceed the simplicity of the method but can, of course, be considered for more advanced classes.

Second, implementing DICE is resource-intensive and should not be done in a short time frame (eg, less than 1 hour). Although this is not a direct limitation of the method, it might be a limitation of its implementation in a classroom.

Third, the effectiveness of DICE in conveying statistical concepts in epidemiology has not been formally evaluated yet. This paper is a description and discussion of the method as implemented in class at a medical university. A formal evaluation of its effectiveness in learning statistics is being devised.

Implementing DICE in the Classroom

Based on the experiences of the authors in using DICE, we summarize the following points for its implementation in the

classroom for graduate students in medical sciences, including public health and epidemiology.

First, to implement DICE in a classroom, we recommend a classroom size of approximately 20-40 students, with small groups of 3-5 students from heterogeneous scientific backgrounds. Each group should consist of students who have different strengths and learning styles. We experienced that this could improve interaction between students and increase the joy of learning statistics.

Second, throughout the group work, students are encouraged to discuss and reflect upon the study design, practice the generation and simulation of data under a certain mechanism, and communicate their findings and interpretation of the study. We experienced that some students require more support to understand and use the provided computer code, particularly in settings with fewer students experienced in coding. It can help to go through an example of a simulated study with Stata or R code in front of the class.

Third, DICE can be implemented within a full day of teaching or over several days. For a 1-day implementation, the morning can be used for students to frame their research question and develop the study using simulations (steps 1-3). The afternoon can then be reserved for steps 4-6, ending with the presentation of the abstracts. It is important to keep in mind that the first 2 steps require most of the time (Figure 1). Students should not be rushed through these steps and should be provided with sufficient guidance and support to find an adequate research question, study design, and set up the simulations. Alternatively, DICE can be implemented over several days. An introduction to DICE is given in class, and students can work over several

days in their respective groups. The final day can be used for presenting and discussing the studies and outcomes of each group.

Conclusion

This paper introduces an engaging simulation-based method, DICE, to learn statistics in the health sciences. We argue that

DICE can boost statistical reasoning and bridge the gap between substantive knowledge and statistics for all major steps of a scientific investigation. Students can learn fundamental statistical and epidemiological concepts with simulations and combine learning of technical aspects such as coding with theoretical concepts such as error probabilities. The materials in this paper can be readily used by teachers and students.

Acknowledgments

We would like to thank all students of the 2023 master's in public health sciences at Karolinska Institutet for participating in the weekly DICE activities and giving us valuable feedback to improve this teaching method. In addition, the authors would like to thank Stephanie Pitt (Karolinska Institutet) for valuable insights into the draft of the manuscript. Figures 1 and 2 were created on the website of BioRender.

Data Availability

All data generated or analyzed during this study are included in this published article and its supplementary information files.

Authors' Contributions

NO supervised the project. RT wrote the original draft of the manuscript. Both authors contributed equally to the conceptualization, methodology, and software. The authors approved of the final version of the manuscript.

Conflicts of Interest

None declared.

Multimedia Appendix 1

Computer code in Stata and R to replicate the example used in the paper.

Abstract

Background: Access to reliable and accurate digital health web-based resources is crucial. However, the lack of dedicated search engines for non-English languages, such as French, is a significant obstacle in this field. Thus, we developed and implemented a multilingual, multiterminology semantic search engine called *Catalog and Index of Digital Health Teaching Resources* (CIDHR). CIDHR is freely accessible to everyone, with a focus on French-speaking resources. CIDHR has been initiated to provide validated, high-quality content tailored to the specific needs of each user profile, be it students or professionals.

Objective: This study's primary aim in developing and implementing the CIDHR is to improve knowledge sharing and spreading in digital health and health informatics and expand the health-related educational community, primarily French speaking but also in other languages. We intend to support the continuous development of initial (ie, bachelor level), advanced (ie, master and doctoral levels), and continuing training (ie, professionals and postgraduate levels) in digital health for health and social work fields. The main objective is to describe the development and implementation of CIDHR. The hypothesis guiding this research is that controlled vocabularies dedicated to medical informatics and digital health, such as the Medical Informatics Multilingual Ontology (MIMO) and the concepts structuring the French National Referential on Digital Health (FNRDH), to index digital health teaching and learning resources, are effectively increasing the availability and accessibility of these resources to medical students and other health care professionals.

Methods: First, resource identification is processed by medical librarians from websites and scientific sources preselected and validated by domain experts and surveyed every week. Then, based on MIMO and FNRDH, the educational resources are indexed for each related knowledge domain. The same resources are also tagged with relevant academic and professional experience levels. Afterward, the indexed resources are shared with the digital health teaching and learning community. The last step consists of assessing CIDHR by obtaining informal feedback from users.

Results: Resource identification and evaluation processes were executed by a dedicated team of medical librarians, aiming to collect and curate an extensive collection of digital health teaching and learning resources. The resources that successfully passed the evaluation process were promptly included in CIDHR. These resources were diligently indexed (with MIMO and FNRDH) and tagged for the study field and degree level. By October 2023, a total of 371 indexed resources were available on a dedicated portal.

Conclusions: CIDHR is a multilingual digital health education semantic search engine and platform that aims to increase the accessibility of educational resources to the broader health care–related community. It focuses on making resources “findable,” “accessible,” “interoperable,” and “reusable” by using a one-stop shop portal approach. CIDHR has and will have an essential role in increasing digital health literacy.

Introduction

Background

Medicine, health care, and wellness will become increasingly digitized. Thus, digital technologies are more than ever taking a pivotal position in clinical practice, making it crucial to educate future professionals to efficiently grasp digital health and health informatics [1,2]. The World Health Organization views digital health as “a broad umbrella term encompassing eHealth, mHealth, as well as emerging areas, such as the use of advanced computing sciences in big data, genomics, and artificial intelligence.” The World Health Organization affirmed that to strengthen health systems using digital health technologies, finding ways to build capacity and creating a digitally capable health workforce should be key objectives [3,4].

The integration of digital technologies has brought about significant changes in the realm of health professions education. Our research identified various digital education–related inquiries, culminating in a comprehensive and diverse research agenda. We proposed a conceptual framework to assist educators and researchers in developing, designing, and studying digital education. However, we acknowledge the need for further data from lower- and middle-income countries [5].

In 2022, the Delegation of Digital Health of the French Ministry of Health and the French National Research Agency published an open call for projects to support the development of digital health teaching and learning technologies, in French, and dedicated to the community of French health–related professions students and practitioners [6]. These include medicine; dental medicine; pharmacy; midwifery; nursing; physiotherapy; ergotherapy; and, more broadly, any related field such as social work, health administration, and biomedical engineering. By 2027, this heterogeneous community, which includes postgraduates and continuous learners, will reach 210,000 members trained simultaneously in France.

Thus, the association of the departments of digital health (DDHs) of the University of Rouen Normandy (URN) and Côte d’Azur University (CAU) is developing and implementing the SaNuRN (*Santé Numérique Rouen Nice*) [7], a 5-year project started in September 2022 and granted with €3,951,200 (US

\$4,163,775) for a total cost of €6,891,923 (US \$7,262,708), in the context of the said open call (grant #ANR_22-CMAS-0014) having an overall budget of €71 million (US \$77.6 million) dedicated by the government to digital health education.

From an educational perspective, SaNuRN is currently based on existing pedagogical resources developed by the DDHs of URN and CAU. In addition, a large part of these resources follows the concepts structuring the French National Referential on Digital Health (FNRDH) [8] that provides French higher education institutions educating health-related professionals with a guideline to support teaching in digital health. Thus, students and lecturers from URN, CAU, and other higher education institutions and professionals have free and unrestricted access to the *Catalog and Index of Digital Health Teaching Resources* (CIDHR) as a platform providing structured and validated information contributing to the body of knowledge necessary to master the field [9].

For example, since 1993, the URN DDH has been developing CISMef (*Catalogue et Index des Sites Médicaux en langue Française*; in English, *Catalog and Index of Medical Sites in French Language*), a catalog of French-speaking health resources currently containing 128,689 inputs, including 9409 teaching resources. Moreover, since 1999, with the foundation of the French Medical Virtual University [10], all these teaching resources have been freely available in open access [11,12].

Dealing with teaching material in digital health for academic purposes is challenging because of the availability of many resources. However, the French-speaking material is globally limited compared with the one available in English. Therefore, we are developing the CIDHR [9].

In contrast to other educational platforms that mainly cater to English speakers and require payment, such as the Healthcare Leadership Academy [13], various platforms supported by the UK National Health Service [14], or the IMD Health cloud-based platform [15], CIDHR plays an important role in freely engaging French-speaking students and the health care practitioners community in digital health teaching and learning.

One of the primary reasons for emphasizing the need for a French-speaking knowledge catalog in the digital health domain, such as CIDHR, is to bridge the language gap. Although English

is a dominant language in scientific literature and teaching platforms, it excludes a substantial portion of the global population, particularly those more comfortable with other languages and, more particularly, French in this specific case. Thus, this language barrier can hinder the dissemination of critical information and knowledge transfer in digital health education and the development of a dedicated platform in French (which can comprise resources in other languages) [16-19].

From an informatics perspective, SaNuRN is based on semantic technologies. Since 2000, the DDH of URN has been developing and maintaining a semantic search engine (Doc'CISMeF) that was developed using primarily the Medical Subject Headings (MeSH) thesaurus [20] to manage the CISMeF resources. Starting in 2010, a multiterminology and multilingual approach is being continuously developed and used to allow any CISMeF resource to be indexed by more than 1 health terminology and

by more than 1 language, although the MeSH thesaurus remains the pivotal terminology and, for CISMeF, the French and the English are the 2 pivotal languages [21,22].

As a natural evolution with the goal to share as much as possible the open access resources, and within the SaNuRN framework, starting in 2022, we have been developing and implementing a multilingual multiterminology semantic search engine CIDHR. We focus on continuously expanding CIDHR to fit the goal of the SaNuRN project and facilitating the daily teaching and learning practice in medical education by offering easy-to-use indexation and retrieval processes of any educational resource in digital health mainly toward not only French speakers but also toward others; the portal is available among other languages in English, German, Spanish, Greek, Croatian, Chinese (Mandarin), and Finish (Figure 1 [9]).

Figure 1. The Catalog and Index of Digital Health Teaching Resources (CIDHR) portal in French.

Aim, Objective, and Hypothesis

Our main aim in developing and implementing CIDHR, as a multilingual multiterminology semantic search engine, is to enhance knowledge sharing and spreading in digital health and health informatics and to expand the health-related educational community, primarily French speaking but also in other languages [23]. In particular, we aim to support the continuous development of initial (ie, bachelor level), advanced (ie, master and doctoral levels), and continuing training (ie, professionals and postgraduate levels) in digital health for health and social work fields.

Our main objective is to describe the development and implementation of the semantic search engine CIDHR in SaNuRN as a way to foster digital health education and continuous training in France. The hypothesis that guided this research is that controlled vocabularies dedicated to medical informatics and digital health, such as the Medical Informatics Multilingual Ontology (MIMO) [24,25] and the concepts structuring the FNRDH [8], to index digital health teaching and learning resources, are effectively increasing the availability and accessibility of these resources to medical students and other health care professionals.

Methods

Highlights

CIDHR is a part of the SaNuRN project. To better understand how we are developing and implementing CIDHR as a catalog of indexed digital health resources, we present the methodological steps in this process in the next lines. First, resource identification is processed by medical librarians; then, based on controlled vocabularies (an ontology and a competency referential organized as a taxonomy), the teaching and learning resources are indexed for each related knowledge domain. In the third step, the same resources are tagged with relevant academic and professional experience levels. The fourth step consists of sharing the indexed resources with the digital health teaching and learning community (with some focus on the French-speaking community). The last step consists of assessing CIDHR by obtaining informal feedback from users.

Resources Identification

To identify new or updated digital health teaching and learning resources, a group of 3 librarians from URN DDH is working on a continuous information watch, according to an internally developed and validated process comprising the steps and actions.

Thus, the librarians search proprietarily on a predefined list of academic websites of Schools of Health Sciences (eg, Medicine, Dental Medicine, Pharmacy, Nursing, Rehabilitation), National Agencies (eg, the French Ministry of Health [26]; the French National Authority for Health—*La Haute Autorité de Santé* [27]; the French national agency for medicines and health products safety—*Agence Nationale de sécurité du médicament*; and the French Agency for Food, Environmental and Occupational Health & Safety—*Agence Nationale de Sécurité Sanitaire de l'Alimentation, de l'Environnement et du Travail*); and other organizations involved in digital health education such as universities in France and around the world. They are also using search engine alerts, allowing reception of emails with potentially interesting content detected by their algorithms.

Moreover, the librarians monitor social media platforms, such as X (formerly known as Twitter), LinkedIn, or Facebook, by following and screening digital health-related accounts and groups sharing potentially relevant educational supports in digital health and health care informatics. The same search is performed by reading newsletters from professional organizations and academic institutions.

Furthermore, direct contacts with librarians and professional networks in digital health, particularly in the educational field, are used to obtain early updates about new and updated resources before their publishing over the web.

Resource identification also comprises the users' engagement with CIDHR as a platform, which can share their comments with the whole team (not only the librarians) and suggest additional resources.

Therefore, by using a variety of identification approaches, the librarians involved in CIDHR can propose to the digital health experts of the SaNuRN project a wide range of digital health educational resources to integrate. It is critical to remember that the resources identified are multilingual (although mostly in French because of the SaNuRN grant requirements).

Librarians evaluate each potential resource against the following three criteria:

1. Is the resource a digital health or health informatics education-related one? The resource should be designed to teach users or to support their teaching (depending on whether the user is a student or a lecturer).
2. Is the resource accurate and up-to-date? The resource should be based on current research and best practices.
3. Is the resource accessible? The resource should be available to many users, including those with disabilities.

If a resource meets all 3 criteria, the resource is added to the SaNuRN or CIDHR repository for tagging and indexing. If a potential resource fails the evaluation, it is excluded, at least temporarily, until the librarians recheck the resource and its positive compliance with the evaluation criteria.

Resources Indexation

For indexing the identified educational resources, CIDHR uses 2 knowledge organization systems (KOSs).

The first is the MIMO, which comprised 3645 concepts in 33 languages as of September 2023 [23-25]. An ontology formally represents a set of concepts within a domain and the relationships between these concepts.

The second KOS was the FNRDH created in 2021. Specifically, FNRDH describes 29 different competencies and 70 different abilities. FNRDH has a 3-level hierarchy. The first relies on 5 main competencies (health data, communication in health, digital tools in health, telehealth, and cybersecurity). The second level relies on 25 subcompetencies (eg, characterizing and managing nominative data, applying [European] regulation [in particular General Data Protection Regulation]), and the last level describes 70 different abilities (eg, understanding the life cycle of the digital health data) [8].

As a side note, MIMO and FNRDH are freely available through the Health Terminology/Ontology Portal [28], also developed by URN DDH over the past 20 years [29,30]. These 2 KOSs are used at an automated stage wherein the resources are preindexed based on keyword identification and then through a librarian indexation validation stage or manual indexation if the automated process is invalid.

Moreover, CIDHR is built around 2 sets of metadata (SoM): the Learning Object Metadata (LOM) set [31] and the Dublin Core Metadata Terms (DCMI-MT) set [32]. LOM is a standard for describing digital learning resources. It provides a set of metadata elements that can be used to describe the characteristics of a learning resource such as its title, description, educational objectives, and technical requirements. DCMI-MT is a simple metadata schema that can describe various digital resources. It provides a set of 15 core metadata elements, including title, creator, and subject. Both SoM are transparent for the final user and allow efficient management of the overall available data related to a selected education resource for being included in CIDHR. These SoM are autocompleted when metadata are available with a resource (ie, a website) and are then validated by a medical librarian. If the automated process fails, the librarian handles this task.

Using 2 KOSs and 2 SoM allows a flexible and comprehensive organization of CIDHR. First, the combination of the KOSs, MIMO as an ontology, and FNRDH as a referential provides a structured way to describe the concepts and skills covered by the teaching resources. Second, the SoM provide a way to describe the characteristics of the teaching and learning resources themselves. Combining KOSs and SoM makes it easy for users to find the appropriate educational resources.

For example, a user (eg, a medical student) interested in learning about the use of artificial intelligence in digital health can use CIDHR to find learning resources that are indexed with the following MIMO concepts: “artificial intelligence,” “digital health,” “machine learning,” and “data mining”; or the same user can find resources indexed with the following FNRDH skill: “use of artificial intelligence in digital health.” Accordingly, CIDHR provides a list of relevant educational resources.

Using KOSs and metadata sets is a common practice in digital learning to organize and represent digital learning resources in a flexible, comprehensive, and user-friendly manner.

Resources Tagging and Integration to the Curricula

Resource indexation is a critical stage of the CIDHR knowledge management process and a pivotal component of the overall SaNuRN project. However, the main aim is to use CIDHR as a support for digital health learning and teaching in integrating the medical and health-related undergraduate, postgraduate, and life continuing education curriculum. It is also important to suggest the right resources to the specific end user (ie, student according to his degree and field of study and lecturer according to his students and his field of teaching). Thus, LOM and its instantiation in France, known as SupLomFr [33], and DCMI-MT were previously used in CISMef that we have introduced above [11].

Thus, the 2 leading metadata are of utmost importance to help health-related students and lecturers find the right educational resources at the right time.

The first metadata is the “field of study” (ie, initial long-path education [>5 years]: medicine [Doctor of Medicine], dental surgery [Doctor of Dental Surgery], pharmacy [PharmD], and midwifery [State Diploma of Midwifery]; initial short-path education [until 5 years]: nursing [registered nurse], physiotherapy [State Diploma of Physiotherapist], and occupational therapy [State Diploma of Occupational Therapist]; and social work [State Diploma of Social Worker]).

The second metadata is the “degree level” (bachelor, master, doctorate, or residency in medicine, dental surgery, and pharmacy). It is important to point out that the graduates of an initial short-path education can continue their education in their fields at the postgraduate levels (master and doctorate degrees and lifelong continuing education).

Therefore, for any query performed on CIDHR, the end user may select and save these 2 metadata, “field of study” and “degree level” (eg, “Nursing” AND “Master Degree”; “Medicine” AND “Residency”). The so-called “training matrix” is generated to provide each combination of learners with a set of resources relevant to their profile. This set of educational resources is defined by consensus by the SaNuRN pedagogical team to be the most exhaustive. The “training matrix” is periodically updated according to the introduction of new resources or updates.

Moreover, any kind of teaching resource is cataloged in CIDHR, thanks to an extensive resources type hierarchy created for CISMef based on a conceptual extension of the MeSH publication type [20,34]. This resource-type hierarchy has been used fruitfully for more than 20 years by users (health students, academics, and professionals) of the CISMef platform searching for clinical-focused resources.

The following teaching resources are cataloged by tagging each one based on the following resource-type hierarchy (Figure 2 [28,35,36]): a “classical” teaching resource supporting a face-to-face course delivered with a series of slides (resource type: teaching material); evaluation of knowledge, such as multiple-choice question; and evaluation of competence, such as Objective Structured Clinical Examination or Script Concordance Test. These last 2 innovative approaches used as competency evaluation tools have been proposed for the nursing curriculum [37]; their use will be extended to other fields in CIDHR.

These combinations of the metadata tags “field of study” and “degree level” with the “resource type” tag as filters allow delivery to the user more or fewer indexed resources relevant to the knowledge fields submitted in the query to CIDHR depending on the filters selection submitted with the query.

Figure 2. List (sample) of resource types for teaching resources in the Health Terminology/Ontology Portal. CISMef: Catalogue et Index des Sites Médicaux en langue Française (Catalog and Index of Medical Sites in French Language).

User Experience Assessment

To assess the reception of CIDHR among users, we conducted an informal assessment including the following steps. First, a group of users consisting of both students (health students in their first year: 10/150, 6.7%) and the 5 teaching staff of digital health (JG, AB, PS, RL, and SJD) from diverse educational backgrounds and institutions was recruited. Then, immediately after the first set of lessons, the student participants were given access to CIDHR and encouraged to explore its features, search for digital health resources, and interact with the platform over a few days. Afterward, each user involved was invited to share, during a short interview, their feedback about their (1)

perception of CIDHR's user-friendliness and "easily navigable" capabilities; (2) comments on content quality comprehensiveness and the ongoing expansion; and (3) perception of CIDHR as a one-stop shop for freely and unrestricted accessible, primarily available digital health resources in their academic (ie, learning, teaching, and research) and professional activities. The last component of the feedback collection consisted of obtaining suggestions from the assessment participants.

Ethical Considerations

This research is dispensed of the ethical committee's approval, the User Feedback for Continuous Improvement being a normal educational practice and classroom management method

conducted in educational settings. Specifically, as non-interventional research dealing with practical habits analysis the Rouen University Hospital ethical committee does not ask for submitting such kind of research to the ethical committee. Moreover, the whole project SaNuRN that comprises CIDHR has been approved as a whole by the Delegation of Digital Health of the French Ministry of Health and the French National Research Agency [38].

Results

Resource Discovery and Indexation in CIDHR

The outcomes of the CIDHR resource identification and evaluation processes were executed by a dedicated team of 3 librarians from the URN—Rouen University Hospital DDH, aiming to collect and curate an extensive collection of digital health teaching and learning resources. Our identification strategies yielded a diverse and expansive pool of digital health educational resources through diligent exploratory searching of academic websites and platforms (eg, a systematic review of French universities' digital health departments and several French national agencies such as *Agence Nationale de sécurité du médicament* and *La Haute Autorité de Santé*) [26,27]. We successfully identified a continuously updating substantial number of resources catering to various aspects of digital health education. The use of search engine alerts (eg, Google Alerts [39] and PubMed alerts [40]), social media monitoring (eg, LinkedIn [41]), newsletters, and professional network notifications (of posts in groups of interests) also contributed significantly to the resource identification process.

In the last year, we identified approximately 500 valuable resources. It is noteworthy that the identified resources reflect a multilingual character (in particular, English). However, to align with the SaNuRN grant requirements, a substantial proportion (>90%) of the resources is in French. However, we ensured a representation of diverse languages to accommodate a wide-ranging audience interested in digital health education. In addition, we supported the ongoing internationalization and English-drafted teaching and self-learning introduced in the French higher education curricula.

Resources Evaluation

The “resource evaluation process” disclosed in the *Methods* section together with its 3 fundamental criteria ensures that each resource included up to now has been evaluated for relevance, “accuracy and currency,” and accessibility.

The relevance was scrutinized to ascertain its suitability for teaching and learning digital health education to serve the needs

of both students and lecturers. As a result, a significant portion of the identified resources clearly aligned with digital health education objectives (323/503, 64.2%). The 35.8% (180/503) of resources that were excluded were in the scope of digital health, but they did not sufficiently focus on real teaching resources.

Furthermore, each one of the remaining resources was subjected to a rigorous assessment of “accuracy and currency” to ensure its alignment with up-to-date research findings and adherence to best practices within the digital health field. The evaluation step revealed that some resources did not meet these accuracy and currency criteria and were rejected (approximately 36%).

The “accessibility” of the educational supports is a critical aspect emphasized in CIDHR resource evaluation to include in the catalog materials that can effectively be used by a broad range of the digital health educational community, including individuals with disabilities. This evaluation highlighted the commitment of many resources to accessibility.

If a potential resource does meet any one of these criteria, it does not move to inclusion in CIDHR and remains in a secondary list of resources to be periodically re-evaluated for future inclusion.

Resources that successfully passed all 3 evaluation criteria were promptly included in CIDHR. These resources are diligently indexed and tagged as described in the *Methods* section.

Tailored Learning Paths: Metadata, Training Matrix, and Resource Cataloging in CIDHR

The semantic search engine of CIDHR based on MIMO and FNRDH allows user-friendly access to previously indexed and tagged resources. At the end of September 2023, CIDHR comprised 371 available resources in the digital health field relevant to students and teaching staff from the first academic year of academic studies to lifelong continuing education. The French grant required that 80% of the effort should focus on the bachelor “degree level.” Therefore, approximately all the 371 resources included in CIDHR are focusing on bachelor's students.

CIDHR is constantly expanding, with plans to incorporate increasingly as much as possible digital health teaching resources from the French health-related studies curricula over the next few years [6].

Figure 3 shows an example of the results for the query “dossiers médicaux électroniques” (in English, “electronic health records” or EHRs).

Figure 3. Example of results to the query “dossiers médicaux électroniques” (in English, “electronic health records” or EHRs). Dictionnaire
 MIMO: *identitovigilance
 Cartes de Professionnels de Santé
 RCSN: *1.1.1 - connaître les enjeux et critères liés à l'identitovigilance vis à vis d'un usager [Identifiant National de Santé (INS), référentiels nationaux d'identité des personnes physiques]

The resource is written in French and focuses on EHRs, a concept defined in both MIMO (ie, “dossiers médicaux électroniques”) and FNRDH (ie, “Interagir de manière adaptée entre professionnels, avec l’usager, les aidants et accompagnants et avec les institutions et administrations,” in English, “Interact in an appropriate manner between professionals, with the healthcare customer, caregivers and companions and with institutions and administrations”); and “Utiliser les outils et services socles adaptés et identifier leur articulation avec

d’autres dossiers partagés,” in English, “Use the appropriate basic tools and services and identify their connection with other shared files”). It educates the learners on the fundamentals and the importance of the EHRs, making it an invaluable resource for anyone looking to enhance their digital health knowledge.

To facilitate the indexing process with FNRDH, which presents considerable complexity for medical librarians, the SaNuRN pedagogical team has established manual associations between

MIMO and FNRDH concepts. For instance, this involves manually linking the MIMO concept with the FNRDH competency. It is essential to clarify that this mapping relation does not constitute a strict “exact match”; instead, it means that when a librarian indexes a teaching resource using a MIMO concept (eg, “electronic medical records”) associated with an FNRDH ability (eg, “Interact appropriately between professionals, with the healthcare customer, caregivers and companions and with institutions and administrations”), the educational resource is also indexed with this corresponding FNRDH competency.

Nevertheless, certain cases require manual indexing with FNRDH by medical librarians, primarily because of the absence of the MIMO concepts for specific capacities, still not defined and implemented in MIMO, such as the “lifecycle of health data.” Thus, to minimize the dependency on manual FNRDH indexing, the SaNuRN pedagogical team is actively developing MIMO concepts and establishing mappings between MIMO and FNRDH concepts, including those pertaining to the lifecycle of health data.

In addition, as a part of CIDHR capacities, the end-user process for any query to deliver an organized list of educational resources is considered. The first item on the list must be studied first, followed by the second item, and so on. This organized list is manually created for each FNRDH competency; in other words, we create a breadcrumb navigation for teaching and learning resources linked to each FNRDH competency. Currently, this organized list is familiar to all the students in all

the fields of study. In the future, this organized list will be, when relevant, adapted to fit with the requirements of each field of study (eg, medicine, nursing), degree level (eg, bachelor, residency), and targeted level competencies or skills (eg, beginner, intermediate, and advanced).

User Feedback for Continuous Improvement

To assess CIDHR’s usability and acceptance among users, we collected informal feedback from a select group comprising both first-year health students (10/15, 67%) and teaching staff (5/15, 33%). Their feedback universally reflected a positive sentiment, characterizing the platform as remarkably user-friendly and easily navigable. Moreover, they lauded the platform’s existing resource collection, founded on rigorous content quality control, and appreciated its ongoing expansion. Notably, users articulated their assessment, highlighting CIDHR’s comprehensiveness, precision, and user-friendliness. Nonetheless, their constructive suggestions included the need for augmenting multilingual resources and offering more comprehensive resource information, particularly with respect to metadata. In the users’ collective perception, CIDHR was deemed a one-stop destination for discovering high-quality digital health resources. An additional commendable attribute was the platform’s unrestricted accessibility, which rendered it a valuable asset for all users.

Moreover, additional suggestions related to the need for more multilingual resources and comprehensive metadata were noted (eg, field of study, resource language, and resource scoring; [Table 1](#)).

Table 1. Summary of the feedback collected during the Catalog and Index of Digital Health Teaching Resources user experience informal assessment.

Feedback category	Students	Lecturers
Usability	User-friendliness and “easily navigable” capabilities	User-friendly and “simple to understand”
Content quality	Valuable, “easy to understand”	Valuable, comprehensiveness
One-stop shop potential	Free resources, easy to access, on various relevant content	Real one-stop shop freely and unrestricted accessible, especially available digital health resources in their academic (ie, learning, teaching, and research) and professional activities
Participants suggestions for improvements	More than French-only resources, in particular English, but also Arabic, Spanish and Portuguese (native language of the students)	More metadata on bibliographic card; more than French-only resources, in particular English

Discussion

Overview

The integration of digital technologies in health care and medical education is becoming increasingly vital. This study introduces CIDHR as part of the SaNuRN project to enhance digital health education in France. CIDHR is a comprehensive digital platform that indexes and organizes educational resources related to digital health, catering to students and health care professionals. This discussion explores the strengths and limitations of CIDHR, potential future perspectives, and the impact on digital health education.

Strengths and Limitations

CIDHR is the heart of a digital health educational platform that provides an extensive array of inclusive and accessible teaching and learning resources to a diverse global audience in the health care professional education landscape. CIDHR has a large and continuously expanding collection of up-to-date and relevant digital health resources that serves as a one-stop shop related to all aspects of digital health education needs, catering to lecturers, students, and professionals alike.

CIDHR is committed to providing comprehensive support to French-speaking individuals seeking digital health education. To ensure that language barriers do not impede access to educational resources, CIDHR has indexed a wide range of materials in multiple languages, in addition to its French language resources. These materials are designed to cater to

diverse linguistic needs and are available to all individuals seeking to enhance their digital health knowledge. With CIDHR's vast collection of indexed educational resources, individuals can access high-quality information and support regardless of their native or daily spoken language.

To improve resource indexing and search precision, CIDHR uses controlled vocabularies such as MIMO and FNRDH, which enable users to locate relevant educational materials that align with their specific digital health skills and competencies with ease. Moreover, CIDHR prioritizes resource accessibility, making its platform suitable for a broad audience, including individuals with disabilities [42,43]. Thus, CIDHR, being based on a multilingual semantic search engine, would enhance accessibility and inclusivity. By looking at all (even mainly French speakers currently) health care professionals, researchers, and students, CIDHR allows them to have access to a broader range of educational resources, fostering a more inclusive learning environment. This inclusivity aligns with the principles of health equity and diversity in medical education [44]. Furthermore, the CIDHR platform's user-friendly interface and straightforward navigation enable users to connect with relevant educational resources quickly and efficiently.

By looking at these advantages and the SaNuRN aim to facilitate digital health educational resources, the current corpus, including 371 elements, will be expanded by continuing the collection and evaluation process, in parallel with cooperation with as many possible faculties and schools of health (ie, 31 medical schools in France). We expect approximately 700 CIDHR resources by mid-2024.

However, some limitations have been identified. First, although CIDHR supports mainly French resources, it would benefit from expanding its multilingual and international support to make it more accessible to a global audience of the digital health education community. Second, it is necessary to expand CIDHR resource collection to incorporate more digital health resources from diverse sources allowing providing them to the educational community and industry insights. Third, although SaNuRN plans to provide personalized learning paths to users, via CIDHR, it is crucial to ensure that these paths are effective and tailored to the individual needs of each user, which requires further research and development [45,46]. Fourth, integrating CIDHR with the learning management systems used by educational institutions would streamline access to digital health resources for students and educators. However, it is crucial to ensure that the integration is smooth and that CIDHR is easy to use within these systems. Finally, developing a feedback and rating system for resources would be helpful in enabling users to identify the most valuable and reliable materials within the platform. However, it is vital to design the system carefully to ensure that it is fair and unbiased. Moreover, it is important to note that CIDHR is under development, and there may be some bugs or glitches in the system. In addition, some features may not be fully implemented.

Future Perspectives

Handling the current limitations of CIDHR opens a wide range of perspectives.

To improve the accessibility and user-friendliness of CIDHR, the SaNuRN team will look at different paths. First, expanding multilingual support to cater to a wider global audience (over the French-speaking community) by indexing (based on MIMO as a multilingual ontology dedicated to digital health) more resources in more languages MIMO on the platform. In addition, CIDHR enrichment will benefit from the SaNuRN team's international partnerships and collaborations to expand CIDHR resource collection and promote knowledge exchange to enrich the user experience [23,47]. Moreover, an additional enhancement is planned to provide personalized learning paths to users based on their profiles, such as their field of study, degree level, CIDHR personal and similar user use, to enable tailored educational experiences and effectiveness. Furthermore, CIDHR will be integrated with the learning management systems used by educational institutions to streamline access to digital health resources for students and educators (eg, Moodle [48]). Finally, CIDHR will benefit from the development of a feedback and rating system for resources not only to help users identify the most valuable and reliable materials within the platform but also to allow the SaNuRN team project to get feedback on the resource collection, indexing, and tagging processes from mass users' practice. All these measures will augment CIDHR utility and enrich the user experience.

Conclusions

CIDHR represents a significant advancement in digital health education, offering a diverse, accessible, and validated resource collection. Although it has strengths in its multilingual approach, controlled vocabularies, and user-friendliness, addressing resource evaluation challenges and enhancing resource information are areas for continuous improvement. The future perspectives for CIDHR include further expansion, collaboration, personalized learning, integration, and user feedback mechanisms, all aimed at enriching the digital health education experience for students and health care professionals.

To the best of our knowledge, no prior published research has described a multilingual semantic search engine to query a digital health educational repository to be used by any health-related field student and lecturer. This is also because of the uniqueness of the development of the Health Terminology/Ontology Portal and MIMO by the members of the SaNuRN team. These projects have no equivalent to date.

The hypothesis that guided this part of the SaNuRN research and that we have validated is that controlled vocabularies and knowledge and skills referential dedicated to medical informatics and digital health, such as MIMO [22,23] and FNRDH [24], to index related educational resources, are effectively increasing the availability and accessibility of these resources to the health care-related community. This approach is possible as MIMO and CIDHR search engine are multilingual.

A European project called the HosmartAI (Hospital Smart development based on AI) project deals with the digital transformation of the European health care sector to make the European health care system more strong, efficient, sustainable, and resilient. CIDHR can play an important role in acquisition of literacy in digital health for professionals [49]. The European

Federation for Medical Informatics is taking part in different projects such as HosmartAI and as a collaboration and cooperation-oriented scientific and academic international organization, it can help disseminate information about CIDHR to promote its use by an increasing number of members of the digital health educational community worldwide.

However, the need to develop and improve digital health competencies for medical learners and broadly for health-related students and professionals is an established objective worldwide [45,50,51]. As a fact, prior studies evaluating digital health competencies among German medical students have shown a significant improvement after a digital health teaching course was introduced in their curriculum, although most students found that digital health is not sufficiently taught in undergraduate medical education, while it may influence everyday work of physicians [52].

Thus, CIDHR will have an important role on the educational grounds to improve digital health literacy of students and lecturers and to increase their engagement with these ubiquitous ways of delivering and receiving health care [46,53].

CIDHR is a fair and findability, accessibility, interoperability, and reusability principles-focused platform looking at making “findable” educational resources by using a one-stop-shop portal approach, “accessible” by integrating these resources available overtime and by anyone (ie, including people with disabilities), “interoperable” by making these resources readable in the most common formats (PDF files and video and audio support on browser-embedded readers, such as YouTube), and finally “reusable” by providing resources freely distributed and under open access licensing [54-56].

Acknowledgments

This work was partially supported by the SaNuRN project (ANR_22-CMAS-0014 3.951.200) granted by the Delegation of Digital Health of the French Ministry of Health and the French National Research Agency.

This work was partially supported by the HosmartAI (Hospital Smart development based on AI) project that received funding from the European Union’s Horizon 2020 research and innovation program under grant #101016834.

Data Availability

The data sets generated during or analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

JG was involved in conceptualization, methodology, software, validation, formal analysis, and investigation and prepared the original draft and reviewed and edited the manuscript. AB contributed to methodology, validation, formal analysis, investigation, and reviewing and editing the draft and acquired funding (HosmartAI [Hospital Smart development based on AI]). F Dufour was involved in validation and reviewed and edited the draft. F Disson performed the software analysis. BD was involved in methodology and software analysis. HC was involved in project administration. RL was involved in conceptualization, methodology, and reviewing and editing the draft. MF reviewed and edited the draft and supervised the study. PS was involved in conceptualization, methodology, formal analysis, and resources; reviewed and edited the draft; supervised the study; and acquired funding (SaNuRN [*Santé Numérique Rouen Nice*]). SJD was involved in conceptualization, methodology, validation, formal analysis, and resources; prepared the original draft and reviewed and edited the manuscript; supervised the study; participated in project administration; and acquired funding (SaNuRN).

Abstract

Background: Clinician educators are experts in procedural skills that students need to learn. Some clinician educators are interested in creating their own procedural videos but are typically not experts in video production, and there is limited information on this topic in the clinical education literature. Therefore, we present a tutorial for clinician educators to develop a procedural video.

Objective: We describe the steps needed to develop a medical procedural video from the perspective of a clinician educator new to creating videos, informed by best practices as evidenced by the literature. We also produce a checklist of elements that ensure a quality video. Finally, we identify the barriers and facilitators to making such a video.

Methods: We used the example of processing a piece of skeletal muscle in a pathology laboratory to make a video. We developed the video by dividing it into 3 phases: preproduction, production, and postproduction. After writing the learning outcomes, we created a storyboard and script, which were validated by subject matter and audiovisual experts. Photos and videos were captured on a digital camera mounted on a monopod. Video editing software was used to sequence the video clips and photos, insert text and audio narration, and generate closed captions. The finished video was uploaded to YouTube (Google) and then inserted into open-source authoring software to enable an interactive quiz.

Results: The final video was 4 minutes and 4 seconds long and took 70 hours to create. The final video included audio narration, closed captioning, bookmarks, and an interactive quiz. We identified that an effective video has six key factors: (1) clear learning outcomes, (2) being engaging, (3) being learner-centric, (4) incorporating principles of multimedia learning, (5) incorporating adult learning theories, and (6) being of high audiovisual quality. To ensure educational quality, we developed a checklist of elements that educators can use to develop a video. One of the barriers to creating procedural videos for a clinician educator who is new to making videos is the significant time commitment to build videography and editing skills. The facilitators for developing an online video include creating a community of practice and repeated skill-building rehearsals using simulations.

Conclusions: We outlined the steps in procedural video production and developed a checklist of quality elements. These steps and the checklist can guide a clinician educator in creating a quality video while recognizing the time, technical, and cognitive requirements.

KEYWORDS

online video; developing video; procedural video; medical education; clinician educator; health education

Introduction

Up to 87% of surgical trainees routinely watch online laparoscopic videos as a part of multimedia learning, meeting a “user demand” [1]. Research has demonstrated that users consider online videos significantly more helpful than other resources due to improved self-confidence and navigability of the resource [2]. Furthermore, videos enhance active learning components for health professionals, foster a community of inquiry, and facilitate social interactions in online courses [3].

From an educator’s perspective, there are pedagogical reasons for using videos, such as creating a student-centered learning environment by enabling students to take an active role in their learning, increasing student engagement, and demonstrating procedures in a standardized and stepwise fashion [4]. While videos can be educational and interactive, these qualities depend on how they are designed and used in a learning context.

There are many options for health educators wanting to create a procedural video, ranging from outsourcing the entire process to doing it all themselves. Educators can engage professionals from the media production department in their institutions or private companies. They can also collaborate with students, residents, and colleagues with experience and interest in creating videos. The choice depends on the time, skills, funding, and, most importantly, the level of involvement the educator desires.

While the reasons for using an online educational video are numerous and well-researched, there is limited literature on developing a high-quality medical educational online video for teaching procedural skills. Several studies have shown that 10%-40% of medical videos on YouTube lack essential safety information [5,6]. Several studies have assessed the quality and content of medical procedural videos on YouTube and found them to be of variable educational value [7,8]. Health educators aiming to create high-quality videos will benefit from a clear understanding of the video development process and the required production skills. Therefore, we provide stepwise guidance and a quality checklist and identify barriers and facilitators to make a quality procedural video.

In this tutorial, we present the adaption of a previously described structure of dividing the development of a video into (1) preproduction, (2) production, and (3) postproduction phases to create a medical procedural educational online video. These phases are further divided into background factors and practical applications.

Methods

Preproduction Phase

Background Factors in the Preproduction Phase

A scoping review before starting the video recording process and previous attendance at courses on clinical education theories informed the steps of the process. In the preproduction phase, certain background factors need to be considered which are listed below in detail.

Needs Analysis

A video’s purpose, format, and content can be determined by performing a needs assessment before incorporating the video into a lesson plan [9].

Learning Outcomes

The learning outcomes should be clearly defined and aligned with an assessment taxonomy for clinical skills, such as Miller’s pyramid [10], as a video relates to procedural skills acquisition. Miller’s pyramid is a clinical assessment framework that defines a learner’s ability into the knows, knows how, shows how, and does categories that test progress from basic knowledge to practical application [10].

Learner-Centered

Allowing for different learning preferences will ensure maximal student engagement and active learning and contribute to a learner-centered environment [4].

Mayer’s Principles of Multimedia Learning

Different parts of the cerebral cortex process audio and visual content, and only a certain amount of information is held in working memory at any given time (cognitive load). Applying Mayer’s principles of multimedia while developing e-learning resources can reduce cognitive overload [11] as these systems can become overwhelmed [12]. These include 12 principles, such as signaling (visual cues are added to multimedia to signal the main concepts), coherence (unnecessary content is removed), and segmentation (an online video is broken into small units or pieces to enable the learner to process this information before moving to the next stage) [11,12]. While narration (using the educator’s voice) is essential [12], adding other audio media, such as music or background noise, adds to the cognitive load [3]. Multimedia principles should be considered when weighing up the optimal combination of text, images, and narration to communicate information.

Guidelines for the Design of Instructional Videos

In 2022, Meij and Hopfner suggested guidelines for the design of instructional videos for software design, which can also provide guidance for medical instructional videos [13]. These include (1) keeping instructional videos short, (2) supporting users in finding a suitable video by including the video purpose in the title, (3) previewing the task, (4) using a screencast with narration, (5) supporting an action-oriented approach, (6) consider key components of a well-designed procedure, (7) make task demonstration easy to follow and mimic, (8) support users in handling the transitory nature of the video, (9) review the task, (10) strengthen demonstration with practice, and (11) occasionally include music.

In addition to these, a clinical educator should be aware that the current video size guidelines for full high-definition videos are 1920×1080 pixels and 149 MB per minute [14].

Storyboard, Script, and Shot List

Preparing a storyboard, script, and shot list outlining the exact steps and scenes of the video optimizes the chance of smooth recording on the day [15,16]. If the content is unfamiliar then this should be peer-reviewed by a subject matter expert (who

confirms the subject content is accurate and in line with the learning outcomes). For advice on audiovisual matters, checking the storyboard and shot list with an audiovisual expert would be useful [9,15]. The audiovisual expert is a person trained in media production who has expertise in producing videos. They may be from the audiovisual department of the organization or an outside company. Following this process ensures optimal video quality [15]. Validating the video script may address 6

questions related to the video's objective, content, relevance, environment, verbal language, and inclusion of topics [15]. A knowledge of common video recording language and techniques will help inform the writing of the storyboard and shot list [12]. These include (1) framing a shot, (2) camera placement, (3) camera angle, (4) zooming in or out, (5) panning, and (6) cutting with purpose. These are explained further in Table 1.

Table 1. Common video recording language and techniques.

Technical word	Definition
Framing a shot	A shot is what is presented on screen. So, aim for the smallest frame necessary for the shot to balance detail and context.
Camera placement	The placement of the camera is essential. Examples include the 180-degree rule and the 30-degree rule. The 180-degree rule states that when recording 2 objects, the camera placement should not exceed 180 degrees from each other to provide consistency. The 30-degree rule states that the camera angles should be at least 30 degrees apart when changing angles.
Camera angle	Camera angles refer to the placement of the camera (ie, what the viewer sees). Examples include eye level, low angle, high angle, and bird's eye, each with a different purpose. Tilting up or down is changing camera angles while the video is still rolling.
Zooming	It adjusts the focal length of the lens (in or out).
Panning	It is moving the camera from left to right.
Cutting with purpose	Is moving between scenes or camera angles on purpose.

Video Duration

The duration of an online video is another factor to be considered. There is no consensus on the optimal length of a procedural video, as this depends on several contextual factors. Videos of shorter duration have been shown to have better viewer engagement, and some authors state that videos should be limited to 6 minutes or less [4,17]. Others suggest they should be 10-15 minutes long [3]. Ideally, the length should range from 6 to 15 minutes, and videos longer than this should be subdivided into shorter parts or chapters labeled with time-stamped content [3,4].

Title

A video title should make the learner aware of the video's goal and the session's intended learning outcomes [13]. A good title increases the ease with which an educator or learner can search for the online video [13].

Educator Presence and Narration

Having the educator's face or head and shoulders in the video and narrating with the educator's voice [18] is also suggested to increase the learner's connectedness with the content and educator [3]. This is especially true in asynchronous and remote learning situations where this "human touch" improves a learner's sense of teacher presence. This improved sense of connectivity, either in a planned lesson or during self-directed learning, can lead to a more learner-centered environment, promote active learning, and create a sense of community [18]. Audio narration in a conversational and enthusiastic tone (Mayer's principle of personalization) and at a reasonably fast pace (185-254 words per minute) is preferable [17].

Table of Contents and Time Stamping

A table of contents with links to specific time points (time stamping, chapters, or bookmarks) within a video also increases

user navigation and control. These features save time as well as improve the ease of access and functional interactivity [17]. In instructional videos, interactive features such as pauses and quizzes can test the learners' knowledge, enable reflection, and improve engagement [17].

Health Information Governance

Health information governance issues are essential in the preproduction phase and can be divided into ethical or professional considerations. Ethical approval might be required from specific jurisdictions and institutional groups before recording. Any patient images (still or video form) must be collected after their consent (in some jurisdictions), used respectfully, and stored to ensure patient privacy and confidentiality. Professional considerations relate to copyright, data protection, and indigenous populations' sovereignty issues. As using content created by someone else may have copyright issues, specific permission may be required, especially if the video content is modified. Live streaming procedures in surgical broadcasting or coaching require knowledge of confidentiality and health information laws [19]. The final video and raw data must be stored with data protection considerations. There may be Indigenous Populations' data sovereignty issues to consider, such as Māori data sovereignty in New Zealand (Te Mana Raraunga Maori Data Sovereignty Network), the US Indigenous Data Sovereignty Network, and the International Indigenous Data Sovereignty Interest Group. Specific bodies within or outside a university or health care organization can provide guidelines on appropriate processes to follow for data sharing for teaching.

Time, Cost, Feasibility, and Permissions

Finally, before recording can commence, the project's time, costs, and feasibility must be considered. Permission might be required before recording at sites such as laboratories, hospitals, and university campuses. The cost and feasibility include a list

of the necessary equipment for recording, the availability and the ability to use the equipment, and the cost of the entire project with a budget. The educator must consider the feasibility of recording time-dependent or rare procedures.

Making Our Video: Practical Considerations in the Preproduction Phase

If doing the recording yourself, this stage should also involve attending courses on videography and editing skills and audiovisual skill building by deliberate practice with feedback, using simulations and rehearsals. Our steps for making an online video are shown in [Figure 1](#).

We identified the target audience for this educational video (postgraduate pathology trainees and histology scientists), conducted a needs assessment, and listed the learning objectives from an educator's perspective. We then converted these to learning outcomes from the learner's perspective. We used the recommendations by Fleming et al [16] to guide our video's script and storyboard, which also involved deciding the sequence of what, how, and where the recording would occur. The latter

was structured in a table with 4-column labeled steps of the procedure, image or scene, audio (script), and photos ([Multimedia Appendix 1](#)).

A subject matter expert (AC), an anatomical pathologist with expertise in skeletal muscle pathology, assessed and validated the educational content of the storyboard and script. The technical content was evaluated by a media production contact from the Media Productions Department at the University of Auckland, who provided input on the technical aspects of the storyboard ([Multimedia Appendix 2](#)). We amended the storyboard and script to incorporate our experts' suggestions. The final script and storyboard used for recording are presented in [Multimedia Appendix 3](#). We created a checklist of the technical audiovisual equipment required on the day, listed under the production phase. We also needed to co-ordinate the participants' schedules involved in the recording. Throughout this process, KS kept a journal to document the time each phase took. The repetitive cycle of feedback from the team and personal reflection led to the documentation of factors that had progressed well or not during each stage.

Figure 1. Steps in developing an online instructional video.

Production Phase

Background Factors in the Production Phase

The background factors to consider in the production phase include ensuring all the equipment on the list is available, the videographer is familiar with using them, the audiovisual technical aspects of the recording process, and the planned recording schedule.

Ensuring that all equipment on the list is available and that the videographer is familiar with using them. The list consists of (1) adequate lighting, (2) a digital camera with a microphone, (3) a digital camera mount such as a monopod or tripod, (4) fully charged batteries, (5) a secure digital (SD) card with speed and capacity to record video, and (6) a method to transfer the video files from the camera to the computer, such as a Wi-Fi enabled connection, an SD to USB card reader, or a camera to computer cable.

An option is to record the images and videos on hand-held devices, such as personal mobile phones. This can be a

cost-effective and convenient option, especially since current devices have sufficient camera resolution to produce high-quality images and increased memory storage options. The user is also familiar with using this device. However, there are patient confidentiality and data protection issues to consider before choosing to use a personal mobile phone. The use of personal mobile devices and personal cloud storage can potentially lead to breaches of data protection and patient privacy [20,21]. The shared video content may be widely accessible, and sometimes not in the way the authors of the video intended, such as by family members on a shared cloud storage. Currently, there is no health information governance legislation that applies worldwide. However, institutions and countries have specific guidance or legislation that must be adhered to (such as HIPAA [Health Insurance Portability Accountability Act] in the United States or the GDPR [General Data Protection Regulation] from the European Union).

Also, the audiovisual technical aspects of the recording process and the planned recording schedule must be considered. Choosing the appropriate demonstrator(s) for the video and

rehearsing the recording process will streamline recording [12]. Tasks and responsibilities can be clarified before the day of recording. Recording more takes and angles than required may create a more time-effective and smoother video [12]. Ideally, the video should have different shots with judicious camera movements.

Making Our Video: Practical Considerations in the Production Phase

Setting

The video was recorded in a histopathology laboratory that routinely processes human skeletal muscle samples, as the video content was on macroscopically handling a fresh skeletal muscle biopsy. The videographer (KS) recorded a pathologist (AC) handling and preparing a fresh skeletal muscle biopsy in the laboratory. FM, FG-S, and AC provided feedback on the video. FM and FG-S are not experts in this content, and their feedback was from a naïve learner perspective informed by the literature. AC, a subject matter expert, also reviewed the initial video and provided feedback on content and editing.

Data Collection

The video was recorded immediately upon arrival of the specimen in the laboratory. KS recorded still images and short video clips using a digital camera mounted on a monopod. The process of recording the video clips and still photos took 4 hours. The equipment checklist, script, and storyboard created in the preproduction phase guided the recording. KS ensured all aspects of recording a particular step were completed before moving to the next step. Some steps needed rerecording as the initial images or shots were technically suboptimal. The suboptimal time-sensitive shots (as a muscle biopsy cannot be delayed in the fixation process upon receipt into the laboratory) were rerecorded immediately. In contrast, images of equipment or steps that were not time-sensitive were rerecorded at the end. FM and FG-S reviewed the initial video and provided feedback. AC provided feedback on the modified version of the video. KS iteratively modified the video in response to this feedback.

Postproduction Phase

Background Factors in the Postproduction Phase

The background factors to consider in the postproduction phase include video editing [9,15,16], video hosting platforms, video quality, and health information governance issues. Various video editing software (such as Microsoft Video Editor, Camtasia [TechSmith], Adobe Premier Pro, iMovie [Apple Inc], Wondershare Filmora [Wondershare Technology] and many others) range in price, complexity, and ease of use. Technical considerations include internet speeds and the video file type (.mp4 file type is preferred). The video editing should conform to the principles of multimedia learning [11] and add audio narration and optional subtitles (or close captioning) to improve accessibility and inclusivity. Educators can also add active learning to a video by embedding the video in software, such as H5P (H5P group), to create interactive videos with quizzes.

The video should be published on an online platform that provides easy access, for example, YouTube or embedded in the learner's learning management system. Many online

platforms include videos for both patient and medical personnel use, and the aim and content of these videos will differ as they target different audiences [22]. YouTube is open access and popular with users; however, in a study, only 12% of medical videos were from university channels and professional organizations [22]. Alternatively, professional organizations like The Royal College of Pathologists of Australasia can host videos on their website such as the open-access macroscopic cut-up manual videos. Novice learners are more likely to access online videos on YouTube.

On the other hand, faculty members are more likely to access videos on professional organization web pages or YouTube channels specific to the organization [23]. However, YouTube hosts videos of variable quality, and novice users may not be able to identify poor-quality ones [23]. This clearly could have safety implications, depending on the procedure being learned.

Finally, the video author must ensure that health information governance issues described in the preproduction phase are all fulfilled before the video is published online.

Making Our Video: Practical Considerations in the Postproduction Phase: Analysis

The analysis phase of making a video involves postproduction editing, refinement, and publishing on a platform. The recorded images were transferred from the SD card into a computer with sufficient hard drive capacity. Various software, each chosen for a different purpose, were used to edit the sequence of scenes into an online video. KS used Wondershare Filmora 11 software to edit the video clips due to familiarity with the software. The final .mp4 file was transferred to Panopto, so that close captions in English could be enabled. The authoring software H5P was used to add a quiz to the video (drag and drop boxes) to provide formative feedback to the students and make the video interactive. H5P use also allowed bookmarking within the video to improve user navigation. The factors that made an effective online video from an educational and technical point of view, derived from the scoping review and broader literature, were incorporated into the video during the editing stage. These factors are elaborated in the Discussion section.

Ethical Considerations

We were granted ethical approval by the Auckland Health Research Ethics Committee (AHREC) on May 6, 2022 (ref AH23813). We obtained appropriate written patient consent before the recording. The patient data is anonymized, and no compensation was provided to the patient. The consent form and the online video will be stored according to the institutional ethics requirements.

Results

General Points About our Video

Our final video is 4 minutes and 4 seconds long. Its creation took 70 hours (20 hours of preproduction, 4 hours of recording, and 46 hours of editing and revising), which KS recorded manually in a journal. A link to the video is available at the following reference [24].

We identified that a clinician educator creating an online educational video needs to align the video with clear learning outcomes and provide an engaging, learner-centric video that promotes active learning. Other aspects involve incorporating the principles of multimedia learning and adult learning theories and producing a video of high audiovisual technical quality. This is shown in diagrammatic form in Figure 2.

We also created a checklist of elements that ensures a high-educational quality video is produced based on previous

literature on this topic and the process of developing a new video. These include a needs assessment, a validated storyboard and script, clear learning outcomes, a title that reflects video content, a video duration of less than 15 minutes, the face of the educator, narration by the educator, close captioning, and factors to enable interactivity with the video. The specific characteristics of our video that align with these elements are summarized in Table 2.

Figure 2. Diagrammatic depiction of components of an effective online procedural video.

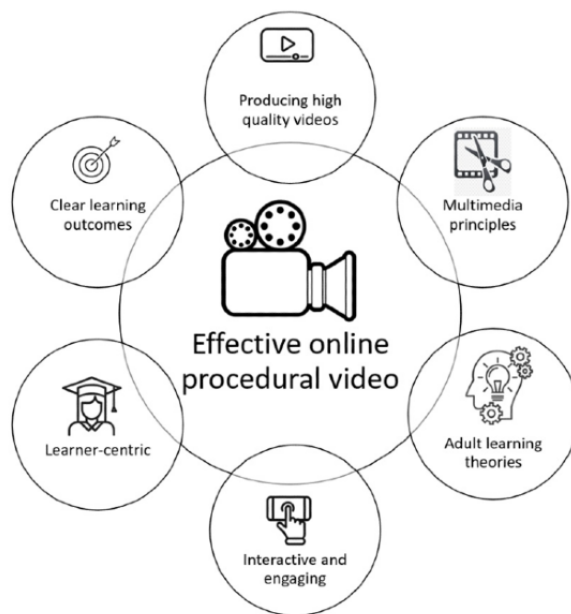

Table 2. Checklist of suggested quality elements in an online video.

Quality elements	Present in our video	Further details
Needs assessment	Not applicable	Needs assessment with learners will follow
Script and storyboard validated by an educational expert	Yes	— ^a
Script and storyboard validated by an audiovisual expert	Yes	—
Easy for a learner to access video	Yes	—
The title reflects the video content	Yes	—
Learning outcomes	Yes	—
Video duration <15 minutes	Yes	—
Time-stamping or bookmarks	Yes	—
Image of the instructor	Yes	—
Audio narration	Yes	—
Principals of multimedia followed:	Yes	—
Signaling	—	Highlighting with arrows
Coherence	—	Removal of extraneous material
Personalization	—	The instructor’s voice was used for narration.
Segmentation	—	Video is broken into small units or segments.
Functional interactivity	Yes	Interactive quiz inserted using H5P software
Close caption option	Yes	—

^aNot applicable.

Barriers and Facilitators to Creating Our Online Video

We documented the barriers and facilitators to creating an instructional video from the perspective of a clinician educator who was a novice at making videos of any type. One of the barriers to developing this video was the significant time required for creation. According to the literature, it takes about an hour to make 1 minute of online video content [25]. Still, with 70 hours of production time for a 4-minute video, the novice video producer (KS) vastly exceeded this. This time estimate is for experienced video creators or professionals. Due to inexperience, all phases of recording a video took a notable amount of time. The preproduction phase involved reading educational resources about theories of adult learning in the clinical setting and principles of multimedia and reading about the technical aspects of audiovisual recording [4,11-13,16,17]. The 46 hours of postproduction time included accessing and learning how to use the editing and interactive software, as well as revising the video based on iterative feedback.

The recording took 4 hours. Performing the videography also proved difficult, especially without previous rehearsal. For example, selecting camera settings, the way to frame a shot, and the lighting and camera placement to get an optimal picture had been learned in theory but proved challenging in practice. This was mainly due to KS having unfamiliarity with the equipment and a lack of technical videography skills. Several retakes were needed. It was also challenging to record shots to avoid confidential patient details. As this was not a simulated procedure, shots could not be repeated, and because the tissue was fresh, the procedure was time-critical.

A facilitator of video creation is the use of deliberate practice with feedback using simulation and rehearsals. The planned rehearsal using a simulated specimen could not be done, therefore technical skills on the day were minimal [26]. Rehearsals would have also identified the extra equipment and the storyboard or shot board adjustments. Therefore, the recording session took longer than scheduled due to necessary repetitions. The videographer (KS) could have completed online video editing courses, visited some video recording sessions with the university's audiovisual department before recording, and practiced video recording and editing using nonmedical subjects, as these practical skills are more important than reading theory around this topic. These steps would have reduced the time spent recording and editing the video as more suitable images would have been captured on the day of recording.

Another facilitator was creating a community of practice (CoP) through discussions with colleagues with various skills and expertise. These discussions included specific technical equipment, audiovisual techniques such as camera angles, and the software to edit the raw recording. This dynamic group helped troubleshoot solutions to practical problems, which was especially important as KS chose software that was not industry standard for editing.

Other facilitators are organized and flexible, resulting in less stress during the recording process. Having a storyboard or script and an equipment list is essential. We found that it was not easy to stick to the storyboard, but the task would have been chaotic without it. Throughout this process, being cognitively

and psychologically flexible to change makes the job easier and less frustrating.

Discussion

Principal Findings

While online educational videos are widely used in medical education, there is a lack of literature on creating a high-quality video. Our tutorial provides a step-by-step method for developing a quality medical video for clinician educators new to video creation.

Numerous studies have shown that the quality of videos on online platforms is heterogeneous [6-8,27]. Therefore, we propose a checklist to ensure that the educational factors in a video are optimized (Table 2). This checklist is a synthesis of the literature on this topic, so using it may ensure a high-quality video that is interactive and creates an engaging and learner-centric environment.

The time required to gain proficiency in making a procedural online video efficiently is a potential barrier. An educator new to making videos requires considerable time to produce new medical video content [25]. The professional body that makes online videos for the University of California San Francisco medical school estimates that 9-30 hours of an educator's time is needed when developing such content, in addition to professional videography personnel time [28]. This time range includes both the time required to learn to create video content and use the technology. Often, for the educator, this is a time in addition to usual work hours. However, this can be a rewarding process, and the time requirements may be lessened by preparing and validating a script and storyboard, repeated rehearsals, especially using simulations to improve skills, creating a CoP, and intentionally developing and transferring video production skills gained in nonmedical settings. The time requirements will also lessen over time as a clinician educator becomes more experienced in video production. As an alternative to the clinician educator learning video production skills, they can engage and work with others with audiovisual expertise to do the production, reducing the time requirements.

The amount of knowledge and skills required to create a quality online video means that a novice may find this task daunting. However, KS found this process was aided by developing a CoP—a supportive and educational system known to be valued by teaching staff [29]. A CoP allows people to connect and learn about a particular topic, such as creating online videos. Our CoP group has variable amounts of experience in developing online medical videos of various types, creating a technically and emotionally supportive environment. Such groups work on the background theory of constructivism as they allow for social learning and mentorship [30]. The iterative process of seeking and providing feedback also improved video quality.

While several quality assessment tools have been developed in the last 4 years [31-34], an easy-to-use tool is desirable to assess the quality of a procedural educational video. Berrocal et al [31] have a one-page rubric for peer-reviewing microlectures. The instructional video quality checklist is another quality assessment tool, that uses a 26-item checklist assessing aspects

of educational design, source reliability, multimedia principle adherence, and accessibility [32]. The LAP-VEGaS (LAParoscopic surgery Video Educational GuidelineS) video assessment tool examines 9 elements of a video [33], but it only applies to laparoscopic videos.

The authors of the LAP-VEGaS guidelines and LAP-VEGaS video assessment tool suggest using these during the preproduction and production phases to ensure a video has high educational value [33,34]. Several studies have subsequently used either the LAP-VEGaS guidelines or assessment tools to assess the quality of online medical videos. When de'Angelis et al [7] used the guidelines to review the quality of videos on appendectomy available on YouTube, 36% of the videos showed poor image quality, audio and written commentary were rarely present, and the overall conformity to the LAP-VEGaS guidelines was low. A similar result was found when videos on robotic-assisted laparoscopic pyeloplasty available on YouTube were assessed using the LAP-VEGaS guidelines [35]. This highlights the use of quality assessment tools or checklists for medical procedural videos.

Using online videos to teach procedural skills is no substitute for hands-on teaching. Karadas and O'Brien have demonstrated that repeatedly watching a video without physical practice can lead to an illusion of skill acquisition, where the learner assumes to have a greater skill level than they have [36]. Instead, online

videos ought to be a part of the learning cycle for practical skills, perhaps based on an experiential learning cycle, so that the online video is followed by repeated practice exercises, such as simulation, adequate supervision, and a feedback cycle [37].

Strengths and Limitations

A strength of this tutorial is the use of theoretical considerations in the preproduction, production, and postproduction phases of making a high-quality video to demonstrate a procedural skill. Furthermore, we illustrate this with our own experience of making such a video from the perspective of a clinician-educator new to making videos, therefore the relevance and usefulness of this tutorial to an experienced video maker will be limited. Furthermore, our checklist of elements for a procedural video that aligns with educational and audiovisual quality factors needs further validation before implementing its use.

Conclusion

The process of creating procedural online videos is rewarding; however, it takes significant time and cognitive requirements, especially for clinician educators new to the process. Barriers include the time required for deliberate practice to gain competence in video production. Facilitators include technical skill building by deliberate practice with feedback, using simulations and rehearsals, and intentionally developing and transferring video production skills gained in nonmedical settings. For some, creating a CoP is supportive.

Abstract

Background: There is a shortage of competent health professionals in managing malnutrition. Online education may be a practical and flexible approach to address this gap.

Objective: This study aimed to identify essential competencies and assess the effectiveness of an online course on pediatric malnutrition in improving the knowledge of pediatricians and health professionals.

Methods: A focus group (n=5) and Delphi technique (n=21 health professionals) were used to identify 68 essential competencies. An online course consisting of 4 educational modules in Microsoft PowerPoint (Microsoft Corp) slide form with visual aids (photos and videos) was designed and published on the Syrian Virtual University platform website using an asynchronous e-learning system. The course covered definition, classification, epidemiology, anthropometrics, treatment, and consequences. Participants (n=10) completed a pretest of 40 multiple-choice questions, accessed the course, completed a posttest after a specified period, and filled out a questionnaire to measure their attitude and assess their satisfaction.

Results: A total of 68 essential competencies were identified, categorized into 3 domains: knowledge (24 competencies), skills (29 competencies), and attitudes (15 competencies). These competencies were further classified based on their focus area: etiology (10 competencies), assessment and diagnosis (21 competencies), and management (37 competencies). Further, 10 volunteers, consisting of 5 pediatricians and 5 health professionals, participated in this study over a 2-week period. A statistically significant increase in knowledge was observed among participants following completion of the online course (pretest mean 24.2, SD 6.1, and posttest mean 35.2, SD 3.3; $P < .001$). Pediatricians demonstrated higher pre- and posttest scores compared to other health care professionals (all P values were $< .05$). Prior malnutrition training within the past year positively impacted pretest scores ($P = .03$). Participants highly rated the course (mean satisfaction score > 3.0 on a 5-point Likert scale), with 60% (6/10) favoring a blended learning approach.

Conclusions: In total, 68 essential competencies are required for pediatricians to manage children who are malnourished. The online course effectively improved knowledge acquisition among health care professionals, with high participant satisfaction and approval of the e-learning environment.

effectiveness; online course; pediatric; malnutrition; essential competencies; e-learning; health professional; Syria; pilot study; acquisition knowledge

Introduction

Severe acute malnutrition (SAM) increases the risk of mortality among children aged younger than 5 years, affecting an estimated 17 million children worldwide, particularly in low- and middle-income countries [1,2]. The Syrian conflict has exacerbated this crisis, with half a million children enduring

chronic malnutrition and 137,000 aged younger than 5 years experiencing acute malnutrition, increasing their susceptibility to preventable diseases [3]. Scaling up the management of SAM is crucial for reducing child mortality [4], but training and resourcing health care professionals to effectively identify and treat children who are malnourished remain major challenges, especially in conflict zones such as Syria [5,6].

While a wealth of knowledge exists about pediatric malnutrition, a crucial gap remains. This gap lies in the delivery of practical, accessible, and contextually relevant training for health care professionals in conflict zones [7]. This study addresses this gap by focusing on the development and evaluation of a self-directed online course for Syrian pediatricians and other health care professionals in the management of pediatric malnutrition.

e-Learning offers a promising solution for addressing this training gap, providing a flexible, scalable, and cost-effective method to deliver high-quality instruction [8]. By using e-learning, we can empower health care professionals with the necessary knowledge and skills to combat pediatric malnutrition; bridge access barriers, particularly in conflict zones; and tailor training to meet specific needs [7,9].

However, existing e-learning platforms may not adequately address the unique challenges and context of conflict zones such as Syria, where resources are limited [10]. Local training initiatives are crucial to ensure contextual relevance and maximize impact. By identifying specific knowledge gaps and skill deficits, developing culturally sensitive materials, and integrating with local resources, tailored e-learning solutions can foster a sense of ownership and engagement, leading to more effective knowledge transfer and application [11].

This study investigates the efficacy of e-learning as a training solution for pediatric malnutrition management in Syria, a context marked by conflict and limited access to traditional training opportunities. Specifically, this study aims to identify essential competencies needed by pediatricians and health care professionals for effective management of pediatric malnutrition, evaluate the efficacy of an online course on pediatric malnutrition in improving their knowledge and skills, and explore the potential of e-learning as a scalable solution for training in challenging contexts. By addressing this crucial training gap, the research seeks to contribute to improved patient care; enhanced staff retention; and, ultimately, a reduction in pediatric malnutrition in Syria.

Methods

Ethical Considerations

This study was approved by the Ethical Committee at the Syrian Virtual University (SVU; #2154/0, November 25, 2021). An electronic consent form was obtained from all participants, ensuring their understanding that their data would be kept confidential and used solely for the purposes of this research study.

Competency Development

Overview

The Delphi technique was used to develop a consensus regarding essential competencies for managing children who are malnourished, as it is a helpful strategy for identifying medical education competencies [12]. Further, 2 qualitative methods were applied sequentially—focus groups and the Delphi technique.

Focus Groups

The online focus group consisted of 5 participants: 3 postgraduate students working in an inpatient stabilization center in Lattakia and 2 pediatricians serving as pediatric malnutrition therapists on projects funded by UNICEF (United Nations Children's Fund). The participants were recruited via telephone and social media to participate in the virtual discussion.

The research approach was fully explained to the focus group participants, who were asked to provide a brief report on the competencies needed by pediatricians to manage pediatric malnutrition. Consequently, a preliminary list of essential competencies was formulated during a 3-hour meeting.

Delphi Rounds

All pediatricians and health professionals enrolled in the Medical Education Master Program at the SVU were invited to participate in this study (n=21). Ultimately, 18 of them took part. Participants were instructed, via the Virtual University Management System, to review relevant protocols and guidelines on pediatric malnutrition published by recognized health organizations, such as the World Health Organization (WHO) and UNICEF [13,14]. A methodology for writing competencies and vocabulary for job descriptions [15] was established to prepare the initial competency list.

Participants were randomly assigned to 1 of 3 groups, each focused on knowledge, skills, or attitudes, for the identification of essential competencies.

Through 3 virtual meetings conducted over a month, all groups agreed on a classification of competencies based on etiology, assessment, diagnosis, and managing pediatric malnutrition. The team leader reviewed all responses, removed repetitive items, reformulated inappropriate ones, and discussed transferring fields between specialties. Participants then independently reviewed the competencies over a 1-week period, and the revised list was distributed to all participants for rating on a 5-point Likert scale within a week.

Competencies endorsed by at least 80% (15/18, 83%) of participants were subsequently combined and merged. The weighted response for each competency was obtained by calculating the responses at each level and the mean score for each competency, ranging from 0.0 to 3.0 [16]. All competencies were ranked, and the relative importance of each competency was identified.

Training Development

Course Design

Drawing upon a variety of sources and expertise, an online pediatric malnutrition course was developed, informed by the competencies identified in the first phase of this study. The course was designed to meet the specific needs and context of Syrian health professionals, taking into account the unique challenges and priorities of the Syrian health care system.

The development of the online course and its accompanying multiple-choice questions involved a collaborative effort among pediatricians possessing years of experience in managing both

inpatients and outpatients with acute malnutrition, as well as in training health professionals.

Available evidence-based guidelines and protocols from reputable organizations, such as the WHO and UNICEF, were carefully reviewed to ensure the content validity and accuracy of the course materials. Visual aids, such as images and videos, were also incorporated to enhance engagement and learning.

Course Content

The e-learning content was categorized into 4 modules covering all identified competencies. Module 1 provided information on definition, classification, prevalence, differentiation between types, and associated pathophysiological changes in pediatric malnutrition. Module 2 focused on the diagnosis and anthropometric measurement techniques for accurate assessment. Module 3 presented treatment modalities according to WHO guidelines and the 10-steps approach. Module 4 addressed the prognosis and medical complications associated with pediatric malnutrition. Each module contained interlinked subunits for easy offline access, designed to be completed in less than 3 hours.

The principal investigator, AS, developed online content, incorporating visual aids such as images and videos, and created 40 multiple-choice pre- and posttests. The course was delivered in Arabic.

Participants

Recruitment

This study's participants comprised 10 individuals: 5 pediatricians and 5 other health care professionals, including medical doctors (general practitioners and specialists), dentists, and pharmacists. These participants, 8 females and 2 males, were recruited via social media to evaluate the online course.

Recruitment for this study was announced via the researcher's email and on social networking sites within official groups for doctors and resident students. Participation was optional, and the purpose of the research was clearly communicated as solely for scientific purposes. Participant grades would not be used outside the research and would remain confidential. Participants provided explicit consent via email, with a "yes" or "no" response.

Training Delivery

The SVU's learning management system was used for the online course presentation, with access restricted to participants via individual usernames and passwords. Data security was maintained through the platform's security protocols.

Prior to accessing the course, participants were surveyed regarding their prior attendance in malnutrition-related training courses. A designated date for the pretest was communicated via email to each participant. Upon completion of the pretest, participants were granted access to the online course, with a 1-month time frame allotted for completion. Following course

completion, a second email was sent to each participant, scheduling a specific date for the online, synchronous posttest.

Evaluation

Assessment Instruments

Both the pretest and posttest, administered electronically via a Google Forms link within the SVU platform, consisted of 40 identical multiple-choice questions, ensuring a consistent measure of knowledge acquisition. The assessment instrument was distributed across the 4 modules, with a weighting reflecting the number of subunits within each module: modules 1 and 2, covering foundational knowledge of pediatric malnutrition, each contained 10 questions; module 3, focusing on assessment and diagnosis, included 5 questions; and module 4, on management, contained 15 questions.

Participant Satisfaction

Participant satisfaction was assessed using a 30-item questionnaire encompassing 3 domains: content presentation style, knowledge gained, and the e-learning environment (10 items per domain). Participants rated each item using a 5-point Likert scale ranging from 0 (strongly disagree) to 4 (strongly agree). Cronbach α , a measure of internal consistency [17], was calculated. The mean and SD were then used to analyze the distribution of responses for each item, providing insights into participant satisfaction levels across the different domains.

The qualitative interpretation of Likert scale measurements is shown in Table S1 in [Multimedia Appendix 1](#).

Data Analysis

To evaluate knowledge gains, paired *t* tests (2-tailed) were used to compare pre- and posttest scores. Subgroup analyses were conducted to examine potential differences in knowledge acquisition based on participant characteristics, including gender, specialty (pediatricians or other health professionals), and prior training experience. Comparisons between groups (eg, male vs female) were facilitated using the Mann-Whitney test, while comparisons within groups (eg, pretest vs posttest scores for pediatricians) were performed using the Wilcoxon signed rank test [18,19].

These nonparametric tests were chosen due to the relatively small sample size ($n=10$) [20], followed by parametric tests, and the results were compared. Statistical significance was set at $P<.05$.

IBM SPSS Statistics for Windows (version 25.0; IBM Corp) was used to perform all the analyses.

Results

The Delphi technique yielded an 85% (18/21) response rate. At least 80% (15/18, 83%) of participants suggested 68 essential competencies for managing children who are malnourished, organized into knowledge, skills, and attitude. As outlined in [Table 1](#), competencies also fall under 3 subheadings: etiology, assessment or diagnosis, and management.

Table . Essential competencies for managing children who are malnourished.

Domain	Competency
Knowledge	
Etiology	<ol style="list-style-type: none"> 1. Recognize malnutrition terminology. 2. Recognize the epidemiology of malnutrition in children. 3. Differentiate between types of malnutrition. 4. Identify the causes and prevalence of pediatric malnutrition worldwide.
Assessment and diagnosis	<ol style="list-style-type: none"> 1. Identify the clinical signs and symptoms of acute malnutrition in children. 2. Recognize different methods for assessing children who are malnourished. 3. Describe admission and discharge criteria for managing SAM^a with medical complications under inpatient care. 4. Identify high-risk groups for SAM in children. 5. Discuss strategies to detect cases of pediatric malnutrition. 6. Recognize complications and prognosis of pediatric malnutrition. 7. Identify target age groups to screen for malnutrition. 8. Explain methods for diagnosing malnutrition in children.
Management	<ol style="list-style-type: none"> 1. Describe outpatient care for managing SAM without medical complications. 2. Describe admission criteria for outpatient care (infants under 6 mo and children 6 - 59 mo) 3. Describe the outpatient care and follow-up process for children 6 - 59 mo. 4. Explain medical treatment for SAM without complications under outpatient care. 5. Explain nutrition rehabilitation for SAM without complications under outpatient care for children 6 - 59 mo. 6. Describe the key messages for mothers or caregivers of children 6 - 59 mo in outpatient care. 7. Explain managing at-risk mothers and infants aged younger than 6 mo without complications in outpatient care. 8. Explain discharge criteria and procedures for at-risk mothers, infants under 6 mo, and children 6 - 59 mo. 9. Outline management of SAM with medical complications under inpatient care. 10. Review medical and dietary treatment in inpatient care. 11. Describe programs to manage MAM^b. 12. Describe the admission and discharge process for MAM management.
Skills	

Domain	Competency
Etiology	<ol style="list-style-type: none"> 1. Classify nutritional vulnerability in at-risk mothers and infants aged younger than 6 mo. 2. Educate parents of children who are malnourished to understand the risks of pediatric malnutrition. 3. Develop a plan to monitor cases of pediatric malnutrition. 4. Monitor and respond to barriers to access.
Assessment and diagnosis	<ol style="list-style-type: none"> 1. Take accurate clinical history. 2. Measure the weight, length, and mid-upper arm circumference of children. 3. Calculate the child's age. 4. Classify acute malnutrition. 5. Perform appropriate medical examination. 6. Provide correct diagnosis in each pediatric malnutrition case. 7. Assess and admit a child to outpatient care. 8. Assess and manage at-risk mothers and infants under 6 mo without medical complications in outpatient setting. 9. Conduct field visits for children who are malnourished in supplementary feeding programs.
Management	<ol style="list-style-type: none"> 1. Provide outpatient care for SAM without medical complications. 2. Identify when further action is required, such as referral to inpatient care and follow-up home visits. 3. Treat a child during outpatient care follow-up. 4. Practice referral between inpatient care and outpatient care. 5. Make referrals from supplementary feeding to outpatient or inpatient care. 6. Complete patient records and interpret findings. 7. Calculate and review service or program performance. 8. Calculate therapeutic doses accurately. 9. Correctly apply treatment in terms of timing and adjustments for each case. 10. Accurate diagnosis of pediatric malnutrition. 11. Manage clinical cases based on stage, development, and complications. 12. Discuss medical and nutritional treatment for MAM management. 13. Discuss treatment protocols according to malnutrition severity in a child. 14. Apply therapeutic protocols. 15. Administer therapeutic foods according to the malnutrition severity. 16. List indications and contraindications of medications and procedures.
Attitude	

Domain	Competency
Etiology	<ol style="list-style-type: none"> 1. Explain all malnutrition information to parents. 2. Promote health education about malnutrition and when to take action.
Assessment and diagnosis	<ol style="list-style-type: none"> 1. Keep children who are malnourished safe and protected from harm. 2. Demonstrate investigative and analytical thinking to meet the needs of children who are malnourished. 3. Provide the best possible health care to children who are malnourished regardless of age, gender, culture, and economic status. 4. Communicate effectively with children who are malnourished and families to explain case progression.
Management	<ol style="list-style-type: none"> 1. Demonstrate professionalism with peers, staff, patients, and families. 2. Collaborate with health care professionals. 3. Respect patient privacy and confidentiality. 4. Show sympathy and compassion for children who are malnourished. 5. Provide spiritual support to children who are malnourished and parents. 6. Develop strategies for consultation, collaboration, and referral. 7. Exhibit leadership, initiative, and optimism to manage cases effectively. 8. Work flexibly under stress and changing conditions while remaining calm. 9. Apply WHO^c general principles for routine care (10-steps).

^aSAM: severe acute malnutrition.

^bMAM: moderate acute malnutrition.

^cWHO: World Health Organization

The final competencies comprised 24 knowledge, 29 skills, and 15 attitudes items. By competencies classification, 10 addressed etiology, 21 assessment or diagnosis, and 37 management.

In total, 10 participants were recruited between July 1, 2021, and July 15, 2021. Following the administration of the pretest, the online course commenced on July 21 and continued for 1 month. The posttest was administered on August 28, 2021, upon completion of the course. The cohort comprised 5 (50%) pediatricians and 5 (50%) other health professionals, with 8 (80%) females and 2 (20%) males. All pediatricians had prior experience in managing children who are malnourished and had received training on pediatric malnutrition, with 3 having been

trained over a year prior and 2 within the past year. None of the other health professionals in the cohort had previous training.

Table 2 displays knowledge gained across participants, assessed before and after the course. Comparisons were made between groups based on gender, specialty, and prior training. All participants achieved higher posttest than pretest scores. The overall mean increase in knowledge scores from pretest to posttest was 11.0 points, representing a 45% relative gain. This significant difference ($P < .001$) indicates that the online course was effective in enhancing knowledge about pediatric malnutrition for the entire cohort.

Table . Knowledge gains between pre- and posttests based on participant demographics.

Variable	n	Pretest mean ^a (SD)	Posttest mean (SD) ^a	Mann-Whitney (<i>P</i> value)		Paired <i>t</i> test (<i>df</i> ; <i>P</i> value)	
				Pretest	Posttest	Pretest	Posttest
Female	8	23.6 (6.7)	35.4 (3.7)	-0.26 (.79)	-0.53 (.60)	-0.58 (8;.58)	0.32 (8;.76)
Male	2	26.5 (2.1)	34.5 (0.7)	-0.26 (.79)	-0.53 (.60)	-0.58 (8;.58)	0.32 (8;.76)
Health professionals	5	20.2 (5.9)	33 (2.5)	-2 (.046)	-2.11 (.04)	-2.73 (8;.03)	-2.81 (8;.02)
Pediatricians	5	28.2 (2.9)	37.4 (2.4)	-2 (.046)	-2.11 (.04)	-2.73 (8;.03)	-2.81 (8;.02)
Nonprior attendance	5	20.2 (5.9)	— ^b	-2 (.046)	—	-2.73 (8;.03)	—
Prior attendance	5	28.2 (2.9)	—	-2 (.046)	—	-2.73 (8;.03)	—
More than 1 year	3	26.3 (1.5)	—	—	—	-3.43 (8;.04)	—
Last year	2	31 (1.4)	—	—	—	-3.43 (8;.04)	—
Total	10	24.2 (6.1)	35.2 (3.3)	-2.81 (.01)	-2.81 (.01)	-7.79 (9;<.001)	-7.79 (9;<.001)

^aMaximum score=40.

^bNot applicable.

Notably, the paired *t* test revealed a statistically significant improvement in posttest scores for all participants (5/5) with prior malnutrition training ($P=.03$). This finding suggests that the course not only builds upon existing knowledge but also serves as a valuable refresher for those previously trained in this area (Table 2).

Female participants had average pretest scores of 23.6 (SD 6.7) and posttest scores of 35.3 (SD 3.7), while males averaged 26.5 (SD 2.1) and 34.5 (SD 0.7), respectively. Gender did not significantly impact knowledge gains, with $P=.79$ for the pretest and $P=.60$ for posttest scores. Pediatricians had higher mean pretest scores 28.2 (SD 2.9) and posttest scores 37.4 (SD 2.4) than other health professionals 20.2 (SD 5.9) and 33 (SD 2.5),

respectively. Specialty significantly affected pre- and posttest scores ($P=.03$ and $P=.02$, respectively). Health professionals with prior training attendance demonstrated a significant difference in pretest scores compared to those without prior attendance ($P=.046$).

Even though gender had little significant impact on test scores, knowledge improved across all educational modules.

When test scores were compared by specialty, pediatricians outperformed health care professionals in module 1 (defining, classifying, and determining malnutrition prevalence) and module 4 (managing pediatric malnutrition; $P=.02$ and $P=.02$, respectively). Details are presented in Table 3.

Table . Comparison of educational modules results by specialty.

Module and specialty	n	Pretest mean (SD)	Posttest mean (SD)	Paired <i>t</i> test (<i>df</i> ; <i>P</i> value)		Mann-Whitney (<i>P</i> value)	
				Pretest	Posttest	Pretest	Posttest
One				-2.15 (8;.06)	-2.89 (8;.02)	-1.89 (.06)	-2.15 (.03)
Health professionals	5	4.8 (1.6)	8.4 (0.5)				
Pediatricians	5	6.6 (0.9)	9.4 (0.5)				
Two				-2.12 (8;.07)	-1.37 (8;.21)	-1.61 (.11)	-1.21 (.23)
Health professionals	5	5.2 (2.8)	8.2 (0.8)				
Pediatricians	5	8 (1)	9 (1)				
Three				-0.45 (8;.67)	-1.27 (8;.24)	-0.35 (.73)	-1.23 (.22)
Health professionals	5	2.2 (0.8)	4.2 (0.4)				
Pediatricians	5	2.4 (0.5)	4.6 (0.5)				
Four				-2.76 (8;.03)	-2.84 (8;.02)	-2.02 (.04)	-2.24 (.03)
Health professionals	5	8 (1.9)	12.2 (1.5)				
Pediatricians	5	11.2 (1.8)	14.4 (0.9)				

The effect size, calculated using Cohen *d*, was 2.25, indicating a very large effect, suggesting a substantial improvement in knowledge among participants from the pretest to the posttest. This finding highlights the significant impact of the online course on participants' understanding of pediatric malnutrition.

The analysis of 30-item participant satisfaction questionnaire revealed a Cronbach α of .74, indicating a satisfactory level of internal consistency and reliability for the instrument.

Participants reported high satisfaction with the content presentation style (mean 3.16, SD 0.24), very high satisfaction with the scientific knowledge gained (mean 3.26, SD 0.30), and high satisfaction with the e-learning environment (mean 3.06, SD 0.4). The details can be accessed on Table S2 in [Multimedia Appendix 1](#).

Most participants (6/10) preferred a combination of traditional and e-learning, while 3 preferred e-learning only, and 1 preferred traditional education.

Discussion

Principal Findings

This study investigates the efficacy of online learning in addressing pediatric malnutrition, a significant global health concern. The research identified 68 essential competencies for effective pediatric malnutrition management, encompassing knowledge, skills, and attitudes. These competencies were developed through a collaborative process with Syrian health care professionals, offering a valuable resource for future training initiatives. This study demonstrated that a self-directed online course significantly enhanced participants' knowledge acquisition, highlighting the potential of e-learning as a scalable

solution for addressing training needs in resource-constrained environments.

This study's findings underscore the importance of comprehensive competency frameworks for addressing pediatric malnutrition, especially in challenging contexts such as Syria. The participants highly rated the online course, suggesting its effectiveness in bridging training gaps in resource-constrained settings. This study provides valuable insights for developing and implementing effective training initiatives to improve the management of pediatric malnutrition in resource-limited and conflict-affected settings.

This study expands upon existing research on essential competencies in medical education and the feasibility of e-learning in Syria [21-23]. While international organizations have focused on pediatric malnutrition in low-income countries [1-3], research specifically addressing the competencies required by pediatricians and other health care professionals to manage these cases has been limited. This study aimed to identify essential competencies for managing pediatric malnutrition and evaluating the effectiveness of e-learning modules in enhancing knowledge among health care professionals.

This study identified essential competencies by drawing upon existing training guides and WHO guidelines on SAM [24,25]. Although this study was conducted before the release of updated WHO guidelines in 2023 [26], future revisions of the identified competencies and online course content are recommended to align with these new recommendations.

This study builds upon previous work by Meeker et al [27] on a technical competency framework for nutrition in emergencies, specifically focusing on pediatric malnutrition and the needs of Syrian health professionals. While prior studies [11,27,28] have highlighted the importance of managing pediatric malnutrition,

this research fills a gap by identifying the essential competencies pediatricians require to effectively manage these cases.

This study demonstrates the potential of e-learning to effectively scale up malnutrition management knowledge, a recognized challenge in most low- and middle-income countries [29,30]. Consistent with Annan et al's [8] findings, knowledge acquisition was enhanced when the course was linked to career and academic progress. Participants reported increased learning and understanding of effective pediatric malnutrition management. These findings align with Choi et al's [7] demonstration across 4 countries that e-learning enhanced health care practices and reduced malnutrition mortality through increased facility-based management of SAM. While this study's time frame precluded measuring clinical outcomes, the significant knowledge gains could be attributed to the course's practical relevance and scientifically sound content, as reflected in high participant approval [31].

Pediatricians' pretest performance was positively influenced by previous malnutrition training, indicating knowledge retention [32]. This highlights the need for posttests and follow-up evaluations to compare the effectiveness of e-learning with traditional training, especially given its lower implementation costs per participant [8].

Developing the educational course in Arabic was a key challenge due to the limited availability of Arabic language online resources [33]. However, offering the course in the local language facilitated better knowledge comprehension and potentially increased long-term retention and practical application [34].

Strength

This study highlights the potential of online learning to improve pediatric malnutrition management, especially in challenging environments such as Syria. By identifying essential competencies and demonstrating the effectiveness of a self-directed online course, it offers a model for developing similar training programs in other resource-constrained and conflict-affected areas. The course's accessibility, adaptability, and positive feedback from participants suggest a promising

way to address the shortage of skilled health care professionals in these regions.

Limitation

This pilot study, conducted with a small sample size, limits the generalizability of the findings to a broader population of health care professionals. While this study demonstrates positive knowledge acquisition, it does not assess the impact on clinical practice or patient outcomes. Additionally, this study does not delve deeply into the specific challenges and facilitators of implementing the online course in the Syrian context, nor does it include long-term follow-up to assess the persistence of knowledge gains and their impact on clinical practice. To mitigate these limitations, we strived to recruit a diverse sample within our limited scope and used rigorous data collection and analysis methods.

Future Research

Future research should expand on this study by (1) conducting larger studies with diverse participants to ensure findings are broadly applicable; (2) assessing the online course's impact on real-world clinical practice and patient outcomes, not just knowledge acquisition; (3) understanding practical considerations and implementation strategies for e-learning in challenging environments such as Syria; (4) translating identified skills and attitudes into practical training methods; and (5) conducting long-term follow-up to track knowledge retention and its impact on clinical practice.

Conclusion

This study demonstrates the effectiveness of self-directed online learning in improving knowledge and skills related to pediatric malnutrition management among Syrian health care professionals. This study identified 68 essential competencies across various domains, highlighting the breadth of knowledge needed for effective pediatric malnutrition management. The findings suggest e-learning as a powerful tool for scaling up training in challenging contexts such as Syria, while acknowledging the need for careful consideration of contextual factors.

Acknowledgments

The authors would like to thank all the participants in this study for their time and willingness to share their experiences. All authors declared that they had insufficient or no funding to support open access publication of this paper, including from affiliated organizations or institutions, funding agencies, or other organizations. Abstract

Background: The COVID-19 pandemic has resulted in a greater workload in the health care system. Therefore, health care professionals (HCPs) continue to experience high levels of stress, resulting in mental health disorders. From a preventive perspective, building resilience has been associated with reduced stress and mental health disorders and promotes HCPs' intent to stay. Despite the benefits of resilience training, few studies provided an in-depth understanding of the contextual factors, implementation, and mechanisms of impact that influences the sustainability of resilience programs. Therefore, examining target users' experiences of the resilience program is important. This will provide meaningful information to refine and improve future resilience programs.

Objective: This qualitative study aims to explore HCPs' experiences of participating in the web-based Building Resilience At Work (BRAW) program. In particular, this study aims to explore the contextual and implementational factors that would influence participants' interaction and outcome from the program.

Methods: A descriptive qualitative approach using individual semistructured Zoom interviews was conducted with participants of the web-based resilience program. A framework analysis was conducted, and it is guided by the process evaluation framework.

Results: A total of 33 HCPs participated in this qualitative study. Three themes depicting participants' experiences, interactions, and impacts from the BRAW program were elucidated from the framework analysis: learning from web-based tools, interacting with the BRAW program, and promoting participants' workforce readiness.

Conclusions: Findings show that a web-based asynchronous and self-paced resilience program is an acceptable and feasible approach for HCPs. The program also led to encouraging findings on participants' resilience, intent to stay, and employability. However, continued refinements in the components of the web-based resilience program should be carried out to ensure the sustainability of this intervention.

Trial Registration: ClinicalTrials.gov NCT05130879; <https://clinicaltrials.gov/ct2/show/NCT05130879>

Introduction

Background

The emergence of the COVID-19 pandemic has led to extensive changes in the health care landscape. Globally, the repeated waves of COVID-19 infections have led to health care professionals (HCPs) grappling with occupational health hazards and overstretched assignments [1,2]. These constant stressors have led to HCPs experiencing a surge in symptoms of burnout, insomnia, and mental health distress [3-5]. Accordingly, the intensification of physical and mental exhaustion has led to a considerable increase in the turnover of HCPs [6]. With a smaller health care workforce, health care administrators need to prioritize and concentrate their efforts on enforcing supportive measures to ensure that HCPs continue to be inoculated against stress and mental health disorders. Thus, reducing workplace-related stress may have encouraging effects on HCPs' intent to stay [7,8].

Contemporarily, more persuasive evidence has alluded to the importance of noncognitive skills as protective factors against mental health distress [9,10]. An emerging interest among noncognitive skills is the development of an individual's resilience. Resilience is the ability to overcome adversities [11,12]. Theoretically, resilience can be understood from various perspectives, as a trait (eg, personality), process (eg, interaction with protective factors), or outcome (eg, becoming resilient). More importantly, building an individual's resilience has positive effects on their mental well-being [13,14].

Figure 1. Process evaluation framework.

First, contextual factors are unique situational factors that influence how the intervention may be delivered or have affected the participants [25]. These contextual factors may have eventual implications on the implementation and mechanisms of impact. Second, the implementation process is the identification of factors that may influence the delivery of the intervention [25]. This may include the collection of data that reflects intervention fidelity [26]. Third, mechanisms of impact describe participants' responses to and interaction with the intervention. In addition, mechanisms of impact identify any potential mediators, pathways, or consequences as a result of their participation in the intervention [25]. Thus, conducting process evaluations of interventions may be worthy in providing recommendations for improvements and supporting the eventual implementation of the program. Although prior qualitative evaluations of resilience

Resilient individuals are adept at using personal, relational, and environmental resources to overcome adversity [11,12]. At the personal level, individuals with certain personality traits such as a positive outlook can appraise stressful situations from an optimistic point of view [15]. Based on the transactional model of stress and coping [16], positive emotions may reduce the negative effect that arises when one experiences adversities. Furthermore, individuals with collegial relationships with colleagues and peers can rely on social support resources to overcome adversities [11]. Finally, environmental protective factors in the form of workplace culture can influence an individual's resilience [11,12]. For instance, an organization that focuses on building a collegial and harmonious workplace culture can in turn facilitate one's access to social support resources and thus develop resilience [17,18].

Existing resilience interventions have focused on modifiable personal and relational factors such as the use of cognitive behavioral techniques [19], mindfulness training [20,21], and social competency skills [22,23]. However, most existing literature focused on evaluating the effects of resilience training using quantitative approaches [13]. In line with the development and evaluation of complex interventions [24], using qualitative approaches will be useful in gathering in-depth information about the various contextual and implementational factors that can alter the intended outcomes of the intervention. Particularly, the process evaluation framework [25] proposes that an intervention should be further examined by identifying the contextual factors, implementation processes, mechanisms of impact, and outcomes of the intervention (Figure 1).

programs [22,27,28] have made valuable contributions toward an in-depth understanding of participants' experiences, its findings may not be transferrable because of several factors, such as population, cultural differences, and type of resilience program. For these reasons, conducting a study to encapsulate the experiences of the participants of the Building Resilience At Work (BRAW) program is important.

Objectives

This qualitative study explores HCPs' experiences of participating in the BRAW program. Guided by the process evaluation framework [25], this study also aims to examine the contextual and implementation factors that affected participants' experiences and identify the outcomes that arose from their participation in the BRAW program.

Methods

Ethical Considerations

This study was approved by the National University of Singapore Institutional Review Board (NUS-IRB-2021-703). This study's procedures were followed in accordance with the Declaration of Helsinki. Eligible participants were recruited from August 2021 to December 2022. Participants were provided with a participation information sheet, and they were allowed to withdraw without penalty. After obtaining informed consent, participants were invited to participate in a web-based semistructured audio- and video-recorded interview via Zoom (Zoom Video Communications). The interview transcripts were de-identified and coded using pseudonyms. Participants were given 20 Singapore Dollars for completing the study.

Research Design

This qualitative study is part of a randomized controlled study conducted in Singapore (ClinicalTrials.gov NCT05130879). A process evaluation approach [25] comprising semistructured individual digital interviews was undertaken to explore participants' experiences of using the web-based BRAW program. This study is reported based on the COREQ (Consolidated Criteria for Reporting Qualitative Research) [29] (Multimedia Appendix 1).

Setting and Participants

This study was conducted from April 2021 to December 2022 in Singapore, a multiethnic and multicultural city-state. Based on the national census [30], there are approximately 70,178 registered HCPs, and most of them are nurses (61.27%). Participants were eligible to participate in this qualitative study if they were practicing as an HCP in Singapore, could comprehend the English language, had access to a device that could connect to the internet, and completed the web-based BRAW program. A total of 33 participants who completed the web-based BRAW program were purposively sampled to participate in this qualitative study.

Web-Based BRAW Program

The web-based BRAW program is a 6-session weekly web-based program hosted via Microsoft Teams (Microsoft Corp). The resilience program was developed based on a systematic review [13] and evidence-based therapies, such as cognitive behavioral therapy [31], acceptance and commitment therapy [32], and problem-solving model [33]. The BRAW program comprised 6 different topics, namely, happiness and positivity, cognitive restructuring, behavioral activation, emotion regulation, positive work climate, and problem-solving (Table 1). It also comprised several elements, short videos, quizzes, and homework (Figure 2). A web-based forum was also provided for participants to interact with each other and provide social support.

Figure 2. Elements of the web-based BRAW program. BRAW: Building Resilience At Work.

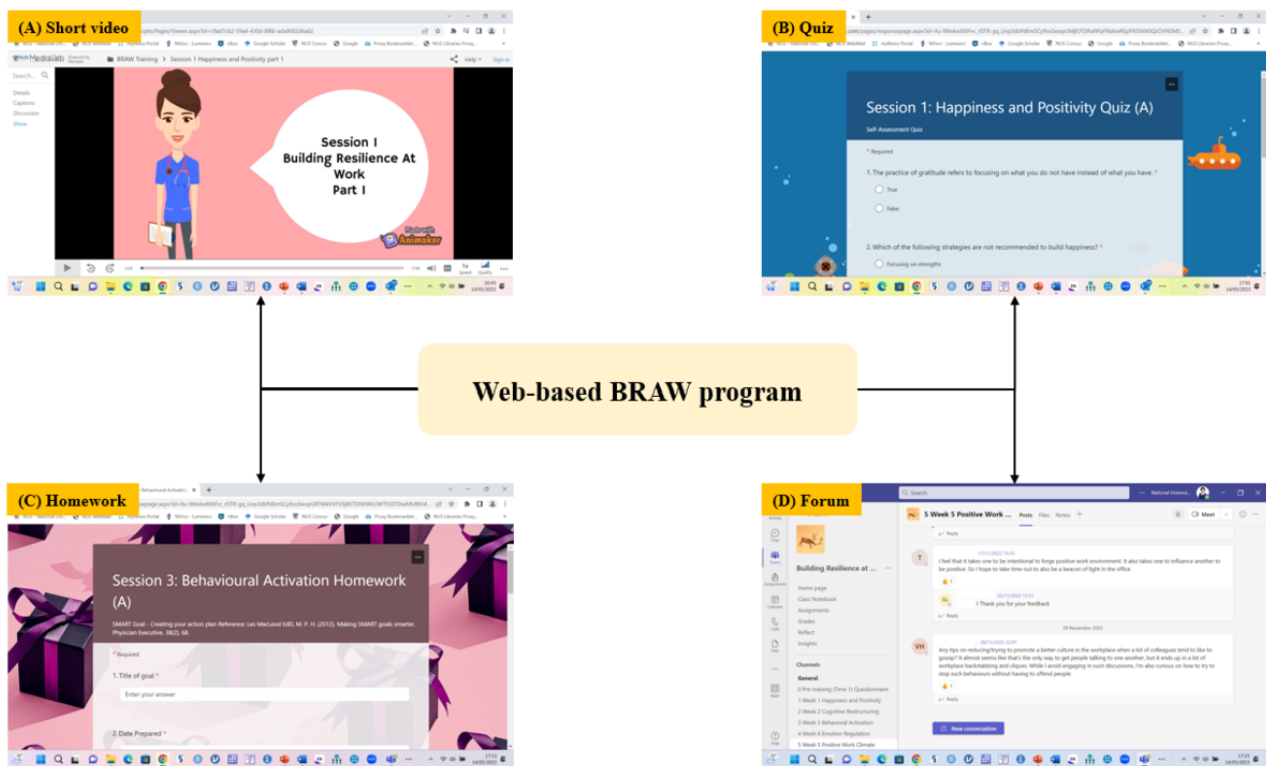

Table 1. Overview of the Building Resilience At Work program.

Week	Topic	Contents
1	Happiness and positivity	<ul style="list-style-type: none">• Understanding strengths and resilience• Fostering positive attitude
2	Cognitive restructuring	<ul style="list-style-type: none">• Identifying dysfunctional automatic thoughts• Using cognitive behavioral techniques to modify dysfunctional thoughts• Formulating rational responses to automatic thoughts
3	Behavioral activation	<ul style="list-style-type: none">• Initiating and using behavioral activation techniques• Building healthy interpersonal relationships and peer support
4	Emotion regulation	<ul style="list-style-type: none">• Regulating emotions• Preventing and managing conflict
5	Positive work climate	<ul style="list-style-type: none">• Forging a supportive work environment• Developing supportive collegial relationships• Promoting coworker support
6	Problem-solving	<ul style="list-style-type: none">• Solving work-life problems using a framework• Importance of work-life balance

Data Collection

The digital interviews were scheduled at a time convenient for the participants. Participants were reminded to ensure that their cameras and microphones were working prior to the interviews. All interviews were conducted by a female researcher (ZQGL) who received formal training in qualitative research. The interviewer was supported by 2 doctoral-prepared researchers (WHDA and YL) who are experienced in qualitative research. During the digital interview, the interviewer started by building rapport with the participants and sharing the aims and processes of this study. In addition, sociodemographic characteristics

including age, sex, ethnicity, and occupation were collected. Afterward, the interview was conducted according to the semistructured guide. The guide was developed based on the process evaluation framework [25] and comprised open-ended questions. Then, the initial guide was circulated to the research team and refined. Subsequently, the interview guide was piloted among 5 participants and was further revised for clarity. The final interview guide can be found in [Textbox 1](#). The mean duration of the interviews was 35.48 (SD 7.83; range 20-54) minutes. Data saturation was achieved at the 31st participant, and 2 additional interviews were conducted to confirm saturation [34].

Textbox 1. Semistructured interview guide.**Questions**

1. What was your experience when completing the Building Resilience At Work (BRAW) training program?
2. What were the issues with the platforms for the training sessions that you have encountered?
3. How did you feel about the duration of each training video?
4. How did you feel about the quizzes?
5. How did you feel about the homework?
6. How did you feel about the forum?
7. How did you feel about the entire duration of the 6-week BRAW training program?
8. What were the aspects of the intervention (eg, homework, quizzes, and forum) that you particularly liked or disliked?
9. Were there any sessions that stood out?
10. How did you feel about the contents?
11. Could you tell me your overall experience with applying the strategies learned from the BRAW intervention at work?
12. How was your experience of applying the strategies at work?
13. Did you encounter any problems or frustrations when trying to apply the strategies at work?
14. Has the BRAW training program influenced your resilience at work?
15. Has the BRAW training program influenced your enthusiasm and dedication at work?
16. Has the BRAW training program influenced your intention to leave?
17. Has the BRAW training program influenced your ability to gain and maintain employment?
18. Has the BRAW training program influenced your work performance?
19. Are there any other strategies that would help you to manage stress and build resilience that we have not mentioned in the BRAW intervention?
20. Do you have anything else to add that we have not covered in this interview?
21. Finally, are you okay for me to contact you for some follow-up questions?

Data Analysis

The video-recorded interviews were transcribed verbatim by 1 researcher (ZQGL) and verified for accuracy by another researcher (WHDA). The transcripts were imported and analyzed using NVivo (version 12; Lumivero). Transcripts were returned to the participants for their comments. A deductive framework analysis method [35] was then undertaken as it provides a systematic approach to analyzing qualitative data [36]. In addition, the use of a matrix structure provides a visually straightforward recognition of patterns in the data that can be useful in identifying similarities or differences between participants' narratives [36]. In line with the research questions, a framework analysis approach is suitable, as this study was guided by the process evaluation framework and sought to examine participants' experiences of the BRAW program. Particularly, it identifies the contextual and implementation factors that affected their participation and the outcomes of participation.

A 5-step framework analysis approach [35,37] was independently performed by 2 researchers (WHDA and YL). First, the researchers familiarized themselves with the data by reading the transcripts accompanied by listening to the interviews. Second, the transcripts were coded based on the process evaluation framework [25]. After completing the coding for the first 5 transcripts, both researchers compared their codes

and developed a standardized code book. Following discussions among the researchers, the eventual code book comprised 11 different categories.

Third, after completing the coding for all transcripts, a total of 347 codes were brought together and discussed among the researchers. The similarities and differences that arose during the coding process were deliberated. Cohen κ was used to calculate the interrater agreement for the coding, and good agreement was found ($\kappa=0.79$). Consequently, the codes were organized and indexed based on the process evaluation framework. Fourth, the codes were further reduced by summarizing the key information for the indexed data in each category. Finally, the identified codes were mapped using a coding tree (Table S1 [Multimedia Appendix 2](#)) and interpreted using visual and narrative forms. Finally, 3 themes and 7 subthemes were derived from the framework analysis. The themes and subthemes were provided to a select group of participants who were willing to provide feedback on the findings.

Rigor

The principles of credibility, transferability, dependability, and conformability were used to demonstrate rigor [38]. First, a reflexivity journal was maintained by all members of the research team to improve their self-awareness and reduce any potential personal influences on the data. Second, the data

analyses were conducted by 2 independent researchers (WHDA and YL). Third, participants were invited to review their transcripts to clarify the context of the statements and ensure that the final themes and subthemes were representative of their experiences [39]. Subsequently, an audit trail detailing the recruitment, data collection, and analysis process was conducted to ensure ease of replication, transparency, and dependability [38]. Finally, a thick description of the context and the intervention was provided, this facilitates the transferability of the findings of this study [38].

Results

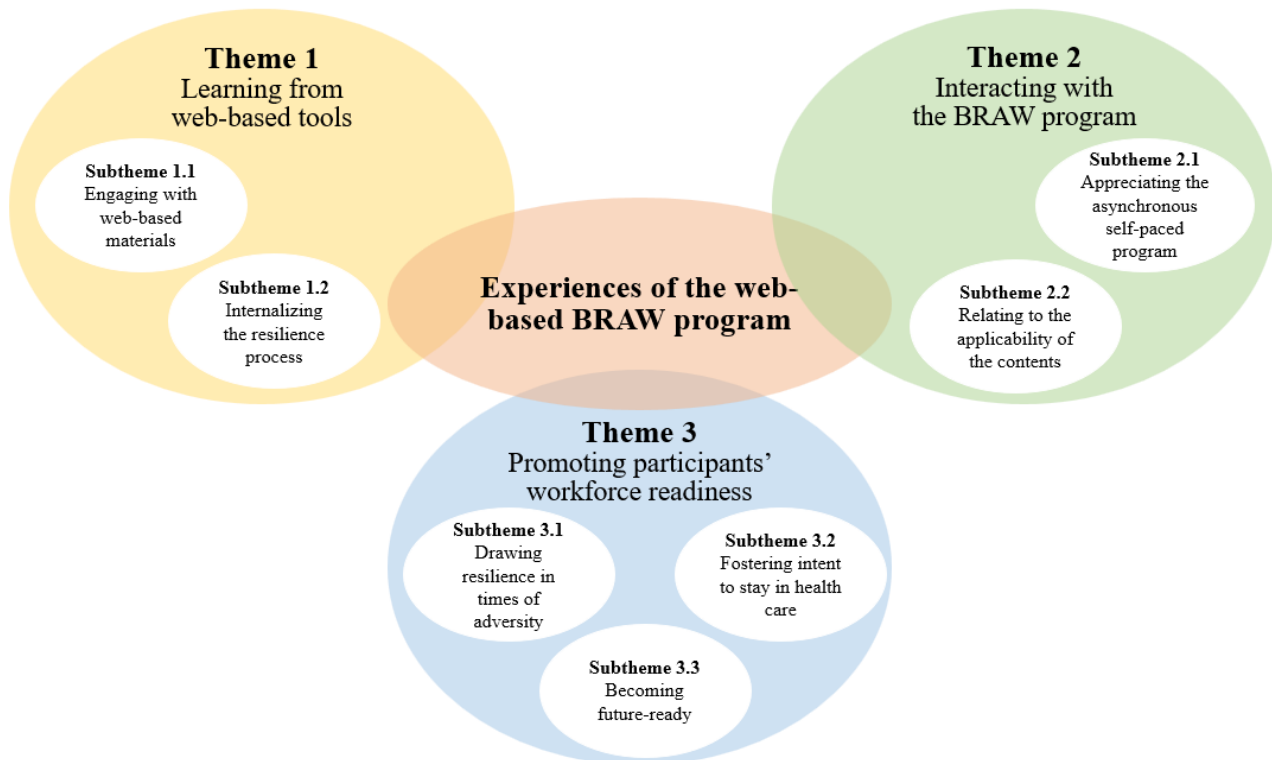

Overview

A total of 33 HCPs participated in this qualitative study. The sociodemographic variables are presented in Table 2. Most of the participants were between the ages of 31-40 years (n=11, 34%), female (n=24, 73%), ethnic Chinese (n=25, 76%), and nurses (n=15, 46%). The findings from the framework analysis unveiled 3 themes and 7 subthemes that depicted participants' experiences, interactions, and impacts from the BRAW program. The 3 themes were learning from web-based tools, interacting with the BRAW program, and promoting participants' workforce readiness (Figure 3).

Table 2. Participants sociodemographic characteristics (N=33).

Variables	Values
Age group (years), n (%)	
21-25	5 (15)
26-30	9 (27)
31-40	11 (34)
41-50	6 (18)
51-60	2 (6)
Sex, n (%)	
Male	9 (27)
Female	24 (73)
Ethnicity, n (%)	
Chinese	25 (76)
Malay	7 (21)
Indian	1 (3)
Profession, n (%)	
Allied health worker	12 (36)
Clinical administrator	1 (3)
Clinical researcher	4 (12)
Nurse (registered and enrolled)	15 (46)
Physician	1 (3)
Duration of interviews (minutes)	
Mean (SD)	35.48 (7.83)
Range	20-54

Figure 3. Participants' experiences of the web-based BRAW program. BRAW: Building Resilience At Work.

Theme 1: Learning From Web-Based Tools

Overview

The first theme depicts the BRAW implementation process. It particularly describes how participants learned through web-based tools via Microsoft Teams. This is elaborated in 2 subthemes, namely, engaging with web materials and internalizing the resilience process.

Engaging With Web Materials

The BRAW program provided various web materials, ranging from short videos to quizzes and homework. The short videos were developed using animations, graphics, and subtitles, which appealed to the participants and supported their engagement with the web materials:

The use of graphics was quite good, the animations and all, so like, it kept me wanting to finish watching, not like stop halfway. Yeah...the pace was also good, and like, just nice, not too much information overload. [Participant 24, female, Chinese, nurse]

However, some participants were encumbered by the number of tasks (eg, weekly quizzes and homework). For instance, the weekly homework was described to be a “chore,” and this can be a disincentivizing factor in completing the program. As an alternative, a participant proposed that renaming the weekly tasks could be a strategy to overcome the inertia:

Because “homework” it sounds like “tsk,” erm, like a chore to be done, you know, but “reflection” is like, you reflect on what you-you need to do. So, sounds more forgiving. [Participant 26, female, Malay, nurse]

Internalizing the Resilience Process

Despite the conflicting work commitments and activities in the BRAW program that participants had to undergo, they credited the quizzes and homework as factors that supported the internalization of the learning process. Particularly, reviewing the questions found in the quizzes and homework facilitated an internalization process:

Just by plain reading the question, it may set you thinking, you see. You don't know what's happening or your subconscious, you're already motivated right, you learn some new content. And that homework may actually be building synapses, you know, trying at the backend that you don't know about. [Participant 10, male, Malay, physician]

However, not all participants were well-versed in the contents of the BRAW program. Several participants highlighted difficulties in appreciating the theoretical aspects of the program:

When it gets a little bit more “science-y,” like the brain and then they tell you, I don't know all the words, I don't remember, but like the brain and then, certain kinds of thoughts and all that. Then, those kinds of stuff, no, like I haven't heard of that before. [Participant 15, female, Indian, clinical researcher]

Notwithstanding, these groups of participants, particularly those who did not receive formal training in health sciences, verbalized how they used the quizzes as an avenue to understand the various technical terms that they were not familiar with:

Especially some of the terms, erm, maybe a bit technical? I'm not that acquainted. So, it [referring to the quizzes] allows me to clarify, review and

understand and get it correct. [Participant 8, female, Chinese, clinical administrator]

Theme 2: Interacting With the BRAW Program

Overview

The second theme describes the BRAW program's mechanism of impact and the relevant contextual factors that influenced it. This theme expressed how participants responded and interacted with the BRAW program and is highlighted in 2 subthemes, namely, appreciating the asynchronous self-paced program and relating to the applicability of the contents.

Appreciating the Asynchronous Self-Paced Program

Due to the higher workload brought upon by the COVID-19 pandemic and the resumption of usual clinical duties, participants had to contend with numerous conflicting priorities. Hence, they appreciated how the BRAW program was designed as an asynchronous self-paced program. This allowed them to learn at their own pace and time:

Healthcare workers are busy, so they don't have to find a specific day and time to attend an intervention, whether be it online or on-site, face-to-face or whatever, so having something that you can access on your own time and target is good. [Participant 4, female, Chinese, clinical researcher]

However, despite the self-paced nature of the program, participants struggled with finding suitable time outside their personal commitments and rest to engage in the program. This was more prominent among HCPs who are on shift work duties:

We are really packed and rushed at work, and there's a lot of multitasking. It's like very draining at work. I think the shifts also, so you do rotating shifts. So, it's quite tiring after work to find time. [Participant 5, female, Chinese, nurse]

Nevertheless, some participants felt that introducing more web-based synchronous elements through videoconferencing tools may be able to better support their learning:

These sessions were to be interactive whereby we can do it via Zoom, to share every participant's experience, it would be even better. [Participant 28, female, Chinese, nurse]

Relating to the Applicability of the Contents

The BRAW program was conducted at the peak of the COVID-19 pandemic in Singapore. Due to the stressors inflicted by the additional workload, participants felt that the program was delivered at an opportunistic time to support their psychological well-being:

I think you kind of met me at the right time and I feel that I need to self-improve. [Participant 3, male, Chinese, nurse]

In particular, participants appreciated how the contents were relatable to their concerns and felt that they were able to translate their newly acquired theoretical knowledge to an actual situation:

I really appreciate the teamwork and emotional regulation, like the ones I could really practice, putting time for myself, things like that. [Participant 6, male, Chinese, nurse]

Theme 3: Promoting Participants' Workforce Readiness

Overview

The final theme describes how the BRAW program has influenced participants' readiness to maintain in the workforce. Through participants' narratives, the BRAW program has a profound impact on their resilience, intent to stay, and employability. This theme is further elaborated in 3 subthemes, namely, drawing resilience in times of adversity, promoting intent to stay in health care, and becoming future-ready.

Drawing Resilience in Times of Adversity

The BRAW program instilled numerous positive aspects in participants. As participants translated their newly acquired knowledge into practice, they demonstrated resiliency by overcoming the challenges and difficulties experienced in the workplace:

Yup, especially when dealing with negative emotions and how to bounce back up again. [Participant 1, male, Chinese, nurse]

When asked about the extent of the improvements, the majority of the participants felt noticeable improvements. For instance, they observed an evident increase in their ability to overcome situations:

In the past...I take quite a while to recover...Then, nowadays, it's a bit better, even though I think about it, I can move on from it. And I can have a more positive mindset about it. So, I don't blame myself for something that happened, or I don't dwell on the thing that happened. Instead, I focused on the future, like if it happens again, what can I do. [Participant 13, female, Chinese, audiologist]

Promoting Intent to Stay in Health Care

Participants also felt that the BRAW program supported their resilience to remain steadfast in the health care sector. This was an interesting viewpoint expressed by most participants because it proposes that the improvement of psychological well-being has increased their intent to stay in their current role:

This course [referring to the BRAW program] actually helps me dispel away negative thoughts, put things in perspective, and reframe my mind away so that I can still go through the job. [Participant 14, female, Malay, medical technician]

However, most of the participants also felt that resilience training alone may not be sufficient to influence their intent to stay. Instead, one's intent to stay may be influenced by a larger environmental factor such as management-related reasons:

The management did not do anything, so I feel that I should just quit this organization because they don't take care of us. [Participant 25, male, Malay, nurse]

Becoming Future-Ready

The majority of the participants felt that resilience is a form of a positive attribute. When asked if being resilient is an important factor in securing employment, participants felt that resiliency was a personal competency and may have indirect impacts on getting one employed:

I won't say, it's directly, okay, this [referring to the BRAW program] will help you get the job, but it's more of like okay, it helps you work on yourself as a person. So, that indirectly translates to being a more employable person. [Participant 13, female, Chinese, audiologist]

Nevertheless, participants perceived that the contents of the BRAW program could help shape an individual's emotional quotient. This may translate to the development of one's leadership skills:

It [referring to the BRAW program] shapes a person who has a lot of EQ and understanding...So, I think it does make, if you can master these techniques very well, I do believe that it can make you a better leader. [Participant 12, male, Chinese, respiratory therapist]

Discussion

Principal Findings

This qualitative study aimed to explore HCPs' experiences of participating in the web-based BRAW program during the COVID-19 pandemic. Based on the framework analysis, participants alluded to the importance of the various web-based elements that supported their internalization of the resilience processes. Particularly, the asynchronous and self-paced nature and applicable materials supported participants' continued engagement with the BRAW program. Finally, after attending the BRAW program, participants became resilient, had greater intent to stay, and were future-ready.

With regard to the web-based elements, the availability of different web-based learning tools has supported participants' learning. This finding was consistent with prior research that evaluated web-based resilience programs [22,40]. Several key characteristics of web-based learning stood out. First, participants alluded to the importance of short attention-requiring materials such as videos, which was similarly reported in other studies [40,41]. Second, participants credited the availability of quizzes and homework that supplemented their learning. Homework and quizzes can augment the learning process by allowing individuals to apply their newly acquired knowledge [42,43]. Despite the benefits, several participants were overwhelmed by the number of tasks (eg, videos, quizzes, homework, and forum). A unique finding from this study was regarding the nomenclature of the tasks. Particularly, participants mentioned that the term "homework" can be considered a chore and may not be preferred in this form of program. This could be due to participants' experiences with homework during their schooling years, where numerous negative emotions were associated with that term [44,45].

With regard to the contents, participants credited how the relatability and applicability of the BRAW contents were

facilitators for completion. This is an important aspect, as several studies have echoed the importance of providing contextually relevant materials for participants [41,46], and this will facilitate participants' understanding and transferability of their newly acquired skills. Furthermore, participants appreciated the resilience strategies and applied them in the workplace. For example, the provision of easily replicable strategies such as the application of the problem-solving algorithm was helpful for the participants [27,47].

With regard to the features, the web-based BRAW program was designed as asynchronous and self-paced training for several reasons, such as wider outreach and the presence of the COVID-19 pandemic. The use of a web-based approach was verbalized as an enabler for HCPs to complete the program, which was consistent with other studies [22,48]. In addition, a web-based approach provided HCPs with an opportunity to learn during the COVID-19 pandemic when induced social distancing measures were required. More importantly, the nature of the BRAW program promoted participants' autonomy and allowed them to gain control over their schedules. This could stimulate personalized learning, which resulted in positive effects on one's learning outcomes [49,50]. However, despite this, most of the participants also experienced conflicting priorities and were unable to timely participate in the web-based BRAW program. Considering that participation in programs of such nature is of lower priority than their formal work-related commitments, this may have led to their reduced participation [22,27].

Through participants' narratives, this study also unveiled the positive effects of the web-based BRAW program on their resilience, intent to stay, and employability. From a resilience perspective, the program provided participants with skills ranging from personal (eg, cognitive restructuring), relational (eg, teamwork), and environmental (eg, workplace environment) that promoted their resilience. Based on the resilience theory [11], the introduction of such resilience protective factors can promote resilience. Interestingly, participants' resilience could also be influenced by the recognition of their resilient potential. Several studies have suggested how the introduction of resilience programs has led to participants becoming aware of their internal strengths and how this influences their resilience [22,51].

Moreover, the web-based BRAW program introduced techniques to enhance cognitive restructuring, positivity, and happiness, and this could be a plausible explanation for improving participants' intent to stay. Despite the dynamic and stressful health care environment, these techniques potentially supported participants' positive reframing of a seemingly negative situation [15,31]. Furthermore, it can have positive direct or mediating effects on one's intent to stay by improving one's optimism and positivity [52,53]. However, participants also surfaced that macro-organization factors such as hospital administration are factors that may negatively affect their intent to stay [54,55]. While not directly explored in other qualitative evaluations of resilience programs, this study found that the web-based BRAW program has encouraging effects on participants' employability and future readiness. This could be attributed to the introduction of various noncognitive skills such as problem-solving and

emotion regulation. More literature has highlighted the pivotal role of noncognitive skills on employment outcomes [56,57].

Based on the findings from this qualitative study, several implications for future resilience programs are outlined. First, HCPs continue to experience mental exhaustion and distress due to the immense workload caused by the COVID-19 waves, and the delivery of a web-based program targeting mental well-being is practical and should be implemented. Second, from a feature perspective, an asynchronous and self-paced program is an acceptable and feasible approach. However, to reduce any potential conflicting work commitments, participants should be provided with protected time to complete these programs. Third, web-based learning should be supplemented by various engagement tools, and it will be helpful to redesignate homework as self-help exercises or tasks to reduce the negative connotation associated with homework. Next, from a content perspective, contextualized personal, relational, and environmental resilience materials should be introduced. Thus, conducting a needs analysis would be necessary to ensure that the resilience program remains acceptable to the target population. In addition, there should be an introduction of technical terms for participants who may not be familiar with the materials. Finally, as resilience programs focus on building an individual's strengths, it will be important that health care administrators consider building supportive workplace environments to complement resilience programs.

Limitations

This study has several limitations, and results need to be interpreted with caution. First, this qualitative study explored participants' experiences of 1 web-based resilience program, and its findings may not be transferable to other settings. Despite this, our findings may provide insight on the design of future psychosocial web-based interventions. Second, most of them were female and ethnic Chinese participants, thereby resulting in an underrepresentation of other sex and ethnic groups. Nevertheless, a rigorous purposive sampling approach was undertaken to ensure that there is a good representation of individuals across various age groups and professions. Finally, this study was limited to a 1-time point and may not be able to encapsulate the long-term effects of the BRAW program on the participants.

Conclusions

This study presented a qualitative evaluation of a web-based BRAW program using framework analysis. Although there were several highlighted facilitators and barriers, the findings show that an asynchronous, self-paced resilience program can be a useful tool in supporting the well-being of HCPs during the COVID-19 pandemic. However, it will be important to ensure that contextually relevant materials, supported by other appropriate web-based engagement tools, such as quizzes and practical exercises are provided to promote learning in a web-based environment. Further work is needed to explore how macro-organization factors can be embedded in resilience programs to promote HCPs' resilience and well-being.

Abstract

Background: Undergraduate medical students often lack hands-on research experience and fundamental scientific research skills, limiting their exposure to the practical aspects of scientific investigation. The Cerrahpasa Neuroscience Society introduced a program to address this deficiency and facilitate student-led research.

Objective: The primary goal of this initiative was to enhance medical students' research output by enabling them to generate and publish peer-reviewed papers within the framework of this pilot project. The project aimed to provide an accessible, global model for research training through structured journal clubs, mentorship from experienced peers, and resource access.

Methods: In January 2022, a total of 30 volunteer students from various Turkish medical schools participated in this course-based undergraduate research experience program. Students self-organized into 2 groups according to their preferred study type: original research or systematic review. Two final-year students with prior research experience led the project, developing training modules using selected materials. The project was implemented entirely online, with participants completing training modules before using their newly acquired theoretical knowledge to perform assigned tasks.

Results: Based on student feedback, the project timeline was adjusted to allow for greater flexibility in meeting deadlines. Despite these adjustments, participants successfully completed their tasks, applying the theoretical knowledge they had gained to their respective assignments. As of April 2024, the initiative has culminated in 3 published papers and 3 more under peer review. The project has also seen an increase in student interest in further involvement and self-paced learning.

Conclusions: This initiative leverages globally accessible resources for research training, effectively fostering research competency among participants. It has successfully demonstrated the potential for undergraduates to contribute to medical research output and paved the way for a self-sustaining, student-led research program. Despite some logistical challenges, the project provided valuable insights for future implementations, showcasing the potential for students to engage in meaningful, publishable research.

Introduction

Undergraduate medical students frequently face limited opportunities for hands-on research experience [1,2]. Current medical school curricula often fail to equip students adequately with fundamental scientific research skills. Despite a high proportion of students expressing interest in research, only a small fraction possesses a thorough understanding of the medical research process [3]. In addition, empirical evidence underlines the contribution of undergraduate research engagement to career progression in medicine [4]. Consequently, medical students,

cognizant of research's significance, are increasingly seeking opportunities to augment their involvement [5]. To facilitate this quest, various course-based undergraduate research experience (CURE) programs have emerged, albeit with room for further refinement [6].

The emergence of remote learning, coupled with the proliferation of web-based platforms and open-access journals, has amplified data accessibility and the availability of research tools. This shift has catalyzed scientific literacy development and enabled self-paced learning among students across diverse disciplines. Students can now opt for extracurricular web-based

courses or access materials of varying media to deepen their understanding of selected topics, acquire new skills, and enhance their overall capabilities. Beyond an individualistic approach, web-based platforms have simplified the process for students to find groups for information exchange, thereby bolstering their scientific understanding. The Cerrahpasa Neuroscience Society, a student-led organization, hosts 4 journal clubs wherein students gather online to discuss neurosurgery, neurology, psychiatry, and neuroscience through selected papers and subsequent discussions [7]. The primary aim of this research initiative is to stimulate and mentor students within these journal clubs to undertake their own research projects, leveraging a structured program replete with experienced near-peer guidance and comprehensive information access. The program's ultimate objective is the inception and publication of fully student-run studies and papers in peer-reviewed journals, marrying theoretical knowledge with research fundamentals in a hands-on setting.

Our organizing team, composed of 1 second-year and 2 final-year medical students (MK, ZO, and BBO), sought to exploit the omnipresence of information and the scientific curiosity of journal club participants. We embarked on a pilot project with the clear ambition of significantly enhancing the research output of undergraduate medical students.

Methods

Ethical Considerations

Ethical approval was deemed unnecessary by the Istanbul University-Cerrahpasa — Cerrahpasa Faculty of Medicine

Table . Study types and topics selected for research project implementation.

Journal club subject and study type	Research topic
Neurosurgery	
Systematic Review	Medulloblastoma subgroup classification with radiomics
Systematic Review	Radiosensitizing agents in medulloblastoma
Neurology	
Original Study	Differentiation of SPMS ^a formation using machine learning
Systematic Review	The concurrence of multiple sclerosis and glioblastoma
Psychiatry	
Original Study	Medical student stress, burnout, and depression in Turkey
Original Study	Substance use and mental health among medical students in Turkey
Neuroscience	
Original Study	Adolescents' sleep and academic standing
Systematic Review	Neuropsychological outcomes following radiation therapy of pediatric posterior fossa tumors

^aSPMS: secondary progressive multiple sclerosis.

Study type selection was based on practical considerations and journal club subjects. Two systematic reviews were assigned

Institutional Review Board as the survey responses were anonymous and participants consented to their data being used for research purposes. Participants' data were anonymized and no compensation was provided for the participants. In addition, the data originated from the activities of the Cerrahpasa Neuroscience Society, which were conducted remotely and independently of the university.

Planning

The project involved participants exclusively from the journal clubs, encompassing undergraduate medical students from various Turkish medical faculties and academic levels. We presented the project idea to all club members in December 2021, with 30 of the 40 members volunteering to partake in the project.

As the organizing committee, we compiled a series of introductory papers and vetted web-based courses centered around research fundamentals, which we arranged into scheduled training modules ([Multimedia Appendices 1 and 2](#)). We slated monthly briefings to guide and track participants' progress, consistent with the project timeline. The final-year students in the organizing team (hereafter referred to as "the tutors"), who had accrued prior research experience, pinpointed research topics appropriate for undergraduate projects ([Table 1](#)).

to the neurosurgery journal club, as conducting original studies in this field would pose challenges for undergraduate students.

The psychiatry journal club was tasked with creating 2 original studies using survey methods, whereas the neurology and neuroscience journal clubs were each assigned 1 systematic review and 1 original study. The project was planned to be entirely online, spanning 6 months from January 2022 to June 2022.

Implementation

In January 2022, participants from the 4 journal clubs were segregated into 2 groups based on their chosen study type: original papers or systematic reviews, resulting in 8 project groups. Each group, composed of 3 - 5 students, incorporated journal club participants and the clubs' tutors. The project was guided by academic supervisors, who ensured methodological rigor and provided expert advice on the research topics. Tutors BBO and MK, both final-year medical students with prior research experience, actively identified suitable research questions, led regular web-based meetings, provided ongoing feedback, responded to participants' queries, and facilitated navigation through the various stages of the research projects. Communication within these groups was facilitated through web-based chat platforms, with the organizing team included.

The educational materials for the project were meticulously selected based on the tutors' personal experiences and an extensive review of available web-based resources. This process ensured that the materials were both relevant and of high educational quality. Following their initial briefing on project fundamentals and expectations, participants embarked on the first training module intended to acquaint them with research basics ([Multimedia Appendix 1](#)). This module contained a video series on using PubMed and Zotero (Center for History and New Media at George Mason University), along with 6 papers detailing the general steps of a research project. Participants were encouraged to complete these materials at their own pace within a 1-month time frame.

In February 2022, we classified tasks into 3 categories: "literature review and data extraction," "statistical analysis," and "manuscript writing." Participants were allocated these tasks primarily based on their skills and interests. The second training module offered specific web-based courses for these tasks ([Multimedia Appendix 2](#)). Unlike the first module, the deadline for the second module was tailored to each participant's task timeline. During monthly web-based briefings, the tutors provided assistance and feedback while illustrating task examples. Furthermore, tutors guided participants in ancillary tasks such as database access and ethics committee application form preparation.

Unexpected constraints led us to revise some study designs and the schedule. Two projects—a systematic review and an original study requiring database access—were discontinued and substituted with bibliometric analysis projects, supplemented by additional peer training. Heeding participant feedback, we also extended the original deadlines.

Bibliometric studies necessitated unique procedures, executed throughout March and April 2022 with regular briefings. In May 2022, a tutor conducted an auxiliary academic writing workshop. Although not every participant was tasked with study

documentation, we believed all could glean valuable insights from this near-peer workshop within the project's ambit. This workshop was made available to all participants, with a recorded version disseminated for those unable to attend the live session.

Results

The project began with 30 undergraduate medical students, some contributing to multiple projects, and concluded with 25 participants successfully adhering to the full schedule. Those who withdrew from the project did so during the implementation of the second module, necessitating adjustments in task assignments and study configurations. The 25 students successfully adhering to the full schedule were from 5 universities, with a significant concentration (18 students) at Istanbul University—Cerrahpasa. The remainder was distributed to 4 other universities. Ten of these participants were enrolled in English language medical programs. The cohort consisted of 19 preclinical students, who were primarily enrolled in basic medical sciences courses, and 6 clinical students, who were completing clerkships and internships. The group included 14 female and 11 male students. None of the students had previous research experience.

The completion of the first module was gauged through participants' feedback on the materials and their demonstrated proficiency in operating the platforms integrated into the module. Given that the second module encompassed verified web-based courses, completion was monitored via certifications from the respective platforms. As this module required the practical application of learned theoretical skills, successful task execution within the research study denoted each participant's successful project completion.

Participants tasked with "literature review and data collection" and "statistical analysis" adeptly applied their theoretical knowledge acquired from the courses and briefings, creating necessary data tables and thus fulfilling their tasks. Owing to requisite timeline adjustments, those delegated to academic writing courses completed their tasks at disparate times relative to the original schedule. Nevertheless, manuscript creation for all studies was achieved, signifying that all participants made their respective contributions to the project.

During the implementation phase, we made some timeline alterations in response to student feedback, with participants requesting more accommodating deadlines. The tutors, who had previously conducted independent research projects, provided substantial support throughout the project's execution. They shared their experiences and offered guidance, aiding participants in gaining a deeper understanding of their tasks. Upon the conclusion of second module training, participants shared feedback on the project's implementation. As of April 2024, 3 papers have been published in peer-reviewed journals [8-10], and 4 papers have been submitted for peer review.

Discussion

Principal Findings

A multi-institutional study revealed that although 83% of the students surveyed believed that participating in research was

educationally beneficial, only 31% thought that there was enough time allocated for it. In addition, just 15% felt that they received adequate training in research methodology, and only 25% considered the training in critical appraisal to be sufficient [11]. CUREs may help alleviate some of these issues, potentially improving access to both time and quality instruction in research skills. In parallel, CUREs have been adopted in universities to inspire students to pursue research, although these programs predominantly involve student participation in laboratory settings for data collection [6]. Efforts to enhance student contributions to research include a microbiology research initiative at a Canadian university aimed at publishing student-authored papers [12] and remote CUREs focusing on ecology at a US university [13]. However, our program offers a distinct approach.

The pilot project's foremost insight is the successful operation of a fully student-run research program, from the training process to paper publication, using a method that is universally applicable to students interested in research. Instead of creating new lectures, we leveraged preexisting, verified web-based resources on research basics for our training modules. This strategy emphasizes the global accessibility of research training for students, as these resources are publicly available and facilitate self-paced learning. Notably, our research initiative aimed to exploit information accessibility not just only for skill acquisition but also for data collection to complete a research project. As undergraduate medical students have limited access to hands-on research, effectively using available information is crucial. To underscore global applicability and facilitate research involvement, the data used were sourced from 2 web-based platforms: academic literature and web-based surveys. Our project enabled the conduct of both systematic reviews and original studies by students lacking prior hands-on research experience, thereby enhancing student research output through remote involvement.

Regarding skill development, the project achieved the anticipated results. All participants completed their respective tasks, culminating in the production of completed manuscripts. This outcome demonstrates a tangible enhancement in participants' research skills, particularly considering their nonexistent prior research experience. It is critical to note that participants did not receive identical training; instead, a division of labor was used. Participants learned about and practiced various aspects of research study design, with the project's methodology allowing them to hone their skills in their chosen task within a study. As an immediate benefit, some participants expressed interest in completing the remaining web-based courses to further their skills, suggesting potential for project continuation. Feedback indicated a keen interest in furthering the concept. For instance, students initially assigned to work with databases expressed a desire to design and conduct a study upon completing their current work. Previous research suggests that students gain an improved understanding of the benefits of research following participation, and our project participants' enthusiasm supports this finding [14].

A key success factor was the experienced near-peer tutoring that accompanied the project's full duration. The final-year students on the organizing team designed the project outline,

selected suitable research questions, monitored progress, and provided guidance as needed. Monthly briefings fostered an environment where participants reported progress and posed questions. Within these meetings, tutors also demonstrated tasks to facilitate student understanding. Participants gained comprehensive insight into the research process by first completing a course, then practicing an example task, and finally executing their respective tasks independently. Participant feedback suggested that near-peer tutoring facilitated question asking, contributing to a comfortable learning environment. Overall, including student guidance in the initiative increased the efficiency of the modules, as also affirmed by participants.

A significant advantage of the project's design is its potential for self-sustainability. The students trained during this pilot project now have the experience to guide subsequent student cohorts looking to enhance their research skills. They can also offer fresh ideas for improving the training modules based on their experiences. Through this cyclical process, we aim to establish a fully student-led research group that cultivates student training, ultimately enhancing medical students' research skills, experience, and productivity.

Research interest among medical students has been found to diminish as they advance through their academic years [15]. Our study supports these findings somewhat, as the majority of our cohort consisted of 19 preclinical students, compared with just 6 clinical students who were involved in clerkships and internships. To counteract this decline, efforts to promote research could be strengthened throughout their university education, potentially through the integration of CUREs. In addition, research indicates a decrease in the number of clinician-scientists in the United Kingdom, attributed partly to an inadequate influx of individuals into the "clinician-scientist pipeline" to replenish an aging workforce [16]. CUREs could potentially boost enthusiasm and familiarity with research, encouraging more individuals to pursue these career paths. Finally, although empirical evidence on the impact of student-led initiatives in academic medicine is limited, their widespread acceptance and popularity may suggest that students recognize a need for these programs and gain some value from participating in them [17]. Our study addresses this gap and serves as a call to action for policy makers.

Limitations

As a pilot project, this research initiative revealed several areas needing revision and adjustment alongside the desired outcomes. First, the journal club's membership was self-selected, which is likely to have influenced the project's results. Participants were predisposed to be more motivated and interested in research, which may have increased engagement and contribution quality. This self-selection helped the project succeed by ensuring that participants were highly committed. However, it introduced a potential selection bias, reducing the generalizability of our findings. The predominance of motivated individuals may not accurately reflect the larger medical student population, particularly those who are less inclined or confident in conducting research. Moreover, while the publication of research papers by participants is an objective indicator of the project's success, it is acknowledged that publication does not

fully capture the breadth of research competencies sought by this program. Focusing solely on publication outcomes has the potential to overlook broader research skills such as ethical considerations, data management, and long-term research planning, all of which are critical to the sustainability of research practices. While we emphasized the importance of ethical considerations during our sessions, it is important to remember that the primary goal of our research was to help students take their first steps into the world of research. As a result, while we acknowledge the project's scope and depth of limitations, it effectively served as an entry point for participants, many of whom had no prior research experience, to begin engaging with the research process.

Furthermore, various challenges surfaced during the project's execution, leading to alterations in specific project elements and deadline extensions. One of these challenges was the inability to gain access to databases initially planned for original research study designs. Our requests were not met with a positive response, necessitating a change in the content and methodology of the projects requiring such access. For future iterations, we intend to include study proposals that leverage access to these databases. Another unexpected obstacle was the delay in obtaining ethical committee approvals for survey studies. This issue was not factored into the original timeline and, in light of this experience, we will allow for greater flexibility in project schedules moving forward. The project implementation process highlighted key factors that require consideration to ensure the project's sustainability and ease of execution. One significant challenge was coordinating teamwork among participants with varied schedules. Sticking to the initial timeline was difficult for all participants, leading us to recommend gathering schedules beforehand and grouping students with similar availability together for future implementations. Decreased commitment from some participants was another issue. Over the course of the lengthy project, some

students withdrew, primarily due to time constraints. This situation required the reassignment of certain tasks and additional courses for some students. Also, the project targeted a small, specific group of students and lacked a selection process. To address this, we propose the inclusion of an application process for more efficient training in future iterations. Another limitation was the lack of active engagement from participants in the question design. The tutors provided guidance and designed the research questions themselves as a starting point. Adding a course on this topic in future iterations could foster more active involvement from participants, thereby potentially improving project outcomes. Finally, dividing tasks among participants posed challenges in ensuring full research competency for all, as each participant focused on specific aspects of the project.

Conclusions

This project effectively capitalized on the widespread accessibility of information to educate and enable students to partake in medical research, irrespective of their lack of direct hands-on experience. This approach carries significant weight as it equips students with the skills to draw data from preexisting studies, thereby exploiting the incremental nature of science. In addition, this method provides students from campuses with limited access to research facilities the opportunity to acquire experience in conducting a scientific project. Despite the encountered challenges, the project was successfully implemented, resulting in a notable advancement of the research skill set among previously inexperienced students. This translated into a demonstrable increase in undergraduate research output. The limitations identified during the project's course provide a crucial understanding for improving future iterations of this initiative. Our goal is to perpetually refine and use this project as a supplement to traditional medical training, thus providing students with a keen interest in research the opportunity for self-paced learning and research training.

Acknowledgments

We would like to thank all Cerrahpasa Neuroscience Society members who contributed to the journal club meetings and this project. This project was funded by the Association for Medical Education in Europe (AMEE), as a part of the Student Initiative Grant Awards (SIGA) 2022.

Abstract

Background: Evidence-based practice (EBP) is an important aspect of the health care education curriculum. EBP involves following the 5 EBP steps: ask, assess, appraise, apply, and audit. These 5 steps reflect the suggested core competencies covered in teaching and learning programs to support future health care professionals applying EBP. When implementing EBP teaching, assessing outcomes by documenting the student's performance and skills is relevant. This can be done using mobile devices.

Objective: The aim of this study was to assess occupational therapy students' EBP skills as reported in a mobile app.

Methods: We applied a cross-sectional design. Descriptive statistics were used to present frequencies, percentages, means, and ranges of data regarding EBP skills found in the EBPsteps app. Associations between students' ability to formulate the Population, Intervention, Comparison, and Outcome/Population, Interest, and Context (PICO/PICo) elements and identifying relevant research evidence were analyzed with the chi-square test.

Results: Of 4 cohorts with 150 students, 119 (79.3%) students used the app and produced 240 critically appraised topics (CATs) in the app. The EBP steps "ask," "assess," and "appraise" were often correctly performed. The clinical question was formulated correctly in 53.3% (128/240) of the CATs, and students identified research evidence in 81.2% (195/240) of the CATs. Critical appraisal checklists were used in 81.2% (195/240) of the CATs, and most of these checklists were assessed as relevant for the type of research evidence identified (165/195, 84.6%). The least frequently correctly reported steps were "apply" and "audit." In 39.6% (95/240) of the CATs, it was reported that research evidence was applied. Only 61% (58/95) of these CATs described how the research was applied to clinical practice. Evaluation of practice changes was reported in 38.8% (93/240) of the CATs. However, details about practice changes were lacking in all these CATs. A positive association was found between correctly reporting the "population" and "interventions/interest" elements of the PICO/PICo and identifying research evidence ($P < .001$).

Conclusions: We assessed the students' EBP skills based on how they documented following the EBP steps in the EBPsteps app, and our results showed variations in how well the students mastered the steps. "Apply" and "audit" were the most difficult EBP steps for the students to perform, and this finding has implications and gives directions for further development of the app and educational instruction in EBP. The EBPsteps app is a new and relevant app for students to learn and practice EBP, and it can be used to assess students' EBP skills objectively.

Introduction

Evidence-based practice (EBP) involves using the best available evidence from relevant research and integrating it with clinical expertise, patient values, and circumstances to make clinical decisions for individual patients [1]. When applying EBP, it is recommended to follow the five EBP steps: (1) identifying information needs and formulating answerable questions (ask), (2) finding the best available evidence to answer clinical questions (assess), (3) critically appraising the evidence (appraise), (4) applying the results in clinical practice (apply), and (5) evaluating performance (audit) [1,2]. These 5 steps reflect the suggested core competencies covered in teaching and learning programs to support future health care professionals applying EBP, including developing EBP knowledge and skills [3].

EBP skills can be understood as applying EBP knowledge by performing EBP steps, ideally in a clinical setting [4]. The literature indicates that EBP knowledge and skills improve when EBP teaching and learning are multifaceted, interactive, clinically integrated, and incorporate assessment [5]. When implementing EBP teaching, it is relevant to document and assess the individual student's performance [3,5,6]. As it is recommended to follow all 5 EBP steps when teaching and learning EBP [1,2], measuring the performance of all 5 steps is relevant when evaluating EBP learning. However, few evaluation instruments measure all 5 EBP steps [5-9], and most instruments are self-reported questionnaires [6,7]. The use of self-reported questionnaires may contribute to biased results due to recall bias or social desirability responses [9,10]. Objectively measuring EBP learning could result in a true

reflection of the situation, and thus, it is recommended to develop objective tools for EBP learning assessment [6,7,11]. To objectively document the performance of the EBP steps, Shaneyfelt et al [6] emphasized using online documentation. Online documentation is feasible through mobile apps, and innovative new methods to evaluate EBP teaching can now be explored [12]. Most students own a smartphone, which makes mobile learning and information sharing possible [13,14]. Thus, mobile apps can potentially be used for documenting and assessing students' EBP performance. The aim of this study was to assess occupational therapy (OT) students' EBP skills as reported in a mobile app.

Methods

Design

This study used a cross-sectional design. The reporting of this study followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) checklist ([Multimedia Appendix 1](#)) [15].

Mobile App

A mobile web app called the EBPsteps app was developed at the Western Norway University of Applied Sciences (HVL) to support health and social care students' EBP learning [16]. An updated version of this web app is now freely available as a native app [17]. Experiences with using the EBPsteps app for learning EBP have previously been explored [16]. The app provides an opportunity for students to document the 5 EBP steps. A description of the content of the EBPsteps app is presented in [Textbox 1](#).

Textbox 1. The EBPsteps app content.

<p>Ask</p> <ul style="list-style-type: none"> • Reflect on information needs • Formulate the clinical question • Identify the type of clinical question (drop-down menu) • Identify the Population, Intervention, Comparison, and Outcome/Population, Interest, and Context (PICO/PICo) elements <p>Assess</p> <ul style="list-style-type: none"> • Report information source used to identify research evidence • Report links to research evidence identified <p>Appraise</p> <ul style="list-style-type: none"> • Choose a relevant critical appraisal checklist • Complete the critical appraisal using the integrated checklist <p>Apply</p> <ul style="list-style-type: none"> • Report how research evidence was applied in practice (drop-down menu) <p>Audit</p> <ul style="list-style-type: none"> • Report if changes in practice were completed and evaluated • Describe changes if changes were implemented • Evaluate the EBP process (ask, assess, appraise, apply, and audit)
--

By documenting the EBP process in the app, students produced critically appraised topics (CATs). A CAT can be explained as a summary of research evidence on a clinical question [18]. The CATs completed in the EBPsteps app included information on all EBP steps, and the CATs could be sent through email and shared as a PDF document. The CATs produced in the app were stored on the HVL research server and were accessible to the researchers in this project.

Participants

A total of 4 cohorts of fifth-semester OT students from different academic years (from 2018 to 2021) at HVL were eligible for inclusion if they used the EBPsteps app.

Setting

In Norway, OT education is a 3-year bachelor's degree of 6 semesters (180 European Credit Transfer System [ECTS]). According to the Norwegian national curriculum, all health and social care students must be able to acquire new knowledge and make professional assessments, decisions, and actions in line

with EBP [19]. At the time of this study, EBP was well integrated into the OT bachelor's degree program at HVL [20].

Textbox 2 provides an overview of the total number of standalone EBP sessions (n=27) that OT students in this study received by their fifth semester (year 3). This amount of EBP teaching hours is a high number [21]. In addition, EBP was integrated into other learning activities, such as problem-based learning (PBL) group activities, written assignments, and exams.

Using the EBPsteps app was part of the EBP teaching. Students were introduced to the app at the start of the fifth semester. The students watched a video presentation of how to use the app and explored using the app while being supervised by a teacher. During the fifth semester, the students were encouraged to use the EBPsteps app on campus (4 weeks) and during clinical placements (11 weeks). While on campus, students had to use either the EBPsteps app or a Microsoft Word document to complete a mandatory EBP assignment that involved producing a CAT on a clinical topic. Similarly, at the end of the semester, an appendix to the home exam was to use either the EBPsteps app or a Word document to produce a CAT.

Textbox 2. Overview of standalone EBP sessions. Year 3 includes sessions given through the fifth semester only. EBP: evidence-based practice.

Year 1

- Standalone sessions about “ask” (2 hours) and “assess” (2 hours). Total duration is 4 hours.

Year 2

- Standalone sessions about “ask” (1 hour), “assess” (1 hour), “appraise” (3 hours), and “apply” (2 hours). Total duration is 7 hours.

Year 3

- Standalone sessions about “ask” (2 hours), “assess” (2 hours), “appraise” (8 hours), “apply” (3 hours), and “audit” (1 hour). Total duration is 16 hours.

Data Collection

CATs produced by students during the fifth semester were exported from students' user accounts in the EBPsteps app to Microsoft Excel [22] at the end of the semester. The Norwegian data, anonymized by authors, are freely available through HVL Open [23] and include our assessment. To objectively assess students' EBP skills based on how they documented the EBP

process in the app, we developed a scoring plan for each EBP step in the CATs (**Multimedia Appendix 2**). The different steps of the CATs were assessed as correct or incorrect, which were the outcomes investigated in this study. Two researchers independently scored each CAT, and disagreements were resolved through discussion. An overview of the scoring plan is presented in **Textbox 3**.

Textbox 3. Overview of the scoring plan. Includes the EBP steps and what was assessed. EBP: evidence-based practice.

<p>Ask</p> <ul style="list-style-type: none"> • Was it reflected on the information needs? • Which clinical question was formulated (eg, prevalence, cause, diagnostics, effect of measures, prognosis, or experiences and attitudes)? • Which clinical question was identified (drop-down menu)? • Was there an agreement between the formulated clinical question and the type of question identified from the drop-down menu? • Was the “population” of the Population, Intervention, Comparison, and Outcome/Population, Interest, and Context (PICO/PICo) correctly reported? • Was the “intervention/interest” of the PICO/PICo correctly reported? • Was the “comparison” of the PICO/PICo correctly reported? • Was the “outcome/context” of the PICO/PICo correctly reported? <p>Assess</p> <ul style="list-style-type: none"> • Which information sources were used (BMJ Best Practice, Cochrane Library, PubMed, etc)? • Was a link to research evidence reported? • Was there an agreement between the information source used and the identified research evidence? <p>Appraise</p> <ul style="list-style-type: none"> • Was there an agreement between the identified research evidence and the chosen critical appraisal checklist used? • Were the questions in the checklist completed? <p>Apply</p> <ul style="list-style-type: none"> • Was the application of the research evidence reported (drop-down menu)? • If reported applied, was this described? <p>Audit</p> <ul style="list-style-type: none"> • Were changes in practice evaluated? • Was the EBP process evaluated?
--

Analysis

Descriptive statistics were used to summarize the assessment of students' EBP skills based on the completed CATs, including frequencies and percentages for categorical variables and mean and range for continuous variables. Associations between correctly reporting the Population, Intervention, Comparison, and Outcome/Population, Interest, and Context (PICO/PICo) elements and finding research evidence were analyzed with the chi-square test with adjustment for repeated measurements [24]. The significance level was set at 5%. Statistical analyses were performed with SPSS Statistics (version 28.0; IBM Corp) [25] and R (R Foundation for Statistical Computing) [26].

Ethical Considerations

The Norwegian Agency for Shared Services in Education and Research approved the study (project 50425). The students were informed, both orally and in writing, about the purpose of this study and that the data would be treated confidentially. The students agreed to participate in the study and signed a consent form when they created a profile and used the EBPsteps app. The students did not receive any compensation for participating. Students could choose to use the app or a Word document to

complete assignments where it was required to produce CATs. The data were securely stored on the research server at HVL.

Results

Participants

Among 4 cohorts with OT students, 79.3% (119/150) of students used the EBPsteps app during their fifth semester. The students who used the app produced 240 CATs. In the first cohort (2018), 41 of 47 students produced 73 CATs; in the second cohort (2019), 25 of 30 students produced 53 CATs; in the third cohort (2020), 21 of 33 students produced 43 CATs; and in the fourth cohort (2021), 32 of 40 students produced 71 CATs. The mean number of CATs produced per student was 2, with a range from 1 to 7.

Step 1: Ask

A need for more knowledge on a clinical problem was reported in 94.6% (227/240) CATs. In 80% (192/240) of the CATs, the type of clinical question was identified using a drop-down menu. A clinical question was formulated in 53.3% (128/240) of the CATs. The “effect of therapy” was the most prevalent clinical question reported (100/240, 41.7%) (Table 1).

All PICO/PICo elements were reported correctly in 10.4% (25/240) of the CATs. Assessing the different PICO/PICo elements separately, the “population” and “intervention/interest” elements were more often correctly reported (187/240, 77.9% and 189/240, 78.8%) than the “comparison” and

“outcome/context” elements (44/240, 18.3% and 103/240, 42.9%). This applied to all question types, including when the question had been formulated as a background question (Table 1). In CATs without a clinical question identified, most PICO/PICo elements were incorrectly reported.

Table 1. Correctly reported Population, Intervention, Comparison, and Outcome/Population, Interest, and Context (PICO/PICo) elements by type of question in 240 critically appraised topics.

	Population, n (%)	Intervention/interest, n (%)	Comparison, n (%)	Outcome/context, n (%)
Effect of therapy (n=100)	90 (90)	96 (96)	30 (30)	53 (53)
Qualitative (n=27)	25 (93)	25 (93)	N/R ^a	13 (48)
Background (n=64)	55 (86)	52 (81)	11 (17)	32 (50)
Other (n=1) or missing (n=48)	17 (35)	16 (33)	3 (6)	5 (10)

^aNot relevant.

Step 2: Assess

In 240 of the CATs, the information source most frequently reported was the Cochrane Library (65/240, 27.1%), followed by CINAHL (43/240, 17.9%), PubMed (36/240, 15%), and Epistemonikos (17/240, 7.1%). In 12.9% (31/240) of the CATs, no information source was reported. Research evidence was identified and linked to in 81.3% (195/240) of the CATs, and the most common type of research evidence identified was systematic reviews (n=85), randomized controlled trials (RCTs; n=51), and qualitative research (n=44).

We observed a positive association between correctly reporting “population” and “intervention/interest” elements of the PICO/PICo and identifying research evidence. Among those correctly reporting the population element, 92.1% (221/240)

identified research evidence, compared to 52.1% (125/240) among those that did not report the population element ($P<.001$). Similar findings were observed for the intervention/interest element.

Step 3: Appraise

A checklist was used in 81.3% (195/240) of the CATs. Of these, the correct checklist was used in 84.6% (165/195) of the CATs; that is, there was agreement between the type of checklist and the research evidence identified (Table 2).

In 98.2% (162/165) of the CATs with a correct checklist, more than 75% of the checklist questions had been answered. Effect estimates from identified research evidence were documented in 27% (21/77) of the checklists for systematic reviews and 36% (15/42) of the checklists for RCTs.

Table 2. Type of research evidence identified and agreement with choice of checklist.

Type of research evidence	The agreement between research evidence and checklist, n (%)
Systematic reviews (n=85)	77 (89)
Randomized controlled trials (n=51)	42 (82)
Qualitative research (n=44)	42 (95)
Guidelines (n=4)	2 (50)
Observational studies ^a (n=11)	2 (18)
The total number of research evidence identified (n=195)	165 (84.6)

^aIncluded the following study designs: prevalence (n=1), diagnostic (n=1), cohort (n=3), case-control (n=1), and cross-section (n=5).

Step 4: Apply

In 39.6% (95/240) of the CATs, it was reported that research evidence was applied in clinical practice. How the research was applied was described sufficiently in only 61% (58/95) of these CATs.

The most common shared decision-making approach reported from a drop-down menu was “identifying preferences” (78/240, 32.5%) and “exploring possibilities” (78/240, 32.5%). Other shared decision-making approaches reported were “presenting choices” (48/240, 20%) and “recommendations” (46/240, 19.2%), “discussing potential” (45/240, 18.8%), “deciding

follow-up” (28/240, 11.7%), and “checking recommendations” (24/240, 10%).

Step 5: Audit

Evaluation of practice changes was reported in 38.6% (93/240) of the CATs. However, details of practice changes were lacking in all these CATs. In 46% (43/93) of the CATs that reported evaluation, it was reported, “did not change practice,” and in 54% (50/93) of these CATs, it was reported that it was “not relevant to change practice.” The EBP process was reported as evaluated in 54.6% (131/240) of the CATs.

Discussion

Principal Findings

This study assessed OT students' EBP skills as reported in the EBPsteps mobile app. We found that students were most often able to perform the EBP steps of "ask," "assess," and "appraise" correctly. A positive association was found between formulating the PICO/PICO elements and identifying research evidence. Applying the evidence and evaluating practice change were the least frequently correctly reported steps of the EBP process.

Comparison to Previous Work

Using data from the EBPsteps app, where students had documented how they followed the EBP process for their clinical question, enabled us to collect objective data on students' EBP skills. Instruments that objectively measure EBP skills are recommended for acquiring a true reflection of the situation [6,7,11], as opposed to more frequently used self-report assessment tools [6,7]. Although objective assessment is advised, it can be time-consuming to complete and assess [4]. Consequently, self-reported questionnaires are often chosen because of their practicality of administration [9]. Developing an easy-to-administer scoring plan for the EBPsteps app has therefore been important. Against this background, the EBPsteps app can be a valuable contribution to objectively assessing EBP skills related to all 5 steps of the EBP process.

Ask and Assess

We found a positive association between correctly reporting population and intervention/interest elements of the PICO/PICO and finding research evidence, indicating that completing the PICO/PICO supports students' ability to retrieve relevant research evidence. These findings align with previous research reporting that a clearly defined question supports students' ability to retrieve relevant information [27,28]. Furthermore, structuring the question using the PICO/PICO format makes it easier to decide on search terms [2].

Appraise

The appropriate critical appraisal checklist was chosen in 68.8% (165/240) of the CATs in this study. Nevertheless, few effect estimates were reported in checklists for RCTs and systematic reviews. This might suggest that the students had difficulties interpreting the statistical results. Lack of confidence in interpreting statistical results has previously been reported among health and social care students [29,30]. Acquiring an understanding of effect estimates is necessary when applying EBP [3], and spending more time teaching the understanding of research results to support the students learning and interpretation of research results is recommended [31].

Apply and Audit

Only about half of the students in this study reported that they applied the research evidence they found, indicating that they struggled using EBP skills beyond the classroom setting, which also correlates with previous research [32,33]. Lehane et al [34] suggest that structural incorporation of EBP during clinical placement, for instance, through easy access to research, EBP mentors, or regular journal clubs, may support the students in

applying research evidence. In addition, incorporating assessment of EBP into clinical placement has been shown to influence EBP behavior [5]. In this study, EBP assignments were mandatory in class but not during clinical placement, which may explain why students in this study struggled with the steps of applying and evaluating practice. Providing a mandatory EBP assignment during the clinical placement may support the students in applying EBP and thus also mastering the 2 last steps of the EBP process.

An alternative explanation for why students struggled with the steps of applying and evaluating practice could be that they experienced fatigue or other difficulties using the app. To explore whether other issues influenced students' skills, we could have further tested the usability of the app. When developing mobile apps for teaching and learning, usability testing is important [35]. Other research methods are necessary to investigate why the 2 last steps of the EBP process were less frequently completed. Future research should include cognitive interview studies (eg, think-aloud methods) and other pilot studies in different populations to evaluate the comprehensiveness and comprehensibility of the app.

Future Directions

Knowledge of which EBP steps students find most challenging has implications and gives directions for further development of the EBPsteps app and educational instruction in EBP. For example, providing a more comprehensive explanation of how to interpret statistical results in the app could be beneficial. In addition, spending more time teaching statistics and how to read the results seems necessary to improve students' EBP performance.

A better alignment between what is taught during classes on campus and what students do at placements could also perhaps better facilitate EBP behavior among students. A mandatory assignment where research evidence must be found and discussed with the clinical instructors may help the students apply and evaluate the use of research evidence during clinical placement.

Currently, the EBPsteps app is available only in Norwegian. In the future, we aim to provide user interface translations for several languages [16]. However, we will need to modify options in the app according to the free access resources available in the different countries (eg, databases, guidelines, and e-learning resources). Efforts will be made to find the best solution and to accommodate needs in low- and middle-income countries.

Methodological Considerations

The main limitation of this study was that we included students from only one profession and from the same educational institution, and thus the generalizability of the results to other institutions and to other health and social care students is reduced. However, the sample consisted of 4 student cohorts from different academic years (from 2018 to 2021; n=119), including 240 CATs. Accordingly, we believe the results from this study can be recognizable and relevant across other populations.

A strength of this study was that the EBPsteps app allowed us to objectively measure the performance of the EBP process using an app that includes all 5 EBP steps. It is recommended that educators select instruments that objectively measure EBP performance [11]. Shaneyfelt et al [6] emphasized the use of online documentation of the EBP steps as a promising approach.

Another strength was that 2 researchers assessed the CATs independently based on a scoring plan, and disagreement was solved through discussion. However, the EBPsteps app and the scoring plan are not validated for assessing EBP, and measurement properties should be examined in future studies.

Conclusions

We assessed the students' EBP skills based on how they documented following the EBP steps in the EBPsteps app, and our results showed variations in how well the students mastered the steps. "Apply" and "audit" were the most difficult EBP steps for the students to perform, and this finding has implications and gives directions for further development of the app and educational instruction in EBP. The EBPsteps app is a new and relevant app for students to learn EBP and can be valuable for assessing EBP skills objectively.

Acknowledgments

The authors would like to thank Johannes Mario Ringheim at Medialab, HVL, for the programming and technical development of the EBPsteps app and data extraction from the EBPsteps app for this study. In addition, the authors would like to thank all the students who participated in the study and used the EBPsteps app.

Data Availability

The Norwegian data, anonymized by the authors, are publicly and freely available through HVL Open [23].

Authors' Contributions

SGJ and NRO conceptualized this study. NRO was responsible for the funding of the study, and the initial analysis of the results and the project administration were performed by SGJ and NRO. The formal analysis was conducted by SGJ and BE. SGJ, BE, LL, DC, and NRO decided on the methodology. SGJ, BE, and NRO provided resources. Validation was done by SGJ, BE, and NRO, and visualization by SGJ and NRO. The writing of the original draft was done by SGJ, and review and editing were done by SGJ, BE, LL, DC, and NRO.

Abstract

Background: The COVID-19 pandemic has highlighted the growing relevance of telehealth in health care. Assessing health care and nursing students' telehealth competencies is crucial for its successful integration into education and practice.

Objective: We aimed to assess students' perceived telehealth knowledge, skills, attitudes, and experiences. In addition, we aimed to examine students' preferences for telehealth content and teaching methods within their curricula.

Methods: We conducted a cross-sectional web-based study in May 2022. A project-specific questionnaire, developed and refined through iterative feedback and face-validity testing, addressed topics such as demographics, personal perceptions, and professional experience with telehealth and solicited input on potential telehealth course content. Statistical analyses were conducted on surveys with at least a 50% completion rate, including descriptive statistics of categorical variables, graphical representation of results, and Kruskal Wallis tests for central tendencies in subgroup analyses.

Results: A total of 261 students from 7 bachelor's and 4 master's health care and nursing programs participated in the study. Most students expressed interest in telehealth (180/261, 69% very or rather interested) and recognized its importance in their education (215/261, 82.4% very or rather important). However, most participants reported limited knowledge of telehealth applications concerning their profession (only 7/261, 2.7% stated profound knowledge) and limited active telehealth experience with various telehealth applications (between 18/261, 6.9% and 63/261, 24.1%). Statistically significant differences were found

between study programs regarding telehealth interest ($P=.005$), knowledge ($P<.001$), perceived importance in education ($P<.001$), and perceived relevance after the pandemic ($P=.004$). Practical training with devices, software, and apps and telehealth case examples with various patient groups were perceived as most important for integration in future curricula. Most students preferred both interdisciplinary and program-specific courses.

Conclusions: This study emphasizes the need to integrate telehealth into health care education curricula, as students state positive telehealth attitudes but seem to be not adequately prepared for its implementation. To optimally prepare future health professionals for the increasing role of telehealth in practice, the results of this study can be considered when designing telehealth curricula.

Introduction

Background

Telehealth has become increasingly important in recent years, particularly considering technological and societal developments. Telehealth is the use of information and communications technologies to deliver health services where there is a physical separation between care providers or recipients over both long and short distances [1]. It has the potential to help overcome barriers to accessing care, particularly in remote or underserved areas [2], and can be particularly beneficial for patients with chronic diseases [3] to improve long-term adherence [4], as well as addressing shortages in the health care workforce [5]. Owing to the COVID-19 pandemic, the integration of telehealth into the services of health care providers was further increased to prevent further infections and to serve patients in isolation [6-10].

However, the growing use has further highlighted the need for telehealth education for health care providers [11-16]. To successfully and sustainably implement telehealth and subsequently reap the benefits, it is necessary to integrate telehealth into the curricula of future health care providers [5]. A lack of knowledge and experience, as well as a lack of appropriate telehealth training, have been identified as major barriers to telehealth implementation among health care providers [17]. Conversely, telehealth education and training can increase the willingness to adopt telehealth, the perceived readiness, and confidence [5,13,18-20].

Providing telehealth services not only requires a basic understanding of telehealth and its applications but also an assortment of competencies spanning from theoretical knowledge to practical skills, closely mirroring the concepts of Miller pyramid of clinical competence [21] or its adapted version, the Miller prism [22]. As they outline, there are different levels of competence, such as knowledge, skills, and attitudes. In terms of telehealth competencies, *knowledge* involves the basic understanding of telehealth, its tools, and its applications. This also includes knowledge on how to ensure privacy and confidentiality [11,23-27]. The second competence level *skills* refers to the know-how. In telehealth, it requires health care professionals to organize and apply their knowledge to conduct physical assessments via telehealth, make perceptive observation-based examinations, and communicate effectively in a nontraditional clinical setting

[5,10,11,15,16,19,23,24,26-29]. In the *performance* or *show* level, professionals demonstrate their ability to select, implement, and use appropriate telehealth tools in a simulated or controlled environment. This is where technological skills become crucial [11,23-27]. Finally, at the *action* or *does* level, health care professionals are expected to perform these skills in real-life situations, providing high-quality and safe telehealth services, and effectively incorporating ethical considerations into their practice [23-25]. *Attitude* is considered a vital component, along with knowledge, skills, and performance, that contributes to actual work competency. It refers to the behavioral and emotional aspects that influence how knowledge and skills are applied in practice [30]. *Attitude* can encompass elements such as motivation, ethical considerations, professionalism, and openness to learning, which seem to be important in the telehealth context.

In accordance with the principles of competency-based frameworks, curricula of health care study programs need to be adapted to qualify health care professionals at all levels of competency, increasing the probability that telehealth is effectively implemented in daily practice [11]. Two reviews [26,31] conducted in 2021 highlighted significant shortcomings in the training and curricula in allied health and nursing. They showed that there was a lack of consistency and absence of a systematic approach in integrating telehealth into these curricula [26,31]. Thus, it is crucial to design telehealth curricula with competency-based frameworks in mind to meet the diverse needs of students and ensure they are equipped with the necessary knowledge, performance skills, and attitude to effectively use telehealth technologies in their future health care practices. An increasing number of standards and guidelines are becoming available to guide the development of individual telehealth courses. They focus on various aspects such as administrative [32,33], ethical [32,34], clinical [32], technical [32,35], or soft skills [36]. However, they often do not address the specialized needs of allied health professionals [37]. Therefore, identifying the specific interests and learning needs of students can help educators to plan their teaching methods and provide tailored curricula or courses in individual study programs. This can further help to promote student engagement and motivation, ensure that the education is relevant and meaningful to their future professional practice, and ultimately improve learning outcomes.

Aim

The primary objective of this study was to assess the perceived telehealth knowledge, skills, attitude, and experience among health care professionals and nursing students to understand students' current self-assessed telehealth competencies and identify their learning needs. Our secondary objective was to evaluate students' preferences for telehealth content and teaching methods within their respective curricula. This dual focus is intended to provide a rounded perspective of the students' perceived readiness for telehealth practice and to inform effective educational strategies.

Methods

Study Design

We conducted an anonymous cross-sectional web-based survey among the total population of selected health care profession students at *FH Campus Wien* (University of Applied Sciences). Reporting followed the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) [38].

Sample Characteristics

Given the exploratory nature of this study, the sample size was not predetermined but was derived from the number of students enrolled in the targeted health care and nursing programs who were available and consented to participate during the survey period. At the time of the survey's release, 2273 students in the following selected academic health care professions were actively studying at the "FH Campus Wien" (University of Applied Sciences, Vienna, Austria) and were thus eligible to participate: BSc dietetics (DIE), BSc occupational therapy (OT), BSc health care and nursing (NUR), BSc midwifery (MID), BSc speech and language therapy (SLT), BSc orthoptics (ORT), BSc physiotherapy (PT), MSc health assisting engineering (HAE), MSc advanced nursing counseling (ANC), MSc advanced nursing education (ANE), and MSc advanced nursing practice (ANP). Participants who answered <50% of the questions were excluded.

Survey Administration

Students of all semesters were contacted directly with an email invitation. The survey was not listed publicly, no advertisement or incentive offers were put in place, and survey participation was voluntary. The survey was created using the web-based platform LimeSurvey (version 5.3.12 [39]), and it was open for participation between May 2 and May 30, 2022. An invitation email was sent on May 2, 2022. As a measure to improve the response rate, a first reminder was sent on May 9, 2022, and a second reminder was sent on May 25, 2022. Data were stored in a password-secured folder to which only selected study team members had access. Cookies were used to prevent users from accessing the survey twice, and IP addresses were not stored. No other measures to identify multiple entries were used. To ensure anonymous participation no registration process was put in place.

Ethical Considerations

Anonymous surveys currently do not require a formal review by a research ethics committee under Austrian research

governance, in which the Declaration of Helsinki defines applicability to research on identifiable human data [40]. Exemption from ethical review has been formally confirmed by the Ethics Committee of the FH Campus Wien University of Applied Sciences (waiver no. W02/24). The survey followed ethical research practices (ie, voluntary participation; reassurance of anonymity, data protection, and confidentiality; advance information on purpose and content; provision of contact details of the research team; and full disclosure of involved organizations). This information was summarized on the first page of the web-based survey. Anonymous electronic consent to voluntary participation was required to begin the survey, but no signatures were obtained. All data processing procedures have been discussed in detail with the data protection officer of *FH Campus Wien* (University of Applied Sciences, Vienna). All data obtained in this survey will be stored for 10 years in compliance with national research legislation and the funding body.

Data Collection Methods

We used a newly developed, project-specific questionnaire (Multimedia Appendices 1 and 2). Feedback from project members on topics, constructs, and scales was iteratively incorporated into a first complete survey draft. Subsequent face-validity testing for usability and technical functionality was performed by 3 persons, not involved in the project, requiring minor usability and wording revisions. The survey consisted of 5 pages with 20 questions, of which 16 questions were mandatory: 6 demographical questions (including a question on the self-assessed information and communications technology competence to further describe the technology skills of the sample), 5 questions about personal perceptions of telehealth, 1 question on professional experience with telehealth, and 4 questions on potential content for telehealth courses or curriculum. The 4 optional questions were included to facilitate additional input or clarification.

Eligibility criteria were queried at the beginning of the survey: "Do you study at FH Campus Wien?" and "Which study program do you attend?" Respondents who clicked the survey link but were not eligible were taken directly to the end of the survey. Telehealth interest and perceived importance of telehealth in education were rated on a 4-point Likert scale (1=not interested/important, 2=less interested/important, 3=rather interested/important, and 4=very interested/important), and perceived relevance of telehealth after the pandemic was also rated on a 4-point Likert scale (1=for sure not, 2=rather not, 3=probably, and 4=for sure). Telehealth knowledge was rated by selecting 1 of 5 statements (1=I have never heard of telehealth, 2=I know the term but not more about it, 3=I know telehealth in medical services but not so much about it in my own profession, 4=I know some telehealth applications in my own profession, and 5=I know a lot of telehealth applications in my own profession). Experience with telehealth was rated among the options "performed," "observed," and "neither nor" for given examples. The perceived relevance of types of telehealth for the profession was assessed with multiple selections of given examples. Participants rated their interest in telehealth content on a 4-point Likert scale (1=for sure, 2=rather yes, 3=rather not, and 4=for sure not) for given

examples. The preferred setting for learning about telehealth was assessed using single choice selection. The option “Don’t know” was implemented, where applicable. Items were not randomized and were always presented in the same order to maintain the survey structure.

Statistical Analysis

Questionnaires with a completion rate of at least 50% were analyzed. Predefined subgroup analysis to compare for study programs, age, gender, and study year was undertaken. Descriptive statistics of categorical variables were reported as absolute and relative frequencies, and ordinal variables were reported with median. Histograms, heat maps, and boxplots were deployed for graphical illustration of the results. Boxplots display the first and third quartiles as a rectangular box, with whiskers extending from the box to indicate the minimum and maximum values, except for outliers. The median is depicted by a horizontal line. Outliers are represented by individual dots, whereas the mean is denoted using an “x” symbol. Stacked bar charts represent the frequencies of positive (right to 0) and negative responses (left to 0) for categorical variables with higher values in the middle. Kruskal Wallis tests were conducted to test for central tendencies in the subgroup analyses. The α value was set at .05, and exact P values were reported. The following mergers were made to achieve a minimum of 5 participants in each subgroup for Kruskal Wallis tests: semesters were merged into study years, for example, first and second bachelor’s semesters combined; age groups were assessed in 8

age group categories (<20, 21-25, 26-30, ..., and >50 years) but combined for subgroup analysis into 3 generation groups. In the literature, generational affiliations vary among different publications [41,42]. In this study, Generation Z was defined as students aged up to 25 years, Generation Y encompassed students aged between 26 and 40 years, and students aged ≥ 41 years were grouped into Generation X and baby boomers. Furthermore, pairwise comparisons were conducted. Test statistic H , SE, standardized test statistic, unadjusted P values, and Bonferroni-adjusted P values were reported. The Bonferroni-adjusted statistical significance was summarized graphically using spider web figures. Pairwise comparisons were not conducted if the alternative hypothesis was rejected by the overall Kruskal Wallis test.

Results

Overview

A total of 2273 students of the selected academic health care professions were potentially eligible to participate. The link to the web-based survey was accessed by 281 students, of whom 261 (92.9%) completed the questionnaire (ie, answered at least 50% of the questions) and were therefore included in the analysis, resulting in a completion rate of 93%. Overall, 206 students were attending a bachelor’s degree program and 55 students were attending a master’s degree program (Table 1). The demographic characteristics of the survey participants are presented in Table 2.

Table 1. Participation across the selected bachelor’s and master’s programs (N=261).

Programs	Values, n (%)	Response rate (%)
Bachelor’s programs	206 (79)	9
Dietetics	20 (9.7)	36
Occupational therapy	24 (11.7)	24
Nursing	32 (15.5)	2
Midwifery	35 (17)	31

Subgroup Differences

A Kruskal Wallis H test (Table 3) showed that there was a statistically significant difference between the study programs in telehealth interest ($P=.005$), telehealth knowledge ($P<.001$), perceived importance of telehealth in education ($P<.001$), and perceived relevance of telehealth after the pandemic ($P=.004$). Corresponding box plots are shown in Figures 1-3. There were no significant differences between genders in telehealth interest ($P=.63$), telehealth knowledge ($P=.19$), perceived importance of telehealth in education ($P=.73$), and perceived relevance of telehealth after the pandemic ($P=.55$). On the basis of age and generation, there were significant differences in the perceived importance of telehealth education ($P=.01$) but no significant differences in telehealth interest ($P=.14$), telehealth knowledge ($P=.19$), and perceived relevance of telehealth after the

pandemic ($P=.06$). There was a significant difference between students of different semesters in telehealth knowledge ($P<.001$) and perceived relevance of telehealth after the pandemic ($P=.008$) but not in telehealth interest ($P=.09$) and perceived importance of telehealth in education ($P=.09$). Details on pairwise comparisons between the different subgroups are described in Multimedia Appendix 3. For each item, smaller values indicate better (more positive) agreement. In summary, significant pairwise differences were observed mainly for the study programs, specifically when comparing the ratings regarding telehealth knowledge (HAE<ORT, HAE<DIE, HAE<ANE, HAE<MID, HAE<NUR, SLT<MID, SLT<NUR, OT<MID, OT<NUR, PT<MID, and PT<NUR), telehealth importance (HAE<PT, HAE<MID, and SLT<MID), and the postpandemic role of telehealth (ANP<PT, ANP<MID, and

ANP<ORT). For gender, the null hypotheses were rejected by the overall Kruskal Wallis tests for all 4 domains, and thus, no subsequent pairwise comparisons were conducted. For generations, the only significant pairwise comparison was for the role after the pandemic, where Generation Z had more

positive ratings than Generation Y. For study progress, the only significant pairwise comparison was for the role after the pandemic, where the first 2 master’s semesters had more positive ratings than the fifth to sixth bachelor’s semesters.

Higher values represent higher interest, knowledge, importance, and perceived relevance. Gen Z (Generation Z): up to 25 years; Gen Y (Generation Y): 26-40 years; Gen X, BB (Generation X, baby boomer): ≥41 years.

Telehealth Interest

Overall, 19.5% (51/261) of the students were very interested and 49.4% (129/261) of the students were rather interested in telehealth. Study programs with the highest interest ratings (very or rather interested) were ANC (7/7, 100%), DIE (17/20, 85%),

and ANP (11/13, 84%). Moreover, 24.1% (63/261) of students were less interested and 0.4% (1/261) were not interested in telehealth. The study programs with the most uninterested students (rather not or not interested) were PT (17/47, 36%), SLT (8/25, 32%), MID (11/35, 31%), and NUR (10/32, 31%). The percentages by study program are presented in Figure 4.

Figure 4. Students' interest in telehealth based on the study program. ANC: advanced nursing counseling; ANE: advanced nursing education; ANP: advanced nursing practice; DIE: dietetics; HAE: health assisting engineering; MID: midwifery; NUR: health care and nursing; ORT: orthotics; OT: occupational therapy; PT: physiotherapy; SLT: speech and language therapy.

Telehealth Knowledge

Only 2.7% (7/261) of the students stated that they have already dealt intensively with telehealth in their own profession and that they knew a lot of applications, 27.2% (71/261) stated that they knew some telehealth applications in their own profession,

20.3% (53/261) stated that they knew telehealth in medical services but not in their own profession, 34.1% (89/261) stated that they knew the term but nothing more about it, and 15.7% (41/261) had never heard of telehealth. The percentages by study program are presented in Figure 5.

Figure 5. Students’ self-assessed knowledge about telehealth based on the study program. ANC: advanced nursing counseling; ANE: advanced nursing education; ANP: advanced nursing practice; DIE: dietetics; HAE: health assisting engineering; MID: midwifery; NUR: health care and nursing; ORT: orthotics; OT: occupational therapy; PT: physiotherapy; SLT: speech and language therapy.

Telehealth Importance in Education

Overall, 31.4% (82/261) of the students thought telehealth was very important for their education, and 50.9% (133/261) of the students rated it as rather important. The study programs with the highest importance ratings (very or rather important combined) were ANC (7/7, 100%), HAE (19/19, 100%), and

OT (22/24, 91%). Moreover, 10% (26/261) of the students thought it was rather not important, and 1.1% (3/261) thought it was not important. The highest percentages of unimportance ratings (not or rather not important) were in MID (8/35, 23%), DIE (3/20, 15%), and ORT (4/23, 13%), PT (3/47, 13%), and ANE (1/13, 13%). The percentages by study program are depicted in Figure 6.

Figure 6. Students' perceived importance of telehealth in education. ANC: advanced nursing counseling; ANE: advanced nursing education; ANP: advanced nursing practice; DIE: dietetics; HAE: health assisting engineering; MID: midwifery; NUR: health care and nursing; ORT: orthoptics; OT: occupational therapy; PT: physiotherapy; SLT: speech and language therapy.

Telehealth Relevance After the Pandemic

Overall, 30.7% (80/261) of the students thought that telehealth will, for sure, be relevant in their profession after the pandemic, and 53.3% (139/261) of the students thought that telehealth would probably be relevant in their profession. The study programs that rated the future relevance of telehealth as highest

were HAE (19/19, 100%), DIE (19/20, 95%), and ANE (15/16, 94%). Furthermore, 12.3% (32/261) of the students stated that it will rather not be relevant and 3.4% (9/261) stated that it will for sure not be relevant. The study programs that least anticipated a future relevance of telehealth were MID (11/35, 32%), ORT (6/23, 26%), and PT (7/47, 15%). The percentages by study program are depicted in Figure 7.

Figure 7. Students' perceived relevance of telehealth after the pandemic. ANC: advanced nursing counseling; ANE: advanced nursing education; ANP: advanced nursing practice; DIE: dietetics; HAE: health assisting engineering; MID: midwifery; NUR: health care and nursing; ORT: orthoptics; OT: occupational therapy; PT: physiotherapy; SLT: speech and language therapy.

Relevance of Different Forms of Telehealth Provision

The given relevance of different forms of telehealth provision in their own profession was confirmed as follows: video call consultation, 82.8% (216/261); apps for self-management, 75.1% (196/261); information for self-management via video courses or websites, 72.8% (190/261); phone call consultation,

68.2% (178/261); sensor-based monitoring of vital parameters, 46% (120/261); sensor-based monitoring of movement or activity, 39.8% (104/261); video call treatment or therapy, 32.2% (84/261); virtual reality or exergaming at home, 25.3% (66/261); and phone call treatment or therapy, 5.4% (14/261). The details of the study program are shown in Figure 8.

Figure 8. Students' perception of the relevance of different forms of telehealth concerning their own profession (the percentage of students that believes this telehealth form is relevant in their profession). ANC: advanced nursing counseling; ANE: advanced nursing education; ANP: advanced nursing practice; DIE: dietetics; HAE: health assisting engineering; MID: midwifery; NUR: health care and nursing; ORT: orthoptics; OT: occupational therapy; PT: physiotherapy; SLT: speech and language therapy.

Telehealth Experience

Overall, 45.6% (119/261) of the students already had telehealth experience. Furthermore, 22.2% (58/261) of the students had observed and 10.7% (28/261) of the students had performed phone call-based or video call-based counseling, treatment, or therapy; 17.2% (45/261) of the students had observed and 9.2%

(24/261) of the students had performed the implementation of apps for self-management and self-training of monitoring; and 5.7% (15/261) of the students had observed and 1.5% (4/261) of the students had performed the implementation of virtual reality, exergaming, or sensors over the distance. The details of the study program are shown in Figure 9.

Figure 9. Students' telehealth experience. The circles represent the percentage of students that have observed this form of telehealth, the squares represent the percentage of students that have performed this form of telehealth. ANC: advanced nursing counseling; ANE: advanced nursing education; ANP: advanced nursing practice; DIE: dietetics; HAE: health assisting engineering; MID: midwifery; NUR: health care and nursing; ORT: orthoptics; OT: occupational therapy; PT: physiotherapy; SLT: speech and language therapy.

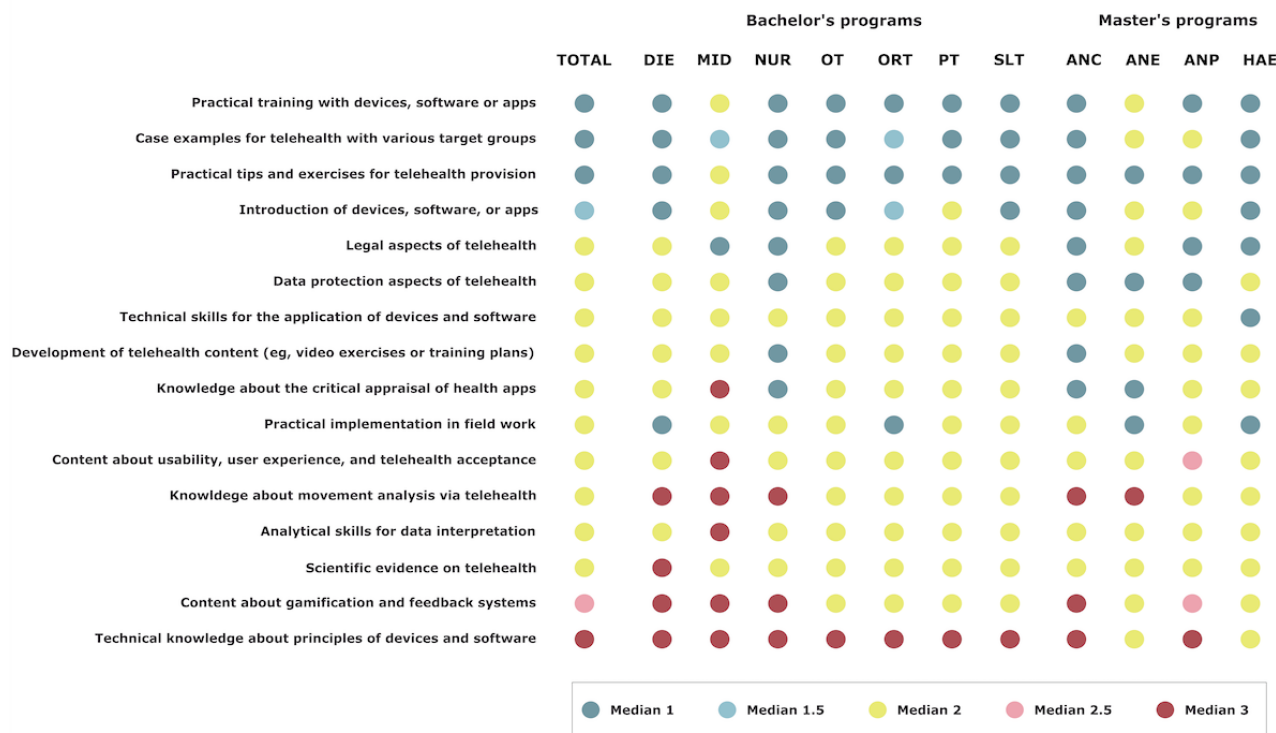

Telehealth Content Within the Curriculum

Students' preferences for telehealth content within their curriculum from highest to lowest ranking were practical training with devices, software, or apps (median 1), case examples for telehealth with various target groups (median 1), practical tips and exercises for telehealth provision (median 1), introduction of devices, software or apps (median 1.5), legal aspects of telehealth (median 2), data protection aspects of telehealth (median 2), technical skills for the application of devices and software (median 2), development of telehealth content (eg, video exercises or training plans; median 2), knowledge about the critical appraisal of health apps (median 2), practical implementation in field work (median 2), content about usability, user experience, and telehealth acceptance (median 2), knowledge about movement analysis via telehealth (median 2), analytical skills for data interpretation (median 2), scientific evidence on telehealth (median 2), content about gamification and feedback systems (median 2.5), and technical

knowledge about principles of devices and software (median 3). Details by the study program are shown in Figure 10.

Overall, 21.8% (55/252) of the students preferred to learn about telehealth with students in their study program, 10% (25/252) preferred interdisciplinary courses, 60.7% (153/252) preferred both of them, 3.2% (8/252) did not want to learn about telehealth at all, and 4.4% (11/252) did not know. Furthermore, 30.6% (77/252) of the students wanted telehealth to be taught within required subjects, 62.3% (157/252) wanted telehealth to be taught within elective subjects, 1.6% (4/252) thought it should not be incorporated into the curriculum, and 5.6% (14/252) did not know. In bachelor's programs, 10.5% (20/190) of the students preferred the first or second semester, 60.5% (115/190) preferred the third or fourth semester, 26.8% (51/190) preferred the fifth or sixth semester, and 2.1% (4/190) of participants preferred none of them. Overall, 30% (13/44) of the master's students thought that the first or second semester and 68% (30/44) thought that the third or fourth semester would be most appropriate, and 1 (N=1, 2%) student felt that none was appropriate.

Figure 10. Students’ preferences for telehealth content based on the study program. The circles represent the median of all answers with 1=for sure, 2=rather yes, 3=rather not, or 4=for sure not. ANC: advanced nursing counseling; ANE: advanced nursing education; ANP: advanced nursing practice; DIE: dietetics; HAE: health assisting engineering; MID: midwifery; NUR: health care and nursing; ORT: orthoptics; OT: occupational therapy; PT: physiotherapy; SLT: speech and language therapy.

Discussion

Overview

Our study provides novel insight into the telehealth knowledge, skills, attitudes, and experience of health care and nursing students and its potential integration into health care and nursing education and practice. The results suggest that there is substantial interest in telehealth among health care and nursing students but a lack of knowledge and experience with it. We discovered similarities and differences among various student groups, which will be discussed in detail and with regard to previously proposed telehealth competency frameworks for health care professionals.

Telehealth Interest

There was a generally high level of interest in telehealth across all study programs. The study programs with the highest median interest in telehealth were 3 master’s programs (ANC, ANP, and HAE) and 1 bachelor’s program (DIE). Interest in telehealth appears to be higher among master’s students than among bachelor’s students, possibly because of their advanced level of education and experience. Students in master’s programs may have gained more professional working experience, which could have raised their awareness of the potential benefits of telehealth, such as increasing access to care [43], improving patient outcomes [44], and reducing health care costs [45]. Moreover, they might have encountered that telehealth has not yet become a ubiquitous component of the health care system. Furthermore, health care master’s programs often place greater emphasis on leadership and innovation, which could make

students more interested in exploring new methods [46]. Students in master’s programs may be more focused on career advancement opportunities and recognize the potential of telehealth to create new roles or expand existing ones in the health care sector. This result also suggests that higher education may play an important role in promoting the adoption and use of telehealth in health care.

However, the students of the bachelor’s programs displayed a substantial level of interest in telehealth, which remained consistent across various semesters and generations. The slight differences in interest between the study programs could be because of differences in their professions and the extent to which telehealth is currently integrated into their practices. For example, dietitians may have a stronger focus on counseling and patient education without manual or physical approaches compared with other professions, such as MID, NUR, PT, and OT. Although these professions also have an important educational role, their physical nature may make in-person consultations more essential for their professions, whereas for DIE, telehealth consultations may be a more practical and effective option. In addition, SLT has a strong focus on communication and telehealth, especially in the form of synchronous videoconferencing, and has been successfully used for several years, for example, in rural and remote areas of countries such as Australia and Canada [47].

The high level of interest in telehealth among health care students shows a positive attitude toward the technology, indicating that many perceive it as a beneficial tool in their future professional practice. However, enthusiasm alone is not

sufficient for effective telehealth practice; it must be supplemented by the right competencies as well as the ability to demonstrate successful performance in using telehealth tools and services.

Telehealth Knowledge and Experience

In general, most students showed some level of familiarity with telehealth, with only a small number of students reporting that they had never heard of it. However, there appears to be a profound lack of specific telehealth knowledge, profession-specific applications, and telehealth experience. Moreover, there were significant differences between the professions in terms of the level of knowledge about telehealth. For example, students from the bachelor's programs PT, OT, and SLT and the master's program HAE reported the highest levels of knowledge about telehealth applications in their professions. We can see that in some professions most students had never heard of telehealth or only knew the term but nothing more about it (applies to DIE, MID, NUR, and ANE). While in 3 of the 4 master's programs all students at least knew the term telehealth, this was not the case for 6 of the 7 bachelor's programs.

A relatively low percentage of students already had experience with telehealth applications. In Austria, health care professionals have worked mostly in face-to-face settings, but the COVID-19 pandemic had a significant influence on the attitudes toward telehealth service provision and its implementation [9,48]. Nevertheless, the findings of this study suggest that especially bachelor's students have only rarely come into touch with it. However, increased exposure to telehealth in academic settings and practical experience are important to enhance awareness and adoption of this emerging health care approach [49]. Only 35.4% (86/243) of all students reported direct or indirect experience with phone or video call-based counseling, treatment, or therapy; 29.5% (69/234) had implemented apps for self-management, self-training, or monitoring; and only 8.3% (19/229) had experience with the implementation of virtual reality, exergaming, or sensors over a distance. However, these percentages vary among different health care profession students. The highest percentage of students with experience in phone or video call-based counseling, treatment, or therapy were studying the bachelor's programs SLT, MID, and DIE and the master's programs ANE, ANP, and HAE. While master's students usually already have gained professional experience and thus determine their chosen methods themselves, the experience of bachelor's students mostly is limited to practical training within the curriculum and placements. Therefore, their experience with telehealth methods highly depends on their implementation by their teachers and supervisors. However, it remains unclear why some professions have had greater exposure to telehealth among their students than others. It is possible that the urgency of certain cases, particularly those related to acute therapy, led to greater adoption of telehealth in some professions. Another explanation could be that some professions, such as MID and DIE, might already have used telephone consultations more often before the pandemic than other professions. Students in the HAE program had the highest percentage of experience in implementing apps for self-management, self-training, or monitoring, and the

implementation of virtual reality, exergaming, or sensors over a distance. This is not surprising as this program has a focus on health care technology and students might have an affinity for integrating more complex technologies into their practice.

Telehealth Attitudes

Most students in all health care programs expected that telehealth will play an important role in their profession also after the pandemic. This aligns with current research that supports the future relevance of telehealth in health care [5,50-52]. The overall high rates of expectations among health care students regarding the integral role of telehealth in the future of health care emphasizes the need for a stronger integration of telehealth education into health care curricula. Previous surveys in other countries also found a strong belief of students that telehealth services will be strongly integrated in the future [49,52]. Approximately 30% of the participants from MID (11/35) and ORT (6/23) form an exemption and believed that telehealth will not or rather not be relevant in their profession after the pandemic. In ORT, in particular, telehealth practices may not yet be as established as in other health care professions. Similar to other professions, orthoptists heavily rely on hands-on procedures, but they may require even more specialized equipment than others for the assessment and treatment of eye disorders.

Video call consultations seem to be the most widely accepted form of telehealth provision, with a high percentage of students from all study programs agreeing that they have an important role in their profession. Students may recognize the benefits of video integration for observations, capturing interpersonal features, nonverbal cues, and eye contact that may be lost when relying solely on phone calls [51]. Moreover, in recent years, videoconferencing has seen substantial growth across various aspects of daily life, driven by technological advancements, faster internet speeds, and the transition to remote work, particularly during the COVID-19 pandemic [53]. Hence, it is conceivable that students can best envision the use of video calls within the scope of telehealth, as they are familiar with this technology from other contexts.

Self-management apps are also widely accepted, with the exception of MID, which has noticeably lower scores. This is in line with previous research that reported that 58% of the surveyed nonphysicians (including MID) categorically rejected self-monitoring apps in pregnancy [54]. Self-management apps hold potential value for a wide range of contexts and stakeholders, including patients, health care professionals, and caregivers [55] and should therefore be incorporated into education [56]. In addition, the provision of information for self-management via video courses or websites was perceived as relevant by a majority of the students. Moreover, simple phone call consultations were perceived as more relevant compared with treatments or therapy over the phone, which received more skepticism among the surveyed students. This appears to indicate students' uncertainty regarding the feasibility or effectiveness of implementing specific interventions, techniques, or procedures through virtual means. Sensor-based monitoring of vital parameters is relatively well accepted among students in NUR and those in master's programs. Compared

with the other students examined, students in NUR likely already had the most frequent experience with monitoring vital parameters in their current roles and constitute a significant portion of patient care. Consequently, students may perceive a direct potential for alleviating their workload in their professional lives through remote monitoring technologies. Virtual reality or exergaming at home is not widely accepted among students, although it is most accepted among students in the OT, PT, and HAE programs. Exergaming interventions have demonstrated effectiveness in enhancing balance, function, physical activity levels, strength, fatigue, emotions, cognition, and pain relief [57]. Consequently, these interventions hold relevance for professionals and students in related fields.

There was a high level of agreement among students in all study programs that telehealth is important for their education. Only a minority of students of MID and ANP programs thought that this was not important. However, curricula for health care professionals have not yet widely incorporated telehealth [26] and are not consistent in their educational approaches [31]. However, health educators have started to recommend or plan to incorporate telehealth into the curriculum [58]. Furthermore, research is being conducted on which telehealth competencies should be implemented in education and with what didactic means [16,31,59-61].

Students expressed a strong desire for practical training that included hands-on experience with telehealth devices, software, and apps; case examples for telehealth with various target groups; and practical tips and exercises for telehealth provision. Previously published telehealth curricula had similarly presented a strong focus on practical experience [61]. As with any new technology or practice, students often benefit from experiential learning and simulation [62]. Therefore, it is reasonable for inexperienced health care students to prioritize practical training with devices, software, or apps; case examples for telehealth with various patient groups; and practical tips and exercises for telehealth provision. This is in line with a prior study reporting that new graduate physiotherapists perceived exposure to and practical skills training for telehealth as essential for their profession [27]. Another study with new graduate speech and language therapists concluded that they should learn to initiate telepractice service delivery through demonstration and role play to reduce initial anxieties [63].

The students' preference for both interdisciplinary and program-specific courses might be because telehealth is a complex and multidisciplinary field that requires a broad range of knowledge and skills [5,31] but still has profession-specific requirements and applications. Previous research has shown that students benefit from an interprofessional telehealth course [60]. The main reason for preferring electives could be that students want the flexibility to choose courses that align with their specific interests and career goals. Moreover, as mentioned by some students with additional comments, the curricula and timetables are already very intense and dense. Students might fear that the introduction of new content into the curriculum would come at the expense of other relevant study content. On the other hand, the preference for compulsory subjects by 30.6% (77/252) of the students could be because students feel that telehealth is an important topic that should be incorporated into

the core curriculum of their program. Most bachelor's students had a preference for learning about telehealth in the third or fourth semester. Master's students also showed a slight preference for telehealth content in the second part of their education. This could be because students have already acquired a foundational knowledge of health care by this time and are better equipped to understand the complex nature of telehealth. In contrast, students in their first or second semester may be overwhelmed with this topic and may not have the necessary foundational knowledge to fully comprehend the nuances of telehealth.

Implications for Telehealth Education

Given the observed high interest and mainly positive attitude, but relatively low levels of perceived knowledge, and experience in telehealth, we conclude that it is important to enhance telehealth education for health care and nursing students. The apparent divide between perceived telehealth competence and importance of telehealth underscores the necessity that telehealth education should be integrated into the core curriculum, despite students having a preference for elective courses when directly asked. On the basis of the limited availability of publicly funded, profession-specific master's programs in Austria [64], we believe that it is important to integrate basic telehealth education at the bachelor's level to reach as many students as possible. However, this might not be applicable to countries with a different educational structure. Curricula should strategically incorporate the principles of Miller pyramid of clinical competence into telehealth education by emphasizing competency across the levels of knowledge, skills, performance, and action and by providing opportunities to form attitudes, as highlighted by other authors [16,60]. We suggest that there is a need for increased knowledge transfer, practical exposure, and training in the use of telehealth applications, especially in professions with lower levels of knowledge about telehealth, to increase their awareness and understanding of the potential benefits of telehealth, their specific skills, and therefore overall competency in their respective fields. It is further crucial to empower educators with the necessary competencies to effectively teach telehealth and to provide organizational framework conditions to integrate telehealth into the curricula [65].

As the students preferred to learn about case examples and hands-on experience with devices, software, and apps used in telehealth, we suggest that they early on can become more familiar and comfortable with using them. Case examples for telehealth with various target groups can help students understand the diverse needs of different patient populations and learn how to adapt their approach accordingly. Practical tips and exercises for telehealth provision can also help students to develop skills and confidence in their ability to provide telehealth services; improve their overall competency; and understand the ethical, clinical, and legal aspects that arise when using them. Furthermore, courses should expand on the essential knowledge details of legal aspects, data protection, technical skills, critical appraisal, and scientific evidence based on or in combination with practical examples. Even if these aspects did not rank highest in the needs analysis, students confirmed their relevance. Students need to build knowledge about the legal

framework in which they will operate, the importance of protecting patient data and how to maintain data privacy, and the potential risks and liabilities involved. As telehealth relies heavily on technology, students need to have the technical skills to use and troubleshoot various telehealth tools and platforms [66]. Furthermore, students need to be able to apply clinical reasoning in a telehealth context and critically appraise the scientific evidence on telehealth, including its benefits and limitations, to make informed decisions about its use [67].

In terms of content, we conclude that future telehealth curricula should focus on teaching the basics and the application of practical training on consultation over the phone with or without video integration, the integration of self-management apps, and the development or integration of video courses or websites for self-management within all study programs. This focus has been previously suggested for nurse practitioner training [5]. Furthermore, specific courses for therapeutical professions (SLT, OT, and PT) could teach the possibilities of direct therapy approaches through video calls and further exergaming and virtual reality. Sensor-based monitoring of vital parameters, movement, and activity might be more appropriate for NUR, PT, and OT students, within specialization courses for students of other bachelor's programs that are interested in this topic, and for master's programs. Guidelines that are specific to each profession and report on implementation, financial, and technical considerations [68] should also be integrated into the development of curricula. For instance, incorporating strategies for executing telehealth practices in fields such as OT [69], musculoskeletal physiotherapy [70], SLT [71], and nursing [72] can be beneficial.

Limitations

This study has several limitations that impact the interpretation of the results. The sample size of 261, representing a small segment of eligible health care students, and the overall low (11%) and variable response rate across programs, may affect the results' generalizability and comparability and raises the possibility of nonresponse bias, whereby the views of those who did not participate may systematically differ from those who did. This issue poses the risk of over- or underestimation of the true distribution of perceived telehealth competencies in the target population. In addition, the cross-sectional design, capturing attitudes at a single point in time, further limits the findings. The generation distribution differed between bachelor's and master's programs, which may confound the perceived importance of telehealth education, knowledge levels, and postpandemic telehealth relevance across generations. Although a large portion (151/206, 73.3%) of students in bachelor's programs belonged to Generation Z, master's programs had a higher representation of Generation Y, Generation X, and baby boomers (49/55, 89%). Therefore, the statistical differences in the perceived importance of telehealth education between generations and differences in telehealth knowledge and perceived relevance of telehealth after the pandemic must be interpreted with caution. It should also be noted that health professionals pursuing a master's degree later in their careers might show more interest in innovation, making these results less generalizable to other health professionals of the same generations. Regarding the statistical analysis, it should be

mentioned that multiple comparisons increase the risk of type I errors. Even with the Bonferroni adjustment, which is conservative, there is a tradeoff with statistical power, potentially leading to type II errors [73]. In addition, self-reported measures of telehealth interest and knowledge may be influenced by social desirability bias or inaccurate self-assessment. Furthermore, it was not possible to directly assess student's telehealth skills and actual performance using a web-based survey. In addition, the study's context, focused on students from specific health care programs in 1 Austrian university, restricts the applicability of the findings to other institutions or countries. Finally, a limitation of this study is the potential impact of the COVID-19 pandemic on the participants' attitudes, experiences, and perspectives toward telehealth. The students who participated in this study in May 2022 were probably affected by the pandemic in various ways, including disruptions in their placements and the rapid adoption of telehealth services in health care settings. As a result, their views on telehealth might be influenced by the unique circumstances of the pandemic, which could limit the generalizability of the findings to other periods.

Recommendations for Further Research

Future research should consider several steps to build on this study. First, expanding the study to include a larger, more diverse sample of health care students from different institutions and countries will allow for examining potential variations in knowledge, skills, performance, action, and attitudes in telehealth. In addition, exploring factors that may act as barriers or facilitators to the adoption of telehealth within health care education, such as the interest, skills, and knowledge of educators, technological infrastructure, legal and ethical considerations, or institutional barriers, is crucial. Second, conducting more intervention-based studies that aim at improving telehealth knowledge, competence, and interest among health care students [74,75] will be valuable for investigating the effectiveness of different teaching methods and content that can help identify the most effective strategies for telehealth education. Moreover, conducting longitudinal research would enable tracking changes in students' attitudes, knowledge, and interest in telehealth over time as they progress through their education, providing a comprehensive understanding of the development and potential factors influencing these perspectives, especially in the time after the COVID-19 pandemic. Assessing the impact of telehealth training on clinical practice is important. Investigating the relationship between telehealth training during health care education and its application in clinical practice, as well as evaluating the impact of telehealth knowledge and competence on patient outcomes and health care delivery, can provide valuable insights. Finally, examining the role of interprofessional collaboration in telehealth education and practice and its impact on students' attitudes and knowledge regarding telehealth is essential [76]. Evaluating the effectiveness of interdisciplinary courses in fostering collaboration and improving telehealth competence among health care students can contribute to the development of more efficient telehealth education strategies.

Conclusions

Our study findings underscore the need for structured telehealth education within health care curricula to equip students with the necessary competencies for future practice. Students recognize the importance of telehealth in their future profession and feel that they need to be adequately prepared. However, the study also revealed that the level of telehealth experience and

knowledge among participating health care students is currently low. Therefore, there is an urgent need to provide comprehensive telehealth education and training to health care students to prepare them for the future demands in their profession. By incorporating telehealth education into health care curricula, institutions can better prepare students for the evolving landscape of health care and promote the successful integration of telehealth into future practice.

Abstract

Background: Professionals with expertise in health informatics play a crucial role in the digital health sector. Despite efforts to train experts in this field, the specific impact of such training, especially for individuals from diverse academic backgrounds, remains undetermined.

Objective: This study therefore aims to evaluate the effectiveness of an intensive health informatics training program on graduates with respect to their job roles, transitions, and competencies and to provide insights for curriculum design and future research.

Methods: A survey was conducted among 206 students who completed the Advanced Health Informatics Analyst program between 2018 and 2022. The questionnaire comprised four categories: (1) general information about the respondent, (2) changes before and after program completion, (3) the impact of the program on professional practice, and (4) continuing education requirements.

Results: The study received 161 (78.2%) responses from the 206 students. Graduates of the program had diverse academic backgrounds and consequently undertook various informatics tasks after their training. Most graduates (117/161, 72.7%) are now involved in tasks such as data preprocessing, visualizing results for better understanding, and report writing for data processing and analysis. Program participation significantly improved job performance ($P=.03$), especially for those with a master's degree or higher (odds ratio 2.74, 95% CI 1.08 - 6.95) and those from regions other than Seoul or Gyeonggi-do (odds ratio 10.95, 95% CI 1.08 - 6.95). A substantial number of respondents indicated that the training had a substantial influence on their career transitions, primarily by providing a better understanding of job roles and generating intrinsic interest in the field.

Conclusions: The integrated practical education program was effective in addressing the diverse needs of trainees from various fields, enhancing their capabilities, and preparing them for the evolving industry demands. This study emphasizes the value of providing specialized training in health informatics for graduates regardless of their discipline.

Introduction

The field of digital health is rapidly advancing, driven by innovative technologies such as artificial intelligence, big data analytics, digital therapeutics, and embedded medical systems [1]. Amid this dynamic progression, there is a pressing need to cultivate aptitudes and insights to remain abreast of these changes. The growing demand for digital health professionals is evident in the United Kingdom, where almost 90% of health

care professionals are projected to require digital proficiencies within the next 2 decades [2]. Additionally, the World Health Organization and World Bank estimate that by 2030, approximately 40 million new health and social care jobs will be created, many of which will be within the field of digital health [3]. Despite the high demand for digital health professionals, there is a substantial gap between the skills health informatics (HI) graduates possess upon graduation and those desired by employers [4,5]. As the health care paradigm shifts

toward digitalization, there is an escalating demand for adept professionals capable of conceptualizing, instituting, and overseeing digital health interventions [6]. Current HI educational frameworks, however, fall short of equipping students with the requisite practical acumen [7], leaving many underprepared for the challenges of the profession.

Globally, substantial progress has been made in developing curricula dedicated to HI, with the United States being at the forefront of these efforts. The American Medical Informatics Association saw the need for expertise beyond traditional academic pathways and established an education committee in 2002 [8], leading to the development of the 10×10 Program, a bold initiative to train 10,000 HI specialists from 2005 to 2010. This 10-week program, covering 10 core topics, was designed to cater to a wide range of professionals, from health information managers to system developers. However, the multifaceted nature of HI challenges the feasibility of a one-size-fits-all curriculum [9]. A substantial proportion of professionals work without formal training and have distinct requirements depending on their role and academic background. In response, the International Medical Informatics Association has created a curriculum that aims to deliver tailored professional education to a diverse cohort [10]. However, despite these notable advances, a consistent strategy for an ideal curriculum or training approach for health care professionals of diverse backgrounds—cultural and educational—wishing to explore HI is lacking.

In recent years, clinical informatics has been incorporated into the primary curriculum of medical and graduate schools in South Korea. However, these trainings also remain somewhat limited. Acknowledging the interdisciplinary essence of HI, the South Korean government initiated multiple intermediate informatics education programs. In 2018, a large-scale educational program was launched in collaboration with 3 major universities, offering the Genomic Specialist Training Program, Advanced Health Informatics Analyst (AHIA) Training Program, and Precision Medicine Workforce Training Program. This 5-year program was taught independently of regular university and graduate courses and was offered free of charge to all participants. The AHIA program, in particular, was important owing to its focus on data analysis using real-world hospital data, a skill essential for medical information analysis experts. To cultivate an HI expert within a postgraduate program, a commitment of at least 60 credits or a year of full-time study is mandatory. This bespoke program entailed an annual workload of 56.5 study hours and mirrored the rigor of a postgraduate curriculum. By March 2023, a total of 206 participants from various academic backgrounds and degree pursuits, some with prior experience in relevant fields, had completed the AHIA program. Given the diverse academic trajectories of the attendees and the in-depth instruction in HI, scrutinizing their posttraining professional applications or shifts in employment status was anticipated to yield intriguing insights. This study was therefore conducted

to survey the program alumni, aiming to discern the educational impact and gather valuable perspectives to shape subsequent informatics curricula. The overarching objective of this research is to validate the efficacy of intensive HI education when delivered to individuals across a spectrum of academic and professional backgrounds. Such insights will underpin the development and refinement of future informatics curricula.

Methods

AHIA Course

The survey was conducted among the 206 students who completed the AHIA course over a period of 5 years (2018 - 2022). This advanced course was conducted once a year in 2018 and 2019, and twice a year from 2020 to 2022. On average, each course had 27.4 students enrolled. Each course consisted of 10 sessions. A total of 206 (97.2%) out of 212 students completed the course, and the failure and dropout rate was 2.8% (6/212). The program is designed to provide practice-oriented education, allowing students to experience the practical needs and challenges faced in the medical field. The curriculum encompasses a range of topics, including electronic medical records, medical images, public health, lifelog data, biosignals, and genome data, which are essential in the medical field. A lifelog is a practice where individuals digitally document their daily experiences with different levels of granularity, serving various aims [11]. Theoretical knowledge and practical training were incorporated into the course, which included a 3-week team project to practice problem-solving skills relevant to real-world scenarios. The curriculum and structure of this course are provided in [Multimedia Appendix 1](#).

Survey Design

We implemented a structured survey to systematically evaluate and analyze the insights for future informatics curriculum design and assess the effectiveness of our training approaches. The questionnaire was organized into four categories, as outlined in [Table 1](#): (1) general information on the respondents: this section collected essential demographic data about the survey respondents; (2) changes before and after program completion: participants were asked to reflect on any changes they experienced in their knowledge or skills after completing the professional program; (3) impact of the professional program on professional practice: this section aimed to assess how the program influenced the professional practices of the participants; and (4) continuing education requirements: this section sought to identify any specific needs or preferences for further education among the respondents. The questionnaire incorporated adaptive questioning techniques to minimize the quantity and complexity of the questions presented. The number of questionnaire items per page was from 2 to 4. The questionnaire was distributed over 12 pages. The respondent was able to modify their response by using the back button. The questionnaire is provided in [Multimedia Appendix 2](#).

Table . Questionnaire composition and questions.

Category	Classification	Questions, n
General information	<ul style="list-style-type: none"> • Sex • Age • Residence • Final education • Major • Employment status • Occupation • Organization • Job before and after completing the program • Duration of work experience • Work related to informatics or health informatics 	12
Changes before and after completing the intensive course	<ul style="list-style-type: none"> • Purpose or reason for program application • Current work impact • Changes in work after completing the program • How helpful (satisfied) was the course? • Positive impact • A change in career or intention to change careers in informatics or health informatics after completing the program 	8
Effects of advanced courses on informatics in performing tasks	<ul style="list-style-type: none"> • Level of change in medical data analysis and processing ability • Performed tasks related to informatics or health informatics • Change in fear of working with informatics or health informatics • Participation in informatics- or health informatics-related activities • Improved skills and abilities related to informatics or health informatics • Change in interest in informatics or health informatics • Change in participation in informatics- or health informatics-related activities • Reasons why informatics- or health informatics-related activities were difficult to do 	6
Demand for continuing education	<ul style="list-style-type: none"> • Continuing education or reinforcement after completing the course • Demand for informatics- or health informatics-related personnel in your organization • Cultivation of specialized personnel related to informatics or health informatics • Improvements and suggestions 	5

Evaluation of the Reliability and Validity of the Survey

The survey was designed to align with the educational objectives and learning outcomes of the AHIA course. The purpose was to evaluate the applicability of the theoretical knowledge and practical training in addressing real-world health care challenges. Survey questions were developed to assess shifts in students' knowledge and skills, the impact on their professional practices, and their needs for continuing education. The initial draft of the survey was designed by our research team of HI experts to ensure the relevance and clarity of the questions, thereby enhancing the survey's reliability and validity. To ascertain the reliability and validity of the survey, we engaged a panel of

experts in HI to review and critique the initial survey draft. Their invaluable feedback led to the refinement of our survey questions, ensuring they effectively captured the educational outcomes and experiences of our students. This step was crucial in validating the survey instrument and ensuring that the data collected were both reliable and reflective of the course's impact.

Participant Recruitment and Data Collection

From January 30 to February 8, 2023, data were gathered using a web-based questionnaire. Links to this questionnaire were emailed to the 206 students who had completed the AHIA course between 2018 and 2022. The first page of the survey provided

information on the purpose of the research, the length of time needed to complete the survey, and the methods of personal information protection.

Statistical Analysis

The collected survey data underwent a comprehensive statistical analysis. Only completed survey data were analyzed. First, basic descriptive analysis techniques were applied to examine the characteristics of the survey respondents, including computing measures such as mean, median, and SD to summarize the central tendency, dispersion, and distribution of the data. Additionally, frequency tables were used to present categorical variables, providing insights into the demographic composition of the respondents. Furthermore, ANOVA was conducted to determine if there were significant differences in informatics medicine work based on the major of the education graduates. Visualization methods, such as pie graphs, were used to illustrate differences among majors and to depict shifts in proficiency levels before and after the training course. All statistical analyses were performed using R software (version 4.1.1; R Foundation for Statistical Computing).

Ethical Considerations

This research paper was reviewed and approved by the Institutional Review Board of Asan Medical Center (S2022-2671-0001). Before commencing the survey, participants were mandated to provide their informed consent, acknowledging the study's objectives and permitting the collection of their personal data. Participation was voluntary, and upon completing all items in the survey, participants were compensated with a small reward. The collected responses were anonymous and used exclusively for analysis and deriving outcomes, with the confidentiality of individual responses being strictly protected under Article 33 of the Statistics Act.

Results

Participant Demographics

Among the 206 trainees, 161 (78.2%) responded. Due to the anonymous nature of the survey, identifying the nonrespondents was not feasible, and in comparison to prior research [8], achieving a response rate of 78.2% is considered substantial. This sample size was deemed sufficient to draw meaningful conclusions, with the sampling error, expressed as a margin of error, calculated to be $\pm 3.62\%$ at a 95% confidence level. Table 2 presents the demographic characteristics of the study population. The sex distribution shows that of the 161 respondents, 54% (n=87) were female and 46% (n=74) were male, with no statistically significant difference between the 2 groups ($P=.31$). The age distribution was as follows: 52.9% (46/87) of female participants and 35.1% (26/74) of male participants were in the 20 - 29 years group; 28.7% (25/87) of female participants and 37.9% (28/74) of male participants were

in the 30 - 39 years group; and 18.4% (16/87) of female participants and 27% (20/74) of male participants were in the 40+ years group. No significant difference between the age of male and female participants was observed ($P=.08$). There were also no significant educational differences between the sexes ($P=.25$). Most participants had a bachelor's degree (34/87, 39.1% of female participants and 19/74, 25.7% of male participants) or a master's degree (39/87, 44.8% of female participants and 38/74, 51.4% of male participants), while a smaller proportion had a high school diploma or a PhD. Job status differed significantly between female and male participants ($P=.01$). Most female participants (52/87, 59.8%) and male participants (56/74, 64.4%) were employed in full-time jobs, while smaller proportions were engaged in job preparation or postgraduate studies. Lastly, there were no significant differences in the locations between the sexes ($P=.14$). Most participants (62/87, 71.3% of female participants and 42/74, 48.3% of male participants) were from Seoul, followed by Gyeonggi-do and other regions.

Among the 161 respondents, 64% (n=103) had a master's degree, PhD, or higher. These respondents' undergraduate majors and changes in their majors in the master's and doctoral courses after the bachelor's degree were compared. The most common undergraduate majors were computer science (n=30, 18.6%), "others" (n=26, 16.1%), statistics (n=25, 15.5%), medicine (n=20, 12.4%), and nursing (n=15, 9.3%), whereas for the master's degree or doctoral major, "others" was the most common at 42.9% (n=69), followed by biomedical or medical informatics and statistics at 13% (n=21) each, medicine at 9.9% (n=16), computer science at 8.7% (n=14), health service research at 8.1% (n=13), and biomedical engineering at 4.3% (n=7). "Others" includes experimental psychology, molecular science, microbiology, psychology, etc (Figure 1).

The primary motivation for enrolling in the AHIA course and the reason for applying to informatics-related jobs were examined. The highest proportion of respondents (n=120, 74.5%) indicated that they sought to enhance or improve their job competencies, followed by 67.1% (n=108) who applied to enhance their future job prospects. Most respondents (n=120, 74.5%) joined the course to strengthen their job-related skills and performance. Moreover, a substantial proportion (n=70, 43.5%) expressed their interest in learning new technologies with promising opportunities, 36% (n=58) highlighted interest in joint research or collaboration, and 32.3% (n=52) considered leveraging the potential for collaboration, indicating the high expectations for collaboration and growth opportunities in the converging field. Furthermore, some participants (n=47, 29.2%) stated that they pursued the course to obtain a completion certificate, and 6.8% (n=11) indicated that they received recommendations or endorsements from others as motivation for enrollment.

Table . Respondent demographics.

Variables	Female sex (n=87)	Male sex (n=74)	<i>P</i> value
Respondents (n=161), n (%)	87 (54)	74 (46)	.31
Age group (years), n (%)			.08
20 - 29	46 (52.9)	26 (35.1)	
30 - 39	25 (28.7)	28 (37.9)	
40+	16 (18.4)	20 (27)	
Education, n (%)			.25
High school diploma	3 (3.4)	2 (2.7)	
Bachelor's degree	34 (39.1)	19 (25.7)	
Master's degree	39 (44.8)	38 (51.4)	
PhD	11 (12.6)	15 (20.3)	
Job status, n (%)			.01
Job preparation	13 (14.9)	1 (1.1)	
Postgraduate student	15 (17.2)	11 (12.6)	
Full-time job	52 (59.8)	56 (64.4)	
Part-time job	5 (5.7)	6 (6.9)	
Region, n (%)			.14
Seoul	62 (71.3)	42 (48.3)	
Gyeonggi-do	17 (19.5)	20 (23)	
Other	8 (9.2)	12 (13.8)	

Figure 1. Respondents' undergraduate and graduate majors.

Informatics Ability After the Training Course

Regarding the current medicine-related work of respondents according to their majors, 117 (72.7%) of the 161 respondents answered that they “preprocess the collected data”; 57.1% (n=92) noted that they “visualize the results to help understand the main analysis results”; and 57.1% (n=92) said that they “write an analysis report applying various modeling techniques.” To identify a difference in the information medicine work currently performed according to the final major of the education graduates, data were visualized according to majors (ANOVA; $P<.001$). With the exception of graduates with mathematics majors, most graduates (n=117, 72.7%) performed plenty of data preprocessing (Multimedia Appendix 3). Data

preprocessing was identified as the main task for graduates of health science research, statistics, and computer science majors. Graduates of medical (doctors and nurses) and double majors often performed tasks related to data utilization plan establishment, and data analysis was performed frequently by graduates with mathematics, statistics, and “others” majors.

Changes in Technology and Knowledge After the Training Course

Regarding the ability to analyze and process medical data before and after the training course, most (68/161, 42.2%) respondents selected “I can see and follow the analysis method (Step 2)” before the course. This stage primarily involves the ability to visually recognize and replicate given analysis methods based

on instructional guidance, which is crucial for foundational learning and initial engagement with medical data analysis. However, after completing the course, 46% (n=74) said “I know and can design the analysis method (Step 3),” indicating that medical data analysis skills and processing abilities had improved upon completion. This progression signifies a deeper understanding and ability, not just to follow but also to design and conceptualize analysis methods independently. Step 3 encompasses a critical transition from merely executing predefined analysis steps to creating customized analysis frameworks suited to specific medical data challenges.

Additionally, of the 6.2% (n=10) of respondents who answered “I did not know at all (Step 0)” before completion, half (5/10, 50%) of them improved to “I understand the concept after hearing the term (Step 1),” while the other half (5/10, 50%) moved to “I can see and follow the analysis method (Step 2),” highlighting the improvement from the beginner to the intermediate step (Figure 2 and Table 3). After completion, 111 (68.9%) students improved their skills by at least 1 step. Excluding the 8 (5%) individuals who began the course at the fifth step, 67.3% (103/153) showed a technical improvement of at least 1 step.

Figure 2. Step of change in medical data analysis and processing capabilities. Steps: 0=I did not know at all, 1=I understand the concept after hearing the term, 2=I can see and follow the analysis method, 3=I know and can design the analysis method, and 4=Expert-level analysis and results can be drawn.

Table . Step of change in medical data analysis and processing capabilities (n=161).

Step	Degree of change	Before training, n (%)	After training, n (%)
0	I did not know at all	10 (6.2)	0 (0)
1	I understand the concept after hearing the term	45 (28)	7 (4.3)
2	I can see and follow the analysis method	68 (42.2)	58 (36)
3	I know and can design the analysis method	30 (18.6)	74 (46)
4	Expert-level analysis and results can be drawn	8 (5)	22 (13.7)

Shift in Job Change Intentions Before and After Training

After completion of the AHIA course, 58.4% (94/161) of respondents in the field of informatics or HI changed jobs or intended to change jobs. Although more than half expressed this intent, actual job change was relatively rare, with only 22.4% (36/161) experiencing a job change. Among those who

responded to further questions (n=91), except for 3 who did not respond, 82.4% (n=75) stated that the course influenced their decision. Specifically, “understanding work contents and characteristics in the field of informatics” (n=58, 63.7%) and “interest in the informatics field” (n=56, 61.5%) were cited as significant factors influencing either the experience of a job change or the intention to change jobs (as depicted in [Table 4](#)).

Table . Impact of the Advanced Health Informatics Analyst course on job change or the intention to change jobs.

Factors that impacted job change or the intention to change jobs	Respondents (n=91; 91/161, 56.5%)
Understanding work contents and characteristics in the field of informatics	58 (63.7)
Interest in the informatics field	56 (61.5)
Confirmation of the potential for growth in the area of IT	50 (54.9)
Improving individual academic skills and gaining academic qualifications	42 (46.2)
Developing jobs skills (like developing technology, analyzing data, etc)	38 (41.8)
Confirmation that the area of informatics and the person’s skills are a good match	36 (39)
Exchange with people interested in medical information	30 (33)

Impact of the AHIA Course on Informatics Activities and Attitudes

To assess the influence of the AHIA course on activities and attitudes within the field of informatics, we formulated 4 questions. These were rated on a Likert scale across 3 key areas: the type of positive impact the course had, the increase in activities related to informatics, and changes in interest toward or apprehension about the field of informatics. Among the 161 respondents, 72.6% (n=117) answered that the course had a positive effect. Among them, 75.2% (n=121) and 60.2% (n=97) highlighted that they had “enhanced knowledge in informatics for personal improvement” and “gained practical experience in utilizing data for academic or professional purposes,” respectively. Regarding the increase in activities in the informatics field and changes in attitudes, 63.4% (n=102) of the respondents stated that their participation in informatics activities had increased. Additionally, 90.1% (n=145) of respondents reported that their interest in informatics increased and 73.9% (n=119) said their fear had decreased.

Examining the Link Between the Impact of the AHIA Course and Respondent Characteristics

To confirm the relationship between the influence of the AHIA course and the characteristics of the respondents, we performed a multivariable logistic analysis for each outcome by adding the age, sex, education level, and field of work of the respondents. Participants showing a positive correlation in the effect of the AHIA course on job performance were those with a master’s degree, PhD, or higher (odds ratio [OR] 2.74, 95% CI 1.08 - 6.95) and workers in regions other than Seoul and Gyeonggi-do (OR 10.95, 95% CI 1.08 - 6.95). The respondent factor significantly associated with increased informatics activity was having a master’s degree or higher (OR 2.84, 95% CI 1.27 - 6.31; $P=.01$), while other factors did not show any correlation. Regarding the increase in informatics activities, the highest observed proportion (83/161, 51.6%) involved the “use of informatics in actual work,” followed by “completing an additional degree in informatics” at 26.7% (43/161), suggesting that these degree-related matters are closely related factors. Respondent sex was associated with increased interest in informatics, and female participants responded that they were more interested than male participants (OR 3.51, 95% CI

1.10 - 11.21). Age showed no significant difference in all 4 items (Table 5).

Table . Course effects on health informatics work and attitudes.

Variables	Effect		Activity		Interest		Fear decreased	
	OR ^a (95% CI)	P value	OR (95% CI)	P value	OR (95% CI)	P value	OR (95% CI)	P value
Age group (years; reference: 20-29)								
30 - 39	0.43 (0.16-1.14)	.009	0.78 (0.33-1.84)	.57	0.88 (0.19-4.08)	.87	0.77 (0.31-1.94)	.58
40+	0.98 (0.31-3.08)	.10	1.00 (0.38-2.65)	.99	0.63 (0.14-2.93)	.56	0.92 (0.33-2.58)	.88
Sex (reference: male)								
Female	1.59 (0.75-3.36)	.23	1.55 (0.78-3.08)	.21	3.51 (1.10-11.21)	.03	1.40 (0.67-2.91)	.37
Education (reference: bachelor's degree)								
Master's degree or PhD	2.74 (1.08-6.95)	.03	2.84 (1.27-6.31)	.01	3.69 (0.96-14.23)	.06	1.30 (0.55-3.07)	.55
Location (reference: Seoul)								
Gyeonggi-do	1.22 (0.51-2.89)	.66	0.96 (0.43-2.15)	.92	1.07 (0.30-3.90)	.91	1.11 (0.46-2.69)	.82
Other areas	10.95 (1.34-89.33)	.02	0.73 (0.26-1.99)	.53	1.30 (0.25-6.85)	.76	0.66 (0.24-1.87)	.44

^aOR: odds ratio.

Discussion

Our study investigated the changes observed in graduates who completed the 56-hour medical information specialist education course, which was offered across a period of 5 years. Graduates from this course had diverse academic backgrounds, and their postcourse informatics work varied accordingly. Graduates of health sciences, statistics, and computer engineering majors primarily focused on data preprocessing. Medical professionals and those with double majors often worked on data utilization plans, while those from mathematics and statistics backgrounds frequently engaged in data analysis. The faculty involved in delivering the course, comprising professors from multiple universities including some authors of this paper, primarily aimed to enhance job competency or equip participants with the necessary skills for future employment opportunities. Regarding the informatics work currently performed by the graduates, most (116/161, 72.2%) cited tasks such as “preprocessing the collected data,” “visualizing the results to understand the main analysis outcomes,” and “processing the data and preparing an analysis report using various modeling techniques.” Additionally, local workers with a master's degree or higher reported experiencing the greatest positive impact from the course. A significant proportion of graduates also indicated that their education impacted their career transitions. Predominantly, comprehension of job roles and characteristics, along with an intrinsic interest in the field, emerged as the primary influencing factors. The results indicate that this convergence practice education program serves as a successful model, effectively addressing the needs of trainees from various fields, enhancing their competencies, and preparing them for the evolving demands of the industry.

This study demonstrates the value of using real-world clinical data for training individuals across various academic fields within HI. The finding that 63.4% (102/161) of participants became more engaged in informatics-related endeavors after the course is compelling evidence for the effectiveness of this educational method in enhancing individual proficiency and involvement. Furthermore, our data suggest that hands-on clinical data education benefits those from diverse academic backgrounds, augmenting their HI activities. This aligns with prior research underscoring the value of hands-on experience in the competencies desired in industry professionals [12]. This could be an important factor to consider in future educational curriculum development or professional training programs. Interestingly, respondents holding a master's degree or higher, or those working in local settings, indicated the most significant benefits from the program. These findings imply that individuals with higher degrees possess a solid grounding in foundational HI concepts. While industry hiring trends often favor individuals with a bachelor's degree [12,13], those with advanced degrees are positioned to derive maximum value from HI training. Their robust foundation in core HI areas, including computer science, statistics, and health sciences, enables them to fully grasp and effectively implement HI concepts. In a field such as HI, wherein cultivating interdisciplinary expertise is crucial, offering specialized courses rooted in real data to master's-level professionals from varied backgrounds can be a potent strategy for developing top-tier talent. Notably, our findings suggest that graduates in rural regions benefited more from the training compared to their counterparts in well-resourced areas such as Seoul or Gyeonggi-do. This highlights the potential of similar targeted programs to elevate the educational standard and bridge the gap in educational opportunities across regions.

In well-resourced nations, medical system computerization is on the rise, with 96% of the general hospitals in South Korea

adopting electronic medical records [14]. These health care digital shifts produce vast data volumes that are essential for decision-making, gauging treatment efficacy, and underpinning evidence-based approaches [15]. To efficiently handle such expansive medical data, experts in medical information are imperative at every phase [16]. As the convergence of health care and technology accelerates, academic institutions are striving to cater to varied aspirants, spanning recent high school graduates to IT and medical professionals [17]. However, there is a scarcity of programs tailored for the HI sector, which is vaguely defined [18,19]. A disparity in the provision of HI degrees exists even in well-equipped nations such as the United States [20]. The 10×10 Program by the American Medical Informatics Association stands out as a robust training model [9]; however, for countries lacking ample educational resources, state-backed initiatives resembling the AHIA course offer a potential solution. The International Medical Informatics Association advocates for dedicated establishments offering continuous education courses [10]. Given the dynamic landscape of health IT, future programs must embed lifelong learning tenets, encouraging graduates to persistently upskill. HI professional development should also extend to current medical staff and those from varied academic realms. Training individuals with profound health care and IT expertise, coupled with a hands-on grasp of the health care structure, remains a formidable challenge. The graduates of the AHIA course, with their varied academic histories, highlight the need for more holistic, adaptive future programs. The assertion by Topol [2] regarding the imminent digital skill requirement for all National Health Services roles emphasizes the paramount importance of digital literacy in health care. Despite the focus of the program being professionals and researchers, 6.2% (10/161) of respondents professed ignorance of informatics jargon. This underscores the pivotal role of informatics education in molding a competent health workforce. Moreover, those possessing an advanced degree reportedly reaped the most benefit from this training, suggesting that upcoming courses should be tailored to the unique educational backgrounds of enrollees.

AHIA graduates hail from a broad array of fields, including computer science, health care, and statistics, with a wide range of focus in their advanced studies as well. While HI skills are crucial, medical schools offer minimal, inconsistent, and rarely updated education, leaving students unprepared for the digital health care landscape [21]. Although the swift evolution of medical technology necessitates continual adaptation of research and educational content within the field, it appears that updates to the undergraduate HI curriculum lag behind these technological advancements. Our findings highlight that, in the fast-evolving domain of medical informatics, implementing a robust and comprehensive curriculum that transcends the confines of specific academic departments or institutions—particularly one that caters to the interdisciplinary education of students from a variety of academic backgrounds—emerges as a crucial strategy. This approach is essential for keeping pace with the rapid developments in the field. We also explored the impact of the program on the career paths of graduates, finding that a majority were willing to consider job changes and that a notable portion had already done so. They attributed a significant influence on their career

decisions to the program. Analyzing web-based job postings, a German study revealed a high demand for medical informatics professionals, with half of the jobs concentrated in hospitals [22]. While hands-on experience is crucial, employers and graduates alike find it challenging to find programs that bridge the gap between computer science expertise and practical hospital knowledge. Considering that the AHIA program offers diverse students hands-on training and real-world experience using actual hospital data while working on projects in teams, the AHIA model suggests a positive strategy for strengthening the competencies of students entering the HI job market and meeting job demands.

Despite its contributions to understanding the impact of an AHIA course on graduates' job roles and competencies, this study acknowledges several limitations. First, the survey's broad focus on the overall educational program might have overlooked the nuanced impacts of specific subjects, such as information security and privacy, on graduates' career outcomes. While this approach captures the general effectiveness of the program, it leaves room for further exploration into how individual modules shape professional skills and knowledge. Potential biases in survey responses due to their self-reported nature represent another limitation. While measures were taken to ensure anonymity and encourage candidness, the inherent nature of self-reporting might introduce biases that could affect the interpretation of our findings. This aspect underscores the need for caution in generalizing the results beyond the surveyed population. The generalizability of our findings is also limited by the specific context of the educational program and its participants. This specificity might not fully capture the diverse experiences across the broader field of HI, suggesting that the findings might not be universally applicable without further validation in different settings. Furthermore, the data collection process, focusing on immediate postgraduation outcomes, does not account for the longitudinal development of competencies or career progression. This temporal limitation highlights the potential for more comprehensive, longitudinal studies to understand the lasting impacts of educational programs. Lastly, our study could not evaluate the characteristics of nonrespondents. A total of 21.8% (45/206) of individuals who completed the course did not participate in the subsequent survey. While survey fatigue, time constraints, or privacy concerns might have contributed to this nonresponse rate, the specific reasons for their lack of participation remain unexplored due to the anonymized nature of our data collection process. This limitation prevents us from fully understanding whether the nonrespondents possess distinct demographic or professional characteristics compared to survey participants, which could potentially introduce a bias in our findings. Despite these limitations, our research offers significant insights into the value of HI education and its role in preparing professionals for the field. It underscores the importance of curriculum design in addressing the evolving needs of the HI sector and provides a foundation for future research.

Our survey of AHIA graduates revealed 2 particularly compelling findings that enrich our understanding of the program's effectiveness and potential areas for future research. First, the reported educational impact of the AHIA program

was more pronounced among graduates holding a master's degree or higher. Second, students residing outside the metropolitan area of Seoul perceived a greater benefit from their participation in the program. These results suggest that advanced educational background and geographic diversity play significant roles in the perceived value and impact of HI education. Incorporating these perspectives, we propose additional areas for future research. Further investigation into the influence of prior academic achievements on the outcomes of HI education is warranted. Specifically, understanding the mechanisms through which graduates with higher degrees report greater benefits from their education can inform the tailoring of programs to enhance benefits across various educational levels. This exploration is essential for developing curricula that are responsive to the educational background of students, ensuring that all participants can achieve significant gains from their involvement. Additionally, the greater perceived impact of HI programs among students from nonmetropolitan areas highlights the need for an in-depth analysis of geographic disparities in educational outcomes. Identifying the challenges faced by students in accessing traditional educational resources and the ways in which alternative models such as the AHIA program can effectively bridge these gaps will be crucial. Such

research could lead to the development of more accessible and inclusive HI education programs, which are particularly vital for students in resource-limited countries and those residing outside major urban centers.

Timely, project-based, and government-supported education programs similar in rigor to degree programs can provide practical education that helps professionals in HI meet the ever-changing needs of the field and continue to upskill. As a case study of a flexible educational program that can accommodate a variety of educational methods and topics, the experience and results of the AHIA program can act as a reference for the global HI education community in the design of integrated educational modules centered on real data and cases.

In conclusion, this study underscores the necessity of flexible, inclusive, and responsive educational models in HI. By addressing the highlighted areas for future research, the field can move toward developing educational programs that not only cater to the diverse needs of students but also prepare them to meet the challenges and opportunities within the dynamic landscape of HI.

Acknowledgments

Abstract

Background: The key to the digital leveling-up strategy of the National Health Service is the development of a digitally proficient leadership. The National Health Service Digital Academy (NHSDA) Digital Health Leadership program was designed to support emerging digital leaders to acquire the necessary skills to facilitate transformation. This study examined the influence of the program on professional identity formation as a means of creating a more proficient digital health leadership.

Objective: This study aims to examine the impact of the NHSDA program on participants' perceptions of themselves as digital health leaders.

Methods: We recruited 41 participants from 2 cohorts of the 2-year NHSDA program in this mixed methods study, all of whom had completed it >6 months before the study. The participants were initially invited to complete a web-based scoping questionnaire. This involved both quantitative and qualitative responses to prompts. Frequencies of responses were aggregated, while free-text comments from the questionnaire were analyzed inductively. The content of the 30 highest-scoring dissertations was also reviewed by 2 independent authors. A total of 14 semistructured interviews were then conducted with a subset of the cohort. These focused on individuals' perceptions of digital leadership and the influence of the course on the attainment of skills. In total, 3 in-depth focus groups were then conducted with participants to examine shared perceptions of professional identity as digital health leaders. The transcripts from the interviews and focus groups were aligned with a previously published examination of leadership as a framework.

Results: Of the 41 participants, 42% (17/41) were in clinical roles, 34% (14/41) were in program delivery or management roles, 20% (8/41) were in data science roles, and 5% (2/41) were in "other" roles. Interviews and focus groups highlighted that the course influenced 8 domains of professional identity: commitment to the profession, critical thinking, goal orientation, mentoring, perception of the profession, socialization, reflection, and self-efficacy. The dissertation of the practice model, in which candidates undertake digital projects within their organizations supported by faculty, largely impacted metacognitive skill acquisition and goal orientation. However, the program also affected participants' values and direction within the wider digital health community. According to the questionnaire, after graduation, 59% (24/41) of the participants changed roles in search of more prominence within digital leadership, with 46% (11/24) reporting that the course was a strong determinant of this change.

Conclusions: A digital leadership course aimed at providing attendees with the necessary attributes to guide transformation can have a significant impact on professional identity formation. This can create a sense of belonging to a wider health leadership structure and facilitate the attainment of organizational and national digital targets. This effect is diminished by a lack of locoregional support for professional development.

(*JMIR Med Educ* 2024;10:e46740) doi:[10.2196/46740](https://doi.org/10.2196/46740)

KEYWORDS

digital leadership; professional identity; dissertation of practice

Introduction

Background

Delivering the digital transformation of the United Kingdom's National Health Service (NHS) has been a long-standing aim. In the "What Good Looks Like" framework, by 2025, the NHS aims to have all integrated care systems and associated trusts reach core digital capability [1]. The key to this digital leveling-up strategy is the need to support professional development and training opportunities across integrated care systems [2]. To facilitate system-wide progress, there is a growing need for digitally proficient leadership teams; however, one of the main barriers identified by the NHS Transformation Directorate has been a lack of a "clear steer" for digital decisions [3].

Digital health resources and digital tools that were adopted through necessity during the COVID-19 pandemic have led to a paradigm shift in routine care. The scope of these resources has been significant across health care, including remote patient-clinician consultations and diagnostics [4-6]. However, as the health care service looks to enact facets of the *NHS Long Term Plan* and scale future sustainable digital change, possessing robust leadership to set this direction is key [7].

The NHS Digital Academy (NHSDA) designed its flagship course to deliver this support to emerging leaders. Each cohort of approximately 100 professionals is selected from applicants who are directly employed by the NHS or social care in England [8]. Digital health leadership is delivered in 2 accredited components. The first, resulting in a Postgraduate Diploma (PGDip) in Digital Health Leadership, uses a blended learning approach to provide a theoretical foundation for topics such as user-centered design [9,10]. This involves web-based teaching on 6 core modules structured around assessment deadlines including the essentials of health systems, implementing change, health information systems, user-centered design, actionable data analytics, and leadership change. Subsequently, students can undertake a 1-year Master of Science (MSc) degree. The MSc degree uses a dissertation of the practice model, where students focus on practicable applications of theory within defined digital transformation projects. This self-directed period of study involves candidates' leading projects within their own host organizations with periodic deadlines to guide progress and continued access to the support of the teaching faculty. In this manner, the course facilitates a workplace-based learning model geared toward supporting students to use research to solve a real-world problem in their organization. Although the course has been shown to effectively impact the attainment of national digital priorities [11], little is known about the effect on participants' perceptions of themselves as digital leaders or their professional identity.

Defining professional identity is difficult owing to a lack of standardization of the term. It has been associated with knowledge acquisition, performance of typical tasks, displays of expected behaviors, or shared ethos and value systems [12].

In other contexts, professional identity involves the integration of the personal and professional selves [13]. A scoping review by Cornett et al [14] identified 5 constructs associated with health professional identity, including lived experience (eg, practicing), the world around me (eg, the workplace), belonging (eg, collective identity), me (eg, self in relation to the profession), and learning (eg, acquiring skills). However, the review examined health professional practice and did not specifically examine digital leaders [14]. Understanding what constitutes the identity of a digital health leader is potentially more problematic, given that the field is relatively nascent. Consequently, understanding what knowledge is needed, the tasks or behaviors that are expected of leaders, and what constitutes core values is likely to remain ill-defined until the digital health landscape has evolved. Furthermore, an individual's perception of their professional role is a dynamic process and can be augmented by one's context [15]. Determinations regarding the extent to which one feels like a professional can therefore be difficult to ascertain.

Despite these challenges, professional identity formation has been shown to be an increasingly important aspect of learning development. Within clinical settings, professional identity contributes to the delineation of practice boundaries as well as avoiding confusion regarding individuals' roles within wider teams [16]. With a growing body of clinicians involved in digital leadership, this is particularly important, as studies have demonstrated that doctors can often encounter difficulties when reconciling managerial and clinical responsibilities. Moreover, aspects of professional identity, such as "belongingness," have been associated with greater workforce retention [17]. Therefore, there is a growing drive to evaluate how courses and educational curricula impact an individual's identity.

Aim

This mixed methods study aimed to understand the influence of the NHSDA Digital Health Leadership program on participants' perceptions of themselves as digital health leaders. This will facilitate a greater understanding of the core values associated with digital leadership and provide insights to improve courses globally.

Methods

This study was conducted as a mixed methods study involving a web-based questionnaire, interviews, and focus groups.

Recruitment

Participants in the first 2 cohorts of the NHSDA's flagship Digital Health Leadership program were recruited for the study. All participants had completed both years of the program and were >6 months from completion to avoid recency bias. This could involve overemphasizing the impact of later teaching in course compared to that which occurred earlier. Studies suggest that a later evaluation can provide a more holistic evaluation [18]. It also provided time for candidates to reflect on future career opportunities. No other exclusion criteria were placed

upon participants; therefore, a nonprobabilistic sampling method to reach the necessary sample size was used. Eligible participants were contacted through email by a member of the research team (AA) with no direct link to the NHSDA. Both cohorts were impacted by the COVID-19 pandemic, particularly with respect to their dissertation projects that were undertaken during the pandemic.

Scoping Questionnaire

A previously validated web-based scoping questionnaire was used to provide insights and feedback on the course [11]. This questionnaire explored the impact of the course on the development of facets such as “social intelligence,” “interpersonal skills,” and “courage.” It also examined the effect of the course on future goals, asking “Would you consider any of the following additional training options in Digital Health Leadership or a related field within the next 2 years?” This questionnaire was developed to map specifically onto the NHSDA program objectives and encompassed questions including individuals’ perspectives on development and digital leadership. It also sought to ascertain feedback on the aspects of the course that were most influential on participants. A total of 2 authors (RCB and AA) developed the survey questions, whereas a third (AS) independent author was involved to discuss disagreements. The participants were recruited via an email containing an anonymous link. The links were delivered to all eligible individuals separately from the program to avoid selection and response biases based on prior performance in the course.

Semistructured Interviews

Following the survey, anonymous responses were quantitatively (multiple-choice questions) and qualitatively analyzed (free-text sections). Themes derived from the analysis were elicited by 2 authors (RCB and AS). The results from the survey were then used to develop the question guides for interviews and focus groups (Multimedia Appendix 1). A third author (AS) was involved to help resolve disagreements. Interviews were designed to gain a more in-depth understanding of individuals’ perceptions of the values and skills associated with digital health leadership and how the course has influenced these areas. Enrollment to an interview was not dependent on completion of the survey or prior performance. All interviews were conducted web-based via Microsoft Teams (Microsoft Corporation). AA conducted all the semistructured interviews, and AA had no formal role within the NHSDA and no prior interaction with any participants to avoid response biases.

Focus Groups

To ascertain the shared experience of participants and paralleling the collaborative learning approach used by the program, web-based focus groups were also undertaken using the Microsoft Teams platform. In addition, the focus groups examined the participants’ contrasting experiences of the course. A total of 3 focus groups were conducted, with the facilitator (AA) not being affiliated with the NHSDA. Each focus group involved 4 to 5 participants. The invitation to participate in the focus groups was not contingent on the completion of any previous phase of the study. As with the interviews, the focus

groups used open-ended prompts to foster responses. In addition, the facilitator encouraged open discussion between participants. Identity involves the development of attributes congruent with the profession, that is, a common set of values about what it means to be a digital health leader [19]. By facilitating focus group discussions regarding how digital leadership is perceived, its underpinning principles, and how one can develop the necessary skills to become a more effective leader, a greater understanding of these shared values was attained.

Analysis

Survey responses were collated through the web-based tool Qualtrics (Qualtrics International Inc). Qualtrics automatically aggregates replies and provides frequencies from the respondents by choice. Given the small number of responses and because the initial survey was used to inform further study phases, no statistical analysis was undertaken. Free-text options were inductively thematically analyzed until data saturation was achieved by an author (AA) and validated by another (RCB). Both qualitative and quantitative responses were used to inform the development of the topic guides following discussion between the authors. Specifically, the authors focused on areas of disagreement or if a particular topic recurred across the responses of different participants.

Audio recordings, obtained with the consent of participants for both interviews and focus groups, were transcribed using the web application Descript (Descript, Inc). The accuracy of the outputs was confirmed by one author (AA), who was present in the interviews and focus groups. Anonymized transcripts were then uploaded to the analysis tool MAXQDA (VERBI GmbH). A deductive thematic analysis was conducted using a technique previously used in similar studies [20]. This involved familiarization with the transcripts by 2 authors (RCB and AA). The transcripts were then coded with the data explored to examine the frequency and relationship of the codes. Similar codes were combined into themes and subthemes, which were aligned with the components of professional identity elicited by Chin et al [19]. This review was selected as a framework on which to base the thematic analysis for 3 reasons: first, because of its comprehensive evaluation of identity with 10 evidence-based facets described; second, the examination of internship or workplace-based learning parallels the educational model of the NHSDA’s second year; and finally, the authors’ examination of how these components map to other contexts can facilitate cross-discipline comparisons was helpful in understanding the participant’s identity across wider teams [21]. Although Chin et al [19] found that only a subset of these components was applicable to higher education internships, this study examined the relevance of all components, as some were more significant in postgraduate studies.

As a means of validation, the anonymized transcripts were reviewed again, and themes were amended until a consensus was attained. All discrepancies within the coding exercise or allocations of themes were discussed until resolution. Themes that were consistently mentioned by different participants, those that aligned with findings from the questionnaire or focus group, and those that were regarded as stronger determinants were considered more impactful influences. A constructivist approach

was used as the basis of this study, which paralleled the active learning undertaken throughout the program. The paradigm focuses on the importance of active learning and its transformation through experience [22,23]. It involves the engagement and reflection of the learner, which can be impacted by context, knowledge, motivation, values, or organizational setting [24]. This is particularly pertinent to identity development, which can be influenced by such intrinsic and extrinsic factors.

High-scoring dissertations across the 2 included cohorts were also evaluated independently by 2 authors (RCB and AA). The authors then mapped the skills exhibited in these manuscripts to the components of professional identity. Students were required to make explicit reference to a particular component for it to be mapped. The authors discussed any disagreements until a consensus was reached.

Ethical Considerations

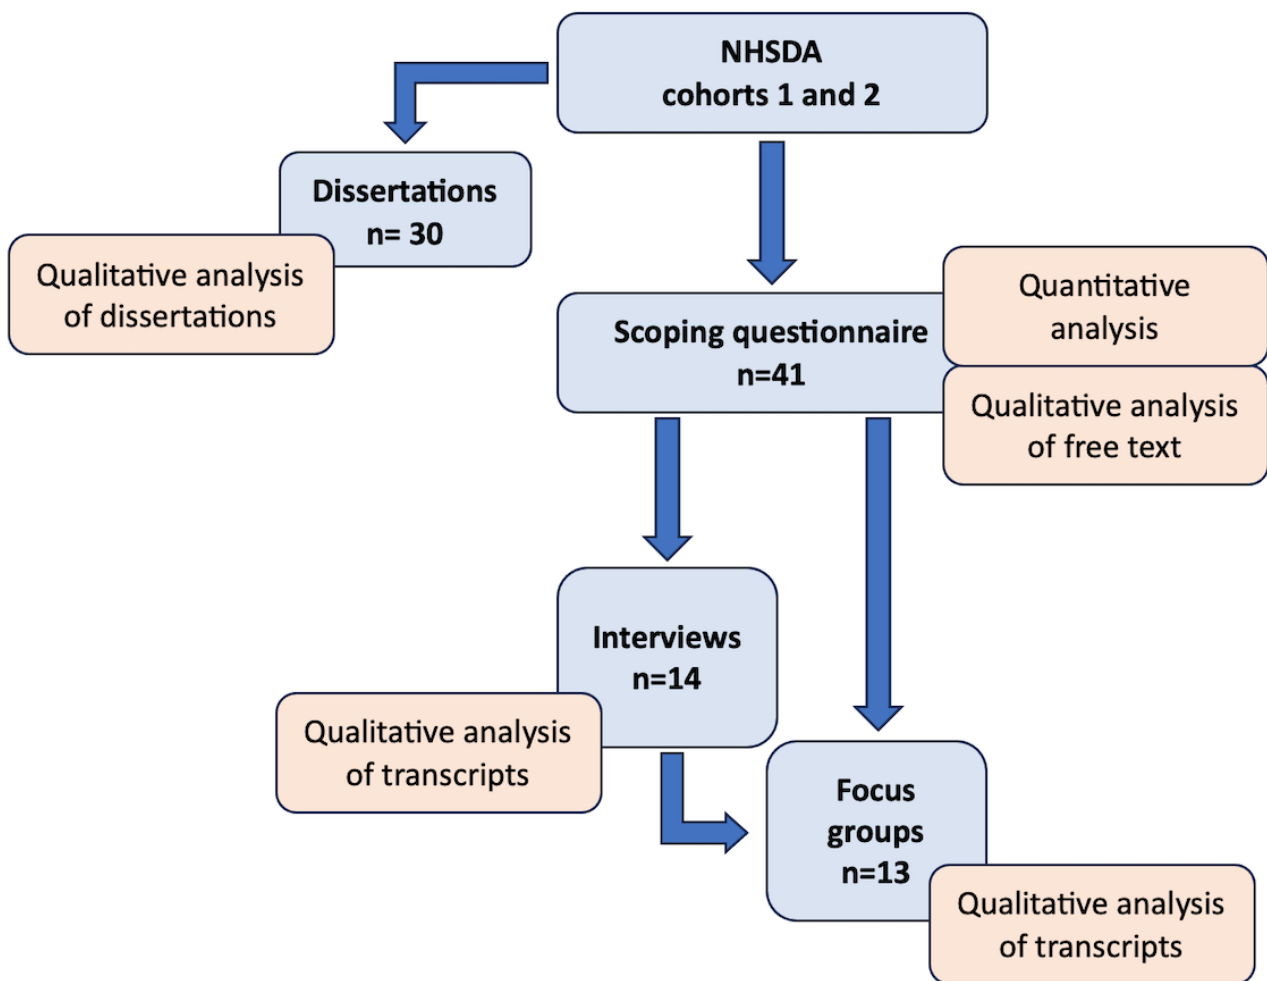

Approval to conduct this study was provided by the Institutional Review Board at Imperial College London (reference EERP2021-026a). All participants provided explicit written consent to participate in the study and were free to withdraw at any time. No participant received financial remuneration for being involved in the study. All data including transcripts and survey data were kept anonymous, in keeping with the secure data storage policies of Imperial College London.

Results

Overview

A total of 41 eligible participants completed the web-based survey, of which 42% (17/41) were female and 59% (24/41) were male. Most participants were in clinical health care roles (17/41, 42%), whereas 34% (14/41) were in program delivery or management roles; 20% (8/41) were in informatics or data science roles, and 5% (2/41) were in “other” roles. Of those surveyed, 59% (24/41) reported that the NHS Digital Academy course had a strong and direct impact on their working practice, 27% (11/41) reported some impact, and only 2% (1/41) reported no effect. In total, 4 key themes were elicited from the inductive analysis of the free-text sections: transformative impact, valuing collaboration, goal setting, and improving positive perceptions. The selected results are presented in [Multimedia Appendix 1](#).

Semistructured interviews were conducted with 34% (14/41) of participants. The demographics of which paralleled those from the wider cohort, with 43% (3/7) of participants identifying as female and 50% (7/14) working in clinical roles. In total, 3 focus groups were held with more than half of the attendees (7/13, 54%) not involved in the preceding interviews. The data sources including the number of participants used in the study is presented in [Figure 1](#).

Figure 1. The flow of participants in the study.

Thematic analysis mapped findings from interviews and focus groups to 8 of the 10 components of professional identity highlighted by Chin et al [19]. Internship experience was not measured, as most of the cohort had been in their roles before the NHSDA and could not be considered entering an internship. However, aspects encompassing skill acquisition during dissertations were covered in other domains. The work environment was also not included, as the participants came from disparate fields, precluding comparisons. However, the findings were mapped to the following domains: commitment to the profession, critical thinking, goal orientation, mentoring,

perception of the profession, socialization, reflection, and self-efficacy. When undertaking the thematic analysis and mapping of the highest-scoring dissertation to the components from the framework by Chin et al [19], only 4 were found to be applicable. These included critical thinking, goal orientation, mentoring, and reflection. This is likely because the dissertation was more descriptive of a specific transformation project rather than reflective of the attitudes of participants toward digital health leadership as a whole.

Table 1 demonstrates how the course impacted these areas through quotations from the respondents.

Table 1. Key domains^{a,b} of professional identity with quotes from participants on the impact of the course.

Domain	Definition	Quote
Commitment to profession	The physical, mental, and emotional commitment to being a digital leader. Understanding the aims of leadership and demonstrating a willingness to achieve them.	<ul style="list-style-type: none"> “People saw what I was learning from the course and my enthusiasm for my career...I was invigorated and it encouraged me to do the best in my career path.” [Interviewee 13] “Having gone through the course, I want to pursue careers in digital in some fashion...it’s shifted the course of my career, I’m aspiring to national level roles.” [Interviewee 7]
Critical thinking	A metacognitive skill to critically evaluate the current standard and elicit new solutions. Involves understanding one’s own role as a digital leader and how one would want it to be.	<ul style="list-style-type: none"> “There is a critical language element to it [digital leadership]...you have more critical analysis aspect to your work...it [the National Health Service Digital Academy] has changed the way I approach and think about problems.” [Interviewee 6] “I became more strategic in my approach... it’s broader...it’s about thinking right...we need it think from top to bottom.” [Interviewee 5]
Goal orientation	How one achieves and defines the specific outcomes associated with being a digital leader. Involves having a conducive environment for task mastery and development as a digital leader.	<ul style="list-style-type: none"> “My perception has shifted...I see myself as a facilitator of digital transformation...I aim to maintain virtual delivery and my organization is helping me meet that need.” [Interviewee 11] “One of the most valuable things from the digital Academy...it made me understand where to make change, improve processes, how to measure that change and feeding it back...it is the core of our aims.” [Interviewee 1]
Mentoring	Acting as a mentor and having mentorship. Involves role modeling, feedback strategies, and encouraging self-reflection as a digital leadership, as well as a conducive work environment for mentor.	<ul style="list-style-type: none"> “I believe in paying it forward, I’ve brought back what I’ve learnt to building my informatics team.” [Interviewee 7] “I became very invigorated by the community...I spent an afternoon with a module lead in user design... then the head of user design centre in the NHS offered me an opportunity to shadow them.” [Interviewee 13]
Perception of the profession	Ideas about what it is to be a digital leader, the skills required, and its place in wider health care infrastructure.	<ul style="list-style-type: none"> “The NHSDA meant I didn’t hold those people on a pedestal...it [digital leadership] is not about having all the technical knowledge, it’s being able to pull together everyone toward the solution.” [Interviewee 11] “It has been transformational...just in the knowledge it has given me...on understanding the role...where it fits into organizational strategy...the scope.” [Interviewee 4]
Professional socialization	A sense of belonging to the wider community and being accepted as part of a group. Includes credentialing and peer networks.	<ul style="list-style-type: none"> “It has a level of kudos...there is good recognition that it, the academy skilled them up.” [Interviewee 12] “Now I’ve got a network of probably 100 or more contacts nationally...I would go and talk to them and say you must know someone locally who does this, any chance you could put me in touch?” [Interviewee 8]
Reflection	Reflecting on knowledge, cognition, professional identity, maturity, and the sense of professionalism within digital leadership. Involves ideas regarding professional development.	<ul style="list-style-type: none"> “It’s highlighted the positives and the negatives of my leadership style, my digital knowledge and also where I fit within an organization and nationally. So it’s given me that sort of self-awareness.” [Interviewee 10] “It helped me become better leader. It helped me understand how would I help people in the organization transform and be more innovative.” [Interviewee 2]
Self-efficacy	Self-belief or belief in one’s own capabilities to perform as a digital leader. Includes imposter syndrome and the impact of external opinions upon one’s own beliefs.	<ul style="list-style-type: none"> “When I first went on the digital academy...it felt like we were interlopers...throughout it continued to build my confidence levels and where I fit as a digital leader locally.” [Interviewee 14] “It made me think that I am a leader...I would never have applied for that Royal College job without it.” [Interviewee 3]

^aWork environment not included as relevant components covered in “mentoring,” and participants came from disparate environments.

^bInternship experience was not included. The participants represent the existing digital health leadership whose roles would not include internship. Areas of skill-building are covered within other domains.

Commitment to the Profession

The program appeared to influence individuals’ commitment to digital health leadership. In total, 59% (24/41) of the cohort reported changing their roles following the course. Among the participants who changed their roles following the course, 46% (11/24) reported that the program had a strong impact on this decision. Inductive thematic analysis of the survey comment elicited this transformative impact of the course upon

candidates’ careers, with several describing “life-changing” or “career-changing” effects. In one focus group, one informatician mentioned that “I do now feel like a leader, and I wasn’t going to stay in that organisation.” This new commitment led them to “find somewhere else that I [they] could be a digital leader.” Others reported that they “were looking at influencing policy, in a way I [they] hadn’t before...because of the course.” This commitment to digital health leadership has led them to apply for chief clinical informatics officer (CCIO) roles. The course

also appeared to reaffirm participants' motivation for undertaking digital health leadership roles. One CCIO stated:

[The course] hasn't necessarily given me all the technical skills...but it's greater than that. It's given the background of how we've got to where we are now and inspired me to change things going forward.

Critical Thinking

Critical thinking, which involves understanding a context and deriving new solutions, was found to be fostered predominantly

through the MSc dissertation. As presented in [Table 2](#), all but 3 of the 30 highest-ranking dissertation topics across the 2 cohorts involved critical analysis.

Providing a supportive environment for change enabled candidates to put theoretical learning into practice. An interviewee said "I [they] approach things differently, I'm [they are] more strategic, more constructed after the project." These cognitive skills have continued postgraduation with individuals feeling they have "different tools that were picked up during the academy, which I [they] use day-to-day."

Table 2. Topics of the highest-scoring dissertations of the 2 cohorts and components of identity that were incorporated.

Goal Orientation

Goal orientation encompasses defining and accomplishing the specific outcomes of digital leadership within the NHS. This may involve achieving national priorities outlined in health policies, such as the *NHS Long Term Plan* or locoregional transformation targets. As the MSc model was designed to provide a supported environment to undertake these projects, it was unsurprising that all the dissertations evaluated involved an element of goal orientation. These projects varied from digitizing diabetes education platforms and booking processes to projects focusing on the implementation of the recommendations of the Topol review [25]. An interviewee said, “The reason I [they] chose this MSc project was because...it was my day job.” This pragmatic approach helped align the goals of the course with those of digital leaders. Survey comment analysis also elicited “goal setting” as a key theme. Several candidates identified future opportunities for further professional development across a broad range of areas, including policy development, finance, teaching, and strategy.

Mentoring

The influence of the NHSDA on the provision and reception of mentorship was variable. Only 27% (11/41) of the survey respondents felt they acquired mentoring skills; however, 59% (24/41) reported that they were more able to develop capabilities within their teams. Moreover, 50% (15/30) of dissertations reflected the provision of mentoring within participants’ local organizations. Following attendance at the NHSDA, some candidates were encouraged to “develop the professional training development with my [their] own teams,” with a common theme being “paying forward” the knowledge they had acquired. Furthermore, the program provided opportunities for candidates to receive mentorship or “shadowing opportunities.” One candidate who developed an interest in user-centered design “spent a really impactful afternoon with a module lead” and, subsequently, connected with designers from NHS England. This culminated in a career change to a health care–based user experience department. These experiences were significantly influenced by candidates’ work environments, with others noting they were “still alone in the organization...with little guidance from management.”

Perception of the Profession

An informatician reported, “since the course...I see myself [themselves] as a facilitator of digital transformation,” as opposed to their previous notions regarding a more technical role. This was echoed by others who perceived digital leaders as change agents: “not just somebody with the skills...but the ability to make connections to bring about transformation.” For more junior candidates, the course also helped level the hierarchy within the digital ecosystem. Having previously put

“digital leaders on a pedestal” and believing that becoming one “was an unachievable target,” following the course, they believed that “it [being a digital leader] is not about having all the technical knowledge but being able to pull everyone together toward a solution.” Conversely, more established digital leaders had constructed their perceptions of digital leadership before the NHSDA, with 1 CCIO explaining, “it [the course] hasn’t changed the way I perceive what I do, it has made me more effective.”

Professional Socialization

Socialization was a key untaught component of the course. In the questionnaire, 46% (19/41) reported that the MSc program influenced their feelings of socialization within digital leadership. Inductive thematic analysis of the survey elicited “valuing collaboration” as a common theme among respondents. Many were reporting that they now found value in a “network of like-minded professionals” and wanted to “understand [their] colleagues better.” Moreover, most respondents highlighted that the program taught them how to maintain effective relationships (29/41, 71%) and inspired a shared purpose among colleagues (30/41, 73%), both facilitating a common sense of belonging. A participant suggests the “main impact of the MSc was this community of leaders who understand transformation...and share knowledge with each other.” This “collaboration is helping me [them] realise they were no different.” This network facilitated wider professional socialization by providing participants with “incredible peer support” as well as “recognition within the wider community” of the NHSDA.

Reflection

Reflection upon practice was a core facet of the dissertation, with candidates actively encouraged to examine their own practice and how it correlates with their perceptions of digital health leadership. Therefore, 80% (24/30) of the dissertations demonstrated evidence of reflective practice. This encouragement to reflect upon practice has led to several candidates reporting the academy “highlighted the positives and the negatives of my [their] leadership style,” fostering a “sort of self-awareness.” Reflection was also associated with candidates refining their perceptions of the nature of digital transformation. One CCIO from cohort 1 notes the NHSDA “makes you reflect on how we embark on this challenge of having to scale digital at pace in the context of the pandemic.”

Self-Efficacy

The development of self-efficacy was found to be a key tenet of the program, with 61% (25/41) of the respondents reporting that the course had positively increased their confidence in their role. One candidate noted that “When I [they] first went on the digital academy there was an element of imposter syndrome,”

being told, “not to think about imposters, you need to think as pioneers.” Others had reflected that the digital academy had given them “the confidence to lead in digital” and “empowerment...to recognize that I [they] have the ability to do anything I [they] put my [their] mind to.” This has led to several candidates being recognized as leaders within the wider digital health ecosystem, but not necessarily in their own organizations. One clinician noted that they “had taken up a few national unpaid roles”; however, another noted that “they [the director] was not interested...did not recognize the training we had.”

Discussion

Principal Findings

This study is one of the first to demonstrate the impact of a focused program on digital health leadership on attendees’ professional identity. The findings demonstrate that the course has a diverse range of impacts including commitment to the profession, critical thinking, goal orientation, mentoring, perception of the profession, socialization, reflection, and self-efficacy. By using a dissertation of the practice model, in which students undertake a supported digital transformation project, participants are provided with an opportunity to develop metacognitive and reflective skills. The effect of this skill development lasts beyond the course, with several participants altering their leadership style and developing more agile and collaborative approaches. Furthermore, the projects enable participants to define and attain digital goals, which may have been more difficult to define, benchmark, and achieve previously. The program reaffirmed attendees’ commitment to being or becoming a digital health leader, leading to more than half of the participants changing their roles after graduation. Among the group of individuals that changed roles, almost half noted that their experience within the NHSDA had a significant impact on this decision. In addition, the program dispelled the imposter syndrome felt by emerging leaders by increasing their confidence and a sense of professional belonging. This was facilitated by the network of alumni, which may help mitigate the organizational isolation felt by some participants.

Professional identity formation has become the focus of a diverse range of fields, including medical education [26]. Among health care professionals, studies have shown that the development of a shared core value set can have substantial benefits, including improving the well-being and resilience of physicians [27]. Professional identity’s influence in other areas is less well documented, but some benefits may be appreciable across a range of disciplines. In a study by Meadows and de Braine [28], industry leaders displayed stronger leadership identities during the COVID-19 pandemic to help overcome challenges such as the implementation of new technologies. Digital health leadership teams who were faced with comparable issues are likely to have also relied on stronger leadership identities during this time. Consequently, there is increasing interest in understanding how educational programs can foster professional identity in their cohorts. Some have suggested that to develop identity requires departing from traditional pedagogy and using greater participatory or sociocultural learning

opportunities [29]. The NHSDA program uses a mixed approach, blending didactic learning with collaborative work in the first year and a dissertation of the practice model in the second year. Therefore, a breadth of impact, both intended and unintended, upon the identity of participants as digital health leaders were noted.

A principle focus of the course and the dissertation project is on reflective practice. Therefore, it was not surprising that 80% (24/30) of the projects incorporated these skills. Reflective exercises are an important component of professional identity and can help leaders hone their metacognitive and inductive reasoning skills. Studies have shown that through these processes, learners can also identify their own cognitive biases and avoid errors [30]. Moreover, the dissertation was also noted to foster critical thinking, with several participants reporting that they had become more “strategic.” Critical thinking is a higher-level cognitive skill in which individuals understand phenomena through their interpretation and inference of contributory factors and variables. Critical thinking enables learners to become more agile [31]. Given that the digital health landscape is continuing to evolve in the United Kingdom following the pandemic and the continued challenge of resource allocation, an ability to acclimatize to these newer contexts would appear integral. In fact, when asked directly “What is a digital health leader?” several respondents referred to this adaptability, noting the need for “fearlessness, curiosity, and being comfortable going into unknown territories.”

One of the key unintended consequences of this course has been its impact on professional socialization. Socialization is crucial for emerging learners to learn the values and beliefs necessary to succeed within their roles as well as to form a robust idea of what constitutes a digital health leader. The peer support, or “sphere of networking,” that has developed among participants has facilitated not only knowledge sharing but also a sense of a community of digital health leaders. Several participants refer to a sense of confidence and validation of their identity as they were able to collaborate with recognized digital leaders. This socialization is seen in other areas of health professional development and provides a sense of “belonging,” as well as facilitating transition across clinical roles (eg, clinician to leader) [14]. This may mitigate the varying support that participants receive within their organizations.

On the other hand, few participants reported being mentored, and many participants felt unrecognized within their local institutions. Mentorship is a crucial facet of identity, as it enables the observation, modeling, and imitation of leadership behaviors, as described by the social learning theory [32,33]. Consistent with previous studies, time pressures and competing demands are often barriers to mentoring in health care environments. Moreover, several participants reported a lack of recognition by their local management teams following the course. This lack of external validation as an emerging leader in digital health may have thus contributed to this shortage of mentorship opportunities. However, having engaged in the collaborative environment of the NHSDA, participants were more open to facilitating the future training of more junior members of their own teams. In addition, these local barriers may underpin the drive to find different opportunities and explain the high rates

of role switching after graduation. Future work should look to examine these findings as well as how accreditation from courses such as the NHSDA can impact organizational buy-in.

Limitations

However, these findings must be considered within the limitations of the study. Despite using a robust approach, the respondents represent a subsection of the eligible cohorts involved. Moreover, only high-scoring dissertations were evaluated, which may have skewed our findings. However, this decision was made because scores were given based on the comprehensiveness of the write-up not the quality or results of the project. Therefore, they provided a more detailed impression of the elements of professional identity included. These selection effects were mitigated by delivering the questionnaire widely, and not all perspectives could be explored. This may affect the generalizability of the results, but it does provide a strong indication of the breadth of influences of the course. Furthermore, as previously mentioned, there is no set definition of what it is to be a digital health leader. As such, components from other contexts have been used to frame this study, which may mean that certain nuances have been omitted. Although the use of a previous extensive systematic review reduced the likelihood of this, it cannot be considered comprehensive. Furthermore, both cohorts enrolled undertook at least part of their study during the COVID-19 pandemic, in which there was a significant change in the delivery of health care and the need

for digital solutions [34]. The influence of these changes on participants' experience of the course or its impact on their professional identity cannot be ascertained. Future work should examine what constitutes a digital health leader and how this differs from health leadership more generally. This could potentially result in defining a core value set to facilitate the evaluation of digital and clinical leadership courses. This examination would need to consider the technical and nontechnical aspects of digital health leadership, as understanding both facets is essential as digital transformation continues to accelerate.

Conclusions

The increasing demand for clinical management to guide the next stages of transformation efforts requires a digitally adept corps of health leadership professionals. These digital leadership proficiencies must not only encompass technical skillsets but also include the values, judgments, and cultural beliefs about what it is to be a digital leader. The NHSDA and similar courses are likely to impact this identity formation through a broad range of effects, including socialization and professional commitment. However, further work is needed to understand what attributes are needed by a digital health leader so that training courses can be iterated and adapted. Moreover, this categorization will support the recognition of potential digital leaders who can be mentored within their local organizations, and key barriers to this progression can be overcome.

Acknowledgments

Funding for this project was provided by the Imperial Biomedical Research Centre. The Imperial Biomedical Research Centre provided the infrastructure to design and conduct the study. The funder had no role in the conduct, analysis, or dissemination of this study. Researchers were independent of funders, and all authors had full access to all the data in the study and can take responsibility for the integrity of the data.

Data Availability

The data that support the findings of this study are available from the authors, but restrictions apply to the availability of these data, which were used under license for this study and thus are not publicly available.

Authors' Contributions

AA, AS, and RCB were all involved in the study design, conduct, and data analysis. AA and RCB drafted the manuscript, with AS involved in editing and reviewing the manuscript submission. AD provided infrastructural support that enabled the study to occur and oversaw study conduct.

Conflicts of Interest

AD is the codirector of the National Health Service Digital Academy and Chair of the Health Security initiative at Flagship Pioneering UK Ltd. RCB is the Principal Teaching Fellow for the Master of Science in Digital Health Leadership and Chair of Master of Science Dissertations across the Institute of Global Health Innovation. Both authors acted independently during the conduct of this study.

Abstract

Background: Multiple-choice examinations are frequently used in German dental schools. However, details regarding the used item types and applied scoring methods are lacking.

Objective: This study aims to gain insight into the current use of multiple-choice items (ie, questions) in summative examinations in German undergraduate dental training programs.

Methods: A paper-based 10-item questionnaire regarding the used assessment methods, multiple-choice item types, and applied scoring methods was designed. The pilot-tested questionnaire was mailed to the deans of studies and to the heads of the Department of Operative/Restorative Dentistry at all 30 dental schools in Germany in February 2023. Statistical analysis was performed using the Fisher exact test ($P < .05$).

Results: The response rate amounted to 90% (27/30 dental schools). All respondent dental schools used multiple-choice examinations for summative assessments. Examinations were delivered electronically by 70% (19/27) of the dental schools. Almost all dental schools used single-choice Type A items (24/27, 89%), which accounted for the largest number of items in approximately half of the dental schools (13/27, 48%). Further item types (eg, conventional multiple-select items, Multiple-True-False, and Pick-N) were only used by fewer dental schools ($\leq 67\%$, up to 18 out of 27 dental schools). For the multiple-select item types, the applied scoring methods varied considerably (ie, awarding [intermediate] partial credit and requirements for partial credit). Dental schools with the possibility of electronic examinations used multiple-select items slightly more often (14/19, 74% vs 4/8, 50%). However, this difference was statistically not significant ($P = .38$). Dental schools used items either individually or as key feature problems consisting of a clinical case scenario followed by a number of items focusing on critical treatment steps (15/27, 56%). Not a single school used alternative testing methods (eg, answer-until-correct). A formal item review process was established at about half of the dental schools (15/27, 56%).

Conclusions: Summative assessment methods among German dental schools vary widely. Especially, a large variability regarding the use and scoring of multiple-select multiple-choice items was found.

Introduction

Summative examinations of theoretical knowledge are an integral part of university degree programs. As they are intended to assess examinees' ability regarding predefined learning objectives, they should reflect examinees' true knowledge as closely as possible. To assess examinees objectively and efficiently, multiple-choice examinations were described as

early as 1916 [1,2]. To date, these types of examinations have been expanded by further item types, and multiple-choice examinations are frequently used within higher education including but not limited to dental training programs [3-5]. Multiple-choice items (ie, questions) can be subdivided into single-choice items (eg, Type A, Type K, Type R, and alternate-choice) and multiple-select items (eg, Pick-N and Multiple-True-False [Type K']) [6]. While dichotomous scoring (ie, 1 full credit point is awarded if examinees mark the correct

answer option or statements, otherwise no credit is awarded) is most commonly proposed for single-choice items [7], scoring methods for multiple-select items are more heterogeneous: Besides dichotomous scoring, further scoring methods resulting in (intermediate) partial credit or even negative points (ie, malus points) have been described [8,9].

Besides paper-based examinations, examinations are nowadays frequently delivered electronically. While electronic examinations are well perceived by examinees [10], comprehensive studies regarding their effectiveness are still lacking [11]. However, the use of different examination software (eg, UCAN's [Umbrella Consortium for Assessment Networks] CAMPUS examination software) might improve the ease of multiple-choice examinations, accelerate the evaluation of examinations and item analysis, and allow for more complex scoring algorithms. Despite the benefits associated with electronic examinations, the availability of hardware and software at the level of individual institutions might limit its use.

In Germany, the revised undergraduate dental curriculum consists of 10 semesters and includes preclinical training (4 semesters), training using simulators or phantom heads (2 semesters), and clinical training (4 semesters). Following the state examinations after each part (ie, after the fourth, sixth, and 10th semester), students receive their license ("Approbation") to practice dentistry. Besides practical skills, theoretical knowledge is taught within the undergraduate dental curriculum, and students' ability is often assessed using written multiple-choice examinations. However, such examinations are not standardized among German dental schools. While general recommendations exist for their design and evaluation [12,13], details such as suitable item types and applied scoring methods are often defined in local examination guidelines at the level of individual dental schools. However, these details might impact examinees' scoring results [5]. To the best of our knowledge, a comprehensive overview regarding the used item types and applied scoring methods at German dental schools does not exist.

Therefore, this study aimed to gain insight into the current use of multiple-choice items in summative examinations in German undergraduate dental training programs. The null hypothesis is that the use of digital examinations does not impact the use of more complex (ie, multiple-select) multiple-choice items.

Methods

Ethical Considerations

The study was designed as a prospective investigation. In preparation for the investigation, the websites of all German dental schools were screened (n=30), and the names of the heads of the Department of Operative/Restorative Dentistry and the deans of studies were noted for later procedures.

The study was performed after approval by the local ethics committee of the University Medical Center Göttingen (approval number 22/1/23). Participation in this study was voluntary, and participants gave their informed consent for the anonymous evaluation of the provided answers by returning the questionnaires. Participants did not receive any incentives or compensation.

Questionnaire

A paper-based questionnaire, consisting of 10 items about the construction and evaluation of summative examinations, was jointly designed by the authors and pilot-tested in the University Medical Center Göttingen (Multimedia Appendix 1). Both closed and open-ended items were used. The opening questions related to different examination types used for the summative assessment of theoretical knowledge, and whether or not electronic examinations were being used. Additionally, it was asked whether the examination items undergo a formal review process and if so, the participants had the chance to give a brief description of this procedure. The more specific questions related to the types of multiple-choice items used and asked for the relative percentage to which these items were being used. Furthermore, the participants were asked to describe the applied scoring methods for each of the item types used. Finally, participants were provided with a text field open for comments and their contact details (ie, if required for further clarification) and were asked to supply a copy of their local examination guidelines or program regulations.

Following the evaluation of the pilot survey among 5 dentists at the University Medical Center Göttingen, the questionnaire was slightly modified for clarification, printed, and mailed to (1) the heads of the Department of Operative/Restorative Dentistry and to (2) the deans of studies on February 1, 2023. The wording was slightly adjusted for each recipient: (1) "used in your department" versus (2) "permitted at your dental school". Mailings included a personalized cover letter, an overview illustrating different multiple-choice item types (Figure 1), and a stamped return envelope. The survey was closed after 12 weeks. Nonresponders were reminded once 6 weeks after the initial distribution of the questionnaires.

Figure 1. Exemplary presentation of the most commonly used multiple-choice item types referenced in the questionnaire. Round marking boxes represent 1 answer option to be selected (1 out of x), while square marking boxes imply that multiple answer options or statements (x out of X) can be chosen.

Statistical Analysis

First, data were manually transferred into a digital chart using a piloted spreadsheet containing columns for each item of the questionnaire. This step was independently performed by 2 authors (LR and PK). In case of disagreement, data were repeatedly extracted from the returned questionnaires.

In case of disagreement between the heads of the Department of Operative/Restorative Dentistry and the deans of studies, results were based on the responses from the heads of the Department of Operative/Restorative Dentistry. For further clarification, responses were cross-validated with the supplied

or publicly available examination guidelines and program regulations. If required, respondents were contacted for further clarification if they had agreed to do so previously.

Second, statistical analysis was performed using the software SPSS Statistics (Macintosh version 29.0.0.0; IBM Corp). The effect of delivering digital examinations on the use of multiple-select items was assessed using the Fisher exact test. The level of significance was set at .05.

Results

Overview

In total, responses from 27 dental schools were received yielding a response rate of 90% (27/30 dental schools). More specifically, 25 Departments of Operative/Restorative Dentistry and 17 deans of studies replied. All dental schools responded that they use written multiple-choice examinations for the assessment of examinees' theoretical knowledge. Therefore, subsequent results are based on the number of respondent dental schools.

Multiple-Choice Items Used

The most commonly used multiple-choice item types at German dental schools were single-choice Type A or Type A_{negative} items

Table . Different multiple-choice item types for the assessment of theoretical knowledge at the respondent dental schools (N=27).

Item type	Dental schools, n (%)
Type A	24 (89)
Pick-N	18 (67)
Type K	14 (52)
Conventional multiple-select	12 (44)
Multiple-True-False (Type K')	12 (44)
Type R	6 (22)
Alternate-choice	4 (15)

Examination Setting

Key feature problems consisting of a clinical case scenario followed by a number of items focusing on critical treatment steps were used by approximately half of the dental schools (15/27, 56%). Not a single school used alternative testing methods (eg, answer-until-correct). Also, a formal item review process prior to the delivery of the examination was only established at about half of the dental schools (15/27, 56%).

Delivery of Examinations

The percentage of dental schools that deliver examinations electronically amounted to 70% (19/27). However, the software used by the dental schools differed: a dedicated examination software (ie, UCAN's CAMPUS or tEXAM, Q-Exam [IQUL GmbH]) was used by 8 dental schools, while learning management systems such as Moodle (Moodle Pty Ltd), ILIAS (ILIAS open source e-Learning e.V.), or OpenOLAT (frentix GmbH) were used by 7 dental schools for the purpose of examination delivery. The remaining 4 dental schools did not provide any information regarding the examination software they used.

Dental schools with the possibility of electronic examinations used multiple-select items slightly more often (14/19, 74% vs 4/8, 50%). However, this difference was statistically not significant ($P=.38$).

Applied Scoring Methods

All dental schools scored single-choice items (ie, Type A, Type A_{negative}, Type K, Type R, and alternate-choice) dichotomously

with 3 to 6 answer options (24/27, 89%). Pick-N items (ie, the number of answer options to be selected is known to examinees) were reported to contain between 3 and 26 answer options and were used by 67% (18/27) of dental schools. Type K items were reported to contain between 3 and 6 statements and were used by 52% (14/27) of the dental schools. Multiple-True-False (also known under further names such as Kprim, Type K', or Type X) and conventional multiple-select items (ie, the number of answer options to be selected is unknown to examinees) were reported to contain between 4 and 6 statements or answer options and were both used by 44% (12/27) of the dental schools. The use of further item types is shown in [Table 1](#).

(ie, 1 full credit point is awarded if examinees mark the correct answer option or statements, otherwise no credit is awarded).

Scoring of multiple-select items was more heterogeneous and no single scoring method that was commonly used was identified: some dental schools used scoring algorithms resulting in partial (ie, 0.5 credit points) or intermediate partial credit (ie, 1/n partial credit for each correct response) besides dichotomous scoring on multiple-select items. However, scoring methods resulting in negative points (ie, malus points) were not used at any location.

Discussion

Principal Findings

The aim of this study was to gain insight into summative assessment methods that involve the use of multiple-choice items and are used at German dental schools. The purpose of summative assessment is to evaluate examinees' knowledge at the end of a course by comparing their scores to a predefined standard (ie, cutoff score) [14]. Our results demonstrate that all respondent dental schools use multiple-choice examinations for summative assessment of theoretical knowledge. Besides individual items, approximately half of the dental schools also use key feature problems.

Single-choice Type A items are the most popular item types used at German dental schools. These items are used by almost every respondent dental school and often account for the largest number of items at the respective dental schools. This might be explained by the demand for ease of scoring (ie, dichotomous scoring, no partially correct responses).

Multiple-select item types such as Pick-N or Multiple-True-False are used by fewer dental schools. For these item types, the applied scoring methods vary considerably: Some dental schools award partial or even intermediate partial credit for partially correct responses while others do not. However, the exact cutoff levels and scoring methods for partial credit differed. For example, Partial Scoring 50% (PS₅₀) was used by some dental schools for Pick-N items: In these cases, 1 full credit point is awarded if all answer options are marked correctly, and 0.5 credit points are awarded if at least half of the true answer options are marked, otherwise no credit is awarded [9,15]. Furthermore, a similar scoring method named Half-point Scoring was used by some dental schools for Multiple-True-False and conventional multiple-select items: 1 full credit point is awarded if all statements or answer options are marked correctly, 0.5 credit points are awarded if the response to 1 statement or answer option is incorrect, otherwise no credit is awarded [8,16]. In addition, some dental schools awarded intermediate partial credit on multiple-select items: In the case of Partial Scoring 1/n (PS_{1/n}), 1/n partial credit was awarded for each correct response [8,9]. Some dental schools also subtracted 1/n partial credit for each incorrect response (Blasberg-Method) [8,9,17].

As a result, the scoring of multiple-select items at different German dental schools can be considered very heterogeneous. This is not surprising, as a vast number of different scoring methods for multiple-select items have been described in the literature [8,9]. As stated previously, it is not possible to suggest a single versatile scoring method. Different requirements as defined in dental schools' local examination guidelines (eg, fixed pass-mark and fixed proportion of true answer options) impact the scoring method to be selected. Regarding jurisdictional requirements, scoring methods resulting in negative points (ie, malus points) must not be used in Germany [13]. Consequently, not a single dental school uses scoring methods resulting in malus points. However, almost half of the dental schools do not use a formal item review process. A formal review process is recommended prior to the delivery of the examinations and might further improve the quality and overall validity of the examinations.

In addition, 70% (19/27) of all dental schools stated to deliver examinations electronically. While the electronic delivery of examinations allows for automatic scoring and more complex scoring methods (ie, within the context of multiple-select items), no statistically significant relation between the type of delivery (paper-based vs electronic) and the use of multiple-select item types was found. Therefore, our results fail to reject the null hypothesis. This might be explained by the software used for the delivery and scoring of electronic examinations: it was found that dental schools use learning management systems such as Moodle, ILIAS, or OpenOLAT besides dedicated examination software such as UCAN's CAMPUS, UCAN's tEXAM, or Q-Exam for the delivery and scoring of summative assessments. This is of relevance, as learning management systems usually support fewer item types and scoring methods than dedicated examination software [8,9]. As a result, electronic delivery of examinations does not necessarily result in an increased use of multiple-select items.

Interestingly, not a single dental school used alternative testing methods that deviate from the standard setting during examinations (ie, examinees mark the answer options or statements they believe to be correct or true but receive no immediate feedback regarding correctly or incorrectly marked answer options or statements). Within multiple-choice examinations, alternative testing methods such as confidence weighting scoring (ie, examinees are requested to indicate the degree of confidence in their marking) [18], elimination scoring (ie, examinees are instructed to mark the incorrect instead of correct answer options) [19], or answer-until-correct [20,21] have been described in the literature. Within the answer-until-correct method, examinees receive immediate feedback and examinees may correct their marking on previously incorrectly marked items, thereby still receiving partial credit. However, the benefit of such testing methods within the field of dental education is questionable. Dental school examinees are becoming future dentists. While treating patients, dentists are required to make informed choices and dentists might not always have a second chance without potentially harming their patients. In addition, such alternative testing methods benefit from the electronic delivery of examinations and set even higher requirements for the used examination software.

Strengths and Limitations

To the best of our knowledge, this is the first study to systematically assess the use and scoring of multiple-choice item types in summative examinations among German dental schools. A number of strengths are present. First, a pretested questionnaire was used. Second, our questionnaire survey study yielded a high response rate of 90% (27/30 dental schools). Third, our results might be considered representative of the current use of multiple-choice items in summative examinations among German dental schools.

Nevertheless, limitations are also present. First, our questionnaire focused on multiple-choice items; therefore, the use of other assessment types (eg, objective structured clinical examinations, oral examinations) remains unknown. Second, the number of dental schools in Germany is limited. Thereby, results from the Fisher exact test might be underpowered despite the high response rate. Furthermore, this study could not control for potential confounders (eg, location, number of students per dental school) due to the overall low number of dental schools. Third, transferability and generalizability to other educational settings might be limited due to different jurisdictional requirements or the overall lower importance of written examinations.

Future Directions

New dental licensing regulations ("Approbationsordnung") have been in effect since 2021, which restructured the undergraduate dental curriculum in Germany. For the first time, a nationwide written board examination with single-choice items takes place at the end of all undergraduate dental programs (ie, after the 10th semester) [22]. Therefore, multiple-choice examinations in general and especially single-choice Type A items will remain a popular format for summative examinations among German undergraduate dental programs. Ideally,

examinees already become familiar with single-choice Type A items during their studies. Therefore, all dental schools should use single-choice Type A items to adequately prepare their students for the final board examination.

Nevertheless, additional examinations (eg, objective structured clinical or practical examinations) are required to test examinees' practical skills [3]. Regardless of the used item type, multiple-choice examinations are not suitable to assess the higher levels Miller's Pyramid of clinical competence (ie, does and shows how) [23].

Conclusion

While students from almost all dental schools can be expected to be familiar with single-choice Type A items, techniques for the summative assessment of theoretical knowledge differ widely among German dental schools. Especially, a large variability regarding the use and scoring of multiple-select multiple-choice items was found. In addition, implementing a formal item review process might further improve the quality and overall validity of the examinations.

Acknowledgments

The authors acknowledge support from the Open Access Publication Funds of Göttingen University. The funder had no role in the study design, data collection and analysis, decision to publish, or preparation of the manuscript. Generative artificial intelligence was not used in any portion of this manuscript.

Data Availability

All data generated during or analyzed during this study are included in this published article.

Authors' Contributions

LR, MH, AW, and PK contributed to the study's conception and designed the questionnaire. LR and PK transferred the data. PK performed statistical analyses. All authors interpreted the data, critically revised the manuscript, and approved the final version of the manuscript.

Abstract

Background: The creation of large language models (LLMs) such as ChatGPT is an important step in the development of artificial intelligence, which shows great potential in medical education due to its powerful language understanding and generative capabilities. The purpose of this study was to quantitatively evaluate and comprehensively analyze ChatGPT's performance in handling questions for the National Nursing Licensure Examination (NNLE) in China and the United States, including the National Council Licensure Examination for Registered Nurses (NCLEX-RN) and the NNLE.

Objective: This study aims to examine how well LLMs respond to the NCLEX-RN and the NNLE multiple-choice questions (MCQs) in various language inputs. To evaluate whether LLMs can be used as multilingual learning assistance for nursing, and to assess whether they possess a repository of professional knowledge applicable to clinical nursing practice.

Methods: First, we compiled 150 NCLEX-RN Practical MCQs, 240 NNLE Theoretical MCQs, and 240 NNLE Practical MCQs. Then, the translation function of ChatGPT 3.5 was used to translate NCLEX-RN questions from English to Chinese and NNLE questions from Chinese to English. Finally, the original version and the translated version of the MCQs were inputted into ChatGPT 4.0, ChatGPT 3.5, and Google Bard. Different LLMs were compared according to the accuracy rate, and the differences between different language inputs were compared.

Results: The accuracy rates of ChatGPT 4.0 for NCLEX-RN practical questions and Chinese-translated NCLEX-RN practical questions were 88.7% (133/150) and 79.3% (119/150), respectively. Despite the statistical significance of the difference ($P=.03$), the correct rate was generally satisfactory. Around 71.9% (169/235) of NNLE Theoretical MCQs and 69.1% (161/233) of NNLE Practical MCQs were correctly answered by ChatGPT 4.0. The accuracy of ChatGPT 4.0 in processing NNLE Theoretical MCQs and NNLE Practical MCQs translated into English was 71.5% (168/235; $P=.92$) and 67.8% (158/233; $P=.77$), respectively, and there was no statistically significant difference between the results of text input in different languages. ChatGPT 3.5 (NCLEX-RN $P=.003$, NNLE Theoretical $P<.001$, NNLE Practical $P=.12$) and Google Bard (NCLEX-RN $P<.001$, NNLE Theoretical $P<.001$, NNLE Practical $P<.001$) had lower accuracy rates for nursing-related MCQs than ChatGPT 4.0 in English input. English accuracy was higher when compared with ChatGPT 3.5's Chinese input, and the difference was statistically significant (NCLEX-RN $P=.02$, NNLE Practical $P=.02$). Whether submitted in Chinese or English, the MCQs from the NCLEX-RN and NNLE demonstrated that ChatGPT 4.0 had the highest number of unique correct responses and the lowest number of unique incorrect responses among the 3 LLMs.

Conclusions: This study, focusing on 618 nursing MCQs including NCLEX-RN and NNLE exams, found that ChatGPT 4.0 outperformed ChatGPT 3.5 and Google Bard in accuracy. It excelled in processing English and Chinese inputs, underscoring its potential as a valuable tool in nursing education and clinical decision-making.

Introduction

The large language model (LLM) technology is a stepping stone in the evolution of artificial intelligence (AI) [1,2]. Through the analysis of a large database, the primary module generates a logical and plain text response to the user's query promptly following the user's textual input [3]. Currently, popular AI software includes ChatGPT 4.0, ChatGPT 3.5, and Google Bard, and research indicates that these 3 AI algorithms perform well when answering queries about lung cancer [4]. AI tools are the result of the advancement of science and technology, and the advent of revolutionary tools will alter the way people learn and work, which is an irreversible trend.

ChatGPT has been controversial since its public release in November 2022 due to its powerful text generation capabilities, and attention has been focused on students using ChatGPT for essay writing and assignment plagiarism [5-7]. With the birth of regulatory software such as GPTZero, AI-Text-Classifier, and ChatGPT Detector, people gradually focused on the application of ChatGPT, trying to explore and expand the application field of ChatGPT. The study found that ChatGPT showed both professionalism and empathy in answering general public health questions [8]. ChatGPT not only showed strong expertise in answering basic research directions but also followed evidence-based clinical decision-making [9,10]. Nevertheless, there may be some ethical problems in clinical application, and it is necessary to consider whether the use of ChatGPT will violate the rights and interests of patients [11-13]. Therefore, more and more researchers have placed the application field of ChatGPT in education [14]. The studies found that ChatGPT performed well on multiple-choice questions (MCQs) about otolaryngology and gynecology [15,16]. In addition, ChatGPT software can pass the Plastic Surgery Inservice Training Examination [17], the American Heart Association Basic Life Support Examinations [18], and the Taiwanese Pharmacist Licensing Examination [19]. ChatGPT is also able to solve higher-order problems related to medical biochemistry while also achieving satisfactory performance in surgical education and training [20,21]. However, ChatGPT is not a training tool for all exams, with the exception of the American Heart Association's Advanced Cardiovascular Life Support (ACLS) exams and Taiwan's Family Medicine Board Exam [18,22]. This might suggest that ChatGPT's application areas may be limited by language and region in addition to speciality.

Both the United States and China have instituted licensing exams to regulate the qualifications of registered nurses [23]. China uses the National Nursing Licensure Examination (NNLE) [23], whereas the United States uses the National Council Licensure Examination for Registered Nurses (NCLEX-RN) [24], both of which seek to standardize the theoretical and practical foundations of nurses through standardized assessment procedures to ensure the professionalism of nurses who are entering the medical field. The content of nursing studies is not medically specialized but rather interdisciplinary and multidisciplinary [25]. On the basis of their nursing work, nurses are frequently required to comprehend clinical decisions made by physicians. As a result, it is easy for society to disregard the

difficulty of nursing education and training, that is, the necessity of a medical foundation for the development of nursing expertise [26]. Presently, there are no professional nursing learning aids to assist nurses in gaining a better understanding of the professional medical issues encountered during the clinical learning process. Huge and intricate, the medical knowledge system necessitates repeated learning, even for specialists, in order to master specialized knowledge [27]. Despite the fact that many researchers attempt to implement various review strategies to increase the passage rate of nursing professional examinations, it is frequently difficult to popularize a single review strategy due to varying local practical policies [28]. No single revision method is appropriate for all individuals. How to assist nurses in gaining a deeper understanding of medical knowledge, enhancing their stockpile of professional theoretical knowledge, and increasing their exam pass rate is a pressing issue for nurses today.

The design of this research is cross-sectional. By incorporating NCLEX-RN and NNLE questions, we evaluated the precision of responses from ChatGPT 4.0, ChatGPT 3.5, and Google Bard. Concurrently, the translation feature of ChatGPT 3.5 was used to convert between Chinese and English, while an examination was conducted into the disparity in the rate of accurate responses provided by ChatGPT across various languages. The aim of this study is to offer a conceptual framework that supports the implementation of ChatGPT and advances nursing education and clinical application.

Methods

Design

With reference to Zong et al [29], we designed a cross-sectional study. The experimental data from our study had been recorded in an Excel file and uploaded as [Multimedia Appendix 1](#). The STROBE Initiative [30] was used in this study and the STROBE Initiative checklist is available in [Multimedia Appendix 2](#).

Ethical Considerations

As this study does not involve interventional experiments on humans or animals, the research does not require approval per the Ethics Committee of the First Affiliated Hospital of Jinan University guidelines.

Data Source

NCLEX-RN practice questions were compiled at the website "nurseslabs" [31]. There were no set questions on the official NCLEX-RN test; instead, a computer produced new questions with a minimum of 75 and a maximum of 265 depending on how accurate the preceding questions were. Thus, we got the most recent 2 sets of practice questions for the NCLEX-RN exam from the internet. In 2 practice sets, we compiled a total of 150 MCQs.

The NNLE question categories were divided into 2 sections: nursing theory and nursing practice, each containing 120 MCQs. On the website "baidu" [32], we used the most current 480 NNLE-MCQs from the 2022 and 2021 exams that were accessible. According to the classification of nursing theory examination and nursing practice, the questions for 2022 and

2021 were merged and then separated into NNLE Theoretical MCQs (n=240) and NNLE Practical MCQs (n=240).

Procedures

According to the research stages (Figure 1), we translated the original English NCLEX-RN-MCQs into the Chinese version of the NCLEX-RN-MCQs. The original NNLE queries were written in Chinese, and we also translated them into English. To avoid systematic errors induced by differences in translation

quality during the translation process, ChatGPT 3.5 was used to translate both from Chinese to English and from English to Chinese. We checked the language both before and after translating using ChatGPT 3.5 to translate between Chinese and English, as well as English and Chinese. About some clear translation mistakes, we entered the incorrect translation points in ChatGPT 3.5's dialog box and requested that ChatGPT 3.5 retranslate the text.

Figure 1. Diagrammatic representation of the progression of exploratory application experiments. MCQ: multiple-choice question; NCLEX-RN: National Council Licensure Examination for Registered Nurses; NNLE: National Nursing Licensure Examination.

Entered all questions on ChatGPT 4.0 (Figure 2A and C) [33] and ChatGPT 3.5 (Figure 2B and D) [34] as well as Google Bard (Figure 2E) [35], then recorded the responses. Both ChatGPT 4.0 and ChatGPT 3.5 support text input in non-English

languages, whereas Google Bard only supports text input in English at this time. The use of “New chat” for each inquiry ensured the independence of each response because it prevented the AI from using context from previous interactions, thereby

eliminating any learning or bias that may have been carried over from earlier questions. Additionally, no plugins were used with ChatGPT, and the “Chat history & training” option was deactivated to preserve the objectivity of each response.

Figure 2. (A) English multiple-choice questions (MCQs) input in ChatGPT 4.0. (B) English MCQs input in ChatGPT 3.5. (C) Chinese MCQs input in ChatGPT 4.0. (D) Chinese MCQs input in ChatGPT 3.5. (E) English MCQs input in Google Bard.

Data Analysis

SPSS program (version 26.0; IBM Corp) was used for statistical analysis. With reference to Zong et al [29]. Collected the responses from ChatGPT 4.0, ChatGPT 3.5, and Google Bard and converted them to the binary variables “true” or “false.”

Pearson The χ^2 test was used to compare the differences between various LLM software or the same software input in various languages. A difference was considered statistically significant when the *P* value was less than .05. Used the web-based VENN diagram drawing website “bioinfog” [36] to draw VENN

diagrams to display different AI software’s results for the same type of subject with various linguistic inputs. Last, bar charts were constructed from a portion of the data using GraphPad Prism 8.

Results

Overview

We collected 150 NCLEX-RN-MCQs in total. We excluded the image questions from the compiled NNLE-MCQs because the picture analysis of ChatGPT and Google Bard required the

use of external plug-ins. After eliminating the image questions, there were a total of 235 NNLE Theoretical MCQs and 233 NNLE Practical MCQs left. Then, ChatGPT 3.5 converted NCLEX-RN-MCQs for English questions into the Chinese version and NNLE-MCQs into the English version.

Performance of LLMs in Responding to English NCLEX-RN MCQs

ChatGPT 4.0 had an accuracy rate of 88.67% (133/150) when answering NCLEX-RN MCQs in English, which was higher

than ChatGPT 3.5 (113/150, 75.3%) and Google Bard (96/150, 64%) (Figure 3C). Statistically, ChatGPT 4.0 performed significantly better than the other 2 categories (ChatGPT 4.0 vs ChatGPT 3.5, $P=.003$; ChatGPT 4.0 vs Google Bard, $P<.001$) (Figure 3C). ChatGPT 3.5 was more accurate than Google Bard and the difference was statistically significant ($P=.03$) (Figure 3C).

Figure 3. (A,B) VENN diagram shows the correct and incorrect intersection of NCLEX-RN practical questions in different large language models. (C) The correct rate of NCLEX-RN practical questions in various large language models. MCQ: multiple-choice question; NCLEX-RN: National Council Licensure Examination for Registered Nurses.

Performance of LLMs in Responding to Chinese NNLE-MCQs

The difference between the correct rates of ChatGPT 4.0 and ChatGPT 3.5 in answering the Chinese version of NNLE theoretical MCQs ($P<.001$) and NNLE practical MCQs ($P<.001$)

was statistically significant (Figure 4E and F). The correct rates of ChatGPT 4.0 answering NNLE theoretical MCQs and NNLE practical MCQs were 71.9% (169/235) and 69.1% (161/233), respectively, compared with 53.2% (125/235) and 50.2% (117/233) for ChatGPT 3.5 (Figure 4E and F).

Figure 4. (A,B) VENN diagram shows the correct and incorrect intersection of NNLE theoretical MCQs in different large language models (LLMs). (C,D) VENN diagram shows the correct and incorrect intersection of NNLE practical MCQs in different LLMs. (E) The correct rate of NNLE theoretical MCQs in various LLMs. (F) The correct rate of NNLE practical MCQs in various LLMs. MCQ: multiple-choice question; NNLE: National Nursing Licensure Examination.

Performance and Variations of MCQs Input Into LLMs in Various Languages

After entering the Chinese-translated version of NCLEX-RN-MCQs into ChatGPT 4.0 and ChatGPT 3.5, we discovered that the accuracy rates were 79.3% (119/150) and

63.3% (95/150), respectively, with a statistically significant difference between the two ($P=.002$) (Figure 3C).

Then, we fed the English-translated version of NNLE Theoretical MCQs into ChatGPT 4.0, ChatGPT 3.5, and Google Bard and determined that their respective accuracy rates were

71.5 % (168/235), 55.7% (131/235), and 49.8% (117/235) (Figure 4E). ChatGPT 4.0 had a higher accuracy rate than ChatGPT 3.5 ($P<.001$) and Google Bard ($P<.001$) for the English-translated version of NNLE Theoretical MCQs while the difference was statistically significant (Figure 4E). ChatGPT 3.5 had a higher accuracy rate than Google Bard, but the difference was not statistically significant ($P=.20$) (Figure 4E).

The accuracy rates of ChatGPT 4.0, ChatGPT 3.5, and Google Bard were 67.8% (158/233), 60.9% (142/233), and 46.8% (109/233), respectively, when the English-translated version of NNLE Practical MCQs was inputted (Figure 4F). In terms of the English-translated version of NNLE Practical MCQs, the accuracy rates of both ChatGPT 4.0 ($P<.001$) and ChatGPT 3.5 ($P=.002$) were higher than those of Google Bard, and the difference was statistically significant; however, unlike before, the difference in accuracy rates between ChatGPT 4.0 and ChatGPT 3.5 was not statistically significant ($P=.12$) (Figure 4F).

When processing NCLEX-RN-MCQs, the accuracy of inputs in the original English version was statistically significantly higher than that of inputs translated into Chinese for both ChatGPT 4.0 ($P=.03$) and ChatGPT 3.5 ($P=.02$) (Figure 3C). The difference was not statistically significant between the accuracy of inputs in the original Chinese version and the inputs of the translated English version for both ChatGPT 4.0 ($P=.92$) and ChatGPT 3.5 ($P=.58$) when processing NNLE Theoretical MCQs (Figure 4E). The accuracy of ChatGPT 4.0's inputs in the original Chinese version was higher than that of inputs translated into English when processing NNLE Practical MCQs, but this difference was not statistically significant ($P=.77$) (Figure 4F). Surprisingly, the accuracy of ChatGPT 3.5's inputs in the original Chinese version was lower than that of inputs translated into English while dealing with NNLE Practical MCQs, and this difference was statistically significant ($P=.02$) (Figure 4F).

Figure 3A and B depicts, respectively, the intersection of correct and incorrect questions when NCLEX-RN practical questions were inputted into various LLMs in various languages. Similarly, Figure 4A and B depicts NNLE Theoretical MCQs, while Figure 4C and D depicts NNLE Practical MCQs. When the same questions were input into ChatGPT 4.0, ChatGPT 3.5, and Google Bard in English, ChatGPT 4.0 had the highest number (n for NCLEX-RN MCQs=14; n for NNLE Theoretical MCQs=33; n for NNLE Practical MCQs=26) of uniquely correct answers and the lowest number (n for NCLEX-RN MCQs=2; n for NNLE Theoretical MCQs=6; n for NNLE Practical MCQs=7) of uniquely incorrect answers among the 3 engines. Instead, Google Bard had a lower number (n for NCLEX-RN MCQs=2; n for NNLE Theoretical MCQs=10; n for NNLE Practical MCQs=6) of uniquely correct answers than ChatGPT 4.0 and the highest number (n for NCLEX-RN MCQs=26; n for NNLE Theoretical MCQs=34; n for NNLE Practical MCQs=36) of uniquely incorrect answers among the 3 engines when the MCQs were input into 3 engines in English. Likewise, after the questions were submitted in Chinese, we found that ChatGPT 4.0 (n for NCLEX-RN MCQs=35; n for NNLE Theoretical MCQs=61; n for NNLE Practical MCQs=63) gives more uniquely accurate responses than ChatGPT 3.5 (n for

NCLEX-RN MCQs=11; n for NNLE Theoretical MCQs=17; n for NNLE Practical MCQs=19) does.

Discussion

Principal Findings

This study is a cross-sectional study that collected a total of 618 nursing-related MCQs, including 150 NCLEX-RN practice questions and 468 NNLE actual exam questions. To observe differences between inputs in different languages, ChatGPT 3.5 was used exclusively for Chinese-to-English and English-to-Chinese translations. The results revealed that ChatGPT 4.0 had a significantly higher accuracy rate when handling English input for NCLEX-RN practical MCQs compared with ChatGPT 3.5 and Google Bard. Similarly, ChatGPT 4.0 also outperformed ChatGPT 3.5 in accuracy when processing the Chinese input of NNLE exam MCQs. Therefore, ChatGPT 4.0 has the potential to be an effective learning assistance software for ChatGPT users, and due to its powerful real-time text generation capabilities, it can also provide additional sources of information and reference for nursing decisions in clinical nursing work.

Despite being a tool that accepts input in different languages, ChatGPT has linguistic bias while processing text input, as this research has shown. ChatGPT 3.5 translates NCLEX-RN practical MCQs from English to Chinese. Following input, it was discovered that while interacting with English, ChatGPT 4.0 and ChatGPT 3.5 had accuracy rates that were noticeably greater than Chinese. When NNLE MCQs were input into ChatGPT in English, ChatGPT 4.0's accuracy of the response was only somewhat less accurate than the Chinese input, while ChatGPT 3.5's English input was even more accurate than the Chinese input. Although there may be some linguistic distortion when translating between languages using software, the findings of our cross-sectional investigation indicated that ChatGPT processes English input more accurately than Chinese input. I asked ChatGPT, an AI program that facilitates real-time communication, questions in an attempt to comprehend the logic behind handling input in various languages. In response, ChatGPT said that it can assess and respond to queries in several languages depending on the language of input. This capability stems from its training of various input kinds in various languages. As a result, the current discrepancy in accuracy caused by input in Chinese and English may be the result of ChatGPT receiving different amounts of training in different languages. This discrepancy may disappear with an increase in language training once ChatGPT becomes more well-known worldwide.

The low passage rate of nursing examinations is partly attributed to the lack of fundamental theoretical and clinical knowledge among nursing staff [24,37]. Researchers have tried to reform and innovate nursing education models within certain limits to improve knowledge levels and exam pass rates [28]. However, due to differences in language and local policies, it is challenging to widely implement a single educational model. MCQs are an effective method to assess student knowledge [38], but existing learning resources often require students to conduct independent searches to expand knowledge, adding to

learning pressure and affecting the coherence of the learning process. ChatGPT's big data analysis and rapid text feedback can help students consolidate and expand knowledge points while completing MCQ exercises [39]. Besides, ChatGPT 4.0 not only enhances the efficiency of nursing education [40] but also provides clinicians and nurses with objective information support based on evidence-based medicine and big data analysis in complex clinical scenarios [41]. For instance, the research discovered that ChatGPT 4.0 not only analyzed imaging data with acceptable accuracy and sensitivity but also assisted physicians in thinking outside the box and offering several helpful recommendations when making individualized clinical treatment choices for tumor patients [41]. Furthermore, ChatGPT may provide nurses with a customized and immersive learning experience, bolster their competence and self-assurance in overseeing remote patient care, and furnish them with the necessary abilities for remote patient monitoring, all of which can contribute to the enhancement of patient outcomes and care quality [42]. Additionally, ChatGPT may assist doctors in streamlining patient data organization and easing the burden of interpreting medical records in order to improve patient communication while doing therapeutic procedures [43].

According to this study and previous research findings, ChatGPT 4.0 is currently the most accurate and repeatable AI software among many LLMs. In answering questions related to electrocardiogram images [44], the Multi-Specialty Recruitment Assessment exam [45], dental professional issues [46], and analyzing radiology data [47], ChatGPT 4.0 provides more accurate and comprehensive responses compared with ChatGPT 3.5 and Google Bard. Since ChatGPT 4.0 is currently the only paid AI software compared with free-to-use LLMs like ChatGPT 3.5, Google Bard, and Bing, it is essential to compare its functionality with these free LLMs when exploring its real-world application value. The economic cost of use is also a factor that must be considered in the popularization and promotion of its application [48].

Assessing ChatGPT's clinical application value in a manner that aligns with the training of experienced clinical workers is the same approach; upon passing the theory test, candidates will be deemed to possess fundamental medical theoretical knowledge and be capable of managing simple clinical scenarios [49]. The intricacy of clinical issues will then continuously increase as a result of ongoing training that corrects incorrect theoretical knowledge and clinical reasoning. Last, they get training to become highly repeatable and capable self-correcting clinical practitioners. ChatGPT has shown that it has a theoretical foundation for supporting clinical practice with its outstanding success in the qualifying exams of many clinical professions [15-22,45,46,49]. However, whether it is used as an auxiliary tool for self-learning and education, to support patient communication, or to aid in the analysis of complicated clinical circumstances, a commensurate regulatory system must be developed. In order to limit the circumstances in which ChatGPT is used, schools, hospitals, and publishing companies must first create pertinent policies [50]. Some examples of these policies include forbidding the use of ChatGPT during exams [51] and obtaining patient consent before using ChatGPT as an auxiliary tool in real clinical settings [52]. Authors must state

that ChatGPT was not directly engaged in the creation of the text for the paper and are forbidden from claiming ChatGPT as an independent author [53]. Furthermore, the most immediate regulators of ChatGPT are its users. ChatGPT can assist with data collection and content integration, but the user has to take part in the quality review process of the content that ChatGPT generates, identify any problems in the responses that ChatGPT generates, and finish training ChatGPT via error correction and continuous input and output. Although many companies developing LLMs claim to avoid the collection and leakage of private information, as users of these software, it is also essential to ensure the content and quality of the input information. Users should intentionally avoid and delete personal and private information, thereby enhancing their personal oversight function during the use of the software. It is also crucial to seek the informed permission of other participants and make suitable declarations while using ChatGPT in public to prevent unwanted confrontations between doctors and patients, moral and ethical disagreements, and concerns with writing integrity.

Implication

Our study has demonstrated that ChatGPT 4.0 exhibits a satisfactory accuracy rate in handling MCQs for the NCLEX-RN and NNLE exams, outperforming 2 other AI engines, ChatGPT 3.5 and Google Bard. Although there were differences in accuracy rates when the same questions were inputted in different languages, the overall accuracy of ChatGPT 4.0 remains commendable. Combined with conclusions from previous research, it can be inferred that ChatGPT 4.0 possesses the knowledge reserve necessary for application in medical education, learning, and clinical scenarios, with the potential to assist in managing complex clinical situations. To promote the rational application of ChatGPT 4.0 in the medical field, it is imperative for relevant authorities to develop effective and reasonable regulatory mechanisms and supervisory bodies in the future. This will ensure that ChatGPT 4.0, a powerful auxiliary AI software, is used appropriately within the health care sector.

Limitation

This study is a cross-sectional analysis, and the findings suggest that ChatGPT 4.0 possesses a certain level of nursing professional knowledge. However, high-quality prospective randomized controlled trials are still required to validate the actual effectiveness of ChatGPT 4.0 in nursing education, learning, and clinical application. Besides, since the logic behind how AI processes questions is part of the company's "black box," we can only understand its logic in processing inputs in different languages by interacting with the AI software. Therefore, we infer that the differences in handling Chinese and English inputs are due to variations in the amount of training between languages.

Conclusion

This cross-sectional study collected and analyzed 618 nursing-related MCQs, including NCLEX-RN practice questions and NNLE actual exam questions, to evaluate the performance of ChatGPT 4.0 in processing different language inputs. The study exclusively used ChatGPT 3.5 for Chinese-to-English

and English-to-Chinese translations and found that ChatGPT 4.0 demonstrated a significantly higher accuracy rate than ChatGPT 3.5 and Google Bard, particularly in handling English input for NCLEX-RN Practice MCQs and Chinese input for NNLE exam MCQs. These findings suggest that ChatGPT 4.0

has substantial potential as an effective learning assistance tool for nursing education and can provide valuable information and reference in clinical nursing settings due to its advanced real-time text generation capabilities.

Data Availability

The data that support the findings of this study are available on request from the corresponding author.

Authors' Contributions

ZW, WG, ZX, and ZN contributed equally. ZW, WG, ZX, and ZN conceived the study, performed the statistical analysis, interpreted the results, and drafted the manuscript. YZ and XZ supervised the entire study. All authors read and approved the final manuscript.

Abstract

Background: Medical students in Japan undergo a 2-year postgraduate residency program to acquire clinical knowledge and general medical skills. The General Medicine In-Training Examination (GM-ITE) assesses postgraduate residents' clinical knowledge. A clinical simulation video (CSV) may assess learners' interpersonal abilities.

Objective: This study aimed to evaluate the relationship between GM-ITE scores and resident physicians' diagnostic skills by having them watch a CSV and to explore resident physicians' perceptions of the CSV's realism, educational value, and impact on their motivation to learn.

Methods: The participants included 56 postgraduate medical residents who took the GM-ITE between January 21 and January 28, 2021; watched the CSV; and then provided a diagnosis. The CSV and GM-ITE scores were compared, and the validity of the simulations was examined using discrimination indices, wherein ≥ 0.20 indicated high discriminatory power and > 0.40 indicated a very good measure of the subject's qualifications. Additionally, we administered an anonymous questionnaire to ascertain participants' views on the realism and educational value of the CSV and its impact on their motivation to learn.

Results: Of the 56 participants, 6 (11%) provided the correct diagnosis, and all were from the second postgraduate year. All domains indicated high discriminatory power. The (anonymous) follow-up responses indicated that the CSV format was more suitable than the conventional GM-ITE for assessing clinical competence. The anonymous survey revealed that 12 (52%) participants found the CSV format more suitable than the GM-ITE for assessing clinical competence, 18 (78%) affirmed the realism of the video simulation, and 17 (74%) indicated that the experience increased their motivation to learn.

Conclusions: The findings indicated that CSV modules simulating real-world clinical examinations were successful in assessing examinees' clinical competence across multiple domains. The study demonstrated that the CSV not only augmented the assessment of diagnostic skills but also positively impacted learners' motivation, suggesting a multifaceted role for simulation in medical education.

Introduction

Japan's medical schools follow a 6-year curriculum comprising 4 years of preclinical and 2 years of clinical education, after which they enter a 2-year postgraduate residency program as "postgraduate residents" or simply "residents" [1-3]. This residency enables new doctors to acquire and practice basic clinical knowledge, problem-solving, general medical and communication skills, and a professional attitude. All residents receive supervised training as they rotate through 7 specialties over the 2 years, including internal medicine, surgery, pediatrics, obstetrics and gynecology, psychiatry, emergency medicine, and community medicine. Most residents then enter specialty-based residency training.

In 2011, the nonprofit Japan Institute for Advancement of Medical Education Program (JAMEP) developed the General Medicine In-Training Examination (GM-ITE), an in-training examination for assessing the clinical knowledge of residents, similar to the US Internal Medicine Residency Examination [4]. The purpose of the GM-ITE is to elicit practical feedback on the training programs aimed at identifying improvement areas using an objective and reliable assessment of residents' clinical knowledge [5].

The traditional assessment of clinical competencies through multiple-choice questions (MCQs), while valuable, may not encompass the full scope of a clinician's diagnostic process in real-world practice [6]. In clinical settings, physicians must navigate through complex problem-solving and decision-making processes, often divided into domains such as leading or working diagnosis, management and treatment, hypothesis generation, problem representation, diagnostic justification, and information gathering [7]. Video simulation, as an assessment tool, can capture these nuances by providing contextualized real-world scenarios where residents must apply their knowledge dynamically, as they would in actual patient interactions [8].

Designed by a committee of experienced attending physicians organized by the JAMEP, the 2-hour GM-ITE comprises 80 MCQs covering multiple domains [9]. The scores range from 0 to 80, with higher scores indicating better performance and knowledge of internal medicine. The content and validity of each question undergo review by JAMEP's question-development committee comprising experienced physicians from various fields, an independent peer-review committee, and examination-analysis experts [10]. The GM-ITE is not used as a pass or fail test for training advancement but only as a source of education feedback. The test is strictly voluntary, and approximately one-third of residents take the examination each year (7669 in the 2020 academic year, 6869 in the 2019 academic year, 6133 in the 2018 academic year,

5593 in the 2017 academic year, and 4568 in the 2016 academic year) [11,12].

An assessment of the validity of the GM-ITE [10] revealed a strong positive correlation between GM-ITE scores and scores on the Professional and Linguistic Assessments Board test, Part 1, designed to assess the depth of medical knowledge and levels of medical and communication skills [13]. In validity testing, the discrimination index (DI) indicates how well the item differentiates between students of high and low aptitude, that is, whether high-aptitude students performed better, worse, or the same as low-aptitude students [14]. Therefore, an item with a high DI is more effective in identifying respondents with adequate knowledge than an item with a low DI. The GM-ITE has indicated better discriminative power than the Professional and Linguistic Assessments Board test, Part 1 examination [10].

The JAMEP based the content of the GM-ITE on the clinical training objectives presented by Japan's Ministry of Health, Labour and Welfare [13], which requires residents to master skills related to professionalism, physical examination and clinical procedures, and the diagnosis and treatment of common diseases. The GM-ITE shows evidence of generalization by covering 4 categories, including medical interview or professionalism (MP), clinical diagnosis (CD) consisting of symptomatology and clinical reasoning, physical examination or procedure (PP), and disease knowledge (DK). However, the relatively small number of questions in the GM-ITE provides evidence of low generalization.

Given the large number of residents taking the GM-ITE each year, using MCQs seems both expedient and appropriate when considering the viability and sustainability of the GM-ITE. However, a 2-hour test comprising only MCQs may not adequately assess the situational variations affecting clinical performance or competence in multiple domains. Therefore, this study developed a clinical simulation video (CSV) named "innovative examination" for the GM-ITE to assess residents' clinical competency in a real-world setting using two components: (1) a high-quality CSV showing a medical interview and physical examinations with a patient and family in an emergency room and (2) follow-up questions for the residents to provide their diagnosis and recommendations. The study then evaluated the relationship between the participants' GM-ITE and CSV innovative examination test scores by comparing their discriminative ability in each assessment domain. Therefore, this study aimed to evaluate the relationship between GM-ITE scores and resident physicians' diagnostic skills by having them watch a CSV and to explore resident physicians' perceptions of the CSV's realism, educational value, and impact on their motivation to learn.

Methods

Study Design

We conducted a multicenter cross-sectional observational study in Japan.

Study Participants

The study extended an invitation to all 8526 resident physicians who took the GM-ITE in the 2021 academic year (January 21-28, 2021) to voluntarily participate in the innovative examination, and 56 residents—23 from postgraduate year (PGY) 2 and 33 from PGY 1—agreed and participated. These individuals were selected from the entire cohort of residents who took the GM-ITE. Owing to the exploratory nature of this study and the extensive distribution of the questionnaire to all eligible resident physicians, no formal sample size calculation or power analysis was performed.

Procedures

Innovative Examination Using High-Quality Patient-Simulated Video

In this study, we wrote a script depicting a simulated clinical interaction. The approximately 5-minute video (“innovative

examination”), shot from a resident’s point of view, depicts a newly arrived patient and his family at an emergency room ([Multimedia Appendix 1](#)). The resident conducts a medical interview and examination, asking and answering questions, while the camera records the patient’s and family members’ verbal and nonverbal responses. Professional actors coached by the medical supervisors played the roles effectively. A professional television production company shot the video and added effects (eg, heart sounds). In total, 3 of the authors (KS, YN, and SF) and 3 JAMEP medical supervisors oversaw the video production. The study participants watched the video immediately after completing the GM-ITE. Next, they answered the CSV innovative examination questions described below.

Extended Matching Questions

We used extended matching questions that listed the patient’s symptoms to obtain up to 3 pertinent positive findings that contributed to the diagnosis (Q1 and Q2 in [Textbox 1](#)).

Textbox 1. Clinical simulation video (CSV) innovative examination questions.

- Q1. Which 3 physical findings would you expect to be positive in this patient? Please choose 3 of the following:
 - Pallor of the eyelid conjunctiva
 - Pupil irregularity
 - Angry external jugular vein
 - Cervical vascular murmur
 - Thyroid gland enlargement
 - “Fixed” splitting of the second heart tone
 - Loud P2
 - Systolic murmur
 - Diastolic murmur
 - Torsion sound at the base of the lung
 - Tender points in the abdomen
 - Fresh blood in stool on rectal examination
 - Barre sign positive
 - Muscle stiffness
 - Loss of tendon reflexes
- Q2. Please state the most likely diagnosis for this patient (free text).
- Q3. Following the SBAR (situation, background, assessment, and recommendation) format, please prepare a patient handoff record for the internal medicine physician in charge of admission.
 - Q3-1. Situation (free text, 100 words maximum)
 - Q3-2. Background (free text, 100 words maximum)
 - Q3-3. Assessment (free text, 100 words maximum)
 - Q3-4. Recommendation (free text, 100 words maximum)
- Q4-1. Do you think the simulated patient-examination video was better suited to assessing your clinical competence than the traditional all-text format?
- Q4-2. Was the video simulation realistic enough for you to assess the patient?
- Q4-3. Did this experience increase your motivation to learn?

Modified Essay Questions

The third question required brief free-form answers (Q3 in [Textbox 1](#)).

Anonymous Posttest Questionnaire

After the participants completed Q1-Q3, we asked them to answer a fourth question (anonymously) to briefly describe (in writing) their experiences with the CSV innovative examination (Q4 in [Textbox 1](#)). Only 23 (41%) of the 56 participants chose to answer Q4.

Measurements

The GM-ITE uses a methodology similar to the US Internal Medicine Residency Examination [4,15,16]. The 80 questions cover 4 main categories: MP (8 questions), CD (18 questions), PP (18 questions), and DK (36 questions). We examined the validity of the GM-ITE questions using the DI ϕ as defined by equation 1 [17]:

where a is the number of correct answers in the top 25th percentile, b is the number of incorrect answers in the top 25th percentile, c is the number of correct answers in the bottom 25th percentile, and d is the number of incorrect answers in the bottom 25th percentile. The range of ϕ is $-1 \leq \phi \leq 1$. Questions are considered unreliable if this index is below 0. A DI of ≥ 0.20 would indicate that the question has high discriminatory power, and a DI of ≥ 0.40 would indicate that the question is a very good measure of the subject's qualifications.

Statistical Analyses

We conducted these analyses using SPSS Statistics for Windows (version 26.0; IBM Corp), following the Strengthening the Reporting of Observational Studies in Epidemiology guidelines. Two authors (KS and SF) independently assessed the answers and then discussed, identified, and agreed on them. We measured the interrater reliability with the κ coefficient (0.8-1.0=almost perfect, 0.6-0.8=substantial, 0.4-0.6=moderate,

and 0.2-0.4=fair) [18]. The Angoff method was used to define the cutoff for the DI calculation [19].

Ethical Considerations

This research was conducted in accordance with ethical standards and the principles of the Declaration of Helsinki. The ethics review board of the JAMEP, Tokyo, Japan, approved the study protocol (21-10). All participants read and signed the informed consent document before participating in the study. To ensure confidentiality, all participant data were anonymized prior to analysis. No compensation was provided to the participants for their involvement in this study. Informed consent was obtained from all participants for publication of identifying information in an online open-access publication. In accordance with ethical standards and journal policy, we have obtained explicit informed consent from all actors appearing in the video material associated with this study. The actors have acknowledged and agreed that the video will be published as part of the study’s material.

Results

A total of 8526 residents from 642 teaching hospitals in Japan took the GM-ITE in the 2021 academic year. Among these, 56 (23 PGY 2 and 33 PGY 1) residents also agreed to take the CSV innovative examination. The mean GM-ITE score of all 56 participants was 47.8 (SD 8.2). A DI revealed that several items had discrimination indices exceeding 0.2 (Table 1).

A total of 6 (11%) out of 56 participants answered Q2 correctly, and all the correct answers came from PGY 2 residents. The DI for the entire CSV innovative examination portion of the GM-ITE indicated high discriminatory power in all domains.

Figure 1 shows the DI for the MP (8 questions) domain, with 6 innovative questions scoring a DI of ≥ 0.20 , indicating its robustness in differentiating examinee proficiency.

Figure 2 focuses on the CD (18 questions) domain, with 5 innovative questions achieving a DI of ≥ 0.20 , which is indicative of its strong discriminatory capability among examinees.

In Figure 3, the PP (18 questions) domain is analyzed, with 5 innovative questions achieving a DI of ≥ 0.20 , demonstrating its effectiveness in assessing the examinees’ clinical skillset.

Finally, Figure 4 presents the DI for the DK (36 questions) domain, with 2 innovative questions achieving a DI of ≥ 0.20 , reflecting its potential as a moderate discriminator of examinees’ understanding.

These figures collectively underscore the CSV innovative examination’s capacity to gauge clinical competence effectively, with each domain’s innovative question serving as a significant indicator of the examinees’ capabilities. In particular, for the innovative question Q2, a DI of ≥ 0.20 was found for both the total score and all 4 domains, indicating its robustness in differentiating examinee proficiency.

A total of 23 (41%) participants answered Q4, the anonymous questionnaire to assess the participants’ views on the CSV innovative examination. Regarding whether the simulated patient examination video was better suited to assessing their clinical competence than the traditional all-text format (Q4-1), 12 (52%) participants answered positively, 4 (17%) answered negatively, and 7 (30%) provided a neutral response. Regarding whether the video simulation was realistic enough for them to assess the patient (Q4-2), 18 (78%) responded affirmatively. Regarding whether the experience increased their motivation to learn, 17 (74%) responded positively.

Table 1. Discrimination index^a.

Domain (questions, n)	Question 1	Question 2	Question 3-1	Question 3-2	Question 3-3	Question 3-4
Medical interview or professionalism (8)	0.48	0.38	0.94	0.74	0.30	0.61
Clinical diagnosis (18)	0.50	0.40	0.77	0.56	0.27	0.18
Physical examination or procedure (18)	0.52	0.35	0.39	0.19	0.22	0.39
Disease knowledge (36)	-0.09	0.58	0.13	0.04	0.27	-0.10
Total (80)	0.06	0.47	0.10	-0.06	0.01	-0.12
Question type	MC ^b	FD ^c	FD	FD	FD	FD

^aA discrimination index of ≥ 0.20 indicates that the question had high discriminatory power; a discrimination index of >0.40 indicates that the question was a very good measure of the participant’s qualifications.

^bMC: multiple choice.

^cFD: free description (<100 words).

Figure 2. DIs of the examination scores of the General Medicine In-Training Examination: clinical diagnosis (18 questions). DI: discrimination index; Q: question.

Figure 3. DIs of the examination scores of the General Medicine In-Training Examination: physical examination or procedure (18 questions). DI: discrimination index; Q: question.

Figure 4. DIs of the examination scores of the General Medicine In-Training Examination: disease knowledge (36 questions). DI: discrimination index; Q: question.

Discussion

Principal Findings

Residency is the final stage of medical education and supervised clinical practice. The traditional all-text GM-ITE was designed to elicit practical feedback on the preresidency training to identify areas of improvement by objectively assessing residents' clinical knowledge in 4 areas: MP, CD, PP, and DK. Medical education has historically relied on MCQs to assess learning [20,21]. However, some studies have explored "context-rich" MCQs that embed test items in a clinical vignette [22,23]. This study delved beyond a written clinical vignette by creating a video simulation of a patient examination in an emergency room. The strength of ratings regarding the measures of different

components of clinical reasoning indicates that although MCQs are effective in leading or working diagnosis and management and treatment, they are weak in hypothesis generation, problem representation, and diagnostic justification [7]. Conversely, it has been found that while differential diagnosis, leading or working diagnosis, diagnostic justification, and management and treatment are effective in essay style (free text), they are relatively weak in information gathering [24]. This finding suggests that CSV-based test modules could provide a more accurate measure of participants' clinical knowledge and abilities than the GM-ITE.

Education, including medical education, has increasingly embraced computer-based testing. Today, students are accustomed to answering questions and writing essays via

computer-based testing. This study designed a single video simulation to assess the knowledge and skills of residents from the nonverbal information portion of the national medical licensing examination domains, particularly general theory. We included information from 3 domains in a single question, and the participants obtained high scores. This finding suggests that a single CSV module could test multiple skills and knowledge areas of residents. In other words, using innovative CSV-based questions could provide more realistic assessments while making the examinations more efficient.

The 3 domains covered in the CSV innovative examination Q1 (MP, CD, and PP) indicated DI of 0.4 or higher; the GM-ITE means were 0.32 (SD 0.13), 0.32 (SD 0.16), and 0.31 (SD 0.18), respectively. Therefore, the successful participants (based on GM-ITE scores) had higher scores on these domains in the CSV innovative examination question than in the GM-ITE. Q1 required participants to select 3 options from the MCQ (2 cutoffs per question). We found that the CSV could cover 3 separate domains in a single MCQ.

CSV innovative examination Q2 required a descriptive response; specifically, the participants needed to name the most likely diagnosis. Two physicians (KS and SF) independently assessed the diagnoses and achieved an agreement rate of 1.00. The DI of Q2 was 0.4 or higher for symptomatology or clinical reasoning and diseases and 0.3 or higher for general theory, physical examination, and clinical techniques. The overall GM-ITE scores had a high identification index of 0.47. Specifically, the CSV innovative examination Q2's requirement for participants to provide a definitive diagnosis allowed for a comprehensive assessment across all domains included in the GM-ITE. Furthermore, Q2 was distinguished as the sole question that demonstrated high DIs across individual disease categories. In addition, Q2 was the only question that also presented a high DI in each disease category.

CSV innovative examination Q3 required participants to provide an SBAR (situation, background, assessment, and recommendation) report using a total of 400 words or fewer. Two physicians (KS and SF) scored the responses independently and then rated each response against the scoring criteria and added them together. The agreement rate was as high as 0.92. It was observed that Q3 lowered the overall DI score to a high level in the general discussion. In other words, Q3 was easier for all the participants to answer than the other questions. For Q3-1 and Q3-2, the high discriminative ability was lowered for symptomatology and clinical reasoning. However, for each theory of disease, all the DIs were low, with some negative results. Therefore, most participants were better able to describe the patient's situation and background than provide an assessment and recommendations.

This study is significant in that it provided "content-rich" clinical information. In addition to obtaining all the information normally provided in the conventional paper-based examinations, the participants had the advantage of seeing and hearing the various symptoms portrayed by a professional actor. In addition, medical interviews with patients and their families can reveal useful nonverbal information such as tachypnea and expressions indicating anxiety and pain levels. Gathering clinical

information through diagnostic inference is critical in real-life scenarios. Participants may have performed better in certain domains covered in Q1-Q3 compared to their GM-ITE scores for the same domains owing to the CSV's heightened sense of immediacy (seeing "real" people rather than reading about them) and the opportunity for diagnostic inferences in workplace-based assessments. This finding may indicate a development of clinical competence from the level of "knows how" to "shows" in Miller's pyramid, which could lead to an advanced assessment in the cognitive domain.

Comparison to Prior Work

The discriminative efficacy of the CSV's innovative examination in this study aligns with similar interventions. A study comparing simulation and video-based training for acute asthma management found that both methods significantly improved MCQ posttest scores, indicating an enhanced understanding of clinical methods [25]. Additionally, a study conducted at a university hospital in Pakistan revealed that a hybrid model combining video-based learning with simulation increased students' confidence and performance in clinical skills. This suggests that digital and multimedia-enhanced methods may surpass traditional teaching modalities in certain aspects of medical education [26]. These comparisons underscore the potential of CSV-based assessments to provide a more nuanced and comprehensive measure of clinical competencies, potentially bridging theoretical knowledge and practical application more effectively in medical training.

Limitations

Although this study reveals important findings, it has several limitations. First, the number of participants included in the study was low. For the data to be more valid, the number of examinees needs to be increased. However, adding more participants would also increase the test-scoring burden, which calls the viability of CSV-based testing into question. In this study, 2 physicians (KS and SF) scored the written questions. Increasing the number of examinees would also increase the time and effort required to score the results. If all of the approximately 8000 examinees who took the GM-ITE completed the CSV innovative examination module, the scoring time required would be untenable, and adding more CSV-based modules would compound the problem. One way to overcome this limitation could be the use of a morphological analysis or to only score a statistically significant sampling.

Another limitation is related to the authenticity of the CSV. We created the abnormalities in the "patient," such as the heart murmur and loud P2, by synthesizing sounds. We could not represent some aspects, such as the enhancement of systolic murmur on inspiration, and the apex beat was not clear, which might have confused the examinees. Furthermore, the time and expense involved in creating high-quality, realistic clinical cases would likely reduce the number of modules that could be used, which might enable the test takers to gain prior knowledge of the "correct" answers, therefore defeating the purpose of the test. Future research should determine the feasibility of including real cases and patients to maximize verisimilitude and reduce personnel and production expenses.

Conclusions

The findings of this study suggest that the CSV showed a high identification index for overall and multiple domains of competence in the conventional GM-ITE. The participants liked

being able to “examine” the patient and receive visual and auditory clinical information, which improved their test scores. Overall, the findings showed that CSV modules simulating real-world clinical examinations assessed residents’ clinical competence successfully in multiple domains.

Acknowledgments

The authors thank the members of the Japan Institute for Advancement of Medical Education Program (JAMEP) for their valuable assistance. The JAMEP was involved in collecting and managing data as the General Medicine In-Training Examination (GM-ITE) administrative organization. It did not participate in designing and conducting the study; data analysis and interpretation; preparation, review, or approval of the paper; and the decision to submit the paper for publication. The authors also like to thank Editage for the English language review. This work was supported by the Health, Labour, and Welfare Policy Grants of Research on Region Medical (21IA2004) from the Ministry of Health, Labour and Welfare.

Data Availability

The data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

KS had full access to all the study data and took responsibility for the integrity and accuracy of the data analysis. KS, YN, SF, DY, and YT contributed to the study concept and design. HK, TS, and YY were involved in data acquisition, analysis, and interpretation. KS performed statistical analysis and wrote the paper. YN revised the content. YN and YT were involved in administrative, technical, and material support. All authors reviewed the final paper.

Authors KS (kshikino@gmail.com) and YN (ynishiza@juntendo.ac.jp) are co-corresponding authors for this article.

Conflicts of Interest

YN received an honorarium from the Japan Institute for Advancement of Medical Education Program (JAMEP) as the General Medicine In-Training Examination (GM-ITE) project manager. YT is the director of the JAMEP. HK received an honorarium from the JAMEP as a speaker for the JAMEP lecture. KS received an honorarium from the JAMEP as a reviewer of GM-ITE. KS, TS, and YY received honoraria from the JAMEP as examination preparers of GM-ITE. No other authors possess any competing interests.

Abstract

Background: An integration of digital medicine into medical education can help future physicians shape the digital transformation of medicine.

Objective: We aim to describe and evaluate a newly developed course for teaching digital medicine (the Bielefeld model) for the first time.

Methods: The course was held with undergraduate medical students at Medical School Ostwestfalen-Lippe at Bielefeld University, Germany, in 2023 and evaluated via pretest-posttest surveys. The subjective and objective achievement of superordinate learning objectives and the objective achievement of subordinate learning objectives of the course, course design, and course importance were evaluated using 5-point Likert scales (1=*strongly disagree*; 5=*strongly agree*); reasons for absences were assessed using a multiple-choice format, and comments were collected. The superordinate objectives comprised (1) the understanding of factors driving the implementation of digital medical products and processes, (2) the application of this knowledge to a project, and (3) the empowerment to design such solutions in the future. The subordinate objectives comprised competencies related to the first superordinate objective.

Results: In total, 10 undergraduate medical students (male: n=4, 40%; female: n=6, 60%; mean age 21.7, SD 2.1 years) evaluated the course. The superordinate objectives were achieved well to very well—the medians for the objective achievement were 4 (IQR 4-5), 4 (IQR 3-5), and 4 (IQR 4-4) scale units for the first, second, and third objectives, respectively, and the medians for the subjective achievement of the first, second, and third objectives were 4 (IQR 3-4), 4.5 (IQR 3-5), and 4 (IQR 3-5) scale units, respectively. Participants mastered the subordinate objectives, on average, better after the course than before (presurvey median 2.5, IQR 2-3 scale units; postsurvey median 4, IQR 3-4 scale units). The course concept was rated as highly suitable for achieving the superordinate objectives (median 5, IQR 4-5 scale units for the first, second, and third objectives). On average, the students strongly liked the course (median 5, IQR 4-5 scale units) and gained a benefit from it (median 4.5, IQR 4-5 scale units). All students fully agreed that the teaching staff was a strength of the course. The category *positive feedback on the course or positive personal experience with the course* received the most comments.

Conclusions: The course framework shows promise in attaining learning objectives within the realm of digital medicine, notwithstanding the constraint of limited interpretability arising from a small sample size and further limitations. The course concept aligns with insights derived from teaching and learning research and the domain of digital medicine, albeit with identifiable areas for enhancement. A literature review indicates a dearth of publications pertaining to analogous courses in Germany. Future

investigations should entail a more exhaustive evaluation of the course. In summary, this course constitutes a valuable contribution to incorporating digital medicine into medical education.

KEYWORDS

medical education; digital medicine; digital health

Introduction

Background

Digital health, the field in which health care is linked to technology [1], encompasses digital medicine, which refers to the specific use of digital technology products in health care [1]. Following the suggestion by Bahagon and Jacobson [2] that the successful implementation of such products is “the expertise of tailoring knowledge and leadership capabilities in multidisciplinary areas: clinical, ethical, psychological, legal, comprehension of patient and medical team engagement etc....” *digital medicine* is defined in this paper as follows: digital medicine is concerned with the holistic development and application of digital health applications, where *holistic* means that nonmedical issues and aspects relevant to such development and application are taken into account.

The World Health Organization recommends implementing digital health—and, consequently, digital medicine—technologies in the health care sector due to the potential positive impact of such technologies on health care [3]. This includes products such as health apps and smart devices for monitoring purposes and the use of technologies such as artificial intelligence, big data analysis, advanced computing, and robotics. Promising fields of application are, for example, for cardiovascular diseases [4,5], diabetes [6], and mental health [7]. Successful implementation of digital technologies is underway in many areas of health care. Still, it depends on a culture of change that results in the reorganization of services based on the public’s health needs. Among other authors, Iyamu et al [8] refer to this process as the digital transformation of medicine. As relevant stakeholders, physicians have a responsibility to shape this transformation. To prepare and enable future physicians to do so, they need to acquire relevant competencies during their studies. For the first time, skills in the field of digital medicine are classified as core competencies for the medical profession in the draft bill of the medical licensing regulations of June 2023 [9,10]. Training should enable future physicians to take an “active and self-designing role to develop a goal-oriented approach to current technological solutions on their responsibility” [11]. In Germany, the National Competency-Based Catalog of Learning Objectives (NKLM), which lists the competencies that medical students should acquire during their studies, specifies that medical students should acquire the competence of knowing and being able to reflect on the areas of application of digital medicine and the

significance of digitalization. For example, they should be able to explain the application scenarios for telemedicine applications and their framework conditions [12]. Courses in digital medicine are necessary to acquire these competencies. Against this background, an integration of topics of digital health and medicine into medical education is recommended [3,11,13-15]. It has already been shown that medical students feel like the early integration of such topics into medical education can help prepare them for their future work environment [16].

Courses on digital health are already offered as part of medical studies in various countries, including Germany [17,18], but the range of classes dealing with digital medicine must be further expanded to enable a true digital transformation of the health care system. Studies such as those by Jacob et al [11], Schreiber et al [15], and Machleid et al [16] show that digital medicine has so far not been given sufficient consideration in medical education. Thus, it can be assumed that future physicians do not yet have the required digital medicine competencies. Many students feel unprepared for the future regarding the digitalization of health care by their teachers and the courses they attended and wish for better integration of digital medicine and digital health topics into their studies [11,16,19]. Against the background of the integration of competencies in digital medicine in the draft bill of the medical licensing regulations of June 2023 [10], an expansion of courses related to digital medicine in Germany may be expected as soon as the new medical licensing regulations come into force.

Following the call for corresponding adjustments, the newly founded Medical School Ostwestfalen-Lippe (OWL; the region of Ostwestfalen-Lippe, Germany) at Bielefeld University has set up a Digital Medicine working group within the faculty and included Digital Medicine in the regular curriculum of medical studies. In addition, a Technological Transformation in Medicine profile is offered for continuing education. In this profile, the Digital Medicine working group contributes with a course called Digital Medicine, referred to in this paper as the “Bielefeld model.” The overarching educational objective is to empower students to feel able to actively engage as prospective architects of digital medicine, transcending their role as mere users or consumers of digital products or participants in digital processes. This means that students will need to be equipped to develop and use digital applications comprehensively.

This overarching educational objective translates to 3 specific superordinate learning objectives of the course (Textbox 1).

Textbox 1. The 3 superordinate learning objectives of the course.

Superordinate learning objective 1

Students will know the factors influencing the sustainable implementation of digital medical products and processes.

Superordinate learning objective 2

Students will be able to apply their knowledge of the factors influencing the sustainable implementation of digital medical products and processes in developing a specific project.

Superordinate learning objective 3

Students will feel empowered to design sustainable digital products and processes in future projects.

The implementation of digital products and processes is considered to be sustainable if it is independent of individual motivated implementers. To design sustainable solutions, it is important to consider a wide range of influencing factors. Only if these are taken into account will products and processes be able to achieve a high level of acceptance in the health care system in the long term, develop their full positive impact, and remain in place.

The first of these 3 superordinate learning objectives, in turn, translates to 17 subordinate learning objectives ([Textbox 2](#)). These subordinate learning objectives include abstract competencies related to the first superordinate learning objective (subordinate learning objectives 1 to 6) as well as specific competencies in relation to the individual factors that are subsumed under the first superordinate learning objective (subordinate learning objectives 7 to 17). Thus, these subordinate learning objectives should capture aspects of the first superordinate learning objective.

Textbox 2. The 17 subordinate learning objectives of the course.

Subordinate learning objective ID and description

- Sub01: the students can identify players and stakeholders in the field of digital medicine.
- Sub02: the students can name and reflect on overarching themes of digital medicine.
- Sub03: the students can identify, address, and discuss problem areas (medical, technical, legal, ethical, and social) of digital medicine.
- Sub04: the students can critically assess digital medicine and evaluate it based on its opportunities and challenges.
- Sub05: the students can explain the product life cycle of digital medicine and plan an applied project based on it.
- Sub06: the students can plan a concrete project with basic knowledge of project management.
- Sub07: the students can identify markets for digital medicine and discuss challenges of market entry for digital applications.
- Sub08: the students can identify and communicate the necessary information required for commissioning a technical development of digital applications.
- Sub09: the students can explain the legal challenges of using digital tools and digital communication media in relation to digital medicine.
- Sub10: the students can explain the regulatory difference between a medical device and other products and explain legal consequences.
- Sub11: the students can identify and discuss the ethical implications of digital medicine for patients, physicians, contributors, society, and the environment.
- Sub12: the students can explain interoperability and know what characterizes interoperability.
- Sub13: the students can assess the quality of digital medicine applications.
- Sub14: the students can recognize the quality of the usability of a digital application and know which factors can influence the usability.
- Sub15: the students can discuss elements of data science and its tools and requirements in data preparation and data analysis.
- Sub16: the students can discuss and evaluate digital medicine with regard to specific aspects in the context of gender and sex.
- Sub17: the students can explain data protection and data security challenges in the development and use of digital tools and digital communication media.

The decision to design an own course concept instead of adopting an existing one was made to be able to design a course that is very specifically geared toward achieving these learning objectives.

Objectives

The aim of this paper is to introduce the Bielefeld model for the first time and undertake an initial exploratory evaluation.

In particular, the aim of the course evaluation is to determine the following:

1. How well the participants objectively and subjectively achieved the 3 superordinate learning objectives (as presented in [Textbox 1](#)) and how well they objectively achieved the 17 subordinate learning objectives of the course (as presented in [Textbox 2](#)).

- Whether the course was well designed. This encompasses how suitable the participants considered the course to be for achieving the superordinate learning objectives, whether they enjoyed the course and benefitted from it, and which aspects they considered as strengths of the course.
- How important the course was to the participants. This encompasses how important the achievement of the superordinate learning objectives was to them personally and the reasons for the participants' potential absences during the course. Those reasons might indicate whether taking part in the course was important for the participants.

Methods

The Digital Medicine Course

Setting

Undergraduate medical students at the Medical School OWL go through a model curriculum with an interdisciplinary specialization in their first 3 years of studies. The students can choose, or, in rare cases, are assigned to 1 of 5 profile options with Technological Transformation in Medicine (TeTraMed) being one of them. Digital Medicine is the third of the 6 mandatory modules the TeTraMed profile comprises. The module is completed with an examination. Students can earn a bachelor's degree in Interdisciplinary Medical Sciences alongside their medical studies, with course credits counting toward both degrees.

Course Concept

The instructors of the course designed the course and developed the learning objectives based on their experience in research and teaching in digital medicine and in the development of digital medicine applications and based on considerations for the design of an effective course concept. The main instructor is a physician, computer scientist, and public health scientist and a professor of digital medicine at Bielefeld University. Coinstructors (a psychologist, physician, and medical engineer) were members of this working group. The overarching goals and learning objectives of the course were to be achieved by the students by developing a digital medicine application in interdisciplinary collaboration with electrical engineering students from Hamburg University of Technology (TUHH; when students are mentioned hereafter in connection with the course, this refers to medical students. Electrical engineering students are only referred to when they are specifically mentioned. When mentioning the course, unless otherwise stated, this refers to the course for medical students). The course was co-designed with a professor of smart sensors who is skilled in computer science and electrical engineering and teaches the electrical engineering students at TUHH. Consistent with the 3 superordinate learning objectives (Textbox 1), the didactic emphasis of the course was directed toward investigating the manifold factors associated with and influencing the domain of digital medicine. Adhering to project-based learning methodologies, medical students collaboratively engaged in small groups in their own projects related to telemedicine (using technologies for providing health care over a distance [20]), an area of digital medicine. The students were divided into 3

groups, and each group was assigned 1 of 3 cases. The cases described circumstances in which individuals required monitoring due to medical conditions or circumstances (for more detail, see Multimedia Appendix 1). The aim of the students was to systematically solve the challenge described in the case by using mobile sensor technology, exemplifying its application in a corresponding product and process. They were also free to design an accompanying app. A course that was separate but linked to the course for medical students was held at TUHH with the electrical engineering students. Their course followed a research-based learning design. The focus of the electrical engineering students was primarily on developing the sensor systems that the medical students designed in their projects. The sensor should have been designed by the end of the course, but the aim was not to actually implement it on the market. The collaboration between the courses at TUHH and Bielefeld University was designed to emulate the fact that, when working on projects such as that in the Bielefeld model in real life outside the university, a collaboration between medical professionals and technicians is often required to technically implement what medical professionals design. The central concept involved both medical and electrical engineering students collaborating without silos, working together as equals. This approach fosters interdisciplinary cooperation, promotes precise and accurate communication, and equips students for project work in professional settings across both fields. Apart from this collaboration, the medical students and the electrical engineering students were taught separately. The electrical engineering students did not take part in the regular sessions of the Bielefeld model.

The students experienced the entire product life cycle within the Digital Medicine course, from brainstorming to planning, developing, evaluating, implementing, operating, and decommissioning digital products and processes. They were confronted with challenges posed by the diverse interests of the stakeholders, frameworks, resources, and settings involved and had to take into account the factors influencing the sustainable implementation of digital medical products and processes. This encompassed an exploration of their interrelationships and their consequential impact on the development and enduring implementation of digital medical products and processes. By doing so, they practiced directly acknowledging, accepting, and addressing these factors.

On the basis of their experience, the instructors identified and addressed the following multidimensional factors in the course: project management, market entry, technical development, quality, data science, interoperability, usability, law, regulation and ethics, sex and gender sensitivity, and data protection and security. These factors result from the interfaces between medicine and health with the fields of technology, informatics, society, law, regulation, ethics, economics, and psychology.

In each session, one or several of these factors were addressed by the course instructors and often also by external experts who were invited as guest lecturers (Table 1; see Multimedia Appendix 2 for more detailed information about the topics of the sessions and the guest lecturers). Table 1 shows which of the 17 subordinate learning objectives relate to the specific sessions. It was assumed that subordinate learning objectives 1

to 6 (Textbox 2) would be achieved throughout the course. The subordinate learning objectives that relate specifically to the factors subsumed under the first superordinate learning objective (subordinate learning objectives 7 to 17; Textbox 2) should be achieved in the corresponding sessions. After the lecture in which the factor or factors were addressed, the students connected the topic to their own projects in a practical unit, reflecting on its impact and identifying what considerations were necessary for their specific work. For example, in the session on law, regulation, and ethics, students were able to consider whether their sensor would be a medical device from a legal point of view, or in the session on usability, for example, they were able to reflect on how usable their product was and

how usability could be increased. The students could exchange ideas, discuss, develop further content, and converse about general and project-related questions with the lecturers alone or in a group. In this process, the students identified and named requirements that their sensors should fulfill. They communicated the technical requirements to the electrical engineering students in Hamburg, who implemented these specifications for the sensors in consultation with the medical students. Progress and outcomes of the small groups were systematically documented in a project outline (as illustrated in Multimedia Appendix 3) subject to continuous updates and revisions throughout the course.

Table 1. Digital Medicine curriculum within the TeTraMed profile.

Session	Topic	Life cycle phase	Subordinate learning objective to be achieved in the session	Guest lecturer
1	Introduction	Idea generation	— ^a	No
2	Project management	Planning	6	Yes
3	Market entry	Planning	7	Yes
4	Technical development	Development	8	Yes
5	Quality ^b	Development	13	No
6	Data science ^c	Development	15	Yes
Additional session A	Meeting with the electrical engineering students	Development	8	—
7	Interoperability	Development	12	Yes
8	Usability	Premarket evaluation	14	Yes
9	Law, regulation, and ethics	Implementation	9, 10, and 11	Yes
10	Sex and gender sensitivity	Postmarket evaluation	16	Yes
11	Data protection and data security	Use	17	No
12	End	Decommissioning	—	No
Additional session B ^d	Ceremony	Memorial	—	—

^aNot applicable.

^bDeviation from the original curriculum (Law, Regulation, Ethics) was changed following the students' wishes as it conflicted with other study responsibilities.

^cDeviation from the original curriculum (Interoperability) was changed following the students' wishes as it collided with other study liabilities.

^dIn this session, it was planned to hand the participants certificates that confirmed participation in the course. This session had to be canceled due to situational circumstances, but the certificates were handed out anyway.

By confronting new issues and challenges, students were encouraged to reflect on their own project on an ongoing basis and then revise it. The course instructors and external experts from the different interface areas provided knowledge transfer and support for the projects. The course concept provided self-management skills (managing oneself and the available resources) as well as project and team management skills, such as preparing, implementing, and recording project meetings. Work, communication, interaction, negotiation, and conflict resolution in interdisciplinary, international, and intercultural teams and exchange and work in English were also part of this. The course was primarily offered in an analog-oriented format; essentially, only the meetings with the electrical engineering students took place in web-based live video formats. The course was supported by web-based materials provided on the

university e-learning platform LernraumPlus. Due to external organizational circumstances, some sessions were only available on the web for self-study.

Course Structure

The Digital Medicine course was structured in 12 sessions, usually held weekly, distributed over 4 months in the summer semester of 2023 (April to July). Each session consisted of a 45-minute lecture, a 90-minute workshop during which the students worked on their projects, and a 90-minute guided self-study for which no contact time with the teaching staff was scheduled but was offered at times. Thus, there were a total of 9 hours of lectures, 18 hours of workshops, and 18 hours of guided independent study. In addition, times without contact with the teachers were set aside for preparation and follow-up

work. In total, 3 further scheduled dates were canceled due to holidays. The structure of each course day is shown in [Multimedia Appendix 4](#).

Evaluation and Analysis

Overview

The course concept was evaluated by recruiting undergraduate medical students at the Medical School OWL who took part in the course between April and July 2023. The students were asked to complete a web-based presurvey at the beginning of the course and a postsurvey after the course had ended (after the 12th session) in German using a customized web-based survey tool. For this, they first had to create a pseudonym. The mapping between the pseudonyms and the participants was unknown to the study staff, so anonymity was maintained. However, using the pseudonyms made it possible to merge the individual data sets of the pre- and postsurveys. A customized instrument (using the form survey framework [21]) was provided for the survey by the Medical Education working group at the Medical School OWL at Bielefeld University. The presurvey was administered on April 3, 2023, and the postsurvey was administered between July 10, 2023, and August 1, 2023. Students were invited anonymously via email and by the instructors during the course. A total of 2 follow-up actions were conducted via email at an interval of 2 weeks after the beginning of the postevaluation.

Instruments

Overview

The presurvey consisted of 27 items: the demographic variables of age and gender, the items related to the objective achievements of the subordinate learning achievements (pre- and postsurvey), as well as the open comments (again, pre- and post-survey, see corresponding tables in the Results section), and an additional 10 items that will not be described or analyzed in this paper but will be focused on in a separate publication. These additional items were administered to assess the achievement of learning goals following a catalog of learning outcomes as described by Foadi et al [22] that partially corresponds to the NKLM. The postsurvey consisted of 47 items and additional 10 items based on the learning outcomes as described by Foadi et al [22] that are neither described nor evaluated in this paper. A comprehensive overview of all items that were used can be found in [Multimedia Appendix 5](#).

All responses to the surveys (except regarding items AB01 and COM01, as described later in the manuscript when these items are presented) were recorded on an ordinal 5-point Likert scale, which was recoded after the study to be more consistent with the usual coding system (the coding in the questionnaire was as follows: 1=*strongly agree*, 2=*rather agree*, 3=*rather neutral*, 4=*rather disagree*, and 5=*strongly disagree*; the scale was recoded as follows for the analyses: 1=*strongly disagree*, 2=*rather disagree*, 3=*rather neutral*, 4=*rather agree*, and 5=*strongly agree*). All items (except those by Foadi et al [22]) were developed in-house, as described in detail in the following sections.

Achievement of the Super- and Subordinate Learning Objectives

The objective and subjective achievement of the 3 superordinate learning objectives was assessed using 1 item each in the postsurvey (for objective achievement: items SUPER1_OA, SUPER2_OA, and SUPER3_OA; for subjective achievement: items SUPER1_SA, SUPER2_SA, and SUPER3_SA). The objective achievement of the subordinate learning objectives was assessed using 17 items (items sub01 to sub17). By recording the objective achievement of the subordinate learning objectives in both the pre- and the postsurvey, it was possible to determine whether the participants would have achieved these objectives better after the course than before.

As the subordinate learning objectives should capture aspects of the first superordinate learning objective, items measuring the objective achievement of these subordinate objectives should capture aspects of the objective achievement of this first superordinate learning objective. In that case, changes in the median of items measuring the objective achievement of the subordinate learning objectives from the pre- to the postsurvey would also indirectly provide information about how the objective achievement of the first superordinate learning objective developed from the pre- to the postsurvey.

Design of the Course

One item per superordinate learning objective was used to record the extent to which the participants considered the course concept suitable for achieving this objective (items SUPER1_SUIT, SUPER2_SUIT, and SUPER3_SUIT). In total, 2 items were used to measure whether the participants enjoyed the course (item FUN01) and whether they felt that they benefited from it (item BEN01). In 4 questions, participants were able to indicate the extent to which they perceived 4 potential benefits as actual strengths of the course (items STR01 to STR04).

Importance of the Course to the Participants

One item per superordinate learning objective was used to record how important it was to the participants to achieve this objective (items SUPER1_IMP, SUPER2_IMP, and SUPER3_IMP).

One item was used to measure the reasons for participants' absences (item AB01) during the course. This item did not use a Likert scale but instead offered various answer options for participants to choose from, allowing them to give multiple answers.

Open Comments

Participants could write comments in an open-response format at the end of the pre- and postsurvey (item COM01).

Development, Validity, and Reliability of the Instruments

All items were developed through an iterative process informed by the insights of 3 authors. The items assessing the objective achievement of the superordinate (items SUPER1_OA, SUPER2_OA, and SUPER3_OA) and subordinate (all items) learning objectives were developed by formulating the learning objectives in first-person singular format and pairing them with a 5-point Likert scale. The development of the learning

objectives and the items based on them was carried out by 2 (in the case of the learning objectives) to 3 (in the case of the items) authors in an iterative process. The consistency of the formulations with the course's conceptual objectives was regularly reviewed to ensure strong content validity. The reason for the development of these new items was that, until now, no instrument has reflected the course concept closely enough to capture what was to be learned in the course. The content validity of the other items was also ensured by matching the formulations in an iterative process with the underlying idea of what should be captured using these items. The items assessing whether the participants enjoyed the course (item FUN01) and whether they benefitted from it (item BEN01) have been used with similar or related wordings in other studies [23,24]. Therefore, content validity was assumed.

The items did not capture common things but were instead considered individually, so they were not combined as a scale. Thus, no internal consistencies were calculated. Interrater reliability was assumed for all items that were recorded and statistically evaluated on the Likert scale as the evaluation was objectively independent of the rater.

Analysis

All items were analyzed descriptively. The mean and SD were calculated to describe the age-related data. The information on

gender was analyzed through the calculation of occurrence frequencies. The Spearman ρ was calculated to investigate a correlation between the item measuring the objective achievement of the first superordinate learning objective and the 17 items measuring the objective achievement of the subordinate learning objectives in the postsurvey. A positive correlation would indicate that the items measuring the objective achievement of the subordinate learning objectives are well suited to capture aspects of the objective achievement of the first superordinate learning objective. The items that were recorded using the ordinal 5-point Likert scales were evaluated by calculating the median and IQR. Using a descriptive account of the aggregated median values of the students for the items assessing the objective achievement of the subordinate learning objectives, we compared a possible change in this achievement from the pre- to the postsurvey. **Textbox 3** shows how the changes in the median of these items from the pre- to the postsurvey will be evaluated qualitatively. The qualitative evaluation was based on considerations of how changes are to be evaluated. Due to the small sample, an inferential statistical analysis was not performed. The comments were analyzed by dividing them into main categories and subcategories based on the structuring qualitative content analysis according to Kuckartz and Rädiker [25]. The frequency of occurrence of each subcategory was determined.

Textbox 3. Qualitative evaluation of the changes in the median of the objective achievement of the subordinate learning objectives.

Size of change and qualitative evaluation

- 0: no change
- >0 to 0.4: minimal change
- 0.5 to 0.9: small change
- 1 to 1.4: rather big change
- 1.5 to 1.9: big change
- >1.9: extensive change

Ethical Considerations

The study was approved by the Ethics Committee Ethik-Kommission Westfalen-Lippe, located in Münster, Germany, under the chairmanship of Professor Dr Wolfgang E Berdel, on May 11, 2023 (2023-233-f-S).

Results

All 15 course participants were recruited for the study. A total of 10 participants (n=4, 40% male and n=6, 60% female; mean age 21.7, SD 2.1 years) completed both the pre- and the postsurvey and were included in the analysis.

Achievement of the Super- and Subordinate Learning Objectives

Table 2 shows the results regarding the objective and subjective achievement of the superordinate learning objectives (for

information on how frequently the individual response categories were selected by the participants, see **Multimedia Appendix 6**). Regarding the objective achievement of these objectives, medians of 4 (IQR 4-5), 4 (IQR 3-5), and 4 (IQR 4-4) scale units were found for the first, second, and third superordinate learning objectives, respectively. Concerning the question of whether the participants also subjectively achieved these learning objectives, medians of 4 (IQR 3-4), 4.5 (IQR 3-5), and 4 (IQR 3-5) scale units were found for the first, second, and third learning objectives, respectively. Therefore, the median values varied between the scale points *rather agree* (scale value of 4) and *strongly agree* (scale value of 5). Thus, on average, the results indicate a rather to very good achievement of the 3 superordinate learning objectives both objectively and subjectively.

Table 2. Objective and subjective achievement of the 3 superordinate learning objectives, the suitability of the course for achieving them, and the importance of achieving them, administered in the postsurvey (N=10)^a.

Superordinate learning objective and item ID	Item	Scale units, median (IQR)
Superordinate learning objective 1		
SUPER1_OA ^b	I know the factors that influence the sustainable implementation of digital medical products and processes.	4 (4-5)
SUPER1_SUIT ^c	The course concept was suitable for teaching these factors.	5 (4-5)
SUPER1_IMP ^d	It was important to me to achieve this learning goal.	4 (3-4)
SUPER1_SA ^e	I have achieved this learning goal from a personal perspective.	4 (3-4)
Superordinate learning objective 2		
SUPER2_OA ^f	I can apply my knowledge regarding the factors that influence the sustainable implementation of digital medical products and processes in developing a concrete project.	4 (3-5)
SUPER2_SUIT	The course concept was suitable to apply my knowledge regarding these factors in developing a concrete project.	5 (4-5)
SUPER2_IMP	It was important to me to achieve this learning goal.	4 (3-5)
SUPER2_SA	I have achieved this learning goal from a personal perspective.	4.5 (3-5)
Superordinate learning objective 3		
SUPER3_OA ^f	I feel empowered to design sustainable digital products and processes in future projects.	4 (4-4)
SUPER3_SUIT	The course concept was suitable to enable me to design sustainable digital products and processes in future projects.	5 (4-5)
SUPER3_IMP	It was important to me to achieve this learning goal.	3.5 (3-5)
SUPER3_SA	I have achieved this learning goal from a personal perspective.	4 (3-5)

^aThe “superordinate learning objective” column indicates to which superordinate learning objective the respective items belong.

^bOA: objective achievement (of the respective superordinate learning objective).

^cSUIT: suitability (of the course concept for achieving the respective superordinate learning objective).

^dIMP: importance (of achieving the respective superordinate learning objective).

^eSA: subjective achievement (of the respective superordinate learning objective).

^fThis item was answered by only 90% (9/10) of the participants.

Regarding the objective achievement of the subordinate learning objectives, on average, the participants performed better on all items after the course than before (Table 3; for information on how frequently the individual response categories were selected by the participants, see Multimedia Appendix 7). While an average median of 2.5 (IQR 2-3) scale units was achieved across the items in the presurvey, it increased by 1.5 scale units to 4 (IQR 3-4) in the postsurvey. This can be rated as a big change (Textbox 3). While, in the presurvey, the median values varied between the scale points *strongly disagree* (scale value of 1) and *rather agree* (scale value of 4), in the postsurvey, they varied between the scale points *rather neutral* (scale value of 3) and *strongly agree* (scale value of 5). While the presurvey results, therefore, indicate a strong nonachievement to rather good achievement on average of the subordinate learning objectives, the postsurvey results indicate a partial to very good

achievement of those objectives on average. When analyzing the change in the median for each session, there was an improvement from the pre- to the postsurvey in 15 of the 17 items (Table 3; range of change in the median between 0.5 and 2 scale units). For items sub03 and sub04, no change in the median values could be found. Still, when looking at how often the individual response categories were selected (Multimedia Appendix 7), it can be seen that, in these items, there was also an improvement from the pre- to the postsurvey. While only 60% (6/10) of the participants strongly or rather agreed with items sub03 and sub04 in the presurvey, 100% (10/10) of the participants strongly or rather agreed with these items in the postsurvey. It can be summarized that, on average, all subordinate learning objectives were achieved better after the course than before by the participants.

Table 3. Objective achievement of the subordinate learning objectives, administered in the pre- and postsurvey (N=10).

Item ID	Item	ρ^a	Presurvey score, median (IQR) ^b	Postsurvey score, median (IQR) ^c	Δ Median ^d
Sub01	I can identify players and stakeholders in the field of digital medicine.	0.37	2 (1-3)	4 (3-5)	2
Sub02	I can name and reflect on overarching themes of digital medicine.	0.56	3 (2-4)	4.5 (4-5)	1.5
Sub03	I can identify, address, and discuss problem areas (medical, technical, legal, ethical, and social) of digital medicine.	0.11	4 (3-5)	4 (4-5)	0
Sub04	I can critically assess digital medicine and evaluate it based on its opportunities and challenges.	0.30	4 (3-4)	4 (4-5)	0
Sub05	I can explain the product life cycle of digital medicine and plan an applied project based on it.	0.73	2 (1-2)	4 (3-4)	2
Sub06	I can plan a concrete project with basic knowledge of project management.	0.85	2 (1-2)	4 (3-5)	2
Sub07	I can identify markets for digital medicine and discuss challenges of market entry for digital applications.	0.14	3 (1-3)	4 (3-5)	1
Sub08	I can identify and communicate necessary information required for commissioning a technical development of digital applications.	0.42	2 (2-3)	4 (4-4)	2
Sub09	I can explain the legal challenges of using digital tools and digital communication media in relation to digital medicine.	0.56	3 (2-3)	4 (4-4)	1
Sub10	I can explain the regulatory difference between a medical device and other products and explain legal consequences.	0.52	3 (2-3)	4 (4-5)	1
Sub11	I can identify and discuss the ethical implications of digital medicine for patients, physicians, contributors, society, and the environment.	0.65	3 (3-4)	3.5 (3-4)	0.5
Sub12	I can explain interoperability and know what characterizes interoperability.	0.79	1.5 (1-3)	3.5 (3-4)	2
Sub13	I can assess the quality of digital medicine applications.	0.60	3 (2-3)	4 (4-5)	1
Sub14	I can recognize the quality of the usability of a digital application and know which factors can influence the usability.	0.38	2 (1-3)	4 (4-5)	2
Sub15	I can discuss elements of data science and its tools and requirements in data preparation and data analysis.	0.62	2 (1-3)	3 (2-4)	1
Sub16	I can discuss and evaluate digital medicine with regard to specific aspects in the context of gender and sex.	0.50	2 (1-3)	4 (3-4)	2
Sub17	I can explain data protection and data security challenges in the development and use of digital tools and digital communication media.	0.44	2.5 (2-3)	4 (3-4)	1.5

^aSpearman ρ (correlation between the item measuring the objective achievement of the first superordinate learning objective and the items measuring the objective achievement of each subordinate learning objective as measured in the postsurvey).

^bAverage median 2.5 (IQR 2-3).

^cAverage median 4 (IQR 3-4).

^dAverage change in the median from the pre- to the postsurvey: 1.5 (IQR 1-2).

We found a mostly medium to high correlation between the item measuring the objective achievement of the first superordinate learning objective and the 17 items measuring the objective achievement of the subordinate learning objectives (Table 3). This suggests that these items are well suited to capture aspects of the objective achievement of the first

superordinate learning objective. Therefore, these results indirectly suggest that achieving the first superordinate learning objective might have also improved from the pre- to the postsurvey.

Regarding the size of the changes in the median, rather big, big, or extensive changes were found for 14 of the 17 items (Tables 3 and 4). The smallest (small) change was observed in item sub11 (Tables 3 and 4). The greatest (extensive) changes were observed in items sub01, sub05, sub06, sub08, sub12, sub14, and sub16 (Tables 3 and 4).

Table 4. Evaluation of the size of the change in the median from the pre- to the postsurvey regarding the 17 items measuring the objective achievement of the subordinate learning objectives (N=17).

Qualitative evaluation	Items, n (%)	Item ID
No change	2 (12)	Sub03 and sub04
Minimal change	0 (0)	— ^a
Small change	1 (6)	Sub11
Rather big change	5 (29)	Sub07, sub09, sub10, sub13, and sub15
Big change	2 (12)	Sub02 and sub17
Extensive change	7 (41)	Sub01, sub05, sub06, sub08, sub12, sub14, and sub16

^aNot applicable.

In addition, as seen in Table 5, there was an average improvement of the median across all 17 items for each participant from the pre- to the postsurvey (range of change in the median between 1 and 3 scale units; in addition, Multimedia Appendix 8 shows the raw data for each participant for each

item in the pre- and postsurvey and how those values changed from the pre- to the postsurvey). To summarize, this means that all participants improved from the pre- to the postsurvey across all these learning objectives.

Table 5. Intraindividual differences in the median from the pre- to the postsurvey in the objective achievement of the 17 subordinate learning objectives (items sub01 to sub17; N=10).

Participant number	Presurvey score, median (IQR)	Postsurvey score, median (IQR)	Δ Median ^a
1	3 (2-3)	4 (4-4)	1
2	3 (2-4)	5 (4-5)	2
3	1 (1-1)	3 (2-4)	2
4	2 (1-4)	4 (4-5)	2
5	3 (2-4)	4 (4-5)	1
6	3 (3-4)	5 (4-5)	2
7	1 (1-1)	4 (3-4)	3
8	3 (2-4)	4 (3-4)	1
9	3 (2-3)	4 (3-4)	1

^aChange in the median from the pre- to the postsurvey.

Design of the Course

Suitability of the Course for Achieving the Superordinate Learning Objectives

Concerning the question of whether the course concept was suitable for achieving the 3 superordinate learning objectives, we found a median of 5 (IQR 4-5) scale units for the first, second, and third superordinate learning objectives (Table 2; for information on how frequently the individual response categories were selected by the participants, see Multimedia Appendix 6). The median values correspond to the scale point *strongly agree* (scale value of 5). Thus, the results indicate that, based on the average ratings, the course concept was strongly suited for achieving the 3 superordinate learning objectives.

Enjoyment of the Course

Concerning the question of whether the participants enjoyed the course, the median was 5 (IQR 4-5) scale units; for information on how frequently the individual response categories were selected by the participants, see Multimedia Appendix 6. This corresponds to the scale point *strongly agree* (scale value of 5). Therefore, this result indicates that, on average, participants enjoyed the course very much.

Benefits Obtained From the Course

Concerning the question of whether the participants felt that they obtained a benefit from having taken part in the course, the median was 4.5 (IQR 4-5) scale units; for information on how frequently the individual response categories were selected

by the participants, see [Multimedia Appendix 6](#). This median varies between the scale points *rather agree* (scale value of 4) and *strongly agree* (scale value of 5). Thus, this result indicates that, on average, participants obtained a benefit rated as rather to very well from taking part in the course.

Strengths of the Course

With regard to the question of which of several proposed aspects were strengths of the course, the median for all proposed aspects fluctuated between the scale points *rather agree* (scale value

of 4) and *strongly agree* (scale value of 5; [Table 6](#)); medians of 5 (IQR 5-5), 5 (IQR 4-5), 5 (IQR 3-5), and 4 (IQR 4-5) scale units for items STR01, STR02, STR03, and STR04, respectively; for information on how frequently the individual response categories were selected by the participants, see [Multimedia Appendix 6](#). Regarding the teaching staff, all the students strongly agreed that this was a strength, as shown in [Multimedia Appendix 6](#). Thus, in total, the results indicate that, on average, all the characteristics mentioned were considered to be strengths of the course either somewhat or strongly.

Table 6. Strengths of the Digital Medicine course, administered in the postsurvey (N=10).

Item stem and ID	Item	Scale units, median (IQR)
Strengths of the Digital Medicine course		
STR01 ^a	The teaching staff (friendliness, openness, appreciation, professionalism, and interdisciplinarity)	5 (5-5)
STR02	The design of the course (content preparation, interaction, material, and equipment)	5 (4-5)
STR03	Timing of the classes (punctuality and time frame for lectures and seminars).	5 (3-5)
STR04	Offline content and preparation in the LernraumPlus platform	4 (4-5)

^aSTR: strengths (of the course).

Importance of the Course to the Participants

Importance of Achieving the Superordinate Learning Objectives

Regarding the question of whether it was important to the participants to achieve the 3 superordinate learning objectives, medians of 4 (IQR 3-4), 4 (IQR 3-5), and 3.5 (IQR 3-5) scale units were found for the first, second, and third learning objectives, respectively ([Table 2](#); for information on how frequently the individual response categories were selected by the participants, see [Multimedia Appendix 6](#)). These median values vary between the scale points *rather neutral* (scale value of 3) and *rather agree* (scale value of 4). Therefore, the results

indicate that the participants varied, on average, between being neutral about the importance of the course to them and rather agreeing that it was important to them to achieve the 3 superordinate learning objectives.

Reasons for Potential Absences During the Course

The reasons for not attending individual course sessions ([Table 7](#)) comprised insufficient time capacity due to other study-related requirements (10/10, 100% of the participants), illness (5/10, 50% of the participants), inadequate time capacity due to personal requirements (2/10, 20% of the participants), and perceived irrelevance for the individual participant (1/10, 10% of the participants). No participants named another reason.

Table 7. Reasons for nonparticipation, administered in the postsurvey (N=10).

Item ID, question, and item	Participants, n (%)
AB01^a: If I was unable to attend course days, it was largely due to the following reasons (multiple choices possible):	
Too little time capacity due to other study-related requirements	10 (100)
Insufficient time capacity due to personal demands	2 (20)
Illness	5 (50)
The course was irrelevant to me	1 (10)
Other	0 (0)

^aAB: absence (during course sessions).

Open Comments

There was 1 open comment in the presurvey and 5 open comments in the postsurvey. [Table 8](#) shows the categories that

appeared in the comments and the frequency of the occurrence of each subcategory. Most of the comments belonged to the main category (*positive feedback on the course or positive personal experience with the course*).

Table 8. Open comments (COM), administered in the pre- and postsurvey (N=5).

Item ID, item, survey, main category, and subcategory	Participants, n (%)

Discussion

Achievement of the Learning Objectives and Design of the Course

This paper presents a newly developed course concept for teaching digital medicine in medical education (the Bielefeld model) and an initial evaluation of this concept. This evaluation was based on feedback provided by undergraduate medical students who took part in this course. By developing and implementing this course, we responded to the calls [3,11,13-15] for integrating the topic of digital health or digital medicine into medical education. According to the students' self-report in the evaluation, they were overall able to achieve the super- and subordinate learning objectives of the course and felt that the course was largely suitable for achieving them.

The evaluation results indicate that, on average, the participants achieved the super- and subordinate learning objectives of the course rather to very well, as recorded after the course. The average change in the objective achievement of the subordinate learning objectives from before to after the course could be rated as big.

The fact that there was only a small change in item sub11 could be related to the circumstance that the participants were supposed to achieve the learning objective captured in this item by autonomously working on it using web-based materials, which they may not have done.

The findings on the achievement of the learning objectives indicate that the course concept was well suited for achieving them and could be interpreted as the course being well designed. This aligns with the finding that, on average, participants perceived the course concept as well suited for attaining the 3 superordinate learning objectives. On the basis of these outcomes, it can be assumed that the course effectively fulfills its overarching objective: empowering participants to feel able to actively engage as future architects of digital medicine, transcending the role of mere participants in digital processes or users of digital products to being able to develop and use such products comprehensively.

The assumption that the course was well designed is also supported by the fact that most to all participants enjoyed the course, benefited from it, and agreed that the course's design and teaching staff were strengths of the course. As outlined, the teaching staff consisted of interdisciplinary experts on the topics covered in the course in addition to the instructors from the Digital Medicine working group. Whether it was this interdisciplinarity, the appearance of the teaching staff (eg, friendliness, openness, and appreciation), or both that the students experienced as a strength is not clear from the results. These results are supported by positive statements in the open comments that relate precisely to the aforementioned points. The statements that the participants felt comfortable in the course and were appreciative of their participation support the overall positive evaluation of the course. However, there was also criticism that the course was not offered in a hybrid form.

In the future, this may be resolved by offering hybrid courses if necessary. Reasons for the statements that participation in the course resulted in stress, frustration, or demotivation were a lack of time and the unplanned absence of course members, over which the teachers had no influence. However, should this negative experience also occur in future courses, the lecturers and students should jointly consider measures to remedy the situation. A further quality assurance evaluation by the Medical School OWL supports the overall positive assessment of the course concept. A total of 50% (5/10) of the students took part in this evaluation, and they agreed that the instructors fostered a positive learning environment, acknowledged the participants' previous knowledge, and explained concepts clearly. These students offered comments that, in terms of content, closely aligned with those from the evaluation that is the subject of this paper, addressing both the positive and negative aspects. Unsystematic, spontaneous observations of the instructors during the course support the finding that the course was suitable for achieving the learning objectives and showed that it was also suitable for the participants to improve their self-, project, and team management skills. Overall, the results indicate that the course concept was well designed, implemented, and perceived and accepted positively.

Perceived Importance of the Course to the Participants

The results showed that many students perceived the achievement of the superordinate learning objectives as important to them and that only 10% (1/10) of the participants felt that the course was irrelevant. This perception aligns with the aforementioned finding that many medical students want the topic of digital medicine to be (more extensively) integrated into their studies [11,16], supporting the relevance of offering this course. However, as the perceived importance of the course was not further recorded or classified, the findings should be interpreted with caution.

Course Concept

Alignment of the Course With Findings From Teaching and Learning Research

From a pedagogical research perspective, the Bielefeld model integrates elements from multiple learning theories, including project-based learning, which has demonstrated efficacy [26], and authentic learning [27]. These approaches offer significant benefits as they may enhance the ability to recall knowledge in real-world problem-solving contexts [28] while also positively impacting student motivation and engagement [29]. In addition, in the Bielefeld model, theoretical and practical components were interwoven. Tempelman and Pilot [30] argue against the background of the theory of constructivism that this might help build knowledge and skills upon one another. In addition, structuring a course in which each unit builds on the previous one, as seen in the Bielefeld model, can promote a more cohesive learning experience. This can be beneficial for learning [31]. Medical education research has shown that the mix of knowledge and skill teaching in simulation-based medical education can be successful, with high effect sizes for learning outcomes of both aspects [32,33]. In light of these findings, the direct link between the theoretical and practical units in the Bielefeld model may enable participants to practically apply

newly acquired knowledge directly and, thus, achieve the goal of holistically developing digital applications. An advantage of developing content in practical sessions, as implemented in the Bielefeld model, is that it makes learning outcomes more tangible, as Kuhn et al [34] point out. This approach may help in demonstrating learning success in a more verifiable and substantial way. The positive effect of including guest lecturers in the course has also been scientifically proven (eg, [35]). The idea of having medical students work on solutions for practical use cases at the interface between medicine and technology and in collaboration with students from other disciplines has already been implemented in a course described by Breil et al [36]. However, this was not geared toward digital medicine. In that course, medical students collaborated with computer science students. For this to work, the students had to develop soft skills such as communication skills and subject-specific knowledge. Almost all the participants in the aforementioned course rated the integration of theory and practice as good or excellent. Although it is unclear what exactly supported the good integration of theory and practice in that course, it can be assumed that this is generally related to the course concept. Therefore, the results suggest that the Bielefeld model, which followed a similar concept, facilitated a good integration of theory and practice as well. However, some aspects could be improved to align with findings from teaching and learning research. For example, although it was pointed out to which life cycle phases the topics of the individual sessions could be assigned in the Bielefeld model, this could have been explained more clearly. This might have helped make the course even more coherent (eg, [31]).

Alignment of the Course With Recommendations for Digital Medicine Courses

The design of the course is supported by recommendations and perspectives in the literature for implementing courses in digital medicine. The interdisciplinary design of the course aligns with the suggestion by Foadi and Varghese [37] that courses in digital medicine should be interdisciplinary due to the significant role that interdisciplinarity plays in the field of digital medicine. The Bielefeld model covered various topics, such as ethical aspects, legal frameworks, and entrepreneurial opportunities concerning digital medicine applications. Bahagon and Jacobson [2] state that successful implementation of eHealth solutions requires expertise in such areas. Students would like for courses on digital health to include precisely these aspects as well as practical training, for example, on developing apps, as Machleid et al [16] found out. Even though it cannot be said with certainty that these were also the wishes of the students enrolled in our course, it can be assumed based on this research finding. Therefore, in that case, these desires were well met by the course concept. Such a match between the students' wishes and the course concept could explain why many of the students perceived the course as important to them and enjoyed and benefitted from it. According to Goldsack and Zanetti [38], clinical and technical expertise must be considered together for a successful digital transformation. In the Bielefeld model, medical students do not receive in-depth technical training. Nonetheless, they learn how to collaborate with people from the technical field and gain some insights into the technical

implementation of digital medicine concepts. The University Digitalization Forum (Hochschulforum Digitalisierung [9]) points out that it is insufficient to teach only technical skills to improve digital transformation and that qualifications in areas such as communication and leadership or constitutional corporate design should also be provided. Although the Bielefeld model does not focus on this, it can be assumed that communication and leadership skills are also being learned during the teamwork units of the course.

As the course concept was geared precisely toward designing a telemedicine application and taking the framework conditions—various interdisciplinary factors—into consideration, it can be assumed that the learning objective of the NKLM stating that students should acquire the competencies to explain the application scenarios for telemedicine applications and their framework conditions [12] was achieved. In addition to this, other authors have described different frameworks regarding what students should learn about digital medicine. Brunner et al [39], for example, describe a framework that stipulates that students in the health care sector should achieve learning objectives related to the areas of (1) digital technologies, systems, and policies; (2) clinical practice and applications; (3) data analysis and knowledge creation; and (4) system and technology implementation. The Bielefeld model covers these areas at least to some extent, albeit more on a theoretical than a practical level. Kuhn [40] points out that, against the backdrop of digital transformation, physicians must be able to understand and categorize the change processes and new digital treatment concepts associated with change, and in addition to learning practical skills, they must also reflect on an attitude toward digital medicine. Due to the wide range of topics covered by the Bielefeld model, this is assumed to have been achieved at least to some extent. Recently, experts identified 40 specific digital health topics from the areas of knowledge, skills, and attitudes that they believe should be taught during medical school [41]. The Bielefeld model covers some of these knowledge and attitude topics.

In total, the Bielefeld model has many similarities with recommendations for the design of teaching in digital medicine. However, there are some aspects that could be given greater consideration in the Bielefeld model in the future to be even more in line with the recommendations. Including other experts or professional groups could be useful. In line with the suggestion that clinical and technical expertise is important for digital transformation [38], including cybersecurity experts or hardware and software engineers, for example, has been proposed [38]. It could also be useful to involve other groups, such as data scientists, ethicists, and patients [38]. To acquire and develop further knowledge and skills and a deeper attitude regarding digital medicine, it might make sense to include more content in the course and allow more time for a critical examination of digital medicine. However, as this is covered by other compulsory courses within the Bielefeld medical degree program, there is no need for the Bielefeld model to cover these aspects as well.

Furthermore, the question arises on whether the didactic formats used in the course correspond to what students want in digital medicine courses. Vossen et al [19] found that many students

would like to be taught about technological developments through real-life scenarios and case descriptions. The Bielefeld model aims in this direction. Teaching in the form of lectures, which was also integrated into the Bielefeld model, was, on average, neither strongly supported nor strongly rejected in the study by Vossen et al [19]. Although, based on these results, this is not the preferred teaching format, it was necessary for the Bielefeld model to impart basic knowledge by offering lectures. The teaching format that received the most support in the study by Vossen et al [19] was remotely following a real-life patient under the supervision of a physician. However, such a teaching format is inappropriate for what needs to be taught and learned in the Bielefeld model. Therefore, the teaching format in the Bielefeld model cannot be meaningfully compared with it.

On the basis of the positive and improvable aspects mentioned in this section, the Bielefeld model will be continued, expanded, and further developed. Following the suggestion that the rapid pace of transformation processes must be taken into account and that it must be possible to adapt the specific curriculum, the Bielefeld model will be continuously refined and updated to adequately reflect current developments in digital medicine and general teaching and learning research.

Student Education in Digital Medicine in Germany

Comparison of the Course With Courses in Digital Medicine or Digital Health in Germany

In this section, the similarities and differences between the Bielefeld model and courses in digital medicine or digital health at other locations in Germany will be analyzed. The Bielefeld model was only compared with courses with a similar focus in terms of content and for which a publication could be found in a literature search. It should be noted that works such as those by Aulenkamp et al [17] or Behrends et al [42] and internet research indicate that there are also other courses on digital health and medicine. As no publications were available for these courses or they were unsuitable for the comparison due to different framework conditions, they were omitted. Although some course concepts described by Aulenkamp et al [17] appear to be related to the courses included in the comparison, it cannot be said with certainty that this is the case. Courses that focus on artificial intelligence or machine learning or place a clear emphasis on topics from the field of medical informatics (eg, hospital information systems) are regarded as connected to digital medicine but were not included in the comparison because they have a completely different focus in terms of content from that of the Bielefeld model. The Bielefeld model was compared to the courses described by the following authors: (1) Ehlers et al [43]; (2) Werner et al [44]; (3) Chaltikyan et al [45]; (4) Behrends et al [42]; (5) Offergeld et al [46]; (6) Nitsche et al [47,48], whereby both works share the same course concept but differ in the names and number of modules and, therefore, probably in the specific content; (7) Poncette et al [49] and Seemann et al [50]; and (8) Kuhn et al [34], Kuhn [40], Kuhn and Jungmann [51], and Kuhn et al [52-54], whereby they all share the same course concept but differ slightly in the names and number of modules and, therefore, possibly in the specific content.

If several publications were found for a course, only one is discussed here if the information used for the comparison was sufficiently clear.

The comparison of the Bielefeld model with other courses did not reveal any immediately comparable courses. However, there were certain overlaps in the design. As in the Bielefeld model, a common feature of many course concepts is the use of guest lecturers from different areas [34,43,44,47,49] (eg, app developers and representatives of the state data protection authority [34], an industry panel with representatives from the biomedical field [44], and lecturers from hospital departments and academic and nonacademic institutions who lectured on interdisciplinary topics [44]). Similarly to the Bielefeld model, topics covering economic, legal, or ethical aspects were incorporated into some courses, such as those described by Poncette et al [49] or Ehlers et al [43]. Another feature that the Bielefeld model has in common with some other courses is combining theoretical and practical units [34,44,49]. A difference between the Bielefeld model and many courses with which it was compared is that many courses followed a structure in which different application areas and examples of digital medicine were often considered in various sessions [34,43,44,47,49]. In contrast, the Bielefeld model is a course in which participants design a digital application independently and continuously throughout the course. The objective was to enable students to develop holistic digital applications independently and become active as future designers of digital medicine. Concepts with which the Bielefeld course can be most closely compared in terms of this focus are the modules described by Poncette et al [49] or Seemann et al [50] and an orientation module described by Werner et al [44]. Although these modules also follow a basic structure that includes numerous different areas of application and examples, one similarity to our course concept is that the focus is on students designing a product for a specific problem in the health care system [49] or developing a business model for digital transformation [44]. This allows them to take on the role of various stakeholders in the health care system [49] or company representatives [44]. A difference between the Bielefeld model and the course described by Poncette et al [49] is that, in the latter, the practical units were individual sessions instead of being integrated into each session as in the Bielefeld model. They seem to be rather separate from the theoretical units. There is no information on this with regard to the module presented in the work by Werner et al [44]. In light of the previously discussed possible advantages that could arise from interweaving theoretical and practical units and building units on each other [30,31], in our opinion, directly linking theoretical and practical units might be more advantageous. Examining numerous application areas and examples of digital medicine, as provided for in the aforementioned courses, is certainly enriching for students to gain a broad overview of digital medicine. However, at Bielefeld University, the students already deal with these aspects as part of an earlier course in digital medicine during their studies.

In summary, it can be said that the Bielefeld model is a newly developed part of a series of courses that contributes to fulfilling the call to train medical students in digital medicine. The

Bielefeld model follows a detailed concept that has not yet been found in other evaluated courses in Germany.

Challenges and Initiatives Regarding the Implementation of Digital Medicine Courses in Germany

Various challenges that can make the integration of digital health and medicine into medical education more difficult [55] must be addressed to offer even more courses in digital medicine nationwide. For example, a sufficient teaching staff with the relevant expertise is needed. However, unlike Bielefeld University, few universities currently have a professorship or chair for this area [55]. There are various approaches to solving these challenges [56]. Initiatives such as the Digitalization of Departments-Medicine working group (Digitalisierung in den Fächern – Medizin), which is part of the University Digitalization Forum, are, for example, developing or presenting solutions [9]. Several initiatives also drive the implementation of educational projects. For example, a reform project in digital medicine [40] was funded by the Stifterverband initiative as part of its joint Curriculum 4.0 program with the Carl Zeiss Foundation. In the field of medical informatics associated with digital medicine, educational programs are also being offered as part of the HiGHmed initiative, which began as part of the Medical Informatics Initiative [57]. Such offers can also enable the teaching of digital medicine. The creation and implementation of initiatives is seen as an important measure [56].

Limitations

The interpretability of the results of evaluating the Bielefeld model is limited due to several aspects. The evaluation questionnaire was not subjected to a pilot test. Although it was designed based on largely careful considerations and reflected upon between the authors, a pilot study would have been favorable to determine its quality and suitability for evaluating the course concept. Although an attempt was made to ensure the validity of the items by carefully formulating them based on detailed considerations, the criterion and construct validity in particular were not statistically tested. Therefore, no reliable statement can be made regarding the existence of criterion and construct validity and, thus, external validity overall. The existence of retest reliability could have been examined to better determine the stability of the instruments, a facet of reliability. As this did not happen, it cannot be said with certainty whether the instruments are reliable in this regard. One limitation with regard to the design of the survey is that the achievement of the superordinate learning objectives was only recorded in the postsurvey. Therefore, no direct statement can be made as to whether they were achieved better after the course than before. Because the data were not analyzed using inferential statistics, the results cannot be reliably transferred to the general population. The interpretability and generalizability of the results are also limited by the small sample size and by potential biases that may have occurred. With regard to the sample, it should be taken into account that the Medical School OWL was only just commissioned in 2021 and that the Digital Medicine course presented in this paper was the first of its kind ever offered at this medical school. Therefore, it was not possible to form a larger sample by summarizing and analyzing data from several

courses. In addition, the teachers had no influence on the number of course participants. Therefore, an evaluation based on the existing sample of 10 participants was the only option.

It was found that only two-thirds of the students who took part in the presurvey (10/15, 67%) also took part in the postsurvey. It is possible that the third who dropped out had little interest in digital medicine and, therefore, were not motivated enough to participate in the postsurvey. The sample would then only consist of students who were interested in the topic. In this case, the results would only be transferable to students with an interest in digital medicine instead of all medical students. It is also possible that the students with a particular interest in the topic also achieved the learning objectives better and rated the course better or that, in general, only students who felt that they had achieved the learning objectives participated in the postsurvey. Both would result in a systematic bias of the results. This is aggravated by the fact that the data were collected via the self-report of the students. If an objective measure of data collection had been used that did not involve any extra effort for the students, it might have been easier to motivate all students to provide data for the postevaluation. Such an objective measure could have been, for example, an analysis of the project outlines.

In addition to the aforementioned aspects, it was observed during numerous sessions of the course that some students were absent, and some sessions were only held on the web and the instructors do not know whether the participants worked on the topics of those sessions by themselves. It is questionable whether the students who were not physically present also improved in the learning objectives of these sessions. If this were the case, the question of what, if not the course, could have led to this improvement would arise. The data showed that not every learning objective was achieved better by all students after the course than before. This is particularly understandable if the students who were not present in the session covering this learning objective did not deal with the topic. However, these questions were not investigated.

The results of this evaluation should only be seen as initial indications of the effectiveness of the course concept in achieving the learning objectives due to the named limitations.

In addition, as part of the study, participants were asked to what extent they perceived various potential strengths of the course as such. This format made it possible to ask about specific aspects but has the disadvantage that other possible strengths of the course could remain hidden. Although we included an optional free-text field at the end of the surveys meant to allow

participants to name strengths and additional aspects related to the course, it cannot be assumed that all participants used this option. A final statement on whether a course similar to the Bielefeld model already exists at other locations in Germany cannot be made as the course was only compared with course concepts for which a publication was found.

Implications

Our results indicate that using the Bielefeld model might improve self-sufficiency in digital medicine instead of letting future physicians passively consume digital medicine's offers. However, due to the small sample size and other limitations, this warrants additional evaluations. The observation made during the course that the medical and electrical engineering students learned what is essential when working with students from another discipline suggests that the course can be offered across disciplines and universities.

Outlook

As inferential statistics were not performed, no direct conclusions can be drawn from this study on whether the same results can also be expected in the general population. In future studies, the concept should be implemented with and analyzed based on more participants and then subjected to an evaluation including inferential statistical procedures. Bielefeld University plans to continue conducting and evaluating the concept over the next few years to obtain a longitudinal sample with a larger number of cases and carry out inferential statistical analyses. To better assess whether the course contributes to the achievement of the superordinate learning objectives, their achievement should be recorded in future studies in the pre- and postsurvey. A more objective assessment of the achievement of the learning objectives could be made by analyzing the students' project outlines. The project outlines make it clear whether the students know the factors that are relevant in the development of a digital application and whether they were able to apply them to their specific project.

Conclusions

A novel approach to teaching digital medicine was conceived, executed, and assessed for the first time. The evaluation outcomes suggest that the course framework has the potential to effectively facilitate the transformation of participating students into future architects of digital medicine. These results signify that the course is poised to play a pivotal role in fostering digital transformation and seamlessly incorporating digital medicine into the medical curriculum, aligning with the aspirations of diverse stakeholders.

Acknowledgments

The authors thank Ute von Jan for the fruitful discussion about the educational aspects of medical informatics related to undergraduate medical education. The authors acknowledge support for the publication costs from the Open Access Publication Fund of Bielefeld University and the German Research Foundation (DFG).

Authors' Contributions

UVA and AM created the concept, developed the methodology, conducted the formal analysis and investigation, contributed to data curation, prepared and wrote the original draft, contributed to review and editing of the draft, and created the visualizations.

UVA and AM validated the data. UVA provided supervision and undertook project administration and funding acquisition. HF programmed the surveys using software and contributed to reviewing and editing the draft. UK and LB contributed to data curation and review and editing of the draft. AB contributed to review and editing of the draft. All authors have read and agreed to the published version of the manuscript.

Abstract

Background: Limited digital literacy is a barrier for vulnerable patients accessing health care.

Objective: The Stanford Technology Access Resource Team (START), a service-learning course created to bridge the telehealth digital divide, trained undergraduate and graduate students to provide hands-on patient support to improve access to electronic medical records (EMRs) and video visits while learning about social determinants of health.

Methods: START students reached out to 1185 patients (n=711, 60% from primary care clinics of a large academic medical center and n=474, 40% from a federally qualified health center). Registries consisted of patients without an EMR account (at primary care clinics) or patients with a scheduled telehealth visit (at a federally qualified health center). Patient outcomes were evaluated by successful EMR enrollments and video visit setups. Student outcomes were assessed by reflections coded for thematic content.

Results: Over 6 academic quarters, 57 students reached out to 1185 registry patients. Of the 229 patients contacted, 141 desired technical support. START students successfully established EMR accounts and set up video visits for 78.7% (111/141) of patients. After program completion, we reached out to 13.5% (19/141) of patients to collect perspectives on program utility. The majority (18/19, 94.7%) reported that START students were helpful, and 73.7% (14/19) reported that they had successfully connected with their health care provider in a digital visit. Inability to establish access included a lack of Wi-Fi or device access, the absence of an interpreter, and a disability that precluded the use of video visits. Qualitative analysis of student reflections showed an impact on future career goals and improved awareness of health disparities of technology access.

Conclusions: Of the patients who desired telehealth access, START improved access for 78.7% (111/141) of patients. Students found that START broadened their understanding of health disparities and social determinants of health and influenced their future career goals.

Introduction

Telehealth is an emergent tool to connect patients with their health care providers [1]. During the COVID-19 pandemic, the number of video visits increased by nearly 50% in the first quarter of 2020 compared to that of 2019 [2]. During this time frame, there was a 63-fold increase in telehealth visits among Medicare patients [3]. Telehealth use in the United States continued to rise, with nearly 38 times as many patients using it in 2021 compared to prior to the onset of the COVID-19 pandemic in 2019 [2,4]. Ensuring that patients have access to their electronic medical records (EMRs) is important for communication and coordination with their health care team and to promote patient self-advocacy [5]. While access to video visits and EMR accounts positively impacts access to health care, fewer than half of adults aged 65 years and older own a smartphone or have reliable internet access in the United States [6]. Additionally, racial minority individuals and patients with low socioeconomic status are less likely to have access to essential devices and high-speed internet and face increased obstacles to digital health literacy [7-10]. Consequently, while telehealth can be a conduit to more accessible health care, many at-risk patients experience heightened challenges in connecting with their providers remotely, which may magnify health disparities [6,7].

In response to shelter-in-place orders during the COVID-19 pandemic, medical practices strove to expand telemedicine options and increase resources to aid patients with telehealth [11]. In an effort to streamline this process, several clinics created video tutorials and step-by-step telehealth training guides for patients [12]. However, these static resources quickly proved to be insufficient, and the need for additional assistance from support personnel became evident [11,12]. One promising approach to making telehealth more accessible is the integration of “value-added medical education,” whereby students’ service learning improves health care [13]. Recognizing patients’ need for individualized technology support and students’ desire to serve the community, we created the Stanford Technology Access Resource Team (START) to help bridge the digital divide.

START is an undergraduate and graduate student course and volunteer program that offers immersive, meaningful patient-engaged experiences to promote patient health equity. START is a quarter-long course that teaches students about social determinants of health and health technologies and then connects them with patients with low digital technology literacy. Since digital literacy has been identified as a determinant of health, we hypothesized that this service-learning course would improve patient access to telemedicine to decrease their digital divide while also improving professional development, learner communication, and understanding of health equity and patient challenges. We conducted a comprehensive program evaluation to assess patient outcomes (connection to digital health and telemedicine and satisfaction) and learner outcomes (relationship-building skills, awareness of patient experiences, and future career life goals or purposes).

Methods

Ethical Considerations

The Stanford University Institutional Review Board determined this was nonhuman participant research (protocol #73006). All data have been anonymized and deidentified.

Study Design

In the fall of 2020, amid the COVID-19 pandemic, we developed START for undergraduate and graduate students. The course addressed social determinants of health for vulnerable populations and included a service-learning component focused on digital literacy for patients in 2 health systems. The study evaluated the impact on student learning through thematic analysis of student reflections and the impact on patients through data on outreach, enrollment in EMR accounts, access to telehealth, and patient reflections.

Study Context

Stanford University School of Medicine and Stanford Healthcare form an integrated academic medical center in Northern California, situated within an undergraduate and graduate campus. Within the surrounding counties (37 cities with large unincorporated rural areas), patients’ social determinants of health vary widely. Surrounding county median income is about US \$100,000, with racial or ethnic distribution of approximately 3% African American, 30% Asian, 25% Latinx, 50% White, and 14% other, with overlap [14]. We collaborated with a federally qualified health center (FQHC) to expand our service-learning project to additional underserved community patients. The FQHC serves a population of whom 82% are living at or below 200% of the federal poverty level; 27% are uninsured; and 81% of patients identify as Latinx, African American, or Pacific Islander [15]. Stanford University encompasses 7841 undergraduate and 9688 graduate students [16]. The second most popular major for students is human biology, and approximately 10% of the campus’ student body apply to medical school each year [17,18].

Course Development

We conducted needs assessments of students ([Multimedia Appendix 1](#)), patients ([Multimedia Appendix 2](#)), and health care teams ([Multimedia Appendix 3](#)) to inform the design of a course that would enable students to support patients who needed help accessing digital health. We distributed the student needs assessment through premed advisors, dormitory email lists, and flyers posted throughout the campus. All except 1 of the 107 student respondents agreed that the proposed course would meet a community need, and 93.5% (n=100) wished to have more information about the course. We distributed patient needs assessments to residents at 2 assisted living facilities in the community, and 125 patients completed the assessment. In total, 28% (n=35) of patients stated they would like to do telehealth visits, while 25.6% (n=32) said they had barriers to using telehealth. The top 3 reasons cited were not knowing how to connect to the telehealth platform, lack of familiarity with the internet or technology, and not having a stable internet connection. We distributed the needs assessments for health care teams to patient care coordinators at 3 of the institutional

primary care clinics. In total, 6 (55%) of the 11 care coordinators recalled that more than 10 patients requested help with telehealth connection. The care coordinators cited the following barriers to providing the help: the lack of a resource line to help troubleshoot (n=8, 73%), time constraints (n=6, 55%), and the lack of training (n=5, 46%). Based on these findings, we developed a 1-unit, repeatable, 10-week-long course consisting of weekly 1-hour didactics combined with service learning to directly support patients in need of digital health support.

This course structure was chosen since the instructor wanted to balance the amount of time spent on didactics, workshops, and reflection with time reaching out to patients. The 10-week format followed the quarter system of the institution. Students are allowed to repeat the course or continue to provide service as volunteer without repeating the course. Due to the tight schedule of 10 weeks, the beginning 2 weeks of the course needed to focus on completing HIPAA (Health Insurance Portability and Accountability Act) training and training on the technical aspects of helping patients set up an EMR account

and video visits. Since the course involved only telephone communication with patients, training on telephone communication skills was deemed essential. Education on the social determinants of health was key to understanding how to decrease the digital divide. Design thinking gave students a practical framework for thinking about how to solve a problem. The availability of speakers to do repeated digital sessions with the students during the COVID-19 pandemic also influenced the topics chosen.

Didactics or Workshops

Weekly didactics and workshops (Figure 1) focused on teaching students inclusivity when interacting with diverse patients and caregivers. Guest speakers provided insight into topics such as the telehealth experience from patient and provider perspectives, social drivers of health, motivational interviewing, and design thinking. These collaborative sessions challenged students to think critically about creating more effective solutions to address community determinants of health that impact health care access.

Figure 1. Structure of START course. EMR: electronic medical record; FQHC: federally qualified health center; START: Stanford Technology Access Resource Team.

Course collaborators	Academic institution 	Primary care clinics 	Information and technology team 	Compliance team 	Intepretation services team 
Course components	Service learning Students completed training and compliance requirements and telephoned patients at their homes.		Didactics or workshops Topics included telephone communication, motivational interviewing, provider and patient panel, community partner engagement, telehealth for vulnerable populations, and design thinking.		Reflections Students reflected on a START experience they had in the past week in any format they chose such as a paragraph, poem, drawing, or song.
Patient identification and matching	Patient lists academic institution Course director generated lists of patients without an EMR account or prior video visit.	Patient lists FQHC Course director obtained lists of patients scheduled for a telehealth visit 2-4 weeks out.	Patient outreach Students received lists of patients matched by preferred language when possible and logged encounters.		
Course evaluation	Outreach follow-up Student called the 141 patients who received services to assess satisfaction and service outcomes. 	Student course evaluations Students completed a course evaluation at the end of the course. 	Reflections analysis Reviewers coded the 134 reflections for thematic content.

University of New Hampshire	The Telehealth Practice Center: Student Learning and Professional Training: - 17-week course open for third and fourth year undergraduate students <input checked="" type="checkbox"/> Didactic <input type="checkbox"/> Experiential <input type="checkbox"/> Community-based <input type="checkbox"/> Longitudinal	HHS 798 or HHS 898: Introduction to telehealth "Learning about rural health, digital divides, assistive technology, innovations, and current practices in telehealth; understanding the roles of healthcare providers as they offer digital visits; working with classmates on a telehealth-related project."
University of Southern California	Keck Service Learning Program: - 1-year course (4-6 hours) open for USC MS-1 students <input checked="" type="checkbox"/> Didactic <input checked="" type="checkbox"/> Experiential <input checked="" type="checkbox"/> Community-based <input type="checkbox"/> Longitudinal	Course in health justice and systems of care curriculum "Learning about structural, social, and psychological influences on health, engaging in a service-learning experience; discussing ways clinicians can partner with community health entities, reflecting on the role of medical students as health professionals and citizens."
University of Utah	University of Utah Health: - 12-week web-based synchronous course open for DBMI and MHA students <input checked="" type="checkbox"/> Didactic <input type="checkbox"/> Experiential <input type="checkbox"/> Community-based <input type="checkbox"/> Longitudinal	BMI 6050 or MHA 6050 "Thinking through ways technology can solve healthcare access challenges facing patients and providers, learning about the legal, ethical, service delivery, and financial aspects of telehealth services."
Veterans Health Administration Palo Alto General Medicine Clinic	Asynchronous Prevention Clinic: - Volunteer program for high school, college, and medical students <input checked="" type="checkbox"/> Didactic <input checked="" type="checkbox"/> Experiential <input checked="" type="checkbox"/> Community-based <input checked="" type="checkbox"/> Longitudinal	Decreasing racial disparities in hypertension "Connecting students with medical teams to make telephone calls; instructing veterans how to take accurate home blood pressures; designing an intervention that reaches Black patients and other poorly resourced veterans to improve clinical outcomes for all."

Service Learning

We partnered with the institution’s informatics and technology, compliance, and interpretation services teams to develop a protocol for students to assist patients in establishing accounts in the EMR portal and video visits. The START course is open to any Stanford undergraduate or graduate student interested in service learning around medically vulnerable populations and

is listed in the Stanford course directory as MED 258: Stanford Technology Access Resource Team: A Primary Care Effort to Bridge the Telehealth Divide. Once enrolled, students completed HIPAA training and other institutional compliance requirements. The institution’s informatics and technology team provided students with technical training. Students used Doximity Dialer,

Cisco Jabber, and Google Voice to keep their personal phone numbers private.

We included patients from Stanford and one of our affiliated FQHCs. We identified and recruited Stanford patients for this program through EMR queries for patients seen in our primary care system in the last 2 years who lacked an EMR account or who never had a video appointment. We discussed a similar recruitment process with our FQHC partners. Many of their patients were using phone visits, and the FQHC leadership was interested in ensuring that these phone-visit patients could participate in video visits, which increased the patient-provider connection and diagnostic potential of the encounter. As such, they preferred to reach out to patients who had been seen by their primary care partner within the past 1 month and who were on the schedule for any remote clinical visit—which included both telephone and video visits within 2 to 4 weeks. We also informed the primary care clinicians of START services and encouraged referrals. After completing the necessary training, START students were each given a list of 10 patients without digital health access and called all the “remote clinical visit” patients, offering technology help to patients who did not have current video visit services. The course director prioritized language concordance between the students and patients when possible.

START students reached out to patients by telephone using scripts and resources tailored to the 2 institutions ([Multimedia Appendix 4](#)). The FQHC provided a student guidebook that included scripts and screenshots for helping patients set up EMR accounts and video visits. The institution’s technology team also developed a PowerPoint presentation to show students how to set up EMR accounts and video visits. Among the various protocols and resources, students had access to sample introductory scripts and university IT phone numbers. We have included the protocols for assistance in [Multimedia Appendix 4](#). Following each call, START students logged each of their patient encounters using a web-based survey tool ([Multimedia Appendix 5](#)). If a patient did not pick up their phone, the student left a detailed voicemail and attempted 2 more calls. Students requested additional lists of 10 patients when ready to outreach to additional patients. Students had access to interpretation services when needed and could reach the course director outside of class time for questions or patient-specific concerns. For the nonresponders who we could not reach after multiple contact attempts, we could not draw conclusions about why they did not respond to our phone calls.

Learner Impact

We asked students to submit weekly reflections in response to the following prompt: “Please upload a reflection of any kind - poem, art, paragraph, recording, etc. on an aspect of START

you encountered this past week.” Students were given opportunities to share their reflections during class. At the end of 6 quarters, 2 independent reviewers (NC and ZND) coded the reflections for thematic content. Thematic saturation was achieved after reviewing 20 reflections. We randomly selected another 5 reflections to review to ensure no additional themes arose. During coding of the remaining 114 reflections, no new themes were identified. Two reviewers (NC and ZND) then independently assigned themes to all reflections (multiple themes could be assigned to a single reflection if applicable). A third reviewer (RB) resolved any discrepancies through consensus discussion [[19,20](#)].

Patient Impact

Students completed patient encounter logs via a survey tool ([Multimedia Appendix 5](#)) documenting details of the call, including whether the outcome of the call was successful. In July 2023, we conducted follow-up calls with all 141 patients who expressed interest in accessing their EMR accounts a year and a half after the start of the course and video visits, and the respondents were given 4 prompts ([Multimedia Appendix 6](#)) to elicit their satisfaction with the student encounter and their success in using telehealth. We took detailed interview notes including patient quotes and conducted a thematic analysis of the responses. We did not follow-up with the 88 patients who declined support when the START student first connected with them.

Results

Patient Outcomes

Over 6 academic quarters (2 years), 57 students reached out to 1185 patients (n=711, 60% from an academic medical center and n=474, 40% from an FQHC). Of the 229 patients reached, 83.8% (n=192) spoke English; 10.9% (n=25) spoke Spanish; 3.9% (n=9) spoke Mandarin; and 1.3% (n=3) spoke Farsi, Korean, or Russian. Two students accessed our institution’s interpretation services. The amount of time spent on the calls ranged from less than 5 minutes to more than 60 minutes, and the majority of calls took less than 15 minutes.

Of the 229 patients reached, 141 patients desired telehealth visits but lacked access ([Table 1](#)). START students successfully established an EMR portal account and video visit setup in 78.7% (111/141) of patients who desired telehealth. The remaining 21.3% (30/141) experienced barriers to establishing access, which included lack of access to Wi-Fi or a device (n=11), absence of an interpreter (n=4), disabilities precluding the patient’s use of video visits (n=2), and unknown reasons (n=13).

Table 1. Outcomes from Stanford Technology Access Resource Team patient encounters (N=229).

Outcomes	Patient encounters (N=229), n (%)
Successful outreaches	111 (48.5)
EMR ^a account established	50 (21.8)
Video visit via Doximity	36 (15.7)
Video visit via EPIC platform	18 (7.9)
Video visit via Zoom	7 (3.1)
Connection but patient declined support	88 (38.4)
Declined assistance or did not specify	44 (19.2)
Account already set up	23 (10)
Preferred in-person or phone visit	18 (7.9)
No longer in health care system	3 (1.3)
Connection but inability to establish telemedicine access	30 (13.1)
Unknown	13 (5.7)
No device or no Wi-Fi	11 (4.8)
Interpreter not available	4 (1.7)
Disability precluding use	2 (0.9)

^aEMR: electronic medical record.

Over a third (88/229, 38.4%) of contacted patients did not engage with START students for the following reasons: 19.2% (44/229) declined assistance for unknown reasons, 10% (23/229) already had accounts or video visits setup, 7.9% (18/229) preferred in-person or phone appointments, and 1.3% (3/229) were no longer part of the health care system.

START Student Outcomes

Over the course of 6 academic quarters, multiple cohorts of students submitted a total of 139 reflections. From the reflections, we identified 7 themes: real-world communication or relationship-building (n=67, 48.2%), logistics of

communication (n=67, 48.2%), value of service, (n=60, 43.2%), improved awareness of patient experiences (n=38, 27.3%), patient demographics affecting telehealth access (n=35, 25.2%), future career life goal or purpose (n=19, 13.7%), and graphical or pictorial reflections (n=18, 12.9%; [Table 2](#)). On the course evaluations, 76% (39/51) of students stated they learned “a great deal” or “a lot” from the course. Future pre- and postcourse student evaluations could provide quantitative measures of student learning including any changes in communication skills and knowledge of health care systems, community-building, team-based care, and design thinking.

Table 2. Samples of Stanford Technology Access Resource Team (START) student reflections and illustrated themes.

Theme	Mentions (n=139), n (%)	Description	Representative quote
Real-world communication or relationship-building	67 (48.2)	Highlights the development of skills in communication or in building rapport	<ul style="list-style-type: none"> “Wanting to go into medicine, communicating with others is a very important skill to have. Many times, it feels like this has been lost in the age of social media, but it has been nice to have this class to sharpen my skills.” “Although the structure was scripted, I was inspired by the glimpses into the lives of the participants that they provided through their answers—from trips to the beach with a pet, to spending time in a garden.”
Logistics of communication	67 (48.2)	Documents the successes and areas for improvement regarding the START course	<ul style="list-style-type: none"> “This past week has been eventful as I called all my patients again that did not answer before. I finalized all my survey responses and submitted them. There were several patients who did not answer and/or had disconnected phone numbers.” “Being able to effectively communicate with people without providing them with visuals or physical assistance is often difficult.”
Value of service	60 (43.2)	Examines the student’s efforts to serve the patient or the community	<ul style="list-style-type: none"> “Every ring of the phone / Every click of the mouse, / Every warm “Hello,” / Every “I can’t access this page,” / Every “Oh! I see it now,” / Every appreciative “Thank you for understanding” / Every concluding “Your help is always cherished.” / Only fuels my drive, my purpose / I feel significant in the never-ending telehealth battle, / Slowly building a bridge of compassion / Within a world filled with divides.”
Improved awareness of patient experiences	38 (27.3)	Explores the student’s exposure to novel patient challenges and the effects of digital literacy on health care	<ul style="list-style-type: none"> “In working with patients with varied technological experience, access, and support, I have developed a strong appreciation for the privilege that we, as members of a tech-fortified community are immersed in daily, and most importantly, gained significant empathy and understanding of the challenges that many patients face in accessing essential and quality healthcare, especially technology-reliant healthcare like telemedicine.”
Patient demographics affecting telehealth access	35 (25.2)	Centers on the student’s recognition of the impact of social determinants of health on patients	<ul style="list-style-type: none"> “Seeing how certain industries and people responded to the pandemic shows the need for telemedicine for people who are more at risk due to age, disability, and other conditions that have made it extremely difficult for them to navigate the world.” “A recurring theme for me is how the rise of advancements in telehealth has enabled expansion of care to populations who have historically experienced high barriers to technology entry.”
Future career life goal or purpose	19 (13.7)	Focuses on the course’s impact on the student’s future career or life goal	<ul style="list-style-type: none"> “Med258 was a really important experience in confirming my passion to become a physician!” “Right now, I’m thinking about going into primary care—in large part because of this course.” “The most common thing I have noticed with the doctors I have shadowed is they are in and out when seeing patients. If this class has taught me anything, it is the importance of taking the time to listen to patients’ stories.”
Graphical or pictorial reflections	18 (12.9)	Illustrates START patient encounters through images and diagrams	

Program Evaluation by Patients

After working with a START student for 1.5 years or more, we reviewed the records from the student logs of the encounters and the patient charts of 50 patients and found that 31 (62%) patients have had successful video visits, 8 (16%) had died, and 5 (10%) established an EMR account but did not have subsequent video visits. The status of 6 (12%) patients could not be determined due to data entry error. We successfully contacted 19 (13.5%) of the 141 patients from our primary care clinics who were helped by START students to conduct a

follow-up survey. Almost all (n=18, 95%) patients reported that START students were either very (n=14, 74%) or somewhat (n=4, 21%) helpful in assisting them with health technology. The majority of patients (n=14, 74%) reported that they successfully gained access to their EMR accounts as a result of student help, while 58% (n=11) said that they connected successfully to video visits. Of the 5 patients who did not gain EMR account access, 3 patients forgot the steps and 2 patients had disabilities hindering their abilities to use the EMR or lacked access to a device.

A detailed analysis of notes regarding patient experiences, including quotes, from the follow-up calls produced 5 themes: patient satisfaction and improvement suggestions (n=19, 100%), navigation of technology logistics (n=14, 74%), activation of electronic health portal access (n=9, 47%), preparation for video visit (n=8, 42%), and support of patient scheduling (n=5, 26%; [Table 3](#)). All patients reached (n=19, 100%) expressed

appreciation for student help in increasing their familiarity with the EMR. Several patients reported that students demystified the digital health experience, which included conversations about data privacy. Some patients expressed gratitude for the companionship from the student calls, highlighting the students' "patience," "kindness," and "effort."

Table 3. Sample patient quotes from follow-up calls and themes illustrated.

Theme (number of mentions)	Mentions (n=19), n (%)	Description	Representative quote
Patient satisfaction and improvement suggestions	19 (100)	Analyzes patient feedback on the support provided by students	<ul style="list-style-type: none"> • "The student was very, very helpful in answering all of my questions. However, when we hung up, I forgot the steps to log into my account. I would have liked it if the student would have followed up with me again." • "The young lady was very very helpful in setting up my EMR portal account." • [When asked "How useful was your meeting with the START student in helping you connect with your doctor by EMR portal? (Scale 1-5) 5 – Very helpful, 1 – Not helpful] Patient replied: "I would rate it more than a 5, it's a 10!"
Navigation of technology logistics	14 (74)	Explores patient struggles with telehealth technology and the assistance they receive, including step-by-step guidance from students	<ul style="list-style-type: none"> • "When the pandemic started, I regularly used Zoom to go to church. But for some reason I couldn't figure out how to connect with my doctor [via telehealth]. The nurses tried helping me, but I would forget the steps. So, I decided to just do voice calls with my doctor each visit ... But when the [START] student called, they walked me through the step-by-step process of how to use Zoom and was really patient with me. After a week of working with the student, I was finally able to connect with my doctor using video. The student also helped me set up my fax machine, which I was very grateful for."
Activation of electronic health portal access	9 (47)	Examines patients gaining access to electronic health portals	<ul style="list-style-type: none"> • "For the longest time, I wasn't able to get an activation code set up for my [EMR portal] account. When the student called me, she was also having trouble getting my account activated ... She [the student] hung up to follow up with my primary care team. The next day, she called me back and we were able to set up my account by using my credit card number."
Preparation for video visit	8 (42)	Focuses on the reminders patients receive from students	<ul style="list-style-type: none"> • "I cannot fully recall the interaction with the student, but I do remember a kind young lady who called me and went through a checklist of items I should have next to me in preparation for my video visit appointment."
Support of patient scheduling	5 (26)	Delves into the assistance provided to patients in scheduling appointments	<ul style="list-style-type: none"> • "My mother is 94 years old ... When the pandemic was really bad, the student helped me set up a vaccine appointment for both my mom and me. Since my mom is 94, she prefers to go in person for her appointments, so we didn't use the video visit services. However, I appreciate the student's effort."

Discussion

Principal Findings

We found that undergraduate and graduate students can function as technology navigators for patients with low digital literacy levels while gaining valuable experience in health disparities. Our students successfully guided over 100 patients through the steps necessary for digital health access, thereby connecting patients with their health care teams, supporting patients in setting up appointments, reminding patients of items to bring to their visits, and providing an empathetic perspective. Overall, patients expressed deep satisfaction with their interactions with

START students, highlighting students' positive attitudes and demystification of technology ([Table 3](#)).

Digital health literacy is an emergent social determinant of health [21]. While telehealth and technology-based tools can make health care more equitable and accessible, they can also create barriers to quality care for patients with low digital literacy [22-24]. The eHealth literacy theoretical framework by Norman and Skinner [25] explains that users of electronic health tools must be able to "seek, find, understand, and appraise" information in order to be technology literate [21]. Our study reinforces previous findings, showing patients with limited digital health literacy may successfully participate in video visits

with proper education in the evolving technology landscape [21,26,27]. While asynchronous web-based tutorials may benefit many patients with technology navigation issues, others require a more personalized, hands-on approach to technology education [11,12,28]. For instance, older adults and patients with cognitive impairments require more individualized resources to increase health literacy [21]. For patients in our cohort, lack of telehealth access was more a consequence of lack of technological support or education, as opposed to lack of internet access or technology ownership.

Treating digital literacy analogously to other social determinants of health can inform both policy and health care practice. Health care providers, educators, and policy makers are well-positioned to integrate digital literacy into patient care and medical education. To address telehealth and other health technology adoption as a social determinant of health, technological support

should be individualized and patient-centered [28-30]. Patient-centered digital literacy can be enhanced through interdisciplinary collaboration between technologists, public health experts, and health care providers (social work, etc) to develop new programs such as START.

In addition to positively impacting patient outcomes, integrating service learning and civic engagement in our course enhanced student learning as future health care providers [13,31-35]. Currently existing service-learning programs incorporate learner practicums on direct patient access and offer valuable opportunities for student immersion in community-based experiential work [36-39]. Building on the foundations of existing community engagement courses and programs (Table 4) [40-47], the START curriculum embeds hands-on experiences in a classroom setting to address technology literacy and access.

Table 4. Examples of current telehealth or service-learning educational programs.

Institution or organization	Course structure	Format	Curriculum content
Florida Atlantic University	<i>Christine E. Lynn College of Nursing (DNP):</i> 4-week course (web-based module) open for the general public	<ul style="list-style-type: none"> • Didactic 	<i>Telehealth certificate:</i> “Learning about health equity; improving access to health care, health disparities, and inter-professional practice with specific populations in relationship to the application and implementation of telehealth platforms.”
Stanford University	<i>Stanford Technology Access Resource Team:</i> 10-week course for Stanford undergraduate, graduate, and medical students	<ul style="list-style-type: none"> • Didactic • Experiential • Community based • Longitudinal 	<i>A primary care effort to bridge the telehealth divide:</i> “Exploring concepts in communication, community-building, design thinking, and team-based patient care while providing a service that will connect vulnerable patients and their caregivers to health care providers through video visits.”
Thomas Jefferson University	<i>College of Health Professions:</i> 12-month course (web-based module) open for Thomas Jefferson graduate students	<ul style="list-style-type: none"> • Didactic • Experiential 	<i>Connected care: telehealth and digital health innovation:</i> “Improving healthcare delivery & outcomes; engaging patients in prevention medicine, early diagnosis, and managing chronic conditions through the successful implementation and practice of digital health.”
Uniformed Services University of the Health Sciences	<i>Defence Health Agency:</i> Asynchronous or classroom course (9 hours) open for MS-3 students	<ul style="list-style-type: none"> • Didactic • Experiential 	<i>Introduction to telehealth and service learning:</i> “Covering telehealth history, applications, ethics, safety, military uses, etiquette, and patient considerations; engaging in faculty-supervised mock patient telehealth encounters; practicing advanced surgical procedures using telehealth equipment.”
University of New Hampshire	<i>The Telehealth Practice Center: Student Learning and Professional Training:</i> 17-week course open for third- and fourth-year undergraduate students	<ul style="list-style-type: none"> • Didactic 	<i>HHS 798 or HHS 898: Introduction to telehealth:</i> “Learning about rural health, digital divides, assistive technology, innovations, and current practices in telehealth; understanding the roles of healthcare providers as they offer digital visits; working with classmates on a telehealth-related project.”
University of Southern California	<i>Keck Service Learning Program:</i> 1-year course (4-6 hours) open for USC ^a MS-1 students	<ul style="list-style-type: none"> • Didactic • Experiential • Community based 	<i>Course in health justice and systems of care curriculum:</i> “Learning about structural, social, and psychological influences on health, engaging in a service-learning experience; discussing ways clinicians can partner with community health entities, reflecting on the role of medical students as health professionals and citizens.”
University of Utah	<i>University of Utah Health:</i> 12-week web-based synchronous course open for DBMI ^b and MHA ^c students	<ul style="list-style-type: none"> • Didactic 	<i>BMI 6050 or MHA 6050:</i> “Thinking through ways technology can solve healthcare access challenges facing patients and providers, learning about the legal, ethical, service delivery, and financial aspects of telehealth services.”
Veterans Health Administration of Palo Alto General Medicine Clinic	<i>Asynchronous Prevention Clinic:</i> Volunteer program for high school, college, and medical students	<ul style="list-style-type: none"> • Didactic • Experiential • Community based • Longitudinal 	<i>Decreasing racial disparities in hypertension:</i> “Connecting students with medical teams to make telephone calls; instructing veterans how to take accurate home blood pressures; designing an intervention that reaches Black patients and other poorly resourced veterans to improve clinical outcomes for all.”

^bDBMI: Department of Biomedical Informatics.

^cMHA: Master of Healthcare Administration.

Comparison to the Literature

Service-learning programs vary in terms of duration, degree of service requirements, direct versus indirect interactions with patients and caregivers, and topics covered in their curricula (Table 4) [40-47]. We found service-learning programs varying in length between a few weeks to a year, usually with a specific scientific or clinical focus, such as telehealth, equity or disparities, community health, and social determinants of health. Programs had relevant experiential components, based on their learning objectives, such as video simulations of patient encounters for video visit experiences. One service-learning

program for medical students involved community-based clinical work [45].

Our START program teaches students about the upstream factors that may hinder patients’ abilities to access health care and offers students the training resources to support patients in connecting with their health care teams via telehealth. As a result, students can apply the didactic lessons they learn in classroom settings immediately to first-hand experiences working directly with patients. Given the dynamic and experiential nature of the curriculum, to our knowledge, START is currently one of the only courses or programs offered to undergraduate and graduate students that combines the best

practices of service learning with direct support for patients seeking assistance in accessing their EMRs and video visits.

Strengths and Limitations

This study has several strengths and limitations. During program development and implementation, we had access to health equity experts, EMR support, and administrative support. However, even with access to patient lists generated from EMR searches, 80.7% (n=956) of patients did not answer calls or had disconnected numbers, illustrating the need to find better ways of reaching our target patient population. When eventually connecting with patients, respondents shared that they were initially unavailable and did not recognize the phone number on the caller ID and therefore did not initially answer the call. Subsequently, calls were made through a service (Cisco Jabber) that provided the institution's caller identification. Future efforts would benefit from appropriate caller identification, when possible, to signal to patients that the caller is an extension of the care team. Our students had the opportunity to work with patients in 2 diverse populations (an academic medical center and FQHC). While successful, student supervision and trust-building within the FQHC community took additional time and resources. This may pose a challenge for institutions without such capacities. Some communities may have additional barriers such as larger portions of patients who are not technology native. It is also worth noting that the START program is an ongoing partnership with the institution's IT team such that the training session for the students would be updated according to changes in the institution-wide digital health platforms. Similarly, the guidebook for the FQHC site would be updated according to updates in digital health technology.

Our results are reliant on student encounter logs, which may introduce consistency bias and the Hawthorne effect in self-reported data. Given the course structure, we did not follow patients over time. Future initiatives may consider having students follow up with patients soon after their scheduled doctor appointments using the same phone numbers. Patients contacted after course may have recall bias, have forgotten specifics of the interaction, or have been influenced by social desirability bias. Subsequent assessment of interaction impact will include patient follow-up within a week regarding their interaction with START students. A total of 4.8% (n=11) of our patients were unable to get digitally connected with their health care providers due to lack of access to essential devices or Wi-Fi. Future programs may consider developing partnerships with technology providers or community organizations to send devices or Wi-Fi

routers to such patients (see [Multimedia Appendix 4](#) for examples of "Links to Local Free Wi-Fi Resources" used in this study). Students had suggested a variety of program improvements, such as collaborative debriefing during sessions and providing in-person services when possible, to mitigate the challenge of navigation solely by telephone. When technical challenges faced by patients and students arose, students connected with patients' family members or caretakers, who were able to troubleshoot. Future initiatives should consider providing students with additional phone numbers to alternate or emergency contacts. Additionally, establishing a schedule for students to enter the clinic at designated times and obtaining direct referrals from clinicians' primary care providers could also streamline the referral process. Finally, we recommend gathering alternative contact information from students (eg, personal emails) to track their career trajectories after completing the course or program. Future studies may also consider using pre- and postcourse student surveys assessing changes in empathy and cultural humility, which could provide quantitative and qualitative measurements of program utility on these qualities.

Conclusions

Helping patients navigate complex health systems has called attention to an arising social determinant of health—digital literacy. Approaching the needs of patients with low digital literacy is crucial to helping them reap the benefits of high-quality and efficient health care. START is an applied, experiential, longitudinal, and community-based program that couples students' desire for service learning with curricula on social determinants of health, health disparities, and patient-centered communication skills. Programs such as START may empower students to serve as digital health navigators and may foster more culturally humble and compassionate health care professionals. START presents a valuable opportunity for our next generation of clinicians to work with patients who are vulnerable and to develop empathy and communication skills earlier on in their academic journeys while addressing digital literacy as an emergent social determinant of health. Future service-learning programs could adapt the START model of integrating a student course with partnerships with the institution's information and technology, compliance, and interpretation and translation services to provide services beyond connecting to video visits such as helping with applications for social services, completing advance directives for health care, navigating transportation barriers, and bridging to community partners.

Acknowledgments

The authors would like to express their gratitude to the students who provided support to the patients and contributed their reflections during the Stanford Technology Access Resource Team course, especially Grace Toluwanimi Adebogun, Sohayla Eldeeb, Catherine Gao, Brianna Gamble, Jennifer John, Japnoor Kaur, Ashley Danielle Nies, Misha Raffiee, and Lea Wenting Rysavy for their featured reflections. The authors recognize Ashley Danielle Nies and Misha Raffiee for their help in reviewing reflections. The authors are indebted to Alice Mau, MD, for her help with the patient needs assessment and Audrey Xu, for her help with the student needs assessment.

Abstract

Background: In the field of research, psychological safety has been widely recognized as a contributing factor to improving the quality of care and patient safety. However, its consideration in the curricula and traineeship pathways of residents and health care students is scarce.

Objective: This study aims to determine the extent to which health care trainees acquire psychological safety competencies during their internships in clinical settings and identify what measures can be taken to promote their learning.

Methods: A mixed methods observational study based on a consensus conference and an open-ended survey among a sample of health care trainee mentors from health care institutions in a pan-European context was conducted. First, we administered an ad hoc questionnaire to assess the perceived degree of acquisition or implementation and significance of competencies (knowledge, attitudes, and skills) and institutional interventions in psychological safety. Second, we asked mentors to propose measures to foster among trainees those competencies that, in the first phase of the study, obtained an average acquisition score of <3.4 (scale of 1-5). A content analysis of the information collected was carried out, and the spontaneity of each category and theme was determined.

Results: In total, 173 mentors from 11 pan-European countries completed the first questionnaire (response rate: 173/256, 67.6%), of which 63 (36.4%) participated in the second consultation. The competencies with the lowest acquisition level were related to warning a professional that their behavior posed a risk to the patient, managing their possible bad reaction, and offering support to a colleague who becomes a second victim. The mentors' proposals for improvement of this competency gap referred to training in communication skills and patient safety, safety culture, work climate, individual attitudes, a reference person for trainees, formal incorporation into the curricula of health care degrees and specialization pathways, specific systems and mechanisms to give trainees a voice, institutional risk management, regulations, guidelines and standards, supervision, and resources to support trainees. In terms of teaching methodology, the mentors recommended innovative strategies, many of them based on technological tools or solutions, including videos, seminars, lectures, workshops, simulation learning or role-playing with or without professional actors, case studies, videos with practical demonstrations or model situations, panel discussions, clinical sessions for joint analysis of patient safety incidents, and debriefings to set and discuss lessons learned.
