Conclusions: This study sought to promote psychological safety competencies as a formal part of the training of future health care professionals, facilitating the translation of international guidelines into practice and clinical settings in the pan-European context.

KEYWORDS

psychological safety; speaking up; professional competence; patient safety; education; adverse event

Introduction

Theoretical Background

Overview

Clinical errors are a common occurrence in health care, and many of them are preventable [1,2]. Adverse events involving health care professionals, including medical students during their internships, are unfortunately widespread [3]. These events have negative consequences for patients, health care professionals, and the health care system, commonly referred to as the first, second, and third victims, respectively [4-6]. Hence, prioritizing error prevention is crucial at both the local and national health care system levels. This focus serves to mitigate harm, reduce costs, and restore trust in health care [7].

While patient safety management in health care institutions was originally based on a reactive approach focused on acting after an incident and detecting what failed behind it, over time, this way of pursuing safety has evolved to a more positive one in which the objective is no longer just avoiding something going wrong (Safety I) but, above all, ensuring that everything goes right (Safety II). Far from being antagonistic, these 2 perspectives complement each other and allow for a more balanced and flexible approach to the reality of health care [8]. Thus, safety is linked not only to concepts such as incidents, errors, failures, or liability but also to other concepts, such as occupational well-being, resilience, or psychological safety.

Second Victims

Improved patient safety, in turn, has a positive impact on patient outcomes [9,10] and helps prevent health care professional

burnout [11]. Health care professionals and even medical students involved in adverse events often experience symptoms akin to those of second victims, with profound implications for their emotional well-being as well as their professional and personal lives [9,12,13]. Recently, Vanhaecht et al [14], based on the literature and the expert consensus, defined a second victim as follows: "Any health care worker, directly or indirectly involved in an unanticipated adverse patient event, unintentional healthcare error, or patient injury and who becomes victimized in the sense that they are also negatively impacted."

Patient Safety Culture

Despite the recognition of the need for safer patient care, there remain various barriers [15-17]. Moreover, the effective processes after the adverse event, such as reporting of an adverse event, the analysis of the event, and open disclosure, can be hindered. These effective practices stem from and contribute to the psychological safety climate within the organization, encompassing elements such as a blame-free culture and a just culture [18,19].

Psychological Safety

Psychological safety is an important part of the safety culture in health care organizations. It is defined as a belief that individuals can feel safe to disagree, ask questions, and report mistakes without negative consequences and that they can cooperate as a team with mutual respect and trust [20]. Psychological safety contributes to improved outcomes in clinical training (eg, willingness to report adverse events [21] and speak up [22]) and, therefore, may be associated with better patient outcomes and improved safety culture [23]. Thus, comprehensive patient safety management combining Safety I

and Safety II approaches requires psychologically safe clinical environments [8].

Speaking Up for Ensuring Patient Safety

Psychological safety is pivotal in transitioning from a proactive to a generative patient safety culture [24]. It enables health care professionals to speak up without fear of consequences, which is crucial for overcoming barriers to safe care practices, including effective adverse event reporting and analysis [25]. Institutions must also prioritize the support and consideration of second victims as failing to do so can compromise patient safety [24].

Creating safe learning environments is essential for fostering psychological safety among future health care professionals. Training programs emphasizing open communication, mutual respect, and psychological safety equip students and professionals with the skills necessary for a safer health care system. By prioritizing these elements, health care organizations can establish a culture that supports both patient and provider well-being, ultimately enhancing safety and quality of care [24,25].

In summary, integrating psychological safety into health care practices creates a comprehensive safety framework, emphasizing a supportive culture, proactive error management, and the development of resilient health care professionals. This approach not only addresses immediate safety concerns but also contributes to the long-term sustainability of health care systems by nurturing a safety culture and psychological well-being [24].

Current Gap

Poor attention has been paid to promoting psychological safety in health care and medical education [26,27]. Future health care professionals' perceptions, attitudes, skills, and knowledge regarding safety culture cocreate a safe health care environment and contribute to better patient safety as well as a psychologically safer climate [28,29]. Strategies to establish

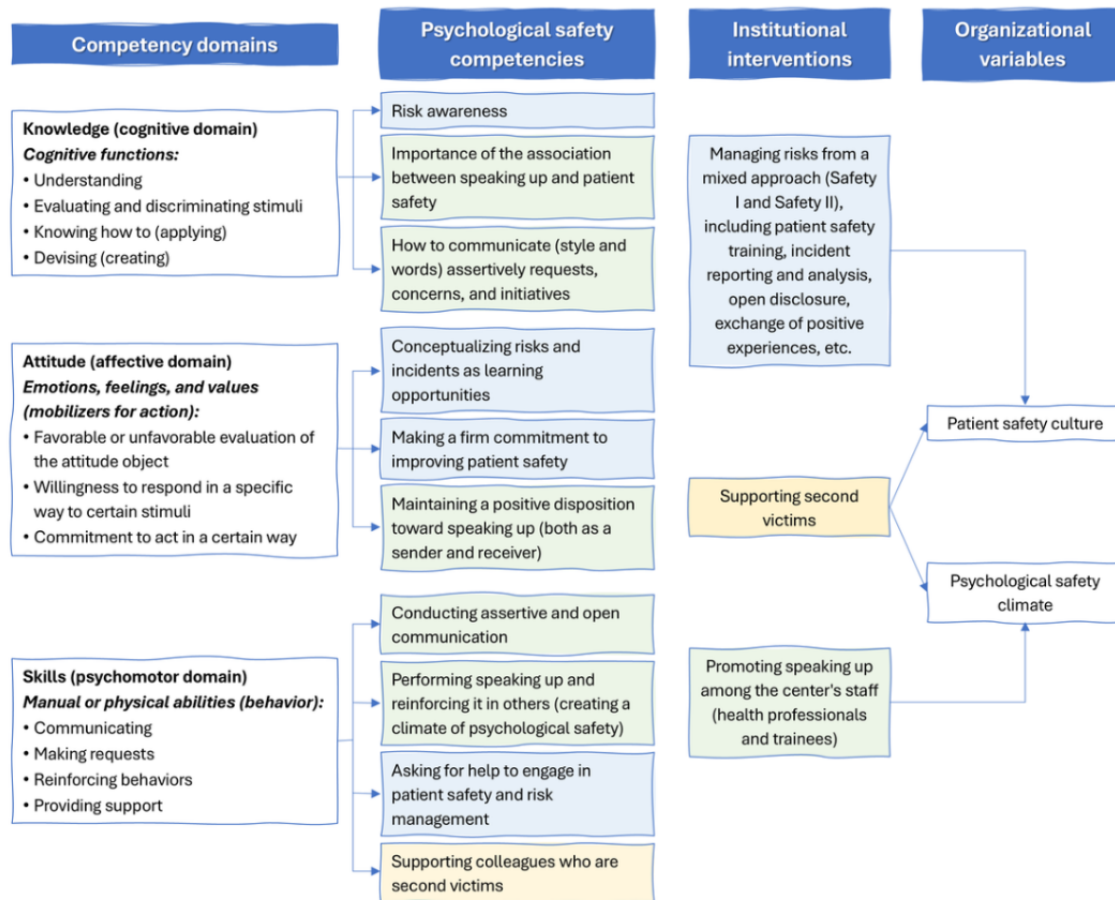

psychological safety in clinical supervision were introduced to improve future health care professionals' training [30]. Little is known about how health care professionals are trained in psychological safety in European countries, which competencies and skills promoting psychological safety they obtain during their clinical internship, and which of them are considered important from the perspective of health care professionals in practice.

Methodological Framework

In the health care field, competence is defined as "the habitual and judicious use of communication, knowledge, technical skills, clinical reasoning, emotions, values, and reflection in daily practice to benefit both individuals and the community" [31]. This study's methodology aligns with the taxonomy by Bloom et al [32], which identifies 3 domains of competencies: cognitive (knowledge), affective (attitudes), and psychomotor (skills), collectively referred to as knowledge, skills, and attitudes or knowledge, attitudes, and skills (KAS) [33].

Figure 1 [32] shows the integration of this study's theoretical background and methodological framework. To assess the professional competence of trainees in psychological safety, they must demonstrate that they know (knowledge), know how to be (attitudes), and know how to do (skills) regarding the topics related to psychological safety described in the theoretical framework. To our knowledge, none of the instruments or frameworks explicitly define competencies in psychological safety. Consequently, this study proposed their measurement based on integrating the KAS model with the variables considered in the instruments available to evaluate speaking up, psychological safety, and support for second victims. Moreover, this approach finds that the culture and climate of the organization play a crucial role in implementing psychological safety competencies. For this reason, we proposed evaluating institutional interventions to promote psychological safety in clinical settings in parallel to assessing these competencies.

Figure 1. Integrated proposal of the study's theoretical background on psychological safety and the methodological framework based on the taxonomy of competencies by Bloom et al [32] and the knowledge, skills, and attitudes model.

Objectives and Hypotheses

The aim of this study was to determine the extent to which health care trainees acquire psychological safety competencies during their internships in clinical settings and identify what measures can be taken to promote their learning.

Our previous hypothesis was that mentors perceive that the level of training and acquisition of psychological safety competencies (as defined in our framework) among European trainees during their internships in clinical settings is low. This hypothesis is supported by the absence of a previous framework that explicitly conceptualizes psychological safety competencies, the relatively low frequency with which trainees speak up on patient safety [34,35], and the generalized lack of formal content on patient safety in the curricula of health care studies in Europe [36]. Regarding measures to promote the learning of these competencies, we expect mentors to identify some of the barriers that currently limit their acquisition by trainees, among which are organizational variables. Therefore, their suggestions will incorporate not only specific initiatives of an educational nature but also others oriented toward cultural forms and patterns of institutional behavior that promote a climate of psychological safety in clinical settings.

Methods

Study Design

We combined quantitative and qualitative research methods and approaches to understand the wideness and depth of the problem of psychological safety training in health care research with mentors of residents and students in health care disciplines from 11 pan-European countries. This study was conducted in 2 phases from February 2022 to July 2023. First, we conducted a web-based consensus conference using a structured questionnaire to prioritize psychological safety competencies and institutional interventions to foster their acquisition among trainees. Subsequently, we performed a second consultation based on an open-ended survey to explore recommended actions to enhance the development of those psychological safety competencies that, according to the results of the consensus conference, were considered significant but the training on them was still lacking or incomplete during internships.

This manuscript was developed in accordance with the Checklist for Reporting Results of Internet E-Surveys [37] (phase 1, survey study) and the COREQ (Consolidated Criteria for Reporting Qualitative Research) [38] (phase 2, qualitative study).

Ethical Considerations

We followed national regulations to obtain ethics approvals in Estonia (Research Ethics Committee of the University of Tartu,

approval 364/T-11; May 16, 2022), Israel (Ethics Committee of the Faculty of Social Welfare and Health Sciences, University of Haifa, approval 036/22; December 21, 2021), Slovakia (Ethics Committee of Pavol Jozef Šafárik University in Košice, approval 11N/2022; March 28, 2022), and Spain (Research Ethics Committee of the San Juan de Alicante University Hospital, approval 22/012; February 23, 2022). In other countries, previous ethics approvals were also considered valid.

Before the participants were registered on the web platform, informed consent was obtained. Likewise, the questionnaire only allowed access to the questions after the participants had explicitly confirmed consent to participate in the study. Participants were given a contact email to exercise their right to withdraw from participation at any time during the study. To allow traceability of the data in the different phases of the study, but at the same time, to guarantee the confidentiality of the participants and their responses, these were deidentified. No form of financial compensation was provided for participation or recruitment.

Recruitment

We invited 256 health care trainee mentors from 11 pan-European countries (20-25 mentors per country), including Croatia, Estonia, Finland, Germany, Israel, Lithuania, Malta, Portugal, Serbia, Slovakia, and Spain, to participate in this study. The invitation to these countries allowed for the collection of information representative of educational models from Northern, Eastern, Southern, and Central Europe. We enrolled professionals assigned to health care institutions (inpatient or outpatient, community, and social care settings) associated with universities or other formal training institutions who were responsible for mentoring and supervising residents and students during their clinical internships in the following areas: family medicine, obstetrics, midwifery, pharmacy, surgery, and other medical fields such as pediatrics. These specialties were chosen based on the main rotation areas of the training and residency programs. Academic-only mentors were excluded. Participants were recruited through convenience sampling by 1 or 2 members of the European Researchers' Network Working on Second Victims (ERNST) Consortium (European Cooperation in Science and Technology Action 19113) [39] from each participating country, who acted as local coordinators. The ERNST includes 28 European countries, integrating experienced research teams focused on patient safety issues, with most working in clinical and academic settings. This network was the vehicle for coordinating the study but not an inclusion criterion for recruiting participants. Thus, all national coordinators were network members, but not all participants involved in the study belonged to ERNST. Only the countries in this European consortium (11/28, 39%) that voluntarily decided to join the study were involved.

In each participating country, trainee mentors were contacted by the national study coordinator through an invitation letter providing information about the study and its objective, content, and procedure. Those participants who agreed to be involved in the study voluntarily completed the questionnaire or survey used for data collection depending on the study phase.

Phase 1: Degree of Acquisition or Implementation and Significance of Psychological Safety Competencies and Institutional Interventions (Consensus Conference)

Procedure

For the first phase of the study, consisting of a web-based consensus conference, we developed an ad hoc questionnaire whose content was structured into 4 blocks of items, the first 3 describing KAS related to psychological safety competencies and the last one describing institutional actions to promote the acquisition of these competencies among trainees. For the development of the questionnaire items, we relied on the validated instrument by Richard et al [40] on psychological safety and speaking up behavior and on those by Lee et al [41] and Schnall et al [42], which propose the assessment of patient safety competencies based on the measurement of KAS that make up each core competency.

The national coordinators from Croatia, Estonia, Finland, Germany, Israel, Portugal, Serbia, Slovakia, and Spain were responsible for the translation and back translation process of the English questionnaire into the language of their country (Multimedia Appendix 1). Participants from Malta and Lithuania completed the English questionnaire.

Before the consensus conference, the questionnaire's readability and face validity were tested between February 2022 and March 2022. In total, 3 mentors per country completed the questionnaire. Given the readability test results, several changes to the questionnaire were made, including rewording some items, reducing the response scale levels, deleting 1 original item, and adding 2 new items for clarity. The overall evaluation of the questionnaire (scale of 0-5) was positive in terms of satisfaction (mean 4.0, SD 0.9), usefulness of the information (mean 4.6, SD 0.7), and usefulness for curricular improvement (mean 4.4, SD 0.6) and somewhat less favorable in terms of length (mean 3.6, SD 0.7).

The final version of the questionnaire consisted of 29 items grouped into the 4 original blocks (Textbox 1). Mentors were asked to assess the degree of acquisition among the trainees of their institution of knowledge (7 items), attitudes (6 items), and skills (7 items) in psychological safety and their degree of significance from their point of view using a 5-point Likert response scale (1=no acquisition at all or not important at all; 5=fully acquired or very important). For institutional interventions (9 items), participants were asked to determine the degree of implementation and significance using a 5-point Likert response scale (1=not yet implemented or not important at all; 5=fully implemented or very important). In the questionnaire instructions, we provided respondents with the definition of the psychological safety concept. We also added a brief conceptual clarification in those items that referred to other secondary terms (such as *second victim*). The questionnaire was distributed via email and using a web-based platform owned by the research group for conducting opinion studies (password-protected survey) between October 2022 and December 2022. A total of 3 reminders were sent during this period to ensure an adequate response rate.

Textbox 1. Final version of the questionnaire to evaluate the degree of acquisition or implementation and significance of psychological safety competencies and institutional actions based on the knowledge, skills, and attitudes framework (phase 1).

Knowledge—in my opinion, internships in my work environment provide trainees with the competency to:

- Understand that an open and direct expression of concerns about patient safety can prevent the occurrence of incidents that could cause harm to the patient.
- Know how to communicate assertively a concern about patient safety to another health care professional (of the same level or higher; eg, what words to choose, how to start and finish the conversation, and what tone of voice or gestures to use).
- Distinguish between situations that could cause avoidable harm to the patient and those that do not represent a high risk for patient safety.
- Choose the best moment to communicate specific concerns about patient safety to another health care professional (of the same level or higher).
- Know how to assertively warn another health care professional (of the same level or higher) of the risk of ignoring an important patient safety rule (eg, words to choose, how to start and finish the conversation, and what tone of voice or gestures to use).
- Know how to deal constructively with the possible negative reaction of a health care professional (of the same level or higher) after having warned them that they were overlooking an important rule for patient safety.
- Know how to express specific proposals that could improve the patient safety in the unit.

Attitude—in my opinion, internships in my work environment provide trainees with the competency to:

- Commit to the identification and prevention of risks for patient safety.
- Perceive risk situations in daily work as an opportunity to highlight the risk and take appropriate measures to prevent harm to patients.
- Respond positively to the expression of warnings or concerns by other health care professionals (of the same level or higher) in relation to patient safety.
- Maintain a positive attitude toward warning other health care professionals if, with their actions, they are ignoring an important patient safety rule.
- Be willing to openly and directly share specific proposals to improve patient safety.
- Be willing to learn from mistakes and patient safety incidents in which other professionals have been involved instead of judging them.

Skills—in my opinion, internships in my work environment provide trainees with the competency to:

- Communicate openly and directly to other professionals (of the same level or higher) specific concerns about patient safety by presenting information, asking questions, or expressing opinions.
- Request the responsible professionals' advice to report, in the appropriate system, the occurrence of a patient safety incident that has been witnessed and make the report (if necessary).
- Warn assertively another health care professional (of the same level or higher) that, with their actions, they are ignoring an important patient safety rule.
- Respond assertively to the negative reaction of a health care professional (of the same level or higher) whom they have warned about ignoring an important patient safety rule.
- Verbally support and reinforce the initiative of other health care professionals (of the same level or higher) to share their specific concerns about patient safety with the rest of the team.
- Set and communicate concrete proposals to improve patient safety in their own unit or service.
- Offer peer support to a colleague involved in an adverse event to reduce the second victim syndrome (characterized by feelings of guilt, inadequacy, anxiety, shame, hypervigilance, or grief).

Interventions—my health care institution:

- Implements a training program for new staff (especially trainees) to foster a positive patient safety culture and a psychological safety climate.
- Appoints an influential group of people to design an intervention plan to foster a trusting climate among health care professionals to ensure patient safety.
- Holds regular clinical sessions with trainees to share patient safety concerns and lessons learned. This measure translates into the set of shared spaces to exchange experiences on patient safety incidents, devise barriers to minimize risks, and provide emotional and instrumental support among peers.
- Raises awareness among the center's professionals, with the collaboration of heads of service, of the need to encourage trainees and colleagues to express their concerns regarding patient safety openly and directly and warn other professionals of the risks they identify in their daily work.
- Raises awareness among the center's professionals, with the collaboration of heads of service, of the importance of responding positively to warnings from other professionals regarding compliance with relevant patient safety rules and reinforcing the open expression of specific patient safety concerns by trainees.
-

Provides trainees with the opportunity to participate as observers during the planning of adverse event disclosure conversations with the affected patient and family.

- Allows trainees to have the opportunity to be present during the discussion and analysis following a patient safety incident.
- Provides trainees with specific training on reporting patient safety incidents through appropriate means.
- Offers institutional support to health care professionals involved in an adverse event to contribute to better safety at the workplace.

Statistical Analysis

For each item, the mean, SD, and coefficient of variability (CV) were obtained. We considered that those competencies with a score of <3.4 in acquisition required more effort to teach during trainees' internships. These areas were selected to explore possible recommended actions for fostering the acquisition of psychological safety competencies among health care students and residents in a second consultation.

Phase 2: Exploration of Measures and Actions to Promote the Acquisition of Psychological Safety Competencies Among Trainees (Open-Ended Survey Questions)

Procedure

On the basis of the results of the web-based consensus conference, a survey of 3 open-ended questions was developed to explore recommended actions to foster the learning of the psychological safety competencies necessary for trainees to be able to communicate their patient safety concerns or initiatives, observe another health care professional ignoring an important patient safety rule and assertively warn them of the risks of their behavior, and support a colleague who is emotionally affected after being involved in an adverse event ([Multimedia Appendix 2](#)). The survey was administered on the web between January 2023 and July 2023 to mentors who had participated in the consensus conference.

Information Categorization and Analysis

For the processing of the information obtained in this second phase, we used the qualitative methodology of content analysis, which consists of systematically transforming a large amount of text into a highly organized and concise summary of the key findings through a process of abstracting the data in consecutive steps to move from manifest and literal content to latent meanings [43]. In total, 2 researchers were involved in the

coding process. The first step consisted of reading and rereading the survey data to obtain a sense of the whole and gain a general understanding of what the participants were referring to in their responses. Then, the raw meaning units or ideas were coded into categories agreed upon by the 2 researchers. In a second round, the researchers grouped these categories into themes. Thus, the coding hierarchy used, from least to most abstract, was meaning units, categories, and themes. The coding of the raw data was carried out independently for each of the questions as, although they were related, they focused on different competencies and problem situations. The formation of themes was carried out through an iterative process and was determined by the productivity of ideas and the weight of categories in the set of each separate question. Thus, the same topic could be represented in one question by a single theme and in another by 2. However, once all the ideas per question had been coded, a consistency analysis was carried out to prioritize the themes for the study as a whole and establish interquestion consistency. For each category and theme, we specified the spontaneity (understood as the number of times that the same idea was repeated independently by more than one participant) and the number of countries whose participants agreed on the same idea. We also calculated the overall productivity of ideas and the relative importance of the different themes identified within each question.

Results

Phase 1: Degree of Acquisition or Implementation and Significance of Psychological Safety Competencies and Institutional Interventions (Consensus Conference)

A total of 173 mentors (response rate: 173/256, 67.6%) from 11 countries in the pan-European environment participated in the study. [Table 1](#) shows the participants' sociodemographic characteristics and other variables of interest for the study.

Table 1. Characteristics of participating mentors and their work centers (N=173).

	Values
Country, n (%)	
Croatia	15 (8.7)
Estonia	24 (13.9)
Finland	12 (6.9)
Germany	18 (10.4)
Israel	4 (2.3)
Lithuania	17 (9.8)
Malta	10 (5.8)
Portugal	15 (8.7)
Serbia	15 (8.7)
Slovakia	20 (11.6)
Spain	23 (13.3)
Sex, n (%)	
Female	129 (74.6)
Male	44 (25.4)
Age (y), mean (SD)	43.6 (9.9)
Years being responsible for trainees, mean (SD)	10.7 (7.5)
Number of personally supervised or mentored trainees in the last 3 years (2019-2021), mean (SD)	23.1 (45.4)
Professional profile, n (%)	
Medicine	72 (41.6)
Nursing	60 (34.7)
Pharmacy	24 (13.9)
Midwifery	4 (2.3)
Physiotherapy	3 (1.7)
Psychology	4 (2.3)
Dentistry	1 (0.6)
Microbiology	1 (0.6)
Occupational health care	1 (0.6)
Public health and organization	1 (0.6)
Radiology	2 (1.2)
Setting of clinical and mentoring performance, n (%)	
Primary care	37 (21.4)
Specialized care (hospital)	132 (76.3)
Social care	4 (2.3)
Specific patient safety training program in place at the center, n (%)	
Yes	48 (27.7)
No	125 (72.3)

Regarding the degree of acquisition of psychological safety competencies among the trainees during their internships, the mean scores assigned by the mentors ranged from 2.9 to 3.8 points, suggesting a medium to low level of assimilation (global mean 3.4, SD 0.8; knowledge mean 3.4, SD 0.8; attitude mean 3.5, SD 0.8; skills mean 3.3, SD 1.0). Concerning knowledge,

mentors believed that trainees had difficulties in knowing how to assertively warn another health care professional (of the same or a higher level) of the risk of ignoring an important patient safety rule (mean 3.1, SD 1.0; CV=33.1) and how to deal constructively with their possible bad reaction (mean 2.9, SD 1.1; CV=38.6). Mentors perceived among their trainees a

medium level of development of attitudes favorable to creating a psychological safety climate. The aforementioned knowledge gap was expected to be reflected in the trainees' lack of skills to warn others about unsafe practices (mean 3.2, SD 1.1; CV=35.6) and manage the possible interpersonal conflict arising from such verbalization (mean 3.1, SD 1.2; CV=37.8). In the mentors' opinion, another of the least trained skills was offering peer support to a colleague involved in an adverse event to prevent or minimize the second victim response (mean 3.1, SD 1.3; CV=41.5).

Without being high, the most widespread knowledge among trainees in the eyes of their mentors was the understanding that open and direct communication of patient safety concerns could prevent adverse events (mean 3.8, SD 1.0; CV=25.0) and the distinction between situations that could cause avoidable harm to the patient and those that pose no risk (mean 3.7, SD 0.8; CV=22.3). Consequently, mentors noted that the most prevalent attitude among residents and students was the commitment to identify and prevent patient safety risks (mean 3.8, SD 1.0; CV=25.3). Of all the skills explored, consulting and sharing patient safety concerns obtained the highest score from mentors, although not reflecting a high acquisition level (mean 3.5, SD 1.1; CV=30.5).

In general, the significance assigned by mentors to the different psychological safety competencies was high, with mean scores ranging from 4.4 to 4.8 points (global mean 4.6, SD 0.6; knowledge mean 4.5, SD 0.6; attitude mean 4.6, SD 0.6; skills mean 4.6, SD 0.7). According to the mentors' opinions, the most relevant components of psychological safety competencies included understanding the importance of openly communicating patient safety concerns to prevent adverse events (mean 4.8, SD 0.6; CV=25.0), adopting a firm commitment to identify and proactively manage patient safety risks (mean 4.7, SD 0.7; CV=14.9), showing a willingness to learn from safety incidents involving other professionals in a nonjudgmental manner (mean 4.8, SD 0.6; CV=13.2), and openly communicating one's patient safety concerns regardless of the hierarchical level of the recipient (mean 4.7, SD 0.7; CV=15.0).

According to the mentors, the level of implementation of actions aimed at promoting the acquisition of psychological safety competencies among trainees in their institutions was low (mean 2.6, SD 1.1; range 2.4-2.8). Despite its perceived importance, mentors indicated that the least implemented action was holding regular clinical sessions with trainees to share patient safety concerns and lessons learned (mean 2.4, SD 1.3; CV=56.9). Overall, mentors rated the 9 institutional interventions explored in the questionnaire as highly significant (mean 4.4, SD 0.8; range 4.2-4.6). Among the interventions assessed as most significant were implementing a patient safety and psychological safety training program for new trainees (mean 4.6, SD 0.9; CV=19.0) and offering institutional support to trainees involved in an adverse event (mean 4.6, SD 0.9; CV=20.0).

The results of the descriptive analysis (mean, SD, and CV) for each questionnaire item are shown in the tables in [Multimedia Appendix 3](#).

Phase 2: Exploration of Measures and Actions to Promote the Acquisition of Psychological Safety Competencies Among Trainees (Open-Ended Survey Questions)

Overview

In this second consultation, 36.4% (63/173) of the mentors who completed the phase 1 questionnaire participated. The participating countries were Croatia, Estonia, Germany, Portugal, Serbia, Slovakia, and Spain. The overall productivity was 353 ideas or meaning units grouped into 9 joint themes. More than half (210/353, 59.5%) were related to training activities, environmental and structural conditions (safety culture and work climate), and individual attitudes. The rest of the proposals referred to the trainees' reference person, institutional resources to support the second victim, curricula content and training pathways, systems and mechanisms to give trainees a voice, institutional management of clinical risks (incident reporting and analysis), regulations and standards, supervision, and resources to support trainees ([Table 2](#)).

Table 2. Productivity and distribution of meaning units by theme overall and per question (N=353).

Theme	Spontaneity (relative priority), n (%)			
	Question 1: communicate patient safety concerns (n=154)	Question 2: warn about an unsafe behavior (n=101)	Question 3: support a second victim (n=98)	Total
Training	46 (29.9)	52 (51.5)	29 (29.6)	127 (36)
Individual attitudes and environmental conditioning factors ^a	35 (22.7)	23 (22.8)	25 (25.5)	83 (23.5)
Person of reference	19 (12.3)	6 (5.9)	15 (15.3)	40 (11.3)
Institutional resources to support second victims	— ^b	—	27 (27.6)	27 (7.6)
Curricula	16 (10.4)	7 (6.9)	—	23 (6.5)
Systems and mechanisms to give a voice to trainees	20 (13)	—	—	20 (5.7)
Institutional risk management, patient safety reporting systems, and incident analysis	8 (5.2)	5 (5)	—	13 (3.7)
Regulations, guidelines, protocols, standards, and policies	10 (6.5)	—	2 (2)	12 (3.4)
Supervision and resources to support trainees	—	8 (7.9)	—	8 (2.3)

^aIn question 1, this theme comprises themes 1.2—safety culture (spontaneity: n=26) and 1.7—organizational structure and culture (spontaneity: n=9).

^bThis theme did not emerge among the ideas proposed by the participants in response to this question.

Independent analysis of each of the questions yielded an individual productivity of 154 ideas for the first question (communication of patient safety concerns or initiatives) classified into 8 themes and 26 categories, 101 ideas for the second question (observing another health care professional ignoring an important patient safety rule and assertively warning them about the risks of their behavior) classified into 6 themes and 22 categories, and 98 ideas for the third question (offer support to a colleague suffering emotionally after being involved in an adverse event) classified into 5 themes and 16 categories. [Multimedia Appendix 4](#) presents a summary figure with the

main results of the qualitative analysis and a set of tables with the coding of the ideas per question with the specification of spontaneity, the number of participating countries per theme and category, and some examples of meaning units.

The following is a brief presentation of the themes that emerged from the analysis of the information provided by the mentors in this second phase of the study. With a practical vision and purpose, the relevant information was transformed into recommendations for fostering the learning of psychological safety competencies among trainees in clinical settings ([Textbox 2](#)).

Textbox 2. Recommendations for fostering the learning of psychological safety competencies among trainees in clinical settings extracted from the information provided by mentors in the study's second phase.

Training

- What:
 - Focus on patient safety, interpersonal communication, assertiveness, active listening, and social support skills.
 - Include emotional intelligence, critical thinking, reflective skills, argument formation, and achievement recognition.
 - Train in clinical interviewing skills, using open and closed questions and standardized questionnaires.
- How:
 - Implement innovative strategies such as seminars, lectures, workshops, simulation learning, role-playing, case studies, videos, panel discussions, clinical sessions, and debriefings.
 - Provide ongoing training tailored to the health care context rather than one-off sessions.
 - Practice these skills in real-world scenarios, including daily professional exchanges, challenging conversations, and conflict resolution.
 - Address communication in the context of patient safety events to prevent risks and ensure safety.
- For whom:
 - Sensitize and train the entire health care organization, including teams, mentors, and management.
 - Implement top-down training strategies, starting with senior management. Ensure that managers and team leaders receive regular compulsory training in patient safety, leadership, and staff management.
- Who:
 - Use psychologists for communication and interpersonal support skill training.
 - Engage patient safety experts for specialized training.
 - Supervision by mentors should cover communication skills, interactions with professionals, patient safety information collection, and reflection on clinical risks.
- When:
 - Begin introductory training in patient safety, communication, and teamwork skills upon joining the center.
 - Ensure comprehensive and continuous training throughout the professional career regardless of professional profile to maintain a shared understanding among all team members.

Individual attitudes and environmental conditioning factors

- *Supportive, respectful, and trustful climate:*
 - Leaders and middle managers should foster positive relationships, teamwork, openness, trust, honest communication, and mutual support.
 - Inclusive and ethical leadership helps integrate trainees into work teams, allowing them to ask questions without fear and express views assertively.
 - Organize social and informal activities to improve team relationships.
- *Positive attitudes toward patient safety and peer support:*
 - Cultivate respect and equality among professionals to facilitate the understanding that everyone's contributions are relevant for quality and safe care.
 - Foster a positive attitude toward seeking and providing peer support in challenging situations, addressing the second victim phenomenon.
- *Just and nonpunitive safety culture:*
 - Move away from a punitive and blame culture; adopt a systemic approach to adverse events and honest mistakes to prevent recurrences.
 - Recognize human fallibility and the multifactorial origins of patient safety incidents.
 - Encourage open communication without fear of punishment, judgment, stigma, or rejection.
 - Middle managers, mentors, supervisors, and senior professionals must act as role models and change agents, promoting a just safety culture.
 - Launch internal campaigns to create a just culture and make patient safety a regular topic of conversation.
- *Open and constructive communication channels:*

- Promote assertive expression and acceptance of constructive criticism as learning opportunities.
- Establish direct communication channels between all team members.
- *Leadership and management involvement:*
 - Leaders and managers should actively seek feedback and suggestions before initiating procedures.
 - Encourage managers and superiors to share personal experiences with adverse events to demonstrate that these issues are a reality in clinical practice.
 - Appoint an institutional patient safety officer and ensure that trainees are aware of their presence.
- *Structural measures to enhance patient safety:*
 - Promote a culture in which all team members regardless of hierarchy are encouraged to contribute to patient safety.
 - Use cocreated checklists to standardize practice and establish a common language across different roles.

A reference person for trainees

- *Role and responsibilities of mentors:*
 - Mentors are ideal figures to establish trust and promote patient safety supported by institutional resources.
 - Act as role models, explaining safety rules, managing risks, and using tools (eg, reporting systems).
 - Define standard behaviors in critical scenarios: safety concerns, adverse events, mistakes, noncompliance with safety rules, unsafe acts, and emotional distress.
- *Support and accessibility:*
 - Mentors should be approachable, providing support, information, and guidance.
 - Link trainees with their teams and institutional resources, guiding interactions with other professionals.
 - Support trainees as peer supporters during emotional distress from incidents.
- *Training and resources:*
 - Mentors need specialized training, resources, and mechanisms for supervising trainees.
 - Legislation may be needed to create specific supervisor positions in medical institutions.

Institutional resources to support the second victim

- *Support program and format:*
 - Raise awareness and train professionals to act as peer supporters providing emotional first aid through individual meetings or confidential group debriefings.
 - Focus on active listening, emotional validation, positive language, empathy, and companionship without investigating the event.
 - Establish multidisciplinary peer teams with personal experience of such events for a sense of identification.
 - Organize Balint groups for critical and self-reflective discussions on emotional reactions to challenging situations facilitated by a psychotherapist [44].
 - Ensure availability of psychological support through mental health, occupational health, or risk prevention structures.
 - Provide clear referral channels to connect grieving trainees with resources, with mentors acting as bridges.
- *Institutional programs for staff well-being:*
 - Implement programs promoting employee well-being and personal development.
 - Host social and recreational activities such as service dinners and hiking.

Curricula

- *Incorporate patient safety into education:*
 - Integrate patient safety and communication skill training into health care degree programs, postgraduate studies, specialization pathways, and doctoral studies.
 - Foster cooperation between academia and health care training institutions for comprehensive competency development.

- *Guidelines and regulations:*
 - Establish European and national guidelines to systematically regulate and implement patient safety training in all health faculties in alignment with World Health Organization recommendations [29].
- *Assessment and certification:*
 - Include patient safety competency assessment, including communication skills, in state and certification tests using methodologies such as the objective structured clinical examination.

Systems and mechanisms to give trainees a voice (highlights)

- *Create common spaces or forums:*
 - Hold regular meetings to discuss patient safety cases, significant issues, and preventive initiatives.
 - Involve all relevant parties: supervisors, mentors, professors, residents, and students.
 - Use forums for supervisors to share personal experiences and learning.
- *Encourage patient safety ownership:*
 - Foster ownership and meaning in trainees' work to encourage communication on patient safety.
 - Involve trainees in supportive supervision roles and patient safety projects.
- *Collect trainee feedback:*
 - Conduct regular one-to-one mentor-trainee interviews.
 - Create an anonymous mailbox for concerns and suggestions.
 - Maintain a trainee diary to document experiences and feedback.

Institutional risk management, patient safety reporting systems, and incident analysis

- *Anonymous reporting systems:*
 - Create systems for anonymously reporting adverse events.
 - Focus on proposing improvement plans with corrective, not punitive, measures.
 - Ensure legal certainty for reporters to mitigate fear of legal repercussions.
- *Trainee involvement in incident analysis:*
 - Allow trainees to be participant observers in the incident analysis process.
 - Ensure that trainees receive feedback on their reports and the resulting preventive and corrective measures.
- *Debriefing and seminars:*
 - Conduct joint and individual debriefings or seminars for trainees involved in critical incidents to review what happened.

Regulations, guidelines, protocols, standards, and policies

- *Institutional level:*
 - Ensure the availability of standardized protocols for safe clinical procedures, emphasizing risk detection and prevention measures.
 - Establish formal channels and communication procedures to enhance patient safety.
 - Structure patient safety rules hierarchically: elemental and mandatory for all professionals and complementary for specific procedures or situations.
 - Reinforce the center's quality and safety policy supporting the health care quality unit.
- *National level:*
 - Advocate for national legislative changes to ensure legal protection for professionals and trainees involved in patient safety processes (eg, incident reporting and open disclosure).
 - Develop and implement accreditation standards for certifying health care institutions as patient safety promoters in teaching and training.

Supervision and resources to support trainees' learning process

- Conduct regular interviews, knowledge checks, and feedback sessions during joint practice.
- Use clinical scenarios to prepare and execute procedures under safe conditions.
- Encourage trainees to detect errors and practice providing feedback.

Training

Most of the proposals made by the mentors to encourage trainees to acquire psychological safety competencies and develop skills in communicating patient safety concerns, warning a professional that their behavior compromises patient safety, and supporting a colleague who is a second victim were related to training actions.

The proposed ideas focused on the content, target audience, teaching methodologies, career stage, and parties involved in training.

Individual Attitudes and Environmental Conditioning Factors (Organizational Structure, Safety Culture, and Work Climate) That Determine Behavioral Patterns

The acquisition of psychological safety competencies by trainees and their commitment to patient safety seems to have a circular and bidirectional relationship with a positive safety culture and a work climate based on trust and respect in the institution. Most mentors identified these 2 contextual factors as prerequisites for trainees to openly discuss adverse events and honest mistakes and support each other.

A Reference Person for Trainees

In environments as changing, novel, and challenging as clinical settings, mentors mentioned the need for trainees to have a permanent reference person with whom they can establish a trusting bond from the moment they join the health care center.

Institutional Resources to Support the Second Victim

Concerning the approach to the second victim phenomenon, the mentors' contributions referred to implementing institutional resources and programs to minimize the impact of adverse events on health care professionals, including trainees. Most of the proposals were along the lines of the reference programs based on the Scott Three-Tiered Interventional Model of Second Victim Support [45].

Curricula

The mentors agreed on the need to incorporate a subject on patient safety in the curricula of health care degree programs.

Systems and Mechanisms to Give Trainees a Voice

The mentors made several proposals to facilitate bottom-up communication and the expression of patient safety concerns and initiatives among trainees.

Institutional Risk Management, Patient Safety Reporting Systems, and Incident Analysis

The mentors agreed on the appropriateness of involving trainees in adverse event reporting and analysis to promote awareness of health care risks and the adoption of a clinical practice style committed to patient safety.

Regulations, Guidelines, Protocols, Standards, and Policies

As additional measures, the mentors highlighted the need to reinforce the institutions' patient safety through regulations, protocols, and policies at the institutional (meso) and national (macro) levels.

Supervision and Resources to Support Trainees' Learning Process

Mentors attached particular importance to supervision as a mechanism for training students and residents in psychological safety competencies.

Discussion

Principal Findings

Our study's first objective was to find out whether health care trainees in a pan-European environment acquire, from the point of view of their mentors, competencies in psychological safety during their internships in clinical settings. This study's results show that, according to the mentors, the competency acquisition level is moderate to low, so in their opinion, the training currently offered in the pan-European context does not guarantee the systematic acquisition of the competencies needed to foster a psychological safety climate in health care institutions. A total of 40% (8/20) of the competency elements analyzed presented a low acquisition value, being more pronounced in the psychomotor domain (skills). Such lack of KAS reported by mentors can prevent residents and health care students from engaging in challenging conversations in clinical settings (eg, warning a senior professional that their behavior poses a risk to the patient, communicating concerns and initiatives, or asking questions related to patient safety) or supporting a colleague who is suffering emotionally after their involvement in an event that caused or could have caused harm to a patient.

A second question not initially raised explicitly in our study but that emerged from the first-phase findings and connects them to the second objective concerns the reasons for the low acquisition of psychological safety competencies among pan-European health care trainees. In the opinion of the mentors, the optimal development of these competencies is hampered by deficiencies in formal patient safety content in health care curricula and training pathways, modeling by trainers, trust, cohesion, team spirit (safe people and safe environments), decentralization of the health care institutions' structure, specific patient safety policies, and institutional resources to support the creation of a psychological safety climate and a proactive patient safety culture.

In response to what needs to be done to promote the training and learning of psychological safety competencies, the mentors offered an extensive list of wide-ranging measures and recommendations to address the deficiencies identified. These

proposals ranged from specific practices, methodologies, models, and content for training in psychological safety competencies to higher-level measures related to the organization's structural, strategic, cultural, and environmental aspects.

These findings support a conceptualization of psychological safety competencies based on the integration of purely academic and formative actions with others of an institutional nature aimed at fostering cultural patterns and work climates that encourage the manifestation of these competencies. In their proposals, the mentors emphasized that both pillars are essential for trainees to show optimal performance in psychological safety. In this sense, an exclusively academic approach is doomed to failure as, if the health care environment does not allow for the implementation of what has been learned, competence acquisition will only be possible in the cognitive and affective domains but not the psychomotor one. The framework that we present in this study for measuring competencies in psychological safety is, to our knowledge, the first to specify what a competent trainee in psychological safety would look like, exemplifying not only what they should know and feel (aspects that are not directly observable) but also what they should do and what others can observe to evaluate their competence.

Comparison With Prior Work

The perception of the mentors in our study is congruent with the levels of psychological safety reported by pediatric nurses and residents in the American context (mean of 3.4 points on a scale of 1-5) [46]. They identified the following as the main barriers to a psychological safety climate in the team: difficulties in interpersonal relationships between professionals of different disciplines and statuses, unsatisfactory communication style and frequency, inadequate resolution of disagreements, work overload accompanied by lack of collaboration, and interpersonal disrespect. The mentors in our study addressed some of these issues in their proposal for measures to promote psychological safety competency training.

As our study suggests, psychological safety and patient safety are closely linked elements of the clinical environment and practice. The mentors who participated in this study's second phase related the trainees' low competence in psychological safety to the lack of formal incorporation of patient safety into the curricula of health care degrees. This result is in line with the findings of Sánchez-García et al [36] in the pan-European context, which show that there is still a long way to go in adapting the curricula as half of the nursing schools and 60% of the medical schools analyzed did not cover any topics related to patient safety. In those cases in which the curricula did cover patient safety aspects, interpersonal communication, quality of care, and other elementary aspects were the most widespread topics. The second victim phenomenon was formally present in only 1 of the 206 curricula reviewed.

The relationship between psychological safety and patient safety has been extensively studied. Research with nurses has shown that psychological safety predicts the intention to report safety incidents and a greater willingness to engage in open communication, which, in turn, may lead to higher job

satisfaction, lower turnover intention, and improved patient safety [47,48]. In this line, Dietl et al [25] observed that the positive effect of psychological safety on patient safety is mediated by interpersonal communication in the team. Therefore, not surprisingly, training in communication skills and teamwork was one of the targets for action identified by the mentors who participated in our study.

Other studies have also suggested that this relationship may run in the opposite direction (ie, a positive safety culture in the health care institution may contribute to developing a psychologically safe work climate). Along these lines, O'Donovan and McAuliffe [49] identified the enablers of psychological safety across the individual, team, and organizational levels of health care institutions, including safety culture and continuous improvement. Our mentors provided solutions related to some of these facilitators. On an individual level, participants highlighted the role of mentors and supervisors in fostering professional responsibility among trainees, recognizing them as full team members. This aspect relates at the team level to the factors of leader behavioral integrity and status, hierarchy, and inclusiveness that our mentors recommend fostering by creating shared spaces free of hierarchical differences. For this purpose, Ulmer et al [50] present the "Mistake Of The Week" initiative, which consists of a weekly semistructured conference in which health care staff are encouraged to voluntarily disclose their mistakes and near misses based on 4 pillars of success, namely, exemplification, fixed time slots and clearly defined dynamics, absence of fear of punishment, and trusting atmosphere. This initiative recalls the morbidity and mortality conferences (M&Ms) widely implemented in North America and included in US residency programs. These conferences aim to critically analyze and discuss safety incidents in a safe environment. When these conferences are cross-cutting, they allow for the participation of different institutional agents in the discussion of incidents, including from students and junior staff to senior leaders or administrators. This model increases the likelihood that M&Ms will become a tool for system-wide improvement [51]. Although presented as an opportunity for learning and improving the quality of care, their inappropriate use can also lead to undesirable results [52]. In Europe, although less widespread, M&Ms are present in surgical services, intensive care units, and emergency departments in some countries, such as Germany, France, the Netherlands, and the United Kingdom [53-56]. Although stakeholders value the M&Ms' implementation positively, there remains a lack of objective outcome measures to determine their impact on patient safety and system-wide improvement and some challenges that jeopardize the effectiveness of these conferences [57]. Although expectations are clear (focus on education and quality improvement, lack of blame, being mandatory for residents and attendings, and orientation toward changes in clinical practices), excessive heterogeneity and lack of structure often limit their impact [53,55]. The European experience suggests better results when M&Ms are interprofessional; incorporate a moderator; are supported by a quality committee; are incorporated as part of the Plan, Do, Check, Act cycle; and include the use of validated instruments for collecting data on complications [53,55-57]. As occurs in the case of psychological safety

competency training, clinician engagement, patient safety culture, and organizational governance and leadership are identified as contributors to effective M&Ms [52]. Facilitators regarding peer support and familiarity of the leader and team members are closely related to the proposals of the mentors, who suggested the formal designation of a reference contact for the trainees with whom they can establish a trusting relationship, the creation of positive team dynamics, and peer support in case of an adverse event. Recently, Seys et al [58] proposed an international multidimensional action plan for second victim support structured in five levels: (1) prevention at the individual health care professional and organizational level, (2) self-care of the health care individual and team, (3) support through peers and triage, (4) structured professional support (eg, mental health or specialized support), and (5) clinical support (pharmacological treatment and long-term psychotherapy). The results of the study by Lyman et al [59] with newly graduated nurses reflect well on how individual factors facilitating psychological safety in clinical settings are built on team experience. Thus, the nurses said that their self-confidence was preserved when team members approached mistakes as opportunities for improvement. Finally, O'Donovan and McAuliffe [49] point out that, when a just safety culture exists in institutions, it is possible to create spaces where trainees and new staff find the courage to speak up. The mentors in our study identified the still widespread existence of “*name-blame-shame*” cultures as a critical barrier to acquiring and implementing psychological safety competencies by any health care team member, especially trainees. In this sense, safety culture is understood as a prerequisite for a psychological safety climate, with culture conceptualized as a more stable element and climate as a more situational and local outcome largely dependent on leadership styles and team dynamics that, in turn, are influenced by the organization's values, norms, and behavioral patterns.

In addition to the attenuation of hierarchies and the establishment of high-quality relationships, McClintock and Fainstad [60] consider other aspects as core features of psychologically safe environments, such as a trainee-driven and flexible learning agenda, the absence of formal assessment, and time for debriefing. In the same direction, the mentors in our study recommended merging supervision and competency assessment with daily clinical practice and creating Balint groups [44] as team debriefings.

Apart from the importance of cultural aspects and the work environment already discussed, the acquisition of psychological safety competencies by trainees requires investing efforts and resources in wide-ranging training actions. According to the categories proposed by O'Donovan and McAuliffe [61] in their systematic review of interventions to improve psychological safety, speaking up, and voice behavior, the proposals of the mentors in our study were based on simulations, video presentations, case studies, workshops, forums, and meetings. The mentors particularly stressed the importance of adopting an organization-wide approach to training on psychological safety and patient safety. To have competent trainees, first, it is necessary to ensure that mentors are trained in patient safety, clinical risk management, communication, leadership, and supervisory skills. Minehart et al [62] implemented an

educational intervention to improve the quality of feedback provided by anesthesia teachers. Those who received the training performed better in maintaining a psychologically safe environment and identifying and exploring trainees' performance gaps.

Given this training gap, it is essential to draw up a general plan with specific guidelines to adapt the incorporation of this content into the training plans and specialization pathways of future health care professionals. As the mentors of our study pointed out, more than a decade ago, the World Health Organization [29] published guidelines for incorporating patient safety into curricula. However, national policies have not yet ensured the widespread implementation of these recommendations in pan-European countries, and as of now, only a few isolated universities have taken the initiative on a discretionary basis [36].

Although psychological safety has been widely recognized as part of successive patient safety and quality improvement processes, it remains a relatively unknown construct among many educators and trainees. Consequently, it is often relegated to the hidden curriculum that becomes tangible through mentors' exhibited norms, values, and behaviors. This hidden curriculum can have both positive and negative effects on professional development. The positive effects manifest through empathy, resilience, perseverance, and psychological safety [63]. The way to prevent the negative consequences of the hidden curriculum and enhance psychological safety is to formalize the teaching of those values and norms that support safe practice and a clinical learning environment based on openness, trust, and respect.

This study provides an overview of how psychological safety competencies are being taught in pan-European clinical learning environments from the mentors' perspective. It also highlights the gaps across the board in the competency training of health care trainees. The recommendations proposed by this group seek to reinforce the formal teaching of patient safety and psychological safety in a multifactorial and multilevel manner, including contextual, attitudinal, and educational elements. Psychological safety is fundamental to achieving learning health care organizations and functions as an enabler of the ability of the system and its teams to remain in a continuous improvement cycle that contributes to safer clinical environments for patients [49]. Therefore, efforts should be synergistically directed toward the simultaneous and bidirectional improvement of patient safety and psychological safety. This synergy is already envisaged in the World Health Organization curriculum guide [29] and Global Patient Safety Action Plan 2021 to 2030 [7], in which preserving the psychological safety of health care professionals by preventing harm to their well-being (eg, burnout) is linked to goal 3 of the United Nations Sustainable Development Goals. Furthermore, fostering psychological safety (eg, speaking up and stopping the line) is considered an enabling competency in the Canadian Patient Safety Institute's proposed framework [64] for making patient safety a reality in health care institutions. Along these lines, the Institute for Healthcare Improvement has been working for decades on improving patient safety with a holistic approach, making a wide range of tools, training, and documentation available to health care institutions and

professionals. One of the most noteworthy initiatives is its Certified Professional in Patient Safety credential, which establishes core standards for certifying a proficiency level of professionals in patient safety [65].

The mentors' proposals in this study may be helpful to materialize in concrete actions the global solution that this problem needs. Some of these interventions have shown improvements in psychological safety, speaking up, and voice behavior; however, longitudinal and multifaceted studies to determine their effectiveness are still required [61]. On the other hand, the items of the ad hoc questionnaire used in the first phase of this study can serve as a prescriptive proposal of the KAS to be trained in residents and students for the development of psychological safety competencies and also as an instrument to assess their degree of acquisition.

Our study adds to previous research that supports that acquiring psychological safety and patient safety competencies requires a global and integrated effort that stems from the coordinated involvement of academia and the health care system and extends beyond merely training actions [48,50,61]. Educating those still in the training process on psychological safety means tackling the problem from the ground up with a commitment to the future. It is important to remember that trainees are not solely responsible for creating a psychological safety climate, at least not initially. However, they can still have a significant impact as a driving force for change. The synergistic combination of training and structural measures at the individual, team, and organizational (culture) levels is the key to a psychologically safe environment in clinical settings [48].

Limitations

Despite the merits of this study, it is important to acknowledge a few limitations. Study participants were recruited through convenience sampling. They were selected by national coordinators who are members of the European ERNST Consortium, so their sensitivity to patient safety and psychological safety topics may be higher than that of the average health care trainee mentor in the pan-European context. Therefore, the sample may not have been representative of the study population. Most of the study participants (129/173, 74.6%) were women. Although this large gender discrepancy in the respondent distribution might suggest a possible representation bias, according to data from the European Commission, 78% of health care workers in the third quarter of 2020 were female [66]. Thus, our sample reflects the current picture as far as gender distribution is concerned. Similarly, there may have been discrepancies in how mentors understood psychological safety or their level of familiarity with the topic. On the other hand, we did not control for possible differences between countries in curricula or the structure and functioning of the academic and health care systems. When generalizing these results, it is necessary to consider the impact of international accreditations on medical programs that include curriculum elements focused on patient safety. These aspects may have affected the mentors' experience and familiarity with patient safety, psychological safety, and the second victim phenomenon. For some participants in this study's first phase, the questionnaire items were too specific, which indicated

difficulty in discriminating between the core components of competencies (KAS) and may have affected the quality of the responses. In the second phase, the response rate dropped drastically, and only 55% (6/11) of the original countries participated. To prevent the representativeness of the results from being affected by experimental mortality, only those countries that ensured the participation of at least 5 mentors were encouraged to be involved in the second phase of this study. Furthermore, the higher productivity of ideas in the first question of the final survey may be because participants were more familiar with the communication aspects, whereas the issue of second victims and initiatives to address it are less known. Alternatively, there may have been a demotivation effect that caused lower productivity in the later questions. As for the study population, the choice of mentors, although justified, only offers a partial view of the level of acquisition of psychological safety competencies by health care trainees. The vision of the students and residents, who are the protagonists of the learning process, may differ, and future studies should directly survey this group. Finally, although the study offers an extensive and exhaustive list of actions to improve psychological safety and patient safety in clinical settings, the proposal was not prioritized or ordered sequentially, so centers wishing to improve these aspects may find it challenging to decide where to start. The answer to this question can be affected by multiple secondary issues such as resource availability, leadership involvement, or facility and staff resistance. While cultural change at the institutional level is essential to ensure psychologically safe clinical environments, changing values and beliefs takes time and may be more effectively achieved through concrete actions and behavioral adjustments even if these are initially short range. In any case, future research should address prioritizing actions and establishing indicators and compliance standards involving the different stakeholders.

Conclusions

To our knowledge, this study is the first to address how psychological safety competencies are being taught to future health care professionals from the point of view of mentors and with a pan-European scope. Our study results showed a medium to low level of acquisition of psychological safety competencies among health care trainees in a pan-European setting as perceived by their mentors. According to this group, the solution to this competency gap should be comprehensive and consider the following aspects: training in communication skills and patient safety, environmental conditioning factors (safety culture and work climate) and individual attitudes, a reference person for trainees, formal incorporation into the curricula of health care degree programs and specialization pathways, specific systems and mechanisms to give trainees a voice, institutional risk management, regulations, guidelines and standards, supervision, and resources to support trainees.

The results of our study emphasize the importance of taking multiple actions to establish psychological safety in clinical environments. Academia should seek to formally teach psychological safety competencies during formal training by incorporating them into the curriculum and using innovative teaching methodologies based on technological tools and solutions. It should also strengthen communication and

coordination mechanisms with the clinical institutions where trainees perform their internships and maintain a contact person in academia to assist them during the process and supervise their experience. Health care institutions, for their part, should actively promote a just safety culture free of blame and punishment by providing training in patient safety and psychological safety to all members of their staff with the commitment and direct involvement of the management. Mentors should receive specialized education to train trainees in patient safety and promote psychological safety behaviors such as speaking up. They should also supervise the development of these competencies in the trainees under their charge and be their reference person. As for trainees, they should develop from the beginning of their careers a solid commitment

to patient safety and a willingness to speak openly about their patient safety concerns and initiatives and stay in a cycle of learning and improvement. They must learn that this commitment is not to themselves but to patients and the delivery of quality care.

The proposal for measures described in this study aims to facilitate the translation of international guidelines into practice and clinical settings in the pan-European context. Further research on the combined effectiveness of these measures is needed to achieve competent trainees and health care professionals in psychological safety and patient safety. Psychological safety is critical in creating learning health care organizations and safer clinical environments for patients.

Acknowledgments

The authors thank all health care trainee mentors who contributed to the study, without whom this research would not have been feasible. This article is based upon work from COST Action, TheERNSTGroup, CA19113, supported by COST (European Cooperation in Science and Technology). During the conduct of this study, JJM enjoyed a research activity intensification contract funded by the Carlos III Health Institute (reference INT22/00012).

Authors' Contributions

JJM conceived and designed the study, and IC coordinated it. IC and JJM developed the questionnaire and survey for data collection, which were revised and improved by the rest of the authors. IS, IB, VK, SGP, BK, AJ, DJ, ST SCB, ES, AMG, KP, RS, PS, and MO acted as local coordinators in their respective countries and were responsible for the processes of translation and back translation of the instruments into their native languages, study dissemination, and recruitment of participants. IC and JJM conducted the data analysis and prepared a manuscript draft. IS, IB, VK, SGP, BK, AJ, DJ, ST SCB, ES, AMG, KP, RS, PS, and MO revised and improved the manuscript. All authors read and approved the submitted version.

Abstract

Background: The 2024 Nephrology fellowship match data show the declining interest in nephrology in the United States, with an 11% drop in candidates and a mere 66% (321/488) of positions filled.

Objective: The study aims to discern the factors influencing this trend using ChatGPT, a leading chatbot model, for insights into the comparative appeal of nephrology versus other internal medicine specialties.

Methods: Using the GPT-4 model, the study compared nephrology with 13 other internal medicine specialties, evaluating each on 7 criteria including intellectual complexity, work-life balance, procedural involvement, research opportunities, patient relationships, career demand, and financial compensation. Each criterion was assigned scores from 1 to 10, with the cumulative score determining the ranking. The approach included counteracting potential bias by instructing GPT-4 to favor other specialties over nephrology in reverse scenarios.

Results: GPT-4 ranked nephrology only above sleep medicine. While nephrology scored higher than hospice and palliative medicine, it fell short in key criteria such as work-life balance, patient relationships, and career demand. When examining the percentage of filled positions in the 2024 appointment year match, nephrology's filled rate was 66%, only higher than the 45% (155/348) filled rate of geriatric medicine. Nephrology's score decreased by 4% - 14% in 5 criteria including intellectual challenge and complexity, procedural involvement, career opportunity and demand, research and academic opportunities, and financial compensation.

Conclusions: ChatGPT does not favor nephrology over most internal medicine specialties, highlighting its diminishing appeal as a career choice. This trend raises significant concerns, especially considering the overall physician shortage, and prompts a reevaluation of factors affecting specialty choice among medical residents.

Introduction

The National Resident Matching Program released the 2024 Nephrology fellowship match data on November 29, 2023 [1], revealing a significant downturn in the specialty's appeal. Only 321 candidates secured nephrology positions, marking an 11% decrease from the prior year, leaving just more than half of the 180 nephrology programs filled. The trend is more obvious when considering that of the 488 spots available, a mere 66% (321/488) were taken [2], underscoring a persistent wane in the candidate-to-position ratio from 1.3 in 2011 to around 0.6 in recent years [3]. Alarming, only a small fraction of these roles

were filled by US MD graduates, ranging from 15% to 26% between 2019 and 2024 [1,4].

This disinterest in nephrology is particularly concerning given the escalating shortage of nephrologists worldwide [5] and the burgeoning prevalence of chronic kidney conditions [6]. It is predicted that the United States alone may face a deficit of more than 139,000 physicians by 2030 [7], a scenario that casts a long shadow over the future of nephrology care and its sustainability. The publication of annual match data consistently amplifies these worries, leading to persistent debates [3,8-11]. Nonetheless, the underlying causes of this critical issue are still largely unexamined.

In this context, there is a growing curiosity about the role of advanced artificial intelligence (AI) tools such as ChatGPT in reshaping medical education and practice [12-15]. This study uses ChatGPT to analyze and juxtapose nephrology with other internal medicine specialties, aiming to illuminate the influences shaping medical career choices today and provide insights into decision-making in the evolving landscape of medical career planning.

Methods

Specialties Examined in This Study

Within the realm of internal medicine, there are 17 fellowship specialties other than Nephrology [4]. There are 4 advanced fellowships such as Adult Congenital Heart Disease, Advanced Heart Failure & Transplant Cardiology, Clinical Cardiac Electrophysiology, and Interventional Pulmonology, which are typically not options for Internal Medicine residents or internists who might consider a nephrology fellowship. Hence, these 4 advanced specialties were not included in our study.

Study Design

GPT-4, a sophisticated iteration of ChatGPT, was prompted to provide insights into choosing between nephrology and other 13 internal medicine specialties. To examine that the ChatGPT's response did not depend on the sequence of fellowships presented in the query, we also asked ChatGPT to choose between other specialties and nephrology in reverse scenarios.

The prompts used in this study have been provided in (Multimedia Appendix 1) and are presented in screenshot format. Specifically, we asked:

If you need to choose nephrology or [insert specialty name] fellowship, which one do you choose, you can describe but at the end you need choose one; each aspect comparisons may choose scores of 1 - 10.

For the reverse scenarios, we used:

If you need to choose [insert specialty name] or nephrology fellowship, which one do you choose, you can describe but at the end you need choose one; each aspect comparisons may choose scores of 1 - 10.

ChatGPT's responses are also presented in screenshot format. To prevent our content from being used to train the models, we disabled the "Data controls—Improve the model for everyone" option in the setting of ChatGPT. To minimize potential biases from the AI's memory of prior interactions and ensure the independence of each prompt and response, we started each query in a new chat session.

Evaluation

In evaluating the decline in interest in Nephrology, we used 7 criteria identified independently by ChatGPT. These criteria include (1) intellectual challenge and complexity, (2) work-life balance, (3) procedural involvement, (4) research and academic opportunities, (5) patient relationships and continuity of care, (6) career opportunity and demand, and (7) financial compensation. These factors were chosen based on their relevance and applicability to fellowship selection in the real world. While these criteria are consistent with those used in the analysis of other specialties, it is important to note that they were not established by the authors themselves.

Each criterion was rated on a scale from 1 to 10. We did not train ChatGPT on how to score each criterion, such as defining what constitutes a 1/10 or a 9/10. We did not use any weighting anchors in the ChatGPT scoring process.

We calculated a cumulative score for each specialty based on the 7 criteria, resulting in a maximum possible score of 70 per specialty. The comparative ratio of nephrology's score in each criterion over other specialties was calculated. Nephrology's score in each criterion was also compared with the average score of all other specialties.

Ethical Considerations

This study does not include human participants (no human subjects experimentation or intervention was conducted) and so does not require institutional review board approval.

Results

ChatGPT favored only nephrology over a single specialty, sleep medicine (Table 1). Despite accruing a total score surpassing that of hospice and palliative medicine, ChatGPT opted for palliative medicine instead (Figure 1). Analysis of the 2024 appointment year match data revealed that 66% of nephrology positions were filled, a rate that exceeded only that of geriatric medicine, which stood at 45% (155/348) (Figure 1).

Upon examining specific parameters, nephrology ranked comparatively lower in terms of career demand, research opportunities, and financial remuneration than most other specialties (Figure 2). Specifically, nephrology experienced a decline ranging from 4% to 14% in 5 principal domains: intellectual challenge, procedural involvement, career demand, research prospects, and financial compensation. Nonetheless, nephrology exhibited a relative improvement, with a 7% increase noted in both the aspects of work-life balance and the development of patient relationships (Figure 3).

The same scores and choices were observed when we asked GPT-4 to evaluate other specialties over nephrology in reverse scenarios (Multimedia Appendix 1).

Table . Scale of nephrology and 13 other specialties on 7 criteria.

	Intellectual complexity	Work-life balance	Procedural involvement	Research and academic opportunities	Patient relationships and continuity of care	Career opportunity and demand	Financial compensation	Total score	ChatGPT's choice over Nephrology ^a
Nephrology	8	8	6	7	8	7	6	50	N/A ^b
Geriatric medicine	8	9	4	7	9	9	6	52	Yes
Infectious disease	9	8	4	9	7	8	6	51	Yes
Hospice and palliative medicine	7	9	4	6	9	8	6	49	Yes
Sleep medicine	7	9	4	6	7	6	6	45	No
Endocrinology, diabetes, and metabolism	8	9	4	8	8	8	6	51	Yes
Pulmonary Disease	8	7	8	8	7	8	7	53	Yes
Critical care medicine	9	6	9	8	5	9	8	54	Yes

Average score ^c	8.5	7.2	6.8	8.0	7.5	7.9	7.2	52.7	N/A

^aChatGPT's preference for Nephrology compared with other Internal Medicine specialties when it comes to fellowship selection.

^bN/A: not applicable.

^cThe average score of individual criterion across all other 13 specialties.

Figure 1. ChatGPT's score and the fellowship position fill rates. Seven criteria for each specialty were assessed by ChatGPT. Each criterion was scored on a scale from 1 to 10, resulting in a maximum possible score of 70. The total score assigned by ChatGPT to each specialty, along with its fellowship recommendations, is presented using diamonds. Nephrology's score (red diamond) surpassed only those of sleep medicine and hospice and palliative medicine (green diamond). ChatGPT recommended nephrology as a fellowship option only when compared with sleep medicine. ChatGPT's score and choice mainly align with the rank of positions filled in 2024 reported by the National Resident Matching Program (gray bar). The fill rate for nephrology fellowships (321/488, 65.8%) was only higher than that of geriatric medicine (155/348, 44.5%). AY: appointment year.

Figure 2. Comparisons of nephrology with other specialties in each criterion. The comparative ratio of nephrology to other specialties in terms of 7 criteria. color label for the ratio of nephrology to other specialties: black <1, white=1, and gray>1.

Figure 3. Comparisons of nephrology with the average score of other specialties in each criterion. Comparisons of the scale of various criteria in nephrology against the average scale for the other 13 specialties. Change in nephrology relative to other specialties shows the reduction in the percentage for nephrology relative to the average scale of the other 13 specialties.

Discussion

Principal Findings

The results underscore a diminished appeal in selecting nephrology as a career path, evident even in the preferences of sophisticated AI models such as ChatGPT when simulating fellowship choices. The factors contributing to this waning interest are likely diverse and personal. However, the significance of this trend cannot be overlooked, particularly in the context of the prevailing physician shortage.

Notably, the nephrology fellowship achieved a total score of 50, marginally surpassing hospice and palliative medicine, which scored 49, and sleep medicine at 45, among the 13 internal medicine specialties. However, ChatGPT recommended only nephrology over sleep medicine. Despite nephrology's higher overall score, ChatGPT favored hospice and palliative medicine due to its superior work-life balance, patient relationships, and career demand—especially pertinent given the aging population and increasing need for quality end-of-life care (Textbox 1). Nevertheless, ChatGPT noted that nephrology might be more suitable for those with a preference for technical aspects such as fluid and electrolyte management and renal pathophysiology. The lower score in intellectual complexity

and procedural involvement for hospice and palliative medicine may have also influenced ChatGPT's decision.

In fact, the reality for nephrologists is increasingly challenging. They face a growing workload and a diminishing control over their schedules, a situation exacerbated by the rising incidence of kidney diseases, especially chronic kidney disease and end-stage kidney disease [6]. The demands of the profession are extensive, involving long outpatient waitlists, demanding inpatient services, unpredictable night calls, and frequent visits to multiple dialysis units. These responsibilities, particularly the travel between units, consume significant time and effort [16]. In addition to their clinical duties, the 2023 Medscape Nephrologist Compensation Report states that nephrologists need to devote an average of 18.1 hours per week to support tasks such as paperwork and administration [17].

In terms of intellectual rigor, nephrology is on par with other specialties (8 vs 8.5). However, a national survey among internal medicine residents revealed that the field's broad scope and the complexity of kidney-related pathologies and physiologies deter many potential entrants [18-20]. The patients under nephrological care often present some of the most medically complex cases, marked by a plethora of comorbidities, intricate medication regimes, and a higher mortality risk. Despite these challenges, some find the diverse clinical conditions and the vast scope of practice in nephrology appealing [21,22]. Studies indicate that intellectual curiosity about kidney-related issues is a primary motivator for some choosing this career path [22]. Factors influencing this choice include a passion for the subject, a favorable work-life balance, mentorship availability, and exposure to the field [23]. However, exposure to nephrology during medical training is limited, with only a minority experiencing a rotation in this specialty during their clinical years, compared with a higher percentage during residency [18]. This limited exposure might be due to the complex nature of renal care, a relative scarcity of hands-on procedures compared with other specialties, and a lack of visible role models or mentors [24]. These factors contribute to the lower proportion of US MD graduates pursuing nephrology [4], highlighting a significant gap in early medical education and potential areas for enhancement in the field's approach to attracting and nurturing future talent.

Nephrology lags behind other medical specialties in financial reward, demand, and research prospects, impacting its appeal. It shows a 16% lower preference score in financial compensation, underscoring concerns highlighted in the 2023 Medscape Nephrologist Compensation Report. Nephrologists' average annual income falls below the median for all specialties [17]. In addition, the report indicates that nephrologists are in the bottom third of all specialties regarding how often they feel fairly compensated for their talents and time. In last year's report, nephrologists were ranked in the bottom spot. Furthermore, a survey among internal medicine residents reveals that the main obstacles deterring them from nephrology also include perceived financial inadequacy, intellectual rigor, work-life balance, and the potential to positively influence patient outcomes [18]. We recognize that financial considerations are multifaceted and significantly influenced by regional differences. Factors such as salary potential, cost of

living, educational costs, and regional demand play crucial roles in deciding to choose nephrology as a specialty. Our study aimed to provide a general perspective, but we acknowledge the critical impact of regional financial factors on this decision-making process.

Recently, the perception of limited advancements and new therapeutic developments in nephrology has been recognized as a significant deterrent for choosing nephrology among internal medicine residents in the United States [25]. Despite ChatGPT scoring nephrology's career demand lower than the average for other specialties, there is, in reality, an increasing demand in the field of nephrology. This rise is observed not just in terms of patient needs but also in career opportunities within the specialty. This increase is driven by several factors, including the rising prevalence of chronic kidney disease, aging populations, and the associated complexities in managing these conditions [6]. As the number of individuals requiring specialized kidney care escalates, so does the need for skilled nephrologists to provide comprehensive and effective treatment. This surge in patient demand is creating more career opportunities within nephrology, indicating a promising future for those entering the field.

To address nephrology fellowship underfill rates, the American Society of Nephrology implemented measures such as the All-In policy, STARS (Students and Residents), and TREKS (Tutored Research Education for Kidney Scholars) programs [3,10]. ChatGPT suggests promoting nephrology's significance; enhancing training; fostering research; incorporating technology; encouraging collaboration, mentorship, and career growth; advocating work-life balance; increasing awareness; ensuring competitive pay; and broadening subspecialty choices.

Our study has certain constraints. It is important to acknowledge that the criteria for ranking established by ChatGPT are not fully transparent. While the criteria seem reasonable and applicable to real-world fellowship selection, the exact methodology and rationale behind their selection remain partially opaque. The overall score differences between nephrology and the 13 other specialties are relatively small. This limitation should be considered when interpreting the findings of our study. In addition, we did not use weighting anchors in the ChatGPT scoring process, recognizing that the importance of each criterion may vary. To mitigate hallucinations, a major concern in ChatGPT's responses, we implemented several measures such as asking the same questions in reverse scenarios, preventing the content from being used to train the models, and starting each query in a new chat session to minimize potential biases from the AI's memory of prior interactions. While these measures reduce the likelihood of hallucinations, we cannot completely exclude their possibility. It remains uncertain whether ChatGPT's choices truly reflect residents' sentiments. Addressing whether this issue originates from biases in perception or from broader systemic problems is crucial. Moreover, ChatGPT's scores and choices were consistent when the same questions were presented in reverse scenarios. However, previous studies, including our own [26], have shown varying levels of repeatability in ChatGPT's responses, indicating that repeatability might depend on the nature and type of the question. Finally, although we obtained

consistent results using another ChatGPT account with the same prompts, we cannot entirely exclude the possibility that different ChatGPT accounts might produce varying results due to differences in settings, usage habits, repeatability, and other unknown factors. Further research is needed to address this issue.

Textbox 1. ChatGPT's conclusion on deciding to pursue a fellowship in Hospice and Palliative Medicine.

Conclusion Based on this analysis, I would recommend choosing a Hospice and Palliative Medicine fellowship. It scores higher in work-life balance, patient relationships, and career demand, particularly relevant in the context of an aging population and the increasing need for quality end-of-life care. This choice should align with personal interests and career goals, especially if one is drawn to patient-centered, holistic care. If a preference lies in more technical aspects like fluid and electrolyte management and renal pathophysiology, then Nephrology might be more suitable.

Conclusions

ChatGPT, as an AI model, shows no bias toward nephrology over other internal medicine branches in fellowship choices, highlighting a broader decline in interest for this specialty. This trend is driven by factors such as financial incentives, career demands, and opportunities for research, which significantly

influence specialty decisions. Moreover, intellectual stimulation and work-life balance are key factors. This issue, whether due to perceived or real barriers, demands immediate action in light of the physician shortage. Addressing these deterrents is essential to boost nephrology's attractiveness and fulfill the increasing demand for nephrologists, thereby maintaining exemplary health care standards.

Conflicts of Interest

None declared.

Multimedia Appendix 1

Abstract

Background: Massive open online courses (MOOCs) are increasingly used to educate health care workers during public health emergencies. In early 2020, the World Health Organization (WHO) developed a series of MOOCs for COVID-19, introducing the disease and strategies to control its outbreak, with 6 courses specifically targeting health care workers as learners. In 2020, Stanford University also launched a MOOC designed to deliver accurate and timely education on COVID-19, equipping health care workers across the globe to provide health care safely and effectively to patients with the novel infectious disease. Although the use of MOOCs for just-in-time training has expanded during the pandemic, evidence is limited regarding the factors motivating health care workers to enroll in and complete courses, particularly in low-income countries (LICs) and lower-middle-income countries (LMICs).

Objective: This study seeks to gain insights on the characteristics and motivations of learners turning to MOOCs for just-in-time training, to provide evidence that can better inform MOOC design to meet the needs of health care workers. We examine data from learners in 1 Stanford University and 6 WHO COVID-19 courses to identify (1) the characteristics of health care workers completing the courses and (2) the factors motivating them to enroll.

Methods: We analyze (1) course registration data of the 49,098 health care workers who completed the 7 focal courses and (2) survey responses from 6272 course completers. The survey asked respondents to rank their motivations for enrollment and share feedback about their learning experience. We use descriptive statistics to compare responses by health care profession and by World Bank country income classification.

Results: Health care workers completed the focal courses from all regions of the world, with nearly one-third (14,159/49,098, 28.84%) practicing in LICs and LMICs. Survey data revealed a diverse range of professional roles among the learners, including physicians (2171/6272, 34.61%); nurses (1599/6272, 25.49%); and other health care professionals such as allied health professionals, community health workers, paramedics, and pharmacists (2502/6272, 39.89%). Across all health care professions, the primary motivation to enroll was for personal learning to improve clinical practice. Continuing education credit was also an important motivator, particularly for nonphysicians and learners in LICs and LMICs. Course cost (3423/6272, 54.58%) and certification (4238/6272, 67.57%) were also important to a majority of learners.

Conclusions: Our results demonstrate that a diverse range of health care professionals accessed MOOCs for just-in-time training during a public health emergency. Although all health care workers were motivated to improve their clinical practice, different factors were influential across professions and locations. These factors should be considered in MOOC design to meet the needs of health care workers, particularly those in lower-resource settings where alternative avenues for training may be limited.

Introduction

During the COVID-19 pandemic, massive open online courses (MOOCs) emerged as an invaluable source of training for health care workers globally [1-4]. Studies have demonstrated MOOCs' effectiveness in facilitating learning among practicing health care professionals [5,6], and their capability to deliver content rapidly and flexibly has established e-learning as a preferred method for transferring clinical skills and knowledge [6]. Their broad applicability, accessibility, and cost-effectiveness make MOOCs particularly appealing for continuing education (CE) requirements, also known as continuing medical education [5,7,8]. Consequently, MOOCs have been used for skill development and retention, competency assessment, and lifelong learning [9]. In low-income countries (LICs) and lower-middle-income countries (LMICs), MOOCs potentially increase access to essential health education content and reduce training costs for health care professionals [5,10,11].

Despite the increasing data on general MOOC enrollee motivations [12-15], there remains a significant gap concerning the specific factors motivating practicing health care professionals. Understanding the motivations of health care workers in LICs and LMICs to enroll in and complete health care-related MOOCs is crucial, as engagement and completion rates among this group are notably low [16-18]. By identifying what drives their participation, we can enhance MOOC design and dissemination, particularly for just-in-time learning initiatives during health emergencies—a time when organizations such as the World Health Organization (WHO) and national governments increasingly rely on MOOCs to rapidly disseminate critical information to health care workers.

This study aims to uncover the characteristics and motivations of health care professionals who enrolled in health care-related MOOCs during the COVID-19 pandemic—a period marked by an urgent need to rapidly disseminate critical health care information. Research indicates several potential reasons for enrolling in MOOCs. As a teaching model, MOOCs support adult learning principles targeting self-directed learners [17]. The self-directed learning model allows individuals to guide their learning process, establish their learning objectives, engage in individualized learning strategies, and manage their time based on their interests while still receiving access to curated content [17]. It can be presumed that learner motivations for engaging in MOOCs differ from those in traditional brick-and-mortar educational venues [19]. Prior studies suggest that primary intrinsic motivations for MOOC enrollment include personal interest and knowledge acquisition [12], whereas extrinsic motivations often involve certification and professional development opportunities [17]. However, the specific motivations driving health care workers, particularly those in LICs and LMICs, remain underexplored.

Although recent studies, such as Garrido et al [20] and a scoping review on MOOCs for health care worker education in low- and middle-income countries [21], have begun to explore the

use of MOOCs for professional and workforce development, these insights predominantly focus on broad educational outcomes and employment advancements. Such research underscores the potential of MOOCs to enhance skill sets and career opportunities, highlighting the alignment of MOOC coursework with job market needs and professional certifications. However, these studies generally do not delve deeply into the specific intrinsic motivations of health care workers in LICs and LMICs to enroll in MOOCs, especially during health emergencies. In fact, in 2023, the WHO commissioned 3 systematic reviews of the literature to support guidelines for building just-in-time training during public health emergencies, finding a gap in the literature regarding the motivations of learners enrolling in relevant online courses, particularly in LMICs (WHO, unpublished data, 2023). Our study seeks to fill this void by examining the unique motivations behind MOOC enrollment, particularly during the unprecedented global crisis triggered by the COVID-19 pandemic.

This study contributes uniquely to the literature by investigating the key motivations for health care workers to enroll in MOOCs, with a special emphasis on provider type and country income level during a global health crisis. These insights are vital as learners in LICs and LMICs face challenges such as linguistic and cultural barriers, limited access to digital technology, low-bandwidth connectivity, infrastructure constraints, and limited digital literacy [5,10]. By understanding what motivates learners in these settings, our study provides foundational knowledge that can inform more thoughtful and effective MOOC design and recruitment strategies, ultimately improving knowledge transmission, learning outcomes, and course completion rates in regions with critical needs for health care worker training. This broad impact underscores the potential of targeted online education strategies to significantly enhance global health responses.

Methods

Study Design

In this study, we present a descriptive analysis of MOOC learner data to identify the characteristics and motivations of health care workers enrolled in 7 MOOCs designed to serve as just-in-time education for clinically practicing health care workers during the COVID-19 pandemic. We examine two sources of data: (1) course enrollment data (n=49,098) collected during course registration and (2) follow-up survey data (n=6272) collected from course completers.

Course Descriptions

In Table 1, we detail the 7 focal courses examined in this study. We selected 6 courses developed by the WHO in early 2020 to respond to the growing COVID-19 crisis. These courses were launched on the OpenWHO online platform, which serves as the WHO's learning hub for health emergencies. These courses build on the WHO's initial introductory COVID-19 course, which had 232,890 enrollments across 13 published languages by the end of March 2020 and provided general information

about the disease for a broad audience [22]. The 6 WHO courses were selected out of all 43 COVID-19 courses offered on the OpenWHO platform due to their greater content relevance to practicing health care workers. The 6 MOOCs focused on introducing health care workers to the novel disease and providing them with strategies to control its outbreak. Three courses were designed to provide health care workers with the

basic tools needed to combat the pandemic and protect themselves from infection when providing health care services. Another 3 courses were designed to provide health care workers with an overview of the COVID-19 disease and provide learners with specific clinical strategies to address the pandemic. The courses were initially published in English and then rapidly translated into over 19 languages in the subsequent 2 months.

Table . Course descriptions.

Source and course title	Description	Languages	Date launched	Course duration	Enrolled learners, n
Stanford University					
COVID-19 Training for Healthcare Workers	This course is designed for health care professionals. It provides an evidence-based approach to life-saving techniques for treating critically ill patients with COVID-19.	English, Hindi, Portuguese, French, and Spanish	July 17, 2020	8 h	101,734
OpenWHO					
Hand Hygiene	This course is designed to summarize the WHO ^a guidelines on hand hygiene, associated tools, and ideas for effective implementation. The WHO guidelines support hand hygiene promotion and improvement in health care facilities worldwide.	Arabic, Chinese, Dutch, English, French, Macedonian, Portuguese, Russian, Shqip, Sinhalese, Somali, Spanish, Tamil, Tetum, and Turkish	June 3, 2020	1 h	274,116
Personal Protective Equipment	The course is a guide for health care workers involved in patient care activities in a health care setting. It aims to show the type of personal protective equipment needed to correctly protect oneself.	Albanian, Arabic, Chinese, Dutch, English, French, Kazakh, Macedonian, Portuguese, Russian, Sinhalese, Somali, Spanish, Tamil, Tetum, Thai, and Turkish	April 15, 2020	15 min	346,200
Occupational Health and Safety	This course is for health workers, incident managers, supervisors, and administrators who make policies and protocols for their health facilities. The WHO recommends a combination of measures for infection prevention and control, occupational health and safety, and psychosocial support.	Dutch, English, Indonesian, Macedonian, Portuguese, Spanish, and Swahili	August 30, 2020	1 h	85,504

Source and course title	Description	Languages	Date launched	Course duration	Enrolled learners, n
Clinical Management: Patient Rehabilitation	The course is devoted to the rehabilitation of patients with COVID-19 by addressing needs of patients recovering from COVID-19, including patients with cognitive impairment, physical deconditioning and weakness, respiratory impairment, swallow impairment, and communication impairment, as well as techniques for rehabilitation.	Chinese, English, French, Macedonian, Russian, and Shqip	January 13, 2021	3 h	22,704
Clinical Management: General Considerations	This course gives background on the pandemic, discusses facility operations, and addresses COVID-19 pandemic preparedness at all levels of health care provision. It also discusses ethical issues arising during COVID-19 care.	English, Indonesian, Macedonian, and Shqip	October 22, 2020	3 h	31,972
Clinical Management: Acutely Ill Patients	Designed to prepare and support health providers as they provide emergency care to seriously ill patients with COVID-19, including a systematic approach via the WHO and ICRC ^b Basic Emergency Care course content.	English, Somali, and Spanish	May 5, 2021	6 h	14,190

^aWHO: World Health Organization.

^bICRC: International Committee of the Red Cross.

To broaden the reach of learners in the study, we also included a Stanford University MOOC launched in August 2020 to equip health care workers with timely in-service education, to improve their ability to safely and effectively treat patients with the novel disease [23]. The Stanford MOOC was launched on both the Coursera and edX platforms, 2 US-based MOOC providers founded in 2012 that routinely provide university-level courses on various topics including health. As of November 2020, nearly 900 health-related courses were available on the Coursera platform alone [24]. The Stanford course was first developed in English and then translated into 4 additional languages.

The courses were promoted via their respective institutional networks. No paid advertisements were published. The Stanford

course was promoted starting in July 2020, with emails sent to over 100,000 Coursera listserve subscribers. The course was also promoted through a variety of Stanford-affiliated social media channels and online publications, YouTube's spotlight channel, and direct sharing with a network of health education collaborators throughout the world by Stanford team members. The WHO courses were promoted as each course launched on the WHO website, the OpenWHO platform, and through WHO newsletters and mailing lists.

Data Collection

Figure 1 describes the flow diagram for study participation and data collection. We obtained data on all course enrollees via the

respective course platforms (OpenWHO for WHO courses and edX and Coursera for the Stanford course). Course completion was defined by course developers and identified through backend data available from the course platforms. Learner background data were collected via the respective platforms at the time of course registration and included the learners' age, gender, geographic location, and profession. The health care worker profession category included those identifying as being employed in the following professions: allopathic medicine

(including physicians and physician assistants); traditional medicine; nursing (including nurses, nurse practitioners, nurse midwives, nursing instructors, and certified nursing assistants); allied health (including physical therapy, occupational therapy, speech pathology, medical assistants, and home health aides); community health; emergency medical services (including paramedics and emergency medical technicians); and pharmacy (including pharmacists and pharmacy technicians).

Figure 1. Flow diagram for study participation. The number of enrollees, course completers, and survey completers is shown for all learners and health care workers. The survey completer sample (shaded in gray) is the focal sample for this study. Health care workers included those who identified as being employed as health care professionals at enrollment and in the follow-up survey. Health care professions included the following: allied health; community health; nursing (including nurses, nurse practitioners, nurse midwives, nursing instructors, and certified nursing assistants); physician assistants; paramedics and emergency medical technicians; pharmacy; physicians; and traditional medicine.

We invited all enrollees who had completed the course they were enrolled in to complete an online survey ([Multimedia Appendix 1](#)) on the respective course platforms. To recruit WHO course learners, we sent 3 survey invitations to the email addresses provided by learners at the time of registration and through the OpenWHO automated course message. To recruit participants from the Stanford course, we sent 3 requests via Coursera and edX email announcements. The survey window was open from December 11, 2020, to September 28, 2021. The survey completion rate was 3.98% (12,170/305,849) among all course completers and 12.77% (6272/49,098) among health care workers completing the courses.

The 23-question survey collected information on learners' personal and professional demographics, information about their professional experience with COVID-19, and their ability to connect with physicians in their daily work. Respondents were asked to rank 6 possible motivations for course enrollment in the order of importance to them. Additionally, respondents were asked about their use of course certificates, including whether their employer required a certificate, if they planned to provide it to their employer, or if they planned to use it for CE credit. Finally, respondents were asked about the cost of MOOCs and how it impacted their decision to enroll in the course. All study authors were involved in the development of the survey. Questions were reviewed by all authors to include appropriate vocabulary, inclusive of globally used terminology. The survey was not adapted directly from any other source; however, the motivations included were drawn from anecdotal course feedback and the extant literature discussing motivations for MOOC enrollment.

Statistical Analysis

Because of the study focus, we limited our analytic sample to health care workers exclusively. To investigate the generalizability of our survey sample, we summarized the characteristics of all health care workers completing the courses (n=49,098) and health care workers completing the survey (n=6272) using descriptive statistics (mean, SD, and response rates). To compare the proportion of learners by characteristic between course completers and survey completers, we used the Pearson χ^2 test. To examine ranked enrollment motivators and compare across learner subgroups, we conducted multiple

comparison tests using 1-way ANOVA, comparing the mean rank of motivations (dependent variable) by learner characteristics. The independent variables compared included differences by occupation (physicians vs nurses and physicians vs other health professionals) and country income classification (LICs and LMICs vs upper-middle-income countries [UMICs] and high-income countries [HICs]). All statistical analyses were conducted using Stata SE V15 (StataCorp).

Ethical Considerations

Informed consent was obtained from all learners. Participation was voluntary and no monetary compensation was provided to the participants. The collected data were anonymized. Approval for all aspects of this study design, including consent, outreach, data collection, surveying, and data analysis, was obtained from the Stanford University School of Medicine Institutional Review Board (protocol 57831).

Results

Learner Characteristics

As shown in [Figure 1](#), as of September 2021, the 7 courses had 856,263 total enrollees, 90.47% (n=774,686) in WHO courses and 9.53% (n=81,577) in the Stanford course. In all, 13.3% (113,902/856,263) of enrollees and 16.05% (49,098/305,849) of course completers identified as practicing health care workers at course registration. The course completion rate was higher among health care workers (49,098/113,902, 43.1%) than overall enrollees (305,849/856,263, 35.72%).

[Table 2](#) shows that nearly one-third (15,238/49,098, 31.04%) of the health care workers that completed a course were between the ages of 18 - 29 years, and 41.25% (20,252/49,098) identified as female. The region with the most health care workers that completed a course was Latin America and the Caribbean (10,665/49,098, 21.72%), followed by South Asia (7264/49,098, 14.79%), North America (7019/49,098, 14.3%), Europe and Central Asia (5365/49,098, 10.93%), East Asia and the Pacific (5278/49,098, 10.75%), Middle East and North Africa (3816/49,098, 7.77%), and sub-Saharan Africa (3502/49,098, 7.13%). Nearly one-third (14,159/49,098, 28.84%) of the health care workers who completed a course were from LICs (828/49,098, 1.69%) or LMICs (13,331/49,098, 27.15%).

Table . Health care worker characteristics, by course and survey completion. This table compares the characteristics of health care workers who completed the focal courses and follow-up survey. A higher proportion of course completers did not specify characteristics compared to survey completers. Because response options for age and gender were voluntary, a number of learners did not specify these characteristics. We show the numbers not specified for each. For course completion, geographic region was identified via course platform analytics; however, we were unable to identify a subset, shown as "not specified" in the table. For survey completion, geographic regions were identified primarily through survey self-reports. In 177 survey responses, location was not reported. For these cases, we used the survey response's IP address to identify the geographic region of the respondent. Percentages are shown for those for whom we have data on characteristics. Percentage for each categorical variable sum to 100.

Table 2 also compares the characteristics of health care workers completing the course, with the 12.77% (6272/49,098) completing the survey. We observe slight differences in the age and gender composition of survey completers with course completers, with the survey sample skewing older and more

male. The survey sample includes a slightly larger share of participants from LICs (222/6272, 3.54%) and LMICs (2468/6272, 39.35%).

Table 3 describes the professions of the health care workers who completed the survey and their levels of physician supervision. Physicians represent 34.61% (2171/6272) of the survey sample, followed by nurses (1599/6272, 25.49%) and allied health professionals (1190/6272, 18.97%). This breakdown of professional roles is similar in LICs and LMICs and in UMICs and HICs. Of the nonphysician health care

workers, more than a third (1315/3639, 36.14%) reported having access to a physician for consultation during less than 50% of their workday, although the majority (1989/2341, 84.96%) could contact a physician by phone if needed. Most health care workers either already cared for patients with COVID-19 (2793/6272, 44.53%) or anticipated caring for them (1940/6272, 30.93%) at the time of survey completion.

Table . Characteristics of the health care worker survey sample. Allied health included physical therapy, occupational therapy, speech pathology, medical assistants, and home health aides. Nursing included nurses, nurse midwives, nursing instructors, and certified nursing assistants. The question about the frequency of physicians being on site was asked of nonphysicians only. The question about physicians being available via phone was asked of nonphysicians who had indicated that physicians were not available on site 100% of the time. Across questions asking about the availability of physician and treating patients with COVID-19, survey respondents could indicate that the question was not applicable in their health care setting.

Characteristics	Total (n=6272), n (%)	HICs ^a and UMICs ^b (n=3582), n (%)	LMICs ^c and LICs ^d (n=2690), n (%)

^eThis survey question was only asked to nonphysician health care workers who work directly with physicians (n=3639). Percentages shown are out of applicable participants only.

^fThis survey question was only asked to nonphysician health care workers that work directly with physicians and do not have a physician on site 100% of the time (n=2411). Percentages shown are out of data provided with applicable respondents only. Not all applicable respondents responded to this question (n=70).

^gData on whether health care workers treat patients with COVID-19 were based on a voluntary question asked of patients at the time of course enrollment.

Learner Motivations

In the survey, health care workers were asked to rank in importance the following 6 potential motivating factors for course enrollment: to improve practice, to earn a certificate, CE, course brand, free cost of course, and employer recommendation. Figure 2 shows the ranking preferences across survey respondents. Among survey respondents ranking all

factors (n=5518), the majority (n=3090, 56%) ranked “improve practice” as their top preference, with an additional 16% (n=883) ranking it as the second most important factor and 10% (n=552) ranking it as the third most important factor. The second and third most important factors were CE and to earn a certificate, with employer recommendation as the least most important factor ranked.

Figure 2. Percent of learners by motivation rank among health care providers (n=5518).

In Table 4, we show the ranking differences by the type of health care worker. Although the motivation of improving practice was ranked the highest across all subgroups, it was ranked higher by physicians, with a mean rank of 1.86, compared to nurses with a mean rank of 2.06 and other health care providers with a mean rank of 2.24. Nonphysicians ranked CE and employer

recommendations higher than physicians. Certification also appears to matter more to nonphysicians, with 69.76% (2861/4101) choosing to obtain a certificate, 63.76% (2615/4101) providing a copy of the certificate to their employer, and 79.18% (3247/4101) using the certificate for a CE requirement. The course brand appears to be a more

important motivating factor to physicians compared to nonphysicians. Course cost did not appear to differentially influence course enrollment by the type of health care worker.

Table . Mean rank of motivation (1=highest rank, 6=lowest rank) and course perspectives by the type of health care worker. Physician is the reference category for comparisons. Nursing included nurses, nurses, midwives, and nursing assistants. Mean ranking does not include observations that skipped ranking altogether (n=745). Course perspectives include observations that skipped ranking but provided responses for these questions.

	Physician (n=2171), mean (SD)	Nursing (n=1599), mean (SD)	<i>P</i> value	Other (n=2502), mean (SD)	<i>P</i> value
Motivation (mean ranking)					
Improve practice	1.86 (1.38)	2.06 (1.51)	<.001	2.24 (1.60)	<.001
Earn certificate	3.52 (1.36)	3.53 (1.36)	.80	3.46 (1.42)	.16
Continuing education requirement	3.63 (1.49)	3.31 (1.47)	<.001	3.46 (1.55)	<.001
Course brand	3.58 (1.61)	4.17 (1.62)	<.001	3.92 (1.68)	<.001
Course is free	3.83 (1.57)	3.77 (1.65)	.27	3.81 (1.61)	.68
Employer recommended	4.66 (1.54)	4.47 (1.55)	.001	4.39 (1.61)	<.001
Course perspectives (proportion agreeing)					
Would have taken course if it was not free	0.47 (0.50)	0.43 (0.50)	.01	0.46 (0.50)	.39
Chose to obtain a certificate	0.63 (0.48)	0.71 (0.46)	<.001	0.69 (0.46)	<.001
Gave a copy of the certificate to employer	0.55 (0.50)	0.65 (0.48)	<.001	0.63 (0.48)	<.001
Will use the certificate for continuing education requirement	0.71 (0.45)	0.81 (0.39)	<.001	0.78 (0.41)	<.001

In Table 5, we show ranking differences by the location of health care workers, comparing differences in UMICs and HICs compared to LICs and LMICs. In LICs and LMICs, health care workers ranked CE and employer recommendation higher on average compared to learners in UMICs and HICs. Conversely, course brand appears to matter more for learners in UMICs and

HICs. Certification was obtained by roughly the same proportion of learners in both subgroups, although learners in UMICs and HICs were more likely to give a copy of the certificate to their employer, whereas learners in LICs and LMICs were more likely to use the certificate for a CE requirement.

Table . Mean rank of motivation (1=highest rank, 6=lowest rank) and course perspectives by country classification. This table shows differences by World Bank income classifications: high-income country (HIC), upper-middle-income country (UMIC), lower-middle-income country (LMIC), and low-income country (LIC). Mean ranking does not include observations that skipped ranking altogether (n=745). Course perspectives include observations that skipped ranking but provided responses for these questions.

	HICs and UMICs (n=3582), mean (SD)	LICs and LMICs (n=2690), mean (SD)	P value
Motivation (mean ranking)			
Improve practice	2.10 (1.52)	2.01 (1.49)	.04
Earn certificate	3.45 (1.38)	3.57 (1.38)	.001
Continuing education re- quirement	3.58 (1.54)	3.37 (1.48)	<.001
Course brand	3.77 (1.65)	3.97 (1.66)	<.001
Course is free	3.68 (1.59)	3.97 (1.61)	<.001
Employer recommended	4.58 (1.58)	4.41 (1.57)	<.001
Course perspectives (proportion agreeing)			
Would have taken course if it was not free	0.45 (0.50)	0.46 (0.50)	.61
Chose to obtain a certificate	0.68 (0.47)	0.67 (0.47)	.22
Gave a copy of the certifi- cate to employer	0.65 (0.48)	0.57 (0.50)	<.001
Will use the certificate for continuing education require- ment	0.73 (0.44)	0.81 (0.39)	<.001

Generally, the fact that MOOCs were free was a lower-ranked motivator. Although interestingly, in the subgroup analysis, the course being free of cost was ranked lower in LICs and LMICs (mean 3.97, SD 1.61) than in UMICs and HICs (mean 3.68, SD 1.59; [Table 5](#)). However, when survey respondents were asked about their perspectives on the cost of MOOCs, more than half (3423/6272, 54.58%) of the health care workers indicated they would not have taken the course if there was an associated cost. This perspective was consistent across subgroup analyses of health care professional types and country-income levels.

Discussion

Principal Findings

Through a survey of 6272 health care workers worldwide who completed MOOCs for COVID-19 training across multiple platforms and organizations, our study provides unique insight into the factors motivating health care workers to enroll in and complete MOOCs during public health emergencies. We identified that the primary motivator for enrollment among health care workers was to improve their personal practice, followed by the pursuit of CE credit and certification. Course cost is an influential factor in the decision to enroll in an MOOC, with 54.58% (3423/6272) of respondents indicating that they would not have enrolled if the course had not been free. This first-of-its-kind analysis of health care worker motivations in just-in-time training MOOCs during a public health emergency fills an important gap in the existing literature, providing key insights for future course development and marketing.

Our findings highlight the widespread demand among health care workers for MOOC training during a public health crisis.

Health care workers from over 200 countries and territories enrolled in and completed the COVID-19 MOOCs examined in this study, with a third (14,159/42,909, 33%) of course completers located in LICs and LMICs. Compared to the typical MOOC completion rates of under 10% [[17,18](#)], the 43.1% (49,098/113,902) completion rate among health care workers in the COVID-19 MOOCs in this study is notably high. Although the high rate of completion likely reflects the limited alternatives for training during the start of the COVID-19 pandemic, it may also indicate intrinsic motivation among health care workers, whose predominant reason for enrollment was to improve their personal practice.

We also observed that the COVID-19 MOOCs attracted a diverse range of health care providers globally. Although the majority (3770/6272, 60.11%) of respondents were nurses and physicians, 39.89% (2502/6272) reported working in other health care capacities including allied health, community health, emergency medical services, and pharmacy. Furthermore, we noted that motivations for enrollment varied by profession. Compared to physicians, nurses and other health care professionals were more motivated by CE credit, employer recommendations, and certification. Nurses and other health professionals were more likely to obtain certificates, provide a copy of the certificate to their employer, and use the certificates for CE requirements. Recognizing these differences in motivating factors across types of health care workers can inform the design of MOOCs that more effectively respond to the interests and needs of the targeted audience.

Despite these differences, the majority of all health care workers, including physicians, indicated their intention to use their certificates professionally, either by providing them to their

employers (3809/6272, 60.73%) or by earning CE credit (4788/6272, 76.34%). This finding underscores the potential for MOOCs to fill a gap in the CE arena, where traditional approaches often present barriers to completion. The common, traditional route for obtaining CE credits involves attendance at national or international medical conferences [7,8]; however, many such conferences were either canceled or transitioned to a web-based format during the pandemic. Given the time and travel requirements associated with conference attendance, MOOCs can serve as a viable and accessible alternative for learners. Interestingly, our study found that the use of course certificates for CE among learners in LICs and LMICs was higher than that in UMICs and HICs, which may reflect a lack of economically feasible options to earn CE credits in resource-limited geographies. Including certification in MOOC design may serve as an important motivator to increase enrollment and completion, particularly in LICs and LMICs, enhancing the attainment of timely health care education for the global health care workforce.

An additional benefit of online learning is the reduced cost for participants to obtain CE credits. Our study found that cost was a significant consideration for course participants, with 54.58% (3423/6272) of learners indicating they would not have taken the course if it had not been free. Although the course being free was slightly less important to learners in LICs and LMICs than those in UMICs and HICs, we speculate that in lower-income countries, learners with access to the technology required to participate in an online course may be relatively better off financially within their respective countries, and that those with lower incomes may not have the technology to enroll in the courses at all—only 3.54% (222/6272) of learners were from LICs. It is also possible that a single course participant may have shared access to the course with others.

Identifying the characteristics and motivations of specific groups of learners, such as those in LICs and LMICs, will aid in the design of future health care-related MOOCs to encourage participation and completion. Although many public health emergencies and disease outbreaks occur in LICs and LMICs with devastating impact, little data exist that examine the motivations of health care workers in these regions to enroll in just-in-time training MOOCs. Nevertheless, the WHO and various national health agencies frequently leverage MOOCs to disseminate critical health information during these emergencies. Future work should particularly investigate how to overcome barriers related to technology access and content accessibility with an eye toward equity, ensuring that the delivery of crucial health care worker training, particularly in times of emergency, is available to all. Likewise, future investigations should examine how online content is used and shared offline in contexts where the broader population has limited access to digital platforms, thereby enhancing the delivery of course materials through offline sharing.

Limitations

We recognize several methodological limitations inherent in our survey-based research. First, the potential for social desirability bias and selection bias due to voluntary participation limits the generalizability of our findings. To mitigate these

biases, we deployed the survey across multiple learning platforms (Coursera, edX, and OpenWHO), each likely attracting different user demographics, and achieved a substantial sample size of 6272 respondents representing a diverse economic and geographic distribution. Additionally, we examined and reported only marginal differences between survey respondents and the overall course participants (as detailed in Table 2), although it remains a limitation that survey completers may not fully represent the broader learner population.

Second, the exclusive use of English for survey dissemination likely influenced the diversity of the respondents and further constrained the study's generalizability. Future studies could incorporate multiple language options to better capture a wider demographic.

Third, although the survey instrument was tailored to the specific contexts of the courses and discussed rigorously by experts across various fields—including educational assessment, emergency medicine, public health, and online learning—its lack of external validation presents a limitation. No prior studies identified during our review provided a validated instrument for assessing learner motivations in MOOCs, emphasizing the innovative aspect of our research while also necessitating a careful interpretation of our findings.

Fourth, our study's scope was restricted by the limitations in identifying patient-facing health care workers among enrollees, due to data collection methodologies on the OpenWHO platform until June 2020. This limitation hindered our capability to fully classify professions among participants. Future studies should aim to enhance the categorization of health care worker types and delve deeper into the differing motivations among these groups.

Finally, the dynamics of the COVID-19 pandemic—characterized by fluctuating case rates and mortality—suggest that motivations for enrolling in COVID-19-related MOOCs likely varied over time. Some health care workers might have enrolled early in anticipation of patient care needs, whereas others joined after gaining firsthand experience. This temporal variation in motivations, coupled with the evolving availability of other educational tools, presents a complex backdrop against which these motivations were formed. Future studies could benefit from aligning course enrollment data with local COVID-19 case trends to better understand these motivations.

Conclusion

Our study examined the motivations and characteristics of health care workers who engaged with MOOCs during the unprecedented COVID-19 health emergency. The analysis showed that the primary motivation for health care professionals was enhancing their personal practice. CE credit also proved to be a significant motivator, especially for those from LICs and LMICs. Additionally, the necessity of free access was clear, with more than half of the participants (3423/6272, 54.58%) indicating they would not have enrolled if fees were charged. These findings are important for the future development and deployment of MOOCs, ensuring that they not only are

accessible but also resonate with the intrinsic and extrinsic motivations of health care professionals from diverse geographic, training, and economic backgrounds. Future research should further investigate these motivations to see if they are consistent across different types and stages of health emergencies.

Acknowledgments

We would like to thank the World Health Organization (WHO) Health Emergencies Programme team, the Stanford Global Emergency Medicine (SEMI) team, and the Stanford Center for Health Education Digital Medic team for their work in developing and distributing the focal courses of this study. Additionally, we would like to thank all the learners who directly contributed to this research, especially the learners who participated in the survey and shared their experiences with our team.

Data Availability

Some data are available on reasonable request to the corresponding author.

Authors' Contributions

JJ and JSJ led the conceptualization and design of the study and oversaw all aspects of study implementation, writing, and editing. NYN and AT conducted the data collection. JSJ and SS conducted the quantitative analysis. NAS contributed to organizing and writing the manuscript. NYN, AT, NAS, HU, and MS contributed to the study's design, interpretation of findings, and revision of all drafts. All authors have read and approved the final manuscript.

Abstract

Background: Electrocardiography (ECG) interpretation is a fundamental skill for medical students and practicing medical professionals. Recognizing ECG pathologies promptly allows for quick intervention, especially in acute settings where urgent care is needed. However, many medical students find ECG interpretation and understanding of the underlying pathology challenging, with teaching methods varying greatly.

Objective: This study involved the development of novel animations demonstrating the passage of electrical activity for well-described cardiac pathologies and showcased them alongside the corresponding live ECG traces during a web-based tutorial for final-year medical students. We aimed to assess whether the animations improved medical students' confidence in visualizing cardiac electrical activity and ECG interpretation, compared to standard ECG teaching methods.

Methods: Final-year medical students at Imperial College London attended a web-based tutorial demonstrating the 7 animations depicting cardiac electrical activity and the corresponding ECG trace. Another tutorial without the animations was held to act as a control. Students completed a questionnaire assessing their confidence in interpreting ECGs and visualizing cardiovascular electrical transmission before and after the tutorial. Intervention-arm participants were also invited to a web-based focus group to explore their experiences of past ECG teaching and the tutorial, particularly on aspects they found helpful and what could be further improved in the tutorial and animations. Wilcoxon signed-rank tests and Mann-Whitney *U* tests were used to assess the statistical significance of any changes in confidence. Focus group transcripts were analyzed using inductive thematic analysis.

Results: Overall, 19 students attended the intervention arm, with 15 (79%) completing both the pre- and posttutorial questionnaires and 15 (79%) participating in focus groups, whereas 14 students attended the control arm, with 13 (93%) completing both questionnaires. Median confidence in interpreting ECGs in the intervention arm increased after the tutorial (2, IQR 1.5-3.0 vs 3, IQR 3-4.5; $P < .001$). Improvement was seen in both confidence in reviewing or diagnosing cardiac rhythms and the visualization of cardiac electrical activity. However, there was no significant difference between the intervention and control arms, for all pathologies (all $P > .05$). The main themes from the thematic analysis were that ECGs are a complex topic and past ECG teaching has focused on memorizing traces; the visualizations enabled deeper understanding of cardiac pathology; and ECG learning requires repetition, and clinical links remain essential.

Conclusions: This study highlights the value of providing concise explanations of the meaning and pathophysiology behind ECG traces, both visually and verbally. ECG teaching that incorporates relevant pathophysiology, alongside vignettes with discussions regarding investigations and management options, is likely more helpful to students than practices based solely on pattern recognition. Although the animations supported student learning, the key element was the tutor's explanations. These animations may be more helpful as a supplement to teaching, for instance, as open-access videos.

Introduction

Electrocardiography (ECG) interpretation is a fundamental skill necessary during medical school education and in the practice of clinical medicine and surgery. Recognizing pathologies such as an ST elevation or non-ST elevation myocardial infarction; bundle branch block (BBB); and arrhythmias, including atrial fibrillation (AF), supraventricular tachycardia, ventricular fibrillation, and ventricular tachycardia, allows for prompt intervention and improves patient care, especially in the acute setting where urgent interventions may be lifesaving.

Despite its importance, medical students struggle with interpreting ECGs, and teaching methods seem to vary greatly between systematic interpretation based on ECG segments and pattern recognition. This leads to a lack of confidence and inaccurate interpretation of ECGs, which could lead to adverse events including treatment delay or incorrect management of the pathology. Although automated computer interpretation may be available, this should not be used by itself to diagnose conditions, since clinical correlation is warranted and these algorithms may be inaccurate [1].

The major disruptions caused by the COVID-19, in which medical students had limited exposure to hospital wards and experienced most lectures and tutorials on the web rather than in person [2], served as a strong reminder of the need for investment in innovative teaching methods.

Literature already suggests that teaching should be focused on the understanding of lead placement, as well as the basics of electrophysiology and ECG, to better identify abnormalities [3]. Teaching should also be correlated with the clinical findings of a case, as this has been shown to lead to more accurate ECG diagnosis in practice. For instance, case-based learning (CBL) has been frequently used in recent years, which increases the practical knowledge and confidence of medical students and junior doctors, through clinically correlating various cardiac pathologies [4]. However, explaining the link between the underlying cardiac pathology and the traces demonstrated by the ECG is not common practice in medical school curricula.

Medical students repeatedly describe ECG interpretation as a challenging skill [5,6]. A study based in Israel reports that despite competence and confidence in ECG interpretation improving throughout medical school, levels remain low among final-year medical students [5]. Moreover, a study of Polish medical students highlighted students' lack of ability to recognize common and emergency cardiac pathologies [6]. Additionally, these results emphasized independent learning as the strongest predictor of competency, as opposed to attendance in formal teaching sessions [6]. This continues following medical school, with rates of accurate ECG interpretation being as low as 55.8% among trainee doctors [7]. These findings suggest the need for a review of ECG teaching methods.

Technology-enhanced learning has grown in popularity and has been trialed as a method to encourage active practice of ECG interpretation among medical students. Students in this cohort demonstrated better diagnostic accuracy, but rates of knowledge attrition 6 months after the study remained high [1]. These findings highlight that despite continued practice remaining important, current methods of teaching ECGs do not support students in gaining in-depth understanding, nor do they enable knowledge retention.

Methods of technology-enhanced education, including visualizations, have been trialed extensively for anatomy teaching [8], with reported increases in student engagement with the content [9]. Although greater engagement does not ensure improved understanding, it may be an important component in supporting effective teaching and learning [8]. Additionally, there is evidence to show that visualization tools are capable of supporting students' understanding of anatomy [10].

Therefore, this research team developed novel animations demonstrating the passage of electrical activity through the heart for different pathologies and showcased them alongside the corresponding live ECG traces during a web-based ECG tutorial for final-year medical students at Imperial College London. The aim of this study was to assess whether these animations are associated with the improvement of final-year medical students' confidence in both visualizing cardiac pathology and interpreting the corresponding ECGs, compared to standard ECG teaching methods that do not involve visual animations.

Methods

The study was designed as a nonrandomized controlled trial.

Recruitment

Year 6 Bachelor of Medicine, Bachelor of Surgery students from Imperial College London were invited to participate in the study. Messages were sent through student communication channels with the description of the study and tutorial. This included a link to the study information sheet as well as a sign-up link to register their interest in participating. The first 20 students to sign up were emailed by a member of the research team with the information sheet and focus group consent form attached. Students were asked to confirm their participation by returning the signed consent form via email. Students were given a week to confirm their participation, after which the space would be offered to others who registered interest until a total of 20 confirmations were reached. The process was repeated in the following year, with a new cohort of Year 6 Bachelor of Medicine, Bachelor of Surgery students at the same point in the academic year as the original cohort.

The sample size of 20 students per teaching session was agreed by the research team based on the tutor's preference, following their experience of what would be a feasible number of students to teach within the agreed timeframe. This decision was also

supplemented by evidence to suggest that cohorts of fewer than 30 students may enable better learning [11] and that cohorts of approximately 19 students may enable greater interaction [12].

Design and Delivery of the Tutorial

Prototypes for the ECG traces and animations were created on Microsoft PowerPoint by 2 junior doctors on the research team. A total of 7 ECG patterns (sinus rhythm, AF, atrial flutter, atrioventricular nodal re-entry tachycardia, atrioventricular re-entry tachycardia, right BBB, and left BBB) that are known to commonly arise in clinical practice and in exams were chosen, and the prototypes were converted into high production value animations using Adobe Illustrator and Adobe After Effects. The animations were produced by skilled members of the research team and took a collective total of 10 hours to produce. The final product consisted of a video animation of the electrical activity passing through the heart alongside an ECG rhythm strip (lead II) for the given abnormality—with the exception of BBBs, which were depicted alongside leads V1 and V6. The animation of electrical activity through the heart and the corresponding ECG trace were synchronized to demonstrate how each ECG deflection corresponds with the electrical activity within the heart. Depolarization was shown in yellow and repolarization was shown in green.

The tutorials were both delivered by a UK-based Academic Foundation doctor within the research team (LR) on Zoom (Zoom Video Communications) at a prespecified time on a weekday evening. LR has vast experience teaching medical students and designing medical educational material and had completed the Membership of the Royal Colleges of Physicians of the United Kingdom Part 1 Examination successfully at the time of delivering the sessions.

Participants logged on using their unique identifier code and kept their cameras turned off to maintain anonymity. The intervention tutorial involved going through each animation in turn and narrating the path of the electrical activity. To ensure the smooth running of the event, questions were reserved until the end of the session.

The control tutorial followed the same lesson plan as the intervention but involved the tutor narrating the path of electrical activity using an example 12-lead ECG without any animations. Participants were not explicitly told this tutorial would be the control arm but were instead invited to a standard ECG tutorial, following the same methods as the intervention. However, all participants would have read the study information sheet and known the aim of the study, which may have compromised the single-blinding process.

Questionnaires

An email was sent to participants 1 week prior to the tutorial with a link to an anonymous Qualtrics questionnaire to be completed before the tutorial (Multimedia Appendix 1). This questionnaire was composed of 5-point Likert-scale questions assessing participants' confidence in interpreting ECGs and visualizing cardiovascular electrical transmission in each of the cardiovascular pathologies covered in the tutorial. The questionnaire also included multiple-choice and free-text questions inquiring about previous formats of ECG teaching

experienced by participants and their views on what could be improved about current ECG teaching generally.

A similar questionnaire was repeated at the end of the tutorial to assess change in confidence using the same 5-point Likert-scale questions, as well as free-text questions inquiring about participants' experience of the tutorial (Multimedia Appendix 1). A link and QR code to this questionnaire was shared at the end of the tutorial, prior to the start of the focus groups.

Participants were given a unique participant code, which they were asked to state at the start of each questionnaire. This enabled questionnaire responses to be paired while maintaining anonymity.

Focus Groups

Focus groups were only conducted at the end of the intervention tutorial. Participants who took part in the control arm were not invited for a focus group, as the primary purpose of this exercise was to understand participants' experience of the visual animations, which were not included in the control arm. Upon the completion of the tutorial, students were divided into 4 breakout rooms on Zoom, each designed to host 5 students and a single researcher. Participants were asked to unmute microphones to participate in the semistructured focus group and were invited to keep their cameras switched off if they wished to remain anonymous. The focus groups further explored participants' experiences of past ECG teaching and the current tutorial, with particular focus on aspects they found helpful and what could be further improved in the delivery of the tutorial and design of the visualizations (Multimedia Appendix 2).

Focus group questions were designed collaboratively by the research team, with feedback from an expert qualitative researcher (see the *Acknowledgments* section), to ensure that the questions were adequate in informing the study's aims and gave participants the opportunity to share their experiences of ECG learning openly. These were also reviewed by the ethics committee (see the *Ethical Considerations* section).

Focus groups were audio and video recorded on the platform. Recordings were deleted upon transcription, which took place within 2 weeks of the tutorial. Participants were asked if they wished to receive a copy of the transcription to review their statements (anonymized using their unique participant codes); those who asked for the transcription were sent the transcript by email and given 1 week to inform the research team of any redactions they wished to make.

Data Analysis

Questionnaire data were analyzed using descriptive statistics on Microsoft Excel. The Shapiro-Wilk test was used to determine the distribution of data. As this showed that the data were nonparametric, Wilcoxon signed-rank tests were used to assess the statistical significance of any reported changes in confidence between pre- and posttutorial questionnaire responses, for each of the intervention and control arms. The Mann-Whitney *U* test was used to compare differences in pre- and posttutorial confidence between the intervention and control arms of the study.

Focus group transcripts were analyzed using inductive thematic analysis, following Braun and Clarke's [13] stages of thematic analysis as guidance. This was done on NVivo 12.0 (Lumivero) by 2 researchers cooperatively. Themes were reviewed by a third researcher. Free-text questions from the questionnaires were analyzed following similar methods on Microsoft Excel.

Ethical Considerations

This study was approved by the Imperial College Education Ethics Review committee (EERP2122-086). Participation in questionnaires and focus groups was voluntary, with participants given the option to withdraw from the study at any point, up until 2 weeks following the completion of the postintervention questionnaire. All participants were provided with a study information sheet prior to confirming their consent for participation in the study. There was no financial compensation involved in this study. Information sheets explained the aim of the study, methods of data storage, and outputs. Participants were also provided with a unique identifier code generated by the research team to be placed at the start of the questionnaires, enabling data to remain paired while ensuring anonymity.

Results

Questionnaire Results

The first 20 students who signed up to participate in each tutorial were allocated a slot.

In the intervention tutorial, a total of 19 students attended. Of these, 15 (79%) completed both the pre- and posttutorial questionnaires.

All participants confirmed at least 1 prior method of ECG teaching, including didactic lectures (13/15, 87%), case-based tutorials (11/15, 73%), memorization of ECG features (9/15, 60%), animations (2/15, 13.3%), and practical sessions (1/15, 7%).

Overall, in the intervention group, median results for confidence in interpreting ECGs increased from the pretutorial scores (2, IQR 1.5-3) to the posttutorial scores (3, IQR 3-4.5; $P < .001$). Improvement was seen in both confidence in reviewing and diagnosing cardiac rhythms (Figure 1) and in visualizing electrical activity throughout the heart (Figure 2), across most of the pathologies illustrated.

Figure 1. Confidence in reviewing and diagnosing cardiac rhythms and pathology on an ECG (median and IQR score on a Likert scale, from a 1=not confident at all to 5=extremely confident) for the intervention group (n=15). Wilcoxon signed-rank test results: * $P \leq .05$, ** $P \leq .01$, and *** $P \leq .001$. AVNRT: atrioventricular nodal re-entry tachycardia; AVRT: atrioventricular re-entry tachycardia; ECG: electrocardiography; LBBB: left bundle branch block; RBBB: right bundle branch block.

Figure 2. Confidence in visualizing electrical activity through the heart in different ECG pathologies (median and IQR score on a Likert scale, from a 1=not confident at all to 5=extremely confident) for the intervention group (n=15). Wilcoxon signed-rank test results: * $P \leq .05$, ** $P \leq .01$, and *** $P \leq .001$. AVNRT: atrioventricular nodal re-entry tachycardia; AVRT: atrioventricular re-entry tachycardia; ECG: electrocardiography; LBBB: left bundle branch block; RBBB: right bundle branch block.

Participants showed the least confidence in reviewing and diagnosing ventricular pathologies compared to atrial pathologies, with atrioventricular nodal re-entry tachycardia and atrioventricular re-entry tachycardia scoring the lowest median confidence scores before and after the tutorial but also showing the greatest levels of improvement following the tutorial (Figure 1; Table S1 in Multimedia Appendix 3).

A similar pattern is observed for median scores in visualizing cardiac electrical activity (Figure 2; Table S2 in Multimedia Appendix 3). However, median confidence levels before the tutorial in this category were, overall, lower than the same

measurement of confidence for reviewing and diagnosing cardiac rhythms. Nevertheless, the level improvement in confidence in visualizing electrical activity in the heart was overall greater than that in confidence in reviewing and diagnosing cardiac rhythms, with median posttutorial confidence levels also achieving higher levels in most cardiac pathologies than those for reviewing and diagnosing cardiac rhythms.

Participants reported greater enjoyment of this tutorial (median 4, IQR 3-4.5) compared to past ECG teaching (median 3, IQR 1.5-3; $P=.02$).

For the control arm of the study, a total of 14 students attended the tutorial, of which 13 (93%) completed both the pre- and posttutorial questionnaires.

Prior methods of ECG teaching were similar to those of the intervention group, including didactic lectures (11/13, 85%), case-based tutorials (10/13, 77%), memorization of ECG features (6/13, 46%), practical sessions (3/13, 23%), animations (2/13, 15%), and a website with example ECGs for self-learning (1/13, 8%).

Overall confidence in interpreting ECGs showed only slight improvement in the control group, from a median of 3 (IQR 2-3) to 3 (IQR 3-4; $P=.01$).

Pretutorial confidence scores were similar in the control and intervention arms (Table 1). For the control group, pretutorial median confidence scores were also lower for ventricular pathologies compared to atrial pathologies, and overall confidence scores for reviewing and diagnosing cardiac pathologies were higher than visualizing cardiac activity, which is similar to the pattern seen in the intervention group (Multimedia Appendix 4).

Table . Pretutorial median (IQR) confidence scores for control and intervention groups with P values (Mann-Whitney U Test).

Scores and pathologies	Intervention, median (IQR)	Control, median (IQR)	P value
Confidence in reviewing and diagnosing cardiac rhythms and pathology on an ECG^a			
Sinus rhythm	4.0 (3.4-4.0)	5.0 (3.9-5.0)	.07
Atrial flutter	3.0 (1.8-3.8)	3.3 (3.9-5.0)	.35
Atrial fibrillation	3.7 (2.4-4.1)	4.0 (3.0-4.0)	.19
AVNRT ^b	1.5 (1.1-2.1)	2.0 (1.3-2.5)	.32
AVRT ^c	1.5 (1.1-2.3)	2.0 (1.5-2.5)	.39
RBBB ^d	2.2 (1.4-2.9)	2.5 (2.0-3.5)	.28
LBBB ^e	2.2 (1.4-2.9)	2.5 (2.0-3.5)	.33
Confidence in visualizing electrical activity on an ECG			
Sinus rhythm	3.0 (2.5-4.5)	4.0 (2.0-4.0)	.59
Atrial flutter	2.0 (1.0-3.0)	2.0 (1.0-2.0)	>.99
Atrial fibrillation	3.0 (1.5-3.0)	2.0 (1.0-4.0)	.98
AVNRT	2.0 (1.0-3.0)	2.0 (1.0-3.0)	.94
AVRT	2.0 (1.0-3.0)	2.0 (1.0-2.0)	.68
RBBB	1.0 (1.0-2.0)	2.0 (1.0-4.0)	.18
LBBB	1.0 (1.0-2.0)	2.0 (1.0-4.0)	.18
Overall confidence in interpreting ECGs	2.0 (1.0-3.0)	3.0 (2.0-3.0)	.50

^aECG: electrocardiography.

^bAVNRT: atrioventricular nodal re-entry tachycardia.

^cAVRT: atrioventricular re-entry tachycardia.

^dRBBB: right bundle branch block.

^eLBBB: left bundle branch block.

There was no statistically significant difference between the enjoyment of this tutorial (median 4, IQR 4-5) compared to past ECG teaching (median 4, IQR 3-4; $P=.052$).

When comparing the change in confidence between the control and intervention groups for both reviewing and diagnosing pathology and visualizing electrical activity, no statistically significant difference was seen across all pathologies (all $P>.05$).

Data for confidence in reviewing and diagnosing cardiac rhythms and pathology showed greater improvements in the intervention group across most pathologies, except for AF. The

greatest absolute difference between the intervention and control groups was seen for left BBB, although this was still statistically nonsignificant ($P=.89$; Figure 3). Data for confidence in visualizing cardiac electrical activity showed similar median changes in confidence across most pathologies, apart from right and left BBBs, where the intervention group showed greater improvement, although not statistically significant ($P=.15$ and $P=.12$, respectively; Figure 4).

There was also no statistically significant difference in median scores for the enjoyment of the tutorial when comparing control and intervention groups ($P=.37$).

Figure 3. Median (IQR) scores for absolute difference in confidence in reviewing and diagnosing cardiac rhythms and pathology on an ECG for control (n=13) and intervention (n=15) groups. AVNRT: atrioventricular nodal re-entry tachycardia; AVRT: atrioventricular re-entry tachycardia; ECG: electrocardiography; LBBB: left bundle branch block; RBBB: right bundle branch block.

Figure 4. Median (IQR) scores for absolute difference in confidence in visualizing electrical activity through the heart in different ECG pathologies for control (n=13) and intervention (n=15) groups. AVNRT: atrioventricular nodal re-entry tachycardia; AVRT: atrioventricular re-entry tachycardia; ECG: electrocardiography; LBBB: left bundle branch block; RBBB: right bundle branch block.

Focus Group Results

Overview

A total of 15 (79%) out of 19 participants who attended the intervention tutorial took part in the focus groups. These were preallocated at random into 4 separate groups, which contained between 2 to 5 students (1 with 5 students, 2 with 4 students, and 1 with 2 students). Three key themes emerged from the analysis of focus group transcripts.

Past ECG Learning Has Been Centered on the Clinical Context and Memorizing Traces

All participants noted varied past ECG teaching, including formal lectures and tutorials focused on the principles of ECG interpretation throughout medical school but also informal teaching while on placement. However, there was an agreement that ECGs remained a challenging concept to learn. For example, one participant noted that they “found [ECGs] hard to understand and engage [with]” (participant 8), whereas another explained how “an ECG can kind of be a different language almost” (participant 7) and hence may take more time and effort to understand.

Past teaching experienced by participants, particularly informal teaching on placement, also focused on pattern recognition and correlating ECG signs to diagnoses.

I think at least with the ones I went through with the doctors and stuff, it was very much like a tick box or like oh the saw tooth pattern is this, this is this...
[Participant 12]

Although this format of learning was concise and focused on key knowledge required to be a Foundation Year 1 doctor, it did not promote deeper understanding of ECGs that could be applied to any ECG pattern.

I'd kind of leave knowing that if that exact ECG comes up, that was helpful, but otherwise I don't know really what or why it is that and then some of the actual understanding came from doing work outside of firms.
[Participant 30]

Participants also highlighted that “the key thing is kind of just repetition” (participant 7) when learning to interpret ECGs, and that “you also have to dedicate time yourself to go through it, if you really want to properly understand it” (participant 33).

Being taught systematic methods for ECG interpretation and presentation was reported to be useful; namely, it was “more relevant to us and our exams and practicals” (participant 15) when going through clinical cases alongside ECGs, which help provide clinical context to the ECG and “also gets you used to different subtleties, because between patients an ECG of the same condition can look slightly different” (participant 6).

The Animations and Associated Explanations Promoted a Deeper Understanding of Cardiac Electrical Activity

Overall, participants found the animations and accompanying explanations during the tutorial to be a helpful tool. The depiction of an ECG trace and heart animation simultaneously helped them understand the correlation between the 2, and hence, as a participant stated, “the first time I've properly understood what is exactly is going on [in the heart]” (participant 1) for the pathologies illustrated. One participant highlighted that “breaking it down into basics...and how it's reflected in the heart as well as it's corresponding trace...feels less like I'm trying to memorise something and more like I'm actually trying to figure it out” (participant 17).

The visual nature of these animations enabled participants to “clearly see how the electricity is conducted in the heart” (participant 2) and was noted to be an effective method to “consolidate what I know about the conditions that we went through” (participant 2).

This more thorough level of understanding was noted to be “quite useful” to participants, as “when going on the wards and I see an ECG, I can actually visualise how the heart is functioning” (participant 17). It was also perceived to be a helpful way of retaining their learning about heart pathologies and associated ECG traces in the longer-term, as “when you understand the reason why something is the way it is you are more likely to remember it” (participant 15).

Participants also stated the value of covering content that they considered relevant to their exams and starting work as

Foundation Year 1 doctors: “I enjoyed the fact that we covered like a lot of a main conditions, so less of the more niche stuff” (participant 7). They also described this tool as more of a helpful “recap” (participant 2) of heart conditions and their associated ECG traces, as opposed to methods of ECG interpretation, which are often the focus in later years of medical school. One participant explained, “I just wish we were taught this way before [in earlier years of medical school]; it would make understanding a lot easier later” (participant 12).

Implementing This 1-Hour Tutorial Is Not Enough: ECG Learning Requires Repetition and Clinical Links Remain Essential

The key differentiating component of this tutorial was its animations: “I'm a visual learner, so I need to see it to understand it. So that's what's been a gamechanger for me, to actually see the animation” (participant 32). However, participants suggested that “having [the animation playing] even slower” (participant 8) or the opportunity to independently “use the scroller to advance” (participant 32) through the animation would be helpful to visualize more carefully “what is happening step-by-step in the heart and on the ECG” (participant 32). One participant also suggested potential value in “3D animations, that would be useful so you can turn the heart around and see all the fibres and all the [conduction activity]” (participant 17).

Despite the value of the tutorial in supporting students' understanding of cardiac pathologies, participants highlighted that there are additional factors that are important in contributing to in-depth learning. For instance, the need for repetition was widely acknowledged. Participants therefore asked that animations be made available for them to view independently. Additionally, the fast-paced nature of the tutorial, which covered multiple pathologies, means that some participants “didn't really have much of a time to get an understanding again, of like the condition” (participant 7), which might be resolved through independent revision with the animations or delivering the content through multiple teaching sessions.

Finally, participants noted the value of greater interaction with the audience, including the implementation of quizzes to test understanding and the integration of clinical cases for stronger clinical correlations.

Discussion

Overall, results for the intervention cohort demonstrate a statistically significant improvement in confidence when identifying abnormalities in ECG traces and visualizing cardiac electrical activity, compared to prior to attending this tutorial. However, a similar improvement was seen in the control group, with no statistically significant differences in improvement in confidence between the control and intervention groups. Although the focus groups highlighted a possible value in the use of animations demonstrating cardiac electrical activity synchronized to the corresponding ECG trace, the overall results suggest that perhaps this tool may be more adequate as a supplement to teaching.

Focus group transcripts provided fruitful data on how students have previously been taught how to interpret ECGs, how their

previous learning compared to how this tutorial was delivered, and what they thought of the animations used to support the tutorial delivery. Moreover, information on how to improve the session was also collected. The main themes that arose were that ECGs are regarded as a complex topic among students and that past ECG learning used CBL and involved the memorization of traces. Other main themes include that the animations and associated explanations promoted a deeper understanding of cardiac electrical activity (compared to past teaching) and that ECG learning requires repetition and clinical links remain essential. Students noted that their most helpful past teaching involved cases and clinical contextualization, which should therefore be considered in any form of teaching implemented to final-year students, as clinical context appears to be their learning priority.

The key commonality between the control and intervention groups was the provision of a concise explanation of cardiac electrical activity in the heart for each section of the ECG trace. Therefore, future studies may benefit from investigating ways of delivering this content most effectively, for example through CBL or team-based learning [14-16], or similar methods of enabling greater interaction between students, but with a focus on understanding the pathology as opposed to focusing on pattern recognition.

This study and its teaching session do not come without some limitations. For reasons described in the *Methods* section, this study was limited to up to 20 participants in each arm and was based in a single study-year group and university. Therefore, it is not possible to confirm that these results are generalizable. No data were collected on the demographics of participants, which would also be helpful in determining the generalizability of the findings. Furthermore, this study also did not directly assess knowledge; instead, it assessed confidence in knowledge. Confidence has greater subjectivity than knowledge-based assessments and is not a reliable alternative to assessing student learning. Therefore, future evaluations of these animations would benefit from a validated assessment of students before and after the tutorial.

The teaching session itself would have benefited from greater interactivity, which has been showed to be an important element to teaching [14-16]. The session was delivered in a more didactic way, compared to CBL or team-based learning methods, which may have compromised student engagement and therefore learning. None of these elements were incorporated in the teaching session mainly due to time constraints but also to maintain the focus of the session on evaluating the value of the animations in improving student confidence. For instance, the inclusion of cases would act as a confounding variable as students may be able to understand the pathology from the case rather than from interpreting the ECG, whereas other students might not have engaged as much with the animations when in a team compared to when working individually. It is important to note that clinical context is important, as supplementing

teaching materials with a patient case helps students to better diagnose, investigate, and manage cardiac conditions, thus improving their clinical reasoning skills [16].

The animations are likely to be even more valuable if used alongside other helpful learning tools, including the design of more interactive tutorials by involving quizzes throughout and gamification, which is a concept recently discussed in the literature, wherein game design elements are used in nongame contexts to promote users' engagement [17]. Moreover, future teaching sessions would benefit from including the aforementioned clinical scenarios prior to demonstrating each pathology, intertwining the learning of relevant pathophysiology with clinical knowledge. Although the latter would allow greater contextualization and demonstrate the relevance of the learning to clinical practice, the former would provide the required background knowledge to understand the clinical manifestations, and management, of disease.

In addition, it is important to acknowledge that for students to confidently be able to interpret ECGs, they need to apply the concepts of spaced learning and repetition. Future teaching could be accompanied by resources such as a recording of the session, the slides and animations used, as well as single-best answer questions to enable students to consolidate and test their learning. A more appropriate method of using these animations may therefore be to provide these to students as an independent learning resource. When doing so, it would enable students to scroll through the animation and independently control its speed to match their learning needs and understanding. Additionally, students suggested to make the animation 3D and to demonstrate the full 12-lead ECG alongside the animation as opposed to a single lead only.

In conclusion, this study suggests that although incorporating visual animations to demonstrate the electrical activity of different pathologies in ECG teaching may be beneficial in improving students' confidence in interpreting ECGs and understanding the underlying pathology, it is not the only way that this can be achieved. Students benefited equally from verbal explanations, suggesting that the most essential part of future ECG teaching is providing emphasis on the relevant pathophysiology, presented alongside clinical vignettes in which discussions regarding investigations and management options can be made. Interactivity within teaching sessions using quizzes and spaced practice is also recommended, in which students can access the resources, including the animation used in the session, later, to help consolidate their learning. Nevertheless, the development of animations was a low-cost intervention enjoyed by students and was reported to support their learning and understanding of cardiac pathophysiology and interpretation of ECG traces. Therefore, it is hoped that making these animations available to students as a revision resource can supplement their current ECG teaching and individual study practices.

Abstract

Background: The growing presence of digital technologies in health care requires the health workforce to have proficiency in subjects such as informatics. This has implications in the education of nursing students, as their preparedness to use these technologies in clinical situations is something that course administrators need to consider. Thus, students' attitudes toward technology could be investigated to assess their needs regarding this proficiency.

Objective: This study aims to investigate attitudes (enthusiasm and anxiety) toward technology among nursing students and to identify factors associated with those attitudes.

Methods: Nursing students at 2 universities in Sweden and 1 university in Poland were invited to answer a questionnaire. Data about attitudes (anxiety and enthusiasm) toward technology, eHealth literacy, electronic device skills, and frequency of using electronic devices and sociodemographic data were collected. Descriptive statistics were used to characterize the data. The Spearman rank correlation coefficient and Mann-Whitney *U* test were used for statistical inferences.

Results: In total, 646 students answered the questionnaire—342 (52.9%) from the Swedish sites and 304 (47.1%) from the Polish site. It was observed that the students' technology enthusiasm (techEnthusiasm) was on the higher end of the Technophilia instrument (score range 1-5): 3.83 (SD 0.90), 3.62 (SD 0.94), and 4.04 (SD 0.78) for the whole sample, Swedish students, and Polish students, respectively. Technology anxiety (techAnxiety) was on the midrange of the Technophilia instrument: 2.48 (SD 0.96), 2.37 (SD 1), and 2.60 (SD 0.89) for the whole sample, Swedish students, and Polish students, respectively. Regarding techEnthusiasm among the nursing students, a negative correlation with age was found for the Swedish sample ($P < .001$; $\rho_{\text{Swedish}} = -0.201$) who were generally older than the Polish sample, and positive correlations with the eHealth Literacy Scale score ($P < .001$; $\rho_{\text{all}} = 0.265$; $\rho_{\text{Swedish}} = 0.190$; $\rho_{\text{Polish}} = 0.352$) and with the perceived skill in using computer devices ($P < .001$; $\rho_{\text{all}} = 0.360$; $\rho_{\text{Swedish}} = 0.341$; $\rho_{\text{Polish}} = 0.309$) were found for the Swedish, Polish, and total samples. Regarding techAnxiety among the nursing students, a positive correlation with age was found in the Swedish sample ($P < .001$; $\rho_{\text{Swedish}} = 0.184$), and negative correlations

with eHealth Literacy Scale score ($P < .001$; $\rho_{\text{all}} = -0.196$; $\rho_{\text{Swedish}} = -0.262$; $\rho_{\text{Polish}} = -0.133$) and with the perceived skill in using computer devices ($P < .001$; $\rho_{\text{all}} = -0.209$; $\rho_{\text{Swedish}} = -0.347$; $\rho_{\text{Polish}} = -0.134$) were found for the Swedish, Polish, and total samples and with the semester only for the Swedish sample ($P < .001$; $\rho_{\text{Swedish}} = -0.124$). Gender differences were found regarding techAnxiety in the Swedish sample, with women exhibiting a higher mean score than men (2.451, SD 1.014 and 1.987, SD 0.854, respectively).

Conclusions: This study highlights nursing students' techEnthusiasm and techAnxiety, emphasizing correlations with various factors. With health care's increasing reliance on technology, integrating health technology-related topics into education is crucial for future professionals to address health care challenges effectively.

nursing education; technophilia; eHealth; technology anxiety; technology enthusiasm; mobile phone

Introduction

Background

Health care costs have been growing faster than the economy for the past 17 years [1]. This upward trend is due to multifactorial causes related to the growth and aging of the population, increased prevalence of lifestyle-related noncommunicable diseases, increased prices of health services and pharmaceuticals, and the risk of global pandemics [2-4]. All these factors put high pressure on the health care systems, which have to deal with many challenges related to efficiency and productivity. The digitalization of the health care sector is strongly influencing the efforts to address health care challenges and involves the use of technologies such as information and communication technologies in health settings, which was later termed as *eHealth* [5].

The integration of eHealth in the health care sector points to greater use of technology to access health data, manage eHealth records, and engage in telehealth platforms, among others [6]. This is such an important topic that the European Commission issued the Digital Decade Policy Program targeting Europe's digital transformation by 2030 [7]. This policy envisions, among other goals, the achievement of a digitally skilled population, highlighting the importance of a highly digitally skilled health care workforce and inspiring initiatives in different European countries. In the United States, a similar government initiative promotes the use of health technologies to improve the quality, safety, and efficiency of and reduce disparities in health care delivery [8]. The merging of health care workforce and digital technologies became so evident that informatics is outlined as one of the core competencies in the nursing profession: "use information and technology to communicate, manage knowledge, mitigate error and support decision making" [9]. Accordingly, it is also increasingly important for registered nurses to become proficient in this aspect.

Incorporation of health technologies into nursing education and the preparedness of the new students to use these in clinical scenarios and practice are highly important and a growing concern for program administrators, educators, researchers, policy makers, and employers [10]. This concern is valid because despite many students having grown up with technology ingrained in their everyday life, they still report low confidence, difficulties, and not-so-positive views about applying digital

skills in clinical contexts [11-15]. Therefore, it is important to investigate the nursing students' attitudes toward technologies, so that appropriate decisions can be made for educational purposes that might affect future patient care.

Many models assess user interaction with technology according to factors such as acceptance, motivation, adoption, adaptivity, and usability, which are known to play a role in technology use [16]. However, it is argued that both cognitive and emotional effectiveness affect behavior, and these are underlying factors that precede the specific, planned, and reasoned actions directed toward technology [17,18]. The concept of technophilia is a personality trait and a psychological construct that is related to a person's enthusiasm or positive feelings toward technology use and the absence of anxiety or fears and doubts regarding technology [19], and it is a general quality that could potentially influence a wide range of aspects of technology use. Contrary to models tailored to specific organizational tasks, the investigation of technophilia could provide a better picture of the students' needs regarding this proficiency.

Objectives

This study comprises a multicenter, cross-sectional investigation of technophilia among nursing students that aimed to (1) establish the levels of technophilia among nursing students of 3 educational institutions in Sweden and Poland regarding their enthusiasm and anxiety and (2) identify factors that could be associated with the students' technology enthusiasm (techEnthusiasm) and technology anxiety (techAnxiety).

Methods

Study Design

This study used a multicenter, cross-sectional design based on questionnaire data collected from nursing students in 3 different universities, in Sweden and Poland, in different stages in their education. The protocol for this study has been described previously [20]. This study adhered to the STROBE (Strengthening the Reporting of Observational studies in Epidemiology) guideline for cross-sectional studies ([Multimedia Appendix 1](#)).

Setting

We collected data in the period between December 2019 and April 2020, using questionnaires administered to students

enrolled in the nurse education programs of 3 universities: 2 in Sweden (Blekinge Institute of Technology [BTH] and Swedish Red Cross University [SRCU]) and 1 in Poland (Medical University of Białystok [MUB]). The undergraduate nursing education of both countries adheres to the European Union requirements, which comprises 180 European Credit Transfer and Accumulation System (ECTS) credits at the university level [21,22]. The educational programs in both countries result in a professional degree (ie, a diploma) and an academic degree (ie, a bachelor's degree), qualifying for a license as a registered nurse. At the time the study, the Swedish nursing education consisted of both theoretical and clinical practice courses—60% and 40% of the total curriculum, respectively. At the Polish institution, MUB, the nursing program consisted of 52% theoretical courses and 48% clinical practice courses. The students' exposure to eHealth or health technology courses at the time of the data collection was as follows:

- At BTH, eHealth is covered in nursing subjects during the whole program and in two dedicated courses in the curriculum:
 1. An eHealth introductory course is offered in the third semester to all students (4.5 ECTS), which was completed at the time of the data collection.
 2. An optional course on digitalization and eHealth was offered in the fifth semester (7.5 ECTS). It was chosen by approximately one-third of the fifth-semester students and was ongoing at the time of the data collection.
- At SRCU, eHealth was also incorporated into nursing subjects during the whole program and 1 optional course (7.5 ECTS) in medical technology, digitalization, and eHealth was offered in the fifth semester. However, this course started 5 weeks after this study's data collection.
- At MUB, eHealth was incorporated into nursing courses during the whole program.

Participants and Data Collection Procedures

A convenience sample of undergraduate nursing students, enrolled at the bachelor of nursing program at BTH, SRCU, and MUB, was used in this study. Students from the first, third, and fifth semesters were eligible to participate in this study. These semesters were chosen to obtain a sample incorporating the beginning, middle, and end of nursing education, which comprises 6 semesters.

Data were collected using a paper-based questionnaire administered to all undergraduate students from the first, third, and fifth semesters of the participating universities by research members who had no educational connections to the students. This was done to minimize response bias.

Questionnaire

The questionnaire was used to collect data about the participants' sociodemographics, self-reported attitudes toward technology, eHealth literacy, perceived skills in using electronic devices, and frequency of using electronic devices.

Data on Attitudes Toward Technology (*Technophilia Instrument*)

The outcome measures of this study are the self-reported data on attitudes toward technology scored by the Technophilia instrument (TechPH) [19]. The TechPH comprises 6 questions to capture behaviors related to adaptation and use of a new technology, which were derived from the content analysis of relevant technophilia measures. It results in 2 numeric scores ranging from 1 (low) to 5 (high): techEnthusiasm and techAnxiety. The TechPH was originally developed for measuring older adults' attitudes toward technology; however, published studies have already applied it on younger individuals, physicians, and dementia caretakers aged 18 to 44 years [23,24]. In this study, techEnthusiasm and techAnxiety have Cronbach α of 1 and 0.925, respectively, showing excellent internal consistency.

Sociodemographic Data

Sociodemographic data consisted of the participants' age; gender; focus of high school studies (health or social care, technology, or other); and previous work experience (health or social care, technology, or other).

eHealth Literacy Data (*eHealth Literacy Scale*)

The eHealth literacy was scored using the eHealth Literacy Scale (eHEALS) instrument [25]. The eHEALS is a self-report tool consisting of 8 questions and has already been validated in many languages and diverse populations including undergraduate health professionals [25,26]. The eHEALS produces a score ranging from 1 (low eHealth literacy) to 5 (high eHealth literacy).

Data on Perceived Skill in and Frequency of Using Technological Devices

Perceived skills in using electronic devices, namely, computers or laptops, tablets, and smartphones, were rated using a Likert-type scale ranging from 1 (not knowledgeable at all) to 5 (very knowledgeable). The frequencies of using electronic devices were rated using a Likert-type scale ranging from 1 (several times daily) to 5 (never).

Data Analysis

The descriptive statistics, namely, frequency, mean, and SD, were used to analyze the collected data. The Shapiro-Wilk test was used to assess data distribution. As the data were not normally distributed, nonparametric tests were used in the statistical analyses. Spearman rank correlation coefficient was used to measure the association among age, semester, perceived skills in using computers or laptops, and frequency of using electronic devices via the self-reported TechPH components—techEnthusiasm and techAnxiety. CIs were calculated to analyze the stability of the results. Mann-Whitney *U* test was used to assess gender differences regarding students' enthusiasm and anxiety toward technology. Sensitivity analyses were performed by removing the outliers and revealed that the interpretations were unperturbed, showing that extreme data points did not impact the study outcomes. For all the analyzes, a significance level of .05 was used. Stratification was used; therefore, results are presented for the whole sample, Swedish

students, and Polish students separately, to control for confounding. Entries with missing data were omitted from the analysis. The analyses were performed using R (version 1.4.1717; RStudio).

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki [27]. Participation in the study was voluntary. All participants were briefed about the study aims; that they could choose to not submit the questionnaire or submit it blank; and that by submitting the questionnaire, they would consent to participate in the study. All collected data were anonymous.

Permission to conduct the study was obtained from heads of the departments at all participating universities. In Poland, ethics approval was obtained from the ethics committee of Medical University of Bialystok (register number R-I-002/148/2017). In Sweden, the study did not require ethics approval according to the requirements of the Swedish Ethical Review Act 2003:460, 3-4§ [28], as the study did not explore sensitive personal data (eg, health, religion, political views, and ethnic heritage) or data relating to criminal offenses, did not involve physical intervention on the participants, and did not aim to affect the participants in any way or involve biological material.

Results

Sample Characteristics

In total, 646 students answered the questionnaire—342 (52.9%) from the Swedish sites and 304 (47.1%) from the Polish site. The response rates were 70.2% (646/920) for the whole sample, 63.1% (342/542) for the Swedish students, and 80.4% (304/378) for the Polish students. Nonresponders include students who decided not to submit the questionnaire or to submit it blank.

None of the variables used in the analyses contained >5% of missing values.

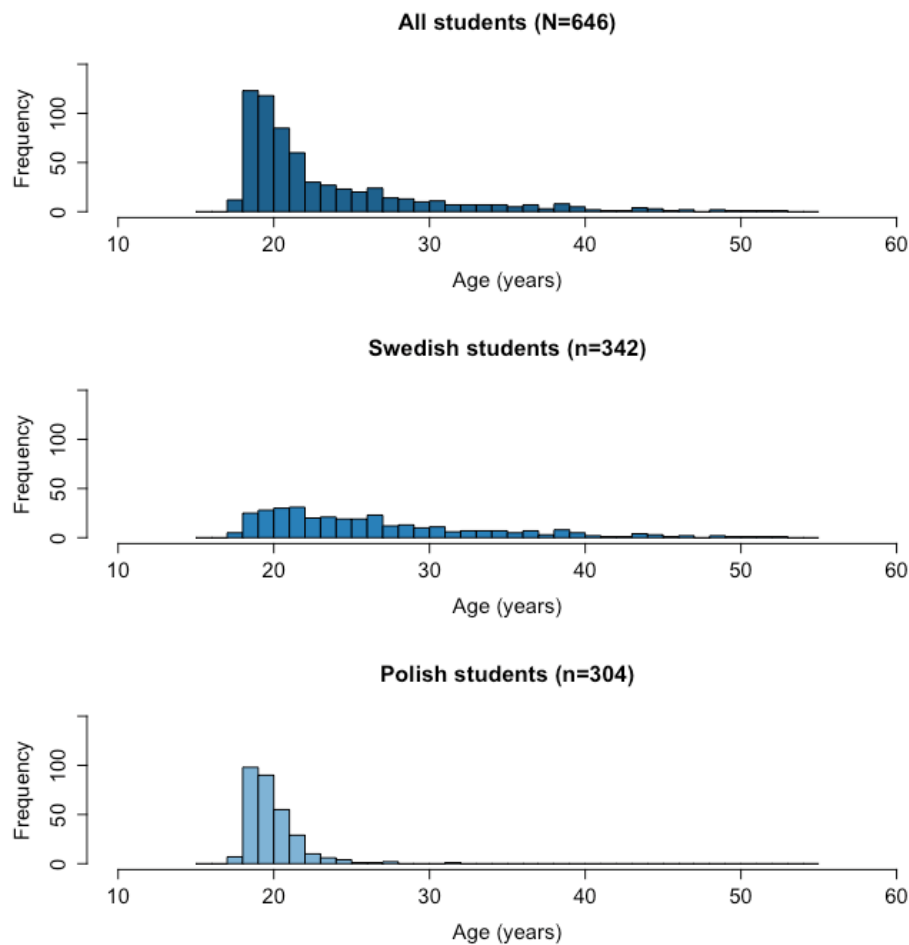

The descriptive statistics are shown in [Table 1](#), for the whole sample and for the Swedish and Polish students separately. [Multimedia Appendix 2](#) shows the descriptive statistics along with the means and SDs for the techAnxiety and techEnthusiasm for each grouping shown in [Table 1](#)—for the whole sample, Swedish students, and Polish students separately. The mean age of the sample is 23.9 (SD 6.39) years, with the Swedish students being generally older and having a higher age variance (mean 27, SD 7.34 years) compared with the Polish students (mean 20.4, SD 1.72 years), as shown in [Figure 1](#). While the Polish sample has a distribution that is more concentrated around the mean, the Swedish sample has a flatter distribution of ages. The sample was majorly composed of women students (555/646, 85.9%). Very few students had a high school focus on or previous work experience with technology before their nursing education. Overall, 50.3% (153/304) of the Polish students had a health and social care focus in high school, while this number was 23.9% (82/342) for the Swedish students. In terms of perceived skill in using electronic devices, most participants perceive themselves “knowledgeable” or “very knowledgeable” in all 3 categories: computers (479/646, 74.1%), smartphones (574/646, 88.9%), and tablets (388/646, 60.1%). Furthermore, 48.6% (314/646) of the participants answered that they use computers or laptops “several times daily” or “daily,” while this number reached 98.8% (638/646) for smartphones and 11.2% (72/646) for tablets. The students showed an overall high eHealth literacy, with 93.3% (603/646) scoring ≥ 3 points. The mean eHEALS scores for the overall, Polish, and Swedish samples were 3.95 (SD 0.75), 3.96 (SD 0.78), and 3.95 (SD 0.73), respectively, constituting high scores and showing an overall high perceived eHealth literacy.

^aeHEALS: eHealth Literacy Scale.

Figure 1. Distribution of ages in the whole sample, Swedish students, and Polish students.

The mean and SD values for the self-reported techEnthusiasm for the whole sample, Swedish students, and Polish students were 3.83 (SD 0.90), 3.62 (SD 0.94), and 4.04 (SD 0.78), respectively, which constitutes a high overall technophilia. On the other hand, the mean and SD values for techAnxiety for the whole sample, Swedish students, and Polish students were 2.48 (SD 0.96), 2.37 (SD 1), and 2.60 (SD 0.89), respectively, displaying midrange values regarding the negative feelings toward technology.

[Multimedia Appendix 2](#) shows the mean and SD values for both techEnthusiasm and techAnxiety according to different levels

of socioeconomic, eHEALS, perceived skill, and frequency variables. The association of these variables with techEnthusiasm and techAnxiety is investigated in the following sections.

Factors Associated With TechEnthusiasm

The Spearman rank correlation coefficient was used to investigate the association of techEnthusiasm and the nonparametric variables of ordinal scale in the study, namely, age, semester, eHEALS score, perceived skill, and frequency of using electronic devices. These results are shown in terms of the Swedish, Polish, and overall samples in [Table 2](#).

Table 2. Spearman rank correlation coefficient calculated for the whole sample, Swedish students, and Polish students separately, regarding technology enthusiasm.

	All students		Swedish students		Polish students	
	<i>P</i> value	ρ (95% CI)	<i>P</i> value	ρ (95% CI)	<i>P</i> value	ρ (95% CI)

^aeHEALS: eHealth Literacy Scale.

A negative correlation was found between age and techEnthusiasm for the Swedish sample and overall sample, indicating that greater the age, lesser the techEnthusiasm score ($P<.001$; $\rho_{\text{all}}=-0.238$; $\rho_{\text{Swedish}}=-0.201$). This association might not have been significant for the Polish sample due to the lack of age variance observed in the Swedish sample (refer to [Figure 1](#)—the Polish students' age distribution presents a heavier tail compared to the Swedish ones). A positive correlation was found between eHealth literacy and techEnthusiasm, indicating that greater the eHEALS score, greater the techEnthusiasm score ($P<.001$; $\rho_{\text{all}}=0.265$; $\rho_{\text{Swedish}}=0.190$; $\rho_{\text{Polish}}=0.352$). A positive correlation was found between perceived skill in all investigated electronic devices and techEnthusiasm, indicating that greater the perceived skill, greater the techEnthusiasm ([Table 2](#)). In terms of frequency of use, a negative correlation was found between the use of computers and techEnthusiasm ($P<.001$; $\rho_{\text{all}}=-0.153$; $\rho_{\text{Swedish}}=-0.176$; $\rho_{\text{Polish}}=-0.146$). The negative values of ρ are due to the inverted Likert scale used for the question, that is, from "several times daily" to "never." Thus, the techEnthusiasm score increases with higher frequencies of use. It is noteworthy that even with low ρ values, the significant associations found are still relevant due to the large sample size.

The narrow 95% CIs indicate low variability and stability of the results.

The Mann-Whitney *U* test was used to assess gender differences regarding the students' reported techEnthusiasm. No significant differences were found for Swedish, Polish, or overall samples ($P_{\text{Swedish}}=.45$, $P_{\text{Polish}}=.38$, and $P_{\text{all}}=.68$).

Factors Associated With TechAnxiety

Analogous statistical analyses were performed on the techAnxiety scores for the Swedish, Polish, and overall samples. [Table 3](#) shows the Spearman rank correlation coefficients calculated for the same variables as for techEnthusiasm. A positive correlation was found between age and techAnxiety in the Swedish sample, indicating that greater the age, greater the techAnxiety score ($P<.05$; $\rho_{\text{Swedish}}=0.184$). Similar to techEnthusiasm, this association might not have been significant for the Polish sample due to the lack of age variance ([Figure 1](#)). A negative correlation was found between higher semesters and techAnxiety in the Swedish and overall samples, indicating that higher the students were in their education, lesser the techAnxiety score ($P<.05$; $\rho_{\text{all}}=-0.101$; $\rho_{\text{Swedish}}=-0.124$).

Table 3. Spearman rank correlation coefficient calculated for the whole sample, Swedish students, and Polish students separately, regarding technology anxiety.

Feature	All students		Swedish students		Polish students	
	<i>P</i> value	ρ (95% CI)	<i>P</i> value	ρ (95% CI)	<i>P</i> value	ρ (95% CI)

Frequency: tablet	.19	0.053 (–0.026 to 0.132)	.77	0.017 (–0.095 to 0.128)	.50	0.039 (–0.074 to 0.151)

^aeHEALS: eHealth Literacy Scale.

A negative correlation was found between eHealth literacy and techAnxiety ($P < .001$; $\rho_{\text{all}} = -0.196$; $\rho_{\text{Swedish}} = -0.262$; $\rho_{\text{Polish}} = -0.133$). A negative correlation was found between the perceived skill in all investigated devices and techAnxiety, indicating that greater the perceived skill, lesser the techAnxiety score (Table 3). Similar to techEnthusiasm, the low ρ values still show relevant associations due to the sample size. In addition, similar to techEnthusiasm, the narrow 95% CIs indicate low variability and stability of the results.

Gender differences regarding the students' reported techAnxiety were observed through the Mann-Whitney *U* test for the whole sample and the Swedish students ($P_{\text{Swedish}} = .002$; $P_{\text{Polish}} = .69$;

$P_{\text{all}} = .01$). A considerable difference in the mean scores of the reported techAnxiety can be observed between men (1.987, SD 0.854) and women (2.451, SD 1.014) in the Swedish sample of students. This was not observed for the whole sample, with means of 2.240 (SD 0.90) and 2.521 (SD 0.963) for men and women students, respectively. However, upon closer inspection of the boxplots shown in Figure 2, the attributed gender differences can be observed when the distribution is analyzed. The Swedish women students present a higher dispersion of techAnxiety scores, whereas men present a heavier tail distribution, which in turn increases the distance between these groups.

Figure 2. Box plots for the reported technology anxiety in the whole, Swedish, and Polish samples.

Discussion

Principal Findings

Overview

This cross-sectional, multicenter study aimed to determine Swedish and Polish students' attitudes toward technology, specifically directed to enthusiasm and anxiety, and factors associated with those attitudes. The principal findings of this study are as follows: (1) in the Swedish sample (mean age 27, SD 7.34 years), the older the students were, the more anxious and less enthusiastic they were about technology; (2) the higher the students' eHealth literacy score was, the more enthusiastic and less anxious they were regarding technology (both Swedish and Polish samples); (3) the higher the perceived skill in using electronic devices was, the more enthusiastic and less anxious about technology the students were (both Swedish and Polish samples); (4) in the Swedish sample, the more senior the students were in their education (higher semesters), the less anxious they were toward technology they were; and (5) gender differences were found in the Swedish sample regarding anxiety toward technology. These will be further discussed in the following sections.

Attitudes Toward Technology and Age

The positive correlation between age and techAnxiety and negative correlation between age and techEnthusiasm, meaning that greater the age, lesser the enthusiasm and higher the anxiety toward technology, is an interesting finding, as many Swedish students (163/342, 47.6%) fall into the mature student category. This concept does not have a definition, but published literature

usually considers the individuals who enter higher education at the age of 26 to 30 as mature students who are believed to be different from their younger colleagues [29]. The fact that many universities have a changing cohort with a higher rate of accepted mature students, meanwhile adopting more and more technologies as teaching enhancements [30], raises concerns about how the students' attitudes toward technology could affect their learning. Technology-enhanced learning methods in the classroom can promote high-order thinking, that is, rationalizing on a level higher than memorizing or telling facts as told [31]. These teaching approaches affect the attainment of the subject being taught and decrease subject anxieties [29,32,33]. In the specific case of nursing, a systematic review of literature by Labrague et al [34] shows positive results in using high-fidelity simulations for enhancing the self-confidence of nursing students in managing their duties. Identifying the students' needs could be important in these scenarios, so that learning could be efficiently delivered. A recent study investigated mature students' attitudes toward technology and found no significant differences from younger students. However, the attitudes considered in the study instrument were confidence and a sense of utility [29]. The hypothesis suggests that the observed phenomenon related to age may not be applicable to the Polish sample due to its younger ages and lower variability (mean 20.4, SD 1.72 years).

Attitudes Toward Technology and eHealth Literacy

The positive correlation between eHealth literacy score and enthusiasm toward technology is not surprising because computer literacy is one of the domains assessed in the eHEALS instrument. The negative correlation between eHealth literacy

score and anxiety toward technology is also important to be considered. Even with different approaches to eHealth in nursing education, it seems important for the nursing students' attitudes toward technology, which would later influence their use of technology in clinical scenarios. Registered nurses commonly rely on advice from their colleagues as their primary information source to inform daily clinical practice [35-37]. However, this information channel has an inherent risk of diverging from the best evidence available in published literature, which could impact the quality of patient care [38]. The best clinical practices can be readily accessed through reference materials and web-based publications in nursing journals. Thus, if anxiety toward technology is a factor that is identified as a barrier to pursuing such information, this means that it should be addressed in their education.

Attitudes Toward Technology and Perceived Skills in Using Electronic Devices

Another study finding suggests that students exhibiting higher perceived skill in using electronic devices (computers or laptops, smartphones, and tablets) also demonstrated more enthusiastic and less anxious attitudes toward technology. Only few studies have investigated electronic device use in nursing education. However, investigating this topic is important because despite nursing students reporting proficiency in computer skills, a lack of exposure to new devices can still lead to hesitancy in their use [39]. In the recent years, mobile apps have been trialed and shown to support the education and practice training of nursing students [40]. This technology facilitates access to patient care resources, fostering self-directed learning and problem-solving [41]. A study by Kenny et al [42] investigated the impact of using smartphones and tablets with a QR code scanning app linking to educational information on the nursing students' anxiety levels while performing psychomotor skills in the patient care setting. The study found that providing students with access to these tools helped to reduce anxiety by offering quick access to reputable patient care information [42]. Previous studies of bank employees also found an inverse relationship between techAnxiety and computer skills [43]. The study did not find any significant associations with the frequency of use, which is consistent with this study, with the exception of techEnthusiasm related to computer or notebook. However, it can be argued that this could simply be a direct result of being enthusiastic and wanting to engage with it daily. While no studies in the literature approached the topic of techEnthusiasm and skill, a study by Revilla Muñoz et al [44] reported lower levels of techAnxiety in high school teachers after information and communications technology training.

Attitudes Toward Technology and Semester

In the Swedish sample, students exhibited lower levels of anxiety toward technology the further in their education they were. This could be related to how health technology topics are being addressed in specific courses given in higher semesters, which was not the case for the Polish university at the time of the study. This could indicate that having specific courses with eHealth and health technology curricula could be useful to address techAnxiety in students. A scoping review by Nes et al [45] highlights that the current state of nursing education

indicates a prevalent lack of focus on technology and technological literacy, favoring teaching over engaging with technological advancements in the clinical field, resulting in limited exposure to such developments. This holds significance because practitioners are likely to navigate ongoing technological advancements throughout their careers. Therefore, nursing education should be viewed as a platform that fosters lifelong learning, placing emphasis on proactive engagement and critical thinking in response to technological progress [46].

Attitudes Toward Technology and Gender

This study also found gender differences regarding techAnxiety in the Swedish students (mature student sample). There is sparse published literature about gender and computer anxiety, and findings do not seem to provide a conclusion [47-50]. Sparse literature has been published in the area of techAnxiety and even less so in the techEnthusiasm domain; this may compromise the credibility of the findings from comparing these studies. It can be argued that the findings of studies conducted more than a decade ago are difficult to interpret without the context of the time they were published in, because with the rapid technological advancements of the past years, the relationship between users and technology has changed drastically.

Implications to Practice

Understanding the factors that influence techEnthusiasm and techAnxiety holds important practical implications, particularly in the context of health care innovation and access to care.

TechAnxiety and techEnthusiasm can impact the technology acceptance level of a new health care solution. Low levels of acceptance are related to implementation delays and even complete system failures [51]. According to the systematic literature review by AlQudah et al [52], which included 142 studies, the key factors associated with health technology acceptance are its ease of use and perceived usefulness, which are measured using the widespread Technology Acceptance Model instrument. In addition, anxiety and computer self-efficacy are the next extensively studied factors related to health care technology acceptance, which aligns with the focus of this study.

A qualitative study conducted with nurses who have lower levels of digital literacy [53] explored factors related to health IT acceptance in this population. The results portrayed that these nurses show little enthusiasm toward technology and even considered the use of such technological tools as "bad patient-centered care." Addressing those attitudes toward technology is a challenge and should be tailored to special needs, as these individuals also reported that the training sessions are conducted in large groups and that the pace is too fast for them.

Telemedicine, eHealth records, health IT systems, and mobile apps emerge as important health technologies that are directed to improve productivity and effectiveness of the health care sector. During the COVID-19 pandemic, digital health strategies, which include such systems, were imperative for providing continuity of care; economic, social, geographical, time, and cultural accessibility; and coordination of care, among others [54]. However, during those difficult times, several health

professionals were unprepared to use such technologies [54]. Having health personnel that is trained to use different health technologies proved to be imperative to build preparedness for unusual health emergency situations. Strategies to address the problem of accessibility of health care in remote or rural areas could also use such technologies [52]. Hence, it is important to understand students' digital savviness to devise strategies to address health technology topics accordingly in the curricula of health-related undergraduate programs.

Limitations

As this was a self-reported survey study, care must be taken when extrapolating the results shown in this paper. Response bias was mitigated by involving researchers with no educational connections with the surveyed participants. An earlier study of self-reported technology use presented only marginal errors to the respondents' true use [55]. Another important limitation of this study is the disproportionate number of women and men participants, with the former consisting of 85.9% (555/646) of the whole sample. Although the statistical tests used in the analyses are robust against data imbalance, the magnitude of such imbalance could have affected the results. In addition, the use of a convenience sample can limit how the findings of this study can be generalized. However, in this study, the

involvement of different universities from different countries as data sources helped to reduce this risk. Finally, the instrument used in this study was initially crafted and validated for use with older adults. Although published evidence exists for its use in younger populations [23,24], the results should be interpreted with caution, recognizing the potential for age-related bias.

Conclusions

This cross-sectional, multicenter study emphasized the importance of nursing students' enthusiasm and anxiety toward technology and highlighted the factors associated with these attitudes. As health care increasingly relies on technologies such as telemedicine, eHealth records, health IT systems, and mobile apps, the integration of health technology topics into educational curricula becomes imperative, taking the students' attitudes toward technology into consideration, so that in the future, these professionals are prepared to address future health care challenges. Future qualitative studies should investigate nursing students who portray high anxiety and low enthusiasm toward technology to further validate the results presented in this paper and understand their points of view, so that pedagogical strategies can be developed to incorporate health technology topics in the curricula.

Acknowledgments

The authors are especially grateful to the study participants for their time and interest in participating in the study. This study is part of the eHealth in Nursing Education (eNurseEd) study and was supported financially by the participating universities as an educational improvement effort. The funding source was not involved in the review design, analysis, interpretation of findings, writing of the paper, or the decision to submit the paper for publication.

Data Availability

The data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

ALD, DB, and PA conceived the study design. EKA, DB, LS, GB, and LM performed the data collection. ALD and BGP performed the data analysis. ALD, EKA, BGP, and PA drafted the paper. All authors have contributed to the authorship and approved the final version of this paper.

Conflicts of Interest

None declared.

Multimedia Appendix 1

STROBE (Strengthening the Reporting of Observational studies in Epidemiology) statement—checklist of items that should be included in the reports of cross-sectional studies.

Abstract

Background: The rapidly aging population and the growth of geriatric medicine in the field of internal medicine are not supported by sufficient gerontological training in many health care disciplines. There is rising awareness about the education and training needed to adequately prepare health care professionals to address the needs of the older adult population. Massive open online courses (MOOCs) might be the best alternative method of learning delivery in this context. However, the diversity of MOOC participants poses a challenge for MOOC providers to innovate in developing learning content that suits the needs and characters of participants.

Objective: The primary outcome of this study was to explore students' perceptions and acceptance of HTML5 package (H5P) interactive content in self-paced MOOCs and its association with students' characteristics and experience in using MOOCs.

Methods: This study used a cross-sectional design, combining qualitative and quantitative approaches. Participants, predominantly general practitioners from various regions of Indonesia with diverse educational backgrounds and age groups, completed pretests, engaged with H5P interactive content, and participated in forum discussions and posttests. Data were retrieved from the online questionnaire attached to a selected MOOC course. Students' perceptions and acceptance of H5P interactive content were rated on a 6-point Likert scale from 1 (strongly disagree) to 6 (strongly agree). Data were analyzed using SPSS (IBM Corp) to examine demographics, computer literacy, acceptance, and perceptions of H5P interactive content. Quantitative analysis explored correlations, while qualitative analysis identified recurring themes from open-ended survey responses to determine students' perceptions.

Results: In total, 184 MOOC participants agreed to participate in the study. Students demonstrated positive perceptions and a high level of acceptance of integrating H5P interactive content within the self-paced MOOC. Analysis of mean (SD) value across all responses consistently revealed favorable scores (greater than 5), ranging from 5.18 (SD 0.861) to 5.45 (SD 0.659) and 5.28 (SD 0.728) to 5.52 (SD 0.627), respectively. This finding underscores widespread satisfaction and robust acceptance of H5P interactive content. Students found the H5P interactive content more satisfying and fun, easier to understand, more effective, and more helpful in improving learning outcomes than material in the form of common documents and learning videos. There is a significant correlation between computer literacy, students' acceptance, and students' perceptions.

Conclusions: Students from various backgrounds showed a high level of acceptance and positive perceptions of leveraging H5P interactive content in the self-paced MOOC. The findings suggest potential new uses of H5P interactive content in MOOCs,

such as interactive videos with pop-up questions, to substitute for synchronous learning. The study underscores the significance of tailored educational strategies in supporting the professional development of health care professionals.

Introduction

Indonesia is one of the most populous countries in the world, with a population of about 268 million people. In 2021, there were 10.8% or around 29.3 million older adults in the population. By 2045, the ratio of older adults is expected to increase to 19.9% [1]. The rising number of older adults poses potential challenges and vulnerability in medical, psychological, economic, and social domains within this population. The aging process is unavoidable and can potentially bring various challenges in terms of health and quality of life [2]. Furthermore, it contributes to increasing mortality from noncommunicable diseases among older adults [3].

In response to this problem, the Indonesian government launched the 2016-2019 National Action Plan for Elderly Health to improve the quality of life of older adults through health service programs. However, this program has not been run optimally. The implementation of geriatric services in hospitals is still not realized. The policy exists and the implementation of the program is quite good, but the instrument for measuring it has not been understood and used by service providers [4]. According to the Central Bureau of Statistics data, Indonesia had 173,779 doctors and 2,287,142 health workers spread throughout the country in 2021 [5,6]. However, data from the Health Human Resources Information System in 2018 reported that only 23% of health community service centers had qualified health care professionals and 15% had none [7]. This indicates that the coverage of health services for older adults has not met expectations and is unevenly distributed [8]. Doctors and health care professionals need to be equipped with the knowledge and skills to ensure a healthy and independent older adult population.

Moreover, while geriatric medicine is a rapidly growing field within internal medicine, gerontological training is still limited across many health care disciplines today [9,10]. This highlights the importance of raising awareness about education and training in geriatric health care, ensuring health professionals are adequately prepared to address the needs of the older adult population. Therefore, education for health professionals and continuing education for practitioners is required to reframe medical care to meet the needs and personal quality of life goals of older adults [11].

Many health care professionals experience difficulties traveling to attend face-to-face continuing training due to their busy work schedules and their location in remote rural areas. However, time and travel restrictions during the COVID-19 pandemic catalyzed a shift from face-to-face to online education [12]. As a form of e-learning, massive open online courses (MOOCs)

have emerged as an invaluable tool to address some of the training challenges experienced in developing countries by supporting content delivery that is efficient, cost-effective, and accessible [13]. MOOCs can provide training for health care professionals and increase the dissemination of information about public health issues to the public [14]. Skinner et al [15] found that health care professionals need MOOC content that is easy to adapt and share. Thus, MOOCs can effectively deliver learning materials in health care education and continuing education for practitioners.

Despite the many benefits of MOOCs, such as their open nature and enabling teachers to reach a large and diverse group of participants, there is a perception of social isolation regarding the lack of interaction between teachers and students and between students [16].

Furthermore, the diversity of participants makes it difficult to engage students, which further adds to the complexity of the students' interactions with the course content [17], even though such interaction is the most common interaction form in MOOCs [18]. This challenges MOOC providers to develop innovative learning content that suits the needs and characters of users to increase student engagement and mastery of learning. The existing MOOC platforms use videos as the main information delivery method. The videos are presented in a 1-way format where students are passive viewers, making learning feel monotonous [18,19].

The use of the HTML5 package (H5P) to develop interactive learning content can make the class more interactive and fun and encourage self-directed learning. Moreover, H5P allows students' learning outcomes to be recorded so that they can be used as evaluation material for instructors [20]. H5P is a simple and easy-to-use open-source technology without the need for plugins or Shareable Content Object Reference Model (SCORM) standards. The interactive learning content can be developed in formats such as interactive videos, course presentations, image hotspots, and branching scenarios [20,21].

Previous studies have demonstrated how H5P interactive content can support online learning environments, including blended learning, flipped classrooms, active learning, and virtual simulations. However, few studies have focused specifically on the use of H5P within Moodle-based MOOC platforms, especially in health profession education and continuing education [22-24]. Moreover, limited research exists on Indonesian students' perspectives regarding their participation in self-paced MOOCs with interactive content H5P, especially in the context of healthy aging. This study explored students'

perceptions and levels of acceptance of H5P interactive content in a self-paced MOOC.

Methods

Design and Settings

The study used a combination of qualitative and quantitative approaches. The participants enrolled in a course comprised of 8 topics on the MOOC platform (Table 1). The course included a pretest, learning material, forum discussions, and a posttest on every topic. At the end of the course, we asked participants

to complete a self-reflection task regarding their experience during the course. The course was developed using a self-paced learning method so participants could progress at their own pace. Learning material provided in the H5P took the form of interactive books and interactive videos. There were between 3 and 8 videos per topic in the module, with an average duration of around 12 minutes for each video, and each interactive video included pop-up questions. A survey was attached at the end of the course for students to answer questions on their acceptance of H5P interactive content and their views on whether it supports self-paced learning.

Table 1. Title and estimated duration to complete for each topic.

Topic	Title	Duration (hours)
1	The Role of Healthy Aging and Risk Factors That Can Lead to Non-Communicable Disease	2
2	Elderly and its Problems	2
3	Metabolic and Hormonal Aspects of Aging	2
4	Risk Factors and Cardiovascular Disease in the Elderly	4
5	Neurodegenerative Diseases in the Elderly and Prevention	2
6	The Role of Physical Activity as Prevention of Non-Communicable Diseases in the Elderly	3
7	The Role of Nutrition as Prevention of Non-Communicable Diseases in the Elderly	8
8	The Role of Social Support and Medical Funding in Overcoming Diseases in the Elderly	4

Participants

Due to their scattered locations throughout Indonesia, the participants were recruited via email and WhatsApp (Meta Platforms). We identified potential participants through various educational networks and organizations dedicated to supporting students across Indonesia. Specifically, we leveraged our existing contacts within these networks and used databases of educational institutions. Additionally, participants were identified based on recommendations from local contacts familiar with the target demographics. Furthermore, to ensure the relevance of participants, we specifically targeted general practitioners practicing in diverse locations throughout Indonesia. The participants were enrolled in an online course on the MOOC platform from August to September 2021. There were 796 participants in the course. This study used purposive sampling as its sampling method. The sample was selected based on participants' completion of the course. A total of 184 participants completed the course and were selected to participate and analyze in this study.

Ethical Considerations

The ethics committee of the Faculty of Medicine, Universitas Indonesia-Cipto Mangunkusumo Hospital, has approved this study (KET-511/UNI2.F1/ETIK/PPM.00.02/2021). Informed consent was obtained from all participants involved in the study. Confidentiality and anonymity were preserved during data collection and processing.

Data Collection

We retrieved data from the online questionnaire attached to the MOOC course. The questionnaires were adapted and modified from a variety of existing instruments [25-27]. The questionnaire

was written in Bahasa Indonesia and included items on the demographic characteristics of students (age range, sex, education, and experience of MOOCs), their computer literacy rated on a 5-point Likert scale from 1 (bad) to 5 (excellent), students' perceptions and acceptance of H5P interactive content rated on a 6-point Likert scale from 1 (strongly disagree) to 6 (strongly agree). The student perception questionnaire was adapted and modified from the study by Muthuprasad et al [27]. The open-ended question was used to emphasize findings from the students' perception questionnaire. The researcher with experts was involved in reviewing the questionnaire items and validated it using content validation methods. Meanwhile, students' acceptance was measured using the Technology Acceptance Model (TAM) adopted and modified from the study by Masrom [26], which consists of 2 variables—perceived ease of use and perceived usefulness. According to Davis [28], these 2 variables of TAM are the 2 main factors that influence behavioral intentions toward new technologies and they affect the actual use of the technologies [28]. The validity and reliability of the instrument were tested in the previous study. The result indicates that the validity test of students' perceived ease of use variables ranged from 0.783 to 1.000, and perceived usefulness ranged from 0.731 to 0.977. Cronbach α values of perceived ease of use and perceived usefulness were 0.975 and 0.973, respectively. Scores greater than 0.7 indicate reliability and good internal consistency [29].

Quantitative Analysis

We analyzed the data using SPSS (version 25.0; IBM Corp). Descriptive analysis was used to analyze students' characteristics, perceptions, and acceptance of the H5P content. A bivariate correlation (Pearson correlation) was conducted to determine the relationships among predictor factors such as

students' computer literacy and their perceptions and acceptance of H5P interactive content in terms of perceived ease of use and perceived usefulness based on the TAM. Conditions for multicollinearity and homoscedasticity were met. No multicollinearity between independent and dependent variables was found in the preliminary study. The variance inflation factor values were all below 5. We investigated perceived ease of use, perceived usefulness, and students' perception as dependent variables, and age, sex, education, computer literacy, and MOOC experience as independent variables.

Qualitative Analysis

In the qualitative analysis, we identified themes related to students' perceptions and opinions from the open-ended survey questions using a constant comparison process [30] and inductive analysis. First, the researchers read each response to gain a grasp of the information. Second, they broke the data into smaller units, coded and labeled the units according to the content they contained. Finally, categories and overarching

themes were defined. During the analysis, the data were constantly compared back and forth between the current data and previous data that had been coded. All data analysis was completed manually using Microsoft Excel.

Results

Student Characteristics

Table 2 presents all the detailed characteristics of students. The participants ranged in age from 36 to 45 years old, with 70.7% (n=130) female participants. Most participants live on Java Island and the rest are scattered throughout Indonesia (Figure 1 [31]).

The educational backgrounds of students were dominated by participants who held bachelor's (40.2%, n=74) and master's (42.9%, n=79) degrees. Most of the participants were doctors (66.8%, n=123). In terms of MOOC experience, most participants had no previous experience of taking MOOCs.

Figure 1. Characteristics of students based on the domicile area (adapted from Vemaps [31], which is published under Creative Commons Attribution (CC-BY) [32]).

Computer Literacy (Self-Efficacy)

Computer literacy or computer self-efficacy of students who participated in the course are presented in Table 3. The mean value of computer literacy responses ranged from 3.92 to 4.28,

and the SD ranged from 0.725 to 0.871. Overall, students' computer literacy was good. The item on computer maintenance ability (installing programs, applications, or software) had the lowest mean value of 3.92 (SD 0.871), and the item related to browsing skills had the highest mean value of 4.28 (SD 0.751).

Table 3. Computer literacy of participants (N=184).

Statements	Values, mean (SD)
CL1—Ability to use computer	4.21 (0.725)
CL2—Basic computer operation skills (typing accuracy and speed, moving cursor)	4.24 (0.773)
CL3—Running computer programs, software, or applications	4.12 (0.759)
CL4—Computer maintenance ability (installing programs or applications)	3.92 (0.871)
CL5—Browsing skills	4.28 (0.751)

Perception and Opinion of the Participant Toward H5P Interactive Content Usage

Table 4 shows the results of a descriptive analysis of students' perceptions of H5P interactive content. The mean value of all responses falls between 5.18 and 5.45, and the SDs range from 0.605 to 0.861, indicating that students generally have a positive

perception toward H5P interactive content leveraging. The results indicate that students perceived H5P interactive content as fun, easier, and more helpful in promoting understanding and improving learning outcomes, and more satisfying than material in the form of common documents and learning videos. Thus, students' perceptions of how interactive content can replace synchronous learning had the lowest mean value of 5.18.

Table 4. Students' perception toward H5Pa interactive content (N=184).

Statement	Values, mean (SD)	Range
SP1—I prefer the presentation of material in interactive form (interactive video and interactive book) than in the form of common documents or learning videos	5.45 (0.659)	3-6
SP2—Presentation of material in interactive form (interactive video and interactive book) provides a more enjoyable learning experience than presentation in the form of common documents or learning videos	5.43 (0.633)	3-6
SP3—Presentation of material in interactive form (interactive video and interactive book) makes it easier for me to understand learning compared to presentation in the form of common documents or learning videos	5.43 (0.605)	3-6
SP4—Presentation of material in interactive form (interactive video and interactive book) is more effective than presentation in the form of common documents or learning videos	5.38 (0.675)	1-6
SP5—Presentation of material in interactive form (interactive video and interactive book) is more effective than compared to presentation in the form of common documents or learning videos	5.36 (0.687)	1-6
SP6—Presentation of material in interactive form (interactive videos and interactive books) makes me more focused than presenting in the form of common documents or learning videos	5.38 (0.691)	1-6
SP7—I am more satisfied with the presentation of material in interactive form (interactive videos and interactive books) than in the form of common documents or learning videos	5.34 (0.786)	1-6
SP8—Presentation of material in interactive form (interactive video and interactive book) can replace synchronous learning	5.18 (0.861)	1-6

^aH5P: HTML5 package.

The students' perceptions and opinions about H5P interactive content were also explored in the open-ended questions supporting the findings from the perception assessment. According to the responses, students believe that H5P interactive content could increase focus and memory retention, as illustrated by the following quotes.

Overall, the learning content is very good. If possible, learning videos with pop-up questions are applied to all materials because they can increase focus and memory retention on related materials. [Female, 27 years old]

... Giving interactive book material in approximately 15 minutes can maintain concentration. Moreover, having a quiz in the middle of a video can help me to stay focused. [Female, 45 years old]

... Videos with pop-up questions really help to increase my attention when taking lessons... [Female, 28 years old]

Furthermore, students also noted the advantages of interactive videos with pop-up questions. They reported that they provide a different and better learning experience than synchronous learning through Zoom (Zoom Video Communications), are

good and interactive, and can cross-check their understanding during the learning process. So, students suggest adding more questions during the video, as highlighted in the quotes.

Increasing number of pop-up questions in the middle of learning materials... [Female, 30 years old]

I suggest applying pop-up questions in the midst of all interactive videos, so that it will provide a different and better learning experience than learning through Zoom. [Male, 24 years old]

I think interactive videos with pop-up questions are good and interactive. If possible, every video should have an interaction (pop-up questions) so we can cross-check our understanding during the learning process. [Male, 31 years old]

Students' Acceptance of H5P Interactive Content

The findings presented in [Table 5](#) indicate that students had a high level of acceptance of H5P interactive content. All 5 items measuring perceived ease of use and the 5 items measuring perceived usefulness recorded mean values above 5 points. This indicates that respondents found the H5P interactive content easy to use and effective for helping them learn on the MOOC.

Table 5. Students' acceptance to H5P^a interactive content (N=184).

Statements	Values, mean (SD)	Range
Perceived ease of use		
PEU1—I can easily access the interactive learning content available in this module	5.36 (0.663)	3-6
PEU2—The navigation provided in the interactive learning content in this module can be easily understood	5.28 (0.728)	3-6
PEU3—I can easily understand the instructions given on the interactive learning content in this module	5.38 (0.683)	3-6
PEU4—I can easily operate the interactive learning content in this module	5.37 (0.742)	2-6
PEU5—Overall interactive learning content is easy to use	5.45 (0.651)	3-6
Perceived usefulness		
PU1—The questions that arise during the learning video playback can increase my attention (attention) to the material presented	5.52 (0.627)	3-6
PU2—The interactive video presented was able to trigger my curiosity further about the material	5.41 (0.679)	3-6
PU3—The interactive video presented was able to make it easier for me to understand the material	5.40 (0.602)	4-6
PU4—The use of interactive learning content (H5P) allows me to better manage my study time	5.43 (0.658)	3-6
PU5—Overall, I find it helpful to have H5P interactive learning content	5.51 (0.572)	4-6

^aH5P: HTML5 package.

H5P Interactive Content Acceptance and Student Performance in the MOOC

This study examined several factors, including age range, sex, education, MOOC experience, computer literacy, perceived ease of use, perceived usefulness, and students' perception. The correlations between these factors are presented in [Table 6](#). The

results reveal a significantly negative correlation between computer literacy and both age and sex. In contrast, there is a significantly positive correlation between computer literacy and MOOC experience. Computer literacy had a positive impact on perceived ease of use, perceived usefulness, and students' perception.

Table 6. Correlation among variables.

Discussion

This study explored students' perceptions and acceptance of H5P interactive content. We found that students have positive perceptions and acceptance, particularly of interactive books and videos with pop-up questions. The lack of instructor presence and student-instructor interactions in a self-paced MOOC potentially hampers students' commitment and intention to commit to further learning. Therefore, student-content

interaction needs to be maximized [33]. Student-content interaction may include reading information, watching videos, completing assignments, interacting with computer-based multimedia, using simulations, searching for information, and working on projects [34]. According to Kuo et al [35], students reported that interaction with the course content increased their satisfaction with the course. MOOCs offer openly accessible online participation, meaning participants can be from diverse backgrounds. The data on the characteristics of participants in

this study show various backgrounds in terms of age, sex, education, job and employment status, computer literacy, previous knowledge of the material or topic, and experience with MOOCs. This indicates that such learning content should be designed to meet the diverse needs of students.

Our findings indicate that students from diverse backgrounds showed a high level of acceptance of H5P interactive content in the self-paced MOOC. They preferred H5P interactive content over traditional teaching methods because it is more fun, easier, more effective, more helpful in facilitating learning and improving learning outcomes, and more satisfying. Moreover, students also found that H5P interactive content (interactive video) provided a different and better learning experience than synchronous learning. Previous research suggests that more satisfying experiences will lead to better learning outcomes [36].

Another interesting finding emerged from the open-ended question analysis. We found that students perceived that pop-up questions during a video increased their focus and memory retention. They even suggested incorporating more questions during the video. This feedback has led to another research question regarding the optimum number of questions needed to make learning more effective and less monotonous. While previous studies have explored the relationship between the length of the intervals between questions and the rates of correct answers [37], the ideal number of questions has yet to be investigated.

Al-Adwan [38] defined computer self-efficacy as individuals' beliefs about their computer abilities and skills. Research indicates that computer skills are one of the critical factors in successful e-learning. Moreover, many empirical studies have demonstrated that computer self-efficacy is a key predictor of perceived ease of use and usefulness in e-learning [34,35]. This aligns with the findings of this study, which indicated computer self-efficacy had a significantly positive impact on participants' perception and acceptance of the perceived ease of use and usefulness of H5P interactive content in the self-paced MOOC. Students with high levels of computer self-efficacy are less

likely to be discouraged by difficulties [39]. In contrast, students with low computer self-efficacy are more likely to give up when faced with challenges. To improve the learning experience, we suggest providing a step-by-step written or video tutorial to familiarize people with lower computer literacy. Students' prior experience of MOOCs positively correlated with computer literacy but had no significant impact on their perception of ease of use and usefulness of H5P interactive content. This contrasts with the findings of Wang et al [40], which demonstrated that students' prior experiences were positively associated with their satisfaction with their current learning experience.

This study has some limitations. First, the sample size is small and the participants share individual opinions. We used open-ended questions at the end of the questionnaire to provide more detailed responses to the survey responses; however, we did not follow up with the participants to confirm their answers. This survey is subject to individual variations among participants; their personal circumstances, work, and educational routines might have influenced their answers. Moreover, this study is also limited to the type of H5P interactive content used, namely H5P interactive video. Nevertheless, these study findings can form the basis for a pilot project to further analyze the potential of H5P interactive content to improve the interaction and engagement of students in self-paced MOOCs. We found that H5P interactive content videos with pop-up questions can substitute for synchronous learning; however, further study is necessary to examine its impact on learning outcomes.

In conclusion, this research suggests the use of H5P interactive content, especially interactive books with pop-up questions, can potentially substitute for synchronous learning in the context of self-paced MOOCs. Positive perceptions and high-level acceptance by students toward the use of H5P interactive content suggest that it is suitable for diverse participants of MOOCs from various regions of Indonesia, with diverse educational backgrounds and age groups. Future research should compare students' learning performance in self-paced MOOCs with and without H5P interactive content.

Abstract

Background: Undergraduate medical studies represent a wide range of learning opportunities served in the form of various teaching-learning modalities for medical learners. A clinical scenario is frequently used as a modality, followed by multiple-choice and open-ended questions among other learning and teaching methods. As such, script concordance tests (SCTs) can be used to promote a higher level of clinical reasoning. Recent technological developments have made generative artificial intelligence (AI)-based systems such as ChatGPT (OpenAI) available to assist clinician-educators in creating instructional materials.

Objective: The main objective of this project is to explore how SCTs generated by ChatGPT compared to SCTs produced by clinical experts on 3 major elements: the scenario (stem), clinical questions, and expert opinion.

Methods: This mixed method study evaluated 3 ChatGPT-generated SCTs with 3 expert-created SCTs using a predefined framework. Clinician-educators as well as resident doctors in psychiatry involved in undergraduate medical education in Quebec, Canada, evaluated via a web-based survey the 6 SCTs on 3 criteria: the scenario, clinical questions, and expert opinion. They were also asked to describe the strengths and weaknesses of the SCTs.

Results: A total of 102 respondents assessed the SCTs. There were no significant distinctions between the 2 types of SCTs concerning the scenario ($P=.84$), clinical questions ($P=.99$), and expert opinion ($P=.07$), as interpreted by the respondents. Indeed, respondents struggled to differentiate between ChatGPT- and expert-generated SCTs. ChatGPT showcased promise in expediting SCT design, aligning well with *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* criteria, albeit with a tendency toward caricatured scenarios and simplistic content.

Conclusions: This study is the first to concentrate on the design of SCTs supported by AI in a period where medicine is changing swiftly and where technologies generated from AI are expanding much faster. This study suggests that ChatGPT can be a valuable tool in creating educational materials, and further validation is essential to ensure educational efficacy and accuracy.

Introduction

Undergraduate Medical Education

Undergraduate medical studies offer a wide range of learning opportunities through various teaching methods for medical students [1]. The competencies required are partly dictated by the Medical Council of Canada, and these skills are regularly assessed throughout the undergraduate medical education (UGME) program. Training programs must incorporate clinical reasoning instruction to aid students in developing this crucial competency [2]. The Bloom taxonomy is a useful tool for clearly identifying the cognitive level targeted by different teaching methods [3]. The taxonomy helps determine the appropriate methods for teaching and evaluating students based on the

desired level of competency. Although various teaching methods are used, clinical situations followed by multiple-choice questions, as well as open-ended questions, are commonly used initially [4]. However, these types of questions have limitations when it comes to assessing a student's analysis and clinical reasoning [5]. To address this, script concordance tests (SCTs) can be used to enhance the development of higher-level clinical reasoning skills [6].

The Use of SCTs

Methods such as SCTs are grounded in clinical cases designed to mirror real-life clinical scenarios, where information may be incomplete or unclear. The process involves presenting an initial vignette with some preliminary hypotheses, followed by additional information given to the student. SCTs assess how

this new information influences the likelihood of the initial hypotheses being considered as correct or relevant [6]. Students express the impact on the initial hypothesis using a 5-level Likert scale ranging from “much less likely” to “much more likely.” This process serves as a proxy for clinical reasoning, aiming to replicate decision-making in actual clinical practice. Typically, specialists in the subject develop the cases, and a robust SCT should comprise a minimum of 60 questions for strong internal validity [7-9]. The student’s responses are then compared to those of an expert panel, ideally consisting of at least 10 experts. Research suggests that 15 experts are necessary for high-impact testing, with minimal added benefit beyond 20 experts [10]. A notable limitation of SCTs is acceptability; a study on SCT acceptability with surgical residents revealed that experts tend to be more satisfied than students. Experts found the questions to be representative of real-life clinical settings [11]. However, SCTs may potentially provide a more precise assessment of students’ clinical reasoning compared to multiple-choice questions [12]. In psychiatry, the use of SCTs is emerging. Early data indicate good internal validity, with a correlation between learners’ education level, test scores, and improvement in evaluations tested before and after a psychiatry rotation [13].

The creation of SCTs demands a substantial investment of human resources [14]. Moreover, the questions are influenced by the designers’ inherent biases, necessitating multiple rounds of refinement with field experts [15]. This iterative process can lead to delays in developing educational materials. In a time when efficiency is crucial—such as during the COVID-19 pandemic or in situations with limited teaching resources—swift adaptations and improvements in the effectiveness of certain teaching methods may be imperative to uphold the quality of medical training [16,17].

Large Language Models and Their Uses in SCT Design

For clinician-educators seeking assistance in crafting educational materials, recent advancements include the availability of generative artificial intelligence (AI) tools, including large language models (LLM) such as ChatGPT (OpenAI) [18,19]. Originally designed for the public, these tools are currently under scrutiny by various companies and educational institutions to assess their limitations and advantages [20]. Numerous studies highlight the tool’s utility in developing clinical vignettes within medical studies and other health science domains [21]. However, to date, there is no study demonstrating the educational quality of SCT vignettes produced using ChatGPT. Before integrating tools such as ChatGPT into the design of educational materials, it is crucial to evaluate the quality of scenarios, questions, and related expertise generated by ChatGPT, as well as its ability to assess clinical reasoning. It is equally important to consider the potential limitations in using such tools for medical education material design. Although these generative models can be beneficial, they may also introduce errors that limit their usefulness [18]. As for medical students’ attitude toward AI, a recent study on the subject reported that medical students viewed AI in medicine as reliable, trustworthy, and technically competent, although they expressed limited confidence in its capabilities. While acknowledging AI’s intelligence, they did not consider it to be anthropomorphic. The consensus was that fundamental AI knowledge, covering its operation, ethics,

applications, reliability, and potential risks, should be integrated into medical education [22].

Objective and Hypotheses

The primary goal of this project is to investigate how SCTs generated by ChatGPT compare to those produced by clinical experts in 3 key aspects: the scenario (stem), clinical questions, and expert opinion. A secondary objective is to assess whether blind evaluators can distinguish between an SCT generated by ChatGPT and one crafted by experts. Additionally, another subobjective aims to identify the advantages and limitations of the clinical vignettes under examination. Our hypothesis posits that the clinical SCTs created by ChatGPT will likely be considered acceptable by the medical community in terms of scenarios and clinical questions. However, we anticipate that their use with learners may necessitate supervision from clinical experts. Preliminary studies have indicated that AI is a promising tool to aid clinician-educators in designing clinical scenarios. Still, given that the underlying algorithms rely on potentially erroneous data, it is crucial to validate and fine-tune the content before using them as educational materials for learners.

Methods

Ethical Considerations

This study received the approval of the ethics of research committee of the Université de Montréal (approval 2023-4906). Participants were given a description of the study in the letter they received and were asked for their consent for their data to be used. Data were anonymized. The participants received no compensation for this study.

Recruitment

The project was aimed at residents and clinician-educators in the field of psychiatry since SCTs are already used in UGME programs. To be included in the study, participants needed to be either clinician-educators in the field of psychiatry or medical residents in psychiatry affiliated with 1 of Québec’s 4 universities that offer UGME programs (McGill University, Université de Montréal, Université de Sherbrooke, and Université Laval). Psychiatrists not involved in an UGME program were excluded. A total of 100 participants were anticipated for this study, according to similar studies to determine whether there were significant differences between clinical vignettes developed by ChatGPT or those developed by experts [23,24]. Convenience sampling was conducted with the help of the departments of psychiatry of the 4 universities listed above, and a letter was sent out by email that includes a link to a survey that contained all the questions from this study.

Data Collection

A web-based survey, hosted on LimeSurvey (LimeSurvey GmbH), featured 3 SCTs generated by ChatGPT and 3 SCTs previously crafted by experts in the field, currently used in the digital learning environment at the Université de Montréal. The experts consisted of experienced psychiatrists and primary care physicians who underwent training in SCT concepts. As the primary language for the participants is French, the survey was

conducted in French. The original, comprehensive survey in French is available in [Multimedia Appendix 1](#), with an English translation provided in [Multimedia Appendix 2](#). Participants assessed the SCTs based on their respective roles. Due to the anonymous nature of the survey and the inclusion criteria requiring respondents to be either psychiatry residents or physicians, additional demographic data were not collected. The study did, however, document information on the participants' level of training (resident doctors vs clinician-educators) and their level of clinical experience (0-5, 6-10, or ≥ 10 y).

Each SCT was evaluated by the participants using the conceptual framework developed by Fournier et al [9] for creating SCTs. This conceptual framework provides a general guideline for SCTs. The SCTs involve real-life medical situations, each describing as a short scenario with some uncertainty. To solve the problem presented in each scenario, there are multiple relevant options available for the medical student. Each scenario, along with its questions, is considered an item. The questions are divided into 3 parts. The first part provides a relevant

diagnostic or management option. The second part introduces a new clinical finding, such as a physical sign or test result. The third part uses a 5-point Likert scale for examinees to express their decision on how the new finding affects the option, considering direction (positive, negative, or neutral) and intensity. Examinees are tasked with determining the impact of the new information, and the Likert scale is used to capture their decisions, as script theory suggests that clinical reasoning involves qualitative judgments.

Three components are evaluated by this framework when constructing SCTs: the scenario, clinical questions, and expert opinion. The scenario refers to the stem presented by the SCTs. The clinical questions are the individual questions adding a key element to the stem to stimulate clinical reasoning. The expert opinion refers to the opinion of an expert in the field giving a subjective appreciation as to the ability of the SCT to generate clinical reasoning. The elements of this framework are presented in [Table 1](#). A common SCT template was used for both SCTs generated by ChatGPT and the experts in the field to ensure that the presentation of the SCTs does not create bias.

Table 1. The script concordance test (SCT) components with their relevant questions as per the framework by Fournier et al [9] for the evaluation and conception of SCTs.

SCT components and questions	Potential answers
Scenarios	
S1. Describes a challenging circumstance, even for experts	Yes or no
S2. Describes an appropriate situation for test takers	Yes or no
S3. The scenario is necessary to understand the question and to set the context	Yes or no
S4. The clinical presentation is typical	Yes or no
S5. The scenario is well written	Yes or no
Clinical questions	
Q1. The questions are developed using a key element approach	Yes or no
Q2. In the opinion of experts, the options are relevant	Yes or no
Q3. The same option is not found in 2 consecutive questions	Yes or no
Q4. The new information (second column) makes it possible to test the link between the new information and the option (first column) in the context described	Yes or no
Q5. Likert-scale anchors are clearly defined and unambiguous	Yes or no
Q6. Questions are expanded to distribute responses equally across all Likert-scale values	Yes or no
Q7. Questions are designed to provide a balance between low and high variability	Yes or no

Expert Opinion

The participants needed to state if the SCT was generated (or not) by ChatGPT (single-blinded mode), give their main hypothesis as to the main diagnosis studied in the SCT, and

state in free-text style the strengths and weaknesses of each SCT.

Creating SCTs With ChatGPT

The ChatGPT tool operates through commands or prompts to enhance its performance. These prompts must offer a context of use, an expertise level, and a specific task. Following the typical steps involved in creating SCTs, we designed the prompts based on the approach outlined in Fournier et al [9]. In this initial study on the subject, we did not explore different sets of prompts, and the generated SCTs were used without modification.

The following commands were entered into ChatGPT to create the SCTs:

1. *Act as an expert in university pedagogy of health sciences, in the field of psychiatry.*
2. *Also acts as an expert in designing thumbnails by script matching.*
3. *Generates a script matching vignette that includes three questions for the following diagnosis: (diagnosis name), according to DSM-5.*
4. *Create questions linked to the vignette which start with if you think of "a diagnostic hypothesis" and you find "a sign or a symptom", this hypothesis is probable or not (from -2 to 2, using a Likert scale)*

Choosing the ChatGPT 3.5 algorithm as the main LLM for this task made sense for a few key reasons. This algorithm has a vast knowledge base covering a wide array of medical topics, making it an adequate tool for instructors crafting medical questions for medical students [25]. Its natural language comprehension, used in various medical fields, aids in question development [26]. The model's flexibility allows educators to create different types of questions to suit various learning styles and assessment methods. Notably, ChatGPT 3.5 supports multiple languages, including French, making it accessible for instructors in French-speaking regions. The model's ability to grasp context enables the creation of questions that build on existing knowledge, providing a more cohesive learning experience [27]. Educators can save time with the model's human-like text generation based on specific prompts or instructions. It is also crucial to highlight that this algorithm is open access and free, a substantial consideration when cost is a factor in choosing educational tools. Additionally, it is noteworthy that generating an SCT takes less than a minute on average with this tool.

Selecting Existing Expert-Created SCTs

Three SCTs were chosen at random from the 10 SCTs currently available to learners on the digital learning platform for the clinical psychiatry clerkship rotation at Université de Montréal. As stated above, a total of 3 ChatGPT-generated SCTs and 3 expert-created SCTs were chosen to limit the possibility that chance alone would identify the SCTs generated by ChatGPT from those produced by experts.

Statistical Analysis

A combined mixed method analysis was conducted with qualitative and quantitative components.

Qualitative Analysis

We conducted a content analysis by examining participants' open responses regarding the advantages and drawbacks of the presented SCTs. The objective was to pinpoint the primary types of benefits and limitations for emphasis. After receiving the open-ended survey responses, we individually extracted emergent themes from respondents using the grounded theory design framework [28]. Subsequently, AH and MP created an initial classification scheme based on these emerging themes. They applied this scheme to annotate the open-ended responses using the Qualitative Data Analysis Miner program (Provalis Research). Any discrepancies in annotations among responders were deliberated upon until a consensus was reached.

Quantitative Analysis

We conducted a descriptive statistical analysis to showcase the proportion of participants accurately identifying SCTs generated by ChatGPT compared to those crafted by experts. This same approach was applied to diagnostic hypotheses.

Additionally, we performed a descriptive statistical analysis to compare SCT scores based on the domains of the scenario and clinical questions, following the conceptual framework by Fournier et al [9]. Using a χ^2 test, we assessed the average results within each domain for the SCTs generated by ChatGPT and those by the experts. This allowed us to observe any statistical differences in the responses (yes or no) for various criteria within the scenario and clinical questions domains. We established a statistical significance threshold of $P < .05$ to identify noteworthy observations between the 2 types of SCTs.

Results

Participants Characteristics

A total of 102 participants completed the survey. Considering that there are an estimated 400 teaching clinicians in psychiatry in Quebec (about a third of the 1200 practicing psychiatrists), as well as 235 medical residents in psychiatry, this represents 16.1% (102/635) of the pool of potential responders. From the 102 participants, 45 (44.1%) identified as medical residents in psychiatry, 2 (2%) identified as teaching psychiatrists with less than 5 years of experience, 16 (15.7%) identified as teaching psychiatrists with between 6 and 10 years of experience, and 39 (38.2%) identified as teaching psychiatrists with more than 10 years of experience.

SCT Evaluation

The pooled averages of evaluations of the SCTs for each domain of assessment, stratified by the respondent categories, are shown in [Table 2](#). A complete table reporting the evaluations of the respondents for each individual component of the domains of assessment is available in [Multimedia Appendix 3](#). SCTs 2, 3 and 4 were generated by ChatGPT. It can be observed that there was no significant distinction between the pooled results for the SCTs generated by ChatGPT as compared to those generated by experts in the field. The questions related to the scenario component of the SCTs received better approval from the participants as compared to the clinical questions component.

Table . Responses for every component of the script concordance test (SCT) evaluations for the 6 SCTs, stratified by respondent categories. “Yes” indicates that the respondents agreed that the domain was elaborated appropriately.

SCT and evaluated component	Medical residents (n=45), n (%)	Teaching physi- cians (≤5 y; n=2), n (%)	Teaching physi- cians (6-10 y; n=16), n (%)	Teaching physi- cians (≥10 y; n=39), n (%)	Pooled average (N=102), n (%)

^aScript concordance tests created by ChatGPT.

Participants could not identify which SCT was created by ChatGPT from those created by experts in the field, as observed in Table 2. Teaching clinicians with more than 10 years of experience tended to better recognize SCTs generated by

ChatGPT than their peers with less experience and medical residents, except for SCT 4.

Comparisons Between ChatGPT- and Expert-Generated SCTs

When using the pooled observations for the scenario and clinical

questions domains across the SCTs generated by ChatGPT and those generated by experts, no statistically significant distinctions were observed when comparing both types of SCTs (all $P > .05$), as seen in [Table 3](#).

Table . Comparisons of the script concordance tests (SCTs) generated by ChatGPT as opposed to those generated by experts in the field.

Components	SCTs 1, 5, and 6 (experts), average score (%)	SCTs 2, 3, and 4 (ChatGPT), average score (%)	P value (ChatGPT-generated vs expert-generated SCTs)
Scenario	66.40	67.27	.84
Clinical questions	70.05	68.86	.99
Identifying if generated by AI ^a	54	40	.07

^aAI: artificial intelligence.

Reported Strengths and Weaknesses of the SCTs

Overview

Only 39 (38.2%) of the 102 participants wrote at least 1 comment on the strengths or weaknesses for each of individual SCT. The strengths and weaknesses of the SCTs generated by ChatGPT were similarly reported across all the respondents and resembled those identified for the SCTs generated by experts in the field. Respondents reported that SCTs generated by ChatGPT were well aligned with the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* but were also too caricatural.

Strengths of the SCTs Generated by Experts in the Field

Overall, 3 (8%) of the 39 respondents indicated for 1 or more SCTs generated by experts in the field that the scenario represented typical clinical challenges. Most of the respondents (27/39, 69%) reported that the SCTs used clear prompts to test clinical reasoning. Sample responses included the following:

This concordance test was easy to follow as because the scenarios were concise and the prompts were clear. [Respondent 1]

In terms of clarity, the prompts were well written and it was very simple to see how they could elicit clinical reasoning. [Respondent 9]

Strengths of the SCTs Generated by ChatGPT

Almost all respondents (32/39, 82%) mentioned that the SCTs were using typical clinical signs and symptoms reported in the *DSM-5*. Some (5/39, 13%) indicated that the SCTs were very well nuanced. Sample responses included the following:

This scenario corresponds to the textbook's description of the presented diagnosis. [Respondent 4]

I see that these prompts do not try to derive too much from the differential diagnoses intended for the suggested clinical presentation. They offered a degree of flexibility to enable the student to use their clinical reasoning. [Respondent 71]

Limitations of the SCTs Generated by Experts in the Field

In all, 2 (5%) of the 39 respondents mentioned that they found the SCTs straightforward and unchallenging. There were no other comments regarding the limitations of the SCTs generated by experts in the field. Sample responses included the following:

This scenario is too easy. I find little value as it is clear for the student that we are looking at the specific diagnosis. [Respondent 1]

I don't see how this is challenging for the medical student who is going to take this test. [Respondent 80]

Limitations of the SCTs Generated by ChatGPT

Most respondents (29/39, 74%) reported the SCTs generated by ChatGPT as caricatural or stereotypical clinical presentations as observed in textbooks with little regard to atypical presentations. A total of 7 (18%) respondents indicated that the SCTs generated by ChatGPT were too simple, as they tended to include additional information that were too trivial when attempting to challenge the responder's clinical reasoning. Sample responses included the following:

This is very trivial. I mean, it is not very difficult to find out what are the answers to these prompts as they clearly hint towards the same diagnosis. [Respondent 3]

It would be interesting to add more challenging prompts as they tend to be very simplistic and poorly represent complex clinical cases as they are very stereotypical to what is found in the DSM-5. [Respondent 4]

Discussion

Principal Findings

The aim of this study was to compare SCTs created by ChatGPT to SCTs produced by clinical specialists on the scenario (stem), clinical questions, and expert opinions. There were no significant distinctions between the SCTs generated by ChatGPT as compared to those developed by experts in the field for the evaluated components. The strengths and weaknesses were similar across the 2 types of SCT. Respondents reported that

the SCTs generated by ChatGPT were well aligned with the *DSM-5* but were also too caricatural.

Comparison With Prior Work

Since the creation of ChatGPT, it has been used in various areas of medical education such as digital teaching assistants and personalized education [29]. As a recent exploration study on the role of LLMs such as ChatGPT demonstrated, these models can provide interactive cases in a medical education context [30]. Considering these previous studies of ChatGPT in the development of medical education tools, it is possible that the inability to recognize a SCT generated by ChatGPT from one developed by experts in the field can be explained by the generative nature of this LLM. As such, a recent review on the use of ChatGPT in health care has identified that this form of AI can be used for problem-based learning and critical thinking in health care education [31]. However, it is mentioned in the literature that although the quality of the scenarios (or information) generated by ChatGPT might appear impressive, there is a need for an expert to assess the content generated, as it might be an amalgamation of erroneous information [32].

Although a few comments were provided regarding the strengths and limitations of both types of SCTs, they align with what is commonly reported in the literature for similar tasks. Some respondents noted caricature-like scenarios, possibly attributed to the robotic and dehumanized nature often associated with vignettes produced by LLMs [33]. It is plausible that more intricate prompts could have resulted in more nuanced scenarios. Therefore, the mentioned strengths of the scenarios and clinical questions, particularly their clinical alignment with the *DSM-5*, may be tied to the fact that this was one of the prompts used when conceptualizing interactions with ChatGPT during the creation of the SCTs.

In the field of psychiatry, applications of ChatGPT to medical education are limited. Among the limited available evidence, a novel study tested the knowledge of ChatGPT by exposing it to 100 clinical cases vignettes, and it performed extremely well [34]. Another similar use of ChatGPT was as an aid to answer clinical questions. A recent study evaluated the performance of users (psychiatrist and medical residents in the Netherlands) using ChatGPT as compared to nonusers for answering several questions in psychiatry, and it was observed that the users had better and faster responses as compared to nonusers [35]. Although these applications differ from this study, they might hint that ChatGPT currently has a database that holds relevant data in the field of psychiatry, which might explain the realism of scenarios and prompts observed for SCTs 2, 3, and 4.

There are substantial ethical considerations that must be accounted for when using such tool to assist medical educators. As an example, it is important to consider that ChatGPT (and other LLMs) are bound to the data they have been trained with along with their inherent biases [36]. Cross-validation of the generated information is often necessary to ensure that learners are not exposed to false information [37].

Limitations

Although web-based surveys offer convenience in distribution, they struggle with the challenge of accurately identifying the characteristics of the assessed population [38]. In our survey, we did not differentiate between those formally trained in SCTs and those who merely encountered them during their medical training, thus introducing potential limitations in generalizing the results. It is plausible that clinicians more experienced with SCTs were more likely to participate in the survey, but our recruitment from psychiatry departments exclusively helps mitigate this bias. Interpretation biases may also be present, as not all participants might be familiar with the framework used in this study. We did not explore acceptability regarding the use of generative AI in SCT creation, marking another limitation. Additionally, we did not compare different prompts, and it is conceivable that alternative sets of prompts could have produced better results for the SCTs generated by ChatGPT. Opting for a different language model might have yielded varied performances, and it is plausible that alternative models could outperform ChatGPT in this context.

Conclusions

In an era of rapidly evolving medicine and where technologies derived from AI are growing even more quickly, this study is the first to focus on the design of SCTs assisted by AI. The primary goal of this study highlighted that no statistical differences were found between the SCTs generated by ChatGPT and those created by clinical experts in the field of psychiatry for the elaboration of a scenario and the clinical questions presented in the SCTs. On average, the respondents incorrectly identified which SCTs were created with the help of AI. The major strength of SCTs generated by ChatGPT was that they were consistent with the *DSM-5*, whereas the caricatural quality or triviality of the SCTs generated by ChatGPT were the main weaknesses reported by the respondents. A possible way to mitigate this effect would be to provide more complex prompts to the generative AI or editing some details of the vignette. This study opens the door to larger-scale studies in this area to assess the impact of such aid on the academic success of medical students and how it can be used to improve efficiencies.

Abstract

Background: Artificial intelligence (AI) chatbots, such as ChatGPT-4, have shown immense potential for application across various aspects of medicine, including medical education, clinical practice, and research.

Objective: This study aimed to evaluate the performance of ChatGPT-4 in the 2023 Taiwan Audiologist Qualification Examination, thereby preliminarily exploring the potential utility of AI chatbots in the fields of audiology and hearing care services.

Methods: ChatGPT-4 was tasked to provide answers and reasoning for the 2023 Taiwan Audiologist Qualification Examination. The examination encompassed six subjects: (1) basic auditory science, (2) behavioral audiology, (3) electrophysiological audiology, (4) principles and practice of hearing devices, (5) health and rehabilitation of the auditory and balance systems, and (6) auditory and speech communication disorders (including professional ethics). Each subject included 50 multiple-choice questions, with the exception of behavioral audiology, which had 49 questions, amounting to a total of 299 questions.

Results: The correct answer rates across the 6 subjects were as follows: 88% for basic auditory science, 63% for behavioral audiology, 58% for electrophysiological audiology, 72% for principles and practice of hearing devices, 80% for health and rehabilitation of the auditory and balance systems, and 86% for auditory and speech communication disorders (including professional ethics). The overall accuracy rate for the 299 questions was 75%, which surpasses the examination's passing criteria of an average 60% accuracy rate across all subjects. A comprehensive review of ChatGPT-4's responses indicated that incorrect answers were predominantly due to information errors.

Conclusions: ChatGPT-4 demonstrated a robust performance in the Taiwan Audiologist Qualification Examination, showcasing effective logical reasoning skills. Our results suggest that with enhanced information accuracy, ChatGPT-4's performance could be further improved. This study indicates significant potential for the application of AI chatbots in audiology and hearing care services.

ChatGPT; medical education; artificial intelligence; AI; audiology; hearing care; natural language processing; large language model; Taiwan; hearing; hearing specialist; audiologist; examination; information accuracy; educational technology; healthcare services; chatbot; health care services

Introduction

In recent years, the rapid advancement of large language models (LLMs) has significantly expanded their usage in various domains. Among the leading artificial intelligence (AI) chatbots—such as Bard, Bing, and ChatGPT—there has been a notable increase in diverse applications in everyday life.

Prominently, ChatGPT, launched by OpenAI in November 2022 [1], stands out in the realm of AI chatbots. This model, known for its proficiency in generating and comprehending human-like text, showcases remarkable natural language processing skills. It has the capability to grasp complex queries, furnish insightful responses, and participate in meaningful conversations, thus

broadening the scope of AI's practicality in everyday scenarios [2,3].

ChatGPT represents a significant advancement in the field of natural language processing, exemplifying the latest developments in LLMs, particularly within the subset of autoregressive language models. Such generative LLMs, including ChatGPT, are predominantly trained on extensive text corpora. They use the decoder element of a transformer model, a groundbreaking architecture introduced by Vaswani et al [4] in 2017. This model is adept at predicting subsequent tokens in text sequences, a capability that has been progressively refined in subsequent research [5,6]. The transformer model, upon which ChatGPT is built, has revolutionized natural language processing. Its core strength lies in its ability to process text sequences efficiently, facilitating tasks such as language translation, question answering, and text summarization. One of the key features of this architecture is the self-attention mechanism, which allows it to understand long-range dependencies between words in a sentence without the need for sequential processing. This feature not only enhances efficiency compared to older recurrent neural network architectures but also offers improved interpretability, linking the semantic and syntactic structures of language inputs more effectively [4]. In addition to these capabilities, ChatGPT has evolved to incorporate real-time and knowledge-based information through various plug-ins. The introduction of GPT-4 by OpenAI in 2023 has expanded ChatGPT's proficiency to include processing both image and text inputs [1], marking a new milestone in the versatility and applicability of AI in diverse contexts.

ChatGPT has received considerable attention and exploration in its application within health care. The integration of ChatGPT into health care demonstrates its significant potential in enhancing patient education and handling general inquiries, marking it as a vital informational and supportive tool [7]. The broad applicability of AI chatbots in health care extends beyond patient interaction, serving clinicians, researchers, and students, with ChatGPT showing effectiveness in personalizing patient interactions and providing consumer health education [8,9]. This trend aligns with the overarching aim in health care AI to increase accessibility to medical knowledge and make care more affordable. Chatbots offer continuous health advice and support, potentially improving patient outcomes by reducing the need for in-person consultations. Additionally, they provide health care professionals with valuable insights for more informed patient care decision-making, though concerns regarding data transparency have been noted [10]. ChatGPT is capable of generating empathetic, high-quality responses to health-related queries, often comparable to those of physicians, and shows promise in producing emotionally aware responses with potential for continuous improvement [11,12]. In low- and middle-income countries, ChatGPT has great potential as a pivotal tool in public health efforts. Its advantages span various domains such as health literacy, screening, triage, remote support, mental health, multilingual communication, medical training, and professional support, addressing numerous challenges in these health care systems [13]. Furthermore, ChatGPT's role as a supplementary educational tool in areas requiring aptitude, problem-solving, critical thinking, and reading comprehension has been

highlighted. The ChatGPT-4 version, in particular, shows potential in applications such as discharge summarization and group learning, enhancing human-computer interaction through verbal fluency [14,15]. However, the need for embracing these advancements while ensuring patient safety and recognizing the limitations of AI in intricate clinical cases is emphasized [16].

The evolution of computational sciences in hearing care services and research has given rise to the field of computational audiology. This approach combines algorithms, machine learning, and data-driven modeling for audiological diagnosis, treatment, and rehabilitation, using biological, clinical, and behavioral theories to augment care for patients and professionals [17]. The rapid development of AI technologies, especially LLMs such as ChatGPT, has significantly contributed to this field's growth. ChatGPT's advanced capabilities position it as a potential tool for patient interaction, education, aural rehabilitation program, and preliminary diagnostics in audiology [18,19]. However, it is crucial to recognize its current limitations. While it can handle complex interactions, it is not a substitute for human expertise in specialized areas such as audiology and is limited in interpreting nuanced medical information or performing physical diagnostics. AI chatbots have shown immense potential in hearing health care, aiding patients, clinicians, and researchers. Their applications range from initial screenings, educational support, and teleaudiology services for patients, to data analysis and decision support for clinicians and researchers [19]. In countries with vast geographical areas and imbalanced hearing care resources, AI chatbots could significantly enhance the development of hearing care services. Very recently, explorations into the use of AI chatbots for answering questions pertaining audiological knowledge have shown that AI chatbots can serve as a tool to access basic audiological information [20]. However, the accuracy and reliability of information provided by these tools remain a concern [19].

Despite the significant potential of AI chatbots to enhance hearing care services, research in this area remains sparse. AI chatbots' ability to understand questions and provide logical responses based on available information is crucial. This capability suggests promising applications in hearing care, including educational support, patient assistance in clinical settings, and aid for clinical staff. By engaging with AI chatbots, students, teachers, patients, and clinical personnel could significantly improve learning outcomes, patient care, and clinical practice efficiency. Therefore, this study starts from the most fundamental aspects to explore the performance of the current commercial version of ChatGPT-4 in taking an audiologist qualification examination (ie, the Taiwan Audiologist Qualification Examination). This investigation not only assesses the accuracy of responses to test questions but also explores the ability of the current AI chatbot to comprehend and logically respond to examination questions. These capabilities form the cornerstone for future integration of AI chatbots into educational support or clinical service assistance.

Methods

Materials

This study used the 2023 Taiwan Audiologist Qualification Examination [21]—a professional licensing examination for audiologists in Taiwan. Candidates of this examination are required to have a bachelor's or masters's degree in audiology and at least 6 months or 375 hours of clinical practice. The examination comprises six subjects: (1) basic auditory science, (2) behavioral audiology, (3) electrophysiological audiology, (4) principles and practice of hearing devices, (5) health and rehabilitation of the auditory and balance systems, and (6) auditory and speech communication disorders (including professional ethics). Each subject consists of 50 multiple-choice questions, except for behavioral audiology, which has 49 questions, totaling 299 questions in all. The examination papers featured 7 images, pivotal for answering 13 of the questions. Notably, these images were embedded directly within the PDF version of the examination rather than being provided as separate attachments. However, it is important to highlight that the images' resolution was relatively low, and they were presented

without color. When extracted and saved in JPEG format, the images ranged in size from 12.7 to 27.2 KB and had resolutions spanning from 82 to 150 DPI. All related PDFs are accessible for download from the official source [21].

Prompt Engineering

Recognizing the significant influence of prompt engineering (where “prompt” refers to the input text provided by the user, which the model responds to) on the outputs of generative LLMs, a standardized prompt format was used in this research: “Please answer the following multiple-choice question as a hearing care professional, providing reasoning and explanation.” This format was chosen to assess the logic and reasoning behind ChatGPT's responses. The original examination questions, a blend of Traditional Chinese and English, often used bilingual terminology for specialized concepts. For this study, ChatGPT was instructed to respond in English. Additionally, ChatGPT was not informed that these questions were from the Taiwan Audiologist Qualification Examination to prevent it from sourcing specific information to increase the accuracy of its responses. An example of a prompt and response is illustrated in [Figure 1](#).

Figure 1. A template of a question posed to ChatGPT-4 and its corresponding responses. The example provided is the first question from the basic auditory science examination. The italicized English translations in the question stem are solely for reader comprehension and are not included in the actual prompt.

Procedure

All questions and correct answers were downloaded from the official website of the Taiwan Ministry of Examination in PDF format [21]. Subsequently, all questions were pre-edited in a Word (Microsoft Corp) document to avoid formatting issues. ChatGPT-4, enhanced with DALL-E (Decoder-Only Autoregressive Language and Image Synthesis), browsing, and analysis capabilities, was used for the test from December 10 to 12, 2023. A separate chat was used for each subject of the examination. Despite being within the same subject, the questions essentially had no overlapping content. For questions presented as images, both the image and the text format of the

question were provided to leverage ChatGPT-4's image recognition capabilities. It is important to note that the resolution of the images supplied in the test was relatively poor, which could have potentially impacted the accuracy of image recognition. Following the approach of Gilson et al [9], the reasons for errors in incorrectly answered questions were categorized as follows: (1) logical errors: the response correctly identifies relevant information but fails to translate this information into an appropriate answer; (2) information errors: ChatGPT either overlooks a key piece of information, whether present in the question stem or from external sources, or shows a lack of expected knowledge; and (3) statistical errors: the error is due to a miscalculation, including explicit arithmetic errors

or incorrect estimations of statistical data. Authors SW and CM, both having a PhD in audiology, reviewed the original questions in Chinese and the GPT's responses in English, and then compared ChatGPT-4's responses to the official correct answers provided for the examination (all multiple-choice questions) to determine whether each question was answered correctly. They then performed a cross-check to ensure the accuracy of this step. Subsequently, SW and CM classified the incorrect answers into the 3 aforementioned categories and compared their classification results. In case of any discrepancies, they consulted with HW, who has a master's degree in public health, to reach a consensus and make a final decision together.

Ethical Considerations

This research did not involve human participants or private data and was therefore exempt from ethics approval by the ethics committee of Ningbo College of Health Sciences.

Data Analysis

The data analysis for this study was straightforward and conducted using Excel (Microsoft Corp). Our primary objective was to calculate the accuracy rate of ChatGPT-4 when tasked with taking the Taiwan Audiologist Qualification Examination.

Table . Performance of ChatGPT-4 in the 2023 Taiwan Audiologist Qualification Examination.

	Questions, n	Correct responses, n	Accuracy rate, %
Basic auditory science	50	44	88
Behavioral audiology	49	31	63
Electrophysiological audiology	50	29	58
Principles and practice of hearing devices	50	36	72
Health and rehabilitation of the auditory and balance systems	50	40	80
Auditory and speech communication disorders (including professional ethics)	50	43	86
Total questions	299	233	75
Questions with images	13	8	62
Images	7	4	57

Information Errors Leading to Incorrect Answers

Lack of Correct Information Sources

Most incorrect answers were due to ChatGPT-4 relying on inaccurate information. For example, in the basic auditory science examination, question 43 involved identifying an incorrect statement about temporal masking among options A, B, C, and D. Option B stated that forward masking occurs when a signal appears after the masking noise, even with a 200-millisecond gap between the 2 stimuli (which is a misconception). The correct answer was that this statement is false, but ChatGPT-4's explanation suggested otherwise:

Forward Masking with 200 ms Gap (B): This is correct. Forward masking can occur when the signal appears after the masking noise, even with a gap as long as 200 ms.

Results

Overall Performance

ChatGPT-4 demonstrated commendable performance in the Taiwan Audiologist Qualification Examination. The accuracy rates for the 6 subjects were as follows: 88% for basic auditory science, 63% for behavioral audiology, 58% for electrophysiological audiology, 72% for principles and practice of hearing devices, 80% for health and rehabilitation of the auditory and balance systems, and 86% for auditory and speech communication disorders (including professional ethics). The overall accuracy rate for the 299 questions was 75% (see [Table 1](#)). The examination's passing criteria include an average accuracy rate of 60% across all subjects. Thus, ChatGPT-4 successfully passed this examination. Records of all ChatGPT-4's responses to the test questions can be found in the supplements ([Multimedia Appendices 1-6](#)). A detailed review of ChatGPT-4's responses revealed that errors were not caused by logical or statistical errors; instead, all incorrect answers resulted from information errors.

This response indicates that ChatGPT-4 did not have accurate information to answer this question. As a matter of fact, no masking occurs when the time interval between the masker and the signal equals or exceeds 200 milliseconds [22]. Similarly, for option D, which stated that forward masking is more effective than backward masking, ChatGPT-4's choice and explanation were as follows:

Forward Masking More Effective Than Backward Masking (D): This is typically incorrect. Backward masking is often found to be more effective than forward masking.

While this appears correct at first glance, it lacks the clarification that backward masking is more effective than forward masking when the same time interval exists between the masker and signal, with more masking occurring when the masker follows the signal [23]. However, from the perspective of the

information available to ChatGPT-4, option D was the most reasonable choice.

Conflicting Information Sources

Multiple sources of information also led to incorrect responses from ChatGPT-4. For example, question 22 in the electrophysiological audiology examination asked about the most appropriate frequency for tympanometry in newborns, with the correct answer being 1000 Hz. Despite its simplicity and lack of complexity in reasoning, ChatGPT-4 provided an incorrect response:

(A) 112 Hz is typically used for infants and young children. Newborns and young children have a more compliant ear canal than adults, and lower frequencies such as 226 Hz can sometimes overestimate middle ear pressure and compliance. Therefore, a lower frequency probe tone is often recommended.

Considering the straightforward nature of this question, the authors expected an accurate answer from ChatGPT-4. Therefore, after the conclusion of all tests, the question was posed to ChatGPT-4 twice more in separate new dialogues to avoid information cross-over. Two completely different responses were generated by ChatGPT-4:

226 Hz Standard: The 226 Hz probe tone is the standard frequency used in clinical tympanometry for all ages, including newborns. This frequency has been proven to provide reliable and accurate measurements of middle ear function in this age group. It is effective in identifying middle ear fluid, a common issue in newborns, and other conditions that might affect hearing. ... In conclusion, 226 Hz (option B) is the most suitable probe tone frequency for tympanometry in newborns, due to its effectiveness in assessing middle ear function accurately in this specific age group.

and

When performing tympanometry on a newborn, the most appropriate probe tone frequency is typically 1000 Hz (Option C). Let me explain why:

Age-Related Differences: The middle ear mechanics in infants, especially newborns, differ significantly from those in older children and adults. These differences are mainly due to the size and composition of the middle ear and ear canal, as well as the compliance of the tympanic membrane.

High-Frequency Probe Tones: A 1000 Hz probe tone is recommended for newborns and infants up to around six months of age. This higher frequency provides more accurate assessments of middle ear function in this age group, as it is less affected by the high compliance of the infant ear canal.

Therefore, the most appropriate option for tympanometry in newborns is 1000 Hz (Option C), as it offers the most reliable assessment of middle ear function in this specific age group.

This indicates that ChatGPT-4 may provide different answers each time based on varying sources of information, particularly when these sources have conflicts or inconsistencies.

Image Information Recognition

In the examination, 13 questions could be answered only through the recognition of images to extract information. ChatGPT-4 correctly answered 8 of these questions. Images 1 to 4 are from the behavioral audiology subject, images 5 and 6 are from the electrophysiological audiology subject, and image 7 is from the principles and practice of hearing devices subject. Out of the 7 images provided in total, ChatGPT-4 successfully recognized 4. The criterion for determining successful recognition was assessing the accuracy of ChatGPT-4's interpretation of image content and its ability to extract pertinent information for answering questions. Authors SW and CM independently evaluated this aspect and subsequently performed a cross-check of their assessments.

Discussion

Principal Findings

This study evaluated ChatGPT-4's performance in the 2023 Taiwan Audiologist Qualification Examination. The eligibility criteria for this examination are having a degree in audiology or a related field and a minimum of 6 months or 375 hours of clinical practice. The minimum required accuracy rate to pass the examination is set at 60%. In the 2023 examination, 88.5% of candidates achieved this accuracy rate or higher, effectively passing the examination. ChatGPT-4 achieved an overall accuracy rate of 75%, meeting the passing criterion necessary for candidates to obtain the basic qualification for practicing as clinical audiologists in Taiwan. It performed notably well in subjects that required more analytical reasoning and contextual decision-making, such as health and rehabilitation of the auditory and balance systems and auditory and speech communication disorders (including professional ethics). The proficiency of LLMs in integrating and interpreting information logically was evident in subjects demanding contextual knowledge. However, in fields such as electrophysiological audiology, which depend more on precise knowledge points, the accuracy of ChatGPT-4 was challenged when confronted with incorrect or insufficient information. In our study, the original questions were in both Chinese and English. We requested ChatGPT to provide responses in English, and the translation between the 2 languages did not negatively impact either the comprehension or the accuracy of the responses. In addition, although this research was a preliminary examination of ChatGPT-4's capabilities in image recognition within audiology examinations, it is important to note that the number of images used was limited, and their quality and resolution were suboptimal. Nevertheless, despite these constraints, ChatGPT-4 demonstrated a moderately acceptable level of image recognition performance, successfully identifying over half of the content within the images.

Comparative analysis with the existing literature indicates that LLMs such as ChatGPT have shown promising results in medical examinations [24-26], particularly GPT-4 [27]. The model's ability to pass examinations that are challenging for

many humans has been noted [9,28]. In our study, which involved multiple-choice questions, ChatGPT was tasked with not only selecting answers but also articulating the reasoning behind its choices. Notably, ChatGPT-4 has substantially reduced the incidence of logical and statistical errors that were more prevalent in its predecessors. Its accuracy rate in examinations based on multiple-choice questions has increased from 53.6% with GPT-3 and -3.5 to 75.1% with GPT-4 [27]. The absence of logical errors, in particular, suggests that ChatGPT-4 has an enhanced ability to understand questions accurately and make decisions that are logically coherent, using the information it has access to [9,27]. This advancement is especially relevant in the context of audiology examinations, especially in the multiple-choice question format, where statistical reasoning has traditionally been less emphasized. In this study, the primary challenge faced by ChatGPT-4 in accurately answering questions was identified as information errors, which primarily manifest in 2 distinct forms: a lack of correct information sources and the presence of conflicting information sources. The former issue directly impacts the ChatGPT's performance; for several questions, ChatGPT-4 lacked the necessary correct information to either directly answer or logically deduce the correct responses. Despite its training on an extensive database of information [29,30], it became evident that ChatGPT-4 does not possess a comprehensive knowledge base required to flawlessly address specialized queries within the field of audiology, a discipline that demands a high degree of professional expertise. Conversely, the presence of conflicting information sources contributed to erroneous responses from ChatGPT. The model, although equipped with a wealth of information, was not developed with a focus on audiological knowledge or audiology best practices. This abundance of data, however, presents a challenge in verifying the accuracy and reliability of the information, especially when multiple sources offer conflicting viewpoints on widely discussed topics. This was exemplified in this study's results, where a question on a fundamental concept in audiology—the use of 1000 Hz in tympanometry for children—resulted in ChatGPT-4 providing 3 distinct answers. Additionally, the lowest scores were observed in questions related to electrophysiological audiology. Apart from the issue of inaccurate sources of information, another possible reason is that information about electrophysiological audiology might be more specialized than that in other subjects, thereby restricting the amount of information that ChatGPT has access to. This is unlike the case with hearing aids or auditory rehabilitation, where a vast amount of information is readily available on the internet. Altogether, this highlights the necessity for further refinement of LLMs, emphasizing the integration of more precise and professionally relevant information. This approach will ensure that responses are derived from verified and accurate data sources, pointing to a crucial direction for future research in this area [31].

AI Chatbots and Audiology

The introduction of advanced AI models such as ChatGPT-4 has significant implications in hearing health care [18]. ChatGPT's capacity to process and analyze extensive data makes it a potentially useful tool for patients, clinicians, and researchers

[19]. Our findings suggest that given training with reliable information, even the current iteration of ChatGPT-4 holds considerable promise for application in hearing care services. This potential is likely to increase alongside the continual advancements in LLMs. The results of this study show that when faced with professional-level audiology questions, AI chatbots can provide answers with a high accuracy rate and logical reasoning. Furthermore, their ability to mimic human-like responses suggests that they are capable of assisting in educational learning and hearing care awareness. However, this is contingent upon first building a fine-tuned model with accurate information sources.

In the context of patient care, AI chatbots could act as digital audiologists, providing answers to a range of hearing-related queries. Their easy accessibility may be beneficial for early hearing screenings and prompt intervention or medical attention. AI chatbots also have the potential to educate patients about hearing issues and offer psychological support for conditions such as tinnitus. They have been shown to have potential in managing mental health concerns and demonstrate a level of empathy that can surpass that of human physicians [11,32]. The development of AI chatbots as qualified audiologists could greatly enhance teleaudiology services. For clinicians, AI chatbots could serve as supportive tools, offering rapid references or recommendations based on current research and guidelines, aiding in diagnosis and treatment suggestions [33], and facilitating the creation of diagnostic or referral reports [34]. This is especially relevant in regions with limited hearing care resources [13], where AI chatbots could play a vital role in both the education of hearing care professionals and in augmenting clinical services. This enhancement could lead to improved overall quality and availability of hearing care services, ultimately benefiting individuals with hearing impairments. Similarly, researchers in auditory science could use AI chatbots to streamline their research processes. However, the effectiveness of these proposed applications depends on the thorough and complete validation of the chatbots' functionality and information accuracy.

Limitations

This study represents a preliminary exploration of an AI chatbot's performance in an audiologist qualification examination. However, several limitations must be acknowledged. First, the selected examination questions were exclusively multiple-choice, with a subset requiring integrated information for reasoning. This format lacks open-ended questions that typically mirror the complexity of real-world clinical scenarios in hearing care, where audiologists address diverse and intricate issues beyond isolated knowledge points. Future research could extend to evaluating AI chatbots in handling complex audiology cases. Second, while this study included an assessment of ChatGPT-4's image recognition capabilities, the quality of the images in the original test files was suboptimal. Additionally, the number of questions involving image information was limited, which constrained the ability of this study to draw substantial conclusions about this functionality.

Conclusions

In conclusion, the findings of this study show that ChatGPT 4 achieved a 75% accuracy rate in the 2023 Taiwan Audiologist Qualification Examination, thus successfully passing it. The primary reason for ChatGPT-4's incorrect responses was identified to be information errors, including both a lack of correct information sources and the presence of conflicting information sources. Therefore, a fine-tuned model containing

accurate hearing care information sources has the potential to further enhance the feasibility of AI chatbot applications in hearing care services. However, passing the examination does not imply that ChatGPT-4 can become a qualified clinical audiologist in Taiwan; rather, it only indicates that ChatGPT-4 has some basic knowledge required for the audiology profession. Adequate clinical internship hours are also a crucial requirement for the actual practice of audiology in Taiwan, and its performance in handling real clinical cases remains unknown.

Acknowledgments

The authors wish to express gratitude for the rapid development of large language models, which brings hope for future improvement in hearing care globally. ChatGPT was used to proofread and correct grammatical issues in this article.

Data Availability

The data supporting the findings of this study are available from the corresponding author upon request.

Authors' Contributions

SW led the study's design, managed the data, performed the analysis, and contributed to drafting the manuscript. CM, YC, and XD helped conceptualize the study. HW also participated in the analysis, while XS oversaw the study's administration.

Abstract

Background: Critical evaluation of naloxone coprescription academic detailing programs has been positive, but little research has focused on how participant thinking changes during academic detailing.

Objective: The dual purposes of this study were to (1) present a metacognitive evaluation of a naloxone coprescription academic detailing intervention and (2) describe the application of a metacognitive evaluation for future medical education interventions.

Methods: Data were obtained from a pre-post knowledge assessment of a web-based, self-paced intervention designed to increase knowledge of clinical and organizational best practices for the coprescription of naloxone. To assess metacognition, items were designed with confidence-weighted true-false scoring. Multiple metacognitive scores were calculated: 3 content knowledge scores and 5 confidence-weighted true-false scores. Statistical analysis examined whether there were significant differences in scores before and after intervention. Analysis of overall content knowledge showed significant improvement at posttest.

Results: There was a significant positive increase in absolute accuracy of participant confidence judgments, confidence in correct probability, and confidence in incorrect probability (all P values were $<.05$). Overall, results suggest an improvement in content knowledge scores after intervention and, metacognitively, suggest that individuals were more confident in their answer choices, regardless of correctness.

Conclusions: Implications include the potential application of metacognitive evaluations to assess nuances in learner performance during academic detailing interventions and as a feedback mechanism to reinforce learning and guide curricular design.

KEYWORDS

naloxone; coprescribing; prescription; academic detailing; metacognition; metacognitive evaluation; pharmacotherapy; pharmaceutical; education; educational intervention; opioid; opioid overdose; harm reduction

Introduction

In 2020, of the 91,799 drug-related overdoses in the United States, 75% involved an opioid [1]. Naloxone is an invaluable tool to prevent opioid overdose [2], and coprescription initiatives (or programs to encourage providers to prescribe naloxone to patients receiving opioids) are a common, important intervention to reduce fatal overdoses. This is especially true in primary care settings, since eligible patients who meet the Centers for Disease Control and Prevention coprescription guidelines are underprescribed naloxone to take home [3].

Academic detailing programs are educational outreach approaches used to improve clinician decision-making, and they have consistently shown a positive effect on altering prescriber behavior and clinical decision-making [4]. Health systems have

implemented naloxone coprescription academic detailing programs with demonstrated positive effects on the number of providers prescribing and patients receiving naloxone [2,5]. Critical evaluations of such programs have shown acceptability and feasibility of such interventions [3], including positive impact on increasing the number of prescriptions despite hesitancy around the logistics of implementation [6] and increasing the number of prescriptions after brief interventions [7].

Learners in the health professions are important allies for combatting overdose; interventions have been developed for health profession students to be trained in overdose education and naloxone distribution [8]. Results from student-focused overdose education and naloxone distribution interventions indicate increases in average participant knowledge around

identifying and responding to suspected overdoses [8]. To extend knowledge on changes in participant thinking during educational interventions, one area to consider is the effect on participant metacognition. Here, metacognition refers to the beliefs, attitudes, and confidence related to influencing a particular cognitive task, colloquially summarized as thinking about thinking. The measurement of participant metacognitive processes is especially important in health education because of the importance of the desired outcomes and the need for a life span approach to learning in the health professions. Improvements in metacognition in health education interventions have been linked to improved content knowledge acquisition, improved clinical reasoning, and decreased avoidable errors [9]. However, assessing metacognition is not often a focus of medical education evaluation, and those who wish to evaluate metacognition are often met with a lack of clarity on how to effectively measure it [10].

The dual purposes of this brief report are to (1) present a metacognitive evaluation of a naloxone coprescription academic detailing intervention for health professions students and practitioners and (2) describe the application of a metacognitive evaluation for future medical education interventions.

Methods

Data

Participants completed a self-paced, web-based academic detailing naloxone coprescription intervention implemented by Rowan University School of Osteopathic Medicine (RUSOM). This brief continuing medical education (CME)-eligible course provided a standardized, evidence-based curriculum to train RUSOM-affiliated health care providers, administrators, students, and executives across a variety of health care settings on how to implement and sustain naloxone coprescribing programs. Participants were recruited via email, and the only incentive was providing the CME credit at no cost. Consent was provided by agreeing to a question prompt to continue each survey after reading the informed consent documentation.

Data for this analysis came from a 20-item knowledge assessment based on the Centers for Disease Control and Prevention naloxone coprescription guidelines [11], previously validated overdose knowledge assessment instruments [12], as well as guidance based on best practices in implementation science [13]. It was delivered in a pre-post design, where participants completed the knowledge assessment before accessing the educational intervention and after course completion. The course was designed as a single module to be completed in 1 session. Participants were eligible for CME credits after completion if they achieved a passing score; multiple individuals had more than 1 posttest score as they attempted to meet that minimum score. To avoid a bias in results, knowledge scores that came chronologically first were used as the posttest score in all analyses.

To assess metacognition, items were designed with confidence-weighted true-false (CTF) scoring, which combines traditional true-false questions with each learner's rated confidence for each item (I am confident this is true; I believe

this is true, but I am unsure; I believe this is false, but I am unsure; and I am confident this is false). CTF is a useful and simple means to measure both cognitive and metacognitive achievements [14].

Study Sample

The sample includes any individual who completed both pre- and posttest assessments for the naloxone coprescription educational intervention between dates April 2020 and July 2021. To access the intervention, participants had to register via a university web application (from which voluntary demographic data were derived) and then log in to their learning management system. While the intervention provided an opportunity for CME credits, any individual was able to register for and take the course, including nonprescribers and students.

Analysis

Descriptive statistics were calculated for individuals in the study sample. For both the pre- and posttest, 3 content knowledge scores were calculated: the summed CTF score (where confidently incorrect scores equal 0 points and confidently correct scores equal 4 points), the percent correct CTF score (based on maximum of 80), and the binary percent correct score (true/false [T/F]) (number correct regardless of confidence or number of items). In addition, metacognitive scores were calculated using the methods described by Dutke and Barenberg [14] and included absolute accuracy of confidence judgments (AC), bias of confidence judgments (BS), confidence correct probability (CCP), confidence incorrect probability (CIP), and discrimination between correct and incorrect decisions (DIS). AC reflects the overall match between participant confidence and the outcome of their choice. An increase in AC suggests that individuals are better able to gauge both when they are confident in correct answers and unconfident in incorrect answers. BS is similar to AC but gives an indication of the direction and severity of participant ability to correctly assess their level of confidence in an answer. Values close to 0 indicate an exact match between confidence or nonconfidence and correctness or incorrectness, positive values suggest overconfidence (more confident but less correct), and negative values indicate underconfidence (less confident but more correct). However, the BS does not indicate the relative contribution of confidence to correct or incorrect answers, and the CCP and CIP are used to discern the respective probabilities of being confident that the answer is correct (CCP) or confident that the answer is incorrect (CIP). A higher CCP score indicates higher confidence when the answer is correct. A lower CIP score indicates less confidence when the answer is incorrect. A high CCP and low CIP suggests improvement in metacognition. Finally, the DIS is the difference between the CCP and CIP probabilities and is used to indicate how reliably a participant discriminates between correct and incorrect answers, with higher values indicating appropriate participant metacognitive monitoring and the ability to discriminate between concepts that are known and those that need reinforcement [14]. To correct for a left-skewed distribution of assessment values, Wilcoxon signed rank analyses were applied to assess changes in individual scores between pre- and posttest assessments. Finally, Rosenthal correlations were calculated to determine

the effect size of the intervention on each metacognitive score. Item-level examinations of CTF distribution were completed to add context to the metacognitive outcomes and identify concepts in the naloxone coprescription framework that may need reinforcement. McNemar tests were used to determine whether there was a significant change in correctness from pre- to posttest for each item. Statistical analyses were completed using Stata 17 (StataCorp LLC).

Ethical Considerations

This study was approved by the Rutgers University Institutional Review Board (ID2019000275). Participants were provided informed consent at pretest and posttest, and data were deidentified prior to analysis. The course and CME credit were provided at no cost to participants, and no additional compensation was provided.

Results

Sample descriptive statistics are shown in Table 1; 307 individuals completed both pre- and posttests. As shown in Table 2, analysis of overall test scores showed a statistically significant improvement in content knowledge after completing the educational intervention, both in CTF score and binary correct-incorrect score. For both, the effect size of the intervention was moderate.

Significant differences in metacognitive scores suggest potential improvements in metacognitive monitoring occurred during the intervention. There is a statistically significant increase in absolute AC with a moderate effect size, suggesting that after intervention individuals are better able to gauge when they are *confident* in *correct* answers and *unconfident* in *incorrect* answers. For BS, median response values changed from negative to positive with a strong effect size, suggesting an overall change from being underconfident (negative values) in answer choices to appropriately confident (null or positive values) after intervention. Both CCP and CIP had a significant, positive change after intervention with strong effects. There was a significant decrease in DIS score after intervention with a very low effect size, which likely reflects an underlying increase in confidence in incorrect answers after academic detailing.

Table 3 shows the CTF and binary T/F frequencies for each item and an indication of significant change from pre- to posttest using McNemar test. Most items saw their binary correct answers increase at posttest; only 1 item (item 15) saw a significant decline in correct answers ($t_{306}=-4.41$; $P=.04$). This item was part of a conceptual group of questions (items 7, 12, and 15) on determining individual risk of overdose using the Risk Index for Overdose or Serious Opioid-Induced Respiratory Depression (RIOSORD) tool. From a metacognitive perspective, this group of questions also saw the frequency of confident incorrect answers increase at posttest between 117% and 350%.

Table . Demographic characteristics of participants (N=307).

Characteristics	Participants

^aRIOSORD: Risk Index for Overdose or Serious Opioid-Induced Respiratory Depression.

^bRE-AIM: reach, effectiveness, adoption, implementation, and maintenance.

Discussion

In summary, findings suggest that the naloxone coprescription academic detailing intervention was effective at delivering content area knowledge and stimulating metacognition about coprescription practices. From a knowledge gain perspective, the intervention saw increases in participant knowledge along the key objectives of a naloxone coprescription program. In addition, metacognitively, results suggest that individuals were more likely to be confident in their answer choices after the intervention. While the confidence gain was seen mostly among participants who chose correct answers, a small number of participants also became overconfident in their incorrect answers. This finding could support the development of refresher courses as a tactic to reexpose those who were overconfident to the material to correct any misunderstanding of course content [15], and for naloxone-prescribing programs, refreshers would be needed to account for the changing nature of the naloxone marketplace or clinical guidelines for overdose risk. The absolute AC significantly improved after intervention. Participants were better able to confidently discern correct and incorrect answers at posttest.

Across medical education settings, metacognitive evaluations have been implemented successfully, which has resulted in improvements in metacognition itself [16], the learning and retrieval of basic science information [17], and moderation of performance test anxiety in observed clinical examinations [18]. Even withstanding the complexity of metacognitive measurement concepts [10], CTF presents itself as a simple mechanism for metacognitive evaluation available to medical educators and evaluators, allowing them to assess potential areas of weakness in content delivery and specific areas where students may struggle with concepts [14]. Academic detailing programs applying metacognitive evaluative processes may be best served by developing feedback loops for learners and curriculum designers driven by the results CTF tests. In our results, learners were the most confident in incorrect answers for questions detailing the specifics of assessing individual risk of overdose. Feedback to learners could provide clarification on application of the RIOSORD tool through follow-up emails, refresher courses, or the development of learning communities to support implementation and adoption. Feedback to curriculum

designers may prompt an evaluation of course content to identify what course updates were needed to ensure key concept delivery.

This specific intervention was self-paced and web-based, a common format available for CME. Electronic interventions have been shown to be no different for metacognition than in-person interventions, despite having no formal educator to guide the process [19]. This is important evidence to bolster the benefit of web-based continuing education [9], especially given the proliferation of web-based education that occurred during the COVID-19 pandemic [20]. Evidence suggests that if learners are going to engage in a self-paced curriculum, adding a metacognitive layer forces learners to critically think about their content knowledge acquisition [21]. The identified potential overconfidence observed in this study after receiving education is consistent with other metacognitive evaluations [22].

This study is not without limitations. The evaluation used a 1-group pretest, posttest design, which limits generalizability of the findings. While the course on best practices for coprescribing was brief and designed to be completed in 1 session, it is unknown how or whether other naloxone initiatives may have influenced participants. The academic detailing program's enrollment was open to RUSOM and its affiliates; it is not possible to rule out selection bias as 1 factor influencing score improvements.

While metacognitive processing was shown to be important for behavior change, we do not have a long-term measure to determine whether the intervention resulted in increased naloxone prescription or even whether learners went on to implement coprescription initiatives in their practice settings. As referenced earlier, there are multiple ways to assess metacognition, of which CTF is one, and the validity of one accepted measure of metacognition has yet to be established. However, this particular method of assessing metacognition with multiple conceptual domains allows evaluators to use several diagnostic measures to understand the conditions under which knowledge gain is occurring in educational interventions. Future research could measure long-term changes in these particular scores, tracking metacognitive monitoring as skills are applied, and potentially correlate both cognitive and metacognitive changes with on-the-ground prescribing and implementation behaviors.

Abstract

Background: Ophthalmology residents take the Ophthalmic Knowledge Assessment Program (OKAP) exam annually, which provides percentile rank for multiple categories and the total score. In addition, ophthalmology residency training programs have multiple subspecialty rotations with defined minimum procedure requirements. However, residents' surgical volumes vary, with some residents exceeding their peers in specific subspecialty rotations.

Objective: This study aims to identify if there is a difference in OKAP examination scores and surgical volume exposure during ophthalmology residency training between nonfellowship and fellowship applicants and among various subspecialties.

Methods: A retrospective review of OKAP scores and surgical procedure numbers of graduating residents in an accredited academic ophthalmology residency program in the Midwest United States was conducted. Data were collected from 2012 to 2022.

Results: A total of 31 residents were identified. Most residents decided to pursue fellowship training upon graduation (20/31, 65% residents), and the rest chose to practice comprehensive ophthalmology (11/31, 35% residents). A total of 18/31 residents had OKAP score reports available. The fellowship group outperformed the nonfellowship group in multiple subsections and the total exam ($P=.04$). Those pursuing fellowship training in glaucoma performed higher on the Glaucoma section ($P=.004$) and the total exam ($P=.005$). Residents pursuing cornea performed higher on nearly all subsections, including External Disease and Cornea ($P=.02$) and the total exam ($P=.007$). The majority of the surgical volume exposure was identical between fellowship and nonfellowship groups. Those who pursued glaucoma fellowship performed more glaucoma filtering and shunting procedures ($P=.03$). Residents going into pediatrics fellowship were primary surgeons in more strabismus cases ($P=.01$), assisted in fewer strabismus cases ($P<.001$), and had no difference in the total number of strabismus surgeries.

Conclusions: In our program, residents pursuing fellowship training had higher OKAP scores on multiple sections and the total exam. There was no significant difference in the overall surgical volume averages between fellowship and nonfellowship groups, but few differences existed in subspecialty procedures among fellowship applicants. Larger multicenter studies are needed to clarify the relationship between OKAP scores and ophthalmology fellowship decisions nationwide.

Introduction

Fellowship and Subspecialty Statistics

The number of ophthalmology residents who pursue further fellowship training has been increasing for more than a decade [1]. In 2005, around 64% of ophthalmology residents in the United States pursued subspecialty training, while 36% pursued comprehensive ophthalmology [2]. However, between 2012 and 2017, the percentage of ophthalmology residents in the United States pursuing subspecialty training increased to 70.3%

[3]. Ophthalmology residency graduates in Canada have similar statistics, with 64% pursuing subspecialty training [4]. In the United States, vitreoretinal (36%), cornea (25%), glaucoma (13%), oculoplastic (10%), and pediatric (10%) fellowships are the most common [2]. Fewer ophthalmologists pursued fellowship training in anterior segment (2%), neuro-ophthalmology (0.7%), and uveitis (0.7%) [2]. These percentages are similar to the 2017 through 2022 San Francisco Match Data [5]. The match rate for all ophthalmology residents applying for fellowship is 73.7% [3]. Subspecialties with the greatest number of positions offered each year include retina,

cornea, glaucoma, pediatrics, and uveitis [3]. The match rate was highest for retina, followed by cornea, glaucoma, pediatrics, and uveitis [3].

Factors Influencing the Decision to Pursue a Fellowship

Based on a survey of ophthalmology residents, the top factors for deciding to pursue a fellowship include the desire for additional surgical training, additional clinical training, and increased job market competitiveness [6]. This is similar to a study stating that gaining more special skills and working with new technology were the top motivating factors for fellowship [7]. Another study found that acquiring special skills, perceived more favorable job market, and prestige were the top motivating factors for pursuing subspecialty training [2]. In contrast, those who pursued comprehensive ophthalmology were motivated by the anticipated work hours and geographical preference [2]. Other studies have also found that those going into comprehensive ophthalmology had significantly higher student loan amounts [7]. It is also noted that those deciding to do subspecialty training were more likely to intend to practice in an academic setting [2,7]. In addition, ophthalmology residents applying for fellowship had significantly more first-author publications than those going into comprehensive ophthalmology [7].

Studies have found that gender has no significant impact on the decision to pursue subspecialty training following ophthalmology residency [2,4,6,8]. However, there were gender differences among specific subspecialties. It was found that significantly more males pursued vitreoretinal surgery, while more females pursued strabismus and pediatric ophthalmology [4,8]. It has also been found that more males pursued oculoplastic [4] and anterior segment [8] fellowships. Females were also more likely to pursue neuro-ophthalmology [8]. Other studies have shown that age, ethnicity, marital status, presence of children, or level of educational debt had no statistically significant impact on the decision to pursue subspecialty training [2].

A survey done in 2005 on graduating residents found that the number of ocular procedures performed during residency did not significantly differ between residents who decided to do a fellowship and those who went into comprehensive ophthalmology [2]. However, there may be more variation when looking at specific subspecialties, as this study only evaluated fellowship versus no fellowship cohorts. Other factors, including elective time, career counseling, and the amount of dedicated time for research, also did not impact the decision to pursue a fellowship [2].

Factors Influencing the Decision to Pursue Specific Subspecialties

One study evaluated residents' decisions to pursue a fellowship in neuro-ophthalmology [9]. The top reasons graduating residents decided not to pursue this fellowship included stronger interests in other fields, types of patients seen, no intraocular surgery, and the assumption that it is a nonsurgical discipline. Factors influencing the decision to pursue neuro-ophthalmology included interest in clinical diseases and interaction with other specialty fields. There were no differences between the groups

regarding the degree of exposure to neuro-ophthalmology in medical school, the presence of a dedicated neuro-ophthalmology rotation in residency, or the rotation timing [9].

Another study evaluating the decisions impacting glaucoma fellowship found that residents entering a glaucoma fellowship had performed more glaucoma filtering procedures, were less likely to publish a paper, and were less likely to have time allocated for research than residents who pursued different fellowship training. Those seeking glaucoma fellowship also found challenging diagnostic problems, types of patient problems, academic careers, and working with new technology as less important. Residents pursuing glaucoma fellowship also decided later than residents selecting other subspecialties [10].

A recent study published in 2023 evaluated ophthalmology residents' perceptions of pediatric ophthalmology, and it was found that the desire to work with children was the most significant factor in pursuing a pediatric ophthalmology residency. The majority of residents also did not believe pediatric ophthalmology to be a prestigious specialty [11], and some residents also found pediatric patients difficult to examine [12], both deterrents to pursuing pediatric ophthalmology. In addition, concerns of economic factors and compensation in this field have also been discussed [11-13].

Ophthalmic Knowledge Assessment Program

The Ophthalmic Knowledge Assessment Program (OKAP) is a multiple-choice nationwide examination used to assess the ophthalmic knowledge of ophthalmology residents compared with their peers at the same training stage (postgraduate years [PGY] 2, 3, and 4). OKAP exams are taken electronically in a supervised environment in March each year. Residents in their first postgraduate year do not take the OKAP exam because the first year is spent rotating through other specialties as an internship year with little time in ophthalmology. OKAP exam scores are frequently requested when applying for competitive fellowship programs. Essential factors to score well on this examination include increased time spent studying, the use of question banks, and the incorporation of OKAP materials into the residency program [14]. In a study surveying retina, glaucoma, and cornea fellowship programs, OKAP scores were ranked as moderately important by program directors for fellowship applications [15]. It is notable that not all fellowship programs evaluate OKAP scores and that OKAP scores are only one indicator of proficiency in ophthalmology. Despite the first national OKAP exam occurring in 1968 [16], no studies have evaluated the performance of OKAP scores on the decision to pursue fellowship training after an ophthalmology residency.

Significance

There is limited literature examining the factors that influence fellowship training selection, especially for specific subspecialties. No studies have evaluated the impact of OKAP scores and intraocular procedural volume on specific subspecialty of choice by residents. This study aims to better understand the factors leading to selecting a subspecialty after graduating from an ophthalmology residency program by evaluating the OKAP scores and the number of surgical

procedures from graduating residents. This research can then provide valuable information to ophthalmology residency program directors as programs can be better designed to graduate ophthalmologists in subspecialties of need.

Methods

Study Methods

A retrospective review of OKAP scores and intraocular procedure numbers of graduating residents in an accredited ophthalmology residency program in the Midwest United States was conducted. Data were collected for all ophthalmology residents graduating from the program between 2012 to 2022. Data collection included OKAP scores, gender, fellowship decision, and procedural volume for all prior residents meeting the inclusion criteria (graduation date from 2012 to 2022). OKAP score reports were available on the San Francisco Match website for residents graduating between 2017 and 2022. OKAP examinations are required and taken by ophthalmology residents during their second, third, and fourth residency training years. The exam is currently taken online while proctored in person. All OKAP scores were available, but only OKAP scores from each residents' final program year were used in data analysis. This is because the final year OKAP scores are the most representative of cumulative ophthalmic knowledge, and are closer to the final decision of practice or fellowship.

Statistical Analysis

Descriptive statistics were completed for the demographics, number of surgical cases, and OKAP scores among the various groups of interest. For comparing the various groups, *t* tests were used with the settings of two-sample unequal variance with a one-tailed distribution. Statistical analysis was performed using Microsoft Excel.

Table . Resident demographics (N=31).

Demographics	Female residents, n/N (%)	Male residents, n/N (%)
Total	13/31 (42)	18/31 (58)
Pursued fellowship	10/20 (50)	10/20 (50)
No fellowship; comprehensive ophthalmology	3/11 (27)	8/11 (73)
Glaucoma	2/7 (29)	5/7 (71)
Cornea	2/4 (50)	2/4 (50)
Pediatrics	2/2 (100)	0/2 (0)
Medical Retina	0/2 (0)	2/2 (100)
Surgical Retina	3/5 (60)	2/5 (40)

Fellowship Versus No Fellowship

A total of 18 OKAP score reports since 2017 were available. Around half of these residents pursued a fellowship (56%, 10/18 residents), while the others pursued comprehensive ophthalmology (44%, 8/18 residents). On the OKAP scores,

Ethical Considerations

Institutional review board (IRB) approval was obtained from the University of Kansas Medical Center (study ID: 00150405). This was a retrospective review with secondary analysis of data. The IRB approval covers secondary analysis performed without the need for additional consent. All data were deidentified immediately following initial collection. No compensation was provided.

Results

Overview

A total of 31 residents were identified. Most residents decided to pursue fellowship training upon graduation (20/31, 65% residents), and the rest decided to practice comprehensive ophthalmology (11/31, 35% residents). Overall, 20 separate fellowships were completed by residents in Glaucoma (7/20, 35% fellowships), Surgical Retina (5/20, 25% fellowships) and Medical Retina (2/20, 10% fellowships), Cornea (4/20, 20% fellowships), and Pediatrics (2/20, 10% fellowships). No residents completed fellowships in Oculoplastics, Uveitis, or Anterior Segment in this residency program.

Out of the 31 residents identified, 42% (13/31) were female, while 58% (18/31) were male (Table 1). Of those who pursued fellowship (n=20), 50% (10/20) were female, and 50% (10/20) were male, while those who did not pursue a fellowship were 27% (3/11) female and 73% (8/11) male. When looking at specific subspecialties, 29% (2/7) of residents who pursued a Glaucoma fellowship were female. In addition, 50% (2/4) of Cornea fellowships, 100% Pediatric fellowships (2/2), 0% (0/2) of Medical Retina fellowships, and 60% (3/5) of Surgical Retina fellowships were female.

the fellowship group outperformed the nonfellowship group in General Medicine ($P=.03$), Ophthalmic Pathology and Intraocular Tumors ($P=.04$), Lens and Cataract ($P=.04$), and Total Exam ($P=.04$). The difference in OKAP percentile rank compared with the entire group average for the fellowship and no fellowship cohorts is detailed in Table 2.

Table . Difference in Ophthalmic Knowledge Assessment Program score average percentile rank compared with the whole cohort.

	General medicine	Fundamentals and principles of ophthalmology	Clinical optics	Ophthalmic pathology and intraocular tumors	Neuro-ophthalmology	Pediatric ophthalmology and strabismus	Orbit, eyelids, and lacrimal system	External disease and cornea	Intraocular inflammation and uveitis	Glaucoma	Lens and cataract	Retina and vitreous	Refractive surgery	Total exam
Fellowship (n=10)	13 ^a	12	8	10 ^a	-1	10	4	8	10	9	13 ^a	8	6	12 ^a
No fellowship (n=8)	-17 ^a	-14	-10	-13 ^a	1	-13	-5	-10	-13	-11	-16 ^a	-10	-8	-15 ^a
Glaucoma (n=6)	12	10	9	19 ^b	9	13	16 ^a	8	13	22 ^b	9	8	8	21 ^b
Cornea (n=2)	18 ^a	17 ^a	23 ^b	19	1	27 ^b	23 ^b	14 ^a	35 ^b	24 ^b	33 ^b	11	35 ^b	21 ^b
Medical Retina (n=2)	11	12	-7	-24	-32 ^a	-15 ^a	-51 ^a	2	-24	-47 ^b	4	6	-26 ^a	-23

^a $P < .05$.^b $P < .01$

All residents had surgical case number reports available. There were minimal differences between the fellowship and no fellowship group in procedural volume. However, the fellowship cohort did assist in more oculoplastic and orbit cases ($P=.02$) and more eyelid laceration cases ($P=.02$). All other surgical volume categories had no statistical significance between the fellowship and no fellowship groups (Tables S1-S4 in [Multimedia Appendix 1](#)).

Subspecialty

The specialties represented among the OKAP score reports were Glaucoma (60%, 6/10 residents), Cornea (20%, 2/10 residents), and Medical Retina (20%, 2/10 residents). Analysis of OKAP scores was then performed on the subspecialty cohorts compared with all other residents. Those who ended up pursuing fellowship training in glaucoma performed higher on Ophthalmic Pathology and Intraocular Tumors ($P=.004$), Orbit, Eyelids, and Lacrimal System ($P=.02$), Glaucoma ($P=.004$), and on total exam ($P=.005$). Those pursuing cornea performed higher on nearly all subsections and on total exam ($P=.007$). The sections they scored higher on include General Medicine ($P=.01$), Fundamentals and Principles of Ophthalmology ($P=.02$), Clinical Optics ($P=.002$), Pediatric Ophthalmology and Strabismus ($P<.001$), Orbit, Eyelids, and Lacrimal System ($P=.004$), External Disease and Cornea ($P=.02$), Intraocular Inflammation and Uveitis ($P<.001$), Glaucoma ($P=.004$), Lens and Cataract ($P=.002$), and Refractive Surgery ($P<.001$). The other fellowship represented in the OKAP scores was Medical Retina. Those who ended up pursuing medical retina did perform lower on some subsections. However, their total exam score and their Retina and Vitreous section scores were no different than the rest of the graduates. Residents who ended up pursuing medical retina scored lower on Neuro-ophthalmology ($P=.05$),

Pediatric Ophthalmology and Strabismus ($P=.02$), Orbit, Eyelids, and Lacrimal System ($P=.02$), Glaucoma ($P<.001$), and Refractive Surgery ($P=.02$).

The procedural volume completed by the various subspecialties was also analyzed. Those who pursued a fellowship in glaucoma performed fewer cases of panretinal laser photocoagulation ($P=.01$) and strabismus ($P=.04$) as primary. They, however, assisted on more eyelid laceration cases ($P=.03$) and had more total glaucoma filtering and shunting procedures ($P=.03$). Those seeking cornea had fewer assist cases for laser trabeculectomies ($P=.004$), laser iridotomies ($P=.01$), and chalazion excisions ($P=.002$). The cornea fellowship group assisted more and had a higher total number of retinal vitreous cases ($P=.002$ and $.007$, respectively). They also performed more open globe trauma cases ($P=.03$). Residents who went into pediatric ophthalmology performed fewer intravitreal injections ($P<.001$), and eyelid laceration repair ($P=.002$), as primary. They also had fewer total keratorefractive surgeries ($P=.003$) and globe trauma cases ($P=.009$). However, those pursuing pediatrics were the primary surgeons for more strabismus cases ($P=.01$) and assisted in fewer strabismus cases ($P<.001$). There was no significant difference in the total number of strabismus surgeries performed by graduates who pursued pPediatric Ophthalmology compared with other residents. Those going into Medical Retina had fewer total keratoplasty cases ($P=.007$) and assisted in more ptosis and blepharoplasty cases ($P=.01$). Those going into surgical retina had fewer total case numbers for cataract, Yttrium Aluminum Garnet capsulotomy, laser trabeculectomy, and glaucoma surgeries ($P=.02$, $.002$, $<.001$, $<.001$, respectively). The surgical retina group also had fewer total pterygium or conjunctival cases ($P=.04$) and keratorefractive surgeries ($P=.001$; Tables S1-S4 in [Multimedia Appendix 1](#)).

Discussion

Principal Findings

To the best of our knowledge, this is the first study to evaluate the effect of OKAP scores on fellowship choice. In this study, it was found that most graduates from this residency program pursued fellowship training, with the most common fellowships being Glaucoma, Surgical Retina, Cornea, Medical Retina, and Pediatrics, respectively. When analyzing the OKAP scores, it was found that residents pursuing fellowship training scored higher on the total OKAP exam and on multiple subsections. It was also found that residents applying for specific subspecialties scored higher on that subsection of the OKAP examination. In addition, the procedural volume did not significantly differ between the fellowship and nonfellowship groups with some variations when analyzing specific subspecialties.

OKAP Scores Difference Between Fellowship and Nonfellowship

In multiple categories and on total exam, ophthalmology residents who pursued fellowship training scored higher than those who did not. One possible explanation for this difference is that OKAP scores are sometimes included in a Fellowship Application and have been identified as a moderately important aspect of a fellowship application by some program directors [15]. Residents considering a fellowship may have prepared more for the exam to be competitive for fellowship applications. In addition, this finding could suggest that residents who scored high on the OKAP were later influenced to pursue fellowship training due to their more competitive applications. Since this is a retrospective review, it is unknown whether residents entered this program with a preexisting interest in fellowship. Therefore, higher OKAP scores in general may serve as a predictor for residency programs that a resident is more likely to pursue fellowship training.

Ophthalmic Knowledge Assessment Program Score Differences Among Subspecialties

Those who pursued glaucoma fellowship also scored higher on total exam and in multiple subsections, including Glaucoma, compared with the rest of the cohort. In addition, those who pursued cornea fellowship outperformed the fellowship and nonfellowship groups on total exam and in many subcategories, including External Disease and Cornea. This could indicate that residents who decided to apply for a specific fellowship in a certain specialty had increased interest and knowledge in the field, spent more time learning that content, and scored higher on the associated OKAP sections. This could be one way for residency programs to identify applicants more likely to pursue fellowship training in a specific area. Those pursuing medical retina scored lower on some OKAP subsections but not on total exam or the Retina and Vitreous section. One potential reason is that medical retina (and retina in general) has an overall higher match rate, and a greater number of positions offered, making it less competitive than some of the other specialties [3]. This may mean OKAP scores were perceived to have less impact on matching into medical retina programs. It is also noted that while there are variations in the OKAP scores, all residents have

successfully graduated from the residency program and are board-certified.

Procedural Volume Between Fellowship and Nonfellowship

Interestingly, in our study, when comparing the procedural volume of residents who pursued fellowship to those who did not, the only statistically significant difference was in the oculoplastics and orbit and eyelid laceration categories, despite no residents seeking fellowship in oculoplastics. This agrees with other studies that have shown the number of ocular procedures did not significantly differ between residents going into fellowship programs versus comprehensive ophthalmology [2]. It is also noted that this study evaluates a greater variety of procedures due to various technological advancements since 2005. This shows that while students might have different career paths, the bulk of surgical training during ophthalmology residency is the same. This is also important for those going into comprehensive ophthalmology, as comprehensive ophthalmologists must be well-versed in many areas.

Procedural Volume Differences Among Subspecialties

In this study, specific subspecialties had some variations within procedural volumes. For example, those who pursued glaucoma fellowship had a greater total number of glaucoma filtering and shunting procedures. This is consistent with another study that found residents entering a glaucoma fellowship performed more glaucoma filtering procedures [10]. This may mean those residents sought more opportunities to get involved in glaucoma cases and pursued extra training. Residents who ended up in pediatrics were the surgeons for more strabismus cases but had no statistically significant difference in the total number of strabismus cases. Interestingly, residents who went into cornea had no differences in corneal surgery procedural volume, and those who went into medical or surgical retina had no differences in retinal vitreous and intraretinal injections. It is also noted that despite these variations, all residents met the minimum training requirements in each area.

Residency Demographics and Nonpursued Subspecialties

The percentage of program graduates deciding to pursue fellowship training (64.5%) is close to the approximately 70% of ophthalmology residency graduates in the United States who pursued fellowship training [3]. The lower percentage pursuing a fellowship in this specific program may be because this program has no associated fellowship programs. Those who selected this residency program may have been less motivated by fellowship programs initially. While retina, cornea, and pediatric percentages are similar to averages in the United States, significantly more residents from this program pursued glaucoma fellowship [2]. It is also noted that no residents pursued a fellowship in oculoplastics despite it being the fourth most common ophthalmology fellowship nationwide [2]. One potential explanation is that the Oculoplastics application is during PGY-3 year instead of PGY-4 like the others, meaning residents must make this decision early [17]. This is also considered to be one of the more competitive fellowship programs, which may deter residents from applying. In addition,

no residents pursued a fellowship in uveitis, neuro-ophthalmology, or anterior segment. However, in the United States, these fellowship programs account for smaller percentages out of all fellowships [2].

Gender

While the majority of residents in this study identified as male, half of the cohort who pursued fellowship training identified as female. Conversely, most residents who did not pursue fellowship training were male. This is consistent with other studies that have shown gender to have no significant impact on the decision to attain subspecialty training in ophthalmology [2,4,6,8]. At least 50% of residents in this program who pursued fellowships in pediatrics (100%, 2/2 residents), surgical retina (60%, 3/5 residents), and cornea (50%, 2/4 residents) identified as female. This is consistent with other studies that have found more female ophthalmologists complete fellowships in Pediatrics and Strabismus [4,8]. However, these studies also found most residents who pursued Surgical Retina fellowship identify as male [4,8]. Interestingly, in our cohort, the majority of residents who pursued Retina Surgery were female. This could be due to the small cohort size or program-specific variations like the presence of female surgical retina attendings.

Other Factors Affecting Decision to Pursue a Fellowship

This study assessed the impact of OKAP scores and procedural volume on fellowship decision. Other studies and surveys have found that other important factors in the decision to subspecialize in ophthalmology include wanting additional training (both clinical and surgical) [2,6], acquiring specialized skills [7], working with new technology [7], increased job market competitiveness [2,6], and prestige [2]. In addition, those who have fellowship training are more likely to practice in academic settings [2,7], and to have first-author publications [7]. Therefore, residents who want to work in research or academics may be more inclined to subspecialize.

Limitations

The limitations of this study include the small sample size of a single mid-western program. The limited sample size can limit the generalizability of this study in a larger program. In addition, this residency program did not have associated fellowship programs during the study period, which, may have influenced residents' decision to pursue fellowship training, or attracted residents who wanted to maximize their surgical experience without fellows to practice comprehensive ophthalmology after graduation. Another limitation is the retrospective nature of this study, which does not allow examining if residents decided on fellowship before or after OKAP examination scores. It is unknown at what point in training each resident decided to pursue a fellowship. In addition, no residents decided to pursue training in certain fellowships (eg, oculoplastics and neuro-ophthalmology), so there are no data on those specific specialties.

Strengths

This study was conducted in an ophthalmology residency program accredited by the Accreditation Council for Graduate Medical Education. All residents in the program passed their minimal required surgical procedure volumes. All graduates of this program are certified by the American Board of Ophthalmology or preparing to set the board exams if graduated in 2022 at the time of the paper submission.

Conclusion

OKAP performance showed there were differences between fellowship and nonfellowship graduates in our program. Overall, residents in this program who pursued a fellowship scored higher than those who did not pursue a fellowship on multiple sections and on total OKAP examination. There were no significant differences in the overall surgical volume averages between fellowship and nonfellowship groups, but a few differences existed in subspecialty procedures among fellowship applicants. Despite these variations, all residents exceeded the minimum training requirements. Larger multicenter studies are needed to better clarify OKAP score relation to fellowship and subspecialty application decisions nationwide.

Abstract

Background: Substance use and overdose deaths make up a substantial portion of injury-related deaths in the United States, with the state of Ohio leading the nation in rates of diagnosed substance use disorder (SUD). Ohio's growing epidemic has indicated a need to improve SUD care in a primary care setting through the engagement of multidisciplinary providers and the use of a comprehensive approach to care.

Objective: The purpose of this study was to assess the ability of the Weitzman Extension for Community Healthcare Outcomes (ECHO): Comprehensive Substance Use Disorder Care program to both address and meet 7 series learning objectives and address substances by analyzing (1) the frequency of exposure to the learning objective topics and substance types during case discussions and (2) participants' change in knowledge, self-efficacy, attitudes, and skills related to the treatment of SUDs pre- to postseries. The 7 series learning objective themes included harm reduction, team-based care, behavioral techniques, medication-assisted treatment, trauma-informed care, co-occurring conditions, and social determinants of health.

Methods: We used a mixed methods approach using a conceptual content analysis based on series learning objectives and substances and a 2-tailed paired-samples *t* test of participants' self-reported learner outcomes. The content analysis gauged the frequency and dose of learning objective themes and illicit and nonillicit substances mentioned in participant case presentations and discussions, and the paired-samples *t* test compared participants' knowledge, self-efficacy, attitudes, and skills associated with learning objectives and medication management of substances from pre- to postseries.

Results: The results of the content analysis indicated that 3 learning objective themes—team-based care, harm reduction, and social determinants of health—resulted in the highest frequencies and dose, appearing in 100% ($n=22$) of case presentations and discussions. Alcohol had the highest frequency and dose among the illicit and nonillicit substances, appearing in 81% ($n=18$) of case presentations and discussions. The results of the paired-samples *t* test indicated statistically significant increases in knowledge domain statements related to polysubstance use ($P=.02$), understanding the approach other disciplines use in SUD care ($P=.02$), and medication management strategies for nicotine ($P=.03$) and opioid use disorder ($P=.003$). Statistically significant increases were observed for 2 self-efficacy domain statements regarding medication management for nicotine ($P=.002$) and alcohol use disorder ($P=.02$). Further, 1 statistically significant increase in the skill domain was observed regarding using the stages of change theory in interventions ($P=.03$).

Conclusions: These findings indicate that the ECHO program's content aligned with its stated learning objectives; met its learning objectives for the 3 themes where significant improvements were measured; and met its intent to address multiple substances in case presentations and discussions. These results demonstrate that Project ECHO is a potential tool to educate multidisciplinary providers in a comprehensive approach to SUD care.

Introduction

Background

In the United States, overdose deaths continue to be a major cause of injury-related deaths. Since the onset of the COVID-19 pandemic, numbers have only accelerated, and the state of Ohio has led the nation in high substance use disorder (SUD) rates, including drug use and prescription drug use. The Centers for Disease Control and Prevention ranks the state among the top 5 across the United States with the highest rates of opioid overdose deaths [1]. While research has shown an increase in the number of people enrolled in substance use treatment in Ohio between 2015 and 2019 there was still a notable high increase in the annual average prevalence of past-year illicit drug use disorder in Ohio (3.6%) compared to the regional average (3%) and the national average (2.9%) [2]. In addition, past-month alcohol use disorder (9.3%), cannabis use disorder (5.8%), and tobacco use disorder (35.2%) were higher than the national average among young adults aged 18-25 years [2]. Ohio's growing epidemic has highlighted the need to improve SUD care in a primary care setting by training providers to better address differences in care and social determinants of health through the use of behavioral techniques, harm-reduction philosophy of care, medication management, and a team-based care approach.

Weitzman Extension for Community Healthcare Outcomes: Comprehensive Substance Use Disorder Care Program

Beginning in 2021, Buckeye Health Plan and Ohio University Heritage College of Osteopathic Medicine have partnered with the Weitzman Institute (WI), a national primary care research, policy, and education institute, to provide targeted support and education to Ohio primary care medical and behavioral health providers working with underserved patients, especially those in the rural, southeastern Appalachian region, using the evidence-based Project Extension for Community Healthcare Outcomes (ECHO) learning model. Project ECHO uses frequent videoconference sessions to connect a target audience of learners with subject matter experts for didactic and case-based instruction and engaged discussion [3]. Through regular attendance at these sessions, Project ECHO aims to equip learners with the knowledge, confidence, and skills to better manage complex cases.

WI has over 11 years of experience in developing and delivering Project ECHO programs to meet the needs of providers working

in resource-limited settings. As an early adopter of the model in 2012, Weitzman ECHO programs have been offered in 22 topic areas to over 8000 health care professionals across all 50 states, Washington D.C., and Puerto Rico. Working in collaboration, Buckeye Health Plan and Ohio University aimed to leverage this expertise and offer multiple Project ECHO programs each year for providers in topics of the greatest need and interest.

As described, one of Ohio's most dire population health needs is to improve outcomes for patients experiencing addiction. Thus, SUD was selected as the second ECHO program developed through this partnership. More specifically, opioids are a heightened concern throughout both Ohio and the United States, and the opioid epidemic has spurred significant funding allocations, such as the Biden Administration's US \$1.5 billion award to states and territories to end the epidemic [4]. However, there are many additional substances of concern, both illicit and nonillicit, such as alcohol, tobacco, cannabis, methamphetamine, and cocaine [5], which may receive less attention given the directed funding for opioids. For this reason, it was decided that the ECHO would address not only opioids, or any one substance, but rather be designed to provide techniques to help providers address SUD overall through a comprehensive, team-based lens and a harm reduction philosophy of care. Reflecting this broad topical approach, the program was titled the Weitzman ECHO: Comprehensive Substance Use Disorder Care (CSUDC ECHO) program.

CSUDC ECHO consisted of 24 twice-monthly sessions held between July 2021 and July 2022. Each 1-hour session included a 20- to 25-minute didactic presentation followed by 1 patient case submitted by a participant before the session and discussed live for the remaining 35-40 minutes. [Textbox 1](#) outlines the didactic presentation topics for each session. A multidisciplinary core faculty facilitated each session and was comprised of 1 physician with dual board certification in family medicine and addiction medicine and experienced in treating SUDs at federally qualified health centers; 1 nurse practitioner who developed and leads a federally qualified health center medication-assisted treatment (MAT) program; 1 supervisory licensed counselor; and 1 population health expert. Together, the faculty built a 12-month curriculum covering diverse topics such as medication management, team-based care, trauma-informed care, stages of change and motivational interviewing, polysubstance use and co-occurring conditions, and coordinating levels of care.

Textbox 1. Weitzman Extension for Community Healthcare Outcomes: Comprehensive Substance Use Disorder Care didactic topic by session.

Session and didactic topic

1. Philosophy of care (no case presentation).
2. Harm reduction strategies.
3. Principals of medication management.
4. Team-based care: care provision partners.
5. Trauma-informed care: an overview.
6. Motivational interviewing.
7. Stages of change for addiction.
8. Assessing stages of change and stage-based interventions.
9. Medications for opioid use disorder basics.
10. Behavioral health and primary care coordination.
11. Transitions of care.
12. Polysubstance use.
13. Social determinants of health including barriers or challenges (no case presentation).
14. Adverse childhood experiences.
15. Legal factors and access.
16. Mental health crisis and coordination of care.
17. Medication-assisted treatment for alcohol and tobacco use disorders.
18. Self-determination and strength-based approaches.
19. Contingency management for substance use disorder.
20. HIV and hepatitis C virus in patients with substance use disorder.
21. Screening, brief intervention and referral to treatment into primary care.
22. Stimulant use disorder treatment and medication management.
23. Co-occurring mental health substance use disorder.
24. Tobacco cessation for polysubstance patients.

Participants were recruited by email blasts targeted to each partner's network of Ohio primary care providers and other members of the care team. A total of 109 participants attended at least one session, 16 participants attended between 7 and 11 sessions, and 23 participants attended over 12 (half) of the sessions. On average, there were 32 attendees at each session. Continuing education credits were offered to medical providers, behavioral health providers, and nurses.

Purpose of Study

The purpose of this study was to assess the ability of CSUDC ECHO to both address and meet 7 learning objectives ([Textbox 2](#)) and address multiple substances by analyzing (1) the frequency of exposure to the learning objective topics and substance types during case discussions and (2) participants' knowledge, self-efficacy, skills, and attitudes related to the treatment of SUDs pre- to postprogram.

Textbox 2. Weitzman Extension for Community Healthcare Outcomes: Comprehensive Substance Use Disorder Care learning objectives.

- Project a harm reduction philosophy of care into your treatment of patients experiencing substance use disorders and explain this concept to peers.
- Use the care team more effectively to improve the management of patients experiencing substance use disorders.
- Use motivational interviewing and other behavioral techniques to improve patient outcomes related to substance use disorders.
- Better differentiate and implement medication management strategies for patients experiencing substance use disorders.
- Illustrate trauma-informed practices in the screening, assessment, and treatment of patients experiencing substance use disorders.
- Describe and manage common co-occurring conditions and polysubstance use more effectively in patients experiencing substance use disorders.
- Distinguish and address factors related to social determinants of health faced by specific populations experiencing substance use disorders.

Methods

Study Design and Data Collection

This study used a mixed methods design, using a conceptual content analysis [6] analyzing ECHO participant-led case presentations, as well as a 2-tailed paired-samples *t* test of participant self-reported learner outcomes. All ECHO attendees who registered and attended the Project ECHO CSUDC sessions are included in the deductive content analysis. All ECHO attendees who registered before and through the first session of the series were invited to complete a preseries survey (n=106) via Qualtrics survey software (Qualtrics). The preseries survey remained open for 3 weeks from June 25, 2021, to July 18, 2021. A total of 79 responses were received (n=79) for a response rate of 75%. Upon completion of the ECHO series, active attendees (ie, those that were still active at the conclusion of the series and did not officially drop from the series, as well as those who enrolled throughout the series) were invited to complete a postseries survey via Qualtrics Survey Software (n=90). The postseries survey remained open for 4 weeks from July 7, 2022, to August 2, 2022. A total of 25 responses were received (n=25) for a response rate of 28%. A total of 16 consented participants completed both the preseries and postseries surveys (n=16) and are included in the paired-samples *t* tests statistical analysis.

Ethical Considerations

This study was approved by the Community Health Center, Inc, Institutional Review Board (IRB; 1190) on January 6, 2022. Informed consent was accounted for by the authors through the administration of a consent form on the postseries survey gathering participant consent to use their deidentified survey data for the paired-samples *t* test analysis. The deductive content analysis was considered a secondary analysis and was given exempt status. All data used in this study were deidentified, accounting for privacy and confidentiality. No compensation for participation in this study was deemed necessary by the IRB.

Survey Tools

The preseries and postseries surveys were internally created and based on the Consolidated Framework for Implementation Research (CFIR) [7] and Moore's Model of Outcomes Assessment Framework [8]. The specific CFIR domains assessed for include intervention characteristics, outer setting, inner setting, characteristics of individuals, and process [7]. Additionally, the levels of Moore's Model of Outcomes Assessment Framework assessed for include level 2 (satisfaction), level 3a (declarative knowledge), level 3b (procedural knowledge), level 4 (competence), level 5 (performance), and level 6 (patient health) [8]. The surveys assessed changes in participants' self-reported knowledge, attitudes, self-efficacy, and skills through statements centered on the series' learning objectives. The preseries survey also collected participant characteristics including provider type and years of experience working with patients diagnosed with SUDs, as well as team-based care practices. Additionally, the postseries survey collected information on engagement and practice

changes. The preseries survey instrument is presented in [Multimedia Appendix 1](#) and the postseries survey instrument is presented in [Multimedia Appendix 2](#).

While the preseries survey and postseries survey tools were based on CFIR [7] and Moore's Model of Outcomes Assessment Framework [8], both surveys were internally designed. The internal research and evaluation and CSUDC ECHO programmatic teams created the survey tools through several iterations of the internal review, which also consisted of selecting the appropriate domain (ie, knowledge, attitudes, self-efficacy, and skills) to assess each series' learning objective. Each domain used a 5-point Likert scale to assess responses. The surveys were then presented to the CSUDC ECHO series stakeholders and faculty for review and approval before administering the surveys to the ECHO attendees. See [Multimedia Appendices 1 and 2](#) for the domain placement of learning objectives and the 5-point Likert scales.

Conceptual Content Analysis

To further evaluate Weitzman ECHO CSUDC aims, researchers conducted a conceptual content analysis [6] using a set of a priori themes extracted from the series' learning objectives. Series' learning objectives are detailed in [Textbox 2](#). To establish a priori themes, researchers met before the launch of the ECHO to examine the series' 7 learning objectives and extracted 7 themes for the content analysis. The themes were: harm reduction, team-based care, behavioral techniques, MAT, trauma-informed care, co-occurring conditions, and social determinants of health. To assess the frequency to which multiple substances were discussed, the themes also included 5 illicit and nonillicit substances of concern: alcohol, stimulants, opioids, cannabis, tobacco, or nicotine, plus polysubstance use when any 2 or more of these substances were identified. A conceptual analysis approach was used to gauge the dose and frequency of all learning objective themes and selected illicit and nonillicit substances. The content analysis aimed to confirm the discussion of the series' learning objectives during case presentations and to determine to what extent multiple substances were able to be addressed.

Researchers evaluated all 22 participant-led ECHO case presentations and discussions for the presence of the selected themes in the prepared participant cases, faculty recommendations, and participant recommendations. Case presentations and discussions consisted of participants independently preparing a patient case to present and receive participant and faculty guidance for a patient treatment plan. Case presentations were recorded and transcribed using Zoom videoconferencing software (Zoom Video Communications, Inc). The transcriptions were then used for the conceptual content analysis.

To ensure coding accuracy, 4 researchers independently coded 27% (n=6) of the case presentations and met to reconcile discrepancies and better establish coding parameters. After reconciling discrepancies, 1 researcher coded the remaining 16 case presentations and discussion transcripts. The content analysis themes and descriptions are presented in [Table 1](#).

Table 1. Conceptual content analysis themes and learning objectives.

Theme	Learning objective
Harm reduction	Project a person-centered philosophy of care into your treatment of patients experiencing substance use disorders and explain this concept to peers.
Team-based care	Use the care team more effectively to improve the management of patients experiencing substance use disorders.
Behavioral techniques	Use motivational interviewing and other behavioral techniques to improve patient outcomes related to substance use disorders.
Medication-assisted treatment	Differentiate and implement medication management strategies for patients experiencing substance use disorders.
Trauma-informed care	Illustrate trauma-informed practices in the screening, assessment, and treatment of patients experiencing substance use disorders.
Co-occurring conditions	Describe and manage common co-occurring conditions and polysubstance use more effectively in patients experiencing substance use disorders.
Social determinants of health	Distinguish and address factors related to social determinants of health faced by specific populations experiencing substance use disorders.

Paired-Samples *t* Test

To determine if Project ECHO CSUDC affected participant learner outcomes, researchers calculated mean scores reported on a Likert scale of 1 to 5 and conducted a paired-samples *t* test to compare pre- and postseries scores at a .05 significance level. The surveys consisted of matching statements assessing knowledge, self-efficacy, attitudes, and skills associated with the series' learning objectives. The data were assessed for normality and homogeneity of variance and the assumptions were met. The data analysis was conducted using SPSS Statistics for Windows (version 26.0; IBM Corp).

Results

Participant Characteristics

CSUDC ECHO participants were asked to report their role type on the preseries survey. Of the participants that responded to the survey items ($n=79$), a majority were other care team members ($n=32$; 41%) followed by behavioral health providers

($n=30$; 38%) and medical providers ($n=16$; 21%). Additionally, participants were asked to indicate their years of experience working with SUDs. Most participants had between 1 and 5 years of experience ($n=23$; 29%) followed by 6-10 years ($n=15$; 19%), 11-20 years ($n=14$; 18%), less than 1 year ($n=13$; 16%), 7 participants indicated they do not work directly with patients ($n=7$; 9%), 21-30 years ($n=4$; 5%), 31-40 years ($n=2$; 3%), and more than 40 years of experience ($n=1$; 1%). Full participant characteristics of the entire CSUDC ECHO attendees, excluding the paired-samples *t* test sample, the paired-samples *t* test sample only, and all combined CSUDC ECHO attendees are provided in [Table 2](#).

The attendance data of participants included in the paired-samples *t* test analysis were analyzed. Further, 6 ($n=6$; 38%) of the paired-samples *t* test participants attended 1% ($n=1$) to 25% ($n=6$) of the 24 CSUDC ECHO sessions, 3 ($n=3$; 19%) attended 26% ($n=7$) to 49% ($n=11$) of the sessions, 4 ($n=4$; 25%) attended 50% ($n=12$) to 75% ($n=18$) of the sessions, and 3 ($n=3$; 19%) attended 76% ($n=19$) to 100% ($n=24$) of the sessions.

Table 2. Participant characteristics of all ECHO^a participants and paired-samples *t* test analysis sample.

	CSUDC ^b ECHO attendees (excluding paired-samples <i>t</i> test participants; n=63)	Paired-samples <i>t</i> test participants (n=16)	All CSUDC ECHO attendees (n=79)

^cSUD: substance use disorder.

Conceptual Content Analysis

The conceptual content analysis indicated that all of the a priori themes relating to the learning objectives resulted in high frequencies and doses, appearing in a majority of case presentations and discussions. Further, 3 themes appeared in 100% (n=22) of case presentations and discussions, including team-based care at a frequency of 156, followed by harm reduction at a frequency of 152, and social determinants of health at a frequency of 135. In total, 4 themes appeared in less than 100% (n=22) of case presentations and discussions, but above 81% (n=18), including co-occurring conditions with a frequency of 118 and appearing in 95% (n=21) of case presentations and discussions, followed by behavioral techniques at a frequency of 108 and appearing in 91% (n=20) of case presentations and discussions, MAT at a frequency of 89 and appearing in 86% (n=19) of case presentations and discussions, and trauma-informed care at a frequency of 79 and appearing in 82% (n=18) case presentations and discussions. Additionally,

multiple substances were represented but at differing frequencies. The substance that resulted in the highest frequency and dose was alcohol at a frequency of 64 and appeared in 81% (n=18) of case presentations and discussions, followed by stimulants at a frequency of 55 and 77% (n=17) of case presentations and discussions, opioids at a frequency of 49 and 59% (n=13) of case presentations and discussions. Cannabis resulted with a frequency of 38 but appeared in 64% (n=14) of case presentations and discussions. Finally, tobacco and nicotine resulted in the lowest frequency at 11 and dose appearing in 27% (n=6) of case presentations and discussions. When evaluating polysubstance use, which was limited to the use of two or more of the listed substances, we found a dose of 95% (n=21) of case presentations and discussions. The frequency of polysubstance use was not included in the conceptual content analysis since it was not a learning objective theme and the emphasis of the conceptual content analysis was focused on the specific illicit and nonillicit substance types. The results of the conceptual content analysis are presented in [Table 3](#).

Table 3. The results of frequency and percentage of case appearances (dose) of conceptual content analysis themes.

Theme	Frequency	Case appearances (dose), n (%)
Team-based care	156	22 (100)
Harm reduction	152	22 (100)
Social determinants of health	136	22 (100)
Co-occurring conditions	118	21 (95)
Behavioral techniques	108	20 (91)
MAT ^a	89	19 (86)
Trauma-informed care	79	18 (82)
Substance type: alcohol	64	18 (81)
Substance type: stimulant	55	17 (77)
Substance type: opioid	49	13 (59)
Substance type: cannabis	38	14 (64)
Substance type: tobacco and nicotine	11	6 (27)
Polysubstance use of substance types	— ^b	21 (95)

^aMAT: medication-assisted treatment.

^b—: not available.

Paired-Samples *t* Test

Knowledge

In total, 4 knowledge domain statements resulted in statistically significant increases: understanding polysubstance use in patients experiencing SUD ($P=.02$), understanding the approach colleagues in other disciplines use to address SUD ($P=.02$),

knowledge of medication management strategies for nicotine use disorder ($P=.03$), and knowledge of medication management strategies for opioid use disorder (OUD; $P=.003$). Additionally, all knowledge domain statements resulted in an increased change in mean score from preseries to postseries. The results of the knowledge domain preseries and postseries scores are presented in [Table 4](#).

Table 4. The results of the paired-samples *t* test for the knowledge domain.

Statement	Preseries mean score (SD; 1-5)	Postseries mean score (SD; 1-5)	Change in mean	<i>P</i> value
I understand polysubstance use in patients experiencing substance use disorders	3.63 (1.03)	4.25 (0.45)	+0.62	.02
I understand factors related to social determinants of health faced by specific populations experiencing substance use disorders	4.13 (0.89)	4.31 (0.60)	+0.18	.38
I understand the approach of my colleagues in other disciplines (ie, behavioral health if you are a medical provider) to substance use disorder care	3.69 (0.87)	4.25 (0.58)	+0.56	.02
Knowledge of the different medication management strategies for patients experiencing—nicotine use disorder	3.40 (1.12)	4.00 (0.76)	+0.60	.03
Knowledge of the different medication management strategies for patients experiencing—alcohol use disorder	3.53 (0.99)	4.00 (0.54)	+0.47	.07
Knowledge of the different medication management strategies for patients experiencing—stimulant use disorder	3.07 (0.10)	3.71 (0.83)	+0.64	.10
Knowledge of the different medication management strategies for patients experiencing—opioid use disorder	3.56 (0.96)	4.19 (0.83)	+0.63	.003

Attitudes

No attitudes domain statements resulted as statistically significant. All attitudes domain statements resulted in an increased change in mean score from preseries to postseries except the statement about a treatment plan for a patient experiencing an illicit SUD only being successful if abstinence

is maintained, which resulted in a negative change in mean score. The negative change in mean score from preseries to postseries was the appropriate direction of change for alignment with promoting a harm reduction philosophy. The results of the attitudes domain preseries and postseries scores are presented in [Table 5](#).

Table 5. The results of the paired-samples *t* test for the attitudes domain.

Statement	Preseries mean score (SD; 1-5)	Postseries mean score (SD; 1-5)	Change in mean	<i>P</i> value
It is important to practice a harm reduction philosophy when treating patients experiencing substance use disorders	4.60 (0.63)	4.73 (0.46)	+0.13	.43
Practicing a harm reduction philosophy in the treatment of patients experiencing substance use disorders leads to better patient outcomes	4.47 (0.83)	4.60 (0.63)	+0.13	.50
It is important to identify factors related to social determinants of health that patients experiencing substance use disorders may be facing	4.71 (0.61)	4.86 (0.36)	+0.15	.44
Addressing factors related to social determinants of health in the treatment of patients experiencing substance use disorders leads to better patient outcomes	4.69 (0.60)	4.81 (0.40)	+0.12	.50
A treatment plan for a patient experiencing an illicit substance use disorder has only been successful if abstinence is maintained	2.25 (1.39)	2.00 (1.27)	-0.25	.43

Self-Efficacy

In total, 2 self-efficacy statements resulted in statistically significant increases: choosing a medication management strategy for nicotine use disorder ($P=.002$) and alcohol use

disorder ($P=.02$). Additionally, all self-efficacy domain statements resulted in an increased change in mean score from preseries to postseries. The results of the self-efficacy domain preseries and postseries scores are presented in [Table 6](#).

Table 6. The results of the paired-samples *t* test for the self-efficacy domain.

Statement	Preseries mean (SD; 1-5)	Postseries mean (SD; 1-5)	Change in mean	<i>P</i> value
Providing trauma-informed care	3.20 (1.01)	3.67 (0.90)	+0.47	.15
Using motivational interviewing techniques	3.31 (1.08)	3.81 (0.83)	+0.50	.12
Creating SMART ^a goals with patients	3.43 (1.09)	3.79 (0.80)	+0.36	.29
Managing co-occurring conditions	3.40 (1.30)	3.93 (1.16)	+0.53	.16
Choosing an appropriate medication management strategy for—nicotine use disorder	2.75 (1.49)	3.88 (1.13)	+0.13	.002
Choosing an appropriate medication management strategy for—alcohol use disorder	2.63 (1.19)	3.75 (1.28)	+1.12	.02
Choosing an appropriate medication management strategy for—stimulant use disorder	1.86 (1.46)	2.00 (1.00)	+0.14	.79
Choosing an appropriate medication management strategy for—opioid use disorder	3.67 (1.41)	3.78 (1.48)	+0.11	.76

^aSMART: specific, measurable, achievable, relevant, timely.

Skill

In total, 1 skill domain statement resulted in a statistically significant increase: using the stages of change theory to provide stage-based interventions to patients experiencing SUDs

($P=.03$). Additionally, all skill domain statements resulted in an increased change in mean score from preseries to postseries. The results of the skill domain preseries and postseries scores are presented in [Table 7](#).

Table 7. The results of the paired-samples *t* test for the skill domain.

Statement	Preseries mean (SD; 1-5)	Postseries mean (SD; 1-5)	Change in mean	<i>P</i> value
Screening patients experiencing substance use disorders for trauma	3.53 (1.13)	4.07 (0.96)	+0.54	.06
Using the stages of change theory to provide stage-based interventions to patients experiencing substance use disorders	3.06 (1.29)	3.69 (0.87)	+0.63	.03
Collaborating with peer support specialists when working with patients experiencing substance use disorders	3.33 (1.29)	3.93 (1.03)	+0.60	.06
Referring patients to a higher level of care, such as IOP ^a , if needed	3.79 (0.98)	4.36 (0.75)	+0.57	.06
Preventing drug overdose of my patients experiencing a substance use disorder	2.83 (1.27)	3.25 (0.97)	+0.42	.10

^aIOP: intensive outpatient.

Discussion

Principal Findings

Ohio's annual average prevalence of tobacco use, heroin use, use of prescription pain relievers, OUDs, illicit drug use disorder, and SUD have been higher compared to both regional and national averages [2]. Considering the need to address this public health concern, CSUDC ECHO was implemented to train Ohio providers and care team members in substance use care. CSUDC ECHO enhanced the Project ECHO work in this field by focusing content and learning objectives on a comprehensive, team-based lens and a harm reduction philosophy of care to address multiple illicit and nonillicit substances including opioids, alcohol, nicotine, cannabis, and stimulants. To assess the ability of the CSUDC ECHO program to meet its 7 program learning objectives (Textbox 2) and address multiple substances, this study analyzed (1) the frequency of exposure to learning objective themes and substance types during case presentations and discussions and (2) participating providers' change in knowledge, attitudes, self-efficacy, and skills related to the treatment of SUDs.

Study results demonstrate that all 7 learning objectives were frequently addressed in the content of case presentations and discussions throughout the program, with team-based care being the most frequently mentioned, 3 objectives appearing in 100% (n=22) of case discussions (eg, team-based care, harm reduction, and co-occurring conditions), and all 7 objectives appearing in >81% (n=18) of all cases discussed. This may have resulted in the learner outcome improvement pre- to postprogram for multiple learner domains (eg, knowledge, self-efficacy, and skill) for the following themes: team-based care, MAT, polysubstance use, and behavioral techniques. No pattern emerged among the participants included in the paired-samples *t* test analysis exposure to didactic topics and changes in learner outcomes.

Alcohol, stimulants, opioids, cannabis, and nicotine were addressed in the content of case presentations and discussions throughout CSUDC ECHO with alcohol being the most frequently mentioned and most common substance appearing in cases, 4 substances appearing in >59% (n=13) of case discussions (eg, alcohol, stimulants, opioid, and cannabis), and all coded substances appearing in at least a quarter of cases. The

dialogue about these substances during case discussions likely resulted in improvements to the following learner outcomes related to medication management: alcohol use disorder, OUD, and nicotine use disorder. Medication management of cannabis use disorder was not assessed in the pre- to postsurveys. Additionally, the didactic presentation topics that centered on alcohol, opioid, and nicotine use disorder resulted in a higher attendance rate with about 40% (n=6) to 50% (n=8) of the participants included in the paired-samples *t* test analysis attending the sessions, as compared to only 20% (n=3) of the aforementioned participant sample having attended the session centered on stimulant use disorder.

These findings indicate that the ECHO program's content aligned with its stated learning objectives; met its learning objectives for the 3 themes where significant improvements were measured; and met its intent to address multiple substances in case presentations and discussions. While case presentations and discussions comprise from half to the majority of content in the sessions (30-35 minutes of a 60-minute session), content during sessions also includes faculty didactic presentations (20-25 minutes), which also addresses these 7 learning objectives and various substances but was not a part of the content analysis. Therefore, learner outcome improvements may also be a result of content addressed in didactic presentations.

While the Project ECHO model has been shown to be effective in training the primary care workforce [9], specifically on OUD [10,11] and addiction medicine [12,13], there has been no documentation, to our knowledge, of the ability of a team-based, comprehensive SUD and polysubstance-focused Project ECHO designed to improve learner outcomes (eg, knowledge, self-efficacy, and skills). Although Komaromy and colleagues [14] investigated the frequency of cases presented based on substance type in a comprehensive SUD-focused ECHO, a content analysis of the case presentation and discussion transcripts was not analyzed to either assess the frequency of substances or learning objectives. Furthermore, to our knowledge, this process has not been combined in a mixed method approach to compare learner outcomes with a content analysis to gauge the ability of an SUD-focused Project ECHO program to meet its stated learning objectives. Our results reported here align with this literature and expand to demonstrate that Project ECHO is a potential tool to effectively educate

multidisciplinary providers in a comprehensive approach to SUD care.

Strengths

This study has several strengths which promote the ability of the Project ECHO model in enhancing health care providers' knowledge, self-efficacy, and skill associated with comprehensive SUD care. The focus of this study is unique as there is minimal research exploring the benefits and training ability of Project ECHO with a comprehensive SUD care focus. This study's noteworthy strength is the use of a mixed methods design that presents a comprehensive evaluation correlating the content addressed in the case presentations and discussions to statistically significant learner outcomes to demonstrate how this telementoring continuing education series improved provider's knowledge, skills, and self-efficacy to benefit participating providers and their practices.

Limitations

This study faced several limitations during data collection and analysis. The first limitation of this study was the limited sample size and low response rate. There was a decline between the number of participants who completed the preseries survey and postseries survey, resulting in a low comparative sample, which restricted the options for statistical analysis. Another limitation was generalizability; the results of this Project ECHO are limited to the target audience of medical providers, behavioral health providers, and care team members from the state of Ohio, which is not a representative sample of broader populations nationally. Additionally, participants self-selected to take part in the Project ECHO series, which presents the potential for self-selection bias. Another limitation this study faced was the lack of available or reliable data on Project ECHO and its ability to meet learning objectives and address multiple substances through providers' knowledge, self-efficacy, skill, and attitudes. Furthermore, self-reported data to assess knowledge and skills, and self-reported data in general, could present participant biases and is difficult to corroborate with outcomes. The use of internally designed survey instruments instead of using validated

instruments presents as a limitation. In light of these limitations, future studies in this subject matter should include a larger data set. Additionally, future studies using a nested analysis approach might provide more insight into how the learning objective themes coincide with the various illicit and nonillicit substance types and would be a useful analysis to contribute to the knowledge base. Another recommendation for future studies in this subject matter should include a deeper analysis of attendance dose and exposure to didactic topics to better understand the impact on changes in learner outcomes. Future research with greater validity will contribute to the significant gaps in literature regarding this subject.

Conclusions

The purpose of this research study was to assess the ability of CSUDC ECHO to both address and meet 7 learning objectives (Textbox 2) and address multiple substances by analyzing (1) the frequency of exposure to the learning objective topics and substance types during case presentations and discussions and (2) participants' knowledge, self-efficacy, skills, and attitudes related to the treatment of SUDs from pre- to postprogram. The results of this study indicate that CSUDC ECHO was able to both address and meet its learning objectives while addressing multiple substances, as demonstrated by improvements in learner knowledge, self-efficacy, and skills. All learning objective themes resulted in high frequencies and doses, appearing in a majority of case presentations throughout the series. These promising results suggest that Project ECHO is a potential tool to educate primary care providers, behavioral health providers, and care team members in a comprehensive approach to SUD assessment and treatment through complex case discussions combined with didactic learning for certain settings. As Project ECHO programs continue to be established globally and existing programs strengthen, further research examining the model's ability to achieve positive learning outcomes and factors that may contribute to these outcomes (eg, frequency of topic dose) is needed to confirm the outcomes in larger population samples, additional topics of focus, and other geographical settings.

Acknowledgments

The authors would like to acknowledge our partners at Buckeye Health Plan and Ohio University Heritage College of Osteopathic Medicine. We would like to thank our funders, Centene Corporation through its subsidiary, Buckeye Health Plan; without their financial support, this work would not have been possible. We would like to thank the faculty that led the ECHO sessions, delivered didactic presentations, and provided high-quality case recommendations, including core faculty members Dana Vallangeon, doctor of medicine, Tracy Plouck, master of public administration, Amy Black, master of science in nursing, advanced practice registered nurse, nurse practitioner-certified, Ericka Ludwig, licensed professional clinical counselors applying for training supervision designation, licensed independent chemical dependency counselor, as well as guest faculty members. We would also like to thank our Weitzman Institute colleagues who helped with the content analysis: Zeba Kokan, Claire Newby, and Reilly Orner. Abstract

Background: The integration of gender and sexuality awareness in health care is increasingly recognized as vital for patient outcomes. Despite this, there is a notable lack of comprehensive data on the current state of physicians' training and perceptions in these areas, leading to a gap in targeted educational interventions and optimal health care delivery.

Objective: The study's aim was to explore the experiences and perceptions of attending and resident physicians regarding the inclusion of gender and sexuality content in medical school curricula and professional practice in Israel.

Methods: This cross-sectional survey targeted a diverse group of physicians across various specializations and experience levels. Distributed through Israeli Medical Associations and professional networks, it included sections on experiences with gender and sexuality content, perceptions of knowledge, the impact of medical school curricula on professional capabilities, and views on integrating gender medicine in medical education. Descriptive and correlational analyses, along with gender-based and medical status-based comparisons, were used, complemented, and enhanced by qualitative analysis of participants' replies.

Results: The survey, encompassing 189 respondents, revealed low-to-moderate exposure to gender and sexuality content in medical school curricula, with a similar perception of preparedness. A need for more comprehensive training was widely recognized. The majority valued training in these areas for enhancing professional capabilities, identifying 10 essential gender-related knowledge areas. The preference for integrating gender medicine throughout medical education was significant. Gender-based analysis indicated variations in exposure and perceptions.

Conclusions: The study highlights a crucial need for the inclusion of gender and sexuality awareness in medical education and practice. It suggests the necessity for curriculum development, targeted training programs, policy advocacy, mentorship initiatives,

and research to evaluate the effectiveness of these interventions. The findings serve as a foundation for future directions in medical education, aiming for a more inclusive, aware, and prepared medical workforce.

Introduction

The contemporary health care landscape is undergoing a significant transformation, with a growing recognition of the importance of integrating gender and sexuality awareness into both medical education and clinical practice [1-5]. This shift in perspective acknowledges that gender and sexuality are not just marginal issues but, on the contrary, are central determinants of health outcomes [6], influencing patient care in complex and diverse ways, affecting various aspects, from the prevalence and presentation of diseases to treatment responses and patient interactions [1,6].

Despite this growing awareness, there remains a significant gap in our understanding of how well attending and resident physicians are trained in these areas [7-10]. This includes a lack of comprehensive data on the depth and breadth of their knowledge, the extent of their exposure to gender and sexuality issues during their training, and their perceptions and attitudes toward these crucial aspects of patient care [1,9]. This paucity of information is problematic because it hinders the ability of medical education institutions and health care organizations to develop targeted educational interventions [9].

Without a clear understanding and an updated picture of the current state of medical education, training, and knowledge, it becomes challenging to craft effective strategies to enhance the competencies and skills of health care providers in dealing with gender- and sexuality-related health issues [10].

Our study aims to fill this critical gap by exploring the experiences and perceptions of attending and resident physicians regarding the inclusion of gender and sexuality content in their education and subsequent professional practice. We intend to paint a clearer snapshot of the current state of awareness and understanding in the medical community. Our objective is to identify not only the strengths but also the potential areas for improvement in medical education regarding gender and sexuality. This will enable us to contribute valuable insights to the ongoing discourse on personalized and gender-sensitive health care. In doing so, we seek to influence the future direction of medical education and practice, steering it toward a more inclusive, aware, and responsive model that takes into account the diverse needs of patients. This, in turn, is expected to lead to more effective, personalized patient care, better health outcomes, and a health care system that is more attuned to the complexities of human diversity.

Methods

Survey Design and Participants

This study used a mixed methods, cross-sectional survey design. We targeted a diverse group of Israeli attending and resident physicians, encompassing various specializations, professional statuses, and levels of experience. The survey was distributed through multiple Israeli Medical Associations and professional networks to ensure a wide reach.

Demographics

The demographic section of the survey covered age, sex and gender, medical specialization, professional status (attending or resident physician), and years of experience in the medical field. This information provided a sociodemographic context for the subsequent analysis.

Survey Content

The survey was devised based on a previous systematic review of the literature [1] and consisted of several sections, each focusing on different aspects of gender and sexuality in medical education and practice.

Experiences With Gender and Sexuality Content

This section assessed the respondents' exposure to and preparedness in gender and sexuality topics during their attendance in medical schools and residency training. More specifically, participants were asked whether medical school curricula and residency programs included content related to gender and sexuality. They were then asked to rate their levels of exposure to gender and sexuality content during their academic studies and residency on a Likert scale from 1 (strongly disagree) to 5 (strongly agree).

Perceptions of Knowledge and Tools

Respondents rated their current levels of knowledge and the adequacy of tools available to address gender and sexuality issues in their professional practice on a Likert scale from 1 (strongly disagree) to 5 (strongly agree).

Impact of Medical School Curricula and Residency Programs on Professional Capabilities

This part evaluated the perceived impact of gender and sexuality training on enhancing professional capabilities and identified essential areas of knowledge in this domain. Participants were asked to what extent they felt they lacked training in the field of gender and sexuality, and to what extent they believed training in these areas would contribute to their professional

capabilities, using a Likert scale from 1 (no contribution) to 5 (very great extent).

Integration of Gender Medicine in Medical Education

Respondents shared their views on when and how gender medicine should be incorporated into medical education, with options including preclinical years, clinical years, both preclinical and clinical years, or not at all.

Integration of Gender Medicine in Clinical Practice

In this section, participants were asked whether they considered the patient's sex and gender when choosing drug treatments and whether they considered the effects of treatment on the patient's life course in relation to sex and gender, both rated on a Likert scale from 1 (strongly disagree) to 5 (strongly agree). They were also asked if they had observed differences in the presentation and nature of symptoms based on the patient's sex and gender and whether they believed there is a distinction in treating the LGBTQI (lesbian, gay, bisexual, transgender, queer/questioning, and intersex) population in terms of common conditions and emotional impacts.

Finally, the survey inquired if participants had mentored students in the past year, with a simple yes or no response.

This comprehensive survey aimed to gather quantitative detailed information on physicians' experiences and perceptions regarding gender and sexuality content in their education and professional practice, highlighting areas for potential improvement in medical training.

Statistical Analysis

Descriptive statistics were used to summarize the sociodemographic data. We used correlational analysis to explore relationships between different aspects of gender and sexuality awareness and training. A gender-based analysis was conducted to discern any differences in responses based on sex and gender. In addition, we compared responses between attending physicians and residents to identify variations based on professional status. Multivariate analyses were performed to uncover associations between survey responses and demographic variables such as age, sex and gender, years of experience, and medical specialization. Effect sizes were computed as Cohen *d* and odds ratios. For all analyses, a significance level of .05 was used as the statistical threshold. To control for the increased risk of type I error due to multiple comparisons, the Bonferroni correction was applied where necessary. All statistical analyses were conducted in the open-source R environment (R Foundation for Statistical Computing).

Qualitative Analysis

In addition to the quantitative survey, qualitative data were collected through the inclusion of 2 open-ended items within the survey itself. These items aimed to gain deeper insights into the experiences and perceptions of attending and resident physicians regarding essential gender knowledge for medical education. More specifically, the 2 open-ended items included in the survey asked the participants to select terms or concepts related to gender knowledge that they believed are essential for medical students to study.

Thematic analysis was used to analyze the qualitative data. The process involved steps, such as familiarization, coding, theme development, defining themes, and reporting. First, responses were read multiple times to become familiar with the data. Initial codes were generated by systematically identifying key terms and concepts mentioned by respondents. Codes were then grouped into potential themes based on commonalities and patterns in the responses. Each theme was defined and named, providing a detailed analysis of its significance in the context of gender and sexuality education. The final themes were integrated into a coherent narrative, illustrating the respondents' views on essential gender knowledge for medical students.

Ethical Considerations

The study was conducted in compliance with the ethical standards for research involving human participants. They were informed about the purpose of the study, and participation was voluntary. Informed, written consent was collected before the commencement of the study. Anonymity and confidentiality of responses were maintained throughout the study.

Results

Sociodemographic Data

The survey data encompassed 189 respondents with an average age of 39.8 (SD 12.1, range 22-70, median 36; [Table 1](#)). Gender distribution showed a majority of women, totaling 57.1% (108/189) of participants. In terms of medical specialization, the respondents represented 27 different fields, with internal medicine being the most common, reported by 37% (70/189) of participants. Regarding professional status, the sample was almost evenly split between attending physicians and residents, with the former category being slightly more common at 104 out of 189 (55%) instances. Concerning their tenure in the medical field across 5 distinct experience categories (0-5 years, 6-10 years, 11-15 years, 16-20 years, and more than 20 years), the survey reflected a less experienced demographic, with the 0-5 years category reported most frequently by 86 out of 189 (45.5%) respondents, thus highlighting a considerable representation of early-career physicians within the surveyed population.

Table 1. Demographics of the survey's sample.

Demographic variable	Details
Sample size	189 respondents
Age	39.8 (range 22-70, median 36) years
Gender distribution	Women: 108 (57.1%) respondents
Medical specialization	27 different medical fields; most common: Internal medicine (37%)
Professional status	Attending physicians: 104 (55%) respondents; residents: 85 (45%) respondents
Years of experience	86 (45.5%) respondents with 0-5 years of experience
Mentorship	Active involvement in student mentorship reported by 65.1% of respondents

Respondents' Experiences With Gender and Sexuality Content in Their Education and Professional Training

The average level of exposure to gender and sexuality content during academic studies was rated at 2.03 (SD 0.98), suggesting a low-to-moderate exposure among participants. Respondents rated their academic program's preparedness in imparting gender and sexuality awareness at an average of 1.99 (SD 1.06), indicating a similar low-to-moderate perception of preparedness. The readiness provided by specialization or residency programs had a slightly higher average rating of 2.18 (SD 1.10). Regarding current knowledge and tools to address gender and sexuality issues, the average rating was 2.74 (SD 0.96). Finally, the extent of perceived lack of training in gender and sexuality fields averaged at 3.26 (SD 1.16), suggesting that respondents generally felt a need for more training in these areas.

On average, respondents rated 2.84 (SD 1.20) on the importance of considering the patient's sex and gender when choosing drug treatment, indicating moderate agreement and some variability in responses. When it comes to accounting for the effects of

treatment on a patient's life course in relation to sex and gender, the mean rating was higher at 3.39 (SD 1.17), suggesting a generally higher agreement on this consideration. Observations of differences in symptom presentation based on the patient's sex and gender had a mean rating of 2.97 (SD 1.12), reflecting that the respondents somewhat agreed that they noticed such differences.

Respondents' Assessment of the Impact of Training in Gender and Sexuality on Professional Capabilities

The majority of respondents valued such training highly. Approximately 47.1% (89/189) believed it can contribute to a great extent, while 20.1% (38/189) felt it can contribute to a very great extent. A further 16.4% (31/189) saw it as moderately impactful, whereas only 9% (17/189) considered its potential contribution small. Notably, 6.3% (12/189) perceived no contribution from this training. A small fraction of respondents (2/189, 1.1%) had mixed views. Overall, these findings indicate a strong consensus on the positive impact of gender and sexuality training in enhancing professional capabilities (Table 2).

Table 2. Major findings of the survey.

Major finding	Details
Exposure to gender and sexuality content	Low-to-moderate exposure during academic studies (Average rating: 2.03 out of a Likert scale from 1 to 5)
Preparedness to gender-sensitive care	Low-to-moderate perception of preparedness (Academic: 1.99; Specialization/Residency: 2.18, out of a Likert scale from 1 to 5)
Perceived need for training	General consensus on the need for more training (Average lack of training rating: 3.26, out of a Likert scale from 1 to 5)
Impact on professional capabilities	Majority see training as beneficial (47.1%=great extent; 20.1%=very great extent; 16.4%=moderate extent)
Essential gender-related knowledge areas	Ten areas identified, including patriarchy, LGBTQI ^a awareness, gender awareness, sexual and domestic violence, gender-specific diseases and symptoms, pharmacology and gender differences, treatment compliance and gender, psychological and social effects of gender, and sex and gender-aware research; Table 3 for further details
Preference for integration of gender medicine	Majority prefer integration throughout medical education (Preclinical and clinical years: 55.6%)

^aLGBTQI: lesbian, gay, bisexual, transgender, queer/questioning, and intersex.

According to the respondents, this training should cover 10 essential gender-related knowledge areas, as reported in Table 3.

Table 3. Ten essential gender-related knowledge areas that should be covered by the training, according to survey's participants.

Gender-related knowledge area	Brief description
Patriarchy	Understanding the social organization where power is primarily held by men and its impact on health care access and treatment outcomes, which is crucial to recognize how patriarchal structures can affect both patient care and the work environment in health care settings
LGBTQI ^a awareness	Knowledge about the health needs and challenges faced by the LGBTQI community, which includes understanding diverse sexual orientations and gender identities, and how these factors influence health risks, disease prevalence, and access to health care
Gender awareness	Recognizing and addressing gender biases and stereotypes in health care, which involves understanding how societal gender roles and expectations can impact health and health care delivery
Sexual violence	Awareness of the medical, psychological, and social implications of sexual violence, which includes understanding how to provide sensitive and appropriate care to survivors
Domestic violence	Recognizing signs of domestic violence and understanding its health implications, which also involves knowing how to provide support and resources to survivors
Gender-specific diseases and symptoms	Understanding differences in disease presentation, symptom onset, and diagnosis between sexes and genders, which is essential for accurate diagnosis and effective treatment
Pharmacology and gender differences	Acknowledging how drugs may affect sexes and genders differently in terms of efficacy, side effects, and treatment response, which is vital for personalized medicine
Treatment compliance and gender	Recognizing that gender can influence treatment adherence and response, with factors such as societal roles, communication styles, and access to health care varying between genders and impacting treatment outcomes
Psychological and social effects of gender	Understanding the broader psychological and social implications of gender on health, which includes the impact of gender roles, expectations, and discrimination on mental health and social well-being
Sex and gender-aware research	Promoting and using research that takes into account sex and gender differences, ensuring that medical knowledge and practice are based on inclusive and comprehensive data

^aLGBTQI: lesbian, gay, bisexual, transgender, queer/questioning, and intersex.

According to the respondents, these topics provide a broad and nuanced understanding of how sex and gender affect health and health care, equipping medical students to deliver more compassionate, informed, and effective care to all patients, regardless of their sex and gender.

Finally, respondents had various opinions on when gender medicine should be incorporated into medical education. The majority believed it should be taught during both preclinical and clinical study years, with 55.6% (105/189) respondents endorsing this approach. Furthermore, 50 respondents, out of 189, felt it should be specifically included in the clinical study years (26.5%), and 23 participants argued for its introduction in the preclinical years (12.2%). A minority of 3.7% (7/189) subjects believed there was little need to teach gender medicine. There are also a few isolated responses that combine these categories or indicate no need at all for such education, each with 1 respondent. Overall, this distribution indicates a strong preference for integrating gender medicine throughout the entire span of medical education, with a significant emphasis on its

presence in both foundational and advanced stages of the medical curriculum.

Among the 189 survey participants, 123 respondents indicated that they have been mentoring students in the past year (65.1%), while 66 respondents have not engaged in student mentorship during that time (34.9%). This suggests a significant portion of the respondents are actively involved in the mentorship and educational development of students.

Correlations and Trends: Insights From Correlational Analysis

There was a strong correlation ($r=0.70$) between respondents' perceptions of their academic program's preparation in terms of gender and sexuality awareness and their views on the preparation provided by their specialization and residency program. Furthermore, respondents' levels of exposure to gender and sexuality content in their academic program strongly correlated ($r=0.68$) with their perception of how well the program prepared them in these areas. There was a moderate

correlation ($r=0.48$) between how well respondents feel their specialization and residency program prepared them and their current perception of having sufficient knowledge and tools to deal with gender and sexuality issues in their field. Furthermore, respondents who felt their academic program prepared them well in gender and sexuality awareness also tend to feel they currently have sufficient knowledge and tools in this area, with a moderate correlation ($r=0.40$).

Gender-Based Analysis

The analysis based on gender reveals null-to-small effect sizes, with only 1 medium effect size concerning the sex- and gender-specific choice of a treatment. Men reported a higher level of exposure to gender and sexuality content during their academic studies (mean 2.23, SD 1.06) compared with women (mean 1.87, SD 0.89; $d=0.38$). Similarly, they also rated their academic study program's preparation in gender and sexuality awareness higher (mean 2.22, SD 1.15 for men vs mean 1.82, SD 0.97 for women; $d=0.38$). In terms of how well respondents felt their specialization and residency program prepared them in gender and sexuality awareness, men's responses were only slightly higher (mean 2.28, SD 1.15) than women's (mean 2.10, SD 1.05; $d=0.17$; not statistically significant). When asked if they currently have sufficient knowledge and tools to deal with issues of gender and sexuality in their field, men's responses were on average comparable (mean 2.79, SD 1.02) with those of women (mean 2.70, SD 0.92; $d=0.09$; not statistically significant). Regarding the extent to which they feel they lack training in the field of gender and sexuality, men had a lower average (mean 3.10, SD 1.21) than women (mean 3.38, SD 1.12; $d=-0.24$), suggesting that women perceive a greater need for training in these areas. Regarding the consideration of patient's sex and gender in drug treatment, men reported an average score of 3.10 (SD 1.22), higher than those reported by women (mean 2.64, SD 1.16), with $d=0.39$. When choosing the treatment, men were more likely to take into account its effects on the patient's life course in relation to sex and gender (mean 3.85, SD 1.02 vs mean 3.07, SD 1.16; $d=0.71$). When questioned about the observation of differences in the presentation and nature of symptoms based on patient's sex and gender, the responses from both men and women participants were similar (mean 2.99, SD 1.18 vs mean 2.96, SD 1.08; $d=0.02$). Similarly, recognition of the unique health care needs and challenges faced by LGBTQI individuals did not differ between men and women (mean 3.11, SD 1.31 vs mean 3.21, SD 1.22; $d=-0.08$).

In terms of subjects mentioned by respondents, men were more likely to mention certain topics like "domestic violence," "homophobia," "LGBTQI awareness," and "gender awareness." Other subjects such as differences in symptom onset and diagnosis of gender-specific diseases, topics related to pharmacology, treatment compliance, gender aspects of heart health, disease prevention, psychological and social effects, and feminism were more common among men respondents. Among women, respondents' topics covered more medically gender-related subjects, such as sexually transmitted infections, sexual education, and safer sex, among others.

To get more insights about gender-specific differences in the responses, further gender-based analyses were conducted. No

gender-specific differences could be found in terms of age (mean 41.0, SD 14.3 vs mean 38.9, SD 10.1; $P=.23$) and the status of the respondent, that is, attending versus resident ($\chi^2_1=0.02$, $P=.90$). On the contrary, there were some gender imbalances concerning the different medical specializations of the respondents ($\chi^2_{26}=36.76$, $P=.08$). In particular, in the field of pediatrics all subjects were practically women (10 vs 1; $P=.03$ at the post hoc test), and in the field of internal medicine, men were overrepresented compared with women (42 vs 28; $P<.001$ at the post hoc test). In terms of years of practice and experience, some slight gender imbalances could be noted ($\chi^2_4=6.94$, $P=.14$), with men being overrepresented in the category "more than 20 years" (24 vs 16; $P=.02$ at the post hoc test). Finally, women were more likely to report not having mentored students in the last year ($\chi^2_1=3.76$, $P=.05$, with an odds ratio of 1.84 [95% CI 0.99-3.43]).

Medical Status-Based Analysis

The comparison between attending physicians and residents yields the following insights. On average, attending physicians reported a lower level of exposure to gender and sexuality content during academic studies (mean 1.88) compared with residents (mean 2.21). Similarly, they rated their academic study program's preparation in gender and sexuality awareness lower (mean 1.86 for attending doctors vs 2.16 for residents). Attending physicians also rated the preparation provided by their specialization and residency program slightly higher (mean 2.21) than residents did (mean 2.14). In assessing whether they have sufficient knowledge and tools to deal with issues of gender and sexuality, attending physicians' average response was higher (mean 2.87) compared with residents (mean 2.59). When it comes to the extent of lacking training in gender and sexuality, attending physicians feel slightly less deficient (mean 3.20) than residents (mean 3.33), indicating that residents may perceive a greater need for training in these areas.

The comparison among the different medical specializations revealed that respondents in the field of internal medicine perceived themselves as relatively well-prepared or exposed to gender and sexuality topics.

Multivariate Analysis

At the multivariate analysis, the reported level of exposure to gender and sexuality content during academic studies was associated with gender ($F_{2,186}=8.89$, $P=.003$), with women reporting lower exposure than men ($\beta=-.46$, 95% CI -0.77 to -0.16). Similarly, perceived academic preparedness in terms of gender and sexuality awareness was found to be associated with gender ($F_{2,186}=7.33$, $P=.007$), with women scoring lower than men ($\beta=-.43$, 95% CI -0.74 to -0.12), while thinking of currently having sufficient knowledge and tools to deal with issues of gender and sexuality in one's field was associated with years of experience in a statistically significant way ($F_{5,183}=2.48$, $P=.045$ at the ANOVA omnibus test). In particular, the category "over 20 years" versus "0-5 years" was more likely to report a higher score ($\beta=1.30$, 95% CI $0.27-2.33$; $P=.014$). The perceived lack of training in the field of gender and sexuality was found to be associated with medical status ($F_{2,186}=4.06$, $P=.045$ at the

ANOVA omnibus test), with residents scoring higher than attending doctors ($\beta=.54$, 95% CI 0.01-1.08). The perceived impact of training in gender and sexuality on professional skills was once again associated with gender ($F_{2,186}=4.89$, $P=.028$), with women reporting greater perceived impact ($\beta=.34$, 95% CI 0.04-0.65) than men. Accounting for the person's sex and gender in the choice of the treatment was associated with the gender ($F_{2,186}=5.26$, $P=.023$), with women reporting this practice less ($\beta=-.37$, 95% CI -0.68 to -0.05) than men. When choosing the treatment, taking into account its effects on the patient's life course in relation to sex and gender was associated with gender ($F_{2,186}=17.12$, $P<.001$), medical specialization ($F_{27,161}=19.62$, $P<.001$), and increasing years of practice and experience ($F_{5,183}=2.21$, $P=.07$). This practice was less reported by women ($\beta=-.54$, 95% CI -0.79 to -0.28), and doctors non specialist in internal medicine ($\beta=-.74$, 95% CI -1.07 to -0.41). No significant predictors could be found for the other items of the questionnaire.

Qualitative Analysis

Participants highlighted 10 essential gender-related knowledge areas that should be covered by training, as identified by survey participants. First, understanding patriarchy is crucial for recognizing how power dynamics, predominantly controlled by men, can impact health care access and treatment outcomes. This knowledge helps in identifying the influence of patriarchal structures on both patient care and the work environment in health care settings. Awareness of LGBTQI health needs is also essential, encompassing knowledge about diverse sexual orientations and gender identities, and their influence on health risks, disease prevalence, and access to health care. Recognizing and addressing gender biases and stereotypes in health care, known as gender awareness, involves understanding how societal gender roles and expectations affect health and health care delivery. Awareness of sexual violence includes understanding its medical, psychological, and social implications to provide sensitive and appropriate care to survivors. Similarly, recognizing signs of domestic violence and understanding its health implications is vital, along with knowing how to provide support and resources to survivors. In addition, understanding gender-specific diseases and symptoms is essential for accurate diagnosis and effective treatment, as is acknowledging how drugs may affect sexes and genders differently in terms of efficacy, side effects, and treatment response. Recognizing that gender can influence treatment adherence and response is important, with factors such as societal roles, communication styles, and access to health care varying between genders. Understanding the broader psychological and social effects of gender on health includes considering the impact of gender roles, expectations, and discrimination on mental health and social well-being. Finally, promoting and using sex- and gender-aware research ensures that medical knowledge and practice are based on inclusive and comprehensive data, leading to improved health care outcomes for all sexes and genders.

Discussion

Principal Findings

This survey offered a rich and nuanced view of physicians' experiences and perceptions related to gender and sexuality in their education and practice. The demographic data revealed an average respondent age of nearly 40 years, with a notable majority of women. Diversity was evident in their medical specializations, with internal medicine emerging as the most common field, whereas the professional status of the respondents was well-balanced between attending physicians and residents, although slightly skewed toward the former. A significant portion of the survey population was relatively new to the medical field, emphasizing the presence of early-career physicians.

In terms of their experiences with gender and sexuality content, the data suggested that the exposure during academic studies was generally low to moderate. This was mirrored in their perception of preparedness in these areas, indicating a gap in the curriculum.

The sociological landscape of LGBTQI rights in Israel has been marked by both significant progress and notable contradictions. Since the early 2000s, there have been considerable advancements for LGBTQI individuals. However, progress has been uneven, especially for the transgender community, which continues to face significant discrimination, violence, and material disadvantages. In key institutions like health care and education, LGBTQI individuals encounter barriers that reflect broader societal tensions. Privatization and economic disparities exacerbate these challenges, particularly for those without the resources to navigate these systems effectively [11].

Our survey findings can be interpreted and discussed against this framework. However, they are challenging to directly compare due to the scarcity of research in Israeli contexts, which is predominantly limited to specific populations, such as physiotherapy students [12]. On the other hand, the findings well align with the broader trends identified in the literature, emphasizing a widespread issue in medical education regarding the adequacy of training on gender and sexuality. According to a survey by Obedin-Maliver et al [13], medical schools in the United States and Canada devote a small amount of time in their curricula to LGBTQI health and other topics related to sexuality, indicating a need for more comprehensive education in these areas. This survey was conducted more than a decade ago (between May 2009 and March 2010) and replicated recently, finding that, while the median time allocated to LGBTQI health-related topics increased in US and Canadian undergraduate medical education institutions, the scope, effectiveness, and quality of this instruction varied significantly. Despite the rise in hours, the total remains below the number recommended by the Association of American Medical Colleges (AAMC) for LGBTQI health competencies [14].

Of note, when it comes to the application of this knowledge in professional practice, there was a moderate level of self-assessed competence, coupled with a general consensus on the need for more comprehensive training. The importance of considering

the patient's sex and gender in treatment decisions showed moderate agreement among the respondents, with a slightly higher emphasis on the impact of treatment in the context of the patient's sex and gender. The impact of training in gender and sexuality on professional capabilities was largely acknowledged by the majority. This aligns with studies suggesting that insufficient training on gender and sexuality issues can lead to lower confidence among physicians when addressing the health needs of LGBTQI patients and other gender-diverse populations. For instance, a study by Marr et al [15] highlighted that many medical residents feel unprepared to provide high-quality care to LGBTQI patients, mirroring our survey's findings on the perceived preparedness gap.

Of note, our survey's participants expressed confidence in their ability to handle gender and sexuality issues in clinical practice, despite a low self-reported exposure to gender and sexuality content during their medical training. This apparent paradox, where a curricular gap was identified but respondents still felt prepared to deliver care, has been observed in other studies. What is particularly intriguing in our study is the differentiation between residents and fully licensed physicians, with responses further stratified by years of practice. These data seem to suggest a pattern; the longer a physician has been in practice, the less gender and sexuality content they recall from their training, yet the more confident they feel in their knowledge and ability to address these issues. This pattern could point to several possibilities. It may suggest that while formal education on gender and sexuality issues is lacking, the day-to-day experiences and challenges of medical practice provide ample opportunities for physicians to develop the necessary competencies. Alternatively, it could imply that confidence increases with experience, even if knowledge gaps persist, potentially leading to overconfidence in areas where additional training would be beneficial. This distinction between learning through experience *versus* feeling prepared due to increased confidence is a critical area for further exploration, as it has significant implications for medical education and ongoing professional development.

Furthermore, the respondents pinpointed 10 critical areas of gender-related knowledge, encompassing a broad spectrum from LGBTQI awareness to the specifics of gendered pharmacology, pointing to the multifaceted nature of sex and gender in medical practice. In discussing the incorporation of gender medicine into medical education, there was a clear preference for its integration across all stages of learning, reflecting a progressive approach toward medical training. The data also highlighted active involvement in student mentorship by a substantial number of respondents. The literature increasingly supports the integration of gender medicine and education on sexuality and gender diversity throughout the entire medical education continuum, from undergraduate education to continuing medical education for practicing physicians. This approach is advocated to ensure that medical doctors are well-equipped to meet the diverse needs of all patients, recognizing the significant role of sex and gender in health outcomes. For example, a consensus statement by the AAMC on the inclusion of gender awareness and LGBTQI health in medical education curriculum frameworks emphasizes

the need for longitudinal integration rather than isolated modules or electives [16,17].

Furthermore, the survey revealed intriguing correlations, particularly between perceptions of academic program preparation and specialization and residency program views on gender and sexuality awareness. The gender-based analysis presented a complex picture, with variations in exposure and perceptions between men and women. Certain topics showed gender imbalances, while others exhibited more parity. Comparing attending physicians and residents, differences emerged in their perceptions of exposure to and preparedness in gender and sexuality content, suggesting variations in training across different stages of medical careers. The multivariate analysis further unraveled associations between various factors such as gender, years of experience, and medical status in relation to the survey responses. Similarly, a survey [18] conducted in Taiwan identified several shortcomings in present medical education and the lack of readiness among medical students and trainees to offer improved care for LGBTQI individuals.

In summary, this survey underscored the growing recognition of gender and sexuality as pivotal components in medical education and practice. It highlighted existing gaps in training and varying perceptions based on demographic and professional factors, pointing toward a need for a more inclusive and comprehensive approach in medical training and practice.

This survey offers valuable guidance for medical teachers and institutional stakeholders on developing and applying effective curricula and training programs, as well as faculty development initiatives. These strategies should aim to furnish medical students and trainees with the self-awareness and skills necessary to deliver gender-sensitive care, including comprehensive care to sexual and gender minorities, align with societal advancements, and advance health equity for a broader range of patients.

Effective communication is crucial for medical doctors, involving active listening, clear explanations, recognition of nonverbal cues, and patient education. By actively listening, health care providers can fully understand patients' symptoms and concerns, leading to more accurate diagnoses and tailored treatments. Clear explanations about diagnoses and treatment options ensure patients can make informed decisions. Recognizing and responding to nonverbal cues enhance understanding and trust, while effective patient education ensures patients comprehend their health conditions and necessary treatments. Cultural competence is essential, requiring awareness of diverse cultural backgrounds, including values and beliefs. Sensitivity to cultural differences and avoiding stereotypes help build trust and provide respectful care. Adapting health care practices to meet cultural needs improves health outcomes and patient satisfaction. Ongoing cultural competence training enhances inclusive care. Empathy involves understanding and valuing patients' feelings and experiences and building therapeutic relationships. Providing compassionate care alleviates anxiety and improves the health care experience. Offering emotional support and reassurance is crucial, and reflective practice helps physicians improve empathetic

interactions. Navigating complex social and ethical considerations related to gender and sexuality is vital in gender-based medicine. Recognizing and respecting diverse gender identities ensures all patients receive appropriate care. Implementing inclusive practices, such as using correct pronouns and offering gender-neutral facilities, supports patient well-being. Addressing ethical dilemmas requires careful consideration of patient autonomy and confidentiality. Staying informed about gender issues, advocating for patients' rights, and working to eliminate health care disparities are integral to ethical medical practice. These competencies—effective communication, cultural competence, empathy, and navigating gender and sexuality issues—are fundamental for medical doctors to provide comprehensive, sensitive, and effective care. Ensuring all patients feel understood, respected, and valued is the cornerstone of excellent gender-based medicine.

A further point that should be stressed is that our findings revealed significant variations in exposure and preparedness between men and women concerning gender and sexuality content in medical education. Men reported a higher level of perceived preparedness in dealing with gender and sexuality issues than women. This discrepancy highlights a crucial point often overlooked in discussions about educational interventions, that is, those in positions of privilege (in this case, men) may report more comfort and may not perceive the existing gaps as those in less privileged positions (women). Men's higher self-reported comfort could stem from their generally more prominent status within the medical community, which may afford them more confidence in professional settings. Conversely, women, who historically and structurally face more barriers in the medical field, may experience and recognize these gaps more acutely. This perception gap is critical as it underscores the need for more targeted and inclusive educational programs that not only address the specific needs of female physicians but also raise awareness among male physicians about these disparities. In addition, it is essential to acknowledge the role of implicit biases and structural inequalities that contribute to these differing perceptions. Training programs must be designed to bridge this gap by fostering an environment where both male and female physicians can gain a more balanced and comprehensive understanding of gender and sexuality issues. This approach can lead to a more equitable and effective health care delivery system, where all practitioners are equally prepared to address the diverse needs of their patients. By incorporating these considerations into the development of medical curricula and professional training, we can work toward reducing the perception and comfort gap between male and female physicians, ultimately leading to improved patient outcomes and a more inclusive medical community.

Future Directions

The World Federation for Medical Education (WFME) sets global standards for quality improvement in medical education. These standards include explicit requirements for integrating gender and sexuality education into medical school curricula. The WFME's standards ensure that medical schools worldwide provide education that prepares physicians to address diverse patient needs, including those related to gender and sexuality.

Our study's findings indicate a significant gap in the integration of gender and sexuality content within medical education, highlighting a discrepancy between current practices and the WFME's curricular requirements. As such, the findings of this survey highlight the need for a comprehensive overhaul of medical education curricula. Future efforts should focus on integrating gender and sexuality content more thoroughly and consistently across all stages of medical training. This includes both preclinical and clinical years, ensuring that medical doctors are equipped with the necessary knowledge and skills from the onset of their careers.

Given the reported gap in preparedness and exposure, there is a clear need for targeted training programs that address specific areas of gender and sexuality in health care. These programs should cover the 10 critical areas identified by respondents, ranging from LGBTQI awareness to gender-specific diseases and symptoms.

Further research is necessary to continuously monitor and evaluate the effectiveness of implemented educational strategies. Longitudinal studies could be beneficial in assessing the impact of improved gender and sexuality training on health care outcomes. In addition, research should explore the evolving needs and perceptions of medical residents and practicing physicians in these areas.

The study's results can be used to advocate for policy changes at institutional and national levels. This involves lobbying for mandatory inclusion of gender and sexuality topics in medical education accreditation standards and continuous professional development requirements.

Furthermore, mentorship programs that emphasize gender and sexuality awareness should be encouraged. This point is crucial and experienced medical doctors who are well-versed in these topics should mentor younger colleagues, fostering a culture of continuous learning and sensitivity toward these issues. Efforts should be made to promote diversity and inclusion within the medical community, addressing gender imbalances in various medical specializations and ensuring that medical education and practice are inclusive of all sexes, genders, sexual orientations, and gender identities.

The latest technological advancements can be leveraged. Using, for instance, virtual reality and e-learning platforms, can provide innovative ways to teach and engage medical students and practicing doctors in gender and sexuality topics [19,20]. This approach can supplement traditional learning methods and offer flexible training opportunities. Future studies investigating the effectiveness of these technological methods in gender medicine education are crucial as they would help in understanding how well these technologies enhance learning outcomes, their impact on the practical skills of medical doctors, and how they compare with traditional teaching methods. Implementing technology in medical education, especially for topics like gender and sexuality, represents a significant step forward in creating a more informed and sensitive health care environment.

Conclusions

This study underscores the critical need for integrating gender and sexuality awareness into medical education and practice,

finding that, despite the recognized importance, there is a notable gap in the current training and preparedness of medical residents and practicing physicians in these areas. The survey results reveal a consensus on the necessity for more comprehensive training, reflecting the evolving landscape of health care where gender and sexuality play a significant role in patient care and outcomes. The variations in exposure and perceptions based on gender, professional status, and years of experience highlight the diversity of learning and training needs within the medical

community. This calls for a tailored approach in educational interventions, ensuring that they are relevant and effective for various groups within the medical profession.

Overall, the study contributes significantly to the ongoing discourse on personalized, gender-sensitive health care, by providing valuable insights for educators, policy makers, and health care providers, emphasizing the need for a more inclusive, aware, and well-prepared medical workforce to cater to the diverse health care needs of the population.

Abstract

Background: Artificial intelligence (AI) chatbots are poised to have a profound impact on medical education. Medical students, as early adopters of technology and future health care providers, play a crucial role in shaping the future of health care. However, little is known about the utilization of, perceptions on, and intention to use AI chatbots among medical students in China.

Objective: This study aims to explore the utilization of, perceptions on, and intention to use generative AI chatbots among medical students in China, using the Unified Theory of Acceptance and Use of Technology (UTAUT) framework. By conducting a national cross-sectional survey, we sought to identify the key determinants that influence medical students' acceptance of AI chatbots, thereby providing a basis for enhancing their integration into medical education. Understanding these factors is crucial for educators, policy makers, and technology developers to design and implement effective AI-driven educational tools that align with the needs and expectations of future health care professionals.

Methods: A web-based electronic survey questionnaire was developed and distributed via social media to medical students across the country. The UTAUT was used as a theoretical framework to design the questionnaire and analyze the data. The relationship between behavioral intention to use AI chatbots and UTAUT predictors was examined using multivariable regression.

Results: A total of 693 participants were from 57 universities covering 21 provinces or municipalities in China. Only a minority (199/693, 28.72%) reported using AI chatbots for studying, with ChatGPT (129/693, 18.61%) being the most commonly used. Most of the participants used AI chatbots for quickly obtaining medical information and knowledge (631/693, 91.05%) and increasing learning efficiency (594/693, 85.71%). Utilization behavior, social influence, facilitating conditions, perceived risk, and personal innovativeness showed significant positive associations with the behavioral intention to use AI chatbots (all P values were $<.05$).

Conclusions: Chinese medical students hold positive perceptions toward and high intentions to use AI chatbots, but there are gaps between intention and actual adoption. This highlights the need for strategies to improve access, training, and support and provide peer usage examples to fully harness the potential benefits of chatbot technology.

Introduction

The rapid advancements in artificial intelligence (AI) have significantly transformed various sectors, including health care. Among these advancements, AI chatbots have emerged as a promising tool with potential applications in medical education [1]. These intelligent systems use natural language processing and machine learning algorithms to engage in human-like dialogues, providing information in an understandable, efficient, interactive, and scenario-specific format, such as ChatGPT, Claude, Google Bard, and Bing's AI [2]. The chatbots can assist

medical students in medical research support, personalized learning, comprehending complex medical topics, developing clinical decision-making skills, and so forth [1,3]. A recent study demonstrated the efficacy of AI chatbots in answering complex medical questions and providing valuable medical educational support [4].

In China, integrating AI technology into medical education is particularly important, given the country's substantial investment in AI development and its growing emphasis on innovative educational methodologies [5,6]. AI chatbots would facilitate personalized learning experiences when facing the situation of

rigorous curricula and high student to teacher ratios in China. Medical students are a crucial target group for AI chatbot technology, as they are early adopters of technology and future health care providers who will play a vital role in shaping the future of health care. While research on AI chatbot applications in medical students has emerged [7-10], the utilization of, perceptions on, and intention to use AI chatbots among Chinese medical students are still unknown.

The adoption and effective utilization of AI chatbots among medical students depend on various factors, including their perceptions, attitudes, and behavioral intentions. The Unified Theory of Acceptance and Use of Technology (UTAUT), developed by Venkatesh et al [11], provides a comprehensive framework to understand the determinants of technology acceptance and usage, which is widely used in health care. Applying the UTAUT model in the context of AI chatbots can yield valuable insights into the factors that drive or hinder their adoption among medical students.

This study aims to explore the utilization of, perceptions on, and intention to use generative AI chatbots among medical students in China, using the UTAUT framework. By conducting a national cross-sectional survey, we seek to identify the key determinants that influence medical students' acceptance of AI chatbots, thereby providing a basis for enhancing their integration into medical education. Understanding these factors is crucial for educators, policy makers, and technology developers to design and implement effective AI-driven educational tools that align with the needs and expectations of future health care professionals.

Methods

Participants and Procedure

The target population was medical students enrolled in Chinese medical colleges or universities. An electronic survey was developed through a web-based survey platform named Wenjuanxing Questionnaire Star (Ranxing Technology Corp.), and the survey link was distributed via WeChat (Tencent Holdings Ltd) to medical college students across the country. Using a convenience sampling method, the questionnaire was posted on WeChat Moments and sent to WeChat groups from the research team's WeChat accounts. We identified relevant WeChat groups that consisted of medical students across various regions in China. These groups were selected based on their active participation in medical education discussions and their membership of medical students from diverse backgrounds and institutions. The research team directly contacted a total of 15 WeChat groups. To further enhance the reach, we used a snowball sampling method by requesting initial respondents to forward the survey link to other medical students in their network. Questionnaires that were considered valid included only the following: (1) each account responded only once, and (2) the total response time for completing the questionnaire was more than 300 seconds. Participants were recruited between June 2023 and July 2023.

To ensure adequate statistical power and precision for the intended analyses, we conducted a sample size calculation using

G*Power software (version 3.1.9.7) [12]. The calculation was based on the following parameters: a small effect size ($f_2=0.05$) was chosen for the multivariable regression analysis; the number of predictors was set at 15; the desired statistical power was set at 0.95; and the significance level was set at .05 (2-tailed). Based on these parameters, the minimum required sample size for the multivariable regression analysis was calculated to be 566 participants. However, to account for 20% missing data and increase the generalizability of the findings, we aimed to recruit 680 participants. Ultimately, we were able to collect 715 questionnaires across China, with 693 determined valid, representing a 96.9% final response rate.

The Theoretical Framework

The study used the UTAUT as a theoretical framework for the research. The UTAUT describes 4 key independent variables: performance expectancy (PE), effort expectancy (EE), social influence (SI), and facilitating conditions (FC). In this study, PE measured the participants' expectation that an AI chatbot will be useful for the study; EE measured the expectation that an AI chatbot is user-friendly and easy to use; SI measured the degree to which a user perceives that important others believe that he or she should use the new technology; and FC measured the degree to which a user believes that an organizational and technical infrastructure exists to support AI chatbot use [13]. The dependent variable BI was determined by PE, EE, SI, and FC. BI measured participants' intention to use the AI chatbot in their future study.

The intention was used as an outcome instead of the actual use of an AI chatbot, because the application of AI chatbot services has not been widely commercialized in China. Most medical students may not have experience with an AI chatbot in their study. Also, BI is a good representation of actual behavior [14]. Previous studies confirmed that these 4 variables (PE, EE, SI, and FC) have a positive influence on the intention to use the AI technology [15-17]. The original UTAUT validation study found that the UTAUT model is robust in explaining a high degree of variance (70%) in BI [13]. Moderating effects of age, gender, and experience were not tested in this study.

In addition, we added perceived risk (PR), resistance bias (RB), and personal innovativeness (PI) as 3 variables to the original UTAUT model. PR is defined as the potential for loss in the pursuit of the desired outcome of using a technology and identified for 7 facets of PR [18]. Here, PR was measured for performance risk, time risk, and privacy risk. RB is resistance to change, referring to people's attempts to maintain previous behaviors or habits that are connected to their past experiences when facing changes [16]. PI was designed to measure an individual's willingness to try out any new information technology [19]. Since AI chatbots are an emerging technology in health care, a user's inherent innovativeness may impact his or her intention to adopt this innovation, and some users may be accompanied by concerns and resistance to change when embracing the new technology. Previous studies found that PR and RB have been regarded as major barriers to health care information technology adoption [20,21], and PI has been statistically significant in predicting the BI of the user [22].

Questionnaire and Instrument

The developed questionnaire consisted of 3 parts (see questionnaire in [Multimedia Appendix 1](#)): (1) participants' sociodemographic information, such as age, gender, and grade level; (2) participants' cognition of, attitude toward, and experience with AI chatbots (these items were designed as categorical variables and were derived through a comprehensive process, including literature review and expert consultation, to ensure their relevance and clarity); and (3) the scale of the research model. The model covered 7 constructs with 29 questionnaire items ([Table 1](#)). The items of the survey were ordered such that items measuring each construct were grouped. The responses were recorded using a 5-point Likert scale (ranging from 1=totally disagree to 5=totally agree) in which the higher score values indicated a higher level of a construct and a higher score of the outcome (BI) indicated greater intention to use the AI chatbot.

In the third part of the questionnaire, each item in the scale was sourced from relevant literature related to new technology

acceptance research. The main modifications to the original instrument were made to fit the context of an AI chatbot used for medical students, such as changing the word "system" to "AI Chatbot." The items that assessed PE, EE, SI, FC, and BI were adopted from the original instrument developed by Venkatesh et al [11]. The original survey was validated and applied to previous studies based on the UTAUT model [16,23,24]. The items that assessed PR and RB were adopted from the validated questionnaire developed by Zhai et al [16]. The reliability of the items' scales was tested by Cronbach α coefficient analysis. The results of Cronbach α are considered to have acceptable reliability ([Table 1](#)), as the generally accepted rule is that α values of 0.6 - 0.7 indicate an acceptable level of reliability, and 0.8 or greater is a very good level [25].

After we developed the questionnaire and before implementing the survey, we conducted a consensus panel of 5 experts to review the questionnaire and ensure clarity of the survey and content validity. We then conducted a pilot study of 20 students to clarify phrasing and eliminate items that were not identifiable in the questionnaire.

Table . The model constructs and its measuring scale items.

Constructs and items	Cronbach α
<p>PE^a</p> <p>PE 1: I would find AI^b Chatbot useful in my study.</p> <p>PE 2: Using AI Chatbot will enable me to accomplish tasks more quickly.</p> <p>PE 3: Using AI Chatbot will increase my productivity.</p> <p>PE 4: If I use AI Chatbot, I will increase my chances of getting better grades.</p>	0.920
<p>EE^c</p> <p>EE 1: My interaction with AI Chatbot will be clear and understandable.</p> <p>EE 2: It would be easy for me to become skillful at using AI Chatbot.</p> <p>EE 3: I would find AI Chatbot easy to use.</p> <p>EE 4: Learning to operate AI Chatbot is easy for me.</p>	0.904
<p>SI^d</p> <p>SI 1: People who influence my behavior (eg, classmates, colleagues, and friends) think that I should use AI Chatbot.</p> <p>SI 2: People who are important to me (eg, department heads, supervisors, and hospital leaders) think that I should use AI Chatbot.</p> <p>SI 3: The senior health administration has been helpful in the use of AI Chatbot.</p> <p>SI 4: In general, my university and hospital have supported the use of AI Chatbot.</p>	0.871
<p>FC^e</p> <p>FC 1: I have the resources necessary to use AI Chatbot.</p> <p>FC 2: I have the knowledge necessary to use AI Chatbot.</p> <p>FC 3: AI Chatbot is not compatible with other systems I use.</p> <p>FC 4: A specific person (or group) is available for assistance with the AI Chatbot difficulties.</p>	0.756
<p>PR^f</p> <p>PR 1: There is a possibility of malfunction and performance failure, so the AI Chatbot fails to deliver accurate information and could mislead my study.</p> <p>PR 2: There is a probability that I need more time to fix the errors and nuances of the AI Chatbot.</p> <p>PR 3: I am worried that AI chatbots will reveal my private information.</p>	0.643
<p>RB^g</p>	0.879

Constructs and items	Cronbach α
<p>PI^h</p> <p>RB 1: I do not want AI chatbots to change the way I study or work because the new AI tools are unfamiliar to me.</p> <p>RB 2: I do not want to use the AI chatbots because of past experiences; these new high-tech products always fall flat during practical application.</p> <p>RB 3: I do not want to use the AI chatbots because there is a possibility of losing my job, as artificial intelligence–assisted technology may do my work better than me.</p> <p>PI 1: If I heard about a new information technology, I would look for ways to experiment with it.</p> <p>PI 2: Among my peers, I am usually the first to try out new information technologies.</p> <p>PI 3: In general, I am hesitant to try out new information technologies.</p> <p>PI 4: I like to experiment with new information technologies.</p>	0.634
<p>BIⁱ</p> <p>BI 1: I intend to use the AI chatbots in the next 2 months.</p> <p>BI 2: I predict I would use the AI chatbots in the next 2 months.</p> <p>BI 3: I plan to use the AI chatbots in the next 2 months.</p>	0.946

^aPE: performance expectancy.

^bAI: artificial intelligence.

^cEE: effort expectancy.

^dSI: social influence.

^eFC: facilitating conditions.

^fPR: perceived risk.

^gRB: resistance bias.

^hPI: personal innovativeness.

ⁱBI: behavioral intention.

Data Analysis

The statistical software SPSS 25.0 (IBM Corp) was used to calculate the Cronbach α coefficient. Data analysis was carried out using descriptive statistics, such as means, frequencies, and percentages, as well as inferential statistics, such as multiple linear regression, to explore the relationships between the dependent variable (BI) and the set of predictors (PE, EE, SI, FC, PR, RB, and PI). The α level was set at .05 for all analyses. Data analysis was performed using Stata (version 17.0; StataCorp LLC).

Ethical Considerations

Ethical approval was obtained from the Ethics Committee on Biomedical Research, West China Hospital of Sichuan University (approval number: 2023 - 834). The research purpose; methods; and participants' rights, including that they

could cease participation at any point without penalty, were explained. All the participants read and signed the electronic informed consent before completing the questionnaire. The detailed information on the informed consent form is given in the questionnaire in [Multimedia Appendix 1](#). This survey was anonymous and voluntary. To promote survey completion and ensure an adequate response rate, postsurvey gifts were randomly raffled as an incentive.

Results

Participants' Information

A total of 693 participants were from 57 universities covering 21 provinces or municipalities. The sample distribution is shown in [Figure 1](#). The demographic characteristics of the participants are shown in [Table 2](#). The majority of participants (251/693,

63.78%) were female, while 36.22% (442/693) were male. The average age was 22.6 (SD 5.2) years, and more than half of the participants were in the 20 - to 24-year age range (413/693, 59.60%). The majority (543/693, 78.35%) were undergraduate

students. The mean self-reported academic score was 73.7 (SD 14.8), and the most common self-reported score range was 80 - 89 (247/693, 35.64%).

^a“Hukou type” refers to the classification within the Chinese household registration system. This system classifies individuals based on their place of household registration and typically includes 2 main categories: Urban Hukou and Rural Hukou.

^b“Academic scores” for medical students refer to the grades or marks they receive in various courses throughout their medical education in college or university. Academic scores are important indicators of a student’s academic performance, reflecting his or her learning effectiveness.

Participants’ Perception of AI Chatbots

Table 3 presents the participants’ cognition, attitudes, usage behavior, and willingness to pay for AI chatbots. While only 24.68% (171/693) of participants reported being fairly familiar with AI chatbots and 4.47% (31/693) were very familiar with AI chatbots, 59.88% (415/693) agreed or strongly agreed with using them for study or work purposes. Of the 28.72% (199/693) who have used AI chatbots for studying, mainly ChatGPT (129/693, 18.61%), 50.25% (100/199) reported occasional usage as needed. Among nonusers, 55.06% (272/494) expressed willingness to learn AI chatbot usage, with the main reasons for unwillingness being no need (15/29, 51.72%) and no interest

(15/29, 51.72%). In addition, 36.45% (242/664) preferred to use AI chatbots without charge.

Table 4 summarizes the participants’ purposes for using AI chatbots and their perceived advantages and disadvantages. The primary purposes were quickly obtaining medical information and knowledge (631/693, 91.05%) and increasing learning efficiency (594/693, 85.71%). Perceived advantages included effectively helping medical students learn (631/693, 91.05%) and providing fast and accurate medical information (624/693, 90.04%). However, data privacy breaches (635/693, 91.63%) and risks of misdiagnosis or underdiagnosis (619/693, 89.32%) were predominant concerns.

Table . Participants' cognition, attitude, usage behavior, and willingness to pay for AI chatbots (exchange rate: US \$1=¥7.22, July 9, 2023).

There may be risks of data privacy breaches.	635 (91.63)	406 (58.59)
There may be risks of misdiagnosis or underdiagnosis.	619 (89.32)	137 (19.77)
They may potentially lead to the degradation or unemployment of medical professionals.	570 (82.25)	87 (12.55)
They may potentially reduce the personal touch and humanization of health care services.	559 (80.66)	58 (8.37)
Others ^e	—	—

^aThe questions in this part of the survey were ranking questions. "Total choices" provide an overall measure of how often an option was selected. "First choice" represents the preference for an option as the most preferred or prioritized choice among respondents.

^bResponse examples: "Make code modifications," "Polishing the content of the documents," "Complete some unimportant homework," and "Online operation training."

^cNot applicable.

^dResponse examples: "Reduce feelings of loneliness," "Regulate emotions of healthcare workers," "Provide arguments for the group work," and "Provide timely and patient answers."

^eResponse examples: "Provide misleading information, such as fabricating references," "Patients may have doubts and mistrust towards these technological products," "AI currently cannot reflect the artistic elements required in medicine," and "It may not be able to provide the desired, high-quality answers."

Descriptive Statistics of the UTAUT Constructs

Descriptive statistics (mean [SD]) were reported to explain and describe the UTAUT constructs (Table S1 in [Multimedia Appendix 1](#)). The value of each construct ranges from 1 to 5 (1=strongly disagree, 5=strongly agree). As shown in [Figure 2](#),

the mean for PE, EE, SI, FC, PR, and PI were higher than 3 and the mean for RB was <3. The highest score was PE at 3.66, followed by EE at 3.56. The mean of BI was 3.26, which shows a higher level of intention to use AI chatbots among Chinese medical students.

Figure 2. Descriptive statistics of the Unified Theory of Acceptance and Use of Technology constructs. BI: behavioral intention; EE: effort expectancy; FC: facilitating conditions; PE: performance expectancy; PI: personal innovativeness; PR: perceived risk; RB: resistance bias; SI: social influence.

Determinant Factors of Intention to Use AI Chatbots

A multiple linear regression analysis was conducted to identify factors influencing medical students' intentions to use AI chatbots ([Table 5](#)). Utilization behavior ($\beta=.27$; $P<.001$), SI ($\beta=.32$; $P<.001$), FC ($\beta=.29$; $P<.001$), PR ($\beta=.27$; $P<.001$), and

PI ($\beta=.35$; $P<.001$) were significantly positively associated with BI. PI had the largest positive regression coefficient ($\beta=.35$) compared with the other significant variables. PE ($\beta=.09$; $P=.12$), EE ($\beta=.03$; $P=.60$), and RB ($\beta=-0.04$; $P=.32$) did not significantly affect BI.

Table . Analysis of influence factors of medical students' behavioral intention to use artificial intelligence chatbots.^a

Variables	Coefficient	SE	<i>t</i>	<i>P</i> value	95% CI
Age (years)	0.01	0.01	1.89	.06	0.00 to 0.02
Gender	-0.04	0.05	-0.83	.41	-0.15 to 0.06
Hukou type	0.10	0.05	1.93	.06	0.00 to 0.20
Education level	-0.02	0.05	-0.46	.65	-0.12 to 0.08
Academic scores	0.00	0.00	0.51	.61	0.00 to 0.00
Cognition ^b	0.01	0.04	0.27	.79	-0.06 to 0.08
Attitude ^c	0.03	0.04	0.89	.37	-0.04 to 0.11
Utilization behavior ^d	0.27	0.07	4.19	<.001	0.15 to 0.40
Performance expectancy	0.09	0.06	1.56	.12	-0.02 to 0.21
Effort expectancy	0.03	0.06	0.53	.60	-0.08 to 0.14
Social influence	0.32	0.05	6.32	<.001	0.22 to 0.42
Facilitating conditions	0.29	0.07	4.13	<.001	0.15 to 0.42
Perceived risk	0.27	0.05	5.33	<.001	0.17 to 0.37
Resistance bias	-0.04	0.04	-0.99	.32	-0.12 to 0.04
Personal innovativeness	0.35	0.07	5.33	<.001	0.22 to 0.48
Constant term	-1.98	0.31	-6.31	<.001	-2.60 to -1.36

^aModel parameters: Probability>*F*=0, *R*²=0.518, adjusted *R*²=0.507, and Root Mean Square Error=0.651. *df*_Total=692, *df*_Model=15, *df*_Residual=677. The results of multicollinearity diagnostics showed that there is no multicollinearity among all independent variables in the multiple linear regression (Table S2 in [Multimedia Appendix 1](#)).

^bThe variable "Cognition" is measured by "Do you know what an AI chatbot is?"

^cThe variable "Attitude" is measured by "Do you agree with the use of AI chatbot applications for study or work?"

^dThe variable "Utilization behavior" is measured by "Have you used AI chatbots in your study?"

Discussion

Principal Findings

In this study, we examined the perceptions of Chinese medical students toward Natural Language Processing-based AI chatbots and investigated the factors that may influence their intention to use such technology based on the UTAUT model. This research yielded several key findings. First, the medical students demonstrated positive perceptions and expressed a high BI to use AI chatbots. Second, among the factors considered, SI and FC emerged as more influential in the adoption of AI chatbots among medical students than PE and EE. However, PE and EE were not found to have a significant relationship with BI. Third, PR and PI positively influenced BI, while RB did not show a significant association with BI.

This study revealed that although most medical students have limited knowledge about AI chatbots at an early time, they hold positive perceptions and demonstrate a strong intention to use this innovative technology. The overall sample displayed high BIs, with a mean score of 3.26 out of 5.00. Furthermore, 81.63% (1697/2079) of participants rated their intention as 3 or higher, indicating their plans to use the technology within the next 2 months. These findings align with previous research indicating that while medical students may lack knowledge about AI and

its applications, they maintain a favorable view of AI in the medical field and are willing to adopt it [26,27]. The majority of participants believe that AI chatbots have the potential to enhance their study or work performance, improve efficiency, and provide fast and accurate medical information, among other benefits. However, limited availability and coverage of AI chatbots in China have resulted in less than one-third of participants actually using these tools and only a few using them on a daily basis. This indicates a gap between intention to use and actual adoption. Practical barriers, such as inadequate technical infrastructure and lack of support, may hinder the actual implementation and use of AI chatbots. In addition, our regression analysis revealed that utilization behavior significantly influences medical students' intentions to use AI chatbots. User experience may impact their perceptions of the technology from multiple aspects, thereby affecting their usage intentions.

This study found that SI and FC have a stronger impact on BI than PE and EE. This finding aligns with research examining the perceptions of Chinese radiation oncologists toward adopting AI-assisted contouring technology [16]. However, it contradicts some prior studies that have established a positive and significant relationship between PE and EE with students' BI to use AI-assisted learning environments [28] or chatbots [29]. This suggests that factors such as PE and EE may be less critical

for the population in this study, although they rated PE and EE higher than other dimensions. It is possible that as medical students are still in training, they rely more on the experiences of their peers and the infrastructure provided by their educational institution to guide their technology use. Thus, demonstrating adoption and endorsement from fellow students, professors, and the academic medical system may be more influential in persuading them to use AI chatbots than emphasizing use and usability. Ensuring accessibility within the educational context appears to shape students' willingness to use AI chatbots more than their individual perceptions of performance and efficiency.

Interestingly, this study found that PR and PI positively influenced the intentions of medical students to use AI chatbots, while RB was not found to be a significant factor. This suggests that concerns regarding the risks associated with adopting AI chatbots were outweighed by the students' openness to embracing new technologies. Those with a greater inclination toward innovation recognized the potential benefits despite the potential risks involved. This finding aligns with previous research indicating that perceived usefulness can override PR when it comes to determining acceptance of technology [18]. It also reflects a growing understanding that AI systems present both opportunities and risks, necessitating ethical analysis and oversight [30], including privacy breaches and the possibility of misinformation. Notably, we found that PI emerged as a key determinant of user behavior intentions, which is consistent with a similar study [31]. However, RB did not negatively impact intentions, suggesting that medical students may have fewer biases against AI than health care professionals in hospitals who may fear a loss of professional autonomy and challenges in integrating AI into clinical workflows [32]. Encouraging PI while addressing risk concerns through testing and regulation may further bolster the adoption of AI chatbots.

Implications for Practice

Based on our findings, we recommend the following specific strategies for educational institutions and AI chatbot developers to enhance the adoption rate among medical students. First, medical schools and health care organizations should prioritize efforts to improve FC and leverage SI to drive the adoption of AI chatbots, rather than solely focusing on performance benefits. Providing integrated access, training, and IT support and sharing peer usage examples can help translate positive intentions into actual usage behaviors. In addition, demonstrating value through pilot studies and addressing valid risk concerns will promote responsible and open adoption of the technology. Targeted training in AI competencies can further equip students to become champions of safe and effective adoption. The key lies in creating optimal environments and processes to enable the proficient use of AI systems such as chatbots as students transition into practice.

Strengths and Limitations

This study was the first to use the UTAUT theoretical framework to analyze medical students' intention to use AI

chatbots. It possesses several strengths, including the robust technology adoption model used, the focus on an important user population, and the identification of key variables influencing intentions. However, there are some limitations that need to be addressed in future studies. First, the unbalanced research sample primarily from Sichuan province may limit the generalizability of the findings, potentially overrepresenting specific regional experiences. Although we distributed the survey widely, future studies should use stratified sampling for better regional representation. Second, the cross-sectional design offers only a snapshot of adoption, which may change over time as participants accumulate knowledge and experience. Future research should consider longitudinal designs to track these changes. Third, it is crucial to acknowledge that the field of AI chatbots is rapidly evolving, and our findings capture perceptions and attitudes at a specific point in time. As AI chatbot capabilities continue to advance, the external validity of our findings may need to be reevaluated.

Future studies with larger samples using longitudinal methods would enhance our understanding of actual perceptions and usage patterns over time. For example, a longitudinal study could follow a cohort of medical students from their entry into medical school until graduation, periodically assessing their perceptions, intentions, and actual usage of AI chatbots. This longitudinal approach would capture how their adoption and experiences with AI chatbots evolve as they progress through their medical education and gain more exposure to clinical settings. Furthermore, mixed methods designs, combining quantitative surveys with qualitative interviews or focus groups, could provide more in-depth insights into specific barriers, challenges, and facilitators influencing AI chatbot adoption among medical students. Overall, this study lays the foundation for a wide range of future research, which can deepen knowledge and generate evidence to guide the implementation of AI in education and health care.

Conclusions

This study offers valuable insights into medical students' utilization of, perceptions on, and intention to use AI chatbots in health care. The results indicate that these medical students have positive perceptions and strong intentions to use chatbots, primarily influenced by SI and FC rather than PE and EE. However, despite these intentions, there remains a gap between intention and actual adoption, signaling the need for strategies that improve access, training, and support and provide peer usage examples to enhance the realization of the potential benefits of chatbots. While concerns about risks exist, the students' general openness to innovation suggests that the integration of AI with proper oversight is well received. As future health care professionals, students serve as early adopters who can shape wider acceptance if barriers to adoption are actively addressed. This research provides a foundation for understanding the technology needs and motivations of this important user population in order to guide the successful implementation of AI.

Acknowledgments

We thank all the respondents who participated in the interviews and survey, as well as the ones who assisted with participant recruitment on the web. This work was supported by China Postdoctoral Science Foundation (grant 2023M732419), National Natural Science Foundation of China (grant 72374146), and Sichuan University Healthy City Development Research Center (grant 2022ZC003).

Abstract

Background: Competence-based medical education requires robust data to link competence with clinical experiences. The SARS-CoV-2 (COVID-19) pandemic abruptly altered the standard trajectory of clinical exposure in medical training programs. Residency program directors were tasked with identifying and addressing the resultant gaps in each trainee's experiences using existing tools.

Objective: This study aims to demonstrate a feasible and efficient method to capture electronic health record (EHR) data that measure the volume and variety of pediatric resident clinical experiences from a continuity clinic; generate individual-, class-, and graduate-level benchmark data; and create a visualization for learners to quickly identify gaps in clinical experiences.

Methods: This pilot was conducted in a large, urban pediatric residency program from 2016 to 2022. Through consensus, 5 pediatric faculty identified diagnostic groups that pediatric residents should see to be competent in outpatient pediatrics. Information technology consultants used *International Classification of Diseases, Tenth Revision (ICD-10)* codes corresponding with each diagnostic group to extract EHR patient encounter data as an indicator of exposure to the specific diagnosis. The frequency (volume) and diagnosis types (variety) seen by active residents (classes of 2020 - 2022) were compared with class and graduated resident (classes of 2016 - 2019) averages. These data were converted to percentages and translated to a radar chart visualization for residents to quickly compare their current clinical experiences with peers and graduates. Residents were surveyed on the use of these data and the visualization to identify training gaps.

Results: Patient encounter data about clinical experiences for 102 residents (N=52 graduates) were extracted. Active residents (n=50) received data reports with radar graphs biannually: 3 for the classes of 2020 and 2021 and 2 for the class of 2022. Radar charts distinctly demonstrated gaps in diagnoses exposure compared with classmates and graduates. Residents found the visualization useful in setting clinical and learning goals.

Conclusions: This pilot describes an innovative method of capturing and presenting data about resident clinical experiences, compared with peer and graduate benchmarks, to identify learning gaps that may result from disruptions or modifications in medical training. This methodology can be aggregated across specialties and institutions and potentially inform competence-based medical education.

Introduction

Medical education is traditionally time-based, which presumes that learners will meet professional standards in a predetermined period of time, whereas competence-based medical education proposes an outcomes-based approach framed by competencies [1]. This latter approach requires robust data to measure

outcomes and link them to competence. One such data set is the number and variety of clinical diagnoses that learners see, grounded in Kolb's framework that emphasizes hands-on experiences and reflection as a basis for experiential learning [2].

Unlike surgical specialties requiring minimum case numbers for procedural competence, nonprocedural specialties do not

endorse minimum numbers of diagnoses trainees should see to be considered competent. Literature exists on this topic across medical specialties [3-9]; however, the methods used to collect volume and variety of clinical cases are frequently incomplete, limiting their use. The variability of literature on this topic may stem from the challenge of capturing these patient experiences in a straightforward, accurate, and abstractable form.

The electronic health record (EHR) is useful for collecting patient encounters for quality improvement and business analytics. It has been incorporated in continuing professional development for practicing physicians to drive practice change [10]. Graduate medical education has also used EHR data to measure training outcomes. In 2023, Lees et al [3] performed a systematic review of the published uses of EHR data to measure competencies in medical trainees. The most common study theme identified was “trainee condition experience,” or the trainees’ involvement in patients with specific medical conditions. While study authors commonly mapped raw EHR data to diagnostic groupings and compared them with national standards or in-training examinations to identify gaps in training, there were limitations in utilization of these data. For example, studies documenting residents’ exposure to patient experiences, such as reporting the volume of diagnoses seen, often excluded important variables such as variety of diagnoses. Others examined data in aggregate rather than individualized data as is needed to link exposure and resident competence [11-16]. There are additional studies that compared individual resident clinical exposures with peer averages using the EHR and most commonly displayed these data using dashboards; however, they did not include benchmark data which provide a necessary framework to analyze the information [3,17-19].

Since 2020, the SARS-CoV-2 (COVID-19) pandemic has provided an opportunity to examine variability in diagnoses exposure for residents and to extrapolate its impact on their education. From June 2020 to February 2021, Yarahuan et al [20] noted a significant decrease in notes authored by pediatric interns on common inpatient diagnoses, on both respiratory and nonrespiratory conditions, compared with the prepandemic group. This variability resulted from the shifting prevalence of seasonal diagnoses and altered patient exposure due to practices such as “platooning” trainees for workforce preservation, shifting trainees from ambulatory to inpatient settings, and implementing telehealth [20-24]. In response, medical education leaders and learners were tasked with identifying gaps in clinical exposure compared with prepandemic standards and creating individualized learning plans; this needs assessment, however, was largely based on recall of clinical experiences in training rather than objective data [22,25,26].

In 2019, Sebok-Syer et al [27] analyzed resident and faculty feedback about the potential use of EHR data to assess gaps

and inform trainees’ learning plans. The authors found that while these data may be valuable to support formative assessment practices, the data, in isolation, would portray an incomplete picture of the trainee and require context for interpretation. Meaningful analysis and presentation of EHR data are necessary in order to explore how volume and variety of clinical experiences may objectively identify gaps and inform competence.

The purpose of this pilot was to establish a process in our residency to extract meaningful EHR data for measuring clinical exposure and address associated gaps in the literature specifically to (1) develop a feasible and efficient method to capture EHR data that measure patient experiences of individual residents; (2) offer context to these data by comparing individual resident metrics to classmates and aggregated graduate residents’ data; and (3) create a visualization that provides residents and program directors with a snapshot of the volume and variety of trainees’ clinical experiences to allow quick identification of training gaps to inform focused learning plans.

Methods

This pilot study was conducted from 2019 to 2021 in a large, urban, pediatric residency program with multiple institutional sites. To assess feasibility, we focused on ambulatory diagnoses at 1 pediatric continuity clinic site. We chose this site since it had a larger volume of general pediatric patients with fewer complex medical needs than the other continuity clinics. Subjects were limited to pediatric residents and excluded rotating residents and students as we were seeking longitudinal clinical experiences and these latter 2 groups completed only 1 block rotation in the clinic. The resident patient panels at this clinic site are a combination of patients assigned by schedulers and those recruited by residents from other settings within the health care system, such as the nursery or inpatient unit. The residents generally stay with the same faculty preceptor for 3 years and have increasing levels of autonomy during the patient visit including billing and coding; however, billing and coding are always verified by the preceptor prior to closing the encounter.

This was a retrospective analysis of EPIC (Epic Systems) EHR metadata of ambulatory clinic notes authored by pediatric residents at this clinic site from 2013 to 2020. This was true EHR metadata attached to the note, not extracted from administrative claims data. Resident data from the graduating classes of 2016, 2017, 2018, and 2019 were used as the graduation benchmarks. Data were extracted up to April 2020, representing nearly 3 years of data from the class of 2020, 2 years from the class of 2021, and 1 year from the class of 2022 (Table 1).

Table . Resident electronic health record data.

Class of	Count, n	Resident category at the time of study	Dates of data extraction	Data used for	Report distribution dates
2016	8	Graduated	7/2013-6/2016	Graduate benchmark	N/A ^a
2017	15	Graduated	7/2014-6/2017	Graduate benchmark	N/A
2018	18	Graduated	7/2015-6/2018	Graduate benchmark	N/A
2019	11	Graduated	7/2016-6/2019	Graduate benchmark for 9/2019 and 4/2020 reports	N/A
2020	18	Active	7/2017-6/2020	Individual reports and 2020 class benchmarks	4/2019, 9/2019, 4/2020

Ethical Considerations

The Phoenix Children's Hospital institutional review board has determined that this project involves quality improvement and does not meet the definition of research; therefore, the approval of the institutional review board was not required and this study was deemed exempt.

Key Stakeholders

Project stakeholders included the residency program director, residency program coordinator, and ambulatory clinic faculty preceptors. For information technology (IT) support, we engaged data analysts who recognized that graduate medical education was connected to the hospital business model and therefore supported this opportunity for improved billing and coding through EHR data analysis. Our pediatric residents were also vital participants in this pilot and were aware of its planning and rollout.

Diagnoses Set

Five general pediatricians from 3 clinic sites determined the key diagnostic groups that pediatric residents should see to be competent for independent outpatient practice. The group created a shared mental model with inclusion and exclusion criteria. For example, high-volume diagnoses (eg, pediatric well-checks) and low-volume, yet important diagnoses (eg, gait abnormality) were included. Common, self-limited conditions (eg, upper respiratory infections) were intentionally excluded presuming that residents in our busy clinics receive adequate exposure of these during residency, and the addition of these common diagnoses in a data report may distract from the more actionable data. The final list was generated through several rounds of review and consensus. Each diagnostic group was converted to *International Classification of Diseases, Tenth Revision (ICD-10)* codes (Table 2).

Table . Diagnostic groups for clinical experiences of pediatric residents and associated *ICD-10^a* codes.

Group name	<i>ICD-10</i> codes	Notes (inclusions)

EHR Data Extraction

The project data set, including resident data, patient data, and encounter data, was abstracted from the EHR. To ensure accuracy and completeness of the data, we performed an iterative process with our IT consultants, starting with smaller subsets of data with 1 resident, to ensure that each piece of data pulled was relevant to the pilot before expanding to larger subsets and more residents. Variety was determined through *ICD-10* codes for all visit diagnoses per encounter and volume was measured as the number of unique visits. When residents authored an encounter note, they were attributed to that patient and his or her associated diagnoses.

A flat file of the EHR data was imported to Microsoft Excel and analyzed using the pivot table function. Pivot tables were created to enumerate the volume of patients for each diagnosis by individual resident. Individual resident data were aggregated to the respective class level of postgraduate year (PGY1, PGY2,

or graduated) to calculate average volumes. An Excel worksheet was created for each individual resident to summarize the resident's volume (column) and variety (rows) of clinical experiences. For comparison, the class and graduated average volumes were appended as columns. These worksheet data were used to generate the visualizations.

Visualization and Data Report

To facilitate the assessment of training gaps, we used Microsoft Excel to translate tabular data into a radar chart (or spider graph) visualization, which is a 2D graphical method of illustrating multiple quantitative variables on axes (eg, diagnostic categories) with the same starting point. Since these data have vastly different scales on the same chart, the data were converted from raw numbers into percentages using the number of patient encounters seen for each diagnostic category (numerator) divided by the average number seen by graduated residents (denominator). The radar chart was rendered to illustrate the percentage of clinical experiences per diagnostic category for

the individual resident and the class average compared with graduated residents (benchmark) as the maximal total area. Not only was this an ideal prototype for this pilot, our residents and faculty were already familiar with using radar graphs for milestone data, in which individual resident progress across a range of competencies is compared with classmates and graduates. We did trial other visualizations, including a dot plot with error bars, but found that these did not give an accurate picture because not every diagnosis was normalized at the same value.

Two comparative radar chart visualizations were created: (1) the percent volume of clinical experiences by the individual resident versus the class average and graduated residents (for individual resident review), and (2) the percent volume of clinical experiences between the aggregated classes (PGY1 and PGY2) and graduated residents (for program leadership review).

Reports with visualizations were distributed approximately every 6 months to align with semiannual reviews with clinic preceptors. Prior to distribution, residents and preceptors were educated on using the reports to stimulate discussion on learning goals.

To enable ongoing data extraction and reports, we identified 3 vital team members: the IT champion to initiate the data extraction into an Excel spreadsheet, the residency program coordinator to provide an updated list of residents at the start of each academic year and transform the raw data into individual reports with radar graph visualizations, and the clinic champion to distribute the reports and educate faculty and residents. The process was semiautomated as once the query was set up, it could be run the same way semiannually to produce a spreadsheet of every patient visit by every resident with benchmark averages calculated.

Resident Postimplementation Surveys

Residents from the classes of 2021 and 2022 were surveyed on their individual data report readability and specific utilization for setting clinical and coding goals. The survey was homegrown by authors without validity evidence. It contained 6 multiple-choice and 2 open-ended questions and was delivered via email with instructions for completion. Results were collected anonymously. Multiple-choice questions were analyzed using frequency of responses and open-ended questions were grossly interpreted for themes and representative quotes.

Results

We extracted information about clinical experiences for 102 residents including 52 graduated residents for the graduate benchmark and 50 active residents for individual reports and class benchmarks (Table 1). Residents from the classes of 2020 and 2021 received 3 data reports and those from the class of 2022 received 2.

Table 3 displays data for an individual resident alongside the class and graduated residents' averages to enable residents to follow their progress against internal benchmarks. Figure 1 uses data from Table 3 to visualize these data in a radar chart. This visualization method makes deficient areas immediately apparent to the resident and identifies which experiences must be intentionally pursued. The second semiannual report was created in Spring of the academic year when equity in clinical rotation experiences is assumed within a class and peer averages are more accurate.

The change in the class-level volumes versus graduate class volumes (Table 4) demonstrated that average volume for each diagnosis group increased progressively with each year. The visualization of this aggregated information (Figure 2) can be used by program leaders for tracking general trends in diagnoses exposure year-to-year.

Table . Sample table with average numbers of patients seen with each diagnosis in continuity clinic, by a single postgraduate year 2 (PGY2) resident, compared with the PGY2 class average and with the average numbers seen by recently graduated residents in this program.

^bPGY2: postgraduate year 2.

^cADHD: attention-deficit/hyperactivity disorders.

Figure 2. Class averages benchmarked against graduated residents. ADHD: attention-deficit/hyperactivity disorders; FTT: failure to thrive; GU: genitourinary; PGY1: postgraduate year 1; PGY2: postgraduate year 2; UTI: urinary tract infection.

We surveyed graduating classes of 2021 and 2022 following implementation of this project and report distribution; 53% (17/32) of the residents responded. Of respondents, 69% (11/16) reviewed their reports with their clinic preceptors, 44% (7/16) used their reports to make clinical goals, such as “see more adolescent patients” and “increase comfort dealing with vaccine hesitancy,” and 38% (6/16) used the reports to make coding goals, such as “include Z-codes regarding counseling” and “bill more on top of well-checks.” Gross interpretation of open-ended comments showed that residents found the radar chart easy to interpret and to identify in which areas they have had less exposure than their classmates.

Discussion

Principal Findings

Our pilot study demonstrated an innovative method to collaborate with IT and leverage EHR data to measure and display the volume and variety of clinical experiences, relative to peers and previous program graduates, in a pediatric residency program continuity clinic. We presented the data in a functional manner to pinpoint gaps that may result from disruptive events such as the SARS-CoV-2 pandemic. For example, in [Figure 1](#), this resident may recognize that he or she has not seen nor coded patients with young women’s health concerns, specific genetic or congenital disorders, or vaccine delay or refusal. He or she

could, therefore, intentionally choose an adolescent or genetics elective as well as ensure that when seeing patients for well-checks, any additional diagnoses, such as vaccine refusal, are coded. While radar charts are not novel for representing competence in medical education, our visualization has not been previously used for this purpose [28,29]. Utilization of reports for this type of goal setting does require preceptor education and comfort with the tool, which can be achieved through faculty development and consistent use.

We believe that this methodology can be used for programs of any specialty, size, or setting. This list of diagnoses can be easily created in internal medicine or dermatology or in subspecialties such as pediatric cardiology. While the amount of resident data used in class or graduated benchmarks may be decreased in smaller-sized programs, an individual resident can still use the data to evaluate progress and set goals. Community settings may have less breadth of diagnoses than academic settings, but this substantiates the value of this innovation; if these training programs were able to review similar data from larger programs, they may be able to examine trends and program gaps that require supplementary clinical or nonclinical experiences (eg, focused didactics, external specialty rotations, or simulation). Notably, while these reports are not intended to inform summative evaluation of resident performance or any high-stakes training decisions, the data provide objectivity and specificity in resident experiences that may enrich the feedback between preceptor and resident.

The ability to access objective data on the clinical experiences of current residents compared with prior years is indispensable for program-wide or individual events that disrupt patient exposure during training, such as rotation-site closures or extended leaves of absence. Obtaining these data is feasible and can be automated with each new class. Moreover, this process may be modified to accommodate the changing landscape of medicine. New diagnoses, such as “exposure to COVID-19,” can be added to the EHR reports. Additional metadata, such as number of telehealth visits or time-to-note-completion, can also be extracted to create a comprehensive individualized “report card” of metrics, as described by Sebok-Syer et al [30], to enhance resident feedback and assessment. For these metrics, data from periodic reports (eg, semiannually), rather than from real-time dashboards, appear to be more beneficial for the recipient to set learning goals, as these data represent trends in experiences or practices over time. Furthermore, peer benchmarks are more reliable in the periodic reports, as residents in the same class will generally complete similar clinical rotations as the academic year progresses.

Limitations

One limitation in our methodology is its dependence on accurate and complete coding of all diagnoses addressed at a patient encounter, which is often performed by residents in the clinic setting. Some diagnoses for which only discussion was required (eg, vaccine refusal) may be underrepresented and lead to gaps as noted in Figure 1. As trainees become familiar with the data, they can differentiate a lack of coding from lack of clinical exposure. In addition, a true lack of clinical exposure may be seen with important but uncommon diagnoses, and it may be

harder to estimate a consistent goal number of patients to seek with these diagnoses. This may lead residents to presume that they will be less successful in managing these diagnoses should they encounter them in the future. In these cases, we rely on our faculty preceptors, when reviewing the reports with residents, to offer perspective and strategies to gain knowledge in advance or “in the moment” when encountering rare diagnoses.

Since this was a pilot study to determine feasibility, we opted to use small-group consensus to determine the diagnostic categories rather than established resources, such as certifying board examination content specifications. We also acknowledge that many diagnostic categories identified, such as urinary tract infection and asthma, are seen in other settings where the residents rotate (eg, emergency department and urgent care) thus offering an incomplete number of total exposures. In addition, there are common diagnoses, such as pain management and mental health disorders, which are not present on the list. We made these decisions as this was a pilot study limited to a single setting with a finite list of diagnoses to demonstrate proof of concept. We anticipate that expanding the list of diagnoses, designating specific categories by age groups, and implementing the process across other clinical settings would offer more representative data.

Another limitation is that the resident survey measuring acceptability and utilization of the reports was not a validated tool and was sent 1 year after the last report distribution, likely leading to recall bias and a lower rate of return. A standardized usability survey distributed in a timelier manner would have strengthened these results. The authors also recognize that while we found our business analysts, rather than clinical informaticians, to be our IT champions, this is institution specific. We encourage readers to explore all potential partnerships between IT and graduate medical education if embarking on a similar project. Finally, despite efforts to automate the process to semiannually extract data for individual resident reports, the project stalled after our 3 main team members, the residency coordinator and IT and faculty champions, left the institution within a short period of time. We were, therefore, unable to study the outcomes of learning goals set by residents and the distribution and utilization of reports for future classes. We learned that expanding teams to allow for cross-training of tasks, proper timing and transitions of responsibilities, and creating standardized operating procedures are essential for sustainability.

Next Steps

Within our residency program, we have identified new champions to reinvigorate this process for our clinics and expand to the inpatient and emergency department settings using a set of diagnoses unique for each location. With additional data sets across varied clinical settings, we anticipate that the trends in volume and variety will be more reflective of the complete resident experience. The authors understand that comparing data internally within a program is not the ideal “gold standard” to measure competence when compared with more standardized benchmarks. Moving forward, this method can be shared across specialties and institutions to develop national benchmarks on

the average volume and variety of patient encounters trainees see and provide a measure for programs to compare their experiences with others and identify gaps in training. Once these benchmarks are compared with other measures of competence, such as milestone assessment ratings, certifying examination scores, and postgraduate performance, we can better inform competence-based medical education and fill the gap in the literature on this topic.

Conclusions

Medical education requires robust data to measure outcomes but gathering data about clinical encounters and making them meaningful can be challenging. This pilot describes a feasible method of capturing resident clinical experiences from the EHR, setting internal benchmarks using class and graduated residents' averages, and creating a radar chart visualization that allows learners to quickly identify gaps in their training.

Abstract

Background: Interoperability between health information systems is a fundamental requirement to guarantee the continuity of health care for the population. The Fast Healthcare Interoperability Resource (FHIR) is the standard that enables the design and development of interoperable systems with broad adoption worldwide. However, FHIR training curriculums need an easily administered web-based self-learning platform with modules to create scenarios and questions that the learner answers. This paper proposes a system for teaching FHIR that automatically evaluates the answers, providing the learner with continuous feedback and progress.

Objective: We are designing and developing a learning management system for creating, applying, deploying, and automatically assessing FHIR web-based courses.

Methods: The system requirements for teaching FHIR were collected through interviews with experts involved in academic and professional FHIR activities (universities and health institutions). The interviews were semistructured, recording and documenting each meeting. In addition, we used an ad hoc instrument to register and analyze all the needs to elicit the requirements. Finally, the information obtained was triangulated with the available evidence. This analysis was carried out with Atlas-ti software. For design purposes, the requirements were divided into functional and nonfunctional. The functional requirements were (1) a test and question manager, (2) an application programming interface (API) to orchestrate components, (3) a test evaluator that automatically evaluates the responses, and (4) a client application for students. Security and usability are essential nonfunctional requirements to design functional and secure interfaces. The software development methodology was based on the traditional spiral model. The end users of the proposed system are (1) the system administrator for all technical aspects of the server, (2) the teacher designing the courses, and (3) the students interested in learning FHIR.

Results: The main result described in this work is Huemul, a learning management system for training on FHIR, which includes the following components: (1) Huemul Admin: a web application to create users, tests, and questions and define scores; (2) Huemul API: module for communication between different software components (FHIR server, client, and engine); (3) Huemul Engine: component for answers evaluation to identify differences and validate the content; and (4) Huemul Client: the web application for users to show the test and questions. Huemul was successfully implemented with 416 students associated with the 10 active courses on the platform. In addition, the teachers have created 60 tests and 695 questions. Overall, the 416 students who completed their courses rated Huemul highly.

Conclusions: Huemul is the first platform that allows the creation of courses, tests, and questions that enable the automatic evaluation and feedback of FHIR operations. Huemul has been implemented in multiple FHIR teaching scenarios for health care professionals. Professionals trained on FHIR with Huemul are leading successful national and international initiatives.

Introduction

A critical requirement for universal access to health is to have interconnected and interoperable health systems that guarantee effective and efficient access to quality data, strategic information, and tools for decision-making and people's well-being [1]. One of the most relevant areas in medical informatics is the interoperability between health information systems. The interoperability eliminates duplication and errors in health data. For this reason, health informatics professionals must be educated about the benefits of interoperable systems. Therefore, strategic education on eHealth and interoperability standards is needed to enable health care professionals to make informed decisions [2].

The Fast Healthcare Interoperability Resource (FHIR) is an interoperability standard used in health information technology, introduced in 2011 by the Standard Developing Organization Health Level Seven International (HL7) [3]. FHIR is based on previous HL7 standards (HL7 versions 2 and 3 and Clinical Document Architecture) and combines their advantages with established modern web technologies such as a Representational State Transfer (REST) architecture [4], application programming interface (API), XML, JSON formats, and authorization tools (Open Authorization). The main idea behind FHIR was to build a set of resources and develop http-based REST APIs to access and use these resources. FHIR uses components called resources to access and perform operations on patient health data at the granular level [5,6].

The adoption of FHIR in health information systems by developers and companies has grown in recent years with multiple applications in various fields [5,7-9]. Thus, FHIR is positioned as an interoperability standard that is easy to understand by nontechnology professionals, with fast learning curves that minimize the development time of applications and new tools. In addition, its technological core is aligned with the latest architectures and web standards that allow the development of open APIs, which facilitates interoperability between systems [10].

Teaching and learning interoperability standards, particularly FHIR, within digital health education programs have been oriented more toward delivering content, presentations, and audiovisual material, considering the solution of practical problems separately [2]. Continuously emerging new technologies (synchronous and asynchronous) promise new and improved experiences for individual users but often bring new challenges [11].

The existing learning management systems (LMSs) are oriented to support cross-cutting activities (forums, chat, and content uploading) with content delivery (videos, documents, and links) [12] but not to evaluate REST operations for accessing and using resources. For the use of APIs, some platforms allow

interaction with FHIR servers, such as Postman (Postman, Inc) or Insomnia (Kong Inc). However, they cannot create content, manage questions, automatically evaluate the response, or provide feedback but only act as an interface between the user and the FHIR server.

The configuration currently used to teach FHIR is to publish the contents in an LMS or website and, for practice, use tools such as Postman [13,14] without the possibility of having automatic feedback and correction of the activities. The results of the practical exercises must be uploaded as a document to the LMS, with written create, read, update, and delete (CRUD) operations and server response in plain text. The teacher must review them, which makes it challenging to implement workshops with many questions for large groups of students. Other websites offer the opportunity to learn FHIR with guides and theoretical content, such as Simplifier (Firely Corporation). It should be noted that Simplifier is a platform for building FHIR implementation guides. It does not claim to be an LMS or to manage courses.

There is currently no LMS for training on FHIR that allows problem-oriented assessment and practice of web-based CRUD operations. Practice is essential to learn FHIR; therefore, a problem-oriented platform is necessary, allowing the creation and administration of practical courses (where a problem is presented) with different levels of complexity and for multiple professionals (clinicians, engineers, and technicians). In addition, each course should be associated with a set of exercises, which the students must answer with CRUD operations (eg, create a patient with the data given in the description or modify the patient information with the new phone number provided). The platform should automatically evaluate these answers, and feedback should be provided to guide each question's achievement (or nonachievement). This would help generate an extensive repository of massive web-based training programs focused on specific problems, where students must practice as requested. The lack of such platforms has motivated the interoperability team of the National Center for Health Information System (CENS) [15] to design a tool capable of automatically teaching and evaluating FHIR.

In this sense, our goal was to develop an API that allows us to integrate and communicate a set of loosely coupled modules that enable teachers to manage FHIR training programs, designing courses, questions, and scenarios. In addition, learners can interact through a web client for self-learning sessions, where the API, in conjunction with an assessment engine, provides feedback for each attempt the learner makes. This undoubtedly streamlines the self-learning process and automates the correction of hundreds of CRUD operations and the submission of learner responses within a context that the platform delivers.

The design and development of a platform called Huemul support the creation of courses associated with multiple questions (which expect a CRUD operation as an answer), automate the evaluation of the responses, and provide automatic feedback to the students in each exercise. We have also created an administrator that allows us to create and manage courses, questions, and users.

Methods

Study Design

The e-learning system requirements for teaching FHIR were collected through interviews with experts involved in academic and professional activities (universities and health institutions). The interviews were semistructured, recording and documenting each meeting. In addition, we used an ad hoc instrument to register and analyze all the needs to elicit the requirements.

The CENS academic committee, formed by 5 senior biomedical informatics researchers (3 engineers: 2 biomedical and 1 informatics and 2 medical doctors), was the initial core of experts consulted. In another focus group, engineers from the interoperability area of CENS, experts in FHIR, were consulted. They presented their requirements and needs to automate both the deployment and evaluation of the different interoperability challenges organized by CENS, where the need to register, quantify, and evaluate the hundreds of requests sent by the participants to the server was a problem when assessing their tests. These interoperability events were part of Chile's CENS human capital training program.

Both academics and CENS engineers were interviewed with the following questions: Do you think a platform for teaching HL7 FHIR is necessary? What functions should it have? What non-functional requirements do you think are essential for the platform? For more details, see [Multimedia Appendix 1](#).

Finally, the students (engineers from health institutions) were consulted on the platform's functionality, modules, and usability in the first application of the pilot. A small instrument with 5 questions on a Likert scale (scale of 1-5) was applied to assess the application and the proposed modules, considering the user interface, quality of feedback, response times, quality of the content, and the response console. In addition, 2 open-ended questions were asked about the advantages and disadvantages of the platform.

The focus group sessions were transcribed, the topics of interest were categorized (user profile, usability, perceptions of use, and design), the patterns present were identified and interpreted, and the information obtained was triangulated with the available evidence. This analysis was carried out with Atlas-ti software (Scientific Software Development GmbH). With this information, the final prototype and the website for its deployment were designed.

End users are classified according to the following profiles: (1) system administrator in charge of the deployment and administration of the modules, client, and all technical aspects of the server; (2) professor who designs the course and describes the clinical context and associated questions; and (3) students in charge of accessing the client to answer questions about the course they are enrolled in.

Requirements

The system design requirements were divided into functional and nonfunctional ([Textbox 1](#)). The system development aimed to support the functional requirements to run e-learning sessions for FHIR courses. Regarding the nonfunctional requirements, security and usability are essential to design functional and secure interfaces by considering technological aspects, learner interactions, and instructional design [16,17] ([Table 1](#)). For more details, see [Multimedia Appendix 1](#).

Textbox 1. Functional requirements to design the system for teaching FHIR (Fast Healthcare Interoperability Resource).

1. Test and question manager:

- Users' management
- FHIR create, read, update, and delete (CRUD)-oriented test management
- FHIR CRUD operations
- CRUD courses
- Create and manage a database with questions, tests, and courses

For an FHIR test (where the context and the problem are explained), examples of questions could be:

- Create the patient with the information given in the description
- Create a medical encounter
- Modify the phone number and address of the doctor
- Delete the patient

2. Application Programming Interface (API) for orchestrating components:

- Users' authentication management
- Call up tests and questions
- Validate user answers
- Save user answers
- Execute FHIR CRUD operation on the server

3. Test evaluator:

- Evaluate answers
- Compare questions and answers
- Build resources with the HAPI FHIR library
- Validate resources with standard

The expected answer should be a CRUD operation for a FHIR test (where the context and the problem are explained). For example, for the creation of a patient, the student must complete the following:

- Method for creating a FHIR resource (post)
- [FHIR Endpoint]/patient (URL server and resource name)
- Patient data (JSON format; patient information)

4. Client application:

- Create responsive front end
- Communicate using the Huemul API
- Decoupled other components

Software Development Methodology

The development methodology was based on the traditional spiral model. The spiral development model starts with a small set of requirements and goes through each development iteration for that set of requirements. Then, the development team adds functionality for the additional requirement in ever-increasing spirals until the application is ready for the production phase [18].

Each iteration has objectives related to the evolution of the components to be developed:

1. **Modeling and management:** in the first iteration, a functional database model was generated with the objective that it can support the definition of models related to tests, users, questions, and courses and the creation of FHIR learning tests. In addition, an administration application (Huemul Admin) was created to maintain the generated models. Once the model was built, a REST API (Huemul API) was developed to consult the information.
2. **Improvements to the data model and API:** in the second iteration, improvements to the model were included with

the analysis of the previous iterations, authentication and security features of the REST API, and the creation of a web client (Huemul Client) for the consumption and interaction of the REST API.

3. **Response processing and evaluation:** in the third iteration, models for response processing are included, an interface for sending responses to the web client is added, and an engine (Huemul Engine) for response evaluation is created. The administrator creates a test planning mechanism, setting start and end times.
4. **Functional improvements and feedback:** in the fourth iteration, modifications are introduced in the processing of answers, feedback in case of incorrect answers, and the enabling of a natural resource query interface.

Each developed component has a set of tools described in [Table 1](#), the languages used are Python (Python Software Foundation) and Java (Oracle Corporation) in the backend, and all interaction between components involves using a REST API. In addition, the front end group has some traditional libraries for client development, as it uses another API to consume resources independently and does not restrict alternative clients.

Three full-time computer engineers and the leader of the CENS interoperability area worked on the platform to create the software. It took 6 months to develop the prototype and 1 month to make modifications during the pilot implementation.

Ethical Considerations

It should be noted that this research complied with ethical standards in accordance with the Declaration of Helsinki (updated in 2013).

Results

Overview

Huemul has 4 components that were designed and named considering the functional and nonfunctional requirements. Therefore, the following modules are necessary to develop a scalable and robust system:

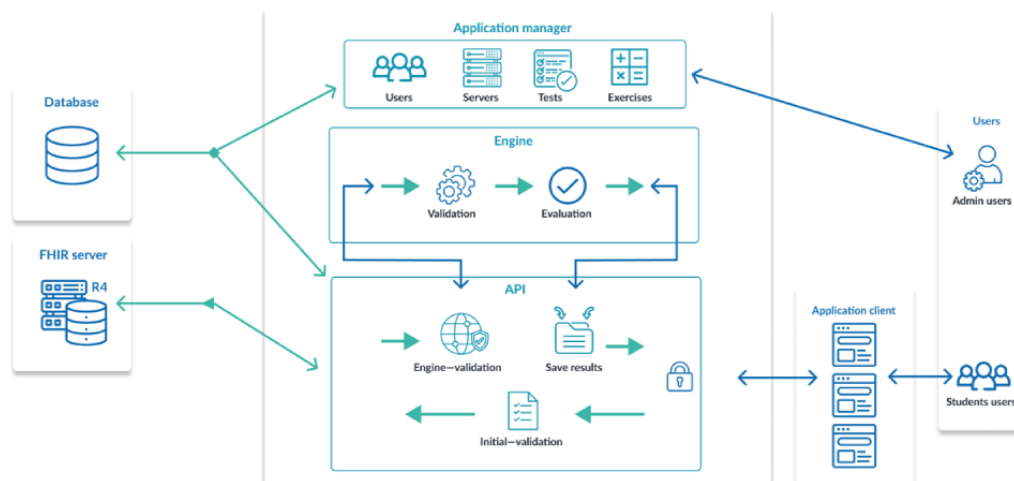

1. Huemul Admin: web application to create users, tests, questions, and scores.
2. Huemul API: communication between different components of Huemul (FHIR server, client, and engine).

3. Huemul Engine: answers evaluation to identify differences and validate responses.
4. Huemul Client: web application for users to show the test and questions.

The architecture of the developed system allows for the separation into different layers. For example, the software was built under the Model-View-Controller architecture [19] to separate the views from the data model and the business logic (Figure 1). Furthermore, since usability is one of the most important nonfunctional requirements, views use web technologies, such as HTML5, JavaScript, and CSS3, to ensure access to different web browsers.

The front end can display the courses created and managed by the administration component, where the users can answer each question. In the business-oriented layer, Huemul API interconnects with the validation engine and communicates the user's answers to this engine, which oversees validating and reviewing their structure and content. The API is Huemul's communication core. Once a user's response has been validated, it connects the operation with the backend (HAPI FHIR server) and communicates the result to the client.

Figure 1. The system architecture of Huemul with the components and their relations. API: application programming interface; FHIR: Fast Healthcare Interoperability Resource.

Huemul Admin

The admin component was developed as a web application to create users, tests, and questions with associated test scores. This component is decoupled from the overall system architecture, providing independence and modularity. Figure 2 shows a set of screenshots with the main functionalities of the Huemul Admin component. It shows the questions created,

associated FHIR servers, tests, users, and courses. Each mentioned element can be modified and associated with generating modular courses that are easy to administer.

It is essential when creating a course to situate the clinical scenario within a context (outpatient, emergency, inpatient, and home). This will help health professionals, who are learning about interoperability, to better design the necessary resources, and CRUD operations required to solve the problems presented.

Figure 2. Huemul Admin component with active FHIR courses in the platform. CENS: National Center for Health Information System; FHIR: Fast Healthcare Interoperability Resource; HL7: Health Level Seven International.

The screenshot shows the 'Courses' management interface. At the top, there is a breadcrumb trail: 'Home > Users And Courses > Courses'. Below this is a search bar with the text 'Select course to change' and a search button. To the right of the search bar is an 'ADD COURSE +' button. Below the search bar is an 'Action:' dropdown menu and a 'Go' button, with '0 of 10 selected' indicated. The main content is a table of courses with the following columns: NAME, CREATION DATE, UPDATE DATE, and OWNER ID. The table lists 10 courses, each with a checkbox in the left margin. The courses are:

NAME	CREATION DATE	UPDATE DATE	OWNER ID
<input type="checkbox"/> Aplicación Receta Electrónica Nacional	March 14, 2022, 9:25 a.m.	Aug. 26, 2022, 3:24 p.m.	sespinozaadmin - CENS
<input type="checkbox"/> Capacitación SSASUR 2021	Dec. 19, 2021, 7:07 a.m.	Dec. 22, 2021, 12:33 p.m.	sespinozaadmin - CENS
<input type="checkbox"/> Curso HL7 FHIR aplicado	Sept. 29, 2021, 1:19 p.m.	Sept. 29, 2021, 1:32 p.m.	sespinozaadmin - CENS
<input type="checkbox"/> Latam Covid Datathon 2021	July 9, 2021, 5:40 p.m.	July 9, 2021, 5:47 p.m.	sespinozaadmin - CENS
<input type="checkbox"/> Curso HL7 FHIR 2021	May 25, 2021, 10:27 a.m.	May 27, 2021, 10:55 a.m.	sespinozaadmin - CENS
<input type="checkbox"/> Asesoría Iquique HL7 FHIR 2020	Nov. 16, 2020, 11:16 p.m.	Dec. 23, 2020, 10:04 a.m.	sespinozaadmin - CENS
<input type="checkbox"/> Techconnect 2020	Oct. 26, 2020, 4:50 p.m.	May 27, 2021, 10:59 a.m.	sespinozaadmin - CENS
<input type="checkbox"/> Demo	July 27, 2020, 4:02 p.m.	May 27, 2021, 12:40 p.m.	sespinozaadmin - CENS
<input type="checkbox"/> TechConnect 2019 - Test	Sept. 27, 2019, 6:08 p.m.	Nov. 6, 2019, 10:22 a.m.	sespinozaadmin - CENS
<input type="checkbox"/> TechConnect 2019	Sept. 10, 2019, 1:16 p.m.	Sept. 10, 2019, 1:51 p.m.	admin -

At the bottom of the table, it says '10 courses'. On the right side, there is a 'FILTER' sidebar with three sections: 'By Name', 'By Creation Date', and 'By Update Date'. Each section has a list of filter options, including 'All', 'Any date', 'Today', 'Past 7 days', 'This month', and 'This year'.

Huemul API

The core of the communication is Huemul API. This API communicates the different components of Huemul (FHIR server, client, and evaluation engine), orchestrating the whole system. An essential task of the API is communicating between the client and the evaluation engine. The test evaluation process begins when the learner sends an answer through the Huemul client application until the response is received. Specifically, the steps are as follows (Figure 3):

1. Send a request from the client: the student sends the response through the client application.
2. Internal validation: the API performs basic validations of the request sent from the client. It validates the server URL, the headers, and the body of the JSON content.
3. Engine validation: performs a full validation by comparing the answer sent by the student with the expected answer configured when creating the question.
4. Evaluation response: once all the validations have been carried out, the result is delivered, either a successful or unsuccessful comparison.
5. FHIR request: once the expected response has been validated against the one sent, if the evaluation in the engine was successful, the student's response is sent to the corresponding FHIR server to be saved.
6. FHIR response: the FHIR server receives the request, processes it, and assigns a destination variable to the resource to identify the student who sends the response and responds to the API.
7. Build success answer: if the response from the FHIR server is successful, the API constructs the response with the summary of the validation process, evaluation, and result from the FHIR server, which will be sent to the client application.
8. Response: the API sends the answer to the client application so that the result of its submission is displayed on the screen to the learner.

Figure 3. Huemul API component that communicates with all the components of the system. API: application programming interface; FHIR: Fast Healthcare Interoperability Resource.

Internal validation
Check method resource matches with the correct request

FHIR validation
This validation only runs if the client request matches an specific resource (PUT, DELETE, GET), this validation checks if that resource exists

Engine validation
This validation compares in a deep way the client request and correct request of the question

Huemul Engine

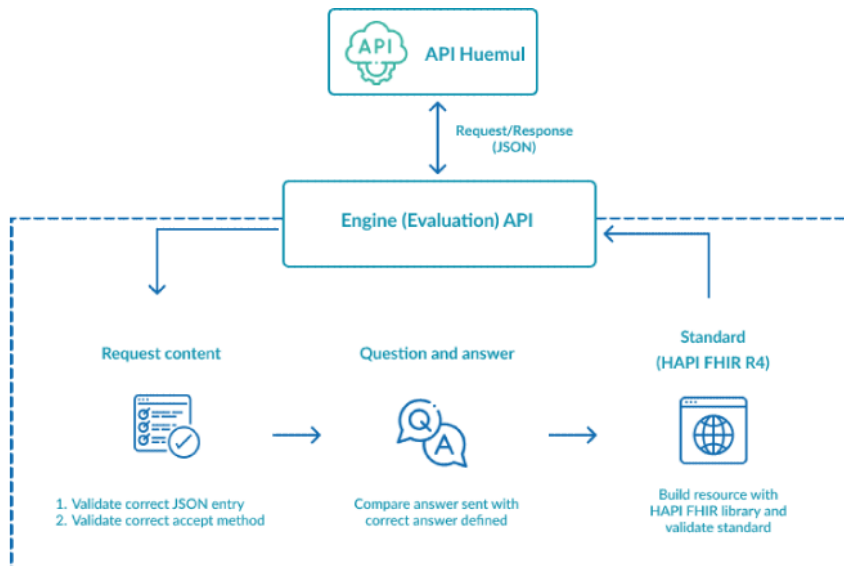

This component has the function of response evaluation, for which it evaluates 2 responses, the expected response and the user’s response. The processing comprises 3 subprocesses to finally have an evaluation result that allows us to assess if the answer is correct or to assess the percentage of completeness (Figure 4).

A FHIR request, by definition, contains the following elements to be assessed:

- Base URL of the FHIR server.
- Path of the resource or query to be made to the server.
- The header of the requested content is JSON or XML.
- The body of the resource is JSON or XML format if, in case, REST methods require a body; otherwise, the body will not have information for the request.

The methods accepted to create a question are POST, PUT, GET, and DELETE.

Figure 4. Huemul Engine component that validates, evaluates, and builds the response. API: application programming interface; FHIR: Fast Healthcare Interoperability Resource.

Huemul Client

Huemul provides a web client for users, allowing them to display the test and the questions, and is the interface with the platform. For example, on the screen for sending the answer, the question statement and essential information for answering (action, precondition, expected task, etc) are presented; there is also a

button to visualize the description of the scenario, and below in notifications, the platform gives feedback to the user to improve and correct the answers (Figure 5). For more details, see Multimedia Appendix 2.

When the user enters a course, the client presents the complete scenario, including information relevant to the test. Below is a

list of the exercises to be answered; each activity has an associated answer button with different colors.

- Orange button: exercise active but still needs to be answered.
- Green button: exercise with the correct answer.
- Red button: exercise with the wrong answer.

Figure 5. Huemul Client with a test consisting of an explanation of the scenario and associated questions. FHIR: Fast Healthcare Interoperability Resource.

Simple Exercises on Patient Resource

In the following exercises, you will see a compilation of basic queries, which will allow you to interact with a FHIR server, in a friendly way and with the aim of creating a resource with the data provided. You will also be able to insert, modify, delete and extract data from a FHIR server.

Patient Data:

- Name: Luis Gomez
- RUN: 10.010.020-3
- Gender: male
- Date of Birth: November 18, 1979
- Marital status: Married,
- Contact number: +56923242526.

Links of Interest:

- <https://www.hl7.org/fhir/patient.html>
- <https://www.hl7.org/fhir/summary.html>
- <https://www.hl7.org/fhir/http.html#history>

The exercises are based on the FHIR R4 specification.

Exercises

1 Creating a patient

The insertion of a patient into the system is required, Luis Gómez, RUN 10.010.020-3, male, born on November 18, 1979, married, whose contact telephone number is +56923242526. ... see answer

Action: Create the Patient with all the data indicated in the test case.

Expected Task: The Patient resource created within the FHIR server.

Additional Information:

- Add the element "active":true inside the resource.
- System for identifier <http://registrocivil.cl/RUN>
- System prepare maritalStatus <http://terminology.hl7.org/CodeSystem/v3-MaritalStatus>

2 Verification of the created patient

Since a Patient was already created in the previous exercise, now it is necessary to verify that this patient exists in the system. ... see answer

Action: Verify the existence of the patient in the system.

Precondition: That the patient is registered in the system and his ID is known

Expected Task: Extract the patient's information from the FHIR server.

3 Deletion of the created patient

To test the system, you want to delete the Patient created in exercise 1. ... Reply

Action: Remove the patient from the system

Precondition: That the patient is registered in the system and his ID is known

Initial Evaluation of Huemul Use

In early 2020, we conducted a pilot project in which we invited 20 health care professionals from different national institutions (10 systems development, 3 physicians, 4 computer scientists, and 3 nurses). They were students in a pilot course that presented a clinical situation and had to answer the questions through CRUD operations with HL7 FHIR. Once the course was completed, we gave them 5 questions. The questions had 5 scores according to the Likert scale for quality: 1=very poor, 2=poor, 3=fair, 4=good, and 5=excellent.

Each question focused on evaluating aspects related to the following five dimensions:

1. End-user interface: the platform is accessible and attractive for students.
2. Quality of response: feedback provided by the platform was helpful.

3. Response times: platform response times are adequate.
4. Quality of content: course description and questions are adequate.
5. Response console: response console is intuitive and easy to use.

In addition, we incorporated 2 open-ended questions that inquired about the advantages and disadvantages of the platform. The most rates of the dimensions scored on average above 4 (response times=4.9, quality of content=5, and response console=4.6). The only dimensions that did not cut above 4 on average were end-user interface and quality of feedback, with averages of 3.4 and 3.0, respectively.

This was consistent with the qualitative analysis of the open-ended questions, where students rated the content, questions, response times, and the working console positively. In general, they expressed the platform's usefulness for self-study of FHIR. However, the usability was criticized

concerning the navigation between the questions and the test, the font and size of the text, and the lack of information to support formatting.

Currently, Huemul has the following usage statistics:

- Users: 416 students with one or more courses in the platform.
- Courses: 10 courses.
- Tests: 60 tests.
- Questions: 695 questions (431 used and 264 unused; 572 general questions that can be used by any teacher with a Huemul account and 123 private questions).
- Response rate: 1725 (1666 completed+59 incomplete).

During the last 3 years, including the COVID-19 pandemic, 416 students have answered the same questions to evaluate the platform (with the exact 5 dimensions applied in the 2020 pilot). The evaluation has been good, with slight improvements since the pilot in dimensions 1 and 2. The same open-ended questions were applied in each course. The general comments are good or excellent, with suggestions for improvements, mainly in usability issues. The main criticisms collected in the open questions coincide with the pilot's answers, making comments for feedback too brief and needing more helpful information to solve the exercise. Another aspect that stands out is usability, color, and font size.

Each comment has helped us to improve, incorporating a graphic designer into the team and improving the navigability of Huemul. In addition, feedback was complemented with templates of the principal associated resources that allow students to learn in a more guided way.

The preliminary impact detected is the increase in interoperability projects associated with FHIR in Chile, where the project leaders are the professionals who participated in the CENS courses with Huemul. In addition, some professionals (clinicians and engineers) were incorporated into the government to work on national strategies linked to FHIR. Other participants were recruited for medical informatics departments in hospitals (both public and private), where they led projects with FHIR.

Discussion

Principal Findings

The Huemul FHIR learning platform was designed and developed with loosely coupled components to communicate through a central API orchestrating module communication. This design was fundamental when starting to plan, considering the development of an API rather than a platform. In addition, its decoupling allows the API to interact with different technologies and with other systems and software that students can use while maintaining the independence of the components.

Integrating information dispersed in different systems is a relevant problem in health informatics. Thus, health informatics professionals must strengthen interoperability by learning standards that allow proper use. Currently, the most promising interoperability standard is FHIR. It builds on the concepts of the previous HL7 standards. The main objective of FHIR is to facilitate the implementation of solutions in various contexts:

mobile apps, cloud communications, telemedicine, and medical records data sharing, among many others. Therefore, one of its main strengths is its ease of use and better learning curve compared to previous standards; this allows doctors, nurses, and engineers to work together in designing interoperable health care informatics solutions.

To develop competencies in FHIR, Huemul has been fundamental for training professionals in Chile. The CENS [15], with its Health Information Systems (HIS) Reference Competency Model [20], has developed and used it to strengthen and generate competencies in interoperability and standards, especially with HL7 FHIR. The model proposed by CENS brings together consensual knowledge, skills, and attitudes as a reference that guides the training of excellence in biomedical informatics. Moreover, the model drives the design of undergraduate and postgraduate training curricula and establishes common training standards in the country and the region. In addition, it makes it possible to make it evident on what is expected of professionals and technicians in this sector and what is expected of them from the point of view of job opportunities or professional development.

In Chile and Latin America, there is a need for biomedical informatics professionals trained in interoperability and standards for sharing data between HIS [2]. Currently, the demand for professionals with these competencies has increased the digital gap in health and, consequently, has slowed down the changes needed to have a more connected health with robust standards, terminologies, and HIS. Huemul is available for training processes that require new ecosystems and models.

In this context, Huemul is a web application that creates users, tests, and questions to define scores and reviews them automatically in interoperability scenarios with HL7 FHIR. Huemul was the learning platform for Chile's annual health interoperability meeting in 2020 and 2021 [21]. The interoperability meeting featured 4 sections of HL7 FHIR exercises (patient, diagnostic report, electronic medical prescription, and electronic health record), with 2 levels of complexity: introductory and intermediate. More than 100 participants each year performed hundreds of CRUD operations per exercise, which Huemul reviewed automatically. In addition, Huemul has been the official CENS platform for delivering HL7 FHIR training courses.

As a result, in the last 3 years, more than 400 technicians, engineers, and health professionals interested in learning FHIR from all over the country have been trained so far [20]. Moreover, the CENS academic team generated 10 courses with 60 associated tests. Huemul has made it possible to create a repository with more than 695 questions with different complexity levels. Each applied course has served as feedback, considering that we asked the students about the quality of our platform; considering all the dimensions exposed in the results, the users have a good evaluation of Huemul. We are still working on usability and feedback on the answers; we believe that we must improve and move forward, for example, to mobile devices and expand the content base and application areas.

Most trained professionals are leading interoperability projects with FHIR from the government, universities, and public or

private health institutions. CENS continues to support capacity building for both professionals and institutions. In this sense, Huemul is an effective tool to support practical activities, enabling the teaching of FHIR. We expect to continue advancing and complementing Huemul with new functionalities and modules in future work.

Future Work

Concerning future work, Huemul is currently in the process of redesigning for a 2.0 version that will allow us to incorporate new functionalities:

- Incorporate extensions, profiles, and extended Huemul for more search parameters. This would allow the number of questions, courses, and scenario options to be expanded as well as the complexity of the tests.
- Incorporate multiple choice and true and false questions to prepare for the HL7 FHIR certification examination. Incorporating content questions would give us a robust tool to prepare the CRUD operations in a clinical scenario and the theoretical context that will enable us to schedule examinations and certifications (eg, HL7 FHIR Proficiency examination).
- Create web-based courses with LMSs (for instance, Moodle) and Huemul. Integration with LMS platforms would extend the teaching ecosystem, incorporating content management systems, chat, forums, and all the tools with LMS.
- Incorporate other FHIR servers. Until now, Huemul has been working with HAPI FHIR, which is a complete implementation of the HL7 FHIR standard for health care interoperability in Java [22]. The advantage of having a decoupled system is the ease and modularity of its components. Huemul currently works with HAPI FHIR as a server; however, another server could be incorporated.

Another interesting aspect is evaluating and certifying interoperability levels in health information systems in a natural context [23]. Huemul could extend its applicability to other domains, for example, the assessment of HIS interoperability in hospitals, clinics, and all types of health institutions. Any modifications to its approach would be minimal, as its original 4-component structure would be maintained: Huemul Admin, Huemul API, Huemul Engine, and Huemul Client. The main changes should focus on the client-submitted request evaluation engine, broadening its focus from teaching HL7 FHIR to a more enterprise-based domain.

Considering a detailed systematic evaluation, the platform's usability is interesting to investigate deeply. Therefore, a study design that allows the application of validated instruments and the collection of information from multiple profiles and professionals is proposed as future work.

Conclusions

Huemul is the first platform that allows the creation of courses, questions, and scenarios that enable the automatic evaluation and feedback of CRUD operations with HL7 FHIR. Huemul has been implemented and applied in multiple HL7 FHIR teaching scenarios for health care professionals. It has demonstrated its efficiency and effectiveness in courses and massive events, managing hundreds of users and evaluating thousands of answers in these 4 years of application.

Of the 416 students who were trained with Huemul, many are currently leading interoperability projects with HL7 FHIR, both in the government and the private sector, contributing to developing digital health and information systems in Chile.

Abstract

Background: Immersive virtual reality (IVR)–assisted experiential learning has the potential to foster empathy among undergraduate health care students toward older adults with cognitive impairment by facilitating a sense of embodiment. However, the extent of its effectiveness, including enhancing students' learning experiences and achieving intended learning outcomes, remains underexplored.

Objective: This study aims to evaluate the impacts of IVR-assisted experiential learning on the empathy of undergraduate health care students toward older people with cognitive impairment as the primary outcome (objective 1) and on their learning experience (objective 2) and their attainment of learning outcomes as the secondary outcomes (objective 3).

Methods: A multiple-methods design was used, which included surveys, focus groups, and a review of the students' group assignments. Survey data were summarized using descriptive statistics, whereas paired 2-tailed *t* tests were used to evaluate differences in empathy scores before and after the 2-hour IVR tutorial (objective 1). Focus groups were conducted to evaluate the impacts of IVR-assisted experiential learning on the empathy of undergraduate health care students toward older people with cognitive impairment (objective 1). Descriptive statistics obtained from surveys and thematic analyses of focus groups were used to explore the students' learning experiences (objective 2). Thematic analysis of group assignments was conducted to identify learning outcomes (objective 3).

Results: A total of 367 undergraduate nursing and occupational therapy students were recruited via convenience sampling. There was a significant increase in the students' empathy scores, measured using the Kiersma-Chen Empathy Scale, from 78.06 (SD 7.72) before to 81.17 (SD 8.93) after ($P < .001$). Students expressed high satisfaction with the IVR learning innovation, with a high satisfaction mean score of 20.68 (SD 2.55) and a high self-confidence mean score of 32.04 (SD 3.52) on the Student Satisfaction and Self-Confidence scale. Students exhibited a good sense of presence in the IVR learning environment, as reflected in the scores for adaptation (41.30, SD 6.03), interface quality (11.36, SD 3.70), involvement (62.00, SD 9.47), and sensory fidelity (31.47, SD 5.23) on the Presence Questionnaire version 2.0. In total, 3 major themes were identified from the focus groups, which involved 23 nursing students: *enhanced sympathy toward older adults with cognitive impairment*, *improved engagement in IVR learning*, and *confidence in understanding the key concepts through the learning process*. These themes supplement and align with the survey results. The analysis of the written assignments revealed that students attained the learning

outcomes of understanding the challenges faced by older adults with cognitive impairment, the importance of providing person-centered care, and the need for an age-friendly society.

Conclusions: IVR-assisted experiential learning enhances students' knowledge and empathy in caring for older adults with cognitive impairment. These findings suggest that IVR can be a valuable tool in professional health care education.

KEYWORDS

immersive virtual reality; undergraduate health care education; empathy; cognitive impairment

Introduction

Background

Empathy is a cognitive ability that involves understanding other people's experiences, concerns, and perspectives, along with a capacity to communicate this understanding and the motivation to help others [1,2]. Showing empathy to patients, such as through active listening and self-awareness, is associated with improved patient outcomes and satisfaction [3,4]. When health care professionals understand the needs of patients, patients may feel more secure in relating their concerns to health care professionals and raising issues that worry them [5].

Although the Association of American Medical Colleges identifies empathy as an essential learning objective in health care education [6], undergraduate health care students have been found to have negative attitudes toward older people, affecting their willingness to work in this specialty [7-10]. This is especially true for older adults with cognitive impairment, about whom undergraduate health care students may hold stereotypes and whom they might socially stigmatize, leading to concerns about a possible lack of attentiveness in the provision of care to this group [11].

Empathy has been found to be positively correlated with the attitude of undergraduate health care students toward older adults and their willingness to care for them [12,13]. The most common methods for cultivating empathy in students include experiential training, didactic training, skills training, and a mixed methods approach [14]. Experiential learning is cognitively stimulating and has an impact on the entire person. It allows students to acquire knowledge, skills, and attitudes cognitively, affectively, and behaviorally [15]. Undergraduate health care students can benefit from experiential learning by considering the perspectives of the patients and experiencing them firsthand [16]. Experiential learning allows undergraduate health care students to gain more insights into how to solve the problems that older adults with cognitive impairment may encounter [17]. It is usually challenging for undergraduate health care students to understand the needs of older adults with cognitive impairment as these older adults may not be able to clearly communicate their needs [18]. However, through experiential learning, students can gain hands-on experiences that can give them a deeper knowledge and understanding of the challenges that older adults with cognitive impairment may be encountering [19].

Despite being suitable for enhancing empathy in undergraduate health care students, the various forms of conventional experiential learning, including service learning, role-play, and

simulation-based workshops, have limitations in terms of replicating realistic scenarios and patients in an authentic environment. In addition, in situations in which students may become distracted, instruction from supervisors is always required [20]. For example, in role-play, not all students can immerse themselves in the role of the patient [21], affecting their learning experience. However, a new type of experiential learning delivered via immersive virtual reality (IVR) provides students with an environment that encompasses them perceptually and gives them the feeling of being within it [22]. Owing to IVR's capacity to stimulate different senses concurrently, it is highly efficient in immersing users and generating a strong sense of presence. It is becoming more common to use IVR in health care education. However, there is a scarcity of research on such IVR experiences in an educational context [23].

IVR provides students with a realistic but safe virtual clinical environment, allowing them to gain insights into patients' perspectives through their eyes, voices, and emotions [24]. Buchman and Henderson [25] reported that undergraduate health care students had enhanced empathy and felt a sense of realism and authenticity in the IVR experience, with empathy being the clear theme arising from the focus group analysis. Undergraduate health care students have undoubtedly also reported positive experiences with receiving different types of experiential learning other than IVR [26]. However, the sense of presence and realism generated from IVR is not possible in conventional experiential learning. IVR-assisted experiential learning is also a highly customized learning method targeted at achieving specific learning outcomes [27]. By using IVR, teachers can put undergraduate health care students in situations that are tailored to their learning needs and outcomes, whereas this level of customization may be challenging to attain in conventional experiential learning, which invariably uses a one-size-fits-all approach. Nursing students have also been found to have a higher level of engagement when taking part in IVR learning compared with their engagement with conventional learning methods, and teachers have found IVR to be helpful in compensating for the limited clinical placements available for students in hospitals [28].

Previous studies have recognized the effectiveness of IVR-assisted experiential learning in improving empathy among undergraduate health care students [29]. The Cognitive Affective Model of Immersive Learning by Makransky and Petersen [30] suggests that the mental state of perceiving a virtual self as one's actual self with a heightened sense of embodiment refers to the sensation of possessing a virtual body. Hence, using a first-person viewpoint with a virtual environment through IVR

as a “perspective taking machine” could lead to a feeling of immersion and improve a participant’s level of embodiment, leading to an increase in empathy [31–33]. Scholars have also recommended that medical students participate in IVR experiential learning to improve their empathy before starting their clinical placement [34].

Despite previous studies, there has been little discussion on whether IVR-assisted experiential learning can enhance students’ attainment of learning outcomes such as understanding the special needs of older adults with cognitive impairment. Although there has been one study examining the improvement in the cognitive skills, such as communication competency, of multidisciplinary undergraduate and graduate health care students after an IVR simulation, its findings were based on the self-perceived evaluation of students [35]. This approach appears to lack a comparatively objective way of measuring learning outcomes, and the results of the study may be inconclusive as they may not reflect actual learning outcomes. To address this knowledge gap, it may be necessary to place more emphasis on comparatively objective assessments, such as teacher evaluations conducted according to preset assessment rubrics related to the learning outcomes.

Objectives

Therefore, this study aimed not only to evaluate the effects of IVR-assisted experiential learning on enhancing the empathy of undergraduate health care students toward older people with cognitive impairment (objective 1) but also to explore the students’ learning experiences, including “students’ satisfaction and self-confidence in learning” and “IVR fidelity” (objective 2), and their learning outcomes (objective 3) after attending the IVR-assisted experiential tutorial.

Methods

A multiple-methods design was used, which included a survey, focus groups, and student assignment reviews [36], to assess the effectiveness of the IVR-assisted experiential tutorial on students’ empathy and learning experiences and outcomes. This design produces more comprehensive findings than those obtained in single-method studies [37].

Participants

Convenience sampling was used to recruit participants for this study. Specifically, those invited to participate were undergraduate year-3 nursing students (n=267) who were taking the subject of gerontological nursing and year-3 occupational therapy (OT) students (n=100) who were taking the subject of human occupations. The nursing students were divided into 33 groups of 7 to 8 students each. They were invited to send a representative to participate in the focus groups. Ultimately, 23 group representatives participated in the focus groups. As a required learning activity, all students were obligated to attend the tutorial. However, they were given the option to join the study and complete surveys to share their learning experiences with the research team, of which 3 members (JYWL, PPKK, and KNKF) were subject lecturers. Only those who consented to join the study were included in the analysis and reporting of the results, and their anonymity was maintained in this paper.

Design of the IVR-Assisted Experiential Tutorial

Overview

To ensure that students had a solid grasp of the foundational knowledge in the subjects of gerontological nursing (for nursing students) and human occupations (for OT students), a 2-hour IVR-assisted experiential tutorial was arranged in week 7, halfway through the 13-week courses. Only the nursing students were mandated to complete and submit a group assignment within 2 weeks following the IVR tutorial.

The research team developed 2 IVR games that simulated experiences commonly encountered by older adults with cognitive impairment. The first IVR game simulated a scenario in which an individual with cognitive impairment gets lost in a community setting (Figure 1). The second IVR game simulated the distorted auditory and visual perceptions commonly experienced by older adults with delirium (Figure 2). These are common challenges faced on a daily basis by older adults with cognitive impairments. These 2 IVR games were used in the 2-hour IVR-assisted experiential tutorial. Each tutorial comprised students aged between 25 and 30 years who were divided into 7 to 8 subgroups. Each subgroup underwent concurrent IVR-assisted experiential learning.

Figure 1. Scenarios simulating getting lost when looking for a supermarket as experienced by individuals with cognitive impairment.

Figure 2. Scenarios simulating the hallucinations experienced by older adults with delirium.

The intended learning outcomes of the IVR-assisted experiential learning tutorial were as follows: (1) students would gain insights into the lives of older adults with cognitive impairment and their problem-solving efforts when facing daily challenges and, thus, develop empathy toward this group of older adults, (2) students would apply the skills and knowledge that they learned about common situations to propose more inclusive solutions targeted at older adults with cognitive impairment, and (3) students would be able to develop age-friendly care plans to meet the whole-person needs of older adults with cognitive impairment.

On the basis of the experiential learning model suggested by Kolb [38], 4 stages were included in the tutorial to enhance the students' learning experiences and outcomes.

Stage 1: Concrete Experience Through Experiential Learning

The students' concrete experience was obtained by exposing them to 10 to 15 minutes of IVR environments through head-mounted devices. This involved creating a realistic and immersive virtual environment that simulated a real-world experience, allowing students to engage with the internet-based environment in a meaningful way. For example, students were required to complete some daily tasks (eg, finding a supermarket) in the virtual reality (VR) environment while overwhelmed by stimuli to mimic the experiences of older people with cognitive impairment or during delirium, such as encountering confusing noises and images played through a VR head-mounted device.

Stages 2 and 3: Reflective Observations and Abstract Conceptualizations Through Reflective and Integrative Learning During Debriefings

Debriefing is considered an important element in experiential-based learning that reinforces and helps consolidate learning [39]. Reflective observation involves reflecting on the experience and considering what happened during the IVR simulation. The subject lecturers guided the students to reflect on and discuss the thoughts, feelings, and emotions that they experienced during the IVR-assisted experiential learning. This

reflective process can help students gain insights into their own behavior and thought patterns as well as identify areas for improvement [40].

Abstract conceptualization involves interpreting and integrating the IVR experience into existing knowledge and understanding [41]. Therefore, students were motivated to reflect on and make connections between their previous experiences with older people and the insights that they gained from the IVR games. Through this process, the students showed that they were acquiring a deeper understanding of the complexities and challenges that older people with cognitive impairment face in everyday life. At the same time, students experienced the frustration and vulnerability associated with these challenges while navigating the IVR environment. The students became aware of the need for empathy, good communication, compassion, a caring and respectful attitude, and patience when working with older people with different impairments. This reflective and integrative learning approach helped cultivate empathy among the students and gave them a deeper understanding of the needs of older people.

Stage 4: Active Experimentation by Applying the Learning in Practical Ways

Afterward, each subtutorial group in the nursing subject was required to submit a written group report to describe the strategies (a plan) for assisting older people with cognitive impairment to remain in society. The students were expected to relate the knowledge and experiences they had gained from IVR experiential learning to the proposed strategies. They shared their strategies with their teachers and fellow students on Blackboard (a web-based education platform; Anthology Inc). The lecturers evaluated the students' performance on this assignment based on the predeveloped rubric. This exercise in active experimentation equipped the students with the skills that they would need to work with older people and develop their advocacy roles in practice.

Outcome Measures

Empathy Toward Older Adults (Objective 1)

Students' empathy toward older adults (objective 1) was measured using the Kiersma-Chen Empathy Scale (KCES). The 15-item KCES was developed from the theoretical perspective of empathy, which includes cognitive (ie, the ability to understand and view the world from the perspective of other people) and affective (ie, the ability to connect with the experiences or feelings of others) aspects [42]. Each item in the KCES is rated on a 7-point Likert-type scale (1=*strongly disagree*; 7=*strongly agree*). The scores on the KCES range from 15 to 105, with higher scores indicating greater empathy toward older adults. The KCES has demonstrated good test-retest reliability, with an intraclass correlation coefficient of 0.78. It correlates positively with the Jefferson Scale of Physician Empathy [43] ($r=0.52$) and negatively with the cynicism subscale of the Maslach Burnout Inventory ($r=-0.24$) [44], providing evidence of its construct validity [42]. Students were asked to complete this web-based questionnaire 1 week before the VR-assisted experiential tutorial and return the posttest questionnaire within 1 week after the tutorial.

Learning Experience (Objective 2)

The students' experiences in learning (objective 2) with IVR-assisted experiential learning were evaluated through a posttutorial web-based survey and a focus group interview. The Student Satisfaction and Self-Confidence scale was administered after the completion of the IVR experiential tutorial. This questionnaire contains 13 items with 2 subscales (ie, satisfaction and self-confidence). Each item is rated on a 5-point Likert scale ranging from 1 (*strongly disagree with the statement*) to 5 (*strongly agree with the statement*). The scores on the satisfaction with learning scale range from 5 to 25, and the self-confidence scores range from 8 to 40, with a higher score indicating greater satisfaction and self-confidence, respectively. Both scales had high internal reliability, with a Cronbach α of .94 and .87 for the satisfaction and self-confidence scales, respectively [45].

The Presence Questionnaire version 2.0 (PQ2) was also used to evaluate the students' sense of presence in the IVR environments (ie, IVR fidelity; objective 2) [46,47] after the IVR-assisted experiential tutorial class. The 29-item questionnaire includes 4 subscales: involvement (score range from 0 to 84), sensory fidelity (score range from 0 to 42), adaption or immersion (score range from 0 to 56), and interface quality (score range from 0 to 21), with higher scores indicating better or higher involvement, sensory fidelity, adaption or immersion, and interface quality. The students rated their experiences on a 7-point Likert scale from 1 (*not at all*) to 7 (*completely*). The PQ2 has been found to have high internal consistency, with a Cronbach α coefficient of .90, and correlate strongly with other measures of presence ($r=0.78$) [46].

A trained research assistant conducted 3 focus groups, with each group comprising 7 to 8 nursing students, to explore their learning experiences (objective 2) with IVR. They were asked questions such as the following: "What was your overall experience with IVR in your learning?" "How did IVR

contribute to your understanding of the daily challenges of older people with cognitive impairment?" "Did you face any challenges or difficulties while using IVR for learning?" "How did IVR compare to other learning methods?" and "What suggestions do you have for improving the use of IVR in learning?" The interviews were audio recorded and then transcribed verbatim.

Learning Outcomes (Objective 3)

In this study, the impact on the students' attainment of the learning outcomes (objective 3) referred to the students' ability to show their understanding of the needs of older people with cognitive impairment (intended learning outcome 1) and their ability to apply this knowledge to identify inclusive strategies to help older people stay in the community (intended learning outcome 2). Only nursing students were required to complete a group assignment to describe the plan and strategies to develop age-friendly care plans to meet older adults' needs (intended learning outcome 3). The Design of the IVR-Assisted Experiential Tutorial section provides details on the intended learning outcomes of the tutorial, and the Stage 4: Active Experimentation section provides details on the arrangement of the assignment. The group assignment was evaluated based on the assessment rubric by the lecturers of gerontological nursing (JYWL and PPKK), who were also members of the project team.

Data Analysis

The numerical data collected via the surveys were summarized as descriptive statistics using SPSS (version 27; IBM Corp) for the analysis. Simple frequencies, percentages, means, and SDs were calculated. For the pre- and posttest assessments, paired 2-tailed t tests and confidence levels were calculated to test the differences before and after the tutorial. The level of significance was set at $P<.05$, and all tests were 2-tailed.

The text data collected through focus groups to identify the students' learning experiences were analyzed using descriptive thematic analysis. To identify the students' achievement of the learning outcomes, their written assignments were also analyzed using a descriptive thematic analysis. In contrast to other similar approaches, in thematic analysis, there is no commitment to a specific theoretical framework; therefore, a thematic analysis can be used between various theoretical frameworks. Thus, it is a more accessible and flexible form of analysis. What researchers do with the themes once they are uncovered will differ based on the aim of the research and the process of analysis [48]. In total, 2 researchers (JYWL and PPKK) read the students' written assignments and independently identified codes from them. Codes with similar content were grouped together to form subthemes. The subthemes were then categorized into themes. Another researcher (KC) reviewed the codes, subthemes, and themes, and any discrepancies were resolved through discussion to achieve a consensus.

Ethical Considerations

This study was approved by the Human Subjects Ethics Application Review System of the Hong Kong Polytechnic University (HSEARS20200423001) and conducted between June 2021 and May 2022. It was carried out in accordance with

the Declaration of Helsinki. This included but was not limited to guaranteeing the anonymity of participants and obtaining the informed consent of the participating students. The participation of the students was voluntary, and their academic results were not affected by their decision to participate in the study.

Results

Overview

Of the 367 students who were enrolled in the 2 subjects, 93.7% (344/367) consented to join the study, of whom 75.6% (260/344) were nursing students and 24.4% (84/344) were OT students. They completed and returned the pre- and posttest surveys with an overall response rate of 93.7% (344/367). Most participating students were female (256/344, 74.4%), 23.3% (80/344) were male, and 2.3% (8/344) did not report their gender. Their ages ranged from 18 to 24 years.

We invited all 33 subgroups from the nursing subject to send 1 representative to join the focus groups. Eventually, 23 group

representatives (a response rate of 23/33, 70%) participated in the focus groups, of whom 16 (70%) were female students. The participants were assigned to 1 of the 3 focus groups, with each group comprising 7 to 8 students to facilitate in-depth group discussions.

Empathy Toward Older Adults (Objective 1)

Participating students showed moderate empathy toward older people, as reflected by a KCES score of 78.06 (SD 7.72) out of 105 before the IVR-assisted experiential tutorial. After completing the tutorial, this score increased to 81.17 (SD 8.93). The results of the paired-sample 2-tailed *t* test showed a significant increase in the mean score from before to after the tutorial ($t_{304}=3.95$; $P<.001$; Table 1). A further subgroup analysis was conducted, and a significant difference was found in the results between the nursing and OT students in KCES scores. There was a significant improvement in KCES scores among the nursing students but a decreasing trend among the OT students (Multimedia Appendix 1).

Table 1. Changes in the Kiersma-Chen Empathy Scale (KCES) score before and after immersive virtual reality experiential learning (n=344)

Question	Before, mean score (SD)	After, mean score (SD)	<i>t</i> statistic	Mean difference (SD)	<i>t</i> test (<i>df</i>)	<i>P</i> value
1. It is necessary for a health care practitioner to be able to comprehend someone else's experiences.	5.80 (0.89)	5.83 (0.91)	0.03 (1.11)		0.46 (304)	.64
2. I am able to express my understanding of someone's feelings.	5.38 (0.92)	5.61 (0.91)	0.23 (1.04)		3.91 (304)	<.001
3. I am able to comprehend someone else's experiences.	5.33 (0.85)	5.65 (0.88)	0.32 (1.06)		5.32 (304)	<.001
4. I will not allow myself to be influenced by someone's feelings when determining the best treatment ^a .	4.62 (1.27)	4.65 (1.43)	0.62 (2.28)		4.88 (304)	<.001
5. It is necessary for a health care practitioner to be able to express an understanding of someone's feelings.	5.77 (0.85)	5.85 (0.74)	0.79 (0.93)		1.48 (304)	.14
6. It is necessary for a health care practitioner to be able to value someone else's point of view.	5.80 (0.88)	5.93 (0.82)	0.13 (1.04)		2.10 (304)	.04
7. I believe that caring is essential to building a strong relationship with patients.	6.06 (0.79)	6.03 (0.82)	0.03 (0.89)		0.58 (304)	.56
8. I am able to view the world from another person's perspective.	5.34 (0.94)	5.69 (0.85)	0.35 (1.15)		5.26 (304)	<.001
9. Considering someone's feelings is not necessary to provide patient-centered care ^a .	3.15 (1.79)	3.78 (2.11)	0.64 (2.28)		4.88 (304)	<.001
10. I am able to value someone else's point of view.	5.43 (0.87)	5.70 (0.84)	0.27 (1.05)		4.52 (304)	<.001
11. I have difficulty identifying with some else's feelings ^a .	3.51 (1.43)	3.98 (1.66)	0.47 (1.88)		4.38 (304)	<.001
12. To build a strong relationship with patients, it is essential for a health care practitioner to be caring.	5.81 (0.88)	5.93 (0.82)	0.12 (1.02)		2.03 (304)	.04
13. It is necessary for a health care practitioner to identify with someone else's feelings.	5.73 (0.87)	5.94 (0.79)	0.20 (0.94)		3.77 (304)	<.001
14. It is necessary for a health care practitioner to be able to view the world from another person's perspective.	5.69 (0.87)	5.90 (0.84)	0.21 (0.92)		4.03 (304)	<.001
15. A health care practitioner should not be influenced by someone's feelings when determining the best treatment ^a .	4.81 (1.36)	4.70 (1.60)	0.11 (1.59)		1.15 (304)	.25
Total KCES	78.06 (7.72)	81.17 (8.93)	3.11 (0.523)		3.95 (304)	<.001

Learning Experience (Objective 2)

Students' Satisfaction and Self-Confidence in Learning

Students were satisfied with the current learning innovation, as reflected by a high satisfaction mean score of 20.68 (SD 2.55) out of 25. For example, 92.7% (319/344) of the students agreed or strongly agreed that IVR-assisted experiential learning was suitable for the way they learned (item 5). The same percentage of students agreed or strongly agreed that the IVR learning experience provided an alternative learning experience to promote their learning interests (item 2). A total of 91.6%

(315/344) of the students agreed or strongly agreed that the IVR simulation was motivating and helped them learn better (item 4).

They also showed a high level of self-confidence in their IVR experiential learning, with a mean score of 32.04 (SD 3.52) out of 40. Approximately 85.5% (294/344) of the students agreed or strongly agreed that they were confident that they would obtain the necessary skills and knowledge through learning with the IVR simulation (items 6-8). A total of 95.1% (327/344) of the participants agreed or strongly agreed that students should take responsibility for their learning (items 10-11; [Table 2](#)).

Table 2. The findings of the Student Satisfaction and Self-Confidence scale (n=344).

Item	Participants, n (%)				
	Strongly disagree (1)	Disagree (2)	Undecided (3)	Agree (4)	Strongly agree (5)
Satisfaction with the current learning subscale					
1. The teaching methods used in the IVR ^a simulation were helpful and effective.	2 (0.6)	4 (1.2)	20 (5.8)	242 (70.4)	76 (22.1)
2. The IVR simulation provided me with a variety of learning materials and activities to promote my learning curriculum.	1 (0.3)	5 (1.5)	19 (5.5)	244 (70.9)	75 (21.8)
3. I enjoyed how my instructor taught the IVR simulation.	1 (0.3)	4 (1.2)	25 (7.3)	233 (67.7)	81 (23.5)
4. The teaching materials used in this IVR simulation were motivating and helped me to learn.	1 (0.3)	5 (1.5)	23 (6.7)	232 (67.4)	83 (24.1)
5. The way my instructor taught the IVR simulation was suitable to the way I learn.	1 (0.3)	3 (0.9)	21 (6.1)	246 (71.5)	73 (21.2)
Self-confidence in learning subscale					
6. I am confident that I am mastering the content of the IVR simulation activity that my instructor presented to me.	1 (0.3)	7 (2)	45 (13.1)	234 (68)	57 (16.6)
7. I am confident that this simulation covered critical content necessary for the mastery of the curriculum.	1 (0.3)	6 (1.7)	47 (13.7)	239 (69.5)	51 (14.8)
8. I am confident that I am developing the skills and obtaining the required knowledge from this simulation to perform necessary tasks in a clinical setting.	1 (0.3)	11 (3.2)	38 (11)	246 (71.5)	48 (14)
9. My instructors used helpful resources to teach the simulation.	1 (0.3)	5 (1.5)	17 (4.9)	244 (70.9)	77 (22.4)
10. It is my responsibility as the student to learn what I need to know from this IVR simulation activity.	1 (0.3)	1 (0.3)	15 (4.4)	260 (75.6)	67 (19.5)
11. I know how to get help when I do not understand the concepts covered in the simulation.	1 (0.3)	6 (1.7)	28 (8.1)	254 (73.8)	55 (16)
12. I know how to use simulation activities to learn critical aspects of these skills.	1 (0.3)	5 (1.5)	30 (8.7)	246 (71.5)	62 (18)
13. It is the instructor's responsibility to tell me what I need to learn of the simulation activity content during class time.	1 (0.3)	27 (7.8)	89 (25.9)	187 (54.4)	40 (11.6)

^aIVR: immersive virtual reality.

IVR Fidelity

IVR fidelity was measured using the PQ2. The results showed that students developed a good sense of presence in the IVR

learning environment, as seen in their scores on adaptation (mean 41.30, SD 6.03 out of 56), interface quality (mean 11.36, SD 3.70 out of 21), involvement (mean 62.0, SD 9.47 out of

84), and sensory fidelity (mean 31.47, SD 5.23 out of 42) (Table 3).

On the basis of the focus group discussions with the students about their experiences of experiential learning with IVR, 4

themes were identified: *enhanced sympathetic feeling toward older adults with cognitive impairment, improved engagement in IVR learning, confidence in understanding key concepts in the IVR experiential learning process, and limitations of IVR technology.*

Table 3. The findings of the Presence Questionnaire version 2.0 (n=344).

Item	Participants, n (%)						
	1	2	3	4	5	6	7
Involvement							
1. How much were you able to control events?	3 (0.9)	4 (1.2)	3 (0.9)	45 (13.1)	73 (21.2)	156 (45.3)	60 (17.4)
2. How responsive was the environment to actions that you initiated (or performed)?	1 (0.3)	5 (1.5)	9 (2.6)	66 (19.2)	116 (33.7)	107 (31.1)	40 (11.6)
3. How natural did your interactions with the IVR ^a environment seem?	8 (2.3)	6 (1.7)	23 (6.7)	64 (18.6)	121 (35.2)	92 (26.7)	30 (8.7)
4. How much did the visual aspects of the IVR environment involve you?	1 (0.3)	1 (0.3)	11 (3.2)	43 (12.5)	80 (23.3)	155 (45.1)	53 (15.4)
6. How natural was the mechanism that controlled movement through the environment?	6 (1.7)	7 (2)	26 (7.6)	48 (14)	134 (39)	99 (28.8)	24 (7)
7. How compelling was your sense of objects moving through space?	2 (0.6)	3 (0.9)	10 (2.9)	55 (16)	133 (38.7)	110 (32)	31 (9)
8. How much did your experiences in the virtual environment seem to be consistent with your real-world experiences?	14 (4.1)	13 (3.8)	24 (7)	69 (20.1)	109 (31.7)	93 (27)	22 (6.4)
10. How completely were you able to actively survey or search the IVR environment using vision?	1 (0.3)	3 (0.9)	6 (1.7)	41 (11.9)	132 (38.4)	121 (35.2)	40 (11.6)
14. How compelling was your sense of moving around inside the virtual environment?	1 (0.3)	4 (1.2)	11 (3.2)	60 (17.4)	140 (40.7)	96 (27.9)	32 (9.3)
17. How well could you move or manipulate objects in the virtual environment?	12 (3.5)	2 (0.6)	22 (6.4)	67 (19.5)	116 (33.7)	100 (29.1)	25 (7.3)
18. How involved were you in the virtual environment experience?	3 (0.9)	5 (1.5)	6 (1.7)	42 (12.2)	115 (33.4)	124 (36)	49 (14.2)
26. How easy was it to identify objects through physical interaction (eg, touching an object, walking over a surface, or bumping into a wall or object)? ^b	10 (2.9)	11 (3.2)	24 (7)	91 (26.5)	126 (36.6)	58 (16.9)	24 (7)
Sensory fidelity							
5. How much did the auditory aspects of the IVR environment involve you?	5 (1.5)	3 (0.9)	18 (5.2)	49 (14.2)	103 (29.9)	118 (34.3)	48 (14)
11. How well could you identify sounds?	3 (0.9)	4 (1.2)	8 (2.3)	43 (12.5)	107 (31.1)	127 (36.9)	52 (15.1)
12. How well could you localize sounds?	3 (0.9)	6 (1.7)	11 (3.2)	50 (14.5)	118 (34.3)	114 (33.1)	42 (12.2)
13. How well could you actively survey or search the virtual environment using touch?	10 (2.9)	9 (2.6)	21 (6.1)	57 (16.6)	120 (34.9)	98 (28.5)	29 (8.4)
15. How closely were you able to examine objects?	2 (0.6)	4 (1.2)	17 (4.9)	59 (17.2)	129 (37.5)	102 (29.7)	31 (9)
16. How well could you examine objects from multiple viewpoints?	1 (0.3)	2 (0.6)	12 (3.5)	64 (18.6)	118 (34.3)	116 (33.7)	31 (9)
Adaption or immersion							
9. Were you able to anticipate what would happen next in response to the actions that you performed?	4 (1.2)	9 (2.6)	39 (11.3)	63 (18.3)	116 (33.7)	88 (25.6)	25 (7.3)
20. How quickly did you adjust to the virtual environment experience?	3 (0.9)	2 (0.6)	11 (3.2)	41 (11.9)	133 (38.7)	86 (25)	68 (19.8)
21. How proficient in moving and interacting with the virtual environment did you feel at the end of the experience?	2 (0.6)	11 (3.2)	34 (9.9)	136 (39.5)	125 (36.3)	36 (10.5)	0 (0)
24. How well could you concentrate on the assigned tasks or required activities rather than on the mechanisms used to perform those tasks or activities?	0 (0)	1 (0.3)	4 (1.2)	59 (17.2)	131 (38.1)	118 (34.3)	31 (9)

Item	Participants, n (%)						
	1	2	3	4	5	6	7
25. How completely were your senses engaged in this experience?	1 (0.3)	2 (0.6)	5 (1.5)	54 (15.7)	111 (32.3)	119 (34.6)	52 (15.1)
27. Were there moments during the virtual environment experience when you felt completely focused on the task or environment?	2 (0.6)	0 (0)	5 (1.5)	66 (19.2)	122 (35.5)	98 (28.5)	51 (14.8)
28. How easily did you adjust to the control devices used to interact with the virtual environment?	0 (0)	6 (1.7)	8 (2.3)	91 (26.5)	139 (40.4)	58 (16.9)	42 (12.2)
29. Was the information provided through different senses in the virtual environment (eg, vision, hearing, touch) consistent?	1 (0.3)	4 (1.2)	5 (1.5)	74 (21.5)	111 (32.3)	93 (27)	56 (16.3)
Interface quality							
19. How much delay did you experience between your actions and the expected outcomes? ^b	7 (2)	32 (9.3)	64 (18.6)	102 (29.7)	57 (16.6)	58 (16.9)	24 (7)
22. How much did the visual display quality interfere or distract you from performing assigned tasks or required activities? ^b	17 (4.9)	79 (23)	66 (19.2)	96 (27.9)	44 (12.8)	24 (7)	18 (5.2)
23. How much did the control devices interfere with the performance of assigned tasks or with other activities? ^b	21 (6.1)	74 (21.5)	106 (30.8)	73 (21.2)	37 (10.8)	15 (4.4)	18 (5.2)

^aIVR: immersive virtual reality.

^bReverse items.

Enhanced Sympathetic Feelings Toward Older Adults With Cognitive Impairment

All participants in the focus group were impressed by the authenticity of the IVR games, which allowed them to experience the daily challenges faced by older people with cognitive impairment. One student remarked the following:

The IVR experience allowed me to see the world from the perspective of an older person with cognitive impairment who was getting lost. This experience helped me to better understand the confusion and disorientation that older people may face, which in turn helped me to be more empathetic and compassionate toward them.

Another student added the following:

This VR experience was so lifelike that it helped me to empathize with their (older people with cognitive impairment) situation and understand their needs better.

Improved Engagement in IVR Learning

Most participants in the focus groups said that IVR helped them stay engaged and interested in the learning process, which could sometimes be challenging in traditional classroom settings. One student said the following:

With IVR, I was able to experience the daily challenges of older adults with cognitive impairment, which made the learning process more exciting and engaging than conventional teaching methods. With this firsthand experience, I am motivated to learn and

identify strategies to help them (older adults) overcome those challenges.

Confidence in Understanding Key Concepts in the IVR Experiential Learning Process

Students also showed confidence in their learning with IVR. They stated that learning with IVR improved their memory retention by providing a more realistic and memorable learning experience. One student commented the following:

The IVR game of delirium was a great way to simulate the condition and learn how to manage it (delirium in patients). It gave me the confidence to recognize and manage delirium in a real-life situation.

This sentiment was echoed by another student, who said the following:

The “get lost” game made me realize the importance of taking extra precautions to ensure the safety of older people with cognitive impairment. Overall, these experiences allowed me to develop a deeper understanding of the challenges associated with caring for them, which gives me more confidence in my ability to provide effective care to them.

Limitations of IVR Technology

Although IVR offered a unique and engaging learning experience for students, technical issues such as equipment malfunctions and slow processing times could limit the effectiveness of the IVR learning experience. One student stated the following:

I encountered some technical issues during the IVR experience, which interrupted the flow of the scenario

and disrupted my immersion in the experience. It was frustrating, and I felt like I missed out on some important learning opportunities as a result.

Another student added the following:

The VR headset was heavy and its size needed to be adjusted continually to fit my head, making it difficult to fully immerse myself in the scenario. I found it challenging to stay focused and engaged during the entire experience.

Learning Outcomes (Objective 3)

Overview

To understand the students' attainment of the 3 learning outcomes after completing the IVR-assisted experiential tutorial, we conducted thematic analyses of the group written assignments. The analysis was based on 33 group assignments from the nursing students. In total, 3 themes were identified.

Understanding the Challenges Faced by Older People With Cognitive Impairment

The analysis of the students' written assignments indicated that they had developed a basic understanding of the challenges faced by older people with cognitive impairment. For example, one group report stated the following:

The psychological well-being of older people would be negatively influenced due to their hallucinations. It is because restlessness and agitation would be provoked by the experiences of distorted images and sounds. The situations may happen at any time, which gives the older people much mental stress.

Another statement also said the following:

Their quality of life would be seriously affected since their cognitive functions are impaired, lowering their independence in daily living. To prevent themselves from making mistakes, they (older adults) may withdraw from society or stop doing things that they used to do. Therefore, some older adults may suffer from depression and become socially isolated due to cognitive decline.

Person-Centered Care

This care approach was mentioned consistently in group assignments. One report stated the following:

Person-centered care is essential to ensure that older people with cognitive impairment receive care that is tailored to their unique needs and preferences.

“Effective communication,” “family involvement,” and “supportive care with patience” were 3 critical aspects of person-centered care that were frequently discussed in the assignments:

Effective communication is a key component in person-centered care to ensure that this vulnerable group can express their needs and preferences so that the care can be tailored for them.

They also mentioned the need for family members to be included in the care planning and decision-making process. One group wrote the following:

Family members play a critical role in providing support and care to older people with cognitive impairment. This is particularly the case during delirium.

Their involvement can promote continuity of care and provide emotional support to their families with cognitive impairment, especially when they are in a distressing situation, such as delirium.

The need to be supportive was stated frequently in the written assignments. For example, one report stated the following:

As nurses, we need to provide support to individuals with cognitive impairment to promote their independence and autonomy. In order to empower them to be able to continue living their life with dignity, we should give them various forms of support.

Creation of an Age-Friendly Society

It was stated that this is an essential strategy to enable older people with cognitive impairment to stay in the community with dignity for as long as possible. In a written report, students recognized the need to reduce the stigma surrounding cognitive impairment and stated the following:

We need to raise awareness and educate people about the common daily challenges faced by older people with cognitive impairment to eliminate negative stereotypes and improve social inclusion for them.

Students also became aware of the importance of social inclusion in creating an age-friendly society, stating the following:

We need to create a supportive and inclusive environment that recognizes the unique needs of individuals with cognitive impairment.

They also suggested some concrete community-based services and support to enable this segment of the population to remain in their community for as long as possible. One group wrote the following:

Community-based services, such as transportation, social activities, and assistive technologies, can help them to stay connected and engaged in their communities.

Another group echoed this with the following suggestion:

Provide more community activities to enhance their interaction with the society, which can help the older adults expand their social circle to reduce the rate of deterioration of their cognitive function.

Discussion

Principal Findings

The results suggest that IVR-assisted experiential learning is effective in enhancing empathy toward older people among undergraduate nursing and OT students, as reflected in their higher scores on the KCES after the IVR simulation. The

students reported a high level of satisfaction with the IVR learning experience, citing its suitability, ability to motivate, and innovativeness in the self-administered survey. In addition, the findings from the survey suggest that the students experienced a strong sense of presence in the IVR learning environment, enabling them to gain a deeper understanding of the challenges involved in caring for older adults with cognitive impairment. In total, 3 major themes were identified from the focus groups with 23 nursing students: *enhanced sympathetic feelings toward older adults with cognitive impairment, improved engagement in IVR learning, and confidence in understanding the key concepts through the learning process*. The thematic findings supplement and are in line with the results from the survey. The analysis of the written assignments showed that the students attained the learning outcomes of understanding the challenges faced by older people with cognitive impairment, the importance of providing person-centered care, and the need to create an age-friendly society.

These findings are consistent with those of previous studies that demonstrated the effectiveness of IVR as a mode of experiential learning to enhance the empathy of students toward older adults [49,50]. However, previous studies have mainly measured changes in students' level of empathy using questionnaires without exploring the underlying reasons.

Empathy Toward Older Adults and Learning Experience

Our survey findings for objectives 1 and 2 are consistent with the insights gained from the focus groups. For example, the PQ2 scores indicated that the students felt a strong sense of presence in the IVR environment, which was also reflected in their comments during the focus groups. Participants in the focus groups mentioned that the authentic IVR games allowed them to better understand and empathize with the daily challenges faced by older people with cognitive impairment, which may have contributed to the significant increase in empathy toward older adults reflected in the KCES scores. Furthermore, both the surveys and focus groups revealed that students were satisfied with the IVR-assisted experiential learning and felt confident in their ability to understand the key concepts through this approach. These consistent findings across multiple data sources provide strong evidence to suggest the effectiveness of IVR-assisted learning in enhancing students' empathy and understanding of key concepts as well as their satisfaction with the IVR teaching approach. Compared with conventional teaching methods, IVR creates a sense of presence and provides an excellent medium for experiencing alternative points of view, allowing undergraduate health care students to virtually "step into the shoes of older adults" [23]. The hands-on experiences provided by IVR enable students to gain a deeper understanding and knowledge of the challenges that older adults with cognitive impairment may encounter [19].

The findings of this study suggest that IVR can promote positive learning experiences, including increased satisfaction, self-confidence, self-assessed competency, self-efficacy, and enjoyment among undergraduate health care students [51]. This evidence is consistent with the positive learning experiences identified in this study based on both quantitative and qualitative

data. In addition, IVR facilitates a constructivist approach to education that emphasizes active participation in the learning process rather than the passive receipt of information [52]. That was why, in the focus groups, students stated that they experienced improved engagement with this innovative learning approach. It provides active and constructivist learning and increases students' engagement in their learning, leading to an increase in the frequency of authentic learning experiences. Being engaged encourages students to become aware of learning concepts such as empathy and other soft skills needed to care for older adults.

The subgroup analysis revealed a notable enhancement in KCES scores among nursing students in contrast to a declining trend among OT students. As the aim of this study was not to draw comparisons between these 2 student groups but rather to evaluate overall empathy levels among nursing and OT students, we are unable to explain the reasons for these differences. This discrepancy could potentially be attributed to the non-discipline-specific design of the intervention, which may have been more beneficial to nursing students than to OT students.

Learning Outcomes

Apart from enhancing empathetic experiences, an analysis of the students' group assignments in this study revealed 3 major themes related to their learning outcomes [53]. These findings indicate that the students improved their understanding of the challenges faced by older people with cognitive impairment. Consequently, nursing students recognized the importance of person-centered care for this population, including effective communication, family involvement, and supportive care. Finally, the students highlighted the need to create an age-friendly society by reducing stigma, promoting social inclusion, and providing community-based services and support.

Implications

By improving empathy levels through IVR experiential learning, students become more capable of comprehending needs and experiences from the perspective of the patients. The empathetic response of the students can provide insights into how newly acquired knowledge of the lived experiences of older adults with cognitive impairment can be used to enhance the quality of life of these older adults [54]. In this way, students will be better equipped to develop individualized care plans tailored to the specific needs of patients [55]. IVR experiential learning also inspires students to adopt a holistic approach when providing care to older people with cognitive impairment, recognizing the significance of social and environmental factors in their care plans [56].

Limitations and Challenges of IVR Learning

Although IVR-assisted experiential learning has shown positive results in enhancing health care education, it is important to acknowledge the limitations and challenges associated with adopting this technology in teaching. Technical issues such as equipment malfunctions and slow processing times could result in missed learning opportunities, as noted by some students during the focus group discussions. Similar technical issues mentioned in previous studies disrupted the flow of scenarios

and limited the effectiveness of the IVR learning experience [57,58]. These technical limitations must be addressed to ensure that IVR can be used effectively for teaching. Other main challenges that we experienced include the cost of implementing and maintaining the IVR technology, including hardware and software [50]. Another challenge is the need for technical support to develop and maintain IVR simulations, which requires collaboration between educators and technologists [59]. This may be prohibitive for some educational institutions to undertake.

Study Limitations

This study had several limitations that should be considered when interpreting the results. First, without a control group for comparison, it is unclear whether the positive outcomes identified from the surveys were based solely on this teaching innovation or because of the Hawthorn effect or the effect of novelty. However, the qualitative analyses were aligned with the survey findings, providing a more comprehensive understanding of this teaching innovation. Second, the use of the self-report method may have induced expectation bias. However, anonymity was adopted when conducting the questionnaires, which may have helped minimize bias. In addition, the objective evaluation of the students' assignments strengthened the study by providing an independent measure of their attainment of the intended learning outcomes. Third, the students' attainment of the learning outcomes was analyzed through a group assignment; thus, we could not differentiate between individual students in terms of performance. Fourth, the study population was restricted to one undergraduate nursing and OT cohort enrolled in a single university, thereby limiting the generalizability of the findings. Fifth, we were unable to confirm the reason behind the significant difference in empathy levels between nursing and OT students as it was beyond the scope of this study. Therefore, future studies are needed to explore the specific types of IVR teaching content suitable for enhancing empathetic feelings in undergraduate students from

different health care professions. Sixth, we could not confirm the transferability of the knowledge obtained through IVR-assisted experiential learning to actual clinical practice.

Future Directions

To address the limitations of our study, we recommend conducting a randomized controlled trial with a control group in the future to evaluate the effects of IVR-assisted experiential tutorials on students' empathy, learning experiences, and outcomes. In addition, individual assignments should be used to assess students' attainment of the intended learning outcomes and explore factors that could affect their performance. Such a study design would allow for a more robust evaluation of the effectiveness of IVR-assisted learning and provide deeper insights into the mechanisms underlying this approach. Moreover, future studies may be needed to determine whether the designs of related interventions have to be discipline specific to enhance empathy and understanding toward older adults with cognitive impairment among students of different health care disciplines. Further observational studies in clinical areas should also be considered to explore the transferability of knowledge to clinical practice regarding IVR-assisted experiential learning.

Conclusions

In conclusion, the findings of this study suggest that IVR-assisted experiential learning appears to have the potential to promote empathy and enhance the learning outcomes of undergraduate health care students regarding the care of older adults with cognitive impairment. Through immersive simulations, students were able to gain a deeper understanding of the challenges faced by this population and the importance of person-centered care. The findings also highlight the need to create age-friendly societies that reduce stigma, promote social inclusion, and provide community-based services and support. However, the challenges and limitations associated with the use of IVR for health care education must be addressed, such as technical issues, cost, and the need for technical support.

Acknowledgments

The authors sincerely thank the students and teachers who participated in this study. They also thank Ms Jay Wong, the research assistant, for her excellent work in ensuring that this project ran smoothly. This study was funded by a Large-Scale Collaborative Teaching Development Grant (2019-2022) from the Learning and Teaching Committee and matching funds from the School of Nursing (.53.XX.49LP), Hong Kong Polytechnic University.

Data Availability

The data sets are not publicly available owing to pending further analysis of the data. The virtual reality scenarios used in this study were just a part of the scenarios present in the complete virtual reality training system. As we may need to conduct further comparisons, we regret not being able to disclose the data sets.

Authors' Contributions

All the authors were involved in the design of the virtual reality (VR) games and the study. JYWL contributed to the conceptualization of the study. JYWL, DSKC, PPKK, KNKF, and TM implemented the VR games in their subjects. JYWL was responsible for data collection, data analysis, and quality control of the study. JYWL and PYM wrote the original draft of the manuscript. All coauthors commented on and rewrote the manuscript. All the authors have read and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Multimedia Appendix 1

The findings on the between-group changes in Kiersma-Chen Empathy Scale scores across the time points between nursing and occupational therapy students.

Abstract

Background: Although history taking is fundamental for diagnosing medical conditions, teaching and providing feedback on the skill can be challenging due to resource constraints. Virtual simulated patients and web-based chatbots have thus emerged as educational tools, with recent advancements in artificial intelligence (AI) such as large language models (LLMs) enhancing their realism and potential to provide feedback.

Objective: In our study, we aimed to evaluate the effectiveness of a Generative Pretrained Transformer (GPT) 4 model to provide structured feedback on medical students' performance in history taking with a simulated patient.

Methods: We conducted a prospective study involving medical students performing history taking with a GPT-powered chatbot. To that end, we designed a chatbot to simulate patients' responses and provide immediate feedback on the comprehensiveness of the students' history taking. Students' interactions with the chatbot were analyzed, and feedback from the chatbot was compared with feedback from a human rater. We measured interrater reliability and performed a descriptive analysis to assess the quality of feedback.

Results: Most of the study's participants were in their third year of medical school. A total of 1894 question-answer pairs from 106 conversations were included in our analysis. GPT-4's role-play and responses were medically plausible in more than 99% of cases. Interrater reliability between GPT-4 and the human rater showed "almost perfect" agreement (Cohen $\kappa=0.832$). Less agreement ($\kappa<0.6$) detected for 8 out of 45 feedback categories highlighted topics about which the model's assessments were overly specific or diverged from human judgement.

Conclusions: The GPT model was effective in providing structured feedback on history-taking dialogs provided by medical students. Although we unraveled some limitations regarding the specificity of feedback for certain feedback categories, the overall high agreement with human raters suggests that LLMs can be a valuable tool for medical education. Our findings, thus, advocate the careful integration of AI-driven feedback mechanisms in medical training and highlight important aspects when LLMs are used in that context.

Introduction

For most medical problems, history taking is the cornerstone of the diagnostic journey. Despite the increase in diagnostic tools such as advanced imaging and molecular and laboratory assays, a comprehensive history is necessary to guide further steps and may sometimes even be sufficient for diagnosing a disease without further testing [1,2]. Conversely, insufficient history taking can risk patients' safety [3,4]. Due to its importance, history taking is taught to health care students worldwide, usually as part of a communication-focused curriculum or clinical clerkship [5-8] and mostly relying on real patients [9].

To enable more student-patient interactions without increasing costs, staff's workload, or the burden on patients, virtual simulated patients have emerged as an adjunctive approach [10,11]. For communication skills in particular, web-based chatbots have been developed to offer an additional learning format [12], and recent advances in artificial intelligence (AI) such as large language models (LLMs) have helped those tools to achieve a new level of realism [13-15]. Indeed, recent work has demonstrated that OpenAI's Generative Pretrained Transformer (GPT) model is capable of providing realistic, positively perceived patient experiences as well as scenarios requiring the breaking of bad news, all of which are simulated [13,16].

However, patient experiences alone are hardly sufficient to develop competence. Indeed, no matter the amount of their exposure to patients, medical students have to have feedback in order to progress in their performance [17,18]. Traditional teaching methods require teachers' significant involvement in providing feedback, either while history taking is performed or in assessing the results afterward. LLM-based education, by contrast, offers the opportunity for repeated, unsupervised exposure to simulated patients. Whereas traditional virtual patients often yield low levels of feedback [10], the linguistic capabilities of LLMs can provide students with higher-quality feedback [19]. LLMs have also demonstrated the capability of providing feedback in other circumstances, including argumentation [20], writing [21], and scientific papers [22]. However, their capability to provide feedback on the quality of history taking has not been elucidated on a large scale, and concerns about the accuracy of AI-based feedback persist [23].

Building on our previous work showing that GPT-3.5 can provide simulated patient experiences [13], we evaluated the extension of our chatbot with an integrated feedback system while using the latest LLM model, GPT-4. In particular, we aimed to investigate whether GPT-4 can provide structured feedback on medical students' performance during history-taking dialogs with a simulated patient, with special focus on such feedback's realism and educational use. We hypothesized that GPT-4, given its capabilities in medical knowledge [24-26] and reasoning [13], can accurately assess

students' performance in history taking despite potential limitations such as logical errors [27] and AI's propensity to generate nonsensical content, known as "hallucinations" [28]. Our objective was to evaluate feedback on medical students' history taking provided by GPT and compare it with human feedback, all to contribute to the broader discourse on integrating AI into medical education.

Considering all of the above, we formulated the following research questions for our study:

1. What are the characteristics of medical students' history-taking conversations (ie, question length and chain questions) with a GPT-4-powered simulated patient chatbot?
2. What is the quality of the GPT-4-powered chatbot's role-play during such conversations (ie, are the questions answered and are the answers medically plausible)?
3. How is the history-taking dialog rated by GPT-4 and a human rater in terms of feedback topics covered?
4. How does GPT-4's feedback compare with the feedback of a human rater (ie, interrater reliability)?
5. How can significantly different feedback between GPT-4 and the human rater regarding certain topics be explained?

Methods

Study Outline

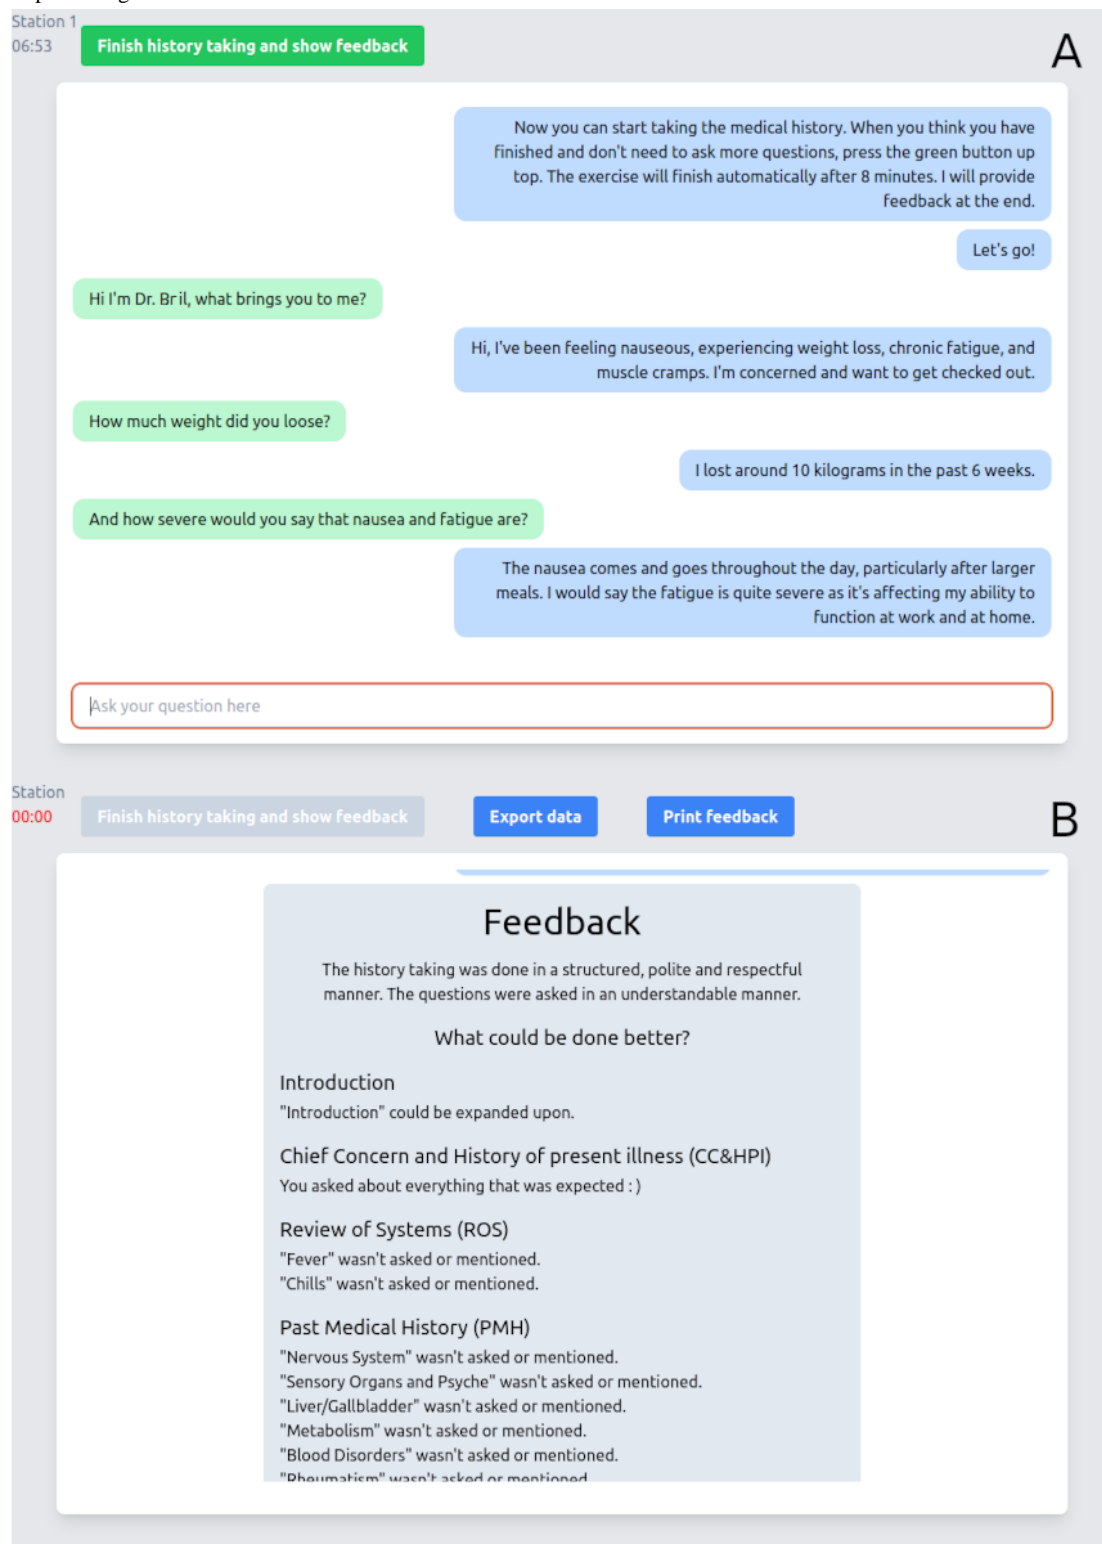

We conducted a prospective study in which students performed a written history-taking exercise with a GPT-powered simulated patient (for more information, see [13]). Afterward, GPT-4 was prompted to provide the students feedback on the topics covered in the history taking. The chat history was analyzed in detail, and the GPT model's feedback was compared with feedback from a human rater.

Setting and Participants

During a scheduled break in a skills training course involving multiple opportunities for practice, medical students were asked to participate at an additional training station affording the opportunity to participate in history taking with our GPT-powered chatbot. Participation was voluntary. Given our study's exploratory nature and aim to broadly assess the use of GPT-powered feedback in medical education, we did not impose any specific inclusion or exclusion criteria on participation beyond the willingness and ability to engage with the chatbot. Neither of those components was associated with any examination outcomes.

The training station consisted of a laptop with the chat interface already prepared (Figure 1A). Given the course in which our station was embedded, the time limit for history taking was set to reflect the time limit of other stations (ie, 8 minutes). After finishing history taking, students were presented with AI-generated feedback (Figure 1B) and proceeded to the next practice station.

Figure 1. Screenshot of the chatbot interface as presented to participants (translated from German): (A) the interface during the interactive dialog and (B) the interface presenting the feedback.

Our chat platform was a major update to the platform for history taking previously detailed by our group [13]. In short, we embedded GPT-4, accessed via an application programming interface (API), in a web page in order to enable participants to ask questions to a virtual simulated patient. Model parameters were left at their default settings, and the full chat history was anonymized and saved for further analysis.

Prompt Development

Two prompts were developed: one for providing the interactive history-taking dialog, and the other for giving feedback.

Behavioral Prompt

For the interactive history taking, we used an updated version of the prompt previously developed by our group [13]. In brief, we provided the model with a script describing an illness

(“illness script”) and used an additional behavioral prompt to make the model behave as a virtual simulated patient. For the updated version of the behavioral prompt used in our study, the prompts for history taking were mostly upgraded by adding sentences describing intended or unintended behavior. We made those upgrades because the earlier prompts made the model too verbose or willing to provide assistance only in certain cases. We added more specific instructions, including that the model should generally answer in 1 sentence or 2, never ask a question unless specifically asked to do so, and never offer assistance.

Moreover, we provided tailored examples of how the simulated patient should respond to certain inputs—for instance, to respond with “OK” if no question was asked. Such modifications aimed to correct for intrusive model behavior in which the model sometimes provided its own question in response to a participant simply writing an affirmation or “OK.”

Feedback Prompt

To make the GPT model generate feedback, we used an entirely different prompt. By calling the API, it is possible to gain full control of any message history that the model can access, as opposed to the common web interfaces of chatbots. In our case, that meant that the prompt for history taking and the prompt for feedback could not influence one another unless we intentionally reused parts of one in the other.

We used the illness script, as described in [13] and already used in the prompt for history taking, to define the categories by which to provide feedback, called “feedback categories.” Next, for each category of the illness script, the model’s task was to judge whether the information had appeared in the chat between the user and the simulated patient or whether it had been asked about. The main dilemma was, thus, the existence of 2 primary sources of information—the illness script and the chat—which complicated what the model paid attention to.

Our strategy was to begin with a description of the task, namely that the model needs to check whether the dialog that follows contains certain information and needs to answer a few questions at the end. We then provided categories from the illness script as fully phrased requirements in the form of “There should have been mention of X in the dialogue, with possible mention of Y”, in which case “X” was a category and “Y” the information given in the illness script. We used that strategy to guide the attention of the model before providing the chat. An example of such a construct was “In the dialogue, ‘Previous illnesses related to the main symptom’ should have been discussed, including information such as ‘I’ve never been like this before. I was usually healthy before.’”

We next pasted the complete chat, scaffolded with “=== START DIALOG ===” and “=== END DIALOG ===” to indicate that the content was a single long block quotation. As previously described [13], we inserted additional formatting into the chat to be presented in the prompt for history taking. However, those modifications were unnecessary and thus absent in the chat reproduced in the feedback prompt—that is, the chat was reproduced in the same way it would be shown to participants.

Following the dialog part, we again described the task of checking the dialog for certain information. We subsequently

told the model that we would repeat the feedback categories and information from the illness script in a highly compact format, which we also added to the prompt. Last, we formulated the main question—“Did these categories appear in the dialog?”—and asked the model to give its answer in the form of a JSON dictionary, a computer-readable, structured way of representing key-value pairs and special feature available in recent GPT models [29]. Using the JSON dictionary allowed us to parse the answer of the model in our interface in order to compute scores for participants.

Another problem was that the amount of information in the prompt was liable to led to exceptionally long prompts. We also observed that inquiring about all categories simultaneously led to a high probability of scrambled answers, in which categories were not fully reproduced in the answers or were simply wrong. Despite the plausibility of asking about 1 category of the illness script at a time and issuing different API calls for each, sometimes called the “divide-and-conquer” strategy [30], doing so in our case may have easily overloaded the limits set by OpenAI for model usage or led to very high computing cost. We, therefore, decided to ask about a certain number of categories at a time and issue prompts for each of those small lists. In small initial experiments, limiting the number of categories to 8 tended to provide a good balance between accuracy and cost.

The full prompt is available as [Multimedia Appendix 1](#).

Analysis of the Characteristics of Conversations

Descriptive methods were used to characterize the conversations and question-answer pairs (QAPs), in which each question was inputted by participants and the answer was outputted by GPT. First, we calculated basic metrics to describe those QAPs, including the number of QAPs per conversation and the number of words per question and answer. To analyze the students’ questions in detail, they were scored for the presence of the following undesirable behavior when asking for a medical history:

1. Foreign terms (eg, use of medical terminology);
2. Chain questions (ie, asking more than one question);
3. Single-word questions (eg, typing simply “smoking” as a question); and
4. Incomprehensive wording or barely understandable input (eg, nonconclusive series of words or spelling mistakes).

Analysis of the Quality of GPT-4’s Role-Play

To assess whether the quality of the GPT’s role-play was suitable for a simulated patient experience, as we have shown and analyzed in detail using GPT-3.5 [13], we had the answers outputted by GPT in the first 20% of the conversations assessed by rater FH and discussed with rater MM in equivocal cases. We assessed whether the participant’s questions were covered by our illness script, whether each answer matched the question, and whether the answer was medically plausible. That process was guided by categories and definitions developed in previous research [13]. [Table 1](#) shows the categories, possible scores, and examples from the conversations.

Table 1. Areas, categories, and examples for the dialogs for the rating process, adapted from [13].

Areas, categories, and examples	Dialogues
Student's question covered by the illness script	
Question not covered by the script	<ul style="list-style-type: none"> Student: "Or was someone in your surroundings ill?" GPT: "No, as far as I know, no one in my immediate surroundings was ill. Both my sons are currently fit, and my wife hasn't been feeling sick either."
Question partly or indirectly covered by the script	<ul style="list-style-type: none"> Student: "And you mentioned feeling listless as well. Are you also experiencing a loss of interest and a low mood?" GPT: "I primarily feel listless, and it's difficult for me to attend to my family duties after a long day at work. But I wouldn't say that I'm experiencing a loss of interest or a low mood."
Question explicitly covered by the script	<ul style="list-style-type: none"> Student: "And do you have any other symptoms like fever or night sweats?" GPT: "No, no fever. But I do occasionally experience episodes of increased sweating, though not only at night and not very intensely."
Statement (no question)	<ul style="list-style-type: none"> Student: "Thank you and see you soon!" GPT: "See you soon!"
GPT's response matches the question	
GPT's response matches the question	<ul style="list-style-type: none"> Student: "Do you have a loss of appetite?" GPT: "Yes, my appetite is indeed much worse than before. Maybe also because I feel frequently more nauseous."
GPT's response does not match the question	<ul style="list-style-type: none"> No example occurred
Not applicable	<ul style="list-style-type: none"> For QAPs with answers provided for a previous question
Answer medically plausible (regarding case and illness script)	
+1: Answer plausible, relevant to case	<ul style="list-style-type: none"> Student: "What was your starting weight?" GPT: "I previously weighed 115 kg. Now I weigh only 105 kg."
0: Answer plausible, not case-specific	<ul style="list-style-type: none"> Student: "All right!" GPT: "Okay."
-1: Answer implausible	<ul style="list-style-type: none"> No example occurred
Not applicable	<ul style="list-style-type: none"> For QAPs with missing answers due to technical reasons

Analysis of the Completeness of History Taking

The completeness of the medical history for the prespecified topics was assessed by GPT-4 (see "Feedback Prompt") and by a human rater (FH). To extract the feedback from GPT-4, we used the JSON file. For the human feedback, the rater assessed each QAP for the categories covered in a Microsoft Excel (version 16.0.10394.20022) spreadsheet. Both data sets were imported into R (version 4.3.1; The R Foundation) [31] for statistical analysis and figure generation. We calculated Cohen κ to compare the feedback from GPT-4 and the human rater on the chat using the R function "CohenKappa" from the "DescTools" package. Categories with $\kappa < 0.6$ were further examined by raters FH and MM in order to identify possible explanations.

All numerical data were assessed for normal distribution and, in this article, are presented as means and standard deviations. If the data deviated from a Gaussian distribution, then we provided the median and interquartile range (Q25-Q75).

Ethical Considerations

This study was approved by the Ethics Committees of the Faculty of Medicine at Tübingen University Hospital (605/2023BO2). Participation in the study was voluntary, without any compensation, and data was collected anonymized. All methods were implemented in accordance with the Declaration of Helsinki.

Results

Participants' Demographic Data

Of the 111 students asked to participate, 5 could not due to experiencing technical problems with the interview platform. All remaining 106 students agreed to participate; 78 (73.6%) identified as female, 25 (23.6%) as male, and 3 (2.8%) as nonbinary, and participants were 22.8 (SD 3.7) years old on average. As for progress in medical school, 93% of participants (N=99) were in their third year of medical school, whereas the remaining participants were in their first (2/106, 2%), second (1/106, 1%), or fourth (3/106, 3%) years, and one student

provided an implausible answer (1/106, 1%). No student had to be excluded from the analysis.

Characteristics of Conversations

In a total of 106 conversations, 1920 QAPs were recorded. Of them, 26 QAPs (1.4%) had to be excluded due to a missing server response, which left 1894 QAPs for analysis. Each conversation yielded a median number of 18 QAPs (IQR 15-23). Whereas questions consisted of a median of 6 words (IQR 4-9), the answers consisted of a median of 22 words (IQR 15-29).

In our analysis of the participants' wordings of questions, most questions did not show any abnormality (1673/1894, 88.3%). Foreign terms were found in 6.3% of the questions (119/1894), chain questions in 3.3% (n=62/1894), single-word questions in 1.2% (23/1894), and incomprehensible wording in 0.7% (13/1894). Four questions (0.2%) contained both a chain question and foreign terms.

Quality of GPT-4's Role-Play

To further assess GPT-4's accuracy in providing a simulated patient chatbot, we assessed the quality of the role-play in the first 20% of conversations, which resulted in the analysis of 410 QAPs, as previously described [13].

Our script covered the majority of questions asked by participants (354/410, 86.3%), with 28 questions (6.8%) partly covered and 13 questions (3.2%) not covered at all by the script (not applicable: 15/410, 3.7%—that is, when no question was asked).

As for the answers provided by GPT-4, 99.3% of them matched the question (n=407), and no answer failed to match the question altogether (not applicable: n=3, 0.7%—that is, provided an answer to a previous question).

Regarding the plausibility of the answers provided by GPT-4, 99.3% (n=407) were rated as plausible, none as implausible, and 0.7% (3/410) as neither implausible nor plausible.

Assessment of History Taking

Coverage of Feedback Categories and Items

Participants' history taking was assessed by both GPT-4 and the human rater (Figure 2). Combining both raters, the first feedback category (ie, introduction) was mentioned by 69.6% of participants, whereas the second category (ie, main complaint) was addressed by 52.7%. A total of 45.1% of participants asked about the vegetative system, and a system assessment was performed by 29.7% of participants. The fifth feedback category (ie, medication, family, social environment, and drugs) was addressed by 52% of participants.

Figure 2. Heat map showing the percentage of conversations mentioning the feedback categories for both raters: Generative Pretrained Transformer (GPT) in the first column, and human rater in the second.

Interrater Reliability

For total feedback, we found an interrater reliability, measured by Cohen κ , of 0.832 (95% CI 0.816-0.848), indicating an

“almost perfect” agreement [32]. We further analyzed Cohen κ for each individual category of feedback, displayed in Figure 3.

Figure 3. Cohen κ for every category of feedback for the human rater and Generative Pretrained Transformer (GPT) as a rater, with the different feedback topics displayed in different colors.

Analysis of Divergent Ratings

As displayed in Figure 3, we found at least substantial interrater agreement for most categories of feedback. If conversations had divergent ratings, then we first inspected them in detail to evaluate whether agreement between the human rater and the

GPT rating could be achieved. After corrections, 8 out of 42 categories still demonstrated lower-than-expected agreement ($\kappa < 0.6$) and were, thus, further inspected (Table 2). For those categories, we performed a throughout analysis of the ratings and discussed possible reasons for the divergent ratings.

Table 2. List of feedback categories with Cohen $\kappa < 0.6$.

Feedback category	Cohen κ	Mentioned (GPT)	Mentioned (Human rater)	Probable explanations for low Cohen's κ with suggested solution and specific example (if appropriate)
Severity	0.25	30%	13%	<ul style="list-style-type: none"> The category "Severity" derived from a pain history. In the context of the illness script, there was overlap with the category "disability degree." Suggested solution: Clarify category "Severity" and possibly rename it "Pain, Numeric Analogue Scale." Specific example (from the illness script): Severity: "Recently, I've been significantly restricted. In the evenings after a long workday, I can't do anything, and I've also noticed that I keep forgetting things at work." Disability degree: "By now, I feel severely limited. This can't continue. I can't manage either my work or the tasks at home with my family like this!"
Current weight	0.20	79%	29%	<ul style="list-style-type: none"> Probably different interpretation: GPT was more liberal than the human rater. For example, when students asked any question related to weight, GPT rated it as "yes," whereas the human rater rated it as yes only when actual weight was mentioned. Suggested solution: Define category more precisely or split category in "Current Weight" and "Weight Dynamics." Specific example (from the illness script): "Overweight, previously 115 kg at a height of 178 cm, but now I only weigh 105 kg."
Kidney	0.20	66%	30%	<ul style="list-style-type: none"> Polyuria has been repeated in the category "Kidney" because it was deemed highly important information. However, it resulted in an overlap with the category "Urination." Suggested solution: Give information only once and precisely. Specific example (from the illness script): Urination: "Lately, I've been experiencing frequent urination during the day and at night. There's no pain during urination, and the urine looks normal, as usual." Kidney: "No pre-existing conditions, but now I constantly have to go to the toilet at night. However, I also haven't been to a urologist in a long time."
Stomach or intestines	0.15	69%	18%	<ul style="list-style-type: none"> Overlap exists with the category "Bowel Movements," however, medically challenging to separate clearly. Suggested solution: Amend prompt to instruct GPT to rate both categories as "Yes" when a question or its answer covers both categories clearly and completely. Specific example (from the illness script): Stomach or intestines: "Mild tendency towards constipation" Bowel Movements: "Tending more towards constipation, but recently having a regular bowel movement once a day. Stool is otherwise normal: brown, without blood, without mucus, and without diarrhoea."
Metabolism	0.47	8%	14%	<ul style="list-style-type: none"> Probably a different interpretation: GPT did not rate conversations positively when students asked for "metabolism disorders" and "diabetes." Because we could not explain those ratings, we prompted GPT to explain its reasoning. The answer included that metabolism "encompasses all the chemical reactions that occur in the body" and includes aspects on "how [the] body converts food into energy," thereby confirming our suspicion of different interpretations. Example of a question rated "Yes" by human rater and "No" by GPT: "Are you aware of having diabetes or hypercholesterolemia?"
Blood disorders	0.49	1%	3%	<ul style="list-style-type: none"> Low prevalence of "Yes" in the feedback category [33]
Rheumatism	0.43	2%	7%	<ul style="list-style-type: none"> Low prevalence of "Yes" in the feedback category [33]

Feedback category	Cohen κ	Mentioned (GPT)	Mentioned (Human rater)	Probable explanations for low Cohen's κ with suggested solution and specific example (if appropriate)
Infections	0.43	21%	35%	<ul style="list-style-type: none"> Category not defined clearly enough with overlaps between "recent infections" and "infectious diseases." Suggested solution: Amend illness script to include both categories and define both categories clearly. Example of statement rated "Yes" by GPT and "No" by human rater: "Additionally, I suffer from many simple infections, an increased sense of thirst, and dizziness."

Discussion

In our study, we assessed GPT-4's performance in providing automatic feedback on learners' history taking in a large cohort of medical students. Our findings suggest that GPT-4, accessed via an API, is capable of not only simulating patient experiences through a chatbot-like interface but also of providing accurate feedback on medical history-taking dialogs.

Principal Results

Extending the line of our group's previous research, the study presented here confirmed GPT-4's capability of offering medically plausible responses in more than 99% of interactions, with a negligible rate of missing server responses (1.4%) that showcases its high reliability and availability in medical training [13]. That technical capability is particularly relevant when considering the asynchronous nature of such feedback systems in educational settings [34]. Building on our past work [13], we have demonstrated that GPT-4 can not only act as a simulated patient chat bot but can also assist the learner in providing structured feedback on the topics covered or not covered by the student.

The high level of agreement (Cohen $\kappa=0.832$) between GPT ratings and human ratings of students' input that we observed indicates GPT-4's capabilities in evaluating history-taking dialogs. It also supports GPT-4's potential to enhance medical education by providing immediate, accurate feedback to students, thereby potentially fostering the learning process by enabling more practice opportunities and instant feedback. Given the importance of feedback for the learning process, the result offers an encouraging perspective on how LLMs such as GPT-4 can be used to cultivate the skills acquisition of medical students [17,18].

At the same time, we also found 8 feedback categories that yielded a Cohen κ of less than 0.6. For those items, in some cases we found GPT-4 to be "overly specific" in its rating. For example, in the category "Current Weight," GPT-4 rated the occurrence of the topic "weight" positively (ie, disregarding whether the actual weight was mentioned), whereas the human rater focused on whether the actual weight was present in the chat. Those cases can probably be attributed to different interpretations of the items rated, and they indicate that the prompting should be as specific as possible in order to achieve higher interrater reliability.

We further hypothesize that those ratings can be improved by providing more detailed specifications for every category—for instance, by including examples and using more advanced

prompting techniques such as chain-of-thought prompting [35]. However, longer prompts might be problematic when using models such as GPT-4, for the context window is limited to 8192 tokens [36]. Although our prompts (ie, system prompt of 2303 tokens and feedback prompt of 1336 tokens) fit well within those limits, longer prompts could require more advanced LLMs with longer context windows.

Furthermore, some lower κ values could have been caused by certain categories overlapping with other categories (eg, "Kidney" and "Urination"). Because medical cases often affect multiple topics, future studies should focus on the clear separation of feedback items. In our study, we did not prompt GPT-4 to provide any reasoning for the ratings (eg, in "chain-of-thought" prompting [37]), which researchers could improve upon in the future in order to better understand the models' output.

Regarding the performance of the participating students, completeness scores for the feedback topics ranged from 31.0% to 68.9%. Although such rates might seem to indicate only modest performance, students also had a time restriction of 8 minutes maximum (ie, owing to the practising circuit that our chatbot was embedded in), which made a complete history-taking dialog exceptionally difficult.

Comparison With Prior Work

Since the development of digital learning systems, automatic feedback has emerged as a topic of interest. Covering the pre-LLM era, a systematic review from 2021 analyzed 63 studies, most of them examining programming and mathematical skills [23]. While the review's authors concluded that automatic feedback can foster students' performance, the main method of generating automatic feedback was a comparison with a desired answer [23]. Further developments then included sophisticated dialog management systems [38], although those systems still performed below the level of feedback generated by LLMs. Because those pre-LLM technologies have been shown to help students [23], it can be expected that properly employed LLMs might provide even more benefits to learners (although the comparison was not investigated in our study).

Consequently, the recent emergence of LLMs such as GPT has been heralded as having the potential to revolutionize how students learn [39]. For example, Dai et al [40] found that ChatGPT was capable of generating more detailed feedback than human instructors while also achieving high agreement with the instructor. Beyond that, and in line with our results, in a study with students learning English as a new language, feedback from GPT-4 was found to be of similar quality to

human feedback regarding learning outcomes and students' perception [41]. Furthermore, LLM-based feedback has been shown to elucidate secondary effects, including increasing positive emotions and task motivation [42]. Indeed, the high motivation of students to participate in our study and in past investigations supports that motivational aspect [13]. Another essential aspect is the curricular implementation of the feedback, which is important for learners to develop a widespread understanding and develop mastery [10]. However, when implemented correctly, LLMs offer new tools for education and can be further improved when combined with speech-to-text tools and personalized databases [43].

However, some studies have also revealed problems with AI-generated feedback. For example, one showed that some participants might have negative attitudes toward the feedback due to being AI-generated feedback [44]. Such attitudes could affect learning outcomes considering that students' perception of feedback is associated with self-regulated learning [45]. Furthermore, LLMs might elicit unexpected behaviors and escape prompts, thereby resulting in problematic interactions [46]. Although we did not observe that unexpected behavior in our study, the feedback provided by the AI might ultimately be understood as "official" feedback and should thus be rigorously assessed for its quality. Last, incorporating AI in teaching might lead students to rely on AI instead of learning from it [47], which indicates the importance of keeping the complete learning task in mind when designing AI-based learning opportunities.

Limitations

Our findings have some limitations that deserve discussion. First, we relied on 1 LLM (ie, GPT-4) and a single prompt in

our study. Although our study has demonstrated GPT-4's potential in medical education, our reliance on a single LLM and type of prompt means that our findings might not apply to all educational contexts. Future research should, therefore, explore a variety of prompts and LLMs. Second, we chose a specific case for the history-taking dialog. Although we believe that GPT-4's observed performance is transferable, our data cannot corroborate that assumption. Exploring a variety of cases and conditions would provide a more robust understanding of GPT-4's applicability and limitations. Third, we used binary criteria (ie, "yes" or "no") for the completeness of history taking in order to provide students with a simple checklist on what was asked or not asked. However, real-world clinical dialogs and history taking are complex and might benefit from more nuanced evaluation in order to accurately reflect which skills and topics students need to improve upon. Beyond that, it is important for students to receive feedback from the AI-generated tool on their social skills (eg, nonverbal communication and comprehensible language) during patient-physician encounters, which should be further investigated in future research. Last, we did not measure any educational outcomes (ie, skill acquisition), and thus, cannot state whether the AI-generated feedback in fact improved students' performance.

Conclusions

In sum, the LLM GPT-4 can provide a simulated patient experience and generate tailored, unsupervised feedback for medical students. The feedback given by GPT-4 was mostly accurate and had few minor flaws, most of which likely stemmed from our prompts. Our findings support the implementation of the system and the evaluation of its effectiveness in subsequent assessments.

Acknowledgments

We wish to thank the Open Access Publishing Fund of the University of Tübingen for supporting our study and Eric Nazareus for his assistance with our analysis.

Abstract

Background: The Objective Structured Clinical Examination (OSCE) is a pivotal tool for assessing health care professionals and plays an integral role in medical education.

Objective: This study aims to map the bibliometric landscape of OSCE research, highlighting trends and key influencers.

Methods: A comprehensive literature search was conducted for materials related to OSCE from January 2004 to December 2023, using the Web of Science Core Collection database. Bibliometric analysis and visualization were performed with VOSviewer and CiteSpace software tools.

Results: Our analysis indicates a consistent increase in OSCE-related publications over the study period, with a notable surge after 2019, culminating in a peak of activity in 2021. The United States emerged as a significant contributor, responsible for 30.86% (1626/5268) of total publications and amassing 44,051 citations. Coauthorship network analysis highlighted robust collaborations, particularly between the United States and the United Kingdom. Leading journals in this domain—*BMC Medical Education*, *Medical Education*, *Academic Medicine*, and *Medical Teacher*—featured the highest volume of papers, while *The Lancet* garnered substantial citations, reflecting its high impact factor (to be verified for accuracy). Prominent authors in the field include Sondra Zabar, Debra Pugh, Timothy J Wood, and Susan Humphrey-Murto, with Ronaldo M Harden, Brian D Hodges, and George E Miller being the most cited. The analysis of key research terms revealed a focus on “education,” “performance,” “competence,” and “skills,” indicating these are central themes in OSCE research.

Conclusions: The study underscores a dynamic expansion in OSCE research and international collaboration, spotlighting influential countries, institutions, authors, and journals. These elements are instrumental in steering the evolution of medical education assessment practices and suggest a trajectory for future research endeavors. Future work should consider the implications of these findings for medical education and the potential areas for further investigation, particularly in underrepresented regions or emerging competencies in health care training.

KEYWORDS

Objective Structured Clinical Examination; OSCE; medical education assessment; bibliometric analysis; academic collaboration; health care professional training; medical education; medical knowledge; medical training; medical student

Introduction

Objective Structured Clinical Examinations (OSCEs) have emerged as indispensable tools for assessing health care professionals, providing structured evaluations of clinical

competencies, communication skills, and decision-making abilities [1,2]. Despite their widespread adoption since the 1970s, the landscape of OSCE research remains multifaceted and dynamic, reflecting ongoing innovations in medical, nursing, and allied health education [3].

While numerous studies have explored various aspects of OSCEs, gaps persist in our understanding of the overarching trends and global dynamics shaping this field. A comprehensive review of the existing literature highlights the need for a systematic approach to mapping the knowledge landscape and identifying emerging trends through bibliometric analysis [4-6]. By applying quantitative methods to scholarly publications, bibliometric analysis offers a unique opportunity to uncover hidden patterns, elucidate research trajectories, and forecast future directions in OSCE research.

Building on this rationale, our study aims to bridge these gaps by conducting a bibliometric analysis of OSCE literature from 2004 to 2023. We hypothesize that this analysis will reveal distinct patterns of publication output, collaboration networks, and thematic clusters within the OSCE research domain. Specifically, we seek to (1) identify key research themes, including but not limited to assessment methodologies, educational interventions, and technological innovations in OSCEs; (2) map the global distribution of OSCE research, highlighting geographic hotspots and areas of collaboration; and (3) explore the interconnections between different disciplines within medical education, shedding light on interdisciplinary collaborations and knowledge diffusion.

By elucidating these aspects, our study aims to provide stakeholders in medical education with valuable insights into the current state and future directions of OSCE research. Ultimately, this knowledge mapping exercise seeks to inform evidence-based decision-making, guide educational practices, and stimulate further research in the field of clinical skills assessment.

Methods

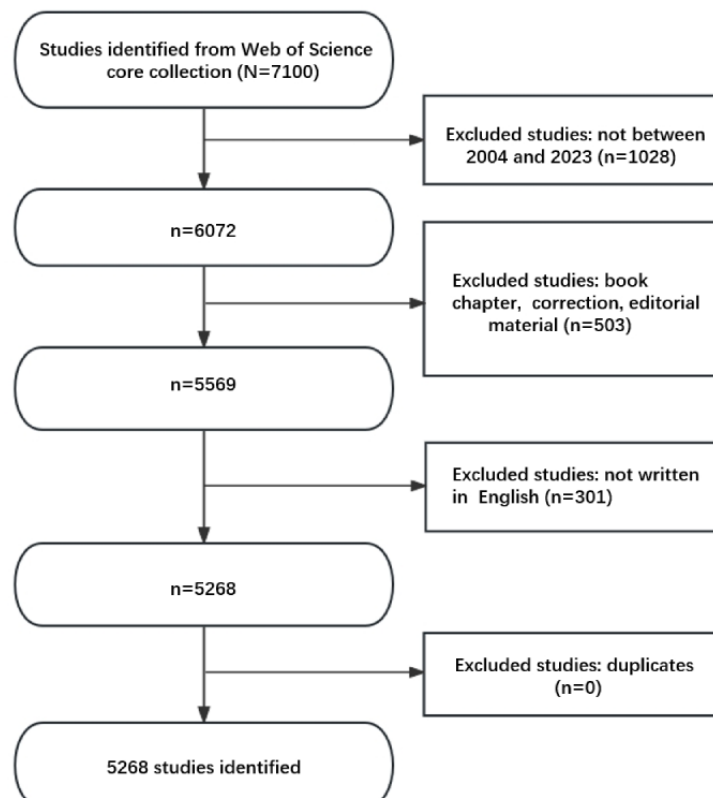

Data Acquisition and Search Strategy

The bibliographic accuracy of literature types in the Web of Science Core Collection (WoSCC) database is superior to any other database, making it the optimal choice for conducting literature analysis [7,8]. Therefore, we opted to perform our search within this database. We conducted a search in the Web of Science (WoS) for all relevant papers published between January 1, 2004, and December 31, 2023. The search formula “(TS=(The Objective Structured Clinical Examination)) or TS=(OSCE)” was used. The literature screening for this study was based on the inclusion criteria: (1) full-text publications related to the OSCEs; (2) papers and review manuscripts written in English; and (3) papers published between January 1, 2004, and December 31, 2023. The exclusion criteria included (1) topics not related to the OSCEs and (2) papers in the form of conference abstracts, news briefs, and so on. A plain text version of the papers was exported.

General Data

Figure 1 shows the process of literature searching and bibliometric analysis. The results indicate that from January 1, 2004, to December 31, 2023, there were a total of 5268 publications related to the OSCE in the WoSCC database, including 1800 papers (84.96%) and 384 reviews (15.04%). The literature involved 133 countries and regions, 5291 institutions, and 24,478 authors.

Figure 1. The workflow of data collection and bibliometric analysis.

Data Analysis

To depict annual publication trends and the distribution of national contributions, we used GraphPad Prism (version 8.0.2; Dotmatics). For the bibliometric analysis and the visualization of scientific knowledge maps, the study used both CiteSpace (6.2.4R, 64 bit advanced edition; Chaomei Chen, Drexel University) [9] and VOSviewer (version 1.6.18; Leiden University) [10]. These tools were selected for their robustness in handling extensive bibliometric data and their ability to graphically represent complex networks.

VOSviewer, a Java-based software pioneered by van Eck and Waltman [9] in 2009, facilitates the construction of various types of network maps, such as bibliographic coupling, cocitation, and coauthorship networks. CiteSpace, developed by Professor Chaomei Chen, provides a dynamic and computer-based platform for identifying and visualizing patterns and trends in scientific literature, thereby enabling the exploration of knowledge domains and predictive analysis of research trajectories [10].

Our methodological approach within these applications involved setting specific parameters for network density, threshold values for the inclusion of nodes, and time-slicing techniques to analyze temporal changes. The references corresponding to the software applications were verified against our citation list to ensure accuracy [9,10].

In our study using VOSviewer and CiteSpace software tools for bibliometric analysis, the criteria for defining country-based collaborations were established based on specific considerations. Collaborations were determined by considering the first authors

and corresponding authors listed in the paper bylines. This approach was chosen to ensure inclusivity and to capture the entirety of collaborative efforts between researchers from different countries.

The burst detection in CiteSpace is based on the Kleinberg algorithm, which is based on modeling the stream using an infinite-state automaton to extract a meaningful structure from document streams that arrive continuously over time [11]. These analyses can show the fast-growing topics that last for multiple years as well as a single year.

Rationale for Analysis Selection

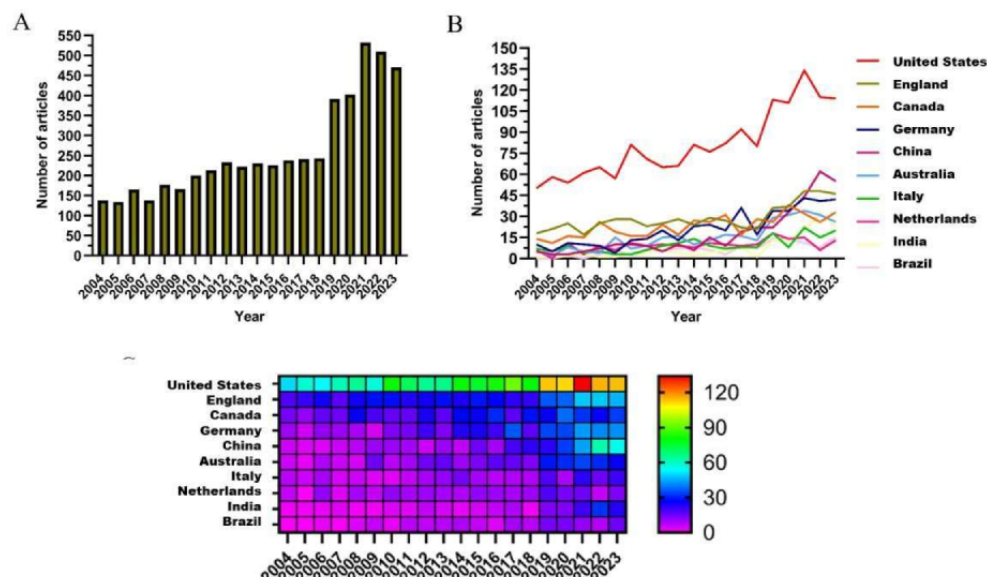

The aforementioned techniques were chosen a priori due to their widespread use and effectiveness in bibliometric studies. They provide robust and complementary insights into productivity, impact, and collaborative patterns within the research field.

Results

Publication Trend

Since 2004, there has been a gradual increase in the number of papers published annually (Figure 2A). We have divided this into 3 periods: from 2004 to 2010, there was a slow growth, with fewer than 150 papers published per year, indicating that the field had not yet captured researchers' attention. From 2011 to 2018, the volume of publications gradually increased, indicating growing interest in the field. After 2019, there was a rapid rise in the number of publications, peaking in 2021, which suggests that the field has received widespread attention since then.

Figure 2. Trend chart of publications in the past 20 years. (A) Annual publication count chart. (B) Line chart of national publication count. (C) Heatmap of national publication count.

Country or Region and Institution Contributions

Figure 2B and C show the annual number of publications from the top 10 countries over the past decade. The top 5 countries in the field are the United States, the United Kingdom, Canada, Germany, and China, respectively. The United States accounts

for 30.86% (1626/5268) of the total volume of publications, significantly surpassing other countries.

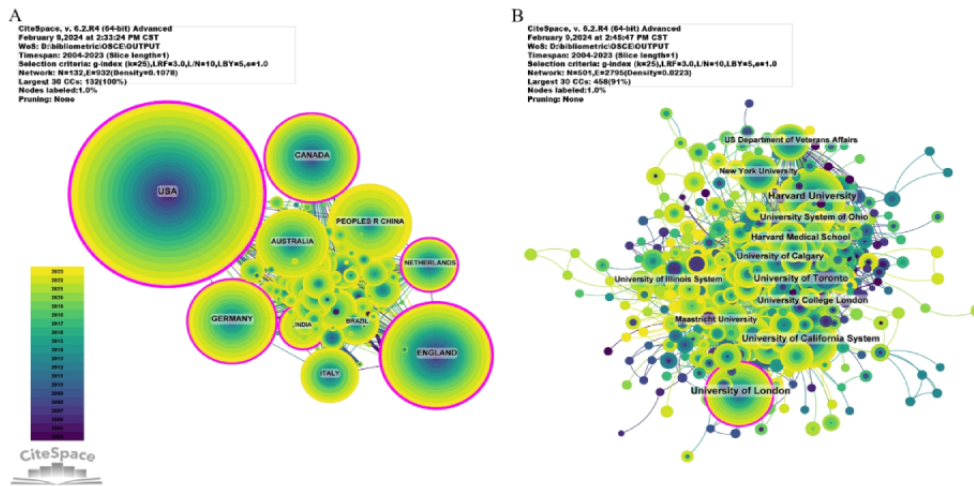

Among the top 10 countries or regions in terms of the number of published papers, the United States had a citation count of 44,051, far exceeding all other countries or regions. Its citation-per-publication ratio (27.13) ranks third among all

countries or regions, which suggests a generally high quality of the published papers. The United Kingdom had the second-highest number of published papers (576 papers) and ranked second in terms of citation count (15,929 citations). The cooperation network, as shown in Figure 3A, indicates close

collaboration between the United States and the United Kingdom, which are the highest producers.

A total of 5291 institutions have systematically published papers related to the OSCE. Among the top 10 institutions in terms of publication volume, 6 are from the United States, 2 are from the United Kingdom, and 2 are from Canada (Figure 3B).

Figure 3. Network graph of national and institutional collaborations. (A) Network graph of national collaborations. (B) Network graph of institutional collaborations. The bubble size represents the number of publications. WoS: Web of Science.

Journals' Contributions

Tables 1 and 2 list the top 10 journals with the highest outputs and the most citations, respectively. *BMC Medical Education*, with 227 out of 5268 papers, accounting for 4.31% of publications in the field, is the journal with the most published papers, followed by *Medical Teacher* (179/5268, 3.40%), *Medical Education* (132/5268, 2.51%), and *Journal of Surgical Education* (66/5268, 1.25%). Among the top 10 most productive journals, *Annals of the Rheumatic Diseases* has the highest impact factor at 27.6. All journals are categorized within either Q1 or Q2 quartiles.

The influence of a journal is determined by the frequency with which it is cocited, which indicates whether the journal has made a significant impact on the scientific community. According to Table 2, the most commonly cocited journal is *Medical Education* with 1868 citations, followed by *Academic Medicine* with 1775 citations, and *Medical Teacher* with 1597 citations. Among the top 10 journals by cocitation count, *The Lancet* was cited 697 times and has the highest impact factor of 168.9 within these top journals. All journals within the most cocited list are in the Q1 or Q2 zone.

Table 1. Top 10 most productive journals.

Rank	Journals	Papers (N=5268), n (%)	IF ^a	Quartile in category
1	<i>BMC Medical Education</i>	227 (4.31)	3.6	Q1
2	<i>Medical Teacher</i>	179 (3.40)	4.7	Q1
3	<i>Medical Education</i>	132 (2.51)	7.1	Q1
4	<i>Journal of Surgical Education</i>	66 (1.25)	2.9	Q2
5	<i>Academic Medicine</i>	64 (1.21)	7.4	Q1
6	<i>Patient Education and Counseling</i>	64 (1.21)	3.5	Q2
7	<i>Advances in Health Sciences Education</i>	60 (1.14)	4.0	Q1
8	<i>American Journal of Pharmaceutical Education</i>	59 (1.12)	3.3	Q2
9	<i>PLoS One</i>	59 (1.12)	3.7	Q2
10	<i>Nurse Education Today</i>	56 (1.06)	3.9	Q1

^aIF: impact factor.

Table 2. Top 10 journals with the highest number of cocitations. Cocited journals refer to 2 or more journals that are simultaneously cited in the reference lists of other research papers.

Rank	Cited journals	Cocitations, n	IF ^a (2020)	Quartile in category
1	<i>Medical Education</i>	1868	4.7	Q1
2	<i>Academic Medicine</i>	1775	7.4	Q1
3	<i>Medical Teacher</i>	1597	4.7	Q1
4	<i>BMC Medical Education</i>	941	3.6	Q1
5	<i>JAMA—Journal of American Medical Association</i>	931	120.7	Q1
6	<i>British Medical Journal</i>	827	107.7	Q1
7	<i>Advances in Health Sciences Education</i>	802	4.0	Q1
8	<i>The Lancet</i>	697	168.9	Q1
9	<i>New England Journal of Medicine</i>	694	158.5	Q1
10	<i>Teaching and Learning Medicine</i>	599	2.5	Q3

^aIF: impact factor.

Authors and Cocited Authors' Contributions

Among all authors who have published literature related to OSCE, [Tables 3](#) and [4](#) list the top 10 authors with the most published papers. Together, these top 10 authors have published 185 papers, accounting for 3.51% of all papers (N=5268) in the field. Sondra Zabar has 26 publications, which is the highest number of published research papers, followed by Debra Pugh with 22, Timothy J Wood with 20, and Susan Humphrey-Murto with 19. Further analysis indicates that among the top 10 ranked

authors, 4 are from the United States, 3 are from Canada, 2 are from Australia, and 1 is from China. CiteSpace visualizes the network of relationships between authors ([Figure 4](#)).

[Table 4](#) displays the top 10 authors who have been cocited and cited the most, respectively. A total of 148 authors have been cited more than 50 times, indicating that their research has a high reputation and influence. The largest nodes are associated with the authors who have been cocited the most, including Ronald M Harden with 751 citations, Brian D Hodges with 330 citations, and George E Miller with 222 citations.

Table 3. Top 10 most productive authors.

Rank	Authors	Papers, n	Locations
1	Zabar, Sondra	26	United States
2	Pugh, Debra	22	Canada
3	Wood, Timothy J	20	Canada
4	Humphrey-Murto, Susan	19	Canada
5	Gillespie, Colleen	17	United States
6	Shulruf, Boaz	17	Australia
7	Yang, Ying-Ying	17	China
8	Durning, Steven J	16	United States
9	Fuller, Richard	16	Australia
10	Park, Yoon Soo	15	United States

Table 4. Top 10 most cocited authors.

Rank	Cocited authors	Citations, n

Figure 4. Network diagram of author collaborations. The bubble size represents the number of publications.

Analysis of Highly Cited References

Over the time span from 2004 to 2023, the cocitation network comprised 1053 nodes and 3508 links (Figure 5). According to the top 10 papers by cocitation frequency (Table 5), the most cocited reference is from the journal *Advances in Medical Education and Practice* (impact factor=2.0), titled “An

evaluative study of Objective Structured Clinical Examination (OSCE): students and examiners perspectives” [12]. The first author of this paper is Md Anwarul Azim Majumder. The paper posits that OSCE is the gold standard and universal form for assessing medical students’ clinical competence in a comprehensive, reliable, and effective manner.

Figure 5. Network diagram of cocited references.

Table 5. Top 10 highest cited references.

Rank	Titles	Journals	IF ^a (2021)	First authors	Total citations, n
1	An evaluative study of Objective Structured Clinical Examination (OSCE): students and examiners perspectives [12]	<i>Advances in Medical Education and Practice</i>	2.0	Majumder, Md Anwarul Azim	38

Keyword Analysis

Through the analysis of keywords, we can quickly understand the situation and development direction of a field. Based on the

co-occurrence of keywords in VOSviewer, the hottest keyword is “education” (n=677 occurrences), followed by “performance” (n=536), “competence” (n=458), and “skills” (n=449; Table 6).

Table 6. Top 20 keywords co-occurrence frequencies.

Rank	Keywords	Co-occurrences, n
1	Education	677
2	Performance	536
3	Competence	458
4	Skills	449
5	Reliability	371
6	Assessment	342
7	Students	337
8	Validity	329
9	Simulation	284
10	Medical education	264
11	Diagnosis	228
12	Care	217
13	Prevalence	207
14	Medical students	197
15	Management	196
16	Medical education	171
17	Curriculum	168
18	Communication	161
19	Impact	156
20	Clinical skills	147

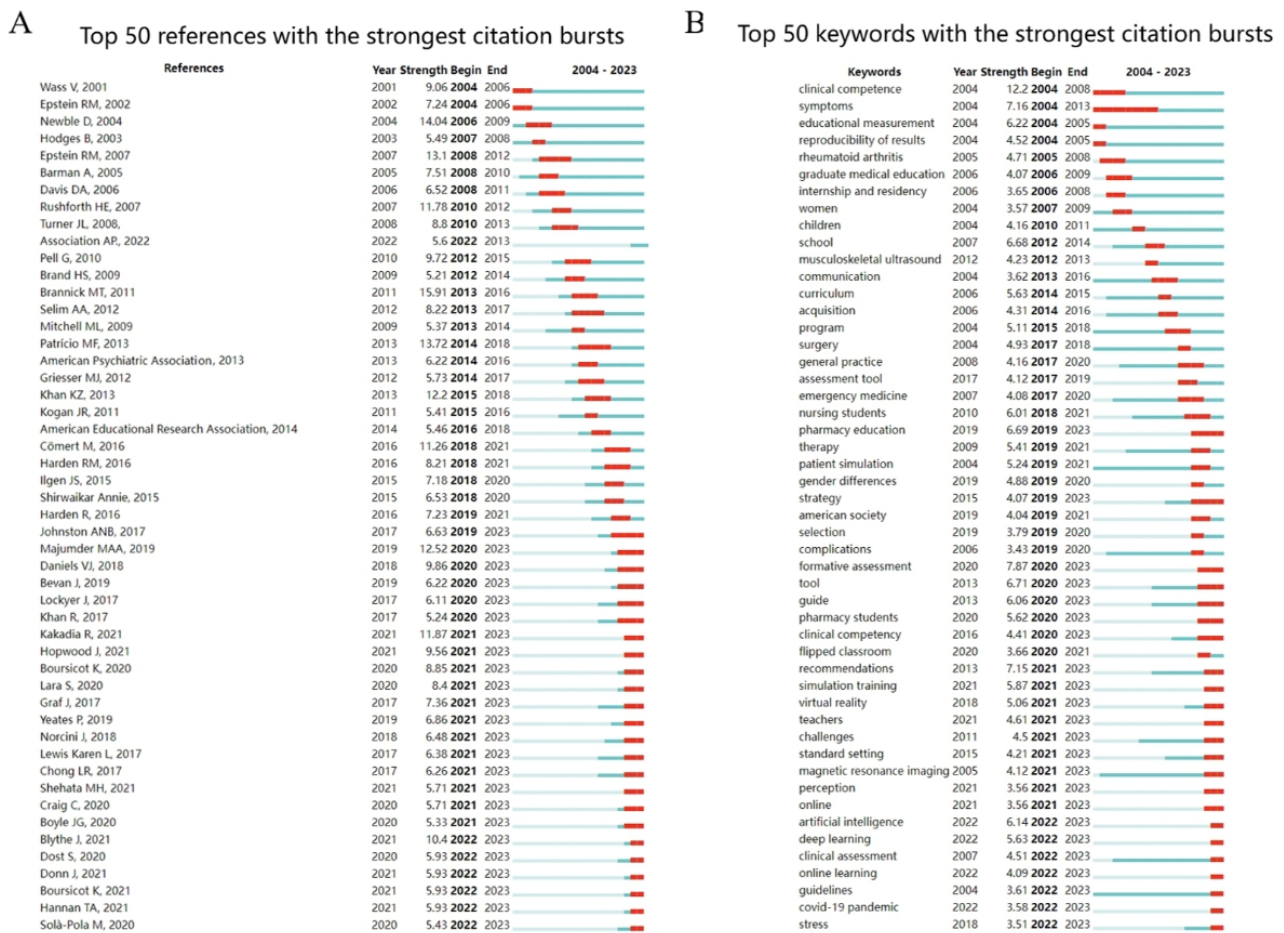

The Burst of Cited References and Keywords

With CiteSpace, we identified 50 of the most reliable citation bursts in the field related to OSCE [12,13,15-62]. The most frequently cited reference, with a burst strength of 15.91, is a paper published in *Medical Education* titled “A systematic review of the reliability of Objective Structured Clinical Examination scores” [15], whose first author is Michael T Brannick. The paper suggests that OSCEs consist of a series of simulated tasks to assess medical practitioners’ skills in

diagnosing and treating patients. Of the 50 references, 47 (94%) were published between 2004 and 2023, indicating that these papers have been frequently cited over nearly 20 years. Notably, 24 of these papers are currently at a citation peak (Figure 6A [12,13,15-62]), meaning that research related to OSCE is expected to continue receiving significant attention in the future.

Among the 768 strongest emerging keywords in the field, we focused on the 50 with the most significant surges (Figure 6B), representing the current hotspots in the field and likely future research directions.

Figure 6. Citation burst graph (A), and keyword burst graph (B; sorted by the beginning year of the burst). The blue bars mean the reference has been published; the red bars mean citation burstness.

Discussion

Principal Findings

This study is pioneering in its bibliometric approach to OSCE, encapsulating a comprehensive view of the dynamic research trends in this field. By analyzing the bibliometric data internationally, we have mapped out collaboration networks, identified prevailing research directions, and forecasted potential future developments in OSCE scholarship. The surge in OSCE-related publications since 2019 underscores the recognition of OSCEs as essential for evaluating health care practitioners, meeting the demands of modern medicine for more robust and comprehensive assessment methods to gauge clinical competency [22,63].

Despite this growth, the concentration of research output in countries like the United States, the United Kingdom, and Canada may reflect deeper issues of resource allocation and priority setting in medical education globally [64,65]. This suggests a need for a more nuanced discussion on the uneven geographical spread of OSCE research and its implications. The disparity in research contribution could hinder the global exchange of innovative practices and perspectives in medical education [66,67].

Furthermore, the bibliometric data point to the importance of technology in OSCEs, particularly the integration of virtual and augmented reality. However, to fully understand the implications of technological advances, a more detailed analysis is warranted. This should include how technology shapes the development of OSCEs, its impact on the validity and reliability of assessments, and the potential barriers to its widespread adoption [68-70].

The high concentration of publications in Q1 and Q2 quartile journals, especially those with a significant impact factor, attests to the intersection of OSCE research with impactful clinical education and outcomes. The association with prestigious journals underlines the extensive influence and critical importance of OSCEs across multiple medical specialties [71-73].

The prominence of a core group of scholars leading OSCE research suggests a centralization of expertise that could be diversified through broader international collaboration. Such collaboration could introduce various cultural and pedagogical perspectives into the OSCE discourse, thereby enriching both the practice and the research of OSCEs worldwide [74,75].

The keyword analysis reflects a continual focus on the foundational elements of clinical education, such as “education,” “performance,” “competence,” and “skills,” which are at the heart of the OSCE methodology. Emerging research trends

suggest a shift toward the integration of innovative educational technologies and methodologies, enhancing both the OSCE process and its outcomes [76,77].

Comparison to the Literature

Our findings align with those of Lim et al [78], who identified issues with construct, content, and predictive validity in OSCEs in pharmacy education, as well as significant resource challenges. These concerns are echoed in our analysis, where similar validity issues and logistical constraints were observed. Other studies, such as those by Hodges et al [79], have highlighted persistent challenges in psychiatric OSCEs, emphasizing the need for continuous refinement and adaptation. Our study extends these discussions by mapping global trends and collaboration networks, underscoring the necessity for continuous re-evaluation and innovation in OSCE methodologies.

Implications of Findings

The challenges associated with OSCEs suggest a need for evolving assessment methods that incorporate simulations, peer assessments, and reflective practices. The resource-intensive nature of OSCEs underscores the necessity for scalable and sustainable alternatives, such as virtual simulations. Policymakers and educators should leverage global collaboration networks to share best practices and develop adaptable, technology-enhanced assessment frameworks. This approach will help address validity concerns and logistical constraints, ensuring that educational assessments remain robust and relevant in the ever-evolving landscape of health care education.

Limitations

Our bibliometric analysis has limitations that may affect our findings. We only used data from the WoSCC database,

potentially excluding studies not indexed there and leading to bias toward English-language literature. This limits the scope of our analysis and overlooks valuable contributions from non-English sources.

Suggestions

To address this, future research should involve a wider range of databases and languages [80,81]. Moreover, the data quality in our study may vary, affecting the credibility of our knowledge mapping. Therefore, caution is needed when interpreting results, and complementary research methods should be considered for a more comprehensive understanding of the field. Longitudinal studies are crucial to assess the impact of OSCEs on medical performance, connecting educational assessments with clinical practice and patient care [82,83].

Moreover, understanding how OSCEs adapt to different health care systems, cultural contexts, and specializations will provide insights into their scalability and adaptability. This is particularly relevant as the health care sector grapples with rapid changes and as medical education seeks to prepare health care professionals for diverse practice environments [19,84].

Conclusions

In conclusion, this bibliometric study not only reaffirms the enduring importance and evolutionary path of OSCEs within medical education but also emphasizes the need for OSCEs to evolve in step with broader health care transformations. The data-driven insights from this analysis should inform future research directions, influence policymaking, and refine educational strategies. By doing so, OSCEs can continue to serve as a dynamic, relevant, and innovative tool in the arsenal of clinical education and evaluation methods.

Data Availability

All data generated or analyzed during this study are included in this published article.

Authors' Contributions

HB conceived and designed the ideas for the paper. HB, LZ, XH, and SL participated in all data collection and processing. HB was the major contributor in organizing records and drafting the manuscript. All authors proofread and approved the manuscript.

Abstract

Background: Current challenges in patient care have increased research on technology use in nursing and health care. Digital assistive technologies (DATs) are one option that can be incorporated into care processes. However, how the application of DATs should be introduced to nurses and care professionals must be clarified. No structured and effective education concepts for the patient-oriented integration of DATs in the nursing sector are currently available.

Objective: This study aims to examine how a structured and guided integration and education concept, herein termed the sensitization, evaluative introduction, qualification, and implementation (SEQI) education concept, can support the integration of DATs into nursing practices.

Methods: This study used an explanatory, sequential study design with a mixed methods approach. The SEQI intervention was run in 26 long-term care facilities oriented toward older adults in Germany after a 5-day training course in each. The participating care professionals were asked to test 1 of 6 DATs in real-world practice over 3 days. Surveys (n=112) were then administered that recorded the intention to use DATs at 3 measurement points, and guided qualitative interviews with care professionals (n=12) were conducted to evaluate the learning concepts and effects of the intervention.

Results: As this was a pilot study, no sample size calculation was carried out, and *P* values were not reported. The participating care professionals were generally willing to integrate DATs—as an additional resource—into nursing processes even before the 4-stage SEQI intervention was presented. However, the intervention provided additional background knowledge and sensitized care professionals to the digital transformation, enabling them to evaluate how DATs fit in the health care sector, what qualifies these technologies for correct application, and what promotes their use. The care professionals expressed specific ideas and requirements for both technology-related education concepts and nursing DATs.

Conclusions: Actively matching technical support, physical limitations, and patients' needs is crucial when selecting DATs and integrating them into nursing processes. To this end, using a structured process such as SEQI that strengthens care professionals' ability to integrate DATs can help improve the benefits of such technology in the health care setting. Practical, application-oriented learning can promote the long-term implementation of DATs.

KEYWORDS

digital assistive technologies; education concept; intention to use; learning effects; digital transformation

Introduction

Background

Digital assistive technologies (DATs) offer novel possibilities for nursing and health care. Therefore, health care institutions must determine how to successfully implement digitization and adapt to the digital transformation in the health sector. Requirements include strategic planning, governing, organizing, controlling, orchestrating, and training technology-intensive processes and services. Therefore, developing competencies among care professionals is necessary. Providing extra education on this topic will help care professionals appropriately implement and integrate DATs—as an additional resource—into their professional practices.

As no structured education concept for the implementation of DATs in nursing care currently exists, this study developed the sensitization, evaluative introduction, qualification, and implementation (SEIQI) education concept. It then evaluated how the implementation of the 4-stage SEIQI benefited nursing care by measuring the changes in care professionals' intention to use DATs in long-term care facilities after its implementation. Long-term care facilities often fail to implement DATs because users have only a brief opportunity to familiarize themselves with and apply such technology. The population of interest for this study was defined as individuals trained and registered in a health or social profession who had worked in long-term inpatient facilities (care professionals). While the initial intention was to study only registered nurses as a target group, it quickly became apparent that this specification was an unrealistic inclusion criterion in current care practice. The care situation demonstrates that, in addition to nurses, other health care professionals, such as care assistants, nursing assistants, social workers, and physiotherapists, also provide a significant amount of care. It is evident that these individuals benefit equally from the implemented educational approach and, as a result, should not be excluded. In this study, a sample of care professionals from 26 long-term care facilities in Germany were examined using a mixed methods approach to understand changes in their intention to use DATs after the SEIQI intervention. This study fills a gap in the literature by closely monitoring and evaluating the implementation of DATs using a structured approach.

Worldwide, health care systems are responding to the pressure created by increasing demand for care and the digital transformation of the health care sector [1,2]. Notably, DATs offer novel opportunities for promoting the independence and participation of older adults in long-term care [3] and improving their quality of life [4]. DATs can facilitate a range of activities associated with daily living, including smart medication management, digitally assisted fall prevention, and communication. DATs represent an evolution of assistive technologies that have been enhanced with digital capabilities [5]. Heinemann and Matusiewicz [6] pointed out that the digital transformation of health care and use of DATs can also be an opportunity to address the health care crisis. The term *health care crisis* is used to describe a phenomenon that has now affected many countries regardless of the structure of their social security systems, which all vary considerably yet are facing

similar crises. These include an aging population, falling birth rates, increasing care needs, social isolation, declining social support networks, a shortage of nursing staff, and so on. The use of DATs is expected to benefit patients, care professionals, physicians, and health care organizations. Nursing care professionals are the leading user group among health care professionals; however, DATs can only be beneficial if care professionals accept and use them.

Some studies have discussed the use of DATs to support care professionals [7] in acquiring transformative competencies [8] and the relevant technological knowledge [9,10]. Care professionals' expertise can reduce the risk of developing impractical and ill-suited technologies [2,11,12]. Thus, to realize DATs' full potential, tailored solutions that address functional limitations are necessary, and DATs' use should be preplanned and problem oriented. Research has established that systems intended for patient interactions, such as those that primarily support individuals in their activities of daily living (ADLs), should be the focus of DAT developments [5] as ADL assistance and support are frequent targets of nursing care. Therefore, it is important to take a differentiated look at the topic of robotics in nursing and, in addition to the technical shortcomings, examine other reasons why colleagues are not yet using robots in nursing care to the extent required. The question arises as to how DATs can be classified in the existing system of support for carers. This research focuses on systems to be used in direct patient interactions to support those affected, for example, in such ADLs as communication, self-feeding, and mobility. The targeted use for each application then has an assistive, supporting character and, therefore, is not new for care professionals.

According to the World Health Organization, *assistive technology* is an umbrella term that includes all adaptive and rehabilitative devices for supporting people with health impairments as well as their selection and use [13,14]. Assistive technologies have expanded to include a digital component that makes it possible to improve quality of life and opportunities for participation by promoting greater independence. Support always occurs when people can complete tasks and perform movements that would otherwise be difficult without technical support. At the same time, DATs reduce the need for formal health, support, and long-term care services by providing dependent care when self-care is no longer fully possible due to limitations.

An educated and trained use of DATs has the potential to reduce the high workload of nursing staff and other health care professionals.

Usability refers to the context-sensitive, application-oriented, and effective relationship between people and technology [15]. The lack of usability and implementation strategies for new technologies frequently results in unsuccessful implementation [16]. The most frequent causes of these failures are the lack of fundamental knowledge of the availability of DATs and poor understanding of their possible uses [9]. To date, innovative nursing technologies, such as those designed to prevent pressure ulcers and falls, provide supportive care for diabetes mellitus, address disorientation, and have predominantly been used as

unconnected individual solutions on a person-by-person basis. To implement these technologies more broadly, the willingness of health care professionals to use them, as well as their actual use of such technology, must be analyzed. Providing opportunities to learn about the digitization of care approaches in the digital transformation era is also necessary.

Education on DATs that offers practical and actionable interpretations that help users better understand and use DATs in their daily practice should be provided to caregivers, care professionals, and health care professionals, which will ultimately lead to better care outcomes [17]. These interpretations are not directly applicable to caring practice. For practicality, arguments need to be transformed and excluded from their social scientific identity; they can then be reconstructed based on practice conditions in a way that is relevant and applicable to the practical situation. Doing so involves translating theoretical concepts and knowledge into practical actions that can be implemented in real-world situations. The transformation of theoretical knowledge into practical applications is an important component of any education approach aimed at integrating DATs into caregiving practices [17]. No theory-guided education concepts introducing DATs have been developed yet. Despite the identification of numerous challenges, strategies for the sound implementation of technology in nursing care can be formulated. These strategies should include training on digital skills [18], and the creation of a positive attitude among health professionals toward technology is essential. Nadav et al [19] argue that this can be achieved through the extensive introduction of professionals to technology operation. Albrecht et al [20] propose that this should be accompanied by a positive attitude toward technology. Therefore, understanding the factors influencing users' intention to use DATs is key to ensuring the optimal integration of DATs within the health care system and achieving measurable benefits. A review of the German health care system (in which this study is also situated) reveals that surveys indicate a positive, open-minded, and inquisitive attitude toward new technologies among care professionals. For instance, one study demonstrated that care professionals tend to embrace DATs and perceive them as beneficial and user-friendly [21]. Conversely, respondents exhibited a more reserved attitude toward the use of robotics, with negative expectations of its use being more frequently expressed [21].

To address this issue, we propose a model based on the extended Technology Usage Inventory (TUI) to explore how users' technology readiness and perceptions of DATs influence their intention to use them. This study's results improved our understanding of caregivers and care professionals' intention to use DATs and contributed to innovative research on the adoption of such technology. The proposed 4-stage SEQI is a novel education concept introduced as a form of learning. Its "evaluative introduction" and "implementation" stages are influenced by previous work [9]. *Evaluative introduction* refers to acquiring the competencies to assess whether DATs are suitable for addressing a functional nursing problem. *Implementation* is defined as on-site testing over a longer period in real use conditions. *Sensitization* means becoming aware of the digital transformation. *Qualification* is defined as the

proficiency and expertise that individuals acquire to operate and use DATs in the given care context effectively and confidently. In summary, this mixed methods study examined whether a structured and guided education concept (ie, SEQI) can change care professionals' intention to use DATs. The changes in intention to use and learning effects were captured through a quantitative survey of 112 care professionals. This study also evaluated the learning effects of the SEQI intervention based on guided interviews with 12 care professionals.

Intention to Use DATs

In the health care context, previous studies have applied the technology acceptance model (TAM) and TAM 2 to explore acceptance and examine physicians' [22-24] and nurses' [25-29] intention to use DATs. Those studies have revealed nurses [30] and nursing care students' intention to accept health care technologies [9,11,31,32]. Theories have conceptualized those factors (ie, barriers and facilitators) that influence the outcomes of implementation efforts spanning both generalized theory building and the development of practical approaches [33]. In particular, previous studies have found that user training and technology acceptance are key factors to successful implementation [33-35]. However, technical specifications and standards cannot simply be transferred to professional nursing from other fields [5]. The practical application of DATs or even the intention to use DATs is also significantly influenced by factors such as usability, usefulness, accessibility, and immersion; these factors are assessed using the TAM. Furthermore, psychological factors that affect the actual use of technology include acceptance, which is determined by personal attitudes such as curiosity, fear of technology, skepticism, and social norms [36], meaning that the individual characteristics of care professionals determine their intention to use DATs.

The acquisition of digital skills is essential for addressing the psychological factors that affect intention to use. The US health care system has slowly evolved from a system built on episodic and ambulatory in-person encounters to one that is digitally based, technology rich, and data informed [37]. The practical use of DATs requires an understanding of not only how to use them but also what opportunities and possibilities they offer for a customized and problem-oriented use in nursing care [37,38]. To achieve this, digital skills must be integrated more strongly into nursing curricula [2,12,39,40] and then expanded through advanced training and further education in later professional life. The nursing profession, for example, is facing a crisis in its education pipeline and professional development. Traditionally, formal health care education and the postgraduate novice-to-expert continuum have not emphasized technology and informatics as integral components of nursing [37]. Hence, solutions that enhance educational pathways should be explored, allowing care professionals to effectively practice in today's health care environment under the digital transformation. It is helpful to distinguish the term *digitization* from the term *digital transformation*. *Digitization* describes a technical concept that includes software programs, corresponding hardware, and the translation of analog values into bits and bytes, whereas the term *digital transformation* generally describes changes that also relate to the values, attitudes, and mindsets of the professional groups concerned [41,42]. Targeted education

programs should provide care professionals with the tools necessary for their profession, including the available DATs and their possible applications, as well as reflective competencies to evaluate and adapt these DATs for practical use in nursing. When properly used, DATs can provide opportunities for relief from providing care [29,33].

While implementing the SEQI education concept, researching and testing a possible education approach to introduce care professionals in long-term care to DATs was challenging. To develop a transformative implementation concept for DATs in the long-term care field, it was necessary to test care professionals' understanding of DATs. The overarching project goal was to increase both care professionals' intention to use DATs and, simultaneously, obtain their assessment of the practicality of the SEQI education concept. Currently available DATs are already an additional resource shaping the digital transformation of nursing processes. However, it was important for care professionals to understand the need to fit a specific DAT to a patient's physical (functional) limitation or relevant care problem. Furthermore, initiating reflection and discussion among care professionals was crucial. As such, the following project goals were highlighted:

1. Focus on further education on DATs in real-world working conditions
2. Link theoretical and practical knowledge (theory-practice transfer)
3. Test currently available DATs
4. Focus on care professionals' acquisition of knowledge and competencies
5. Build on care professionals' expertise, knowledge, and learning habits
6. Improve practical testing experience to reduce uncertainty
7. Prepare for the digital transformation in the health care sector

Theoretical Framework

Changes in professional, technical, and organizational conditions often lead to shifts in employees' competencies or even require new competencies. The potential to sustainably change professional requirements, tasks, activities, and job profiles is a factor in the digital transformation of workplaces. In this situation, requirements for health care professionals' competencies should also be evaluated. For example, the German Ethics Council calls for curricula to be supplemented to include new nursing techniques, including their ethical implications [12], to ensure the continuing education of care professionals. While transformative learning on how to manage the digital transformation of the health care sector is scarce, there is a great deal of interest in DATs as part of this transformation. Hence, the demand for professionals to acquire expertise in the field is increasing [9,43]. Thus, creating structured guidance to introduce care professionals to the use of DATs in nursing processes and planning is sensible. The theoretical considerations of transformative learning [44,45] provide a suitable framework for developing this type of guidance.

Beginning with the concept of lifelong learning [46], transformative learning allows earlier experiences to be

reinterpreted and re-evaluated through the lens of experience-based assumptions and attitudes. Developing new perspectives through the dynamics of learning (intentional, intuitive learning) embedded in a problem-solving process is a focus of the concept [8,44,45,47]. This learning initiates a process of transformation, that is, the development of new perspectives on previously unquestionable attributions of meaning [8,47]. Care professionals can then embed the abstract construct of the digital transformation into their own experiences and reflect on it both as a starting point and as an end point for integrating technology into nursing processes [9]. By drawing on existing and experience-based knowledge, the possible applications for currently available DATs can be better assessed. The precise and solution-oriented use of currently available DATs as well as the development of new and innovative DATs offer great potential for defining nursing care problems both now and in the future.

Problem Statement and Study Objectives

Overview

Despite the potential benefits of DATs in improving health care, their integration into nursing practices remains underdeveloped. The principal challenge is the absence of structured and efficacious educational methodologies that facilitate the patient-oriented integration of DATs in the nursing sector. The implementation of DATs is frequently impeded by the limited opportunities available to care professionals to become acquainted with and use these technologies effectively in actual clinical settings. This gap underscores the necessity for a comprehensive educational framework to guide the integration process.

Research Gap and Objectives

This study addressed the critical need for a structured approach to the education on and integration of DATs into nursing practices. The SEQI education concept was developed with the objective of providing a structured approach to support care professionals in understanding, adopting, and effectively using DATs. The objective of this study was 2-fold: first, to evaluate the impact of the SEQI education concept on care professionals' intention to use DATs and, second, to assess the practical application and learning effects of this intervention in long-term care facilities.

Research Question

The primary research question guiding this study was as follows: how does the structured SEQI education concept affect care professionals' intention to use DATs in long-term care settings?

A Priori Hypotheses

The first hypothesis was as follows: the implementation of the SEQI education concept is expected to significantly increase care professionals' intention to use DATs.

The second hypothesis was as follows: care professionals who undergo the SEQI intervention will demonstrate enhanced understanding and practical application of DATs, leading to an improved theory-to-practice transfer of DATs.

This study aimed to provide a validated educational framework that can be widely adopted to facilitate the digital transformation in nursing and health care, ensuring that care professionals are well equipped to leverage DATs in their daily practices.

Methods

Overview

This mixed methods study used a combination of qualitative and quantitative data collection methods. The sequential explanatory design facilitates the determination of which quantitative results require further elucidation [48]. The sequential explanatory design with mixed methods comprises 2 distinct phases: a quantitative phase and a qualitative phase. The researcher initiates the study with a quantitative phase, which is followed by a second qualitative phase. The purpose of this second phase is to provide a more in-depth explanation of the initial results [48]. This research and development project ran from September 2019 to September 2022. It began with the question of what multimodal, transformative learning concepts presented in a structured manner could aid the digital transformation in the health care sector and encourage the use of DATs by health care professionals. It is recommended to understand multimodal educational offerings on DAT should present caregivers with a variety of approaches to addressing and thematically dealing with the topic. To ensure methodological quality, the Good Reporting of a Mixed Methods Study checklist [49] and the Mixed Methods Appraisal Tool [50] were used. The analysis of the in-depth interviews served to ascertain the needs and requirements of caregivers regarding an educational concept, thereby enabling the development of an intention to use DATs in the first place. This process of “connecting” the qualitative and quantitative phases was achieved through the sampling design. At the same time, the subject areas and subjects identified in the analysis of the interviews were used to estimate the dimensions and indicators of the results derived from the TUI questionnaire used in the quantitative part of the study. As noted previously, this study’s primary objective was to determine changes in the intention to use DATs. The secondary objective was to assess the learning effects following the principles of data triangulation [51,52].

Survey Development

For the quantitative part of the study, a survey was conducted at 3 measurement points (T0, T1, and T2) at the end of stages 1, 2, and 4 of the SEQI education concept. The survey was developed using the TUI, a valid measurement instrument based on the TAM [36,53,54] that was created to evaluate the intention to use specific technologies by identifying factors that play a role in the technology adoption decision. Its basis is the theory of reasoned action, which holds that attitudes and behaviors are closely connected. Therefore, the behavioral intention to use a certain technology is determined by a person’s attitudes and social norms.

According to Kothgassner et al [36], the TUI distinguishes 3 main factors that affect technology acceptance and, thus, predict the actual use of technology: perceived usefulness, perceived ease of use, and attitude toward use. Perceived usefulness is defined as the subjectively perceived likelihood of improving

performance by using a technology, whereas perceived ease of use is defined as the degree to which a product, system, or interface is designed and structured in a way that allows users to interact with it comfortably, intuitively, and with minimal effort. It encompasses elements such as user-friendly design, simplicity, and the overall accessibility of the system, contributing to a positive and efficient user experience. Both perceived usefulness and perceived ease of use directly influence an individual’s attitudes toward using a technology, which then directly affect their behavioral intention to use and, thus, their actual use of that technology [36].

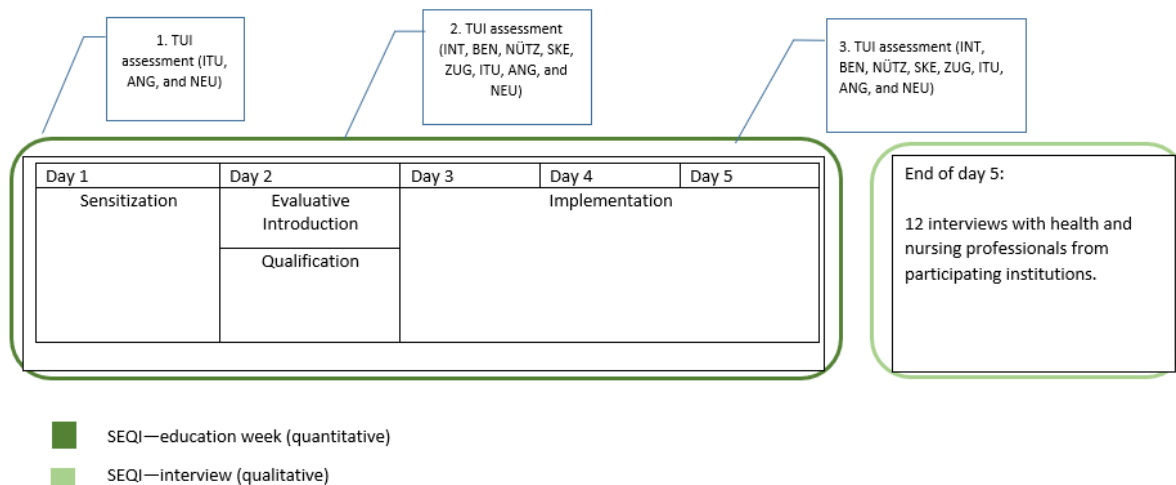

The TUI consists of 30 items divided into 8 subscales. Of these subscales, 5 (curiosity, fear of technology, interest, immersion, and skepticism) have 4 items, whereas the accessibility, usability, and usefulness subscales each have 3 items. In this study, we adopted 7 of these subscales for our analysis: curiosity, fear of technology, interest, skepticism, accessibility, usability, and usefulness [36].

Implementation of the SEQI: 5-Day Training Course

The 4-stage SEQI education concept was implemented in 26 long-term care facilities across the state of Saxony-Anhalt in Germany. For recruitment, a list of all long-term inpatient facilities in Saxony-Anhalt was made available by the discharge management of the University Hospital Halle (Saale). The list contained a total of 446 long-term inpatient facilities distributed across the state of Saxony-Anhalt. All facilities with a minimum occupancy of 50 beds (ie, 225/446, 50.4% of the facilities) were contacted and asked about their willingness to participate. In total, 26 facilities consented to participate in the study and were subsequently recruited. A total of 5 care professionals participated in each of the 26 training courses. On day 1 (sensitization), a workshop was used to sensitize and introduce participants to the digital transformation in health care and DATs. On day 2 (evaluative introduction), case vignettes and real-world nursing situations were discussed, and the care professionals selected a DAT based on the needs assessments of their patients. In addition, on day 2 (qualification), training was given on the proper use of the DATs. On days 3 to 5 (implementation), the selected DAT to be tested in the facilities was introduced.

This multistage structure of the SEQI education approach helped meet the core objective of this study, which was to raise awareness among care professionals of the digital transformation in health care and convey the use of DATs as a possible resource when planning nursing processes as this approach allowed for sufficient time for processing the extensive information provided in the 4 stages. Therefore, this training approach met care professionals’ desire for transparent information and training on new technologies.

In total, 2 researchers from the project team, a technician, and a nursing care researcher led the 5-day training course. Participants received additional informational material about the overall project and each DAT (see the next subsection). They were informed that they could contact the study team by telephone or email at any time during the trial period if they had any questions. Figure 1 shows the time frame of the SEQI intervention.

Figure 1. A schematic timeline of the sensitization, evaluative introduction, qualification, and implementation (SEIQ) process.**Legend:**

ANG: fear of technology (Technologieängstlichkeit); BEN: ease of use (Benutzerfreundlichkeit); INT: interest (Interesse); ITU: intention to use (Nutzenabsicht); NEU: curiosity (Neugierde); NÜTZ: usefulness (Nützlichkeit); SKE: scepticism (Skepsis); TUI: Technology Usage Inventory; ZUG: accessibility (Zugänglichkeit).

Included DATs

The Assessment Instrument for Determining Care Dependency (BI) describes 8 modules [55-57]. In this study, these modules were understood as areas of care dependency within which specific nursing problems and a corresponding DAT assigned to achieve a defined nursing goal could be used [57]. On the basis of the assessment of the actual needs of the patients they were caring for, care professionals selected a suitable DAT. Six currently available DATs for use in long-term care facilities were selected:

1. A noninvasive sensor (DFree) that uses an app to determine bladder capacity and informs the user about the right time to go to the toilet [58]
2. A total of 2 robotic technologies belonging to the “social robotics” field (PARO and Pleo) [59,60]
3. A passive exoskeleton for relieving physical strain during demanding care tasks [61]
4. A mobile telepresence system with a self-balancing wheel and display for videoconferences [62,63]
5. Virtual reality applications for stress reduction and mindfulness [64]
6. A total of 2 communication robots for interaction using voice control and speech output (Pepper and Nao robots) [65]

Assessment of the Change in the Intention to Use DATs

The TUI allows for inferences about the intention to use specific technologies [36], whereas other subscales assess the actual use of a technology (electronic supplement in [Multimedia Appendix 1](#) and measurement time and instruments in [Multimedia Appendix 2](#)). The 3 measurements were taken at the beginning of the intervention (T0), the end of day 2 (T1), and the end of the intervention (T2). Thereafter, participants evaluated their experience with the DAT and the educational intervention. The data analyses were conducted by health and nursing scientists (MZ and CB) and a colleague from the technical team (DB).

Assessment of the Learning Effects

A total of 12 guided interviews were conducted through theoretical sampling. The interviews were analyzed using systematic text condensation (STC) based on the work by Malterud [66,67]. The STC scheme, as proposed by Malterud [66,67], requires a structured approach to qualitative data analysis. This approach entails a bottom-up categorization process implemented inductively and, thus, hinges on a transparent and systematic methodology. This method begins with a comprehensive reading of the data to gain an overall impression followed by the identification of meaning units that relate to the research question. Subsequently, the meaning units are systematically coded into groups. These groups are then condensed, whereby the content is abstracted into a few comprehensive categories while the integrity of the original data is maintained. In conclusion, the essence of each category is synthesized into a theme or topic, thereby providing a clear and structured understanding of the data. This process guarantees that the analysis remains firmly anchored in the participants’ perspectives while enabling the formulation of meaningful interpretations.

Guided Interviews

For the qualitative part of the study, 12 health care professionals participated in guided interviews. A total of 12 interviewees was deemed to be sufficient for facilitating an intensive data analysis, providing deeper insights, and achieving data saturation considering the resource constraints and research objectives. Interviewees were selected using convenience sampling. Statistical representativeness was not sought; rather, the interviews aimed to gather the specific knowledge necessary to understand participants’ assessment of the SEIQ education concept.

The interviews were conducted after the SEIQ intervention in 46% (12/26) of the participating long-term care facilities. In every second facility, the participating care professionals were

asked whether one from the group would volunteer to be interviewed. The interviews were useful for obtaining both practically relevant background knowledge on the implementation of the SEQI education concept and guidance during the practical presentation of the research results [68]. The interviews focused on the meaningful, planned, and systematic integration of DATs into nursing processes from care professionals' perspectives.

The interview guidelines were developed iteratively based on the SPSS method described by Helfferich [69]. The interviews were recorded and transcribed verbatim. The discussions were centered on the pivotal question of the suitability of the SEQI education approach for health care practice. The objective was to examine the concept in the context of the 5-day practical trial, identify potential improvements from a practical perspective, and enhance the content of the concept. The interviews were conducted by a health and nursing scientist (SH and BK) and a colleague from the technical team (DB and CK). The interviews were coded and documented independently by 3 members of the research team (SH, BK, and AW). The objective of data saturation was not initially established. The practical implementation of the saturation principle is contingent upon the availability of a somewhat larger sample and the flexibility to determine the number of interviews conducted. In this case, the sample size was not predetermined; rather, interviews were conducted until no new information or categories were added to the existing information or categories. In the pilot study, data saturation was not reached due to the project team's awareness that data saturation is rarely achievable with regard to the comprehensive subject of the research. Instead, the interviews were to take into account the criterion of "internal representation," which replaces the criterion of representativeness as a quality criterion for samples [69]. Given the inherent difficulties in achieving high concordance between

coders, no effort was made to measure it. This is particularly the case in the first round of coding, which often leads to a revision of the category system. Therefore, the resulting data will depend heavily on the extent and differentiation of the category system developed. The data analysis followed the STC method determined by Malterud [66,67] using the MAXQDA analysis software (version 20.0.7; VERBI GmbH).

Ethical Considerations

The ethics committee of the Medical Faculty of Martin Luther University Halle-Wittenberg approved this study on April 14, 2021 (approval 2021-021). The study was registered in the German Clinical Trials Register (DRKS00024967), and the protocol has not been published. Informed consent was obtained from all participants. No reward was given for participation.

Results

Survey Findings

A total of 122 participants were sampled from the 26 participating long-term care facilities. Of the 122 questionnaires returned, 10 (8.2%) were excluded from the analysis because they had incomplete responses or failed to select the specific DAT necessary for evaluating the intention to use DATs. In 41% (50/122) of the questionnaires, missing data were imputed using mean values (individual values were also attributed for various items). This procedure was performed after previous statistical consultation. As a simple random sample was used, the chosen imputation method was sufficient and did not affect the results. However, both simple and multiple imputations were performed to eliminate potential sources of error. The imputations were found to have only a minimal impact on the results. Half (62/112, 55.4%) of the participants were aged >41 years (Table 1). Most of the participants (78/112, 69.6%) had <20 years of professional experience.

Table 1. Sample characteristics (N=112).

Characteristic	Participants, n (%)
Sex	
Female	87 (77.7)
Male	22 (19.6)
No answer	3 (2.7)
Qualification	
3-year duration of training	54 (48.2)
2-year duration of training	3 (2.7)
At least 1-year duration of training	6 (5.4)
Therapist (speech, occupational, or physiotherapy)	13 (11.6)
Social worker	17 (15.2)
Social or welfare worker	3 (2.7)
Other qualification	11 (9.8)
No answer	5 (4.5)

Intention to Use

Intention to use was scored using the selected 7 subscales of the TUI. The total score ranged from 0 to 300. High subscale scores indicated a high level of the corresponding construct, whereas low scores indicated a low level. The mean intention to use score was 232 (SD 55) out of 300 points at the beginning of the intervention (T0; Table 2) and remained at almost the same level throughout the intervention (T1 and T2).

No significance tests were conducted. Statements regarding significance were not necessary in this context because the trend was clear. Among the subscales, the participants were curious about DATs (21 out of 28 points), whereas their skepticism about DATs was low (13 out of 28 points; Table 3). In summary, the intention to use DATs and, thus, the predicted actual use of such technology in health care can be considered high.

Table 2. Results for the intention to use digital assistive technologies.

Time point	Scores, mean (SD)	Scores, median (IQR)
T0 ^a	232 (55)	241 (203-275)
T1 ^b	231 (66)	247 (208-280)
T2 ^c	227 (72)	250 (187-288)

^aT0: beginning of the intervention (n=111).

^bT1: end of day 2 (n=112).

^cT2: end of the intervention (n=112).

Table 3. Results for the intention to use digital assistive technologies by subscale.

	Score at T0 ^a		Score at T1 ^b		Score at T2 ^c	
	Mean (SD)	Median (IQR)	Mean (SD)	Median (IQR)	Mean (SD)	Median (IQR)
Curiosity ^d	21 (5)	22 (18-24)	21 (5)	21 (18-25)	20 (5)	21 (17-24)
Fear of technology ^d	13 (6)	12 (7-17)	9 (4)	8 (6-12)	10 (5)	8 (6-12)
Interest ^d	— ^e	—	21 (5)	22 (17-25)	21 (5)	22 (18-25)
Ease of use ^f	—	—	16 (4)	17 (14-19)	17 (4)	17 (14-20)
Usability ^d	—	—	20 (5)	21 (17-24)	19 (6)	20 (15-24)

Interview Findings

As detailed in the Methods section, 12 health care professionals participated in guided interviews. The analysis of the interview data produced 14 codes that were condensed into 4 conceptual themes related to the learning effects: evaluation of the education concept (theme 1), effects on work and care structures (theme 2), need for reflection and discussion (theme 3), and improvement potential for health care and nursing care practice (theme 4). The 14 codes are presented in detail in [Multimedia Appendix 3](#). Theme 1 describes the assessment of the SEQI education concept by health care professionals with a focus on the learning effects as SEQI focuses on training under real working conditions and, therefore, links theoretical and practical knowledge. Theme 2 addresses the impact of the education concept on work and care structures when using DATs. SEQI

encourages the recapitulation and re-evaluation of work processes and care activities. The possibility to test already available DATs makes this recapitulation more realistic as it allows for the examination of integration possibilities under real working conditions. Theme 3 represents a synthesis of the preceding 2 themes. Care professionals assess application scenarios and determine the interactions among patients, DATs, and health care professionals based on the SEQI education concept. This entails a focus on knowledge and competence acquisition as well as the determination of interactions among patients. The opportunity to learn in a group of colleagues aligns with nursing learning habits and the availability of nursing expertise and previous knowledge. Theme 4 addresses the necessity to expand the scope of education and educate other professional groups on the subject matter. In this context, the dearth of DATs that are specifically tailored to patients'

functional limitations was also discussed. Practical testing experience reduces uncertainties and helps estimate which DATs can be used by other health care-related occupational groups. It is preparation for the possibilities of digitized health care, although it became evidently clear that the currently available DATs lack usefulness and usability for nursing care. This approach appears to be beneficial as it allows for the assessment of DATs using nursing expertise and the redesign of DATs to better align with the specific needs of nursing care.

Discussion

Principal Findings

The qualitative and quantitative findings reflect both the positive and negative aspects of DATs. To facilitate a more nuanced

interpretation of the results, we will initially focus on the less complex quantitative survey data before subsequently turning our attention to the qualitative interview findings. This will facilitate the establishment of a clear link between the 2 sets of data. The survey results indicate that the reluctance of care professionals to implement DATs is not the primary cause of the issues that were identified. Rather, the perceived lack of usability and suitability was a significant contributing factor.

This mixed methods study was conducted to investigate the integration of DATs in nursing practices. This was achieved through the use of a structured education concept termed SEQI. [Textbox 1](#) summarizes the key findings and insights derived from the study.

Textbox 1. Representative findings.

- Willingness to integrate digital assistive technologies (DATs) in real-world working conditions. This study revealed that care professionals demonstrated a general willingness to integrate DATs into their nursing processes even before the implementation of the sensitization, evaluative introduction, qualification, and implementation (SEQI) intervention. This suggests that care professionals have a fundamental openness to adopting new technologies.
- Impact of the SEQI intervention. The SEQI intervention furnished care professionals with indispensable background knowledge and sensitized them to the digital transformation. The intervention enabled the participants to evaluate the suitability of DATs in health care settings more effectively, understand the qualifications required for their appropriate application, and identify factors that would facilitate their use and integration.
- Practical and application-oriented learning. This study underscored the significance of practical, application-oriented but structured learning in fostering the long-term integration of DATs. The SEQI approach proved effective in enhancing care professionals' understanding and acceptance of DATs.
- Requirements for technology-related education built on care professionals' expertise, knowledge, and learning habits. Care professionals learn to express specific ideas and requirements for technology-related care as well as education concepts. This feedback is crucial for developing effective training programs that address the practical needs and challenges faced by care professionals due to the digital transformation of health care.
- Active matching of support and needs to be prepared for the digital transformation in the health care sector. The active matching of support and needs is a crucial aspect of this process. This study highlighted the significance of aligning technical support with patients' physical limitations (need to fit) and requirements when selecting and integrating DATs. This need-to-fit approach guarantees that the technologies used are beneficial and appropriate for the patients.

In the statistical methodology, the mean is a widely used measure of the central tendency of a given data set. However, the mean is susceptible to influence from values at the extreme high and low ends of the results. Consequently, the median is a superior measure of central tendency in instances in which a small number of outliers can significantly influence the mean. The median values identified in this study indicate a marginal increase in willingness to use, which is not apparent when interpreting the mean values. This indicates that the care professionals identified shortcomings in the selected DATs during the 3-day practical testing. A survey was conducted with 112 care professionals at 3 distinct measurement points to ascertain their intention to use DATs. The results indicated a positive shift in intention to use DATs following the implementation of the SEQI intervention. No sample size calculation or *P* values were provided. Nevertheless, the overall trend indicated an increase in acceptance, willingness, and intention to use DATs among the participants.

Qualitative interviews with 12 care professionals yielded further insights. The participants expressed appreciation for the SEQI program's structured approach, particularly the evaluative introduction and on-site testing stages, which they found to

foster confidence and competence in the use of DATs. In total, 4 primary themes were identified.

In theme 1, "Evaluation of the education concept," the care professionals described the preparatory and theoretical introduction in stage 1 (sensitization), along with stages 2 to 4, as meaningful. Stages 1 and 2 (evaluative introduction) provided knowledge of the digital transformation and served as preparation for the practical experience in stages 3 (qualification) and 4 (implementation). The care professionals noted that a focused discussion of DATs is more effective than a pure knowledge transfer, such as only providing a user manual. Previous theoretical knowledge helps classify new information on DATs both ethically and normatively, and problems are related and supported based on the theoretical background as they arise, which is necessary for integrating DATs into practical work. Furthermore, the interviewees emphasized that practical teaching using case studies and group work is helpful for deepening understanding.

In theme 2, "Effects on work and care structures," the care professionals reported that the use of DATs could enhance the quality of care and optimize work processes. However, it was

also identified that the practical introduction of DATs presents challenges, such as the need for familiarity with new systems and the adaptation of processes.

In theme 3, “Need for reflection and discussion,” the care professionals indicated that the workshops facilitated reflection on the role of DATs in care facilities and on their own attitudes while using DATs. The opportunity to discuss these topics helped them gain a deeper understanding of the digital transformation and learn about different perspectives.

In theme 4, “Improvement potential for health care and nursing care practice,” the care professionals emphasized the importance of careful selection of DATs and the necessity of training on their proper implementation to improve the quality of care. In addition, cooperation between care professionals and technical experts was identified as a key factor in the successful introduction of DATs [40].

Takeaways and Themes

The incorporation of structured educational methodologies such as the SEQI intervention is of paramount importance for the integration of DATs into nursing practices. The SEQI intervention provides care professionals with the requisite knowledge and skills to use these technologies in an effective manner. In addition, a positive attitude toward technology among health care professionals is essential for successful integration.

It is imperative to assess the usability of DATs in long-term care settings. The emphasis on practical application and real-world testing in SEQI proved to be a significant contributing factor to its success. By integrating theoretical knowledge and hands-on experience, SEQI ensures that technologies are tailored to meet specific patient needs, a recurring theme in our discussions. The structured and guided education concept of SEQI serves to enhance care professionals’ capacity to integrate DATs into their practices, facilitating this process through practical, application-oriented training. In the initial phase of the SEQI educational approach (sensitization), the theoretical underpinnings of digital transformation in health care were elucidated and deliberated with care professionals. Given that care professionals constitute the largest group in the health care system, they were encouraged to identify potential applications and areas of use for DATs based on their expertise (evaluative introduction). This process enabled them to evaluate DATs from the perspectives of their patients and the specific care challenges they face. The SEQI education concept can play an instrumental role of the profession as it invites care professionals to assess the usefulness of DATs. The structured theoretical knowledge transfer and the gradual transition from passive knowledge consumers to active users through consecutive training units were well received by the participants. This mutual approach proved conducive to the development of practical applications for DATs.

The qualitative findings provide information on 4 themes.

The SEQI initiative enhanced the comprehension of alternative courses of action and resolutions pertaining to the use of DATs in nursing procedures. The direct interaction during the testing phase enabled care professionals to assess the potential benefits

and limitations of DATs, thereby fostering realistic and independent evaluations. The potential for technology to dehumanize care was countered through practical application testing, which demonstrated that care is fundamentally an interpersonal interaction that cannot be replaced by technology. Dehumanization is defined by Biniok [70] as a form of the denial of the human characteristics and qualities of other individuals. For example, social interactions and relationships could become devalued if care professionals were replaced by robots. The opportunity for direct testing highlighted the possibilities and shortcomings of DATs. The importance of the “human factor” for the high-quality provision of services became clear to the participating care professionals, and concerns about care professionals being replaced by DATs were refuted. The care professionals exhibited an awareness that care is fundamentally an interpersonal interaction that cannot be readily substituted by technology [12]. The interview data revealed that the care professionals’ lack of interest in DATs should not be interpreted as a general lack of interest [71-73]. This interpretation has arisen due to a methodological limitation in numerous previous studies in which care professionals were asked about a topic with which they lacked direct experience [29,74,75]. The lack of objective, tangible information on DATs and their potential applications makes it difficult for care professionals to formulate unbiased opinions. Consequently, they may only provide superficial responses to inquiries about their interest in DATs as it has been demonstrated that empirical evidence is essential for making well-informed decisions [76]. The focus was not on the DATs themselves but on the care professionals’ questions, conflicts, and behavioral uncertainties regarding DATs. This process-oriented approach to knowledge transfer, also known as the genetic method, aims not only to convey knowledge but also to acquire practical skills, thereby directing the focus to new or alternative situation interpretations.

The SEQI intervention can have a lasting impact when both cognitive transfer (knowledge, skills, and abilities) and emotional transfer (attitudes, values, motives, and feelings) are achieved [77]. An emotional transfer occurred when the relevance of DATs to specific care problems was perceived, thereby reducing skepticism and increasing willingness to engage with their implementation. SEQI helped defuse the often emotional discussion around robotics in health care because a realistic assessment of DATs was possible for the care professionals. One illustration of the emotional transfer achieved through practice with DATs was when a caregiver described the interaction of an introverted older adult with the PARO device. Upon being stimulated by the device, the older adult relinquished his self-imposed isolation, commenced laughing, and “began to tell stories.” Furthermore, a relatively young man with spinal cord injuries was able to experience a visit to a Rammstein concert through virtual reality immersion. The care professionals were impressed by the absence of any reservations or fears about the virtual environment.

Furthermore, SEQI facilitated the practical transformation of theoretical knowledge, as evidenced by the descriptions of necessary adjustments to workflows and care activities provided by the participating care professionals. Theme 2 (“Effects on work and care structures”) showed that the multiday on-site

training was met with a positive evaluation, with participants noting the rarity of such opportunities for testing DATs in long-term care for older adults [78]. The results of the survey indicated that care professionals, the largest health care group, play a crucial role in the formation of sociotechnical care arrangements. The high scores on the interest and curiosity subscales and the low scores on the fear of technology subscale indicated that the participants were open to testing new technologies provided that they are usable and tailored to patient needs. In line with the theory of transformative learning by Mezirow [44], care professionals developed application ideas through reflective transformation, thereby ensuring long-term applicability in their professional practices. These considerations also extended to their own work processes, such as the integration of exoskeletons into shift planning or the logistics of outpatient care. To accomplish this, nursing professionals would be required to operate a vehicle while wearing the exoskeleton to visit and provide care for their patients and clients in their residences.

The survey results indicated the importance of actively involving nursing care professionals, the largest group of health professionals, in the design of socio-technical care arrangements (as evidenced by the high scores on the interest subscale and the low scores on the fear of technology subscale). In addition, the high scores on the curiosity subscale suggest that caregivers are open to trying new technologies, including DATs, if they are usable and tailored to the needs of target populations [79]. The consistently high scores on the overall intention to use scale were noteworthy as all participants demonstrated a willingness to use DATs at the outset of the study and retained this willingness even when the fit of the DAT to the patient was deemed to be inadequate. This indicates that care professionals perceive the potential for enhancing the suitability of DATs for their needs through participatory development and are willing to use them in the future.

In theme 3 (“Need for reflection and discussion”), the pragmatic aspects of the SEQI, such as sufficient time for questions, reflection during breaks, and mutual exchange with colleagues, were described in a positive light. It is imperative to reflect on DATs for the advancement of one’s professional capabilities, facilitating the expansion of personality traits and meta-competencies. The high score on the overall intention to use scale, despite the low fit of some DATs, indicates a fundamental interest in using technologies and a willingness to participate in their development and adaptation. This indicates that care professionals have a high level of self-responsibility and self-reflection about their professional practice and are willing to continuously educate themselves [80]. Through practical experiences and encounters, participants can easily acquire theoretical knowledge and apply it to their professional practice. If the acquired knowledge yields positive results when applied in practice, it is more likely to be remembered and applied in the long term. Therefore, practical training such as SEQI is often more effective than purely theoretical training as it offers the opportunity to directly implement learned knowledge and gain practical experience [80].

In theme 4 (“Improvement potential for health care and nursing care practice”), care professionals across the 26 facilities

recommended an extended testing period on weekends to allow for a realistic assessment of DATs considering increased workloads and reduced staff capacity. Although facility management is ultimately responsible for procurement, care professionals acknowledged the necessity of balancing cost and benefit considerations. It was further proposed that additional health care professionals, such as nursing assistants, be trained in the use of DATs to ensure the maintenance of professional standards and appropriate delegation of caregiving tasks. Care professionals emphasized the importance of careful selection of DATs and the necessity of training on their proper implementation to improve the quality of care. In addition, cooperation between care professionals and technical experts was identified as a key factor in the successful introduction of DATs [40].

In conclusion, the SEQI educational concept effectively integrates structured education with practical application and real-world testing, thereby fostering positive attitudes toward DATs among care professionals. This comprehensive approach guarantees that DATs are adapted to the specific requirements of patients and residents and integrated into nursing practices, thereby improving the quality of care and optimizing work processes.

Limitations and Strengths

The mixed methods approach, which focuses on qualitative, sequential exploration, was a strength of this study. The basic research design was critically reflected upon using the Good Reporting of a Mixed Methods Study checklist [49]. Furthermore, we classified and reflected on the quality criteria following Lincoln et al [81] and Lamnek [82]. The quality criteria of the survey were discussed using the Mixed Methods Appraisal Tool [50]. The openness of the mixed methods approach proved to be effective for this study considering the complexity and range of topics thus far underexplored. In particular, this approach allowed the researchers to provide a flexible response to the problems in the sampling strategy and the design of the empirical study.

This study had certain limitations. Primarily, it was conducted exclusively in long-term care facilities, and thus, the results are applicable only to this area. The recruitment of facilities was carried out exclusively at the management level, which may have introduced a positive selection bias (ie, only technology-friendly facilities were willing to participate). In addition, because all the visited facilities were informed about the observation element for ethical research reasons, the possibility of biased responses should also be considered. One of the key strengths of this study is that it marks the first time that caregivers have had access to DATs on a large scale and been able to test them in practice over a longer period in the context of nursing care. In preliminary work, the validity of the data would need to be critically questioned due to skepticism, which is particularly pronounced among care professionals in cases of lack of access to DATs or predefined media ignorance. However, research on DATs presents a complex picture. Although the self-image of care professionals indicates a high degree of conformity with traditional nursing practices [81],

these practices have expanded, changed, and transformed the professional self-concept [33].

The question of whether it is reasonable to assume that nursing professionals are unable to manage intervention and interview situations independently is open to debate. This suggests that societal trends are employed to delineate uncertainties pertaining to the utilization of DAT in relation to the fundamental tenets of nursing practice, the incorporation of DAT into nursing processes, and the associated protection claims of individuals requiring care. In this context, societal trends are employed to describe nursing and healthcare professionals as occupying a subordinate position within a hierarchical healthcare system. This line of reasoning relies on a pervasive trope that portrays the purported uncertainty of nursing professionals with regard to the utilization of DAT. This gives rise to a debate about the possibility of technological reductionism undermining professional claims to individualized services and the expertise of nurses and healthcare professionals, particularly in the event that automated decisions are made by DATs in the future.

Moreover, there is a concern that the physical aspect of the interaction between care professionals and patients could be substituted by technology in the long term [83,84]. Within the group of participating care professionals, the fear of being replaced—a serious concern from the early days of discussion on DATs—is gradually giving way to the recognition of DATs as a useful complementary support tool [5,9]. Health care professionals are increasingly recognizing that digital technologies and robotics can complement and support their work rather than replace them. This indicates that the attitudes toward and perceptions of the role of technology in care have changed over time. Care professionals are increasingly seeing the interaction between technology and human care as improving caregiving for people [37]. This shift in attitudes suggests a growing recognition of the potential benefits of technology in nursing practices.

The primary challenge remains the development of methods to make DATs accessible and useful for care professionals in long-term care facilities. DATs have the potential to reduce the necessity for formal health, support, and long-term care services by assuming care tasks that are required when limitations prevent a patient from completing self-care independently. This, in turn, could result in a reduction in the workload of care professionals. Consequently, DATs are being developed in nursing to support patients and improve their compliance, which benefits care professionals. Thus, in conjunction with sufficient staffing, DATs can diminish the continuous work performed under time constraints and effectively digitize nursing care [5]. However, the impact of DATs on patients was not a primary focus of this study. Therefore, future studies should assess the extent to which the potential and effective alleviation of care professionals' workload using DATs affects overall care quality.

Ultimately, the best DATs do not serve their purpose if they do not benefit the people being cared for. A strength of this study was that care professionals were granted broad access to DATs for the first time and, thus, experienced the actual usability of DATs in a real-world context. This indicates the conditions and

situations in which care professionals accept or are skeptical about the use of DATs in long-term care facilities.

Conclusions, Outlook, and Implications for Practice

This study revealed that care professionals are open to using DATs; however, they need information and knowledge on how to reflect on DATs critically. This study also highlights the effectiveness of the SEQI education concept for transferring theory into practice. Information, real-world practice, and learning are essential for reducing barriers and promoting an understanding of potential application fields and limitations. Our participants' critical reflections revealed that currently available DATs only offer limited relief for care professionals as they merely support social care and daily life management. Hence, the targeted and patient-oriented use of DATs is necessary to promote critical reflection on the suitability of such technologies for nursing processes. The SEQI education concept can be used to strengthen care professionals' competencies in dealing with DATs and enable a realistic assessment.

To achieve the long-term implementation of DATs in practice, practical and economic factors such as the creation and expansion of a comprehensive digital infrastructure must be considered. This study's results underline the important role that care professionals play in the interprofessional team of health care professionals when using DATs as part of nursing processes. In this paper, the structured approach of SEQI was presented as a useful way to integrate DATs into nursing processes. The approach was positively received, and interest in DATs remained high throughout the study. The SEQI approach can help evaluate the suitability of DATs for identified functional nursing problems and integrate DATs into nursing processes. However, because of time restrictions for care professionals, it may be beneficial to involve other professional groups, such as social workers, in structured technology education. In addition, the exclusion of other health care professionals (eg, nursing assistants and station assistants) as potential users seems excessively limiting and should be avoided. In addition, while SEQI supports a more realistic understanding of DATs by care professionals, it can be used to stimulate discourse about DATs. As an education approach, SEQI has strong practical relevance, and its stages can be transferred to different nursing processes. This approach is easily implemented in long-term care facilities and could be included in the professional education of health care workers. Care professionals' lack of experience with DATs highlights the importance of answering questions about the actual approaches regarding the sustainability of implementing these technologies in nursing practices. It is also essential to determine who qualifies to use these technologies.

The participants' high willingness to use DATs in practice should be supported through holistic and application-oriented concepts that also consider ethical and normative aspects. SEQI, accompanied by the creation and expansion of a comprehensive digital infrastructure, can be implemented to build competencies to create the necessary conditions for the long-term implementation of DATs in practice. Regarding the use of DATs in nursing processes, care professionals play a central role among health care professionals.

Acknowledgments

The authors would like to thank the staff of the institutions involved in the implementation of this study for their excellent collaboration, without which this study would not have been possible. This work was created as part of the research project Forschungs-basierte Entwicklung einer beschleunigten praktischen Implementierung assistiver & digitaler Technik in der pflegerischen Versorgung älterer Menschen in Sachsen-Anhalt (FORMAT)-Continuum (Autonomy in Old Age research association, Europäischer Fonds für regionale Entwicklung [EFRE] funds; project duration: September 1, 2019-December 31, 2022; funding reference: ZS/2019/02/97281). We acknowledge the financial support of the Open Access Publication Fund (Publikationsfond) of the Martin-Luther-University Halle-Wittenberg.

Abstract

Background: Patient safety is a fundamental aspect of health care practice across global health systems. Safe practices, which include incident reporting systems, have proven valuable in preventing the recurrence of safety incidents. However, the accessibility of this tool for health care discipline students is not consistent, limiting their acquisition of competencies. In addition, there is no tools to familiarize students with analyzing safety incidents. Gamification has emerged as an effective strategy in health care education.

Objective: This study aims to develop an incident reporting system tailored to the specific needs of health care discipline students, named Safety Incident Report System for Students. Secondary objectives included studying the performance of different groups of students in the use of the platform and training them on the correct procedures for reporting.

Methods: This was an observational study carried out in 3 phases. Phase 1 consisted of the development of the web-based platform and the incident registration form. For this purpose, systems already developed and in use in Spain were taken as a basis. During phase 2, a total of 223 students in medicine and nursing with clinical internships from universities in Argentina, Brazil, Colombia, Ecuador, and Spain received an introductory seminar and were given access to the platform. Phase 3 ran in parallel and involved evaluation and feedback of the reports received as well as the opportunity to submit the students' opinion on the process. Descriptive statistics were obtained to gain information about the incidents, and mean comparisons by groups were performed to analyze the scores obtained.

Results: The final form was divided into 9 sections and consisted of 48 questions that allowed for introducing data about the incident, its causes, and proposals for an improvement plan. The platform included a personal dashboard displaying submitted reports, average scores, progression, and score rankings. A total of 105 students participated, submitting 147 reports. Incidents were mainly reported in the hospital setting, with complications of care (87/346, 25.1%) and effects of medication or medical products (82/346, 23.7%) being predominant. The most repeated causes were related confusion, oversight, or distractions (49/147, 33.3%) and absence of process verification (44/147, 29.9%). Statistically significant differences were observed between the mean

final scores received by country ($P<.001$) and sex ($P=.006$) but not by studies ($P=.47$). Overall, participants rated the experience of using the Safety Incident Report System for Students positively.

Conclusions: This study presents an initial adaptation of reporting systems to suit the needs of students, introducing a guided and inspiring framework that has garnered positive acceptance among students. Through this endeavor, a pathway toward a safety culture within the faculty is established. A long-term follow-up would be desirable to check the real benefits of using the tool during education.

reporting systems; education; medical; nursing; undergraduate; patient safety

Introduction

Background

Patient safety is an objective of health care practice in the health systems of all countries. However, the complexity and uncertainty that accompany health care makes this a practice not without risks. The World Health Organization leads the World Alliance for Patient Safety with the purpose of implementing safe practices and other actions with which to generate a safer environment in all health centers [1].

The information available regarding safety incidents focuses primarily on adverse events (AEs), which are incidents that result in harm to a patient. Slightly more than half of these AEs could have been prevented [2]. The results of research studies show that, in high-income countries, approximately 10% of patients admitted to hospitals experience an AE [3]. In primary and outpatient care, approximately 3% to 10% of patients experience an AE over the course of a year [4]. In 80% of cases, the damages are avoidable. In low- and middle-income countries, there are higher rates of AEs due to deficiencies in infrastructure, facilities, and accessibility [2]. So-called safe practices aim to reduce these figures and have proliferated across all countries [5]. Among them, incident reporting systems (IRSs) have emerged as a valuable tool to prevent safety incidents stemming from the same cause from recurring [2].

Studies indicate that up to 30% of students are involved in an AE during an academic year [6]. Moreover, during their internships, students observe decisions and procedures that may lead to errors or cause harm (AEs) to patients [7]. While access to IRSs is widespread in all health care systems, students of health care disciplines are often not adequately trained on how to use and benefit from these tools to create safer environments for patients. This lack of training restricts students' acquisition of crucial competencies in several ways.

The familiarization of students with incident reporting addresses a significant educational practice gap. First, the absence of IRS exposure hinders students' ability to understand what an incident report is, how to complete it, the extent of the information required, and how it functions to promote safer environments. This exposition to IRSs not only enhances their capability to effectively report incidents in future real-world contexts but also helps reduce the initial reluctance toward reporting. Second,

reporting unsafe events can enhance practice and prevent future safety incidents. This active learning helps students identify and avoid recurring incidents by raising awareness of their causes. Third, providing students with access to IRSs raises awareness among future professionals of the critical importance of patient safety. It serves as a vital learning resource and offers an opportunity to change attitudes and foster the development of a proactive safety culture [8].

Despite this, the interventions designed and validated to achieve the goal of promoting incident reporting among health care discipline students are scarce [9]. There are also no tools to introduce these students to the analysis of the remote and immediate causes of safety incidents and the identification of barriers to prevent them from recurring. However, there are digital tools that are starting to be used to increase patient safety, particularly those based on gamification [10,11].

The effectiveness of gamification in health care education has been analyzed in several studies [12,13], showing improvements in knowledge, skills, satisfaction, behavior change, and attitudes compared to control groups. However, the usefulness of engaging health care discipline students in patient safety has not been assessed.

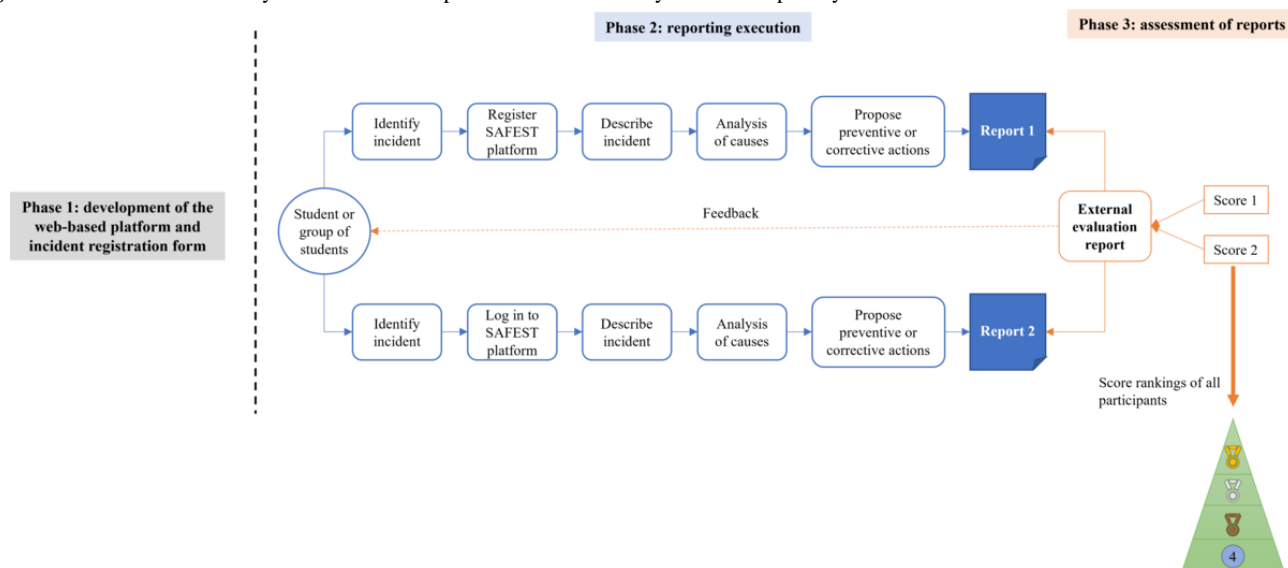

Objectives

The primary objective of this study was to develop a patient safety IRS tailored to the needs of health care discipline students. The secondary objectives were to study the performance of different groups of students in the use of the platform and train them on the correct procedures for reporting.

Methods

Study Design

This was an observational study developed in 3 phases (Figure 1), in which safety incident reports made by final-year students in medicine and nursing during their clinical internships were analyzed. The students were enrolled in universities from Argentina, Brazil, Colombia, Ecuador, and Spain once they had gained experience from their clinical placements. All these universities are members of the European Researchers' Network Working on Second Victims Consortium, with the Latin American ones as third-party or observer countries and Spain as the promoter of the network.

Figure 1. Workflow of the study divided into the 3 phases. SAFEST: Safety Incident Report System for Students.

In the participating countries, medical studies are typically completed over 6 years, with the last 3 years progressively incorporating more clinical practice. However, nursing studies exhibit greater variability and can range from 4 to 6 years in duration. In these programs, the final year is usually dedicated to clinical practice. Nursing curricula also show more diversity in their content, with some programs focusing more on hospital-based activities whereas others emphasize community health practice. Nonetheless, due to international guidelines on required competencies and clinical practice hours, these programs are standardized to ensure consistency in training.

In countries such as Argentina, Brazil, Chile, Ecuador, and Spain, medical and nursing programs follow this general structure but with some national variations. For example, in Spain, medical students undergo a rigorous 6-year program with a strong emphasis on clinical rotations in the later years. Nursing programs in Spain typically last 4 years, with the final year focused on intensive clinical practice. In Brazil and Argentina, similar patterns are observed, although the specifics of the curriculum and clinical exposure may differ slightly due to local health care needs and educational frameworks. As in other places, teaching patient safety is limited, representing one of the gaps highlighted in various studies [14].

This study is reported according to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines for cross-sectional studies ([15]; see [Multimedia Appendix 1](#)).

Phase 1: Development of the Web-Based Platform and Incident Registration Form

This phase consisted of the development of the web-based platform and the incident registration form, named Safety Incident Report System for Students (SAFEST).

To design the content for the incident registration form, various existing systems at different levels were used as references. The existing systems in health care centers require users to be part of the center's staff, making them inaccessible to other groups, including students. In addition, while these systems collect the

reporter's assessment of potential causes, they do not advance to propose alternatives for preventing future safety incidents. This aspect of our educational initiative is crucial to influencing students' attitudes toward safety reporting. Due to these limitations, the available safety systems in the health care facilities were not suitable for student practice and, therefore, deemed inappropriate for our purposes. Consequently, we decided to design a new system that closely mimics the systems that students will encounter in their professional practice. This approach ensures that students receive relevant and practical training, enhancing their ability to effectively report and analyze safety incidents in the future.

A database was then constructed incorporating fields gathered from the Patient Safety Reporting and Learning System of the Spanish National Health System [16]; the Adverse Event Reporting and Registration System of the Valencia Health Agency [17]; and Based on Root Cause Analysis (BACRA) [18,19], a web-based application based on root cause analysis and failure mode and effects analysis.

One of the key features of SAFEST is that each section and registration field (eg, center type, care complications, damage type, or care received after the incident) offered an extensive range of response options in different formats (single-select drop-down menu or multiple-choice answer). This design facilitated the reporting task for the students as they rarely needed to use natural language to describe a situation. This approach aligns with the latest advancements in reporting systems, minimizing errors in subsequent coding while providing a comprehensive catalog of options. However, in some cases in which the preset options may limit the recording, students can add a qualitative description to complement the recording. For example, when describing the incident, the student should characterize the event according to the classic typification of its nature, that is, whether the origin of the incident was related to complications of care, care-related infection, effects of medication or medical devices, complications of a procedure, or other situations not covered by the previous categories (eg, unexpected death of the patient). All these categories are detailed in a list of possibilities in a

multiple-choice format. However, in all categories (including “Other”), the student may choose a final option as “Other,” in which case they should describe in words the situation in question. The first version of the database was created in Spanish.

From this database, common and specific aspects of each form were identified, and a preliminary draft of the proposal was developed accordingly. This draft underwent review by 3 subject matter experts from different Latin American countries, and the resulting changes and suggestions were incorporated to produce a high-quality form. This latest version of the tool was translated into English by EB and VRN, both of whom use the 2 languages regularly in the academic setting, ensuring the equivalence of the versions through back translation. The necessary modifications to ensure the adequacy of the system were made. Simultaneously, the visual identity and acronym for the platform were developed ([Multimedia Appendix 2](#)).

Phase 2: Introduction Seminar and Incident Reporting Execution

Overview

During this phase, students received an introductory seminar on patient safety and reporting and were given access to the platform. These introductory seminars were conducted by the responsible coordinators from the 5 universities (1 from each country; see [Multimedia Appendix 3](#) for the educational materials used during the seminars). During these seminars, the project and the platform were presented, and attendees were given the opportunity to ask any questions they had.

The seminars contributed to the recruitment of participants based on voluntary participation without offering any academic grade advantages. To incentivize student engagement, they were provided with the opportunity to obtain a Miguel Hernández University nanocourse certificate. Moreover, the highest scores qualified for a draw with 4 new smartwatches as the prize, thus incorporating classic elements of gamification strategies. Of the smartwatches, 2 were assigned to the people with the highest and second-best scores and who had also submitted their feedback, whereas the other 2 were drawn among all reports with a score of >3.0 and who had also completed their feedback.

The specific instruction given to the students was to report any safety incidents that had occurred in their training health care center and of which they were aware, either because they had been involved or because they were witnesses. To introduce students to this exercise and standardize explanations and instructions on how to respond, concise use instructions were created along with video tutorials on navigating the website and submitting reports and a schematic diagram of the operation ([Multimedia Appendix 4](#)). The same presentation was used in all countries. In accordance with the academic calendars of the

participating countries, the report submission period spanned from September 14, 2022, the day when the first seminar was held, to November 8, 2023.

Participants

Medicine (n=176) and nursing (n=47) students who had completed more than half of their educational program and were performing clinical internships were invited to participate. Recruitment was conducted by the professor in charge in each country with students in the corresponding academic years who met the selection criteria.

Study Size

According to existing literature, in pilot studies, if a problem exists with a 5% probability in a potential study participant, a sample size of 59 participants will almost certainly identify the problem with 95% confidence [20].

Phase 3: Assessment of Reports and Feedback on the Experience

Feedback

This phase ran in parallel to the previous one and involved external evaluation and feedback on the reports received that could prove useful for the students' improvement in continuing to send reports. In total, 2 independent assessments were conducted for each incident report by members of the platform's promoting team. As a final exercise, students who had submitted at least 1 report were invited 1 month after this activity was over to fill out a satisfaction questionnaire.

Data Sources

The information provided in this study stems from the firsthand experiences of each student.

Variables

The outcomes we aimed to assess were the students' performance in reporting using the platform, which includes an estimation of potential causes to raise awareness of the inherent risks in health care activities, and their satisfaction with the experience.

To study their ability in reporting, a rubric ([Table 1](#)) was followed, in which the 2 reviewers independently rated the information provided about the incident, the analysis of immediate and latent causes, and the corrective or preventive plan proposed by the student using a scale of 1 to 5 points for each one, where the higher the score, the better the assessment. In addition, strengths and areas for improvement were included in the evaluation as an open-text field. The individual score from each evaluator was obtained by calculating the arithmetic mean of these 3 points. The final score for that report was the average of the 2 scores obtained from each evaluator.

Table 1. Rubric designed to assess the correctness of the reports made by students.

Points	Description
To what extent is the information complete and descriptive enough?	
2 points	The provided information allows for the understanding of the events.
2 points	The information is consistent throughout the entire report.
1 point	All fields are properly filled out.
To what extent is the analysis of immediate and latent causes complete and adequate?	
2 points	The provided information is comprehensive, and reasons with a high probability of influence are not overlooked.
2 points	The provided information offers sufficient details to envision the scenario of what happened.
1 point	The selected information is logical and does not appear to have been chosen merely for completion.
To what extent the corrective or preventive plan proposed is realistic and responds to the problem?	
1 point	The plan has a corrective or preventive nature.
1 point	The proposed plan is realistic.
1 point	The proposed plan is understandable.
1 point	Details are addressed to implement the proposed plan.
1 point	Language and spelling are appropriate.

To analyze their satisfaction with the experience, they were asked to complete a questionnaire with 3 aspects to rate on a scale of 1 to 5, with 1 being *not at all* and 5 being *very much*: “Do you believe that after this experience you would be capable of generating reports accurately?” (question 1), “Has viewing the assessments and comments you received on your reports been beneficial for your learning?” (question 2), and “Have you felt confident in terms of the privacy and anonymity of your reports?” (question 3). In addition, they had a text field available to input any suggestions that could contribute to improving the platform (question 4).

The independent variables used included the country from which the report was made, the sex of the reporter, their ongoing studies, and the number of internship hours completed up to the moment of reporting. All these data were incorporated into the incident registration form itself.

Bias

When the form was sent to the partners for review, a language check was also requested to address any idiomatic barriers that may have existed to allow for cross-cultural conclusions of the study and avoid possible biases related to linguistic nuances. Cultural differences were also considered, ensuring that items were comparable across countries.

Statistical Methods

To gain a comprehensive understanding of the reported incidents, descriptive analyses were conducted. To obtain the results of the phase of assessment, various statistical analyses were conducted. Descriptive statistics were computed for each of the 3 dimensions under analysis as well as for the overall score, with stratification by country, sex, and educational background. The weighted Cohen κ was computed to evaluate the agreement among the scores assigned by different pairs of evaluators for each dimension. Before proceeding with the analysis of the final scores of each report, the normality of the

sample was assessed using $Q-Q$ plots and the Shapiro-Wilk normality test. The relationship between the number of internship hours and the final score was examined using the Spearman correlation coefficient. Finally, differences in scores among countries, sexes, and educational backgrounds were investigated using the nonparametric Kruskal-Wallis test and the Mann-Whitney U test. The P value significance was set at .05. Data analyses were performed using SPSS Statistics (version 28.0.0; IBM Corp).

Ethical Considerations

This study was authorized by the Research Ethics Committee of Sant Joan d’Alacant University Hospital (22/027) and registered on ClinicalTrials.gov (NCT05350345).

Informed consent for study participation was obtained at the time of registration on the platform, whereby individuals were required to select the corresponding checkbox with instructions provided regarding the process for revoking their participation. After reporting, the report was automatically encoded with a numerical identifier by the platform. Throughout the assessment process, participant sociodemographic data were concealed to ensure evaluator objectivity.

No form of financial compensation was provided for participation or recruitment.

Results

Phase 1: Development of the Web-Based Platform and Incident Registration Form

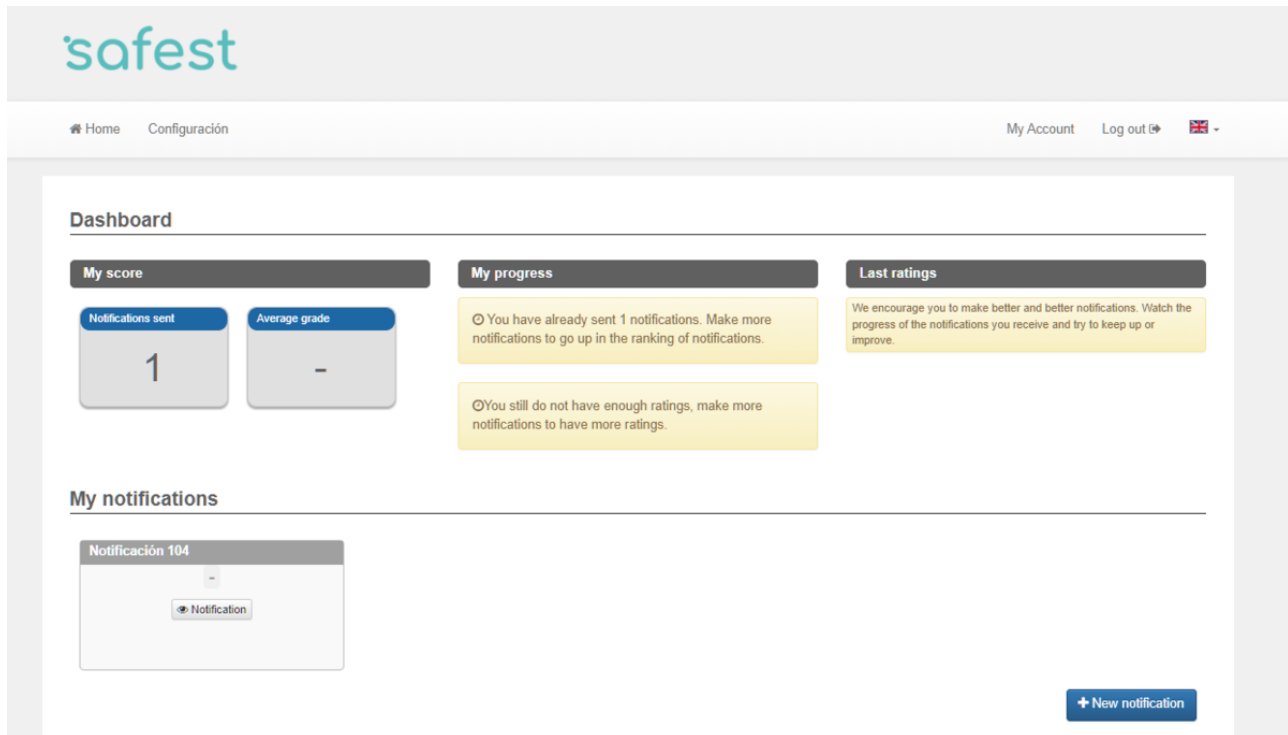

SAFEST [21] and the servers were located in Miguel Hernández of Elche University (Spain). Participation was allowed both individually and in groups of 2 to 3 students.

When accessing the page, users could find an explanatory text about the project, logos of collaborators, and buttons to access the platform or register. Upon initial access, the user was

required to provide consent to participate in the study. The platform was available in both Spanish and English. Once logged in, the dashboard was shown (Figure 2), where they could view the total of submitted reports, their average score,

and the progression of their results, as well as their position in the score ranking at any time. In addition, they had access to previously submitted reports, as well as the button to access the incident registration form.

Figure 2. Appearance of the Safety Incident Report System for Students (SAFEST) platform dashboard.

The final form was divided into 9 sections: data of the reporting center, patient data, notifier data, incident data, description of the incident, damage assessment, factors influencing the incident, care received after the incident, and reflections.

In total, it consisted of 48 questions (distributed as depicted in [Textbox 1](#)) that allowed for obtaining the necessary information about the incident, conducting an analysis of the causes, and proposing corrective or preventive actions. The complete form can be found in [Multimedia Appendix 5](#).

Textbox 1. Questions asked on the reporting form and types of responses.

Data of the reporting center

- Center type (drop-down menu)

Patient data

- Patient's age (drop-down menu)
- Patient's sex (drop-down menu)
- Patient's risk factors (multiple choice)

Notifier data

- Notifier's sex (closed-ended question)
- Country from which the notification was made (drop-down menu)
- Studies in the course (drop-down menu)
- Institution (drop-down menu)
- Year (closed-ended question)
- Internship hours carried out so far in that department (open-ended question)

Incident data

- Date of the incident (date)
- Time of the incident (time)
- Date of the notification (date)
- Time of the notification (time)
- Where it took place (drop-down menu)
- Number of people related to the incident (open-ended question)
- Position or positions of the person or people involved (multiple choice)
- Frequency or probability of recurrence (drop-down menu)
- Participation in the incident (drop-down menu)

Description of the incident

- Care complications (multiple choice)
- Care-related infection (multiple choice)
- Effects of medication or medical products (multiple choice)
- Complications of a procedure (multiple choice)
- Other (multiple choice)

Damage assessment

- Damage type (drop-down menu)
- Severity (drop-down menu)
- Patient autonomy (drop-down menu)
- Estimation of the damage duration (drop-down menu)

Factors that conditioned the incident

- Patient or family factors (multiple choice)
- Equipment and resource factors (multiple choice)
- Individual factors of the health care professional or professionals (multiple choice)
- Work environment factors (multiple choice)
- Oral and written communication between professionals factors (multiple choice)

- Patient communication factors (multiple choice)
- Teamwork and leadership factors (multiple choice)
- Task-related factors (multiple choice)
- Organizational and management factors (multiple choice)
- Other factors (open-ended question)

Care received after the incident

- Care received after the incident (multiple choice)

Reflections

- Has the center been notified? (drop-down menu)
- Could the incident have been prevented? (drop-down menu)
- How could it have been prevented? (open-ended question)
- How could the probability of occurrence or the severity of this event be reduced? (open-ended question)
- To what extent was all the information necessary to analyze the causes of the event available? (open-ended question)
- Have measures been put in place to prevent it from happening in the future? (drop-down menu)
- What measures have been put in place to prevent it from happening in the future? (open-ended question)
- Do you consider that the analysis could have been different if you had had access to another source of information? (open-ended question)
- Write here any other comments you may have (open-ended question)

To streamline the use of the system, selection questions and drop-down menus were used to report incidents. Both the *Description of the incident* and *Factors that conditioned the incident* blocks allowed for more than one option to be selected. Written input was only necessary in the *Reflections* part.

Phase 2: Introduction Seminar and Incident Reporting Execution

A total of 105 students from the 5 countries participated voluntarily and actively by submitting at least 1 report (participation rate: 105/223, 47.1%). By country, this corresponds to 16.2% (17/105) of students from Argentina, 12.4% (13/105) of students from Brazil, 10.5% (11/105) of students from Colombia, 32.4% (34/105) of students from Ecuador, and 28.6% (30/105) of students from Spain. Of the 105 participants, 35 (33.3%) were male, 68 (64.8%) were female, and 2 (1.9%) specified their sex as *other*. Only 1.9% (2/105) of them formed a team. Regarding their studies, 66.7% (70/105) were pursuing a degree in medicine, 28.6% (30/105) were enrolled in nursing studies, 1.9% (2/105) were part of the pediatric specialization program, 1.9% (2/105) were students from the radiology and diagnostic imaging specialization

program, and 1% (1/105) belonged to the orthopedics and traumatology specialization program.

A total of 147 reports were submitted as 14 users provided >1 report. Of the 147 received reports, 18 (12.2%) were from Argentina, 13 (8.8%) were from Brazil, 44 (29.9%) were from Colombia, 35 (23.8%) were from Ecuador, and 37 (25.2%) were from Spain.

Of the 147 safety incident reports, a substantial majority, specifically, 144 (98%) reports, occurred in a health care setting, with most occurring in a hospital context (n=132, 89.8%). Within this hospital-centric subset, most incidents were concentrated in hospitalization units (45/132, 34.1%). Other noteworthy locations included surgical block areas (21/132, 15.9%), emergency departments (17/132, 12.9%), support services (14/132, 10.6%), day hospitals (12/132, 9.1%), and intensive care units (10/132, 7.6%).

Regarding the nature of the incidents, [Table 2](#) illustrates the frequency with which each major classification category was selected. On most occasions, events from different blocks were registered in the same report.

Table 2. Nature of the reported safety incidents (n=346).

Type of incident	Reports, n (%)
Care complications	87 (25.1)
Effects of medication or medical products	82 (23.7)
Complications of a procedure	67 (19.4)
Other	60 (17.3)
Care-related infection	50 (14.5)

Specifically, from the available list of the most common safety events included in SAFEST (drop-down list), students' reports were related to "Worse evolutionary course of the main pathology" (27/147, 18.4%), "No harm" (24/147, 16.3%), "Ineffective analgesia-related pain" (19/147, 12.9%), "Falls and consequent fractures" (18/147, 12.2%), "Surgical site or traumatic wound infection" (15/147, 10.2%), "Contusion" (14/147, 9.5%), "Unexpected death" (14/147, 9.5%), "Headache" (13/147, 8.8%), and "Prescription error" (13/147, 8.8%).

The reported causes are shown in [Table 3](#). According to the number of reports in which they appear, we established the

following categories: "Patient or family factors" (112/147, 76.2% of reports), "Equipment and resource factors" (71/147, 48.3% of reports), "Individual factors of the healthcare professional(s)" (118/147, 80.3% of reports), "Work environment factors" (103/147, 70.1% of reports), "Oral and written communication between professionals factors" (76/147, 51.7% of reports), "Patient communication factors" (64/147, 43.5% of reports), "Teamwork and leadership factors" (93/147, 63.3% of reports), "Task-related factors" (91/147, 61.9% of reports), and "Organizational and management factors" (81/147, 55.1% of reports).

Table 3. Causes and contributing factors of the incidents grouped by category (n=147).

Factor	Reports, n (%)
Patient or family factors	
Comorbidity or complexity of the condition	33 (22.4)
Low economic level	30 (20.4)
Noncooperative attitude (noncompliance)	35 (23.8)
Lack of family or support networks	40 (27.2)
Poor communication with relatives	18 (12.2)
Altered cognitive status	8 (5.4)
Does not provide correct or enough information	14 (9.5)
Recent surgery	15 (10.2)
Educational and social factors to consider	20 (13.6)
Other patient factors	18 (12.2)
Mental disorder	3 (2)
Equipment and resource factors	
Improper storage or accessibility	19 (12.9)
Malfunctions	14 (9.5)
Equipment maintenance issues	12 (8.2)
Lack of alternative materials	11 (7.5)
Incorrect labeling	11 (7.5)
Equipment deficit (including nonsterile material)	10 (6.8)
Inadequate resource design (eg, bell)	10 (6.8)
Product or drug unavailability	10 (6.8)
Improper calibration	9 (6.1)
Nonstandard equipment	7 (4.8)
New equipment or resource	5 (3.4)
Failure to access or unavailability of the digital medical record	4 (2.7)
Expiration	2 (1.4)
Similar container or name	2 (1.4)
Individual factors of the health care professional or professionals	
Confusion, oversight, or distractions	49 (33.3)
Overload or work pressure	37 (25.2)
Lack of knowledge of regulations or protocols of performance	25 (17)
Uncooperative attitude	24 (16.3)
Inadequate or insufficient anamnesis, examination, or tests	23 (15.6)
Medication error (prescription or dispensing)	21 (14.3)
Inadequate or insufficient knowledge or skills	20 (13.6)
Low motivation	15 (10.2)
Diagnostic error	13 (8.8)
Inadequate or insufficient training	13 (8.8)
Not verifying the treatment that the patient is currently taking	12 (8.2)
Little experience in the workplace	10 (6.8)
Inadequate timetable	8 (5.4)
Inappropriate interpretation of analytical or test results	5 (3.4)

Factor	Reports, n (%)
Work environment factors	
Distractions in the environment	38 (25.9)
Shift-related fatigue	36 (24.5)
High care pressure	29 (19.7)
Inadequate environment—cleaning, beds, or space	26 (17.7)
Inadequate environment—noise, light, or temperature	19 (12.9)
Performance of outside tasks	14 (9.5)
Excessive staff turnover or inexperience	12 (8.2)
Inadequate staff-to-patient ratio	11 (7.5)
Security and access to restricted areas	2 (1.4)
Oral and written communication between professionals factors	
The information does not reach the entire team	30 (20.4)
Ambiguous verbal indications	23 (15.6)
Insufficient or inadequate records	20 (13.6)
Using an inappropriate channel	19 (12.9)
Inappropriate body language	15 (10.2)
Incorrect use of language	11 (7.5)
Patient communication factors	
Insufficient or inadequate records	23 (15.6)
Ambiguous verbal indications	17 (11.6)
Using an inappropriate channel	16 (10.9)
Incorrect use of language	14 (9.5)
Inappropriate body language	12 (8.2)
Language barrier	6 (4.1)
Teamwork and leadership factors	
Lack of coordination in the team	40 (27.2)
Inadequate supervision	40 (27.2)
Low risk awareness	31 (21.1)
Inaccurate assignment of tasks	20 (13.6)
Conflict between team members	12 (8.2)
No effective leadership	9 (6.1)
Task-related factors	
Absence of process verification	44 (29.9)
Unknown protocol or noncompliance	30 (20.4)
Absence of guidelines or protocols	19 (12.9)
Inadequate or outdated protocol	18 (12.2)
Too complex task	7 (4.8)
Organizational and management factors	
Absence of evaluation systems	16 (10.9)
Error in health information	16 (10.9)
Nonexistent or inadequate risk management	16 (10.9)
Error in medical documentation	12 (8.2)
Insufficient organizational structure	12 (8.2)

Factor	Reports, n (%)
Absence of support mechanisms in a risk situation	11 (7.5)
Incorrect patient identification	11 (7.5)
Insufficient deployment of a proactive security culture	11 (7.5)
Delays in the performance of tests or interconsultations	9 (6.1)
Insufficient care structure	9 (6.1)
Wrong appointment or scheduling	7 (4.8)
Gaps or failures in the information system	6 (4.1)
Inadequate or nonexistent treatment plan	5 (3.4)
Long waiting list	5 (3.4)

When asked about whether the event had been reported at the center, in 41.5% (61/147) of the reports the answer was “Yes”; in 34.7% (51/147) of the reports, the answer was “I don’t know”; and, in 23.8% (35/147) of the reports, the answer was “No.” Finally, 93.9% (138/147) of the reported events were classified as preventable compared to 6.1% (9/147) that were categorized as nonpreventable.

Phase 3: Assessment of Reports and Feedback on the Experience

Considering the 147 reports received, the mean final score obtained was 3.40 (SD 0.92) out of 5, and 111 (75.5%) reports had a final score of ≥ 3.0 . For each of the 3 aspects studied, an average score of 3.38 (SD 1.29) was obtained for the section on giving information about the incident, an average score of 3.54 (SD 1.21) was obtained for the analysis of causes, and an average score of 3.30 (SD 1.30) was obtained for the proposal of a corrective or preventive plan. Table 4 shows the means of the final scores segregated by category.

Table 4. Mean final scores segregated by country, sex, and studies.

Variables	Values, mean (SD)
Country	
Argentina	3.66 (0.89)
Brazil	3.65 (0.75)
Colombia	3.28 (0.88)
Ecuador	2.81 (0.88)
Spain	3.89 (0.73)
Sex	
Male	3.06 (0.99)
Female	3.64 (0.84)
Team	3.46 (0.60)
Other	3.58 (0.42)
Studies	
Medicine	3.34 (0.95)
Nursing	3.66 (0.82)
Pediatric specialization	3.25 (0.92)
Radiology and diagnostic imaging specialization	3.55 (0.59)
Orthopedics and traumatology specialization	2.75 (1.30)

Significant differences were found in the final scores based on country ($P < .001$) and sex ($P = .006$). However, no significant results were obtained when comparing scores based on studies ($P = .47$). Similarly, when focusing on the 2 main groups

(medicine and nursing), there were no significant differences ($P = .11$). Comparisons by groups for the significant variables are presented in Tables 5 and 6.

Table 5. *P* values for final score mean comparisons (country).

Country	Argentina	Brazil	Colombia	Ecuador	Spain
Argentina	— ^a	.92	.15	.004	.40
Brazil	.92	—	.19	.004	.36
Colombia	.15	.19	—	.01	.003
Ecuador	.004	.004	.01	—	<.001
Spain	.40	.36	.003	<.001	—

^aNot applicable.

Table 6. *P* values for final score mean comparisons (sex).

Sex	Male	Female	Other	Team
Male	— ^a	.001	.44	.25
Female	.001	—	.82	.33
Other	.44	.82	—	.69
Team	.25	.33	.69	—

^aNot applicable.

Regarding the internship hours carried out in that department, no correlation was found with the score obtained on each report (-0.079 ; $P=.18$). Finally, the interrater agreement analyses

revealed consistency between each pair of evaluators across all cases (Table 7).

Table 7. Weighted Cohen κ values obtained for each pair of evaluators.

	Pair 1		Pair 2	
	Cohen κ	<i>P</i> value	Cohen κ	<i>P</i> value
Complete and descriptive information	0.324	<.001	0.304	<.001
Analysis of immediate and latent causes	0.420	<.001	0.195	.009
Corrective or preventive plan	0.344	<.001	0.258	<.001

A total of 15 students participated in discussing the experience through the satisfaction questionnaire, providing an average rating of 4.06 (SD 1.00) for question 1, an average rating of 4.18 (SD 1.22) for question 2, and an average rating of 4.56 (SD 1.09) for question 3. Moreover, they provided the following feedback in the improvement suggestion section: “The platform has been very useful to me, and I suggest that similar projects continue to be conducted virtually to encourage widespread participation,” “It would be beneficial if the platform allows the upload of images as evidence for each incident,” and “Consider incorporating a text comment box, allowing individuals involved in the incident to narrate the events rather than solely selecting an option. This would prevent overlooking crucial details that might be of interest for subsequent management and error prevention.”

Discussion

Principal Findings

A platform named SAFEST was developed, allowing students to submit reports and receive feedback regarding provided information, causal analysis, and proposed improvements. The educational practice simulates the environment they will encounter in their professional practice regarding the reporting

of safety incidents. Students from 5 countries participated in this initiative, sending reports in which most incidents occurred within hospital settings and involved complications related to care and medication.

The identified causes of safety events reported by students using SAFEST included confusion, oversight, or distractions and absence of process verification. Across all countries, the average score exceeded 2.5, although significant differences in average scores among some countries are observed. Overall, the experience was highly regarded.

This paper delves into a comprehensive portrayal of the SAFEST platform, focusing on its inception, development, and implementation. The SAFEST platform stands as a pivotal reporting system strategically crafted to initiate health care discipline students into the realm of identifying and reporting current safety lapses within health care environments. In addition, this paper describes the perception that medical and nursing students had regarding incidents impacting patient safety, their attributed causes, and potential preventive or corrective measures. This reflection on what they identified as incidents can provide professors with feedback for planning their teaching.

The platform and designed materials allowed medical and nursing students to be introduced to safety incident reporting. SAFEST recreated the natural context in which reporting occurs, providing students with an experience close to reality but facilitating the process by allowing for step-by-step guided reporting. The IRS form follows the same structure and covers the same fields as those available for health care professionals as it was developed based on 3 existing systems. However, there are differences in terms of approach or responsibility. Students report situations that they observe or are involved in but are not the authors of. In addition, they encounter disparities regarding the accessibility of information for cause analysis as they do not have full access to the patient's medical history. The gathered information is not disseminated, nor does it bring consequences for the involved parties. This type of active learning can also facilitate a better understanding of the impact of safety incidents and their causes. By doing this, students can grasp the basic concepts of fostering a proactive safety culture for patients. Once in clinical settings as professionals, they will be able to overcome the natural barrier hindering reporting through their participation in SAFEST. They will also have gained experience in analyzing both the immediate and remote causes of safety incidents and identifying preventive or corrective measures. These types of educational interventions prompt reflection on how errors occur in clinical practice, aiding in distinguishing between honest mistakes and intentional errors. If specific patient safety content is taught during regular classes while conducting the reporting practice, one can expect a greater impact of this practice on instrumental and attitudinal competencies. This aspect should be verified in the future.

Notably, the existing literature predominantly reflects studies conducted within the field of nursing [7,8,22], leaving a noteworthy void in the examination of reporting mechanisms across broader health sciences education. Breaking away from this convention, our research introduces a groundbreaking element not only by incorporating medical students into its purview but also by providing a system that can be extended to other disciplines that develop their practices in the clinical field.

Moreover, the provision of feedback helps students learn and improve their skills. Similarly, the integration of a gamified environment adds an element of engagement and motivation to the learning process. By incorporating elements of game design such as rewards and progression systems, the learning experience is transformed into a user-friendly practice.

Reporting systems constitute one of the fundamental tools for creating increasingly safe environments for patients [2]. It has been demonstrated that they also have a positive impact on the safety culture within health care institutions. However, students in health care disciplines typically become familiar with this tool once they are in health care settings either as residents or professionals. Simulation, as portrayed in this case, stands as one of the most used approaches in teaching-learning methods [23]. The approach of this exercise ensures active student engagement in reporting. The feedback provided to the students facilitated the enhancement of their proficiency and enabled them to report accurately. This aspect has been highlighted as significant in other studies [24].

The data from this study suggest that introducing a practice on how to report and why it is important was well received by the participants in this academic exercise, resulting in reports of suitable quality. Previous studies [25] have suggested that students demonstrate enhanced proficiency in detecting and analyzing incidents when they are not involved in them. Therefore, incorporating a reporting exercise during their internship period would contribute to cultivating a patient safety culture among students. This approach facilitates experiential learning, enabling students to comprehend the intricacies of incidents, empowering them to identify and mitigate such occurrences in their future professional endeavors.

The incident reporting by students has 2 strengths: the firsthand experience in clinical risk management within a health care institution and the provision of specific information that can contribute to enhancing comprehensive patient safety education among students. When delving into the results obtained in terms of scores, we found congruence with the results of other studies [25] in that the analysis of causes emerged as the strongest aspect, whereas the proposal of an improvement plan proved to be the weakest. This is particularly evident in cases in which patient safety content was integrated into the curriculum, where greater familiarity with patient safety was correlated with higher-quality reporting. The variations in the scores obtained can be explained by the curricular differences between each country. The Argentinean university involved offers 2 subjects on patient safety during the 5 years of the degree. It also has a patient safety program in which theoretical, simulation, and practical modules on patient safety (international goals and risk management) are offered so that students receive training throughout their degree, from first to fifth year, in all subjects that involve field practice. In contrast, the Ecuadorian university involved lacks any specific courses on the subject during the 6 years. Spanish students receive specific lectures on patient safety in 4 subjects starting in the second year before entering the internship in the sixth year. One of these subjects also incorporates specific topics on AEs and their communication. In the Colombian university involved, there is no specific subject in the curriculum dedicated to this matter in the first 5 years of study. However, before engaging in clinical internships in the final year, students are required to complete a course on clinical management and health, which delves into introductory topics related to patient safety. In the case of the Brazilian university, the term "patient safety" is explicitly referenced in the curriculum of 6 subjects, spread out from the second to the fourth year of studies. Moreover, in another 17 subjects, while there may not be an explicit mention, faculty members address the subject matter throughout the duration of the academic term.

Similarly, female students achieved higher scores in the evaluation of their reports. Nevertheless, there is no existing literature to substantiate this observation, prompting the need to consider the influence of other factors that could account for it. In our case, these outcomes might be influenced by the sample distribution as reports submitted by male students were predominantly concentrated in Colombia (23/147, 15.6%) and Ecuador (21/147, 14.3%), the 2 countries exhibiting the lowest mean scores. Therefore, these differences might not be explained solely by sex but rather by the background in patient safety.

In this study, 47.1% (105/223) of students participated submitting at least one report. This percentage contrasted with the findings of other studies, which reported participation rates of approximately 12% [26]. This increase opens the door to a more in-depth exploration of the factors that may be influencing this elevated level of student participation. One potential line of inquiry focuses on student motivation and how it may be linked to the design or implementation of the reporting system. Examining the effectiveness of strategies used to encourage participation could shed light on the dynamics that lead to more active engagement by students in this particular context.

It is not surprising that many incidents took place in hospitals. First, students from both disciplines undertook most of their practical training in this environment, and this clinical exposure increases the likelihood of witnessing or being involved in safety incidents. Moreover, hospitals typically handle more complex and critical cases compared to other health care settings as well as conducting a greater quantity and variety of procedures. However, this figure may be influenced by the students' risk perception. It is plausible that primary care settings are perceived as less prone to safety incidents, leading students to pay less attention to their surroundings in such environments. In analogous studies, the most frequently reported type of incident was associated with medication administration [7]. However, in our case, what emerged most frequently throughout the reports were incidents related to caregiving. This outcome is likely related to the information more readily accessible to students, explaining why they witness fewer medication errors than expected during their practice [22].

During their clinical placements in health care settings, students frequently witness safety incidents of different severities, triggering conflicting emotions—from fear of speaking up to guilt for remaining silent. Studies suggest that approximately 4 out of every 10 students in training admit to having made at least one medical error during their training period [27]. Most of these errors involve lapses in clinical judgment (7 out of 10 cases). The primary causes of these errors have been associated with deficiencies in supervision and in the students' own technical competencies [28]. They often feel that the causes of these events are not adequately addressed. Once the practice session ends, they are left without information on whether the incident was reported, whether its causes were analyzed, or whether any subsequent actions were taken, all of which they might be unaware of. The attitudes and coping strategies of nursing students following the recognition of a medical error have been explored [29-31]. On the basis of our understanding, students who become implicated in an AE or near-miss situation tend to manifest symptoms aligned with the experience of second victims [27,32]. Familiarizing themselves with reporting and analyzing incident causes offers them a new perspective that we can also expect to aid them emotionally.

Finally, following the suggestions provided by the students and, thus, incorporating user-centered design principles, we found it highly beneficial to incorporate a text box for a brief narrative of the events. We believe that the optimal approach would involve presenting a comprehensive set of options to encourage reflection, prompting individuals to consider aspects they might not have otherwise. Subsequently, a field will be provided for

participants to describe the unfolding of events in their own words. This aligns with the findings of King et al [33], who advocate for a balanced approach in future patient reporting systems, integrating closed-ended questions for cause analysis and classification alongside open-ended narratives to accommodate patients' potential limitations in understanding terminology.

Implications of Findings

By providing a guided process, students are aided in considering a variety of factors that could pose potential risks, ranging from material resource deficiencies to patient attitudes or workload overload. Moreover, they learn to analyze different variables, weigh consequences, and make informed decisions based on available information. Consequently, students acquire skills and experience that they are expected to be able to apply in similar situations in the future. Similarly, by increasing awareness of risks and sources of mistakes and empowering students to identify them, the likelihood of involvement in dangerous or problematic situations is expected to be reduced [34], thereby contributing to the creation of safer environments.

The apprehension surrounding potential negative outcomes of reporting has been present since the initial implementation of reporting systems in Australia in 1993 [35]. Introducing students from health-related disciplines to the reporting process, emphasizing the understanding of why, how, and for what purpose they should contribute, aims to foster a safety culture among the forthcoming generations of health care professionals. Encouraging students to view errors as valuable learning opportunities rather than indicators of incompetence is highly necessary. Embracing mistakes as integral components of the learning process can foster a growth mindset where challenges become stepping stones to improvement. This positive approach not only cultivates resilience but also promotes a more constructive and proactive attitude toward learning.

Since digital systems offer a more enduring record-keeping mechanism and facilitate a higher volume of reports than their paper counterparts [9], approaches such as this one can increase the correctness and impact on the future rate of reporting. In addition, this educational practice should help overcome the initial reluctance that discourages reporting safety incidents. To know and have used an incident reporting tool, describing a safety incident and reflecting on its potential causes and the measures that could actively and thoughtfully prevent it, should have an impact on attitudes toward reporting [36,37].

Future Research

Several scales have been developed to assess students' knowledge and the information they receive, aiming to model their safety culture. Among these, the scales proposed by Flin et al [29] and Mira et al [38] are remarkable. However, we need to identify which mechanisms are most effective in integrating curriculum content that matches the students' knowledge levels and attitudes, fostering a cross-disciplinary education in patient safety.

In addition, although the students scored 4.0 out of 5 regarding the fact that after this experience, they would be capable of making reports properly, a follow-up over time is required to

really verify the benefits brought by this experience. Furthermore, it would be interesting to consider the use of this tool in students of earlier courses, provided they undergo some period of their training in clinical settings, to analyze its utility in earlier stages of education. This would also facilitate the development of longitudinal studies to monitor the impact in terms of reporting.

Limitations

The aim of this experience was not to detect the safety incidents themselves but rather to train students to make correct reports in their future professional practice. Thus, the frequencies and features described in this paper did not necessarily represent the actual safety incidents occurring and what students could witness in their countries.

Recognizing an error is not straightforward. Students in training may consider it risky for their future to report an incident, leading to a restriction in the information they provide to the system. If they end up working in an environment where psychological safety is at risk, despite actively participating in this educational practice, they might choose silence, and fear of potential negative consequences could undo what was gained from this practice. The same can happen with other organizational factors that may hinder and make reporting difficult for the group of professionals in a center. This practice does not prevent this from happening in some contexts.

It cannot be guaranteed that the reports accurately reflect incidents that actually occurred. A convenience sample was used, which restricts the generalizability of the results. The medical and nursing curricula in the different participating countries were not identical. Although participation in the study was offered in the context of subjects related to patient safety, it was not possible to control for students' baseline knowledge of incident reporting. These differences may have influenced the quality of the reports. It will be necessary to delve into the safety culture in the course of subjects with patient safety content in training programs. The constant technological evolution requires timely updating of the proposal, adapting it to possible technological solutions. Student involvement should

be facilitated by the participation of academics in the project. However, the project schedule may be affected by the academic obligations of this group (eg, exams, vacations, and internship periods).

With this exercise, students become familiar with a fundamental tool in patient safety that they will encounter at the beginning of their professional careers and often approach with some hesitation, particularly in the countries where the study was conducted. However, the reports are based on observations made during their placements, and the analysis of the proposed improvement plan was conducted without accessing all the clinical information necessary for a precise analysis of root and immediate causes. In this case, the remote causes could not be determined during the exercise.

The sample size and the study's cross-sectional nature did not allow for assessing the impact of evaluators' feedback on students' learning and the quality of their subsequent reports. In the future, longitudinal studies with repeated measures over time would make it possible to establish the effect of feedback.

Finally, we would have liked to establish a user-centered platform from the outset. However, due to the lack of previous information from students regarding the subject matter, it was not feasible to conduct a consultation to determine which elements to consider. We have endeavored to compensate for this by incorporating the feedback provided subsequently.

Conclusions

In Europe, only a handful of medical or nursing schools have incorporated curriculum plans addressing patient safety [14]. Studies examining the nature of patient safety training received by students in health care disciplines are limited [39,40]. Faculties and schools might consider these reflections and data, incorporating reporting as a practical exercise into their curriculum. This study presents an initial adaptation of reporting systems to suit the needs of students, introducing a guided and inspiring framework that has garnered positive acceptance and evaluation among students. Through this endeavor, a pathway toward a safety culture within the faculty is established.

Acknowledgments

The students participated voluntarily, making this educational practice possible. The authors disclose receipt of the following financial support for the research, authorship, and publication of this paper. This work was supported by the Grants for the Development of Research Projects for Consolidated Groups 2021 provided by the Foundation for the Promotion of Health and Biomedical Research of the Valencia Community with reference UGP-21-215. Throughout the execution of this study and composition of this manuscript, JJM benefited from an augmented research activity contract granted by the Carlos III Health Institute (reference INT22/00012). In addition, during the execution of this study and composition of this manuscript, EG-H received funding through a Predoctoral Fellowship for Research Training in Health from the Carlos III Health Institute supported by the European Union NextGenerationEU and the Recovery, Transformation, and Resilience Plan from the Spanish Government (reference FI22/00277).

Data Availability

The data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

All the authors meet the International Committee of Medical Journal Editors criteria for authorship. JJM, IC, MG, and CF were responsible for the design of the study. IC and EGH were responsible for obtaining ethics approval and registration in ClinicalTrials.gov. IC and MG conducted the review and compilation of the existing tools, and JJM and EGH drafted the first version of the form. PCS, JMD, and MMM reviewed the form and made the necessary clarifications. EB and VRN translated the contents into English, and finally, all authors approved the final form. Regarding the platform, CF developed the acronym and visual identity; EGH, IC, MG, and VRN prepared the instructional and introductory materials; and JJM, PCS, JMD, MMM, and EB were in charge of the recruitment and introductory seminar in each country. Finally, EGH, IC, and MG carried out the evaluation and feedback of the reports, and CPE performed the statistical analysis and interpretation of the results. JJM and EGH developed the first version of the manuscript. All authors revised the paper critically for important intellectual content and read and approved the final version of the manuscript.

Abstract

Background: Mobile health (mHealth) is an emerging mobile communication and networking technology for health care systems. The integration of mHealth in medical education is growing extremely rapidly, bringing new changes to the field. However, no study has analyzed the publication and research trends occurring in both mHealth and medical education.

Objective: The aim of this study was to summarize the current application and development trends of mHealth in medical education by searching and analyzing published articles related to both mHealth and medical education.

Methods: The literature related to mHealth and medical education published from 2003 to 2023 was searched in the Web of Science core database, and 790 articles were screened according to the search strategy. The HistCite Pro 2.0 tool was used to analyze bibliometric indicators. VOSviewer, Pajek64, and SCImago Graphica software were used to visualize research trends and identify hot spots in the field.

Results: In the past two decades, the number of published papers on mHealth in medical education has gradually increased, from only 3 papers in 2003 to 130 in 2022; this increase became particularly evident in 2007. The global citation score was determined to be 10,600, with an average of 13.42 citations per article. The local citation score was 96. The United States is the country with the most widespread application of mHealth in medical education, and most of the institutions conducting in-depth research in this field are also located in the United States, closely followed by China and the United Kingdom. Based on current trends, global coauthorship and research exchange will likely continue to expand. Among the research journals publishing in this joint field, journals published by JMIR Publications have an absolute advantage. A total of 105 keywords were identified, which were divided into five categories pointing to different research directions.

Conclusions: Under the influence of COVID-19, along with the popularization of smartphones and modern communication technology, the field of combining mHealth and medical education has become a more popular research direction. The concept and application of digital health will be promoted in future developments of medical education.

KEYWORDS

mHealth; mobile health; medical education; bibliometric; knowledge map; VOSviewer

Introduction

The rapid development of information and communication technologies in recent years has enabled greater connections to the mobile internet to access any information desired at any time and place, providing favorable conditions for the development of mobile health (mHealth). mHealth offers a full range of health care and medical education services, transcending geographical, time, language, and even organizational barriers [1,2].

mHealth was first defined as “unwired e-med” by Laxminarayan and Istepanian [3] in 2000. In 2003, mHealth was defined as an

emerging mobile communication and networking technology for health care systems [4]. mHealth can provide diagnostic and treatment support services through mobile communication devices such as mobile phones, iPads, and personal digital assistants. An mHealth system and its associated app functions have a significant impact on typical health care, clinical data collection, record maintenance, health care information awareness, detection and prevention systems, drug counterfeiting, and theft. Thus, mHealth services have a powerful impact on all health services, including hospitals, care centers, and acute care, and are designed to significantly improve the lives of patients, especially older adults, individuals with physical disabilities, and patients with chronic conditions [4].

Currently, medical resources are extremely unevenly distributed among populations. In many developing countries, medical services have not yet been updated to incorporate current technological capabilities and the level of medical education often lags far behind that of developed countries. The integration and development of mHealth and medical education can help to address this situation. Through mHealth, doctors can provide basic health care and concepts to people living in areas where health services are lacking, and researchers who are experts in the field can share their clinical experience and theoretical knowledge with their peers through mobile communication technologies such as mobile phones. Thus, the widespread adoption of mHealth can not only rapidly raise the level of medical services in a region but can also help to somewhat reduce the gap in health services between different regions of the world and promote the progress of the global health care industry. From the perspective of medical education, medical students have traditionally only been able to acquire theoretical knowledge in the classroom and obtain hands-on experience through clinical practice. With the development and promotion of various medical-related mobile apps, medical education is no longer limited to face-to-face interactions, and more advanced and quality teaching resources can be disseminated through mobile software and other digital means. The combination of mHealth and medical education has provided more access to educational resources for medical students and physician groups at different levels [4].

Bibliometric analysis is a quantitative analysis method combining mathematics and statistics that focuses on the bibliometric characteristics of a research field to help researchers better understand the development trends in the field for guiding more in-depth research [5-7]. As research on mHealth continues to deepen, there have been an increasing number of articles published in the field. However, to date, there has been no bibliometric analysis of research related to the applications of mHealth in medical education. Therefore, in this study, we summarized the literature related to mHealth and medical education to help deepen our understanding of mHealth and identify future directions for its in-depth research in the context of developing medical education.

Methods

Ethical Considerations

All of the data collected and analyzed in this study were obtained from online public databases and did not involve any human or animal; thus, ethical approval was not required.

Data Sources

The Web of Science (WoS) literature database was selected to search, export, and analyze the relevant literature linking mHealth and medical education. Although the concept of mHealth was first proposed in 2000, since it was only officially defined in 2003, we set the start date for the search to 2003 [3,4,8]. We searched the WoS platform on April 2, 2023, selecting the WoS Core Collection, which contains articles included in the SCI (Science Citation Index)-EXPANDED, SSCI (Social Science Citation Index), AHCI (Arts & Humanities Citation Index), CPCI-S (Conference Proceedings Citation

Index-Science), CPCI-SSH (Conference Proceedings Citation Index-Social Science & Humanities), BKCI-S (Book Citation Index-Science), BKCI-SSH (Book Citation Index-Social Science & Humanities), ESCI (Emerging Sources Citation Index), CCR (Current Chemical Reactions)-EXPANDED, and IC (Index Chemicus) databases.

Search Strategy

The search in the WoS Core Collection was performed in advanced search mode and the search option was set to “exact search.” The search terms included a combination of “mHealth,” “mobile health,” and “medical education” as follows: “TS=[(mobile health) OR (mHealth)] AND [medical education].” The time span was from January 1, 2003, to March 31, 2023; the document type was limited to “Articles”; and English was selected as the only language of publication. The first output of the articles retrieved was obtained according to this strategy without setting any other inclusion criteria.

Data Analysis and Visualization

The literature retrieved based on the search strategy outlined above was exported in both plain-text (txt) and tab-delimited (txt) file formats. Descriptive statistics were obtained using HistCite Pro 2.1 [9]. Microsoft Excel 2021 was used to summarize the results from the HistCite Pro 2.1 analysis quantitatively and present the data graphically. VOSviewer (version 1.6.17) was used for cocitation correlation analysis and knowledge mapping [10]. VOSviewer (version 1.6.17) [11] and Pajek64 (version 5.16) were used jointly to analyze the current state of research and time trends. Visualization of country/region coauthorship trends was achieved using the combined powerful mapping capabilities of VOSviewer (version 1.6.17) and SCImago Graphica (version 1.0.34).

VOSviewer Software Settings

We used VOSviewer to perform a keyword co-occurrence analysis on the exported documents, setting the unit of analysis to “all keywords” and the counting method to “full counting”; the minimum number of occurrences was set to 10. For the overlay visualization, we utilized Pajek software for classification assistance. In the national and regional coauthorship trends analysis, we set the minimum number of coauthors for each country to 5 in VOSviewer. In the cocited references analysis, we set the minimum number of citations to 10. In the cocited journal sources analysis, we set the minimum cocitation count to 35. In the cocited authors analysis, we set the minimum number of citations to 20.

Results

Search Results and Publication Trends

A total of 790 publications related to mHealth and medical education were retrieved based on the search strategy outlined in the Methods, which were analyzed by HistCite Pro 2.1. The local citation score (LCS) and global citation score (GCS) were calculated by the HistCite Pro software based on the information provided in the documents. The LCS refers to the number of times a document is cited within a given topic, reflecting the extent of recognition of research findings within the peer

community. The GCS represents the number of times a document is cited across all fields globally, serving as a significant indicator of the interdisciplinary and cross-domain impact of research outcomes. The GCS for the 790 articles was 10,600, with an average of 13.42 citations per article, and the LCS was 96.

Figure 1 shows the number of mHealth and medical education–related publications and the associated changes in the LCS over time. In the last two decades, especially since 2007, the annual number of publications has been steadily increasing year by year. Since 2020, the annual number of publications has exceeded 100, rising to 130 in 2022. However,

data for 2023 only include publications from the first 3 months and are thus incomplete, making it difficult to determine the publication trend for that year. In terms of the LCS, the highest value was 15 in 2016, indicating a significant reference value for research in mHealth and medical education in that year. Additionally, there were peaks in the LCS detected in 2008 (7), 2013 (14), 2014 (14), and 2016 (15), indicating that studies in these years had large contributions to the research published in this field in the subsequent years. However, due to limitations of the search time frame, articles submitted in 2022 and 2023 may still be under review and not yet been published (and therefore not yet cited), resulting in an incomplete calculation of LCS values for the past 3 years.

Figure 1. Annual trend in the number of publications and local citation score (LCS) in the field of mobile health and medical education from 2003 to 2023.

Contributions of Countries and Institutions

We analyzed the top countries and institutions that have published research related to mHealth and medical education. [Figure 2A](#) shows the top 10 countries in terms of publication volume, with each country publishing over 20 articles. The United States ranked first with a total of 318 articles, accounting for 40.25% of the total publication volume, representing a contribution far greater than that of other countries. China (n=70) and the United Kingdom (n=62) ranked second and third, respectively. The top 5 countries with respect to the LCS are

presented in [Figure 2B](#), with the LCS for the United States reaching 47, which was much higher than that for any other country. [Figure 2C](#) lists the top 5 countries in terms of the article H-index, with the United States again ranking first with an H-index of 32; followed by the United Kingdom (17) in second; and China, Canada, and Australia tying for third with an H-index of 14 each. Therefore, the United States leads in both the quantity and quality of publications related to mHealth and medical education, while China and the United Kingdom also rank in the top three for all indicators.

Figure 2. Ranking of top publishing countries and institutions in the field of mobile health and medical education. (A) The top 10 countries with the largest number of publications and their proportions. (B) The top 5 countries with the largest LCS and their proportions. (C) The top 5 countries with the largest H-index values. (D) Institutions with more than 10 publications. (E) The top 6 institutions with the largest LCS. (F) The top 5 institutions with the largest H-index values. Hlth Bur Gansu Prov: Health Bureau of Gansu Province; LCS: local citation score; MCPHS: Massachusetts College of Pharmacy and Health Sciences; Minist Hlth: Ministry of Health; Peoples R China: People's Republic of China.

We subsequently analyzed the institutions that published the retrieved articles in this field. [Figure 2D](#) shows the institutions with more than 10 publications on the topic, with The University of Sydney ranking first with 18 articles, followed by The University of Toronto (n=16), and Harvard Medical School and Johns Hopkins University tied for third place with 15 relevant publications each. In terms of the LCS, The University of Pennsylvania ranked first with a score of 10 ([Figure 2E](#)). [Figure 2F](#) compares the top 5 institutions in terms of the H-index, with The University of Pennsylvania and The University of Sydney having the highest H-index of 9 each. Thus, overall, the world's leading universities such as The University of Pennsylvania and The University of Sydney are producing relatively advanced research in mHealth and medical education, and this institutional-based analysis is largely consistent with the country-based analysis.

Journal of Publication and Authors

A total of 420 journals were involved in publishing mHealth and medical education-related articles according to statistics

compiled with HistCite Pro 2.1. *JMIR mHealth and uHealth* ranked first with 67 related publications, *Journal of Medical Internet Research* ranked second with 35 articles, and *JMIR Formative Research* and *BMJ Open* ranked third with 19 articles each. Among the journals with more than 10 publications, five are from JMIR Publications ([Figure 3A](#)). In terms of the H-index, *JMIR mHealth and uHealth* again ranked first with an H-index of 20, *Journal of Medical Internet Research* ranked second (15), and *Telemedicine and e-Health* ranked third (9) ([Figure 3B](#)). This finding demonstrates the comprehensiveness and authority of the JMIR Publications journal series in the field of mHealth and medical education.

The authors with the highest number of publications published 5 articles each, and since most of these authors are repeated coauthors, this field appears to be dominated by a relatively small set of researchers. [Table 1](#) lists the authors with more than 4 articles published along with their LCS and GCS; among them, Littman-Quinn R, Aungst TD, and Kovarik CL are at the top of the list in terms of both the quantity and quality of publications.

Figure 3. Contributions of journals to the field of mobile health and medical education. (A) Journals with more than 10 publications. (B) Top 5 journals with the largest H-index values.

Table . Authors with more than 4 publications and their associated local citation score (LCS) and global citation score (GCS).

Author	Number of publications	LCS	GCS

Keyword Co-Occurrence and Research Trends

We used VOSviewer to conduct keyword co-occurrence analysis on the exported 790 documents. A total of 3288 keywords were extracted, with 105 keywords meeting the threshold. The 105 keywords were then plotted using VOSviewer for density, network, and overlay visualization.

Figure 4 shows the density visualization of the 105 keywords, revealing that the majority of research in this field revolves around mHealth or education, which, to a certain extent, verifies the objectivity and scientificity of our search strategy and analysis.

Figure 5A shows a network visualization of the 105 keywords. A color node can roughly represent a research direction and a larger node area typically indicates a more popular keyword. The software divided all keywords into 5 categories. The red cluster consists of 34 keywords, primarily focusing on clinical medical education (including the keywords “education” and “medical education”), demonstrating that the application of mobile medical software (ie, mobile apps) in medical education and knowledge is widely studied. The green cluster comprises 33 keywords, mainly focusing on the management and development of mobile medical devices and software as well as their application in different age groups through the internet and mobile apps (including the keywords “internet,” “mobile app,” “management,” “outcomes,” “adults,” “children,” and “adolescents”). The blue cluster includes 21 keywords, emphasizing the promotion and education of mHealth in public health and epidemiology (including the keywords “public health,” “medical informatics,” “health education,” “epidemiology,” “HIV,” and “COVID-19”). The yellow cluster contains 16 keywords, primarily investigating the association of mHealth with smartphones, applications in remote diagnosis and treatment, and its role in digital medicine (including the

keywords “mHealth,” “smartphone,” “mobile phone,” “telehealth,” “telemedicine,” and “digital health”). As the purple cluster contains only one keyword, “qualitative research,” this serves as a link between various research areas owing to its vague directionality.

Figure 5B presents an overlay visualization of the 109 keywords highlighted in research related to the field of mHealth and medical education. According to the color legend, over time, the main keywords in this research area have gradually shifted from the purple (prior to 2017) to yellow (after 2020) category. This indicates that initially, this field was limited to the understanding and learning of mobile information (including the keywords “information,” “mobile,” and “mobile learning”). With the development and popularity of the internet and mobile devices, their use in medical education began to be promoted (including the keywords “internet,” “mobile devices,” “mobile technology,” and “medical education”). Further, with the development of mobile phones and mobile software, the application of mHealth in medical education is no longer limited to the teaching of professional knowledge to students but is also oriented toward the general public and the promotion of educational medical health concepts among different groups of people (represented by most keywords in the teal-colored small-sized nodes).

In recent years, mHealth has increasingly shifted into the research spotlight with the continuous support of smartphones and a greater inclination toward public health, along with the implementation of inclusive medical services and health communication (yellow small-sized nodes). In the future, increased promotion and use of mHealth care may push digital health (highlighted as “digital health” in yellow in Figure 5, referring to the application of digital technologies such as the Internet of Things, artificial intelligence, and big data in health management) to a focused area of research.

Figure 4. Density visualization of the top 105 keywords. The higher the keyword density, the redder its surrounding color.

Figure 5. (A) Network and (B) overlay visualization of the 105 keywords.

National and Regional Coauthorship Trends

Different countries and regions tend to collaborate on the same research topics rather than working in isolation. VOSviewer identified 37 countries with coauthorship relationships. As shown in [Figure 6A](#), the red clusters (12 countries) have the strongest coauthorship relationships, with the United States (as the country with the highest number of publications) having the most significant coauthorship relationships. We then exported

the results of the VOSviewer analysis to SCImago Graphica for further analysis of country coauthorship correlations in a world map ([Figure 6B](#)), which provides a clearer visual representation of the strong coauthorship links between countries on all continents, mainly comprising European countries. This map also shows that researchers working in different countries have a large breadth of interactions, even communicating with each other across continents.

Figure 6. National and regional coauthorship trends. (A) Network map of national coauthorship. (B) Country coauthorship correlations in a world map.

Cocitation Analysis

Cocited References

Cocited references are an important indicator of the extent to which a particular field is linked to different researchers or research areas. A total of 25,986 cited references were considered valid in VOSviewer, with a total of 28 articles meeting the minimum threshold. These 28 references were

divided into three interconnected clusters (Figure 7A), with 11 articles in the red cluster, 9 articles in the green cluster, and 8 articles in the blue cluster. The article “Smartphone and medical related app use among medical students and junior doctors in the United Kingdom (UK): a regional survey” by Payne and colleagues [12], published in *BMC Medical Informatics and Decision Making* [12], showed the highest cocitation frequency, with 28 citations.

Figure 7. Cocitation analysis. (A) Network map of cocited references. (B) Network map of cocited journal sources. (C) Network map of cocited authors.

Cocited Journal Sources

The analysis of cocited journal sources demonstrates the extent to which research in the fields of mHealth and medical education is published in journals that have previously published relevant literature on these topics. A total of 83 journal sources met the minimum threshold (Figure 7B), with the *Journal of Medical Internet Research* having the most cited articles at 898. The 83 journals were divided into six clusters, including 23 journals in the red cluster, 15 in the green cluster, 14 in the blue cluster, 13 in the yellow cluster, 11 in the purple cluster, and 7 in the cyan cluster.

Cocited Authors

The number of cocited authors serves as an important indicator for bibliometrics analysis, highlighting the closeness of scholarly relationships and research directions among scholars. In VOSviewer, 22 authors met the minimum threshold of 20,821 citations. According to the network of cocited authors (Figure 7C), a larger area of a color node indicates more citations. The World Health Organization (WHO) had the highest number of citations, reaching 160, reflecting its authority in the field of mHealth combined with medical education. Although each of the four colors represents a different research focus for different authors, the different clusters are not absolutely isolated from each other.

Discussion

Principal Results

In this study, we conducted a search of the literature in the WoS Core Collection and obtained 790 relevant articles on mHealth and medical education published from 2003 to 2023 according to the search strategy. In the past two decades, especially since 2007, the number of published papers in this combined field has gradually increased, reaching 130 published papers in 2022. The GCS is 10,600, with an average of 13.42 citations per article, and the LCS is 96. The United States stands out as the country with the greatest application of mHealth in medical education, and most of the institutions with in-depth research in this field are also located in the United States. The depth of research in China and the United Kingdom followed closely behind. Based on current trends, global coauthorship and research exchange will continue to expand. Among the journals publishing research on this topic, JMIR Publications journals have an absolute advantage in this joint field. The 105 keywords identified were divided into five categories pointing to different research directions.

An important indicator of research trends in a field is the number of relevant articles published each year. The results of this analysis show a general upward trend in research in mHealth and medical education, a field that has received a great deal of attention in recent years. As of 2020, research in this joint field can be divided into two phases: the nascent phase and the stable growth phase. The nascent phase spans from the introduction of mHealth in 2003 to 2007 when the model of combining mHealth and medical education was first proposed and associated research was in its infancy, as represented by the small number of relevant articles published in this period. The period from 2007 to 2020 represents a phase of steady growth, with a gradual increase in the number of relevant research articles. In terms of the LCS, there were four peaks detected in 2008, 2013, 2014, and 2016, respectively. Considering the annual publication volume over the entire period of mHealth research, it can be inferred that the research achievements in 2008 played a crucial role in the development of mHealth applications in medical education.

From Figure 5B, it can be seen that the main keywords representing the direction of mHealth before 2017 were “health care,” “internet,” and “information”; however, after 2019, the main keywords changed to “mobile phone,” “mHealth,” and “education,” indicating that the direction of mHealth development has been changing in recent years. This may be due to the popularity of smartphones, development of mobile software, spread of the internet, and rapid development of communication technology. mHealth has evolved from an initial focus on understanding and learning about mobile information and health care information to a combination of mHealth and mobile devices for research and medical education. On January 9, 2007, Steve Jobs, as the Chief Operating Officer of Apple, presented the iPhone 2G and its operating system iOS to the world. This event triggered the rapid development of smartphones and associated apps, as well as the emergence of new mobile platforms. Likely due to these breakthroughs in

smartphones and mobile-related technologies, mHealth began to enter the minds of researchers, attracting the attention of scientists worldwide, and thus the number of annual publications related to mHealth began to rise steadily. In addition, the rapid development of communication technology, increasing popularity of smartphones, and development of mobile software provided a suitable platform for medical schools, hospitals, and research institutions in different regions to collaborate and communicate with each other.

On March 11, 2020, the WHO announced COVID-19 as a global pandemic caused by SARS-CoV-2, which affected the daily lives of billions of people [13-15]. The COVID-19 pandemic not only posed a serious challenge to global medical care systems [16] but also limited access to learning and education, with most students having to access knowledge via the internet using communication devices such as mobile phones, iPads, and computers at home. This led to the rapid development of online teaching and learning software, and ultimately accelerated the integration of mHealth and medical education. Consequently, the number of mHealth-related research articles exceeded 100 in 2020 and rose to 130 in 2022. The development and application of 5G mobile technology and the rapid development of online teaching-related software collectively contributed to the deeper integration of mHealth and medical education [17]. Analysis of keyword clusters (Figures 4 and 5A) showed that mHealth research in the last two decades can be roughly divided into four clusters: a clinical education-related cluster, an mHealth equipment and software-related cluster, a health care and public health mission cluster, and a telemedicine cluster. The development of the discipline requires mutual cooperation with other fields. Promoting the integration and development of mHealth and medical education is extremely important to improve the health care conditions in less developed areas such as developing countries and to promote the common development of the world's health care standards, which is in line with the WHO's aim to improve the health of people around the world as much as possible.

The high number of citations in this joint field is somewhat indicative of the quality of the research cited. The study by Payne et al [12] received a particularly high number of citations, indicating its significant impact on medical education and mHealth. This study found that medical students and physician groups enjoy acquiring theoretical knowledge through an mHealth teaching model, which is consistent with the overall findings of this bibliometric analysis. In terms of researchers, the WHO has the highest number of cited articles in the field of mHealth combined with medical education, which not only reflects the authority of the organization but also shows the importance the WHO attaches to mHealth combined with medical education. The top three cited journals for mHealth and medical education research are *JMIR mHealth and uHealth* (impact factor 4.948, Q1), *Journal of Medical Internet Research* (impact factor 7.077, Q1), and *BMJ Open* (impact factor 3.007, Q2). According to their impact factors obtained from Journal Citation Reports 2022 [18], these three journals are considered Q1 and Q2 journals, indicating their strong contributions to their respective fields. The cocitation analysis demonstrated the authority of *Journal of Medical Internet Research* in the field

of mHealth and medical education research, with an annual volume of 318 articles, an LCS of 47, and an H-index of 32. Although the United States is clearly the world leader in mHealth and medical education, making a significant contribution to the field, academic exchanges between different countries are also ongoing.

Limitations

There are limitations of our study that should be acknowledged. First, data completeness may be inadequate; although the WoS database has the most complete coverage of articles, our literature search was limited to the English language, which may have resulted in the omission of some key information for some countries where research was published in other languages. In addition, the search strategy was limited to the string “TS=[(mobile health) OR (mHealth)] AND [medical education]” and therefore may not have been sufficiently comprehensive.

Second, we only searched under the category “Articles,” which may have also led to missing relevant publications in other formats.

Conclusion

Bibliometric analysis indicates that mHealth-related research has been growing at an accelerating rate over the last two decades. In the area of combining mHealth and medical education, the WHO is playing an important leadership role, with many researchers following suit. With the influence of COVID-19, the spread of smartphones, and constant developments in modern communication technologies, the field of combining mHealth and medical education is becoming increasingly popular, and the concept and application of digital health will be promoted in the future drive for medical education.

Acknowledgments

We thank the Web of Science database for providing all of the data used in this analysis. We are also grateful to Stable Diffusion, a deep learning model used to convert text into images, which was used to generate the table of contents image. This work was supported by the National Natural Science Foundation of China (grants 82170654 and 82100675), Key Research and Development Program of Heilongjiang Province (grant 2022ZX06C06), Excellent Youth Foundation of the First Affiliated Hospital of Harbin Medical University (grant 2021Y12), and Postgraduate Research & Practice Innovation Program of Harbin Medical University (grant YJSCX2023-207HYD).

Data Availability

The data sets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Authors' Contributions

YH designed the study and analyzed the data. YH and ZX wrote the manuscript. JL and ZM prepared the figures and tables. CH reviewed and revised the manuscript. DX and CH supervised the research and thus made equal contributions to the work. All authors approved the final manuscript.

Abstract

Background: Carers often assume key roles in cancer care. However, many carers report feeling disempowered and ill - equipped to support patients. Our group published evidence-based guidelines (the Triadic Oncology [TRIO] Guidelines) to improve oncology clinician engagement with carers and the management of challenging situations involving carers.

Objective: To facilitate implementation of the TRIO Guidelines in clinical practice, we aimed to develop, iteratively refine, and conduct user testing of a suite of evidence-based and interactive web-based education modules for oncology clinicians

(e-Triadic Oncology [eTRIO]), patients with cancer, and carers (eTRIO for Patients and Carers [eTRIO - pc]). These were designed to improve carer involvement, communication, and shared decision-making in the cancer management setting.

Methods: The eTRIO education modules were based on extensive research, including systematic reviews, qualitative interviews, and consultation analyses. Guided by the person-based approach, module content and design were reviewed by an expert advisory group comprising academic and clinical experts (n=13) and consumers (n=5); content and design were continuously and iteratively refined. User experience testing (including “think-aloud” interviews and administration of the System Usability Scale [SUS]) of the modules was completed by additional clinicians (n=5), patients (n=3), and carers (n=3).

Results: The final clinician module comprises 14 sections, requires approximately 1.5 to 2 hours to complete, and covers topics such as carer-inclusive communication and practices; supporting carer needs; and managing carer dominance, anger, and conflicting patient-carer wishes. The usability of the module was rated by 5 clinicians, with a mean SUS score of 75 (SD 5.3), which is interpreted as good. Clinicians often desired information in a concise format, divided into small “snackable” sections that could be easily recommenced if they were interrupted. The carer module features 11 sections; requires approximately 1.5 hours to complete; and includes topics such as the importance of carers, carer roles during consultations, and advocating for the patient. The patient module is an adaptation of the relevant carer module sections, comprising 7 sections and requiring 1 hour to complete. The average SUS score as rated by 6 patients and carers was 78 (SD 16.2), which is interpreted as good. Interactive activities, clinical vignette videos, and reflective learning exercises are incorporated into all modules. Patient and carer consumer advisers advocated for empathetic content and tone throughout their modules, with an easy-to-read and navigable module interface.

Conclusions: The eTRIO suite of modules were rigorously developed using a person-based design methodology to meet the unique information needs and learning requirements of clinicians, patients, and carers, with the goal of improving effective and supportive carer involvement in cancer consultations and cancer care.

Introduction

Background

Carers (including but not limited to spouses, partners, adult children, siblings, parents, or friends [1]) of adults with cancer assume many responsibilities in supporting and caring for their loved one [2]. Carers can experience many challenges in this demanding role and often report high distress [3,4], poor physical health, low quality of life, and unmet needs [5,6]. As carer burden increases, carers may neglect their own needs, which can also impact their ability to support and care for their loved one [7,8].

While issues faced by carers are well recognized by health care professionals [9], many clinicians report that they do not know how to appropriately engage with carers or address their unique challenges [9,10]. Oncologists have reported a lack of education about communicating with carers [10], and suboptimal carer-clinician communication is common [11]. Some carers report being overlooked in medical consultations and feeling disempowered and unprepared in their caregiving role [12]. Clinician inclusion and support of carers have been reported as highly valued by both carers and patients [12].

Improving carer engagement and support needs to be addressed from multiple perspectives. Not only are clinicians uncertain about how to include carers in consultations [9] but also many carers often lack confidence and skills in caregiving [12,13], and some patients are unsure about what role their carer should assume in medical consultations and decision-making [14]. Therefore, interventions targeting *all* members of the clinician-patient-carer trio are needed.

Web-based delivery of education offers efficacy, efficiency, ability to undertake training in discrete periods, lower cost, flexibility, and greater reach than traditional face-to-face formats [15]. A systematic review of web-based health education by George et al [16] found web-based training for health professionals to be as effective as or better than face-to-face formats on outcomes such as knowledge, skills, and attitudes. Web-based communication skills interventions have been found to be effective in improving self-rated clinician confidence, communication skills, and knowledge among cancer clinicians [15]. For example, a web-based module developed by our group to educate nurses about managing conflict involving patients and carers (the Triadic Oncology [TRIO]-Conflict module) was found to improve cancer nurses' attitudes and confidence in interacting with carers [17].

Patients and carers can also benefit from web-based resources and educational tools [18]. A systematic review of digital psychosocial interventions for patients with cancer and carers found web-based interventions to be both feasible and acceptable [19]. Digital interventions for carers have been shown to improve carer outcomes, knowledge, and skills, with the additional benefit of being accessible from home, thus minimizing the demands on carers' time [20]. For example, a web-based psychosocial intervention for patients with cancer, Stress-Aktiv-Mindern (STREAM), has demonstrated beneficial patient outcomes including reduced stress and improved quality of life [21]. Similarly, the psychoeducational platform, Comprehensive Health Enhancement Support System (CHESS), has demonstrated favorable outcomes among carers such as significant reduction in negative mood and carer burden [22]. These beneficial effects were comparable to those of traditional psychoeducation interventions [23,24]. While STREAM and

CHESS demonstrate the efficacy of web-based patient and carer support, their focus is on *psychosocial* support. To date, there have been no web-based education modules dedicated to empowering and upskilling patients and carers in *carer-relevant communication and engagement* with cancer clinicians and in carer participation in cancer treatment decision-making. Therefore, we aimed to develop and evaluate a web-based learning tool to address these needs.

Interventions to support cancer carers are often difficult to implement in clinical practice and face barriers to implementation including problems with design, feasibility, acceptability, and cost [25]. One way to improve the acceptability and sustainability of an intervention is to use a co-design approach with the target population as stakeholders, to ensure that the program targets user needs and preferences. The person-based approach [26] ensures that intervention development is grounded in the perspectives and psychosocial context of end users via iterative, qualitative research with relevant stakeholders. This approach has been effectively used in the development of web-based health care interventions [27,28].

Objectives

This paper describes the development, iterative refinement, and user testing of evidence-based and interactive web-based interventions designed to improve engagement and communication with carers in cancer care. We have published the study protocol for a randomized controlled trial to test the efficacy of the e-Triadic Oncology (eTRIO) modules elsewhere [29]. However, necessary amendments to the planned randomized controlled trial due to the COVID-19 pandemic

were made after publication of the protocol. The evaluation approach was revised to hybrid effectiveness and implementation studies using a pre-post, single-arm intervention design.

In this paper, we have reported about the development of web-based education modules for all 3 relevant stakeholder groups, including oncology health professionals and patients with cancer and carers (eTRIO for patients and carers [eTRIO-pc]).

Methods

Overview

The person-based co-design approach by Yardley et al [26] underpinned the module design. Development and user experience testing of the clinician (eTRIO) and patient-carer (eTRIO-pc) modules was undertaken in multiple cyclical phases of data collection, analysis, and integration, in a process of iterative refinement [30]. Consistent with the approach by Yardley et al [26], this involved (1) *planning*: development of module content based on evidence, qualitative interviews with stakeholders, and input from our expert advisory group; (2) *design*: iterative review and refinement based on advisory group feedback; and (3) *development and evaluation of acceptability and feasibility*: formal heuristic evaluation, System Usability Scale (SUS) questionnaire, and think-aloud review of the eTRIO modules by stakeholders (Figures 1 and 2). The final phase of implementation and trialing is currently being conducted in a separate pre-post evaluation study, which will be reported elsewhere.

Figure 1. e-Triadic Oncology (eTRIO; clinician) module development process. SUS: System Usability Scale.

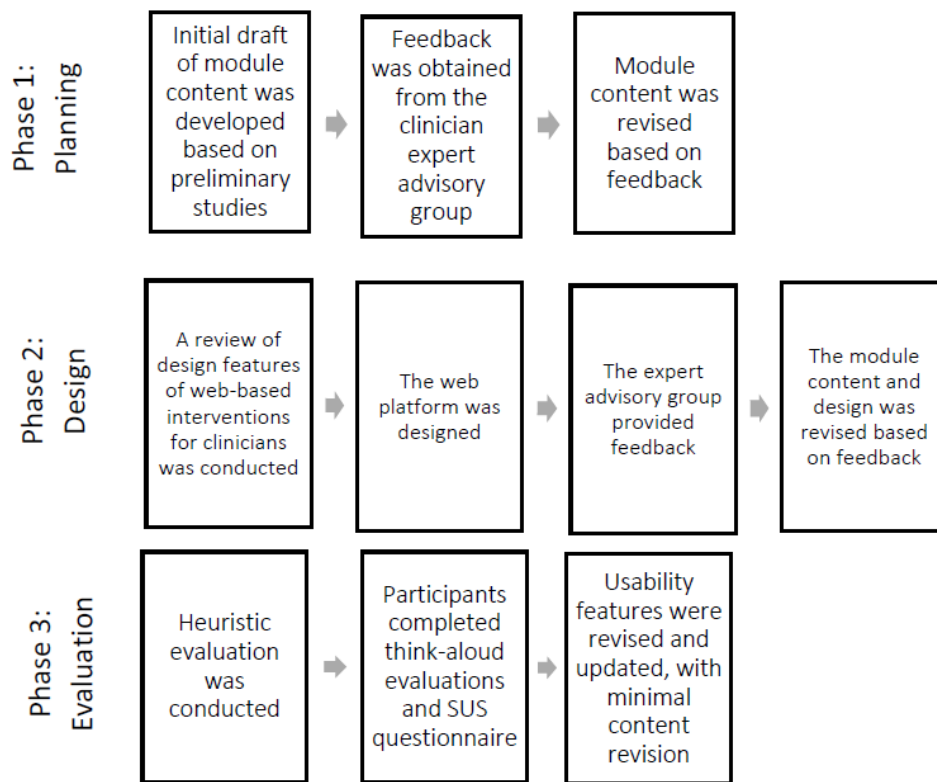

Figure 2. e-Triadic Oncology for patients and carers (eTRIO-pc) module development process. CCNSW: Cancer Council New South Wales; SUS: System Usability Scale.

Phase 1: Development of eTRIO and eTRIO-pc Module Content

Development of the eTRIO Clinician Module

The content of the modules was informed by our extensive Triadic Oncology (TRIO) research program, which includes a systematic review of carer involvement in consultations [31]; qualitative interviews with oncology clinicians, patients, and carers [9,14,32]; quantitative and qualitative analyses of audiotaped oncology consultations [11]; a conceptual framework of carer involvement in medical decisions [33]; and carer communication guidelines for clinicians (TRIO Guidelines) developed via a Delphi consensus process [34,35]. Key clinician training needs, strategies, and behaviors relevant to the module were ascertained through this extensive research program.

On the basis of this prior research, we developed an initial draft of the eTRIO content. The draft module comprised 14 study sections (1 introductory section and 13 strategy areas covered in the TRIO Guidelines [34,35]). A clinician expert advisory group was formed to provide feedback about the module content, comprising medical oncologists (3/13, 23%), oncology nurses (2/13, 15%), psychologists (2/13, 15%), a radiation oncologist (1/13, 8%), an oncology surgeon (1/13, 8%), and the research team comprising psycho-oncologists (4/13, 31%). Each member of the clinician expert advisory group reviewed a text-based draft of the module content and provided written feedback about each module section, including interactive activities, reflective exercises, and wording of strategies. Multiple teleconferences were conducted, where group members provided feedback about the content and structure of each section. Major changes were discussed with the group until consensus was reached. Feedback from the advisory group was collated, and the module content was iteratively refined.

Development of the eTRIO-pc Patient-Carer Module

The eTRIO-pc module content was drafted based on a review of current web-based guidance for carers about involvement in medical consultations [18], qualitative studies of patients and carers [9,14,32], and analyses of audiotaped consultations [11]. A meeting with the staff at a leading nongovernment cancer support and advocacy organization (n=5) was also conducted to inform the content of the eTRIO-pc initial draft. The staff members were asked to describe the key content that should be included in the eTRIO-pc module, based on their experience in supporting patients and carers via a telephone information and support service.

Consumer advisers (3/5, 60% cancer carers and 2/5, 40% patients with cancer) also provided iterative feedback about the module content during a half-day workshop and via email. Consumer advisers were asked to comment about whether the module content was understandable, the relevance of the module content and feasibility of the suggested strategies, the language, and tone of the module. All feedback from the Cancer Council New South Wales support staff and consumer advisers was collated and discussed with the project team until consensus was reached through revisions.

After the development and iterative revision of the module content was complete, video vignettes modeling key carer

communication skills were developed to supplement the written content. Video vignettes have been demonstrated as an effective educational tool for patients and carers and can improve accessibility for those with low literacy [36,37]. We engaged a professional medical education and communication production company to develop a script covering key learning areas for carers, as determined by the consumer advisory groups. The script was iteratively reviewed by the research team, consumer advisers, and a physician to ensure that the videos aligned with the TRIO communication guidelines [34,35] and were clinically relevant and feasible.

Phase 2: Iterative Design, Review, and Refinement of eTRIO and eTRIO-pc Web-Based Modules

Design and Refinement of eTRIO Clinician Module

As shown in Figure 1, phase 2 involved consumer input and refinement of the modules. To translate the text-based content into an interactive web-based educational module, we studied the best practice principles for the delivery of e-learning to health professionals [16,38-40]. This included a review by de Leeuw et al [38] about e-learning features targeted at postgraduate medical students and health professionals completing ongoing professional development, which identified 6 domains of important elements for e-learning quality (preparation, design, communication, content, assessment, and maintenance). Informed by a previous review [38], we developed a base design and catalog of potential design features.

A prototype web platform was developed by a professional web development company. In 2 sessions conducted via Zoom (Zoom Video Communications), the clinician advisory group completed a walk-through of the module and provided comprehensive feedback. Their verbal and written feedback was collated and integrated into a revised web-based module.

Design and Refinement of the eTRIO-pc Patient-Carer Module

Similarly, as displayed in Figure 2, phase 2 involved the conversion of the text-based module content for patients and carers into an interactive web-based platform. We conducted a review of the content and design features of other available evidence-based web-based platforms for carers [18], drew on the evidence base surrounding education for carers [41-43], and received input from the consumer advisory group. To inform the website design, we reviewed the publicly available web-based resources for carers.

The final design features of eTRIO and eTRIO-pc were implemented by a professional web development company and included interactive activities, video vignettes, and text-based content. The clinician and consumer advisory groups were given access to the draft module, and its content and format were revised based on their extensive feedback. An expert in human-centered IT design was involved in all stages of development of the clinician and patient-carer modules.

Phase 3: Heuristic Evaluation and “Think Aloud” User Experience Evaluation of eTRIO and eTRIO-pc Web-Based Modules

As shown in Figures 1 and 2, phase 3 involved usability evaluations of the developed web-based module. We conducted a heuristic evaluation to discover technical and usability issues [44]. The modules were examined by the researchers to identify problems that did not comply with the usability principles recognized by Nielsen [45], which include consistency and standards, error prevention, and aesthetic and minimalist design. The severity and prevalence of the issues were ranked from 1 to 5, with a high rank indicating that the problem was a priority to fix, and the web platform was updated accordingly.

Usability and user experience testing for the penultimate versions of eTRIO and eTRIO-pc were conducted using think-aloud methodology with 11 participants, including clinicians, patients, and carers, all of whom were naïve to the TRIO Guidelines and modules. Think aloud is an effective evaluation method in which participants are provided with an interface and asked to verbalize their thoughts as they work through it [46,47]. Potential participants were identified through the research team’s professional networks and via social media advertisements.

The consenting participants completed a demographic questionnaire and a 4-item self-report measure of health literacy [48]. Participants were provided access to the relevant eTRIO module and asked to speak aloud their thoughts and impressions as they were completing the module (think-aloud). These sessions were conducted face to face or via videoconferencing. After working through the module, participants completed the SUS [49]. Think-aloud evaluations were audio recorded and transcribed verbatim. Transcripts were qualitatively analyzed using thematic analysis [50], which involved familiarization with the transcripts, coding of salient initial ideas as codes, identification of patterns in the codes to generate themes and subthemes, and iterative review of the themes and subthemes to ensure a coherent and comprehensive thematic structure. This process was conducted collaboratively and through iterative discussion by RLP, PB, ZB, MB, and IJ. Themes were related to the following: usability and technical issues, positive aspects of design and function, attitudes toward the content of the program, and perspectives about the impact or implementation of the program. All transcripts were analyzed based on the established thematic framework and were grounded in illustrative quotations. Subsequently, the modules were iteratively refined based on this feedback.

Ethical Considerations

Ethics approval was obtained from the University of Sydney Human Research Ethics Committee (protocol 2015/468). Participants provided informed consent and were given the opportunity to opt out at any point in time. Participant data were

deidentified. Participants were provided a gift card worth Aus \$20 (US \$13.22) as compensation for their time.

Results

This section describes the clinician, patient, and carer feedback; iterative revisions made; and lessons learned in the design and development of the eTRIO and eTRIO-pc modules.

Phase 1: Development of eTRIO and eTRIO-pc Module Content

eTRIO Clinician Module

The clinician advisory group members (n=13) emphasized the importance of the module being concise. They suggested more content for the introductory section such as including a broad and inclusive definition for “carers,” content about culturally diverse carers, and more information about the legal and ethical aspects of involving carers. Clinicians also suggested the inclusion of self-reflections about one’s own attitudes and potential biases toward carers. Additional suggestions included addressing the diversity of settings in which family or carer interactions can occur (eg, outside traditional outpatient consultations such as at the patient’s bedside or via the telephone). Several clinicians stressed the importance of including clear learning outcomes and summaries for each of the 14 sections.

eTRIO-pc Patient-Carer Module

Cancer support staff (n=5) suggested a clear definition of the role of carers, tailoring based on the cultural backgrounds of patients and carers, and consideration of power imbalances that may exist in patient-carer relationships. They emphasized checking in on patient and carer emotions such as grief and distress, suggested that modules could include opportunities for self-reflection, and highlighted the need to include information about available support for carers.

The overall impression of the consumer advisory group (n=5) was that the language and tone of the draft module was very formal and academic; they wanted the tone to be more “personal,” “empathetic,” and “softer” and the language to be less prescriptive. They suggested additional strategies for patients with newly diagnosed cancer and carers, such as making notes during medical consultations, and suggested including quotes and stories from actual carers to illustrate examples.

Phase 2: Iterative Design, Review, and Refinement of eTRIO and eTRIO-pc Web-Based Modules

Overview

Table 1 describes the results from phase 2 using the e-learning design features by de Leeuw et al [38] applied to the eTRIO and eTRIO-pc modules.

Table 1. e-Learning design features identified by de Leeuw et al, as applied to the e-Triadic Oncology (eTRIO) and e-Triadic Oncology for patients and carers (eTRIO-pc) modules.

Elements of e-learning	Description	Use in eTRIO and eTRIO-pc
Preparation	Identifying the needs of the target audience	<ul style="list-style-type: none"> • The research team conducted an extensive program of previous studies on the needs of carers • Stakeholder input, feedback, and evaluation
Design	Including elements of accessibility, reliability, user-friendly navigation, and visual appeal	<ul style="list-style-type: none"> • Web-based program, simple layout, and designed for easy use • Font, color, size, and layout are optimized for accessibility • User progress is saved when users log out • Website is designed and tested on various software and hardware
Communication	Communication with users and program facilitators	<ul style="list-style-type: none"> • Landing page introduces users to the learning objectives and goals (ie, communication skills and strategies, understanding carer roles, and benefits of carer involvement in cancer care) • Clear information about program use and navigation is included
Content	Including words, images, videos, interactive activities, summaries, and so on	<ul style="list-style-type: none"> • All modules include multimedia content such as several clinical vignette videos, audios, text, images, and interactive features. Interactive activities were designed, including the following: <ul style="list-style-type: none"> • <i>eTRIO (clinician)</i>: sorting and drag-and-drop activities, true-or-false exercises, open-text written responses, click-to-expand sections, and identifying behaviors in a vignette video • <i>eTRIO-pc (patient-carer)</i>: resources that can be individually tailored (eg, assembling a caregiving team, building a question prompt list, and checklist for patients and carers to discuss carer role), click-to-expand sections, and open-text written responses • Downloadable summaries are provided to allow access after completing or outside the module
Assessment	Assessing learning and acquiring feedback	<ul style="list-style-type: none"> • Each section of each module contains clear learning objectives, displayed on the first page of each section. For example, section 9 of eTRIO (clinician), related to the use of interpreters, states the following: “In this section you will explore reasons why patients/carers might resist professional language interpreters, and understand strategies to overcome these issues. You will learn practical strategies to engage and use formal interpretation services.” • All modules include assessment activities to facilitate learning and reflection: <ul style="list-style-type: none"> • <i>eTRIO (clinician)</i>: self-reflection and assessment of own attitudes and practices, true-or-false assessment of content with correct answers and explanations, multiple choice questions asking users to reflect about how they would navigate a clinical scenario, and open-ended responses • <i>eTRIO-pc (patient-carer)</i>: self-assessment of emotions, opportunities to reflect about own preferences and attitudes and to plan future actions or behaviors, and open-text reflections about video vignettes modeling key skills
Maintenance	Providing long-term access and updating information and links	<ul style="list-style-type: none"> • Website is regularly maintained and updated • All users will have access to the program after completion of the training

eTRIO Clinician Module

During the transformation of content to a web-based module, features of e-learning [38] were applied as described in Table 1. The design features of other web-based clinician training modules were examined, revealing display, navigation, and interactive activity styles (eg, minimal use of text, prominent navigation buttons, and clickable and expandable content). Our team worked closely with graphic and web designers to develop a consistent color scheme and intuitive navigation system and aimed to minimize visual noise on each page. The refined content and design features were transformed into a web-based web platform.

All members of the clinician advisory group (13/13, 100%) commented that there was excessive content and that there would not be clinician appetite for web-based training that extended beyond 2 hours in total. The content was subsequently condensed, with the core content displayed with the option of more extensive content, which could be expanded for clinicians interested in deeper learning regarding an issue.

The final eTRIO clinician module comprises 14 sections (submodules), of which clinicians must complete a minimum of 8. The sections range between 3 and 15 minutes in duration. The following 4 sections were deemed to be mandatory by the clinician advisory group, based on their critical relevance to all clinicians: section 1—introduction, section 4—building rapport

with carers, section 7—supporting carers’ emotional and informational needs, and section 10—managing conflicting patient-carer treatment preferences. Clinicians could select additional 4 sections based on their interest and preference. The eTRIO module requires approximately 1.5 to 2 hours to complete, as determined by multiple stakeholders working through the content and documenting the amount of time each section required to complete.

eTRIO-pc Patient-Carer Module

Consistent with the principles of computer-based teaching for adult learners by Lau [51], the web-based eTRIO-pc module was created by transforming the written content into interactive, engaging learning activities. Our review of carer resources demonstrated several useful stylistic, formatting, and usability features, for example, the use of bullet points to convey written information, 1-page displays eliminating the need to scroll, and use of simple navigation buttons. These features and principles of web-based education were collated and discussed with the team’s academic IT expert and web developers to select and finalize the most appropriate features to be included. The resultant module prototype included video vignettes that could easily be played and paused, interactive activities such as “drag-and-drop” and “click to reveal” exercises, and type-your-response activities (Multimedia Appendix 1). We maintained consistency in design and formatting across the clinician, patient, and carer modules.

We sent the prototype to the members of the consumer advisory group (n=5), and they provided written feedback via email and offered additional personal quotes that could be included in the module to personalize the content. They re-emphasized the need

for content that was empathetic and offered practical advice. The final eTRIO-pc modules contain 7 sections for patients and 11 sections for carers and requires approximately 1 to 1.5 hours to complete.

Phase 3: “Think Aloud” Usability Evaluation of eTRIO and eTRIO-pc Web-Based Modules

Heuristic Evaluation

Using the heuristic evaluation method [44], we identified 37 usability issues across the draft eTRIO and eTRIO-pc modules, and each was rated for severity. The main areas of the identified problems were as follows: (1) inconsistency of icons and redundancy in buttons (5/37, 14% of the issues; eg, inconsistent use of star and book icons to indicate the bookmark function), (2) buttons and interactions were not working (16/37, 43% of the issues; eg, nothing happens when the print button is clicked), (3) layout problems (6/37, 16% of the issues; eg, text is not aligned with the textbox), and (4) presentation of content (10/37, 27% of the issues; eg, color selection in the bar-slider activity may be confusing) [52]. Following this evaluation, problems with high severity and prevalence were prioritized, and all issues that could be corrected were fixed before conducting the think-aloud user evaluations.

Think-Aloud User Experience Evaluations

Overall, 11 individuals (n=5, 45% health professionals; n=3, 27% patients; and n=3, 27% carers) participated in the think-aloud evaluations in individual sessions lasting between 40 and 60 minutes. Participant characteristics are displayed in Table 2.

Table 2. Characteristics of participants of the think-aloud evaluations.

Participant category and characteristics	Values

eTRIO Clinician Module

The usability of the module was rated by 5 clinicians, with a mean SUS score of 75 (range 68-80), which is interpreted as good [49]. All clinicians gave high ratings to their ability to use the module independently without technical assistance. Clinicians identified technical and navigation issues, which were subsequently rectified (such as the side scroll bar not appearing, text appearing outside the text bubble, and a sliding bar not working responsively). For some, the use of specific web browsers corrected these issues. Clinicians described the overall navigation through the module as “straightforward.” Formatting issues with font size and background color were highlighted. Clinicians commented that the ability to easily navigate back to certain sections to “refer back to later” was valued.

Content analysis of think-aloud evaluations revealed 7 categories related to clinicians’ attitudes toward the design and formatting of eTRIO. Clinicians appreciated that the modules could be completed in small “snackable” periods in any order, that they could keep track of what sections were completed (*trackable*),

and that they were able to refer back to any module at any time. Clinicians enjoyed the “clickable” activities where they interacted with the content. Despite attempts to make the sections as short as possible (average 5-10 min/section), a few clinicians still perceived them as “too long,” with some stating that the videos were “slow” at times. They highlighted a preference for material that is brief, uses simple language, is easy to digest, and “skimmable.” A few clinicians reported “glossing over” or “tuning out” when sections were perceived as very long. They suggested simplifying the language and formatting the text to highlight important information (eg, use of bullet points and bold and italic style). Revisions were made to the text to further improve conciseness, including rephrasing the core content, moving some content to the expandable ‘additional information’ section, and greater use of bullet points and bold text. Where possible, videos were edited to remove nonessential scenes. Most participants appreciated that the content and activities were relevant and “relatable” to them as clinicians, that claims were “supported” by evidence, and that the activities and media were “diverse” and varied to facilitate engagement and interest. Illustrative quotes are provided in [Table 3](#).

Table 3. Illustrative quotes from think-aloud evaluations by clinicians.

Usability and content feature	Description	Illustrative quotes
Snackable	Ability to complete the module in small segments	<ul style="list-style-type: none"> “So, you’re saying you don’t have to do it all in one go...oh, I think that’s really important because you do get called away and the phone is ringing...because I know even with our mandatory online training in the past, you just [had to] forfeit [all progress] if you couldn’t finish.” [Nurse 2]
Trackable	Ability to know what has been completed and refer to the content later	<ul style="list-style-type: none"> “It’s nice to have things you can refer back to because this might trigger things that make you think oh yeah, I did read about that.” [Physician 2]
Clickable	Importance of interactive content	<ul style="list-style-type: none"> “I like this section - it’s really good. I like that activity. I’ve never done one of those before - that’s really good. [Interactive activity clicking points of rapport building throughout a video vignette]. You definitely engage a thousand percent more with the activities.” [Physician 2] “I think [the activities] are quite good because at least you are giving people a little bit more of themselves...I think it’s good to have that interaction rather than just reading...that gets a bit boring. And then, that you ask people to actually write something is good.” [Nurse 2]
Skimmable	Importance of simple, concise language	<ul style="list-style-type: none"> “After reading articles all day I don’t want to read something that has too much jargon in it...Go back and simplify the language...when I read something apart from patients notes, I skim it. So, it’s got to be something that I can get the message with a glance.” [Physician 1] “Uhm why I am I finding it difficult to understand? I think it could be worded more simply.” [Physician 2] “Yeah. I hate the time pressure...It’s so built into our working day, it’s like get on, get it done, that you gloss over so much. I actually didn’t realize before doing this how much I gloss over...I probably would watch [the video] to the end but there’s a part of me thinking yeah it’s going on a little bit.” [Physician 2]
Relatable	Relevance of content to the user	<ul style="list-style-type: none"> “Yeah, I like that there is the suggestions of things to say. That makes it really relatable - I think those are good.” [Physician 2] “I like scenarios...Just sort of triggers you to think a little bit more rather than just reading through something. I think the scenario allows me to put it into practice or put it into place a little bit more.” [Nurse 3]
Supported	Evidence-based content	<ul style="list-style-type: none"> “I like the use of the quotes. It gives a bit of a supportive evidence to it, as nurse I like that...It has got some stats [statistics] there...When you hover over it...it gives the reference.” [Nurse 3]
Diverse	Importance of variety in media and activities	<ul style="list-style-type: none"> “Oh a video, that’s interesting, it’s sort of mixing it up, it’s nice to have the different things.” [Physician 2]

eTRIO-pc Patient and Carer Module

The average SUS score as rated by 6 patients and carers was 78 (SD 16.2; range 55-97.5), which is interpreted as good [49]. Patients and carers were generally happy with the content and usability of the eTRIO-pc module. They commented that the content was relatable and were pleased by the emphasis placed on carers. Overall, they found the web platform easy to navigate and enjoyed the interactive activities; however, 1 (17%) of the 6 patients found the interface to be “overwhelming.” A major critique of the formatting and layout was that the pages were

“too busy” and contained excessive information. Illustrative quotes are provided in [Table 4](#).

The final eTRIO and eTRIO-pc modules were updated based on this feedback. All technical and navigation issues were addressed by the web developers.

For both modules, the text was condensed and reformatted with the use of bold and italic style to highlight the important points and allow for easier reading and a more streamlined user interface.

Table 4. Illustrative quotes from think-aloud evaluations by patients and carers.

Usability and content feature	Description	Illustrative quotes
Snackable	Ability to complete the module in small segments	<ul style="list-style-type: none"> “Looking at this dashboard I like it that it tells you how long each part is going to take just so you know in advance. You’re busy and maybe you just have time to do half of it and then you can sort of plan how you’re going to tackle it.” [Carer 1]
Clickable	Importance of interactive content	<ul style="list-style-type: none"> “Some of the activities like the questions, I really liked. The ones where you wrote down what you thought the carer might do for you if you then use it as a communication tool, really good as well.” [Patient 1]
Usable	Ease of navigation	<ul style="list-style-type: none"> “I think [navigation] is pretty easy and straight forward. I think anybody who’s used to doing online training, modules and so on will probably find it really easy.” [Carer 1]
Relatable	Relevance of content to the user	<ul style="list-style-type: none"> “I think this is a very useful slide. When we went in to our first meeting we were just there, me and my son did this.” [Carer 1]
Visually simple	Cleanness of layout, formatting, and images	<ul style="list-style-type: none"> “I think you are making this page very busy with text and it’s a bit confronting.” [Carer 2] “It is pretty text-heavy and I guess that I am more of a visual learner so it might be nice to have some more pictures, icons, to make it a little bit more visually appealing.” [Patient 1]

Final Web Platform Design and Content Summary

The eTRIO modules reflect the reported informational needs of health professionals, patients with cancer, and carers. A full description of the module content has been published elsewhere [29]. The eTRIO modules have been rigorously designed to be easy to use, require minimal time commitment, and be flexible in terms of when and how the platform can be used. The modules are optimized for use on a computer but can also be used on a smartphone or tablet. Some notable features include

the following: navigation buttons and a progress bar along the bottom of the page, expandable content for those who want deeper information about a specific topic, and downloadable summaries and lists. Notable interactive activities include the following: testing of knowledge through true-or-false exercises, identifying specific behaviors in a short video vignette, and building a question prompt list. Refer to Table 5 for descriptions and images of key features; full explanations of the interactive activities are provided in Multimedia Appendices 1 and 2.

Table 5. Key features of the e-Triadic Oncology (eTRIO) modules.

Feature	Description	Images
Interactive activities	Includes self-reflection, knowledge tests, and free-text responses	
Learning outcomes	The eTRIO clinician module features sign-posted learning outcomes at the beginning of each section	
Downloadable content	Includes materials and personalized checklists for patients and carers and downloadable summaries for clinicians	
	and	
Video vignettes	Realistic scenarios modeling communication skills	
Intuitive navigation features	Navigation buttons are explained in the module’s introduction	

Discussion

Principal Findings

The web-based modules described in this paper represent a crucial step in the development and design of education for clinicians, patients, and carers that is evidence based, practical, and interactive and can be easily disseminated. Drawing on the evidence for best practice web-based learning design [38,51], we sought input from a variety of stakeholders to develop a unique learning experience strongly informed by the needs of the target populations. Rigor was ensured via 3 stages of development in which module content and design were continually revised and refined. Overall, participants were positive about the content and interface. The final prototype was appraised as highly acceptable, relevant, and feasible among the small sample of users; however, more studies are needed to confirm this and to ascertain the effectiveness of the intervention. We are currently conducting a pre-post evaluation of these modules to explore their potential effectiveness in improving communication within the patient-carer-clinician trio.

Lessons Learned

Throughout the development and design of these modules, we observed the specific needs and preferences of end users. The person-based approach to developing eTRIO and eTRIO-pc was highly dynamic, and the modules underwent numerous iterations throughout all phases of the design process, which included the involvement of consumers and user-driven evaluations. While there are multiple approaches to developing health interventions, the benefits of the person-based approach include grounding the design in user contexts and lived experiences, integrating feedback based on the actual use of an intervention, and investigating user needs and perspectives beyond just the usability of the intervention [26]. The utility of the person-based approach has been extolled in recent studies [53-55] and is supported by the findings of this study. The eTRIO development process (Figures 1 and 2) provided the necessary building blocks to revise and refine the module for effective use in the real world. Consistent with other studies [56,57], we found that the collaborative co-design process led to positive evaluations of acceptability and usability and high levels of end-user satisfaction.

As highlighted in the person-based approach, the 3 user groups (clinicians, patient, and carers) demonstrated diverse learning preferences and needs. This was accommodated via tailoring the formatting or content to the strengths and contextual demands of different user groups and differentiating the content based on user needs. We found that clinicians had a strong desire for content that was written in simple, concise, and “sharp” language; could be “skim read”; and could be completed in brief, “snack-sized” sections. For example, clinicians in our advisory group often stressed that they lacked time and that training needed to be short, precise, and able to be stopped and restarted due to interruptions. On the other hand, the structure and time demands of training appeared to be less important to patients and carers. Instead, these groups emphasized the need for the module to be easy to use and navigate and for the content

to be more conversational, empathetic, and in plain language (in contrast to the preferences of clinicians). Clinicians in our study valued the integration of academic literature and referencing, whereas some carers advocated for greater inclusion of carer experiences and quotes. The preferences of carers in our study are consistent with previous studies, which have similarly found that carers often prefer web-based education to have an empathetic and supportive tone, the web program to be easy to navigate, and the integration of other carers’ experiences into the content [58-60]. While several differences were identified between the clinician and carer user groups, there were also several similarities across all user groups in how the web-based modules should be structured and delivered. This is reflected in the evidence base, where health professionals, patients, and carers alike report that they prefer flexible, self-paced delivery of web-based programs that are interactive and include a variety of activities across media (visual, written, and auditory) [19,38]. These detailed insights are valuable in designing future training modules to facilitate their acceptability among users in each specific group.

The final interface used design principles to ensure engaging and interactive content. There is robust empirical evidence suggesting that interactivity in e-learning improves quality, efficacy, and learning outcomes [38,61]. For example, users of a web-based public health program had better learning outcomes when they used a gamified, interactive version featuring responsive design, learning challenges, visible progress, and rapid feedback compared to those using a minimally interactive, survey-based program [62]. Such interactivity was also demonstrated as important for users of the eTRIO modules. For example, in the initial design phases, when content was largely text based, the advisory committee members noted how dense the information appeared. While this was never intended to be the final format of the educational intervention, comments obtained from users in phase 1 highlighted the limitations of passive, didactic, text-heavy information. There is evidence suggesting that people do not learn effectively when information is given without any opportunity to reflect on, test, or demonstrate their knowledge and views [63]. Interactive activities, including assessments of learning and personal reflection activities, offer users the opportunity to reflect and reinforce their learning and become active participants in their education rather than passive consumers of information. Multimedia Appendices 1 and 2 display the engaging interactive activities that were acceptable to eTRIO users, which may be used in other web-based learning interventions and resources.

For both the clinician and patient-carer modules, we also incorporated a variety of media (text, audio, video, graphics, and images) to cater to different learning styles and preferences. There is evidence suggesting that the use of multimedia may increase user satisfaction, acceptability, and engagement [64,65] and thus may improve adherence and broad implementation. The modules were designed such that users could navigate through them at their own pace and read, view, and explore the sections in a self-directed manner based on how they like to engage with and process content. For example, we found that users had mixed responses to the videos embedded in the training module. Some users commented that the videos were

very long and that they would mentally switch off or skip them. Others claimed to be “visual learners” and thoroughly enjoyed the opportunity to observe scenarios in this format, especially because the videos included interactive “trigger” questions such as “What would you do next?” where they were required to apply some of their learning to a scenario. This approach has been used in other web-based health interventions [66,67], which include complementary text, images, videos, audios, and interactive content to convey the educational content and cater to these diverse user preferences.

Strengths and Limitations

A thoughtful process of iterative design was conducted over a 2-year period, ultimately producing a suite of web-based interventions intended to improve communication between cancer clinicians, patients, and carers. However, important limitations should be noted. While extensive end-user feedback was collected through iterative feedback from clinician and consumer advisory groups, the sample size of participants (patients with cancer and carers) naive to the modules in phase 3 was small, and there was limited diversity among consumer advisers and participants. In addition, we did not measure the computer literacy of the participants, which may have impacted their views about the program’s usability. Thus, the attitudes and preferences of participants may not be reflective of the wider population. For example, we were unable to recruit a carer with low health literacy, and there was an overrepresentation of women.

Further usability and acceptability testing is currently underway in a larger study with a more diverse sample of patients and carers. Recruitment of participants in phase 3 was conducted through professional networks and social media, and therefore, the participants may have had a strong interest web-based learning or carer communication, which could have biased their views. This study focused only on development and user testing, and therefore, no assessment of the effectiveness or uptake of the modules has been conducted. Larger evaluation studies of the modules are currently being conducted, which will provide insight into the utility of the eTRIO modules in improving carer-related communication and inclusion.

Finally, while most patients with cancer have a carer or support person, some patients do not. Further studies are required to better understand the needs of people without a carer, which is beyond the scope of this study.

Future Directions

The eTRIO and eTRIO-pc modules are now undergoing pre-post evaluation with additional qualitative learner feedback to inform the broad implementation and uptake of these educational resources.

Conclusions

By including and being receptive to the needs of our user groups throughout the design process, we were able to create interventions that end users are likely to be more engaged and satisfied with.

Abstract

Background: Official conference hashtags are commonly used to promote tweeting and social media engagement. The reach and impact of introducing a new hashtag during an oncology conference have yet to be studied. The American Society of Clinical Oncology (ASCO) conducts an annual global meeting, which was entirely virtual due to the COVID-19 pandemic in 2020 and 2021.

Objective: This study aimed to assess the reach and impact (in the form of vertices and edges generated) and X (formerly Twitter) activity of the new hashtags #goASCO20 and #goASCO21 in the ASCO 2020 and 2021 virtual conferences.

Methods: New hashtags (#goASCO20 and #goASCO21) were created for the ASCO virtual conferences in 2020 and 2021 to help focus gynecologic oncology discussion at the ASCO meetings. Data were retrieved using these hashtags (#goASCO20 for 2020 and #goASCO21 for 2021). A social network analysis was performed using the NodeXL software application.

Results: The hashtags #goASCO20 and #goASCO21 had similar impacts on the social network. Analysis of the reach and impact of the individual hashtags found #goASCO20 to have 150 vertices and 2519 total edges and #goASCO21 to have 174 vertices and 2062 total edges. Mentions and tweets between 2020 and 2021 were also similar. The circles representing different users were spatially arranged in a more balanced way in 2021. Tweets using the #goASCO21 hashtag received significantly more responses than tweets using #goASCO20 (75 times in 2020 vs 360 times in 2021; z value=16.63 and $P<.001$). This indicates increased engagement in the subsequent year.

Conclusions: Introducing a gynecologic oncology specialty-specific hashtag (#goASCO20 and #goASCO21) that is related but different from the official conference hashtag (#ASCO20 and #ASCO21) helped facilitate discussion on topics of interest to gynecologic oncologists during a virtual pan-oncology meeting. This impact was visible in the social network analysis.

KEYWORDS

social media; academic tweeting; hashtag; gynecologic oncology; Twitter; ASCO; gynecology; oncology; virtual; engagement; software application; users; cancer; social network; health promotion

Introduction

X (formerly Twitter) has emerged as one of the social media platforms most frequently used by health care professionals [1]. In addition to individuals sharing information and networking, several academic groups, scientific societies, medical journals,

and conference organizers use Twitter for educational purposes [2-4]. The reach and impact of conference hashtags have been studied previously [5-7]. Scientific conferences and academic meetings promote dedicated “conference hashtags” and encourage attendees to share their insights, experiences, and learning on the web through social media. Similarly, a study

demonstrated the significant impact of a social media ambassador program during the European Society of Gynaecological Oncology (ESGO) congresses on Twitter, highlighting substantial increases in engagement metrics and follower growth, thus advocating for the efficacy of such initiatives in enhancing congress-related engagement and visibility [8]. Furthermore, another study assessed the impact and reach of the 2020 World Gynecologic Oncology Day Twitter campaign, revealing significant participation from health care professionals and the effectiveness of the #WorldGODay hashtag in raising awareness for gynecologic cancers [9].

The official hashtag is announced in advance and widely disseminated on various social media channels [3]. These hashtags are also displayed across conference venues, and some conferences even display live tweeting during designated scientific sessions or plenaries. The aim is to disseminate meeting information and learning to attendees as well as the wider scientific community.

The COVID-19 pandemic has had a profound impact on scientific conferences. Many meetings were canceled, and others became virtual. Going virtual has affected the use of Twitter during meetings. Beste et al [10] found that the number of tweets and Twitter users at a virtual conference compared to the previous year's in-person meeting reflected the decline in the number of registrations between the 2 years.

The American Society of Clinical Oncology (ASCO) annual meeting has used its official hashtag, #ASCO, since 2011 [11]. ASCO meetings are one of the largest gatherings of oncology professionals globally. Conversations on the web and offline center around particular topics of interest, subspecialties, and the latest evidence. The COVID-19 pandemic forced both the 2020 and 2021 ASCO meetings to be held virtually. New hashtags (#goASCO20 and #goASCO21) were created for the ASCO virtual conferences in 2020 and 2021 to encourage focused gynecologic oncology discussions at the ASCO meetings. As ASCO meetings cover all oncology topics, subspecialties conversations relating to particular tumor types or subspecialties could get lost in the general discussion. Our study aimed to investigate the impact of virtualization on Twitter engagement during virtual-only ASCO annual meetings, with a focus on gynecologic oncology, and explore strategies for enhancing focused discussions and knowledge dissemination through dedicated conference hashtags.

Methods

Data Collection

Twitter data were retrieved using the hashtags #goASCO20 and #goASCO21 for 2020 and 2021, respectively. Data from the whole year were retrieved from the year each conference took place (from January to December) for each meeting using the Academic Track Twitter application programming interface, which provides access to all tweets [12].

Data Analysis

Data (influential users, topics, web sources, and social network analysis) were analyzed using social network analysis in the NodeXL software application (Social Media Research

Foundation) [10], allowing an understanding of the shape of the conversation. Both graphs' vertices were clustered using the Clauset-Newman-Moore cluster algorithm to generate network visuals. The graphs were then laid out using the Harel-Koren Fast Multiscale layout algorithm. Authors in previous publications have used this methodology successfully [13-15]. Circles with lines between them represent individual Twitter users or accounts: the "mentions" and "replies." The size of the circles means how influential the user is, with bigger circles representing more influential users. The visuals presented illustrate the interactions between Twitter users. [Multimedia Appendix 1](#) provides a compiled list of terms related to social media research for readers' ease of understanding. We also applied a 2-proportion z test to determine whether the change in response rates between 2020 and 2021 were statistically significant. This allowed an understanding of the shape of connections resulting from conversations to be visualized.

Visuals were created to provide an overview of the resulting social networks. Dots represent users. The green lines shown between users are known as "edges." Edges indicate both the presence and strength of a relationship between a user. There is an edge for each "reply" and "mention" and a "self-loop edge" for each tweet that is neither a "reply" nor a "mention." The "betweenness centrality" score was used to rank the size of the nodes. This score measures the influence of an individual "vertex" (an individual Twitter user, also referred to as a "node") on the flow of information between all other "vertices." This score assumes that information flows along the shortest paths between vertices. In each group, various color dots are bigger than others, indicating that these users are more influential. In addition, green lines from these groups indicate a serious relationship with other users and highlight how they have a strong influence.

Ethical Considerations

This study gained ethical approval from Newcastle University (Ref: 26055/2022). Twitter users who have been named in the study were personally contacted by the authors and provided their consent before their names or Twitter handles were published.

Results

Overview of the Social Networks

The most frequently used words or hashtags are highlighted in each group in [Figure 1](#). At the top right of each group, the most used hashtags in order of interaction can be seen. For example, in group 1, the hashtag used the most was #ASCO20, while in groups 2, 3, and 4, it was #goASCO20. It is evident from the figure that different groups discussed varied topics, as depicted by other hashtags apart from #ASCO20 and #goASCO20. [Figure 1](#) illustrates how the various communities of users shared and tweeted the #goASCO20 hashtag. Groups 1, 2, 3 and 4 have an increased number of green lines between them, indicating that their users were tweeting and mentioning one another frequently. Group 3 additionally has red lines connecting itself to groups 2 and 4. The red lines indicate stronger connections in social networks.

Figure 1. A visual overview of the #goASCO20 Twitter network. ASCO: American Society of Clinical Oncology; G: group.

The most used hashtag was #goASCO21. Different groups of users talked about various topics using the same hashtags. Green lines between groups indicate their relationship and influence on other users. [Figure 2](#) illustrates the various communities of users who shared and tweeted #goASCO21, and all the groups have many green lines between them, indicating that the users were tweeting and mentioning one another. In addition, group 3 strongly influences other groups (red lines), especially group

2. Only 1 circle is more prominent than others in groups 1 and 3, indicating that these users were more influential. Other groups have circles of variable size, showing no clear influential user. In [Figure 2](#), group 3 has more relationships (edges) with other groups than in [Figure 1](#). The most promoted hashtags by group 3 in 2020 were #goASCO20, #ASCO20, #ASCO, and #gynscm and in 2021 were #goASCO21, #ASCO21, #ASCO, and #ovariancancer.

Figure 2. A visual overview of the #goASCO21 Twitter network. ASCO: American Society of Clinical Oncology; G: group.

In 2021, the circles representing Twitter users were spatially arranged in a more balanced way, indicating that there were more users among the different groups in 2021. The increased lines between them illustrate an increase in cross-group discussion.

Overview of Network Metrics

Table 1 summarizes the network metrics for #goASCO20 and #goASCO21. The 240 tweets using #goASCO20 had 150 unique users and 2519 total edges. The 243 tweets using #goASCO21 had 174 unique users and 2062 total edges. A 16% (174 vs 150 unique users) increase in Twitter use was observed between 2020 and 2021. In 2020, the tweets formed 5 types of edges (mentions, retweets, replies, mention in retweets, and quote

tweets) in which #goASCO20 was tagged. These tweets were mentioned 903 times, replied to 75 times, retweeted 367 times, and mentioned in retweets 934 times. In 2021, the tweets also formed 5 types of edges in which #goASCO21 was tagged: these tweets were mentioned 870 times, replied to 360 times, retweeted 33 times, and mentioned in retweets 556 times. To determine if the increase in responses to tweets using the #goASCO21 hashtag compared to the #goASCO20 hashtag was statistically significant, a 2-proportion *z* test was conducted. We compared the proportion of responses for each hashtag (360/2062, 17.5% for #goASCO21 and 75/2519, 3% for #goASCO20). The test resulted in a *z* value of approximately 16.63 and a *P* value <.001, indicating that the difference in response rates is statistically significant.

Table . Overview of network metrics (#goASCO20 and #goASCO21).

Graph metric	#goASCO20, n	#goASCO21, n	Change, n (%) ^a
Graph types	Directed	Directed	— ^b
Vertices (unique users)	150	174	24 (16)
Unique edges	505	505	0 (0)
Edges with duplicates	2014	1557	−457 (−22.7)
Total edges	2519	2062	−457 (−18)
Edge types	5	5	0 (0)
Mentions	903	870	−33 (−3.6)
Mentions in retweet	934	556	−378 (−40.5)
Replies	75	360	285 (380)
Retweets	367	33	−334 (−91)
Tweets	240	243	3 (1.2)

^aThe denominator (N) is the #goASCO20 value.

^bNot applicable.

Table 2 presents an overview of the top 10 users promoting #goASCO20 and #goASCO21. This study identified 10 influential users based on their location in the network and their “betweenness centrality” score. The rank column orders the users by their “betweenness centrality” score, which reports the influence a user exerts on other users. The “in-degree” value depicts the number of times other users have mentioned an account in their tweets. Users having a high “in-degree” value means that other Twitter users consider them to have high levels of trustworthiness. For example, the user who ranked first in 2020 (@esragbilir) has been mentioned 30 times by other users.

The “out-degree” value measures the number of times users mention other users in their tweets. The user who ranked first in 2020 had mentioned other users 90 times in her tweets. The top 3 users in the 2020 ranking (@esragbilir, @Bhandoria, and @ChristinaUwins) belong to the accounts of 3 authors of this study. They have a similar level of trustworthiness, and the first in the 2020 ranking is the user who has mentioned other users the most. The fourth rank in 2020 belongs to @ASCO, the user with the highest level of trustworthiness because of its high “in-degree” value.

Table . Overview of top users (#goASCO20 and #goASCO21).

Rank	#goASCO20					#goASCO21				
	User	In-degree value	Out-degree value	Betweenness centrality score	Followers, n	User	In-degree value	Out-degree value	Betweenness centrality score	Followers, n
1	@esragbilir ^a	30	90	7688.582	1355	@esragbilir ^a	17	110	13315.076	1355
2	@Bhandoria ^a	30	58	4150.223	1174	@Bhandoria ^a	37	70	11371.626	1174

^aProject team members.

^bTwitter handle anonymized.

The user who ranked first in 2021 (@esragbilir) was mentioned 17 times by other users in their tweets and mentioned other users 110 times in her tweets. The top 2 users in the ranking in 2021 belong to the accounts of 2 authors of this study, as in the previous year. @Bhandoria had a higher level of trustworthiness than the first user in the ranking, and @esragbilir mentioned other users more than @Bhandoria. The third in rank is

@BatistaTP, a gynecologic oncology surgeon. The fourth place in the ranking in 2021 belongs to @DrFMartinelli, a gynecologist specializing in oncology. The fifth place in the ranking belongs to @gyncsm, a community for those impacted by gynecologic cancers.

Table 3 provides an overview of the top 20 cowords used with #goASCO20 and #goASCO21.

In 2020, the cowords used the most with the studied hashtag were #gynscsm and #some4gynonc (130 times). #Gynscsm is a community for those impacted by gynecologic cancers. #Some4gynonc is a social media group promoting the goal of curing gynecologic cancer globally. In second place, 2 users were mentioned 106 times with #goASCO20: @Bhandoria, a gynecologist and obstetrician, and @ChristinaUwins, a surgeon and senior research fellow in robotic gynecologic oncology. In third place, 2 hashtags (#womeninstem and #gynscsm) were used 100 times. The hashtag #womeninstem promotes women and gender equality in science, technology, engineering, and mathematics. In fourth place, there were 2 users, both of whom were mentioned 94 times with #goASCO20. Finally, the fifth place belongs to the hashtags #asco and #goasco20, and both were mentioned 92 times with #goASCO20.

In 2021, the cowords used the most with #goASCO21 were #asco21 and #asco (88 times). In second place, #asco21 and #eva_asco2021 were used 72 times. The first refers to the ASCO, and the second (#eva_asco2021) refers to a group focused on gynecologic tumors from Brazil. The third most used cowords (72 times) were hashtags that promoted the spread of clinical knowledge (#goASCO21 and #asco21). The fourth-ranked cowords (60 times) were sbco_oficial, a Brazilian society of oncologic surgery, and br_gynoncgroup, a Brazilian

gynecologic oncology group. The last word pairs in the top 5 most used cowords were #eva_asco2021, a group focused on gynecologic tumors from Brazil, and #sbco, a hashtag used to refer to the Brazilian Society of Oncologic Surgery.

Discussion

Principal Findings

This study hypothesized that introducing a new hashtag specific to gynecologic oncology could provide a focus for tweeting about gynecologic cancers. A new hashtag, #goASCO20, was presented on Twitter during the ASCO 2020 virtual conference and was replaced with #goASCO21 in 2021. Conference attendees were encouraged to use these new hashtags when discussing anything related to gynecologic cancers. The use of these new hashtags was actively encouraged. Users who promoted the hashtag in 2020 did not tend to respond to tweets but, in 2021, increased their response rate (75 times in 2020 vs 360 times in 2021). This shows that the gynecologic oncology community started engaging better in the second virtual congress. Consistent use of hashtags has enhanced Twitter engagement, as evident in the study by Morgan et al [15]. The cumulative number of impressions for #ASCO16 was 468.2 million compared with approximately 1.12 billion for #ASCO20

[15]. We predict a similar growth of #goASCO if its use is continued.

COVID-19 played a crucial role in social media use among the oncology community. It forced the annual meeting to go entirely virtual. As evidenced by our study, the conference attendees used social media channels more to interact.

The 2 users who promoted the hashtags the most were the same in 2020 and 2021. It should be noted that @esragbilir and @Bhandoria significantly increased their “betweenness centrality” score, indicating that their location in the network became more influential among the users. Establishing a core social media team that actively promotes it is essential.

Strengths and Weaknesses

This is the first study where a new hashtag was introduced and social media interaction was measured. This study contributes to the literature on this topic, highlighting how networks can be used to spread trustworthy information and share relevant information among the scientific community on Twitter.

A limitation of this study is that it was not designed to assess the validity of any tweets but to evaluate the success of

promoting the use of a gynecologic oncology-specific hashtag in increasing interaction between individual Twitter users and organizations. Misinformation on Twitter is a recognized phenomenon; future studies should investigate whether the quality and quantity of discussion are affected [16]. Since the inception of oncology hashtags, we acknowledge the existence of the gynecology-specific hashtag #gynccsm [17]. We created the #goASCO hashtags to study its impact as #gynccsm is used more by patients with gynecologic cancer and their advocates [18]. We should have examined the effect of #gynccsm during these virtual meetings, and this may be seen as a weakness, with no comparator group being available. Lastly, some of the “influential Twitter users” named in the results included a few authors. However, this is not aimed at self-promotion but is part of the results’ description.

Conclusion

The use of a gynecologic cancer-specific hashtag helped facilitate discussion on topics in gynecologic oncology on Twitter during the 2020 and 2021 ASCO virtual meetings. This impact was visible in the social network analysis.

Abstract

Background: Social media (SoMe) have taken a major place in the medical field, and younger generations are increasingly using them as their primary source to find information.

Objective: This study aimed to describe the use of SoMe for medical education among French medical students and assess the prevalence of smartphone addiction in this population.

Methods: A cross-sectional web-based survey was conducted among French medical students (second to sixth year of study). The questionnaire collected information on SoMe use for medical education and professional behavior. Smartphone addiction was assessed using the Smartphone Addiction Scale Short-Version (SAS-SV) score.

Results: A total of 762 medical students responded to the survey. Of these, 762 (100%) were SoMe users, spending a median of 120 (IQR 60 - 150) minutes per day on SoMe; 656 (86.1%) used SoMe for medical education, with YouTube, Instagram, and Facebook being the most popular platforms. The misuse of SoMe in a professional context was also identified; 27.2% (207/762) of students posted hospital internship content, and 10.8% (82/762) searched for a patient's name on SoMe. Smartphone addiction was prevalent among 29.1% (222/762) of respondents, with a significant correlation between increased SoMe use and SAS-SV score ($r=0.39$, 95% CI 0.33 - 0.45; $P<.001$). Smartphone-addicted students reported a higher impact on study time (211/222, 95% vs 344/540, 63.6%; $P<.001$) and a greater tendency to share hospital internship content on social networks (78/222, 35.1% vs 129/540, 23.8%; $P=.002$).

Conclusions: Our findings reveal the extensive use of SoMe for medical education among French medical students, alongside a notable prevalence of smartphone addiction. These results highlight the need for medical schools and educators to address the responsible use of SoMe and develop strategies to mitigate the risks associated with excessive use and addiction.

KEYWORDS

medical student; social network; social media; smartphone addiction; medical education; mobile addiction; social networks

Introduction

In today's globalized world, social media (SoMe) have taken a significant role in the medical field, serving as essential tools for promoting research, medical innovations, and updates from various specialties (eg, techniques and congresses). With the explosion in the number of platforms and their evolution, several definitions of SoMe have been proposed and gradually amended [1,2]. Recent definitions agree that true SoMe are defined as "web-based technologies that facilitate multi-user interaction that goes beyond fact sharing, centering around content creation, curation, and community engagement, placing user interaction at their art" [3]. These platforms include, for example, major actors like Facebook, Twitter (now X), Instagram, YouTube, TikTok, Snapchat, LinkedIn, or WhatsApp, and exclude

websites or blogs with comment sections and podcasts due to their primarily unidirectional nature [3]. SoMe are now widely used by health care professionals for numerous purposes, such as education, patient communication, and colleague discussions [4,5]. SoMe provide a platform for the rapid dissemination of research findings and facilitate networking and collaboration among researchers and clinicians worldwide [6].

Younger generations increasingly rely on SoMe as their primary source of information about brands or organizations, with this usage even surpassing that of internet search engines among 16 - to 24-year-olds [7]. The main reason for using SoMe is to "stay up-to-date with news and current events" [8]. Time spent on SoMe has consistently grown, rising from 1 hour and 51 minutes per day in 2015 to 2 hours and 24 minutes per day in 2023 [8]. Furthermore, several studies have documented the

benefits of using SoMe for medical education [9,10]. Consequently, a growing number of educators and medical societies are leveraging SoMe to showcase their educational content [11,12]. The COVID-19 pandemic has acted as an amplifier of the trend toward distance learning, with SoMe playing a significant role in this regard [13,14]. However, there is a lack of comprehensive data on medical students' use of these educational resources from SoMe for knowledge acquisition.

Several studies have identified significant risks associated with prolonged SoMe use. Notably, smartphone addiction correlates with the intensity of SoMe usage [15]. This addiction, in turn, can negatively impact students' quality of life, leading to sleep disorders, musculoskeletal disorders, severe social withdrawal, decreased physical activity, and hypertension [16-19]. Finally, all available data on smartphone addiction among medical students originate from Asia, with no data from Western countries.

The purpose of this study was to address the gap in knowledge regarding the use of SoMe by medical students in Western countries, specifically in France, for medical education. We aimed to describe, on a nationwide scale, how medical students use SoMe for medical learning, their motivations and preferences, and the extent to which they rely on these platforms for educational purposes. Additionally, we sought to determine the prevalence of smartphone addiction in this population and explore its potential impact on academic performance and professional behavior. We hypothesized that a significant proportion of medical students use SoMe for educational purposes; that this usage correlates with specific patterns of SoMe behavior, including misuse such as breaches of patient confidentiality; and that high levels of SoMe use are associated with increased rates of smartphone addiction.

Methods

Objectives

The primary objective was to describe how medical students use SoMe to learn about medicine. Secondary objectives were to evaluate their use of these platforms for choosing a medical specialty, analyze the prevalence of smartphone addiction in this population, and describe their potential misuse of SoMe. SoMe misuse was defined as the disclosure of information about hospital internships (text, photo, or video) that may breach patient confidentiality and the active internet-based search for private information [20].

Ethical Considerations

The study was approved by the Ethics and Evaluation Committee for Non-Interventional Research of Rouen University Hospital (E2023-06). Participation was entirely voluntary. Participants were informed about the study's objectives and provided their consent before completing the survey. The survey was conducted anonymously, and no identifying information was collected or attempted to be gathered at any stage, ensuring participants' privacy and confidentiality. No compensation was offered to participants, and they had the right to withdraw from the survey at any time without any consequences. According

to institutional guidelines, as this was a noninterventional, anonymous survey with no personal health data collected, the study did not require further ethical exemptions or waivers beyond the initial approval.

Population Selection

We conducted a prospective study in France using a declarative survey. The link to an open Google Form internet survey, consisting of 32 items on 1 web page, was emailed to the board of the French medical students' association (Association des Etudiants en Médecine de France). This board forwarded the questionnaire to the association's representatives at each of the 35 medical schools in France. These 35 representatives were instructed to share the link with their respective faculty's students via email. All contacted students were asked to forward the survey link to their colleagues. All participants received information about the survey objectives, which were reiterated in the questionnaire's introduction. There was no incentive to answer the questionnaire. As responses were anonymous, no information was collected to prevent multiple entries by the same individual. Also, as the questionnaire was open-ended, anyone with the link could answer it. The distribution via medical student representatives was intended to restrict the questionnaire's visibility to the target audience only.

This survey was developed according to available guidelines for self-administered surveys [21]. Responses were submitted on a single web page with 1 "submit" button, which only allowed submissions via these unique links, making uninvited responses extremely unlikely. The request was sent to 35 representatives in France; however, as we were unable to determine how many students the request was forwarded to, we do not know the overall number of students who received the request to participate in the survey. We did not organize any specific follow-up on the distribution of the questionnaire with the contacted representatives. The survey was conducted in accordance with the Checklist for Reporting Results of Internet E-Surveys (CHERRIES; Checklist 1) [22].

The participants included in the analysis were medical students in their first (second to third year) and second (fourth to sixth year) cycles of medical study. The medical curriculum in France consists of 6 years of study before residency, although the first year of medical school is a competitive year with a success rate of about 15%; students in this year of study were not included in this analysis, which concerned only students who were certain to become physicians after their studies.

Survey Design

The survey was developed by a team consisting of medical students, medical educators, and an expert in SoMe to ensure comprehensive coverage of relevant topics. The questions in the "use of social network" sections were designed based on a thorough review of existing literature on SoMe usage in medical education and consultations with subject matter experts [1,3,10]. The initial draft was reviewed by a panel of medical educators and students to assess face validity and to validate the list of social networks that met our definition. To further ensure the validity and reliability of the survey, a pilot test was conducted with the participation of the board of the French Medical

Students' Association to ensure the comprehensibility and relevance of the questions. Feedback from the pilot test was used to refine the survey questions for clarity and relevance. The psychometric properties of the survey were not formally assessed.

The survey consisted of 3 sections. The "demographic data" section collected information on city, age, gender, year of study, and whether the student had already retaken an exam (catch-up exam). The "use of social networks" section gathered data on personal and professional use of WhatsApp, types of social networks consulted at least once a week, average daily time spent on SoMe, usage of SoMe for learning about medicine and choosing a medical specialty, and the misuse of SoMe (searching for a patient's name and spreading information from hospital internships).

We defined the sharing of content from hospital internships on SoMe as a misuse based on professional standards. It is generally considered unprofessional for students to share details about their clinical experiences on SoMe, as this behavior can undermine patient confidentiality and trust. The Health Insurance Portability and Accountability Act (HIPAA) regulations in the United States clearly state that sharing any patient information on SoMe is unacceptable [23] and medical societies have issued strict recommendations against such practices [24]. Since most student internships involve direct patient contact, sharing content related to these internships often involves discussing patient care experiences, which is inappropriate even if no identifiable patient information is shared.

Students also rated, using a 6-point Likert scale (1 point="completely irrelevant" and 6 points="completely relevant"), whether they thought it was appropriate to offer a teaching module on the professional or educational use of SoMe in medical school.

Finally, the "assessment of smartphone addiction" section evaluated smartphone addiction using the short version of the Smartphone Addiction Scale Short-Version (SAS-SV) developed by Kwon et al [25]. The SAS-SV was already translated into French, demonstrating the validity and reliability of the translated version adapted to French [26]. The scale comprises 10 positive 6-point Likert questions describing smartphone usage, with the total score ranging from 10 to 60 and higher scores indicating a greater risk of addiction. According to the threshold recommended for student populations, and given previous data concerning the absence of gender difference for

the cutoff value of the SAS-SV among French-speaking students, the cutoff point was determined as superior or equal to 32 points to identify smartphone addiction [25,26]. The SAS-SV scale covers 6 addictive symptoms and they are loss of control, disruption of family or schooling, disregard for consequences, withdrawal, preoccupation, and tolerance. Each item is associated with an addictive symptom, except for 4 item clusters that are items 1 and 8 (both assessing "loss of control"), items 2 and 10 ("disruptions"), items 3 and 7 ("disregard for consequences"), and items 4 and 5 ("withdrawal") [26]. As previously described, a rating of 4 or higher for each symptom was considered to signify the presence of this specific symptom [26]. Participants had to answer all questions to validate the questionnaire but could go back at any time to change their answers before the final validation. The original version of the questionnaire and its English translation can be found in [Multimedia Appendices 1 and 2](#).

Statistical Analysis

The values are presented as the number and percentage (n, %) for qualitative variables and as the median (IQR) for quantitative variables. Statistical analyses were performed in complete case analysis on fully completed questionnaires [27]. After ensuring the abnormal distribution of the data via a Shapiro-Wilk test, quantitative variables were compared using a Mann-Whitney test. Qualitative variables were analyzed using a Fischer exact test. The Spearman correlation test was used to assess the strength of the association between 2 quantitative variables. All statistical tests were 2-sided, and the $P < .05$ probability threshold was used to establish statistical significance. All statistical analyses were performed using R (version 4.1.3; R Core Team).

Results

Demographic Data

The compilation of responses took place from May 22 to October 26, 2021. A total of 762 medical students responded to the survey. Among them, the median age was 22 (IQR 21 - 24) years, and the gender ratio was 0.39 (212 males and 547 females; 3 students identified themselves as "gender neutral/non-gendered"). Respondents came from all the French metropolitan regions ([Table 1](#)). The participants were distributed as 149 (19.5%) second-year students, 121 (15.9%) third-year students, 139 (18.2%) fourth-year students, 119 (15.6%) fifth-year students, and 234 (30.7%) sixth-year students. Among the 762 respondents, 287 (37.7%) had retaken an exam at least once during their medical curriculum.

Table . Distribution of respondents by region.

Region	Respondents, n (%)
Auvergne-Rhône-Alpes	105 (13.8)
Bourgogne-Franche-Comté	106 (13.9)
Bretagne	21 (2.8)
Centre-Val de Loire	29 (3.8)
Grand Est	25 (3.3)
Hauts-de-France	24 (3.2)
Normandie	134 (17.6)
Nouvelle-Aquitaine	24 (3.2)
Occitanie	88 (11.5)
Pays de la Loire	61 (8.0)
Provence-Alpes-Côte d'Azur	90 (11.8)
Île-de-France	55 (7.2)

Use of SoMe

Among the 762 respondents included, 624 (81.8%) were WhatsApp users and 762 (100%) were SoMe users, spending a median time of 120 (IQR 60 - 150) minutes per day on them. A total of 555 (72.8%) students felt that their time spent on SoMe impacted their study time and 656 (86.1%) used SoMe

to learn about medicine. The 3 most used SoMe for this purpose were YouTube (504/762, 66.1%), Instagram (433/762, 56.8%), and Facebook (320/762, 42%; [Table 2](#)). A total of 115 (15.1%) students used WhatsApp for professional purposes (internship questions, exchange of night shifts, and discussion about a patient).

Table . Proportion of medical students using specific social networks for medical education, exploration of medical specialties prior to selection, and sharing content related to hospital internship.

SoMe ^a	Usage, n (%)		
	Exploring medical specialties	Medical education	Sharing content about hospital internships
Facebook	235 (30.8)	320 (42.0)	47 (6.2)
Instagram	375 (49.2)	433 (56.8)	157 (20.6)
LinkedIn	2 (0.3)	3 (0.4)	1 (0.1)
Pinterest	1 (0.1)	7 (0.9)	0 (0)
Reddit	3 (0.4)	8 (1.0)	0 (0)
Snapchat	2 (0.3)	9 (1.2)	68 (8.9)
TikTok	9 (1.2)	20 (2.6)	1 (0.1)
Twitch	1 (0.1)	0 (0)	0 (0)
Twitter	70 (9.2)	63 (8.3)	18 (2.4)
YouTube	220 (28.9)	504 (66.1)	0 (0)

^aSoMe: social media.

On SoMe, 79.1% (604/762) students followed 1 or more physicians whom they knew (resident or senior physician), and 25.9% (197/762) followed 1 or more national medical societies. A total of 522/762 (67.9%) students used SoMe to learn about a medical specialty in anticipation of choosing one. We identified significant misuse of social networks in a professional context, as 27.2% (207/762) of students had already posted content on SoMe (text, photo, and video) related to their hospital internship, and 10.8% (82/762) had ever searched for a patient's name on a SoMe platform. SoMe that used to post content related to hospital internships are presented in [Table 2](#).

Regarding the interest in teaching modules on the professional or educational use of SoMe in medical school, 61.4% (468/762) students found this proposal relevant (204/762, 26.7%), very relevant (156/762, 20.4%), or completely relevant (108/762, 14.2%). The remaining students (294/762, 38.6%) did not find this teaching relevant.

Smartphone Addiction

Among the 762 students analyzed, 222 (29.1%) had an SAS-SV score of at least 32/60, defining smartphone addiction. Nonaddicted students had a median SAS-SV score of 24 (IQR

20 - 27), while addicted students had a median score of 37 (IQR 35 - 42; $P < .001$). There was a significant correlation between the time spent on SoMe and the SAS-SV score ($r = 0.39$, 95% CI 0.33 - 0.45; $P < .001$; [Figure 1](#)). There were no demographic differences between smartphone-addicted and nonaddicted students ([Table 3](#)). However, addicted students spent more time on SoMe, with a more frequent impact on their study time, and a higher tendency to post content from their hospital internships

on SoMe ([Table 3](#)). Among the 222 addicted students, the most frequent addiction symptoms were tolerance (207/222, 93.2%), loss of control (166/222, 74.8%), disruption of family or schooling (138/222, 62.2%), and withdrawal (127/222, 57.2%). Only a few students displayed disregard for consequences symptoms (30/222, 13.5%) and none presented preoccupation about their smartphone use.

Figure 1. Correlation between the time spent on social media and the SAS-SV score. SAS-SV: Smartphone Addiction Scale Short-Version.

Table . Characteristics and social media behavior of medical students with or without smartphone addiction.

	Overall (n=762)	Nonaddicted students (n=540)	Addicted students (n=222)	P value
Gender, n (%)				.36
Male	212 (27.8)	150 (27.8)	62 (27.9)	
Female	547 (71.8)	389 (72.0)	158 (71.2)	
Other	3 (0.4)	1 (0.2)	2 (0.9)	
Age (years), median (IQR)	22 (21 - 24)	22 (21 - 24)	22 (21 - 23)	.71
Cycle of study, n (%)				.91
First cycle	270 (35.4)	192 (35.7)	78 (35.1)	
Second cycle	492 (64.6)	348 (64.3)	144 (64.8)	
Retook an exam, n (%)				.09
Yes	287 (37.7)	193 (35.7)	94 (42.3)	
No	475 (62.3)	347 (64.3)	128 (57.7)	
Time spent on social media (minutes per day), median (IQR)	120 (60 - 150)	94 (60 - 120)	150 (120 - 200)	<.001
Impact on the study time, n (%)				<.001
Yes	555 (72.8)	344 (63.6)	211 (95.0)	
No	207 (27.2)	196 (36.4)	11 (5.0)	
Social media use to learn about medicine, n (%)				.98
Yes	656 (86.1)	465 (86.0)	191 (86.0)	
No	106 (13.9)	75 (14.0)	31 (14.0)	
Posts related to the hospital internship, n (%)				.002
Yes	207 (27.2)	129 (23.8)	78 (35.1)	
No	555 (72.8)	411 (76.2)	144 (64.9)	
Ever searched a patient's name on social media, n (%)				.07
Yes	82 (10.8)	51 (9.4)	31 (14.0)	
No	680 (89.2)	489 (90.6)	191 (86.0)	

Subgroup Analyses

First- and second-cycle students show different patterns of social network use. Compared to their second-cycle peers, first-cycle students are less likely to use Facebook for their medical education (77/270, 28.5% vs 243/492, 49.3%; $P<.001$), and more inclined to use Instagram or Snapchat for example (Figure S1 in [Multimedia Appendix 3](#)). Smartphone addiction is the same between first- and second-cycle students (78/270, 28.9% vs 144/492, 29.3, respectively; $P=.91$), but graduate students are more likely to exhibit SoMe misuse behaviors (Table S1 in [Multimedia Appendix 3](#)).

Regarding gender differences, female and male students spent the same amount of time on SoMe (median 120, IQR 60 - 150 minutes per day in both groups; $P=.80$) and had the same prevalence of smartphone addiction (158/547, 28.9% vs 62/212, 29.2% respectively; $P=.92$; Table S2 in [Multimedia Appendix 3](#)). They presented differences in the use of different social networks (Figure S2 in [Multimedia Appendix 3](#)). Female students were more likely to use SoMe for medical education

(482/547, 88.1% vs 173/212, 81.6%; $P=.04$). The 2 genders showed different patterns of misuse, with a greater tendency to post content relating to hospital internships for female students (160/547, 29.1% vs 47/212, 21.8%; $P=.04$) and a greater tendency to search a patient's name on SoMe for male students (33/212, 15.6% vs 49/547, 9%; $P=.009$).

Discussion

Principal Findings

This nationwide web-based survey aimed to describe the use of SoMe by medical students in France for their medical education and to evaluate the prevalence of smartphone addiction in this population. Our findings indicate that among the respondents, a significant majority (656/762, 86.1%) used SoMe to learn about medicine, with YouTube, Instagram, and Facebook being the most popular platforms. Respondents reported spending a substantial portion of their day on SoMe, with a median time of 120 (IQR 60 - 150) minutes per day. However, misuse of SoMe was also reported, with 10.8%

(82/762) of students searching for patients' names on SoMe platforms. Nearly one-third (222/762, 29.1%) of respondents met the criteria for smartphone addiction according to the SAS-SV. Our study is the first nationwide survey to explore the use of SoMe for medical education among medical students in France and to investigate smartphone addiction on such a large scale in this specific population.

Use of SoMe for Medical Education

Our study highlights the extensive use of SoMe among respondents for medical learning mainly by following physicians' accounts (603/762, 79.1%) and, to a lesser extent, by following scientific societies (197/762, 25.9%). The main SoMe platforms used for this purpose were YouTube and Instagram, suggesting a preference for visual and multimedia content over textual information. While our survey did not assess whether SoMe were used more often than school-provided content, it indicates that SoMe was a significant supplementary source to traditional medical education, fostering collaboration among students and health care professionals. The COVID-19 pandemic has likely accelerated this trend [13,14], making it crucial for medical schools and educators to recognize the potential of these platforms and to integrate SoMe effectively into their teaching strategies.

However, it should be noted that 72.8% (555/762) of students surveyed felt that their time spent on SoMe negatively impacted their study time, highlighting the ambivalence of these platforms. Although students use SoMe for educational purposes, they also engage with these platforms for noneducational activities, which can detract from their study time. This point is acknowledged by the respondents, as 61.4% (468/762) of them found it relevant to add a teaching module on the professional or educational use of SoMe in medical school.

It is important to note that the quality and reliability of educational content on SoMe can vary widely [28,29]. There is also a need to consider how to produce and validate medical educational content on these platforms. Some authors proposed their personal guidelines on this topic, but there is still a lack of large consensus on how to provide medical education on SoMe [30,31]. Medical teachers who publish and moderate content on SoMe should probably be valorized at an institutional level, as they play a significant role in the current dissemination of knowledge to students. However, further research is still needed to evaluate the impact of these resources on students' medical knowledge, skills, and professional development.

We describe that 79.1% (603/762) of students follow a physician they already know on SoMe and that 68.5% (522/762) use SoMe to help them choose a specialty. This is an important message, showing that physicians who are active on SoMe are seen (and are likely to be imitated) by students. This reinforces the absolute necessity to maintain perfect professionalism when communicating on SoMe as a health professional or as a teacher. Our results also suggest that SoMe could be an effective communication tool for medical academic societies to promote and present their specialty among students.

Misuse of SoMe in a Professional Context

Our study also identified significant misuse of social networks in a professional context. Posting content related to hospital internship was reported by 27.2% (207/762) of respondents, and 10.8% (82/762) admitted to searching for patients' names on SoMe platforms. Second-cycle students were more likely to present misuse with the risk of a breach of confidentiality, which is consistent with the fact that they spend more time on in-hospital internships than first-cycle students. We also observed a gender difference in misuse behavior, with female respondents more likely to post internship-related content and male respondents more likely to search for patient information. These results have already been reported in other studies [32,33]. These behaviors pose ethical and legal concerns, as they can lead to breaches of confidentiality and compromise patient privacy. Additionally, these actions may have severe consequences for medical students and their future careers, including disciplinary action and damage to their professional reputation. French law strictly forbids sharing any medical information with anyone other than the caring team, and any information apart from the ones strictly necessary to the patient's course of treatment or care, except for some listed exceptions [34].

The platforms that seemed to be more problematic were Snapchat and Instagram, possibly due to the sensationalist nature of sharing photographs or videos, particularly ephemeral ones ("stories"). This is particularly worrying, as we recently showed that, on SoMe, photographs are much more likely to breach medical confidentiality than written posts [35]. In contrast, YouTube, which requires more effort to upload a video, appears much less likely to be used to share such content. Therefore, we suggest for the first time that the risk of SoMe misuse and medical confidentiality breaches seem to vary greatly among the different platforms. This information should probably be used to provide relevant information on the individual risks of each SoMe, which are not a uniform entity.

This problem of unprofessional use of SoMe by medical students is the subject of significant research literature, with which our results are consistent. Some authors report interesting results after implementing "social media and professionalism" course in medical school, with improvement in students' SoMe behavior [36]. It is crucial for all medical schools and health care institutions to address these issues and promote the responsible use of SoMe among their medical students through the development of policies and educational interventions. SoMe misuse, particularly breaches of confidentiality, is not only a problem among students but also among physicians. Ahmed et al [32] identified tweets from 656 health care professionals' Twitter profiles, including 486 (74.1%) doctors. Through these tweets, friends and family were able to identify clinical scenarios in 242 of the 754 (32.1%) tweets. In a study of the profiles of anesthesia and intensive care professionals, 5.3% of doctors' accounts had posted content posing a confidentiality problem [35].

Prevalence and Impact of Smartphone Addiction

Our findings indicate a concerning prevalence of smartphone addiction among medical students, with nearly one-third

(222/762, 29.1%) of respondents meeting the criteria for addiction. This finding is consistent with the literature, which reports a smartphone addiction rate between 15% and 40% among students [19,37-39]. The SAS-SV score for addiction diagnosis is well established, and this scale has been already validated in French, increasing its reliability and reproducibility [26]. Our results showed a significant correlation between increased length of SoMe use and SAS-SV score. It is impossible to establish a causality link here, as students can become addicted to these platforms through overuse, but they may also use them intensively because of their addiction. In a Norwegian student population, Hjetland et al [40] also found a strong association between addiction and daily time spent on SoMe, particularly when this usage occurred in the evening.

The negative psychological, social, and physical effects of smartphone addiction are well described—lower academic performance, sleep disorders, anxiety, musculoskeletal disorders, severe social withdrawal, decreased physical activity, and hypertension [16-19]. It is thus recognized that this addiction has a negative impact at the individual level. However, our results also showed that addicted students reported more impact on their study time and a higher tendency to share hospital internship content on social networks, suggesting that students' smartphone addiction could also have a negative impact on patients. There are no data on the potential link between medical students' smartphone addiction and unprofessional behavior on SoMe, and further works are needed to explore this hypothesis.

Limitations

Despite these interesting results, our work has several limitations. First, the response rate was low. Even if we were unable to determine the total number of medical students who received the survey invitation, the targeted population is approximately 42,000 students (which would give a response rate of 1.8% if we consider that all students received the invitation). As a result, it is not possible to estimate the nonresponse bias, which is probably significant, as students who chose to participate in the study might have different characteristics or behaviors than those who did not. Additionally, the study relied on self-reported data, which may be subject to recall and social desirability biases. Participants might have underreported their SoMe use or smartphone addiction due to concerns about stigma or privacy. Furthermore, the mode of distribution, an online survey distributed via email, may have introduced a selection bias. It is possible that students who are more active on SoMe were more likely to respond to the survey, potentially leading to an overestimation of the prevalence of SoMe use and smartphone addiction among the general population of medical students. Conversely, respondents may

have different patterns of SoMe use compared to nonrespondents, which we were unable to assess.

Moreover, the response rate among female students (547/762, 71.8%) was significantly higher compared to male students. According to national statistics, the gender distribution in French medical schools was approximately 66% female and 34% male in 2021 [41]. This overrepresentation of female respondents might have influenced the results, as female students could have different SoMe usage patterns and concerns compared to their male counterparts. This limits the generalizability and interpretation of our findings to the overall population of medical students.

To address these limitations, future research should aim to achieve a higher and balanced response rate, possibly by using multiple distribution methods and follow-ups to reach a more representative sample of the student population. Additionally, qualitative studies could explore the reasons behind nonresponse and differences in SoMe patterns among different student demographics.

The use of the SAS-SV as the sole instrument to assess smartphone addiction has its limitations. While the SAS-SV has demonstrated good validity and reliability, it may not capture the full spectrum of addictive behaviors related to smartphone use. Further research could enable a better understanding of these behaviors in the medical student population and, more specifically, their impact on medical students' results at the national final examination at the end of the sixth year of the medical course. Furthermore, the cross-sectional design of our study does not allow us to establish causal relationships between the use of social networks, smartphone addiction, and the potential consequences on medical students' academic performance and well-being. Longitudinal studies would be required to better understand the directionality of these relationships. In addition, the psychometric properties of the "use of social network" section were not formally assessed, which is acknowledged as a limitation of this study. Future research should include a comprehensive psychometric evaluation to confirm the reliability and validity of the survey instrument.

Conclusions

In conclusion, this study highlights the extensive use of SoMe for medical education among respondents and the concerning prevalence of smartphone addiction. Educators should recognize the potential of these platforms, promote responsible use, and address addiction issues. Further research is needed to optimize SoMe usage for medical education while minimizing risks associated with excessive use and addiction.

Acknowledgments

The authors would like to express their gratitude to the ANEMF (Association des Etudiants en Médecine de France) and all the student representatives for their assistance in disseminating this questionnaire.

Authors' Contributions

TC performed the conceptualization, methodology, investigation, formal analysis, and writing—original draft. EC contributed to the investigation, formal analysis, and writing—review and editing. ZD contributed to the supervision and writing—review and editing. BV performed the supervision and writing—review and editing. Abstract

Background: Social media is a powerful platform for disseminating health information, yet it is often riddled with misinformation. Further, few guidelines exist for producing reliable, peer-reviewed content. This study describes a framework for creating and disseminating evidence-based videos on polycystic ovary syndrome (PCOS) and thyroid conditions to improve health literacy and tackle misinformation.

Objective: The study aims to evaluate the creation, dissemination, and impact of evidence-based, peer-reviewed short videos on PCOS and thyroid disorders across social media. It also explores the experiences of content creators and assesses audience engagement.

Methods: This mixed methods prospective study was conducted between December 2022 and May 2023 and comprised five phases: (1) script generation, (2) video creation, (3) cross-platform publication, (4) process evaluation, and (5) impact evaluation. The SIMBA-CoMICs (Simulation via Instant Messaging for Bedside Application–Combined Medical Information Cines) initiative provides a structured process where medical concepts are simplified and converted to visually engaging videos. The initiative recruited medical students interested in making visually appealing and scientifically accurate videos for social media. The students were then guided to create video scripts based on frequently searched PCOS- and thyroid-related topics. Once experts confirmed the accuracy of the scripts, the medical students produced the videos. The videos were checked by clinical experts and experts with lived experience to ensure clarity and engagement. The SIMBA-CoMICs team then guided the students in editing these videos to fit platform requirements before posting them on TikTok, Instagram, YouTube, and Twitter. Engagement metrics were tracked over 2 months. Content creators were interviewed, and thematic analysis was performed to explore their experiences.

Results: The 20 videos received 718 likes, 120 shares, and 54,686 views across all platforms, with TikTok (19,458 views) and Twitter (19,678 views) being the most popular. Engagement increased significantly, with follower growth ranging from 5% on Twitter to 89% on TikTok. Thematic analysis of interviews with 8 out of 38 participants revealed 4 key themes: views on social

media, advice for using social media, reasons for participating, and reflections on the project. Content creators highlighted the advantages of social media, such as large outreach (12 references), convenience (10 references), and accessibility to opportunities (7 references). Participants appreciated the nonrestrictive participation criteria, convenience (8 references), and the ability to record from home using prewritten scripts (6 references). Further recommendations to improve the content creation experience included awareness of audience demographics (9 references), sharing content on multiple platforms (5 references), and collaborating with organizations (3 references).

Conclusions: This study demonstrates the effectiveness of the SIMBA CoMICs initiative in training medical students to create accurate medical information on PCOS and thyroid disorders for social media dissemination. The model offers a scalable solution to combat misinformation and improve health literacy.

Introduction

In July 2023, there were more than 4.9 billion social media users globally, equating to over 61% of the world's population [1]. Social media usage has increased by 3.7% in the past year, with 173 million new users (5.5 new users every second). Checking one's social media profile has become a predominant activity for 9 out of 10 internet users. Furthermore, 7 of the top 10 most popular social media platforms claim over 1 billion monthly active users. These are Facebook (Meta; 2.989 billion), YouTube (Google; 2.537 billion), WhatsApp (Meta) and Instagram (Meta; 2 billion), WeChat Inc or Weixin (Tencent; 1.319 billion), TikTok (ByteDance; 1.081 billion), and Facebook Messenger (Meta; 1.038 billion). In addition, 4 platforms are owned by the same company, Meta (Facebook, Instagram, WhatsApp, and Facebook Messenger). These are followed by Snapchat (Snap Inc, 750 million users), Douyin (ByteDance, 730 million users), and Telegram (Telegram Messenger Inc, 700 million users). Social media reach extends beyond personal interactions on each platform as users adopt multiple platforms. For example, nearly 78% of Facebook users also use Instagram.

GWI's data from DataReportal reported that 49% of active users aged 16 to 64 (outside China) use social media to keep in touch with friends and family, 37% to fill spare time, 35% to read new stories, 30% to find content (studies and videos). While some platforms are used for passive entertainment (eg, TikTok), Instagram, Facebook, and Snapchat are used for content creation by sharing posts and videos. Given its reach, social media has also emerged as a powerful tool for promoting health and disseminating health-related research findings, surgical education, and medical information [2-4].

However, the role of social media in sharing clinical experiences is complex and carries potential benefits and challenges. Some benefits include rapid and wide dissemination of information at minimal costs to the end user, bridging the gap to health care access, and patient education [5]. However, this unprecedented access to information may also provide a breeding ground for misinformation. This spread of misleading or false information can have dire consequences in health care, where accurate knowledge is crucial for making informed decisions about one's well-being [6]. This risk comes with the exponential growth of short video platforms such as TikTok, mimicked by Instagram

reels, Facebook stories, and YouTube shorts, whose algorithms tend to propose similar content based on the users' histories and preferences. Short video platforms are echo chambers [7] that reinforce beliefs, prejudices, fake news, and misinformation. There is a need to address this by producing evidence-based content to ensure the dissemination of accurate information without bias [7,8].

Considering the negative consequences of misinformation, in the last 2 years, the World Health Organization partnered with major technology companies that have leverage on major social networking sites such as Alphabet (Google and YouTube) [9] and Meta (Facebook, Instagram, and WhatsApp) [10] to minimize misinformation. Solutions included semiautomated flagging, labeling, or removing content that violates community guidelines and misinformation policies [11]. Google and YouTube have recently invested US \$13.2 million in the International Fact-Checking Network [12] to enhance misinformation response. Video creation platforms, such as YouTube, Twitch, or TikTok, have their community guidelines, which try to regulate the content produced. Nevertheless, there is little to no guidance on creating content before it is uploaded on social media platforms.

Regarding medical or health-related content, social media platforms generally include content that rarely reflects clinical guidelines (eg, low back pain and laparoscopic hysterectomy) [13,14]. Many studies report methods for evaluating medical content on social media, specifically YouTube [15], but few describe medical education videos' development, implementation, and evaluation.

Since, to the best of our knowledge, there are no specific international guidelines to create evidence-based medical and health content related to polycystic ovary syndrome (PCOS) and thyroid disorders, an international medical education initiative was launched to create evidence-based and peer-reviewed bite-sized videos on various medical conditions in collaboration with various patient support groups [16-19]. The initiative named "SIMBA CoMICs" (Simulation via Instant Messaging for Bedside Application-Combined Medical Information Cines) involves medical students, junior doctors, and patient groups who collaborate to create bite-sized videos for different social media platforms. Combined Medical

Information Cines (CoMICs) initiative is a novel approach merging intricate medical concepts with illustrative graphics, presented in video format for swift assimilation. Each CoMIC video meticulously portrays distinct medical conditions, encompassing their presentations, diagnostic tools, subsequent treatment options, and recommended follow-up measures. The content for each presentation aligns with national and international guidelines and undergoes rigorous evaluation by leading experts in the corresponding medical domain.

This study describes generating, creating, disseminating, and evaluating evidence-based, peer-reviewed, short social media videos about PCOS and thyroid diseases. The project followed a collaborative approach with people living with these conditions and health care professionals with a special interest in these conditions. We analyzed the project outreach and audience engagement on social media (specifically TikTok, Instagram reels, YouTube shorts, and Twitter). Furthermore, we gathered participant experience for effective engagement and evidence synthesis. This examination of public discourse through social media platforms provides insights into disseminating and perpetuating viewpoints regarding thyroid conditions and PCOS.

Methods

The SIMBA-CoMICs (Simulation via Instant Messaging for Bedside Application–Combined Medical Information Cines)

Figure 1. Overview of the main steps to complete this project. HCP: health care professionals; PCOS: polycystic ovary syndrome.

Script Generation

A literature search of the frequently asked questions in PCOS and thyroid conditions was conducted across various databases, including PubMed, Cochrane Library, and Embase. Key MeSH (Medical Subject Headings) terms, including “frequent,” “questions,” “popular,” “topics,” “Thyroid,” “conditions,” “PCOS,” and “Polycystic Ovary Syndrome,” were explored

across all databases in this scoping review. Based on this, a list of the most popular topics was created. The experts and representatives of patient support groups reviewed the topics independently to arrive at 5 main topics for both PCOS and thyroid. Each topic was subdivided into 3-5 subtopics. We then created corresponding scripts and guidance on when and how to seek medical intervention or advice. The scripts' scientific accuracy and ease of understandability were checked by 2 early

initiative provides a structured framework for simplifying medical concepts and converting them into visually engaging, evidence-based videos. The initiative actively recruited medical students and resident doctors, who were guided through the script creation and video production process. The SIMBA-CoMICs initiative emphasised on collaboration among health care professionals, content creators, and individuals with lived experience of PCOS and thyroid conditions to ensure that the final content was scientifically accurate and relatable to the public. This structured approach ensured consistency across all phases of the project, from initial script development to final video dissemination on social media platforms.

Design

This mixed methods prospective study was conducted between December 2022 and May 2023 and consisted of 5 phases: script generation, video creation, cross-platform publication, process, and impact evaluation (Figure 1). This study was inspired by the “Knowledge-to-action (KTA)” framework, whereby the content of the videos is based on scientific evidence synthesis, translation, and validation through expert consultation and patient engagement [20]. The content is then produced, and its fruition is monitored, evaluated, and critically appraised for improvement and for generating recommendations.

career researchers, a consultant endocrinologist, and members of patient support groups to ensure they align with the relevant international guidelines.

Video Creation

We invited medical students and junior doctors globally to contribute to this project by advertising the role of video creation on our social media handles (Twitter: SIMBASimulation, TikTok: simbacomic, Instagram: simba.comic, YouTube shorts: @simbasimulation8047). Medical students at the University of Birmingham and other authors' institutes were also invited by email to express interest in creating these videos. Similar invites were sent to members of UK-based and international patient support groups supported by partnering institutions (PCOS Vitality and British Thyroid Foundation). Patient support groups were invited to contribute to the videos. Participants were incentivized by certificates acknowledging their contribution to this project. The invitations included a brief role description and instructions on the format that the volunteers will be asked to film themselves.

Upon expressing interest, each volunteer received an email with the script of the content they were allocated in the video series. The emails also included a sample video for participants to visualize the expected product. Participants were requested to film in portrait orientations in keeping with the main format of short videos on TikTok, Instagram reels, YouTube shorts, and Twitter. In addition, we advised participants to keep the videos under 30 seconds to match the average video duration on social media [21]. Participants who submitted a video were invited to create more videos within an agreed set of personalized deadlines. A total of 5 volunteers agreed to this. After we received all the videos, we added the transcripts to the video as captions, one line at a time, and highlighted keywords, with the relevant pictures and emojis to help the audience better understand and interpret the videos. We edited the videos where necessary to ensure they did not exceed 30 seconds. The finalized videos were shared with early-career endocrinologists and members of patient support groups, who reviewed them and helped finalize the transcripts. Further changes were made to the videos to ensure accuracy and acceptability.

Content Publication

The finalized videos were uploaded to TikTok to be edited using the app's video editing features, followed by sharing them as Instagram reels, YouTube shorts, and Twitter as a series of video posts. A target minimum of one video was posted every day between March 2, 2023, and March 26, 2023, with a 1-day break after each video series. The videos were posted with their subheading as the video's public title, and relevant, popular hashtags were included for each video to stimulate the social media algorithm and help redirect the videos to interested audiences. Volunteers were tagged in the videos they filmed if they had an account on the social media platform used after their consent.

Process Evaluation: Participants' Experience

We invited our content creators to share their views about the project in a semistructured online interview. The interview specifically aimed to explore their experiences, motivation to participate, and interest in developing similar videos for other subjects. Participants were reassured that their responses would be anonymized and would not impact whether they received a certificate for contributing to this project. These interviews were conducted on Zoom (Zoom Video Communications, Inc) and lasted approximately 10 minutes. Each interview was recorded after consent, and participants were allowed to have their cameras switched off during the meeting. All study data were stored in a password-protected folder, with only the study team having access to it. All questions were asked to each participant following the set order, as indicated in the interview guide provided in [Multimedia Appendix 1](#). Interviews with the participants were anonymized and transcribed verbatim. Furthermore, 2 independent authors did the coding of interview transcripts using NVivo (version 12.0). The codes were combined to identify themes using thematic inductive analysis [22,23]. The research team discussed the codes and agreed on the thematic structure proposed.

Impact Evaluation: Quantitative and Thematic Analysis

We evaluated the impact of the produced videos using a combination of quantitative and qualitative data. Quantitative data analyses were based on video analytics on each platform, including the total number of views, the highest number of views on a video, total shares, total number of saved videos, total likes, and change in the number of followers or subscribers were extracted along with other similar variables across all platforms after a month of publishing the video. Considering the proprietary algorithms, recommendations, and search engines followed by each platform, comparative statistical tests were not run across platforms. Qualitative data was based on a content analysis of the comments posted under each video to understand the viewers' perspectives. Comments were inductively coded.

Ethical Considerations

No patient data were collected, and this study was approved by the ethics committee of Delhi Heart Institute and Multispecialty Hospital (DHIMH/IEC/2023-008). Informed consent was taken from each participant, and participation was voluntary.

Results

Script Generation

The topics and subtopics of the videos we generated through our literature searches and validated through expert consultations are presented in [Textbox 1](#).

Textbox 1. Outline of topics and subtopics of the videos.

Thyroid nodules:

- Definition and differentials
- Red flag symptoms
- Investigations
- Management

Hypothyroidism:

- Symptoms and signs
- Investigations
- Risk factors
- Management

Diagnosing polycystic ovary syndrome (PCOS):

- Diagnostic criteria
- Symptoms
- Associated complications
- Risk factors
- Emotional well-being

PCOS implications and associations:

- Impact on menstruation
- Impact on pregnancy and its likelihood
- The link between PCOS and thyroid

Thyroid and pregnancy:

- Conception
- Effect of hypothyroidism
- Effect of hyperthyroidism
- Impact on infants
- Breastfeeding

Study Participants and Content Created

We recruited 38 content creators, mostly students (33/38, 87%), 2 people with 1 or more of the conditions, and 2 social media influencers. In total, 11 students and 1 self-identified influencer created 21 videos.

Process Evaluation: Participants' Experience

Out of the 12 volunteers who filmed the videos, 8 (67%) completed an interview on their experiences and views on the project. Thematic analysis of the anonymized interview transcripts yielded 4 main themes, that are, views on social media, advice when using social media, the reason for taking part in this project, and thoughts on this project ([Table 1](#)).

Table 1. Outline of central themes and subthemes from the thematic analysis of participant interviews.

Theme	Subthemes
Views on social media	Disadvantages, advantages, and uses of social media.
Advice on making the most of social media	Factors impacting public engagement, how to improve engagement, and general advice.
Reason for taking part in this project	Barriers, motivation, and previous experience.
Thoughts on this project	Positive aspects, tips to improve the project, and project outreach.

Views on Social Media

Participants highlighted several advantages of social media, including “large outreach” (12 references), “convenience of getting things done from the comfort of their homes” (10 references), and “accessibility to opportunities” in fields of interest (7 references). Participants also noted that social media is beneficial for “finding information” (8 references), advertising and fundraising (5 references), and expanding audience and outreach (7 references). However, several participants shared their concerns about social media. A total of 7 participants referenced “misinformation” as a key threat in social media that should be taken seriously. Some participants expanded to explain the consequences of inaccurate information, such as anxiety (5 references), confusion (3 references), or a false sense of reassurance (3 references). A total of 4 participants commented on the potential of “wasting time” on social media.

Advice on Making the Most of Social Media

The most common themes were being aware of “audience’s demographics,” “sharing on more than one social media platform” (5 references), “collaborating with well-known organizations” (3 references), and “linking the videos to reliable web pages with more information” (2 references). There were also comments on how to maximize positive outcomes and minimize negative ones when using social media generally, including “the importance of monitoring and limiting the unproductive time spent on it” (9 references) and the importance of verifying any information for an unknown source (7 references).

Thoughts on the Project

Participants mentioned “non-restricting participation criteria,” “convenience” (n=8), and “ability to record videos from home with a pre-written script” (6 references), which made it a lot easier to participate. In addition, 3 participants mentioned the time needed to memorize the scripts (3 references), the need to

step out of their comfort zone (1 reference), and the dates the volunteers were recruited (1 reference), made their participation challenging.

Tips to improve the project included having a “meetup with other volunteers” (6 references), increasing the “variety of video formats” submitted (4 references), and “extending the period that students had to submit their project” (2 references). Participants believed the project is beneficial for people “impacted by the respective conditions” (16 references), “healthcare professionals” (7 references), and “medical students” (6 references). All participants also stated that they believe this project design is “sustainable” for the long-term (n=8).

Impact Evaluation

Quantitative Assessment

The 21 videos generated a total of 108,210 views across platforms, with Twitter and TikTok generating the most views (n=47,342), followed by Instagram (n=13,207), and YouTube (n=13,773), as of September 19, 2023, as summarized in [Table 2](#) below. The highest number of views and shares on a single video were found in TikTok (4327 views, 57 shares), followed by Twitter (4176 views, 53 shares), whereas YouTube had the lowest views and shares (738 and 0, respectively). TikTok was also the platform with the highest number of likes, saves or bookmarks, and likes and saves for a single video, compared with the other platforms. The videos viewed and shared the most across all platforms were those about thyroid nodules, thyroid and pregnancy, and PCOS and thyroid. Between March 2, 2023, and March 26, 2023, the project’s social media profiles had an overall increase of 259 subscribers or followers (64.8 on average), with 178 new users subscribed on YouTube, followed by TikTok (n=31), Twitter (n=28), and Instagram (n=22). TikTok was the best-performing platform for new users and subscribers.

Table 2. Summary of data from the videos posted across all social media platforms as quantified on May 25, 2023.

Indicators and platforms	TikTok	Instagram	YouTube	Twitter	Total (average, SD)
Total number of views	47,342	13,207	13,773	28,888	108,210 (27,052, 13,935.80)
Highest number of views for a single video	12,140	1440	4118	4252	21,950 (5488, 4001.25)
Total likes	611	124	138	94	967 (241.5, 213.78)
Most likes for a single video	114	20	33	14	211 (53, 40.28)
Total shares	82	20	0	53	155 (39, 31.33)
Highest number of shares for a single video	24	3	0	9	36 (9, 9.25)
Total number of saves or bookmarks of videos	101	9	0	0	110 (27.5, 42.59)
Highest number of saves for a single video	29	3	— ^a	—	32 (16, 13)
Change in number of followers or subscribers (between March 2023 and September 2023)	+38	+22	+356	+128	+544 (136, 133.29)
% change in the number of followers or subscribers (between March 2023 and May 2023)	+950%	+8%	+32%	+26%	—

^aNot applicable.

Qualitative Evaluation of Comments

A total of 38 comments were posted across all platforms as of September 19, 2023. Out of these, 17 were either emoji-based comments or commended the video without providing further context. In addition, 21 comments were further analyzed. Of these, 8 included praises for the project team, and 3 came from a spammer who promoted their services maliciously and spread misinformation. Furthermore, 5 asked for advice and further elaboration on conditions discussed in the videos. In total, 3 viewers shared their journey, specifically fears linked to the diagnosis and dissatisfaction with the diagnosis process. One of the viewers mentioned it provided helpful academic context as they had an assignment on a related topic. Another user shared that they had no idea about these conditions and thanked the team for publishing this information.

Discussion

Principal Findings

This report describes our experience generating, creating, disseminating, and evaluating evidence-based, peer-reviewed short social media videos. In this experience, we focused on PCOS and thyroid diseases based on our collective expertise. To our knowledge, this is the first study that describes the development and evaluation of videos for multiple social media platforms and discusses the abovementioned topics. Previous research has focused on other conditions (eg, low back pain) or specific surgical procedures (eg, laparoscopic hysterectomy) without guiding medical content creation [13,14].

Several studies have evaluated the content of short videos published on social media networks, highlighting unsatisfactory quality videos and warning about blind reliance on online content [24-26]. These studies acknowledged misinformation and invalidity as major factors compromising video content and negatively influencing the audience. This, paired with the acknowledgment of the increase in reliance on social media for medical information, flags the importance of starting evidence-based awareness campaigns and medical education initiatives for the masses. While previous researchers assessed the quality of online short videos across multiple social media platforms, none directly tackled the issues or attempted to generate evidence-based short videos.

This study builds on the KTA framework and focuses on knowledge dissemination [20]. After noting the rise in popularity and the increase in public reliance on short-video platforms as a source of medical information and acknowledging the issues linked to it, our study decided to use the short-video social media platforms to translate accurate knowledge and evidence-based information to the public. We adapted the information to be translated in lay terms and duration suitable for such platforms. Awareness of the social media algorithms, such as hashtags in promoting videos and attracting the right audience, allowed us to minimize barriers and facilitate knowledge transmission. Assessment of post video release of engagement and content creator feedback helped select and highlight obstacles and facilitators to this process of video dissemination. This methodology can be used to tailor further videos in other specialties. The dissemination of correct information could

positively impact health behaviors, encouraging prompt diagnosis, preventing disease prognosis, and allowing an early management plan to be followed. Using the framework for content creation in the project is a way of standardizing and easing this process [27].

Involving medical professionals as content creators on social media brings a unique blend of credibility and educational value to combat misinformation and build trust in public health care. Their expertise allows for accurate and impactful messaging, addressing complex health topics, and debunking myths effectively. Time constraints, oversimplification, and regulatory considerations are some of the challenges that need to be addressed. Alongside creating misinformation-debunking videos, leveraging medical professionals' knowledge can significantly contribute to raising awareness, promoting healthy behaviors, and fostering a culture of informed decision-making among the public.

Process Evaluation

Responses from participants suggest that this project benefits health care professionals, patients, and the public. The experience gained from working on this video series has been noted to help medical students and health care practitioners at different levels of training. It also harnesses their skills and knowledge to ensure that the patient and public get the most up-to-date and accurate information while allowing them to ask questions and suggest further video topics. While some participants emphasized the potential for reaching wider audiences and fostering connections, others expressed concerns about social media engagement's competitive nature and potential negative impacts. These varying viewpoints indicate the complex interplay between the benefits and drawbacks of using social media platforms for content dissemination. Our thematic analysis underscores the multifaceted nature of content creators' motivations, which extend beyond monetary incentives and highlight the intrinsic rewards associated with engaging in creative endeavors. Participants' positive feedback and constructive suggestions indicate ownership and investment in the project's success. These insights contribute to the academic discourse on digital content creation and offer practical implications for educators, marketers, and content creators aiming to navigate the dynamic landscape of social media platforms. This study's findings underscore the need for a holistic approach to understanding content creators' motivations and behaviors within the ever-evolving realm of digital media.

Impact Evaluation

We noticed an incremental engagement with our videos on all social media platforms over time. The videos were shared and saved across all platforms, implying their circulation as the audience uses multiple social media platforms. All social media platforms also witnessed an increase in followers, indicating that the public found our video series helpful. The varied number of views received underscores the diverse audiences on different platforms and highlights the potential for content to resonate strongly within specific communities. TikTok's exceptional performance in likes, shares, and saves further highlights its potential for viral content dissemination and user interaction

while aligning the content per platform-specific trends, formats, and audience preferences.

Our qualitative analysis highlights the dual nature of online engagement, from spammers spreading misinformation to genuine users sharing personal experiences and expressing gratitude. The presence of spammers underscores the need for robust moderation mechanisms to ensure a safe and accurate information-sharing environment with proactive community management. The inquiries and comments seeking further information about specific medical conditions suggest an avenue for generating additional content that addresses viewers' questions and unmet needs. We highlight the diverse nature of

engagement on different platforms and reveal the potential for meaningful engagement, education, and community-building through project-specific content. These findings offer insights for future content creation, platform selection, and audience engagement strategies, emphasizing the importance of tailoring content to different platform dynamics and user expectations.

Recommendations

In the absence of evidence-based guidelines to generate medical social media content, this study allowed us to formulate a set of recommendations, which we summarized in a checklist that can also be used in further studies (Table 3).

Table 3. Recommendations for creating videos on medical topics for dissemination in the public domain.

Recommendation	Rationale
Recommendation 1: involving all stakeholders, including health care professionals at all levels, students, patients, and the public.	All stakeholders mutually benefited from the diverse perspectives to deliver easily understandable content for a large audience.
Recommendation 2: using a variety of video formats (ie, interview-style videos, role play, or Q&A ^a format).	Content creators explained that they believe this will prove more engaging and, hence, be more appealing to participants.
Recommendation 3: linking the videos to information pages.	This will join between both the recent reliance on social media videos and the use of accurate research-based findings.
Recommendation 4: signposting the audience to relevant peer-reviewed studies or pages or organizations.	Misinformation spreads from the inability to distinguish reliable and nonreliable information. By signposting credible organizations, you point the audience in the right direction.
Recommendation 5: allowing the content creators to meet beforehand and familiarize themselves with one another and the project leads.	Volunteers suggested that familiarizing themselves with their colleagues would have helped build context and reach out for feedback on their respective videos to optimize video quality.

^aQ&A: question and answer.

Strengths and Limitations

The strengths of our initiative include using a collaborative approach of involving multiple stakeholders to generate credible peer-reviewed videos with ease of understanding. Feedback from viewers and volunteers who made the video provides essential insights into the public's unmet needs and the importance of disseminating reliable information to debunk misinformation. Furthermore, according to Bloom's Taxonomy [28], allowing students to engage with patients and health care professionals, analyze and evaluate video content, and generate these videos constitutes the highest form of learning. On the other hand, our study was limited by the small sample size of volunteers, videos, and total viewers. The sample size of content creators, consisting primarily of medical students and junior doctors, may not represent a diverse range of perspectives or experiences in content creation. This could limit the generalizability of findings regarding motivations, challenges faced, and overall experiences of content creation on social media platforms. In addition, as the results of online social media platforms are dynamic over time, similar studies conducted at different times or regions may yield different results. While this study focused on creating and disseminating peer-reviewed videos on PCOS and thyroid conditions, it may not encompass the full spectrum of health-related topics relevant to broader public health concerns. Furthermore, the evaluation period of 2 months for video engagement and audience outreach

may provide only a snapshot of the long-term impact and sustainability of such initiatives. Future research could address these limitations by including a more diverse range of content creators, expanding the scope of health topics covered, and conducting longer-term evaluations to assess maintained audience engagement and behavior change. Obtaining detailed demographic and socioeconomic profiles of both volunteer and nonvolunteer groups will offer invaluable insights into the barriers hindering participation. These data will not only aid researchers in understanding the dynamics influencing volunteerism but also furnish crucial information for the design and implementation of future projects. Furthermore, uncovering these barriers could shed light on broader societal issues, potentially informing policies and interventions aimed at fostering greater community engagement and participation.

Conclusion

Our study demonstrates how to codesign, disseminate, and evaluate evidence-based, peer-reviewed medical information for short videos to be distributed across social media platforms. This experience focused on PCOS and thyroid diseases and showed how social media could be used to increase awareness and tackle misinformation about these issues. In particular, social media videos can be used to engage the public and stimulate patients who might ask questions. This benefits both the viewers and the video creators, especially if they are medical students or junior doctors.

Acknowledgments

We thank all the health care professionals who participated in this study. Volunteers in this project made valuable contributions to the project delivery and constituted responses for thematic analysis. We thank Ms Anna Woollven from the British Thyroid Foundation (BTF) and Ms Maureen Ann Busby from the PCOSvitality for their continuous support throughout the project. This project received a Public Engagement Grant from the Society for Endocrinology in November 2022.

Data Availability

All data generated or analyzed during this study are included in this published article (and its supplementary information files). Further inquiries can be directed to the corresponding author.

Authors' Contributions

ME and KM are the joint first authors, having made all-round contributions to the study. ME contributed to the study conception, supervised executive aspects of the project, interviewed participants, wrote the first draft, and conducted the thematic analysis. KM contributed to interview coding, qualitative result analysis, fine-tuning the research methods, and writing the first draft. KG contributed to fine-tuning the research methods, writing the first draft, and obtaining ethics approval. PK supervised executive aspects of the project, finalized the research methods, and critically reviewed and revised the manuscript. MB critically reviewed and contributed to the revised manuscript's introduction, methodology, and results. All authors contributed substantially to drafting and approving the final draft of the manuscript. The SIMBA (Simulation via Instant Messaging for Bedside Application) and CoMICs (Combined Medical Information Cines) team included Ms Alexander Browne, Ms Hannah Khan, Ms Anum Chaudry, Ms Shubhi Ratra, Ms Pavithra Sakthivel, Ms Damilola Akande, Mr Matthew Smith, Ms Shruti Attarde, and Ms Kayleigh Harrylal; created the content for all videos. The final version has been reviewed and approved by all the authors.

Conflicts of Interest

None declared.

Multimedia Appendix 1

Public Engagement interview questions asked to volunteers who filmed the videos.

Abstract

Background: The Primary Trauma Care (PTC) course was originally developed to instruct health care workers in the management of patients with severe injuries in low- and middle-income countries (LMICs) with limited medical resources. PTC has now been taught for more than 25 years. Many studies have demonstrated that the 2-day PTC workshop is useful and informative to frontline health staff and has helped improve knowledge and confidence in trauma management; however, there is little evidence of the effect of the course on changes in clinical practice. The Kirkpatrick model (KM) and the knowledge, attitude, and practice (KAP) model are effective methods to evaluate this question.

Objective: The aim of this study was to investigate how the 2-day PTC course impacts the satisfaction, knowledge, and skills of health care workers in 2 Vietnamese hospitals using a conceptual framework incorporating the KAP model and the 4-level KM as evaluation tools.

Methods: The PTC course was delivered over 2 days in the emergency departments (EDs) of Thanh Hoa and Ninh Binh hospitals in February and March 2022, respectively. This study followed a prospective pre- and postintervention design. We used validated instruments to assess the participants' satisfaction, knowledge, and skills before, immediately after, and 6 months after course delivery. The Fisher exact test and the Wilcoxon matched-pairs signed rank test were used to compare the percentages and mean scores at the pretest, posttest, and 6-month postcourse follow-up time points among course participants.

Results: A total of 80 health care staff members attended the 2-day PTC course and nearly 100% of the participants were satisfied with the course. At level 2 of the KM (knowledge), the scores on multiple-choice questions and the confidence matrix improved significantly from 60% to 77% and from 59% to 71%, respectively ($P < .001$), and these improvements were seen in both subgroups (nurses and doctors). The focus of level 3 was on practice, demonstrating a significant incremental change, with scenarios checklist points increasing from a mean of 5.9 (SD 1.9) to 9.0 (SD 0.9) and bedside clinical checklist points increasing from a mean of 5 (SD 1.5) to 8.3 (SD 0.8) (both $P < .001$). At the 6-month follow-up, the scores for multiple-choice questions, the confidence matrix, and scenarios checklist all remained unchanged, except for the multiple-choice question score in the nurse subgroup ($P = .005$).

Conclusions: The PTC course undertaken in 2 local hospitals in Vietnam was successful in demonstrating improvements at 3 levels of the KM for ED health care staff. The improvements in the confidence matrix and scenarios checklist were maintained for at least 6 months after the course. PTC courses should be effective in providing and sustaining improvement in knowledge and trauma care practice in other LMICs such as Vietnam.

Introduction

Health Care Burden of Road Trauma

Road traffic trauma is a leading cause of morbidity and mortality globally [1]. Road trauma is responsible for 1.3 million deaths and 20-50 million injuries annually with 90% of these occurring in low- and middle-income countries (LMICs) [2,3]. It is predicted that the prevalence of road trauma will increase to become the third leading cause of death by 2030 in LMICs [4]. While there are many contributing factors to the higher impact of road trauma in LMICs than in high-income countries, including infrastructure, vehicle design, underdevelopment of health care systems, and lack of trauma care education [5], the latter factor was highlighted among the 5 key World Health Organization targets for the first decade of action on road safety for LMICs from 2011 to 2020 [6,7]. If this target is achieved, it is estimated that one-third of annual global trauma deaths could be prevented [8,9].

As in other LMICs, road traffic trauma is a major public health problem in Vietnam [10]. In the last 15 years, approximately 10 people per 100,000 population have been killed in road accidents in Vietnam each year, with an equal number hospitalized [11,12]. Road traffic injury is the second most common cause of death for people in Vietnam in the age group of 5 - 14 years, representing the most vulnerable and dependent population, and is the most common cause of death and disability for those in the age group of 15 - 49 years, representing the most productive population [13]. The Vietnamese health care system is built on a “pine tree” model in which a trauma center has responsibility for various “satellite” hospitals and receives patients experiencing severe trauma. In a satellite or frontline hospital, the staff first encountering a trauma patient may be a surgeon, nurse, anesthetist, or general practitioner who may not be trained in a trauma subspecialty. Indeed, the trauma training system in Vietnam is not adapted to this circumstance [14]. There is therefore a need for a training system to solve this education gap.

There are several trauma training courses that have been delivered around the world, such as the Advanced Trauma Life Support (ATLS), Trauma Team Training, and Primary Trauma Care (PTC) courses. Several trauma courses are currently being used in LMICs effectively, resulting in increases in knowledge and at a lower reported cost than the gold-standard ATLS course [15]. Among these, the PTC course is designed and structured to fit within health care systems in LMICs such as Vietnam. In particular, the PTC course requires minimal resources and is therefore sustainable for these countries [16]. For this reason, since 2007, the PTC course has been run in many regional and provincial areas of Vietnam, including Binh Dinh (2007), Hanoi (2008), Ninh Binh (2008), and Ho Chi Minh City (2018) [17-19]. However, none of these Vietnamese courses has been evaluated with respect to the effect on the clinical practice of health care staff.

Education Frameworks

One of the methods commonly used to assess educational programs is the 4-level Kirkpatrick model (KM). This model was developed by Kirkpatrick in 1959 and has since been widely used to evaluate the effectiveness of continuing education in many fields, including medicine [15]. The KM evaluates the training outcomes of a course at 4 levels depending on the amount of time the evaluation is undertaken after the course. Level 1 evaluates trainees’ satisfaction toward the instructors and the training program, level 2 assesses trainees’ learning of professional knowledge or skills, level 3 measures the changes in trainees’ behavior or performance, and level 4 quantifies the improvement of the outcomes closely linked to the training program that will work effectively in the long term. This model has been considered a suitable assessment tool for educational programs as it has a simple process, measures a limited number of variables, and does not depend on individual variables [20].

Moreover, previous studies in education have identified that trainees’ knowledge of issues and possession of skills are required for this knowledge to transfer into behavioral change [21], and that positive attitudes and behaviors could lead an individual to be better motivated toward an issue [22]. Since trauma care is a common and vital practice of many health care staff working at the frontline of the Vietnamese health care system, the effectiveness of PTC training courses should be improved and consolidated through knowledge, attitude, and practice (KAP)-based education. As such, the KAP model can be an appropriate approach to help identify knowledge gaps, attitude barriers, and practice patterns that may facilitate understanding the knowledge and practice of health care professionals after attending a PTC training course [23].

Previous studies have used the KM and KAP model as theoretical frameworks to evaluate the effectiveness of training courses in the health care field [20,24]. In applying these models for this study, we aimed to: (1) measure the outcomes of the PTC course by asking the participants to clarify their reaction to the relevance and usefulness of the course (level 1 of the KM); (2) test the knowledge and level of confidence at the precourse, immediately postcourse, and 6-month postcourse time points (level 2 of the KM); and (3) observe changes in the practice of participants in scenarios and handling trauma patients in their daily work (level 3 of the KM) (Figure 1). Level-4 changes have not yet been assessed but are the subject of an ongoing investigation.

To gain a more comprehensive understanding on the effectiveness of the education of PTC training courses, this study was performed to assess the impact of the PTC course on health care staff by using a conceptual framework involving two theories of evaluation: the KAP model and the 4-level KM. The specific study objectives were to (1) investigate the impact of the PTC training course on the satisfaction, confidence, and change of knowledge and skills of participants in two hospitals in Vietnam; and (2) evaluate the retention of the participants’

knowledge and changes in skills 6 months after the PTC training course.

Figure 1. Theoretical framework of the study based on the KAP and Kirkpatrick models of evaluation. KAP: knowledge, attitude, and practice; PTC: Primary Trauma Care; L1: level 1; L2: level 2; L3: level 3; L4: level 4.

Methods

Setting

This study was carried out in the emergency departments (EDs) of 2 provincial hospitals in Vietnam, the Thanh Hoa and Ninh Binh hospitals. There are 78 beds in both EDs with 86 staff comprising 35 doctors and 51 nurses.

PTC Course

The 2-day PTC courses were delivered by local PTC instructors from Hanoi Medical University following the standard format

of the PTC Foundation [25]. The PTC course included lectures, skills workshops, and case scenarios to cover a range of topics and practical skills. The objective of the course was to train participants to approach trauma patients in a sequential manner without missing life-threatening symptoms and processes.

All health care staff at the 2 EDs were invited to participate in the course. To maintain an effective clinical workforce in the respective EDs, each site was divided into 2 classes that rotated and ran over 3 days. In Thanh Hoa Hospital, the courses ran from February 17 to February 20, 2021, whereas in Ninh Binh Hospital, the courses ran from March 3 to March 6, 2021. Each

class received the same training and assessment. All material is available on the PTC website [25].

Study Design

This study followed a pre- and postinterventional design. We used validated instruments to assess the participants' satisfaction and confidence prior to the course and immediately after training, as well as to compare their level of trauma knowledge and skills at the precourse, postcourse, and 6-month follow-up time points. We also stratified participants into doctor and nurse groups for further investigation. The trial has been registered in the Australian New Zealand Clinical Trial Registry (ACTRN 12621000371897) [26].

Outcome Measures

KM Level 1: Satisfaction

A self-completed questionnaire was developed to explore participants' reactions to the PTC course. The questionnaire contained 5 items regarding the relevance and usefulness of the course. Trainees indicated their agreement with the corresponding statements using a 5-point Likert scale, with 1 indicating "strongly disagree" and 5 indicating "strongly agree" (Multimedia Appendix 1).

KM Level 2: Knowledge

Twenty multiple-choice questions were used to evaluate the complete teaching content in the course, which have also been used in previous evaluations [16]. Most of the items assessed the trainees' knowledge domain in the knowledge and comprehension categories according to the Bloom taxonomy [27]. The multiple-choice questions focused on knowledge in trauma management, including the areas of head, thoracic, and abdominal trauma, requiring the trainees to remember key fundamental points from serial lectures in the course (Multimedia Appendix 2). The results were calculated as the percentage of correct answers. This multiple-choice question set was developed for the PTC program, translated into Vietnamese by local PTC instructors, and edited by experts and educators from the PTC Foundation.

A confidence matrix was also included with 8 questions assessing the level of confidence while dealing with various circumstances related to patients experiencing trauma. Each question was rated according to 5 levels of confidence, ranging from 1 (the lowest level of confidence) to 5 (the highest level of confidence). This result was also calculated as a percentage for analysis (Multimedia Appendix 3).

KM Level 3: Practice Skills

Scenario checklists, which included various clinical scenarios, were used to evaluate participants' practice skills in a simulation. The participants at the 2 hospitals were divided into small groups of 6 - 7 people. Each group included both doctors and nurses to replicate an emergency team on duty in the ED. The assessments were conducted using an Objective Structured Clinical Examination format [20,24] with 4 stations, each station lasting up to 10 minutes, with one observer who used a standardized checklist to rate the performance of the team. Each

scenario checklist comprised 10 key actions. If the examined group achieved this action, they were given 1 point; otherwise, they received 0 points. We chose 4 scenarios for the evaluation and rotated all groups within these 4 scenarios to ensure that the maximum amount of skills were evaluated (Multimedia Appendix 4).

For the bedside clinical checklist, we used an observed checklist with 10 vital points that had been stressed in the course. This checklist was used by experienced clinicians who were local PTC instructors. To minimize observation stress, all participants were informed about the presence of the examiners before and after the course. The examiners were allocated cases randomly in both the pre- and postcourse phases (Multimedia Appendix 5).

Statistical Analysis

We used Stata version 15.1 software for statistical analyses. The Fisher exact and Wilcoxon matched-pairs signed rank tests were used to compare percentages (multiple-choice questions and confidence matrix) and the mean scores (scenario and bedside clinical checklists) among the precourse, postcourse, and 6-month follow-up time points for the participants. A P value $<.05$ was considered statistically significant.

Ethical Considerations

The University of Tasmania Human Research Ethics Committee approved this study (reference number H0023982) [28]. All participants who volunteered to take part in the study (without compensation) were required to sign the consent form (Multimedia Appendix 6). All data were deidentified and stored online in a password-protected Google drive of the research group's account to ensure privacy and confidentiality.

Results

Participant Characteristics

Among the 86 health care staff in the EDs, 80 participated in the course; the 6 individuals who could not participate in the course were excluded owing to testing positive for COVID-19 at the time of course delivery. All participants completed the pre- and posttest assessments and the scenarios checklist. Only 57 (71%) of the 80 participants completed the joint evaluation of knowledge and scenarios checklist at the 6-month follow-up. The cohort consisted of 34 doctors (mean age 28.0, SD 2.5 years) and 46 nurses (mean age 32.0, SD 6.4 years). Nurses had more general medical work experience than doctors (mean 6.3, SD 5.6 years vs 2.4, SD 1.7 years). Male staff accounted for 68% of the doctors and 65% of the nurses.

KM Level 1: Survey Responses

All participants responded to the survey, with 78 of the 80 participants (98%) indicating satisfaction with the course. Likewise, an equal number of respondents stated that "the course enhanced their knowledge" and 79 of the 80 participants (99%) stated that they would "suggest the course to others." Furthermore, 77 of the 80 participants (96%) agreed that "the course was relevant to ED staff" (Table 1).

Table . Level 1 of the Kirkpatrick model: participant reactions to the Primary Trauma Care (PTC) course (N=80).

Question	Strongly disagree (1), n (%)	Somewhat disagree (2), n (%)	Neither agree or disagree (3), n (%)	Somewhat agree (4), n (%)	Strongly agree (5), n (%)
I was satisfied with the PTC course overall	1 (1)	1 (1)	0 (0)	8 (10)	70 (88)
This course enhanced my knowledge of the subject matter	1 (1)	0 (0)	1 (1)	6 (8)	72 (90)
The course was relevant to what I might be expected to do (to prevent, prepare for/respond to a trauma) in an emergency department ^a	1 (1)	0(0)	1 (1)	9 (11)	68 (86)
This course provided content that is relevant to my daily job	1 (1)	0 (0)	2 (3)	16 (20)	61 (76)
I would recommend this course to others	1 (1)	0 (0)	0 (0)	4 (5)	75 (94)

^aOne respondent is missing for this question (N=79).

KM Level 2: Knowledge and Confidence Matrix Assessments

There was a significant improvement in correct multiple-choice question responses between the pre- and postcourse assessments in both the doctor and nurse groups, as these scores increased from 67% and 59% to 82% and 74%, respectively (both $P < .001$). Comparing the immediate postcourse assessment to the 6-month follow-up, there was a significant reduction in correct

multiple-choice question responses among nurses (74% vs 67%; $P = .005$) but not among doctors (82% vs 77%; $P = .31$). Compared to the precourse scores, the confidence matrix assessment improved significantly immediately following the course in both the doctors and nurses, from 60% to 76% ($P < .001$) and from 58% to 68% ($P = .02$), respectively. Both figures declined after 6 months, although these changes were not statistically significant for doctors ($P = .07$) or nurses ($P = .51$) (Figure 2).

Figure 2. Level-2 assessment of the Kirkpatrick model. The left y-axis shows the percentage of correct multiple-choice questions (MCQs) and the right y-axis shows the percentage of correct responses to the confidence matrix (CM) for the entire cohort and in the nurse and doctor subgroups over time.

KM Level 3: Practice Skill Evaluations

Scenarios Checklist

In the scenarios section, the average postcourse score in all groups significantly improved ($P < .001$). Six months later, the

average scenarios checklist score did not deteriorate ($P = .99$) and this pattern was observed at both hospitals, with $P = .99$ and $P = .81$ for Thanh Hoa and Ninh Binh, respectively (Table 2).

Table . Scenarios checklist results at the 2 hospitals prior to, immediately following, and 6 months after the course.

Site and assessment	Scenario checklist score, mean (SD)
All sites	
Precourse	5.9 (1.4)
Post course	9.0 (0.9)
6-month follow-up	8.5 (0.8)
Thanh Hoa Hospital	
Precourse	6.1 (1.1)
Post course	9.1 (0.9)
6-month follow-up	8.4 (0.7)
Ninh Binh Hospital	
Precourse	5.8 (1.6)
Post course	8.9 (0.8)
6-month follow-up	8.7 (0.8)

Bedside Clinical Checklist

There were 157 possible observed bedside clinical cases precourse and 161 such cases post course at both sites. The bedside clinical scores equally achieved a mean of 5 (SD 1.3) for both sites precourse and increased significantly to 8.4 (SD 0.8) at Ninh Binh and to 8.6 (SD 0.9) at Thanh Hoa, resulting in an overall significant increase of 8.5 (SD 0.8) ($P < .001$) (Table 3).

The responses to all questions showed a significant improvement, with the most significant effects seen for the

questions “Is a primary survey/secondary survey undertaken?”, “Was the cervical spine stabilized (manual/collar)?”, and “Was the patient fully exposed and assessed for other injuries?” with changes in percentage post course of 99%, 92%, and 71%, respectively. By contrast, the questions “Was a log roll performed to evaluate the full length of the spine?” and “After any intervention (eg, insertion of an endotracheal tube, treatment of pneumothorax, rapid infusion of fluids) was the ABC (airway, breathing, circulation) reassessed?” showed the lowest rate of correct responses in both pre- and postcourse observed cases, with a change from 1% to 17% and from 10% to 56%, respectively (Table 4).

Table . Bedside clinical checklist results at the 2 hospitals prior to and immediately following the course.

Site and assessment	Bedside clinical checklist score, mean (SD)
All sites	
Precourse	5 (1.3)
Post course	8.5 (0.8)
Ninh Binh Hospital	
Precourse	5 (1.3)
Post course	8.4 (0.8)
Thanh Hoa Hospital	
Precourse	5 (1.3)
Post course	8.6 (0.9)

Table . Correct percentages of pre- versus postcourse clinical checklist scores of all observed cases.

Question	Precourse (n=157), n (%)	Post course (n=161), n (%)	Change, %	P value
Is a primary survey/secondary survey undertaken?	2 (1.3)	161 (100)	98.7	<.001
Was the cervical spine stabilized (manual/collar)?	11 (7)	160 (99.4)	92.4	<.001
Was oxygen administered/a pulse oximeter probe attached?	111 (70.7)	161 (100)	29.3	<.001
Was the airway assessed? (breathing or not, chest moving or not, obstructed sounds or not)?	131 (83.4)	161 (100)	16.6	<.001
Was the breathing clinically assessed by looking (breath count), feeling (palpation of trachea, percussion of chest), and listening (auscultation)?	123 (78.3)	161 (100)	21.7	<.001
Was the circulation assessed by measurement of heart rate and blood pressure? Was there an assessment of the quality of the pulse, capillary return, and temperature of the peripheries?	140 (89.2)	161 (100)	10.8	<.001
Was blood taken for cross match and hemoglobin/hematocrit analysis? Was an intravenous infusion started?	144 (91.7)	161 (100)	8.3	<.001
Was an AVPU/GCS ^a neurological assessment of disability done?	89 (56.7)	160 (99.4)	42.7	<.001
Was the patient fully exposed and assessed for other injuries?	3 (1.9)	117 (72.7)	70.8	<.001
Was a log roll performed to evaluate the full length of the spine?	2 (1.3)	30 (18.6)	17.3	<.001
After any intervention (eg, insertion of an endotracheal tube, treatment of pneumothorax, rapid infusion of fluids) was the ABC ^b reassessed?	15 (9.6)	90 (55.9)	46.3	<.001

^aAVPU/GCS: Alert, Voice, Pain, Unresponsive/Glasgow Coma Scale.

^bABC: airway, breathing, circulation.

Discussion

Principal Findings

This study demonstrated that the PTC course led to improvements at all 3 levels of the KM. This improvement was maintained for at least 6 months post intervention, except for knowledge in the nurse group. These findings suggest that the knowledge and skills acquired in the PTC course are likely to be translated into clinical practice.

Most of the doctors in the ED who joined the course were junior doctors. This is because, in the Vietnamese medical system, ED work is poorly paid and nonspecialized. In addition, the majority of the nurses and doctors were male. These trends are consistently found in ED staff across the Vietnamese medical system, with most of these staff moving out of the ED into a recognized specialty within a few years [29]. Like many LMICs, ED staffing in the Vietnamese medical system is built on the Franco-German model where staff are not trained as a specialty [30]. Therefore, staff turnover requires frequent redelivery of

the PTC course. For this reason, a trauma course such as the PTC course is more suitable for this country. A male predominance among health care staff has also been reported in PTC research of Alwawi (64%), Ologunde (66%), and Nogaro (77%) [31-33]. However, this predominance was not explained in these papers.

Impact of PTC on Level 1 of the KM: Participants' Reactions to the Course

Nearly all participants were satisfied with the course. This is in line with the study of Tolppa et al [34], who found that the majority (56/59) of participants agreed or strongly agreed that trauma services are important and 57/59 of participants would recommend the PTC course to their colleagues. In addition, Jawaid et al [35] organized a PTC course with 20 participants, which received a rating of 100% satisfaction, and 100% of the participants also agreed or strongly agreed that their knowledge and skills were enhanced after the course. The authors of these studies argued that having extremely high postcourse ratings was attributed to the course being well-structured/organized as well as having a local champion, along with two other reasons. First, unlike other medical training programs, this course is free of charge. Second, the course is organized locally; therefore, participants were not required to move to other locations, which avoided travel-related logistic issues. Our results are in line with these previous findings and suggest that future courses in limited-resource settings, if organized, should be held locally.

Impact of the PTC Course on Level 2 of the KM (Knowledge and Confidence Matrix Retention): A Refresh Course on Demand

Our study showed that multiple-choice question scores improved significantly after the course (60% vs 77%; $P < .001$). This finding is similar to those of other studies assessing PTC courses. Amiri et al [36] reported that multiple-choice question scores improved from 63% to 89% for 64 participants comprising physicians and surgeons. Other studies demonstrated significant increases in scores after the course, ranging from 12% to 32% [31,32,35,37-40]. There are 2 multiple-choice questionnaires available in PTC resources (20 and 30 multiple-choice question forms) [25], with comparable results for either form. This reflects the high level of reliability of PTC multiple-choice question tools.

Furthermore, the confidence matrix scores in our study also improved significantly by 17%, which matches the degree of improvement of 20% - 23% reported in previous studies [32,37,39].

However, although multiple-choice question and confidence matrix scores of the doctors and nurses remained unchanged after 6 months, the multiple-choice question scores of nurses declined significantly (74% vs 67%, $P = .005$). This may be explained by the fact that nurses, unlike doctors, are less likely to apply the multiple-choice questions in their routine clinical activities so that there is no reinforcement of these concepts in the workplace after the PTC course. Tolppa et al [34] found that the knowledge gained from a PTC course can be maintained for up to 2 years; this difference from our findings may be

related to the fact that Tolppa et al [34] did not report the findings for different subgroups.

Impact of PTC on Level 3 of the KM: Translation From Acquired Learning to Practice

In simulation situations, the simulation check scores improved significantly from 5.9/10 to 9/10 ($P < .001$). Our result matches that of Jawaid et al [35] on assessing the effectiveness of a PTC course with 20 participants, demonstrating an increase in the median simulation check score from 3.5/20 to 9.5/20 ($P < .001$).

Furthermore, improvement was also seen in clinical application after the course. The bedside clinical checklist score increased significantly from 5/10 to 8.5/10 ($P < .001$). This change demonstrates that the knowledge and skills acquired in the course are effectively converted into clinical practice. In contrast, in a study conducted in El Salvador, Cioè-Peña et al [41] found that despite a significant improvement in the median correct response rate of multiple-choice questions from 74% to 86% after the course, there was no significant change in clinical practice in 194 observed cases for both assessment periods ($P = .94$). This difference could be explained by this study's different setting along with the different assessment tools and criteria used [41]. Additionally, in the observed cases, we found a significant improvement of all clinical checklist scores ($P < .001$). In particular, the correct response rate for the question "Is a primary survey/secondary survey undertaken?" increased from 1% in the precourse assessment to 100% in the postcourse assessment. This demonstrates that the primary/secondary survey skill, which is a key point of the PTC and other trauma courses (eg, ATLS), was relatively unknown prior to the PTC course, but was greatly improved post course. By contrast, the questions "Was a log roll performed to evaluate the full length of the spine?" and "After any intervention (eg, insertion of an endotracheal tube, treatment of pneumothorax, rapid infusion of fluids) was the ABC reassessed?" demonstrated the least improvement (1% vs 17% and 10% vs 56%, respectively). In the scenarios checklist evaluation, both participant groups demonstrated an understanding of these fundamental aspects. However, in clinical practice, ED staff might still ignore these concepts due to the excess clinical workload. It is recommended that local hospitals adequately support their ED staff to ensure they can provide care to the best of their knowledge and abilities.

Unlike knowledge assessment, it is a long-standing challenge to evaluate clinical activities due to various barriers and obstacles, including time, high cost, availability of skilled clinical supervisors, and other bias/confounding variables such as evaluation and selection bias [42,43]. As we were cognizant of these difficulties, our study was designed to minimize this bias and the potential impacts of confounding factors. However, because the assessment was direct and intermittent, the presence of examiners may have led to a Hawthorne effect, which causes the alteration of behavior by the presence of examinees due to the awareness of being observed [44,45]. It is worth noting that a previous PTC course had been organized in Ninh Binh Hospital in 2008 [17]. Perhaps some residual education and clinical practice effects may have persisted at the time this study was carried out. However, none of the staff who attended the PTC course had been working at the ED prior to when the 2008

course was conducted; thus, a residual educative effect is likely to be negligible or nonexistent.

Application of the KM and KAP Model in Training

From an educational aspect, among the many factors that affect training program outcomes, the knowledge, attitude, and practice of the trainees are critical components, as they will influence the process of behavioral change, which is the most desired outcome of these courses. In this study, the knowledge, practice, and attitude of health care professionals after the PTC training course were evaluated and showed positive outcomes. When trainees have sufficient and technical knowledge of trauma care, they have positive attitudes and good clinical practice when dealing with trauma patients in the ED. This result is similar to the work of other authors who also applied the KAP approach in their course evaluation [46,47]

Using the KM to evaluate the effectiveness of education/training intervention is not a novel approach [48-50] and it is considered to be more appropriate than other models [51,52]. This study's results confirmed the effectiveness of PTC training courses at the first 3 levels of the KM, similar to the findings of previous studies [16,34,35]. However, the simple 4-level KM does not help to explain the impact of individual or contextual factors in the evaluation. In the situation of PTC training, contextual factors such as the hospital's or ED unit's goals, values, and work environment would impact the application of trained skills on the job of trainees after the courses. In our study, the overloaded situation of the provincial hospitals may be assumed to prevent health care staff from performing the learned procedure to the full capacity when handling trauma patients. In addition, the nature of the tasks of nurses in an ED team may affect their long-term knowledge retention, which could be an expression of the impact of contextual factors on the effectiveness of the training courses. These assumptions warrant deeper investigation in future study, which should consider

several organizational factors such as staff turnover, relationships among professionals, and the gender distribution of ED staff. Moreover, in our study, although nearly 100% of the participants were satisfied with the course, which indicates the effectiveness of PTC training courses at the first level of the KM, we do not have evidence to link this positive reaction of the participants to their knowledge transfer and absolute positive postcourse results. A qualitative approach such as in-depth interviews with participants would be useful in detecting the hidden factors that may influence the effectiveness of both the process and outcomes of training, including the organizational aspect of the course, teaching methods, or adequacy of material resources in the courses.

Limitations

This study has some limitations. To minimize evaluation bias, we informed all examinees of the assessment process. Level 4 of KM is considered a primary endpoint of medical intervention; but, this was not assessed in our study. This will be reported in the subsequent papers by the corresponding author. The study had only a 6 months follow-up and thus lacked a longer evaluation and did not evaluate directly how the actual trauma system changed post intervention. The trauma system includes components such as leadership, professional resources, and financial budget, etc, and therefore may require multiple efforts to be improved [53,54]. Future studies which include these components are required to clarify these issues.

Conclusions

The PTC course undertaken in 2 provincial hospitals of Vietnam was successful in improving 3 levels of the KM for ED health care staff. This improvement was maintained for at least 6 months after the course. The PTC courses are effective in providing sustained improvement over 3 levels of the KM for LMICs such as Vietnam.

Acknowledgments

This work was funded by the Elphinstone Group and Broadreach Holdings Pty Ltd via an unconditional grant. BTN holds a University of Tasmania scholarship. The Primary Trauma Care course has been completed and fully evaluated with the great assistance from the lectures team of the Anaesthesia Department of Hanoi Medical University, including the Thanh Hoa Hospital leaders Dr Van Sy Le, Dr Van Cuong Le, Dr Tien Tung Lam, Thi Nga Linh Luong, and the Ninh Binh Hospital leaders Dr Chinh Chuyen Le, Dr Tu Vu Ngoc Dinh, Dr Thanh Nam Phan, Sy Thuoc Phan, and Thi Hoa Do. The courses also received support from Dr Huu Hoang Nguyen, anesthetist, Vietnamese French Hospital, Hanoi, Vietnam.

Authors' Contributions

BTN, VATN, and MN conceived the idea for the study. BTN, TCQ, and HTN collected the data. BTN, VATN, and VT drafted the manuscript. BTN and CLB were responsible for the statistical analyses. AP, CLB, TCQ, MS, HP, and HTN revised the manuscript. MN contributed to the critical revision of the manuscript for important intellectual content and approved the final version. All authors have read and approved the final manuscript.

Abstract

Background: Effective peritoneal dialysis (PD) training is essential for performing dialysis at home and reducing the risk of peritonitis and other PD-related infections. Virtual reality (VR) is an innovative learning tool that is able to combine theoretical information, interactivity, and behavioral instructions while offering a playful learning environment. To improve patient training for PD, Fresenius Medical Care launched the *stay•safe* MyTraining VR, a novel educational program based on the use of a VR headset and a handheld controller.

Objective: This qualitative assessment aims to investigate opinions toward the new tool among the health care professionals (HCPs) who were responsible for implementing the VR application.

Methods: We recruited nursing staff and nephrologists who have gained practical experience with the *stay•safe* MyTraining VR within pilot dialysis centers. Predetermined open-ended questions were administered during individual and group video interviews.

Results: We interviewed 7 HCPs who have 2 to 20 years of experience in PD training. The number of patients trained with the *stay•safe* MyTraining VR ranged from 2 to 5 for each professional. The *stay•safe* MyTraining VR was well accepted and perceived as a valuable supplementary tool for PD training. From the respondents' perspective, the technology improved patients' learning experience by facilitating the internalization of both medical information and procedural skills. HCPs highlighted that the opportunity offered by VR to reiterate training activities in a positive and safe learning environment, according to each patient's needs, can facilitate error correction and implement a standardized training curriculum. However, VR had limited use in the final phase of the patient PD training program, where learners need to get familiar with the handling of the materials. Moreover, the traditional PD training was still considered essential to manage the emotional and motivational aspects and address any patient-specific application-oriented questions. In addition to its use within PD training, VR was perceived as a useful tool to support the decision-making process of patients and train other HCPs. Moreover, VR introduction was associated with increased efficiency and productivity of HCPs because it enabled them to perform other activities while the patient was practicing with the device. As for patients' acceptance of the new tool, interviewees reported positive feedback, including that of older adults. Limited use with patients experiencing dementia or severe visual impairment or lacking sensomotoric competence was mentioned.

Conclusions: The *stay•safe* MyTraining VR is suggested to improve training efficiency and efficacy and thus could have a positive impact in the PD training scenario. Our study offers a process proposal that can serve as a guide to the implementation of a VR-based PD training program within other dialysis centers. Dedicated research is needed to assess the operational benefits and the consequences on patient management.

KEYWORDS

peritoneal dialysis; virtual reality; patient education; patient training; chronic kidney disease; nursing; qualitative assessment

Introduction

Background

Compared with in-center dialysis, peritoneal dialysis (PD) confers significant benefits to patients with chronic kidney disease (CKD), including better preservation of residual renal function and higher treatment flexibility [1,2]. As a result, kidney health organizations recommend facilitating and increasing patients' access to home dialysis [3]. The SARS-CoV-2 pandemic emphasized the importance of expanding PD use [4]. However, only 11% of patients on dialysis are currently treated with PD [5]. Poor patient education and inadequate training were identified as significant factors contributing to the global underuse of PD [6,7]. In line with this, patients who received structured training more likely chose home dialysis over in-center treatment [8]. In addition, in a telemedicine patient education study, patients with CKD stages 4 and 5 receiving telemedicine predialysis education had increased health literacy and increased home modality choice [9].

Besides learning theoretical concepts, patients with CKD need to acquire physical skills to perform the PD procedure by themselves. Therefore, PD training programs mainly involve individual sessions between patients and nephrology health care professionals (HCPs) [10,11], with most of them represented by nurses [11]. According to an international survey, a successful PD training program typically requires an average training time of 30 hours or 6 days per patient and is predominantly conducted in a one-to-one setting with both the patient and the nurse [11,12]. Increasing evidence demonstrated that efficient patient training can also lead to improved patient outcomes [13-15]. In fact, longer training time was associated with lower PD-related peritonitis rates [13,15], while frequent patient retraining reduced the risk of exit-site infections [14]. Consistently, the International Society for Peritoneal Dialysis guidelines recommended PD training standardization and optimization to reduce peritonitis rates [16]. On the basis of these observations, the International Home Dialysis Roundtable prompted the adoption of new strategies to improve education programs and boost patient engagement in training activities [3]. Of interest, the use of visual or audio aids and computer-assisted instructions was proposed to enhance patient learning [17].

To meet these requirements, Fresenius Medical Care (Bad Homburg, Germany) launched a novel training program for continuous ambulatory PD (CAPD) based on the use of virtual reality (VR), referred to as *stay•safe* MyTraining VR [18]. VR is an innovative technology with a huge potential in medical training [19-25] and patient education [26-32]. VR uses head-mounted displays to create an immersive, computer-generated, 3D, and interactive environment. *Stay•safe* MyTraining VR equipment includes a VR headset and a handheld controller designed to support the training of patients

on hygiene procedures, preparation and posttreatment steps, and bag exchange and operation. The novel digital training tool was introduced to support the classical PD training at 3 dialysis centers in Germany. As for the traditional PD training, nurses and nephrologists continue to be responsible for patient education when being supported by the *stay•safe* MyTraining VR.

This Study

This qualitative research investigated, for the first time, HCPs' perspectives, preferences, and attitudes toward the implementation of the *stay•safe* MyTraining VR within CAPD training. We sought to describe how and when the tool was integrated in the traditional training framework and to evaluate whether VR introduction had an impact on patient learning. Moreover, HCPs' opinions about the potential benefits and limitations related to VR were explored. Professionals' and patients' acceptance of the new technology was likewise investigated.

Methods

Study Design and Study Sample

This study is an integrative qualitative research involving convergent, narrative, problem-centered, and discursive interviewing designed to investigate the following aspects: (1) integration of the new tool into the classical PD training framework and professionals' perspectives on its usability, (2) target patient groups who can benefit from the new technology, (3) benefits and advantages, (4) limitations and weaknesses, (5) HCPs' and patients' acceptance of the new technology, and (6) additional applications. The collected information was then used to derive a process through which VR training can be implemented in the conventional training curriculum. All nursing staff and nephrologists in the 3 NephroCare dialysis centers where this technology was piloted, who already gained practical experience with the *stay•safe* MyTraining VR, were invited by mail to the respective medical administration for voluntary participation. Overall, 6 nurses and 1 nephrologist agreed and participated in this study.

Ethical Considerations

All participants read and signed the informed consent document, including a privacy policy explaining data collection, data use, and data storage, before participating in the study. To ensure confidentiality, all participant data were anonymized before analysis. No compensation was provided to the participants for their involvement in this study. Participants were free to withdraw from the study at any time and were informed so, and participation was carried out on a voluntary basis.

This study did not undergo formal ethics review. This is justified based on the anonymity of responses and because no risk was expected to survey participants and basic ethical principles (individual autonomy, self-determination, avoidance of harm,

care, and justice) were not violated, as mentioned by the ethics commission of Bavarian universities (Gemeinsamen Ethikkommission der Hochschulen Bayerns [33]), where it is outlined that no ethics commission review is needed when no risk of damage is to be expected for participants and if basic ethical principles are not violated. As an example for such an exemption, a questioning of experts is mentioned, as this does not cause any particular risk or burden beyond what is witnessed in everyday life, as in this study.

Data Collection

To maximize information gathering, the interviews included open-ended questions and were conducted digitally as individual and group video interviews.

More specifically, the interviews included the following phases (Multimedia Appendix 1): (1) introduction and transparency of objectives, approach, and methodology; (2) introductory question for topic identification and prioritization by the interviewee; (3) narrative phase with nondirective (only encouraging) interventions by the interviewer; (4) discursive phase, in which the interviewee is questioned about their views, opinions, and evaluations and is asked to analyze and reflect in greater depth; and (5) open guiding questions according to the interview guide.

During the discursive phase, initial hypotheses were confirmed, concretized, adjusted, or rejected in an iterative process through repeated testing and feedback. To this aim, different forms of intervention were used: request for justification, explication of gaps and contradictions, validation of conclusions, target-actual comparison, and hypothesis-guided and solution-oriented questions.

All the interviews were conducted by SP and TR, took approximately 60 to 90 minutes each, and were recorded in writing.

Definitions

VR “effectiveness” was investigated considering the following aspects: (1) patient satisfaction (question 1: what is the feedback from patients? question 2: what is the range here?), (2) patient learning success (question 1: how do you rate the learning success in comparison to classic training? question 2: where is it greater, where less?), and (3) risks related to the use of the VR technology in the PD educational setting (question 1: what risks do you see in a full transition to VR?)

By contrast, “efficiency” involved the evaluation of (1) time committed by HCPs to present the technology to patients

(question 1: how does your time commitment compare to traditional training?), (2) ratio of effort to benefit (question 1: is the cost-benefit ratio appropriate?), and (3) patient throughput (question 1: can you care for more patients with the new method?)

Qualitative and Statistical Analyses

A category system (Multimedia Appendix 1) for the core statements was inductively formed based on the material so that frequency distributions of topics or core statements and the associated evaluation were possible (descriptive statistics). The results were compressed, structured, and interpreted by means of a qualitative content analysis.

We computed the absolute value and relative frequency for categorical variables.

Results

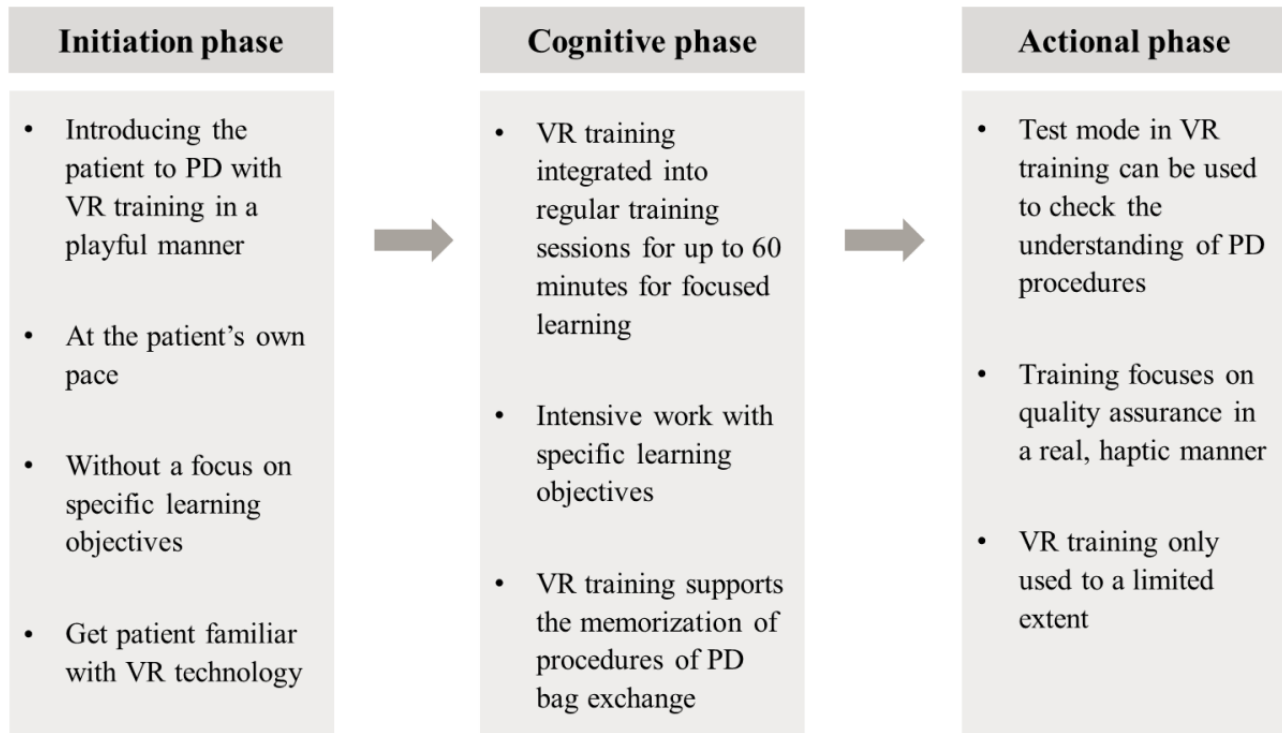

HCPs' Characteristics

A total of 7 HCPs were interviewed, of whom 5 (71%) were nurses and 2 (29%) were nephrologists. All the respondents had >10 years of work experience with patients with CKD. HCPs had 2 to 20 years of experience in PD training, with an average of 1.5 months of experience with the *stay•safe* MyTraining VR. The number of patients trained using the VR technology ranged from 2 to 5 for each professional.

HCPs' Use of the VR Technology Within the PD Training Program

HCPs believed that the VR technology was a valuable complementary tool to the traditional PD training program. On the basis of the collected statements, the classical PD training takes approximately 2 weeks and comprises 3 different phases (Figure 1). It typically begins by providing patients with essential information needed to get a basic understanding about how PD works and how it will impact their lifestyle and habits. This process imposes a significant emotional overload on patients (motivational phase). Next, patients are instructed with all the theoretical concepts needed to successfully perform home dialysis (cognitive phase). Finally, once basic knowledge is acquired, patients start practicing the procedures using the dedicated materials and consumables. In this phase, HCPs assess patients' understanding, detect eventual risks or mistakes in performing the different tasks, and provide instructions to successfully manage any critical events (actional phase).

Figure 1. Use of the Stay•safe MyTraining virtual reality (VR) within the classical workflow of patient education for home dialysis. According to the interviewed health care professionals (HCPs), peritoneal dialysis (PD) training involves three consecutive phases: (1) motivational phase, where patients are instructed with the basic information about PD without excessive pressure due to initial emotional load; (2) cognitive phase, where patients acquire all the theoretical concepts as well as the procedures to perform home dialysis alone; and (3) actional phase, where patients practice using the various materials and consumables and HCPs check whether the different learning objectives are effectively achieved. HCPs reported a successful integration of the novel VR tool into the routine activities during the motivational and cognitive phases. Notably, the VR training provided substantial advantages and benefits, allowing the improvement of patients' learning experience. By contrast, the use of the VR tool was limited in the actional phase because the acquisition of the practical skills required a real, haptic experience with the various materials and aids.

According to the interviewees, the novel approach was easily integrated into these routine training activities. Timings and modalities of VR administration were selected by each professional based on individual patient characteristics, receptivity, and interests. More specifically, our analysis indicated that the respondents used the VR tool with different aims depending on the particular training phase. For instance, after catheter insertion, VR was frequently offered to help patients approach PD in a playful manner, without immediately focusing on specific learning objectives:

I think the tool is especially good for providing systematic information and orientation to strengthen compliance to treatment.

The VR tool was particularly helpful during the cognitive phase. Indeed, the use of VR enabled HCPs to more effectively explain the relevant instructions and to make the procedures clearer, facilitating patients' internalization of both cognitive and procedural skills. Hence, most of the interviewees thought that the VR technology significantly improved patient learning experience by enabling patients to anchor learning success, process routine, procedural safety, and efficiency in home dialysis. HCPs believed that at this training stage, the VR-based approach could replace parts of the classical program:

VR is a focused learning medium that can be used when the patient has established orientation and acceptance [for the therapy]

It's probably not only good for decision making, but maybe also for learning the basic home dialysis process in more depth.

VR can serve as a support, it facilitates learning...But with VR, we have a different learning level. As a patient, you have to work it out for yourself. The training serves to deepen the knowledge and sets a different focus...With the VR glasses you can internalize the sequence, that is what it is good for, that is what this technology supports.

By contrast, HCPs reported limited use of the VR technology during the actional phase, when patients need to perform tactile dialysis-related tasks using all the equipment or consumables in sterile conditions. In fact, in the view of the interviewees, the VR technology could not replace classical training during this final phase because safe handling requires real experience with the various materials and aids. In addition, HCPs believe that error prevention and management as well as "quality control" need to be achieved through classical one-to-one sessions:

VR training does not replace classical training. In any case, the patient has to learn well the handling during bag change even without VR training. VR training is a supplement.

The patient should first see the practical procedures such as turning on the exercise material first. Only then can VR be used. However, the handling still has to be experienced haptically.

After the virtual trial, he then has to perform it independently in real life under observation.

Definitive coverage with VR training is not possible. However, it can be a large component. But you also need a haptic test in real life.

Target Patient Groups for VR Training According to HCPs

In the interviewees' opinions, the VR technology was suitable for most patients, including older adults. Patients' basic motivation and willingness to engage in the VR technology were indicated as essential prerequisites for the success of VR-based training:

There are no clear patient groups that you can include or exclude...Mental flexibility is crucial.

The use of VR technology is not age-dependent. The interest depends on the personal attitude.

PD may also be used in patients with limited capabilities in some cases. This was also addressed by the respondents in the study, but overall, the use of VR training was not considered suitable for patients with dementia. Limited use with patients experiencing severe visual impairment or lacking sensomotoric competence was also mentioned:

VR training is basically possible for almost all patients, but the key is how the patient receives it. Only in patients with dementia VR training is not applicable.

The glasses are not suitable for participants with severe visual impairment because they cannot see and recognize sufficiently. A younger colleague with impaired vision was also unable to see sufficiently in the glasses here.

Benefits and Advantages of VR Training

VR training was perceived as a tool able to improve cognitive learning effects and make the training process more efficient in terms of personnel and material resources. The advantages and strengths of the technology pointed out by HCPs are listed in [Table 1](#).

First of all, according to responders, VR introduction into PD training facilitated patient education and improved learning experience. First, VR training allowed patients' immersion into a focused learning environment and provided an efficient shielding from external stimuli (point 1, [Table 1](#)). This maximized patients' engagement in the different educational activities. Second, VR offered learners the opportunity to repeat training activities according to their individual needs (point 2, [Table 1](#)). This enabled patients to correct errors and learn a standardized curriculum in a safe learning environment. Training session repetition allowed learners to get familiar with the use of dialysis equipment and supplies, boosting their confidence in performing the specific tasks. Third, HCPs noted that by providing multiple learning stimuli, VR-based training improved the efficiency of knowledge transmission (point 3, [Table 1](#)). In addition, the creation of a playful learning environment contributed to enhancing patients' engagement and, consequently, to improving their learning experience while avoiding overwhelming them with too much information (point 4, [Table 1](#)).

Besides facilitating patients' learning process, the use of technology conferred different benefits to HCPs (point 2, [Table 1](#)). In fact, VR helped professionals explain the operating principles of PD, allowing them to convey the information in a simplified and intuitive manner (point 5, [Table 1](#)). Moreover, because HCPs were able to perform different activities (point 7, [Table 1](#)) while the patient was practicing with the devices, VR was perceived as a significant tool to increase their productivity (point 6, [Table 1](#)). Nurses also reported that VR-based training enabled an individual operator to care for more patients at the same time due to higher training efficiency (point 7, [Table 1](#)). In the HCPs' view, another relevant advantage provided by the VR-based training was the opportunity to standardize the educational program, following the systematic content of the VR software (point 10, [Table 1](#)).

Finally, as the virtual experience does not require the use of additional PD supplies, the costs of training can be significantly reduced, as the number of dialysis fluid bags needed for training can be reduced (point 11, [Table 1](#)).

Table 1. Benefits and advantages of virtual reality (VR)-based training according to the interviewed health care professionals (HCPs).

Benefits and advantages	Representative quotes
For patients	
1. Focused learning environment	<ul style="list-style-type: none"> “In VR, the patient has no distractions, but is completely concentrated in the system. Those who like to move around in this system and are focused in it learn quickly.” “In conventional training, patients are very distracted by stimuli from their immediate environment and their minds are then elsewhere. In VR training, for example, you do not see the nurse who suddenly comes into the room and disturbs you.” “VR can serve as a support, it facilitates learning...But with VR, we have a different learning level. As a patient, you have to work it out for yourself. The training serves to deepen the knowledge and sets a different focus...With the VR glasses you can internalize the sequence, that's what it's good for, that's what this technology supports.”
2. Unlimited repetition of the procedures	<ul style="list-style-type: none"> “The patient then repeats it as often as he wants and until it works.” “It is good for the mindless rehearsal of the procedures. The patient then repeats it as often as he wants and until it works. This is a learning effect.” “More security is created because the process is replayed over and over again.”
3. Multiple learning stimuli	<ul style="list-style-type: none"> “With VR, we have a different learning level. As a patient, you have to work it out for yourself. The training serves to deepen the knowledge and sets a different focus.” “The VR training can connect well to the therapy concept in the center to also bring variety into the training.”
4. Playful learning environment	<ul style="list-style-type: none"> “VR mainly serves to support the theory in a playful way, not doctrinal, but a different approach, not like an exam.” “The VR is playful, not schoolmasterly. It's a different approach with less pressure.” “VR takes the pressure out of the learning process.”
For HCPs	
5. Simplified knowledge transfer	<ul style="list-style-type: none"> “In classic training, I do a lot of words and that may then lead to mental shutdown. VR shows that in a much shorter time.” “The training replaces what I do verbally otherwise. Important aspects like turning off air conditioning, pets out of the room, etc. they see in the movie.”
6. Enhanced HCPs' efficiency or productivity	<ul style="list-style-type: none"> “The training replaces what I do verbally otherwise. Important aspects like turning off air conditioning, pets out of the room, etc. they see in the movie. In classic training, I do a lot of words and that may then lead to shutdown. VR shows that in a much shorter time.” “The patient had good observation skills...Therefore, I was only fully present the first time. The second time, I just put on my glasses and was gone for 15-30 minutes. I went to another patient and she stayed alone in the training room.”
7. More effective time management	<ul style="list-style-type: none"> “We can perform the following activities in parallel, for example, in the same room in the presence of the patient: Prepare laboratory for the next patient, evaluate laboratory tests, calculate peritoneal equilibrium test (PĀT), write prescription, arrange appointments, sort and file findings, etc...” “I can imagine that you can still do something in parallel in the same room at the desk (e.g., look at lab values, do documentation, prepare classic PD, e.g., tear open bags).” “The patient had good observation skills...Therefore, I was only fully present the first time. The second time, I just put on my glasses and was gone for 15-30 minutes. I went to another patient and she stayed alone in the training room.” “I can do other things in parallel, there I have a discretion. There would be further efficiency if several patients are cared for in parallel in one room with VR goggles. I would try this.” “Many parallel/routine activities in the room are possible, which are not possible in classical training.”
8. Induction and motivation of HCPs	<ul style="list-style-type: none"> “New young non-specialized nursing staff, can get orientation via the VR. One can also see in the VR glasses a motivational approach for employees who do not yet have a connection to dialysis or home dialysis and are in training or further education. They can then realize ‘oh, this is a very interesting area of work for me.’” “The VR training is useful for the introduction of staff, including trainees and physicians.”
9. HCPs' training	<ul style="list-style-type: none"> “It is good for nurse training, doctor training and patient training.”
For dialysis centers	
10. Standardization of training programs	<ul style="list-style-type: none"> “The VR technique is not so subjective in its application. The program allows objectification, unification and a standardized approach. One forgets then nothing.”
11. Cost saving	<ul style="list-style-type: none"> “Material costs: The number of bag exchanges is reduced. One consumes 11-15 €per training. You can save about 5 bags.”

Limitations and Weaknesses of VR Training

A list of the potential drawbacks of VR training is provided in [Textbox 1](#).

According to HCPs, the most significant weakness of VR training resides in the inherent inability to provide learning effects in the area of tactile perception and sensorimotor fine control (point 1, [Textbox 1](#)).

Moreover, the traditional approach was still perceived as the best strategy to manage the emotional aspects related to PD

treatment and address any patient-specific educational needs. In fact, according to the interviewees, the establishment of a trusting relationship between HCPs and learners is an essential prerequisite to identify emotional barriers and motivational obstacles toward PD (point 2, [Textbox 1](#)). Despite being indicated as a tool to reduce HCPs' workload, some respondents were concerned about a possible additional workload to acquire the concept of VR training both in their curriculum and for their patients during the first VR-based training sessions (point 3, [Textbox 1](#)).

Textbox 1. Drawbacks and weaknesses of virtual reality (VR)-based training according to the interviewed health care professionals (HCPs).

Drawbacks, weaknesses, and representative quotes

1. Lack of tactile education
 - "It's difficult in VR technology to get that shown virtually with the dressings. You don't get a feeling for the catheter connection in VR, for example the resistance when screwing it shut."
 - "VR cannot replace the haptic real-world experience."
 - "VR training does not replace classical training. In any case, the patient must learn well how to handle the bag change even without VR training. VR training is a supplement and VR training does not replace classical training. In any case, the patient must learn well how to handle the bag change even without VR training. VR training is a supplement."
 - "...the handling still has to be experienced haptically...VR is not a substitute for traditional training."
2. Relationship with the patient remains important
 - "The nurse cannot be replaced by the device. The events and intermediate questions must be clarified. There are quite spontaneous questions."
 - "The relationship aspect of care is indescribably important. VR does not change that."
 - "The device is a supplement, the nurse cannot be replaced by the device. The events and intermediate questions must be clarified. Questions arise spontaneously."
 - "It's all schematic in VR training. Unusual events can't be handled in the system."
 - "Everything is schematic. Unusual events cannot be processed in the system. There are typical critical events that are not mapped."
3. Initial workload for HCPs
 - "The time for preparation and implementation of VR technology is then missing in the dialogue with the patient."
 - "In the beginning you have some effort, but only later there is a time effect."

HCPs' Perspectives, Motivation, and Attitudes Toward the VR Technology

An investigation of respondents' attitudes toward VR revealed some differences among HCPs ([Textbox 2](#)). A large proportion

of professionals was willing to use the new tool but felt the need to first gain self-confidence in using the technology. Some HCPs found VR exciting and were interested and enthusiastic. By contrast, others showed a nonpositive feeling and distrustful attitude toward the tool.

Textbox 2. Health care professionals' (HCPs') perspectives, motivation, and attitudes toward the virtual reality (VR) technology.

HCPs' attitudes and representative quotes

Positive

- "The VR training can connect well to the therapy concept in the center to also bring variety into the training."
- "I find the technology innovative."
- "You also have to see it as a technology of the future. I think it is good when things develop. I'm fundamentally interested and open."

Open to learn

- "I have to develop confidence first."
- "There is probably already an acceptance in the team, but for me it means a learning curve. The trust in VR has to develop first."
- "The first attempt was very confusing for me. Each subsequent one went better each time."
- "I find the VR application basically exhausting, but interesting. I find it fascinating."
- "VR is still a bit awkward to use: to grip the disinfectant, you have to use your hand, but before that you have to do something else...Other than that, I'm thrilled."
- "In the beginning you have some effort, but only later there is a time effect."

Negative

- "...there are also employees who only have a smartphone but no other IT skills. They tend to reject it."

VR Acceptance by Patients According to HCPs

In HCPs' opinions, patients' feedback on VR training was overall positive, and the acceptance was high, including that of older patients:

One patient [aged 82 years] has always wanted to exercise, but has not felt that well yet. VR is appropriate for him because he is really interested, because he really wants to learn. He thought it was great, is open minded.

...we initially dealt with the topic of home dialysis rather "playfully"...She [older patient aged approximately 75 years] found the VR training enjoyable and interesting.

Of note, HCPs were aware of the importance of adopting a patient-tailored approach to present the technology. In fact, the respondents highlighted the need to determine the patient's learning style and then to provide an initial clear and simple explanation of the use and purposes of the VR technology:

VR training is basically possible for almost all patients, but the key is how the patient receives it.

You first have to check whether it makes sense, taking into account native language and level of education, acceptance of the medium, etc.

You have to think carefully about when exactly to use the VR. The patient first has to get to know a lot of the basics and deal with the PD. Then, the patient needs a technical briefing: How does VR work? How do the individual elements such as the controller, etc. work? Then you first have to do 2-3 learning units and then a certain habit develops.

HCPs reported a lower VR acceptance among patients not familiar with electronic or audiovisual media and devices, irrespective of their age:

Not many, but some find it awful if there was no computer experience. One patient did not understand it properly.

People who are inexperienced with computers find it difficult to use them.

Additional Applications of VR Training

HCPs believed that, besides patient education, the VR technology can be applied with other relevant goals and functions in the context of PD.

The administration of VR training before obtaining informed consent could significantly support patients in their decision-making about home dialysis. In fact, allowing an in-depth understanding of the PD procedures, VR training can improve patients' awareness and understanding about home-based treatment and, consequently, help them take more informed decisions:

The VR glasses can be used at the beginning in the patient consultation before the treatment decision is made...It can support the patient's decision making for home dialysis.

At a later stage, VR can be used as a motivational tool to enhance and reinforce patients' decision about home PD:

If it is clear that the patient needs dialysis, then you can explain different procedures to them and then for explaining PD you can use VR. That is great.

In addition, HCPs believed that VR could be offered to patients' family caregivers, who often play an important role in patients' decision-making as well as in their care activities:

VR training can also be used for training of family members.

Another field of application of VR training could be within educational programs addressed to the HCPs themselves. Target users include both professionals already working with patients with CKD, such as nurses from cooperating ambulatory care services, and HCPs who are not directly involved in the PD process:

The VR training is useful for the introduction of staff, including trainees and physicians. VR training can also be used as training for family members. Retirement homes: nursing staff there, are yes very tightly staffed. The VR training can also be used in nursing homes and in hospitals with nursing staff for further training purposes.

It is good for nurse training, doctor training and patient training.

Discussion

Principal Findings

This qualitative assessment shows that according to nephrology professionals, the *stay•safe MyTraining VR* may significantly improve PD training efficiency and efficacy. In fact, VR was perceived as a valuable complementary tool able to enhance patients' learning experience by providing the experiential learning necessary for a deeper understanding of medical information. In addition to the positive effects for patients, the *stay•safe MyTraining VR* may also provide HCPs with the opportunity to improve their productivity, both by saving their time and by facilitating the transmission of medical information to patients.

VR is an immersive experiential technology that emulates the physical world through digital simulation. Although originally intended for entertainment purposes, VR has a huge potential as a learning tool due to its unique ability to combine procedural information, interactivity, acoustic and visual information, and behavioral instructions [34]. In the medical field, VR-based education opened a new era of professionals' training on surgical and endoscopy techniques [19-25,35]. More recently, the VR technology has also been implemented for patients' education and training [26-32]. An increasing number of studies demonstrated that the use of simulation media can support different patients' learning styles by providing a mix of visual, auditory, interactive, and text elements [29,30] and improve patients' understanding and comprehension of their diseases as well as of the treatment or lifestyle interventions required to cope with them [26,29,32,36-38]. In addition, by enabling the repetition of training sessions according to individual patient needs, the technology facilitates the acquisition of competences and skills by learners. The possibility to build muscle memory through experiential training [30] and to learn from mistakes in a safe environment further improves patients' learning experience. VR is similarly emerging as an innovative strategy to foster self-management and self-care in patients with chronic conditions [28]. Finally, VR-based education could increase

patient engagement and empowerment [26] while reducing anxiety and pressure related to medical procedures [26,39-41].

In nephrology, effective patient education and training have an impact on the risk of peritonitis [13-15]. In fact, training for home therapies poses unique educational challenges, as patients need to acquire not only the theoretical concepts of dialysis but also the technical skills required to manage all the procedures on their own [2,42]. Recently, Zgoura et al [43] proposed the use of VR headsets and gamification elements in support of PD training with the aim to standardize, facilitate, and accelerate patients' learning process. Here, we report HCPs' perspectives, opinions, and attitudes toward the implementation, into PD training programs, of the *stay•safe MyTraining VR*, a novel PD training program based on the use of a VR headset and a handheld controller [18]. We first explored the timings and modalities of VR integration within the classical training curriculum. Overall, the VR technology was perceived as a helpful supplementary tool, but HCPs specified some functional differences between the traditional and VR-based training programs. According to HCPs, VR-based training was particularly useful during the cognitive phase of the PD training program, where it not only enhanced patients' learning experience and facilitated information internalization but also assisted nurses in explaining the theory and procedures in a more effective and simplified manner. VR was a valuable support also during the initiation phase, during which it helped HCPs overcome potential patients' emotional barriers and lack of self-confidence. Conversely, according to the respondents, the actional phase still required a more classical approach, as a real, haptic experience was indicated as essential to learn the correct handling of the various materials as well as how to manage any critical steps or mistakes.

In HCPs' opinions, a significant added value of the VR technology resides in its ability to improve patients' learning experience and make the entire training process more effective and efficient. These relevant effects are achieved, thanks to the inherent characteristics of immersive or interactive media, which were clearly identified by the interviewees, including a focused learning environment and multiple learning stimuli. The opportunity to repeat the training modules based on patients' individual needs and cognitive skills was also highlighted. The impact of task repetition in education and training is currently well known [17,44]. In the context of health care educational interventions, the repetition of training activities resulted in faster skill acquisition and improved transfer of learning to practice [45]. The mechanisms underlying repetition benefits in cognitive learning include the induction of long-term memory [46] and internalization of procedures as unconscious habits [47]. With each repetition, the cognitive effort required for memory performance, behavior planning, and action control is reduced [30]. This allows rapid recall of habits from memory and improves learners' performance and confidence. Moreover, HCPs noted that repeated training sessions can offer patients the opportunity to correct errors and refine their skills in a safe learning environment. Therefore, patients could get instructions and learn from their mistakes. Learning by doing is one of the central features of interactive education because it allows acquiring a high level of experience and becoming accustomed

to the therapy or procedure [17,25,48]. The playful and interactive learning environment may increase motivation in PD training. As shown by Kyaw et al [20], VR interventions with more interactivity showed better results in terms of knowledge and skills outcomes than interventions with less interactivity. Therefore, the *stay•safe* My Training VR, as a highly immersive training program, may lead to higher patients' motivation and, consequently, increased learning success. These unique attributes of VR could bring substantial benefits especially for older adults, who often need more training time to learn the procedure of PD [42].

Besides the positive effects on patients' cognitive learning, HCPs identified distinctive benefits associated with the use of *stay•safe* MyTraining VR as an informative tool. In fact, VR helped HCPs to illustrate the home dialysis process to patients without providing them with too much stressful information. Similar results were obtained with the use of immersive media to prepare patients for medical procedures [32] and radiotherapy [37] and to increase patients' knowledge about their disease and its associated consequences [26,29].

Concerning patients' acceptance of the new tool, HCPs reported that most of them showed a positive attitude toward VR. These observations confirm and expand the results provided by previous studies in populations with CKD, in which the use of VR either as a distraction or an educational tool was associated with high levels of satisfaction [31,49-51]. On the basis of the HCPs' statements, there was no difference in patients' engagement in the VR-based training between older and younger people. Consistently, recent research in participants with abdominal aortic aneurism and stroke indicated that patients' age does not affect their engagement in VR-based educational programs and is not associated with cybersickness [32,52,53]. As CKD is becoming more prevalent in older individuals [54], these observations appear particularly relevant for a future implementation of the VR training tool into PD education. By contrast, HCPs noted that people who were not familiar with the use of electronic or audiovisual devices tended to build emotional barriers or showed a greater uncertainty in their use of VR. These findings are in line with the studies performed by Specht et al [52] and Huygelier et al [53], who found that patients with a negative attitude toward electronic media were more likely unwilling to use VR. Psychological research showed that acceptance toward computer media is significantly influenced by users' perceptions of the ease of use, usefulness, and playfulness of the different tools [55,56]. Of interest, studies conducted among older adults showed that users' perception that VR was useful, easy to use, and fun promoted a positive attitude toward the tool [57,58]. Moreover, interactivity was indicated as an important factor influencing the intention of continuous use of virtual practices [59]. Therefore, recommendations to boost patients' initial motivation toward VR include maximizing the positive aspects through increasing interactivity, enhancing users' perceptions of utility, reducing the difficulty associated with its use, and enhancing the playful nature of the training.

In addition to the several advantages for patients with CKD, the interviewees were able to identify different positive effects on their working activity. Indeed, in the HCPs' experience,

professional assistance during VR-based training became increasingly unnecessary once patients acquired the skills to use the technology. Thus, HCPs were able to focus on numerous parallel activities and routine administrative tasks during training sessions. This allowed more effective time management among nurses [60]. Moreover, the respondents reported that by providing simple and schematic contents, VR helped convey the medical information more easily. This facilitated HCPs' teaching activity and contributed to boosting patient engagement in PD training. Consistent with these observations, professionals' acceptance toward the new tool was overall high. However, many employees highlighted that they felt the need to undergo structured training to get familiar with VR before using the technology with patients. Therefore, confidence in using the VR technology must be built up to recognize and use its full potential.

Another important improvement offered by VR-based PD training is related to cost-effectiveness. In fact, as the virtual experience does not require the use of additional dialysis fluid bags for mock training, the costs required to successfully train each patient in performing PD can be reduced [43]. Given the increasing prevalence of CKD [61], a more effective health care resource use is essential to ameliorate patient care. By providing the opportunity to save money on dialysis supplies and improving nurses' time management, VR-based training could contribute to reducing the economic burden of PD training while ensuring a high-quality educational offer.

HCPs mentioned other possible applications of VR beyond direct patient preparation for home dialysis that have not yet been tested in practice. The *stay•safe* MyTraining VR was used within the educative conversation with people who need to start dialysis with the aim to enhance the visibility of home therapies as a treatment option and to prepare patients psychologically and emotionally for PD. In this context, VR can support patients to make informed decisions about their treatment of choice. Of note, the gaming factor could have a crucial role in reassuring patients and boosting their self-confidence. Barriers for home dialysis training could thus be overcome by using VR as a complementary tool, which may in turn lead to increased uptake of home dialysis. HCPs also proposed to take advantage of the VR tool to inform patients' relatives about CAPD as a treatment option. As patients' and caregivers' low awareness about and poor understanding of home therapies are important factors underlying the low uptake of PD [6,62], the use of the VR technology as an informative motivational tool can have an important clinical impact among patients with CKD.

Some drawbacks related to the technology were also highlighted by HCPs. In the respondents' view, VR's inability to provide real, tactile education limits its use during the final phase of the PD training program. At this stage, while patients need to practice the procedural skills required to complete each task, HCPs check patients' ability to perform the procedures independently and manage eventual critical steps or mistakes. Therefore, the conventional approach was perceived as the best option for both patients' skill acquisition and professionals' quality assurance. The respondents similarly identified a potential limited use of VR training with specific patient groups,

mainly among people experiencing cognitive disabilities or visual impairment.

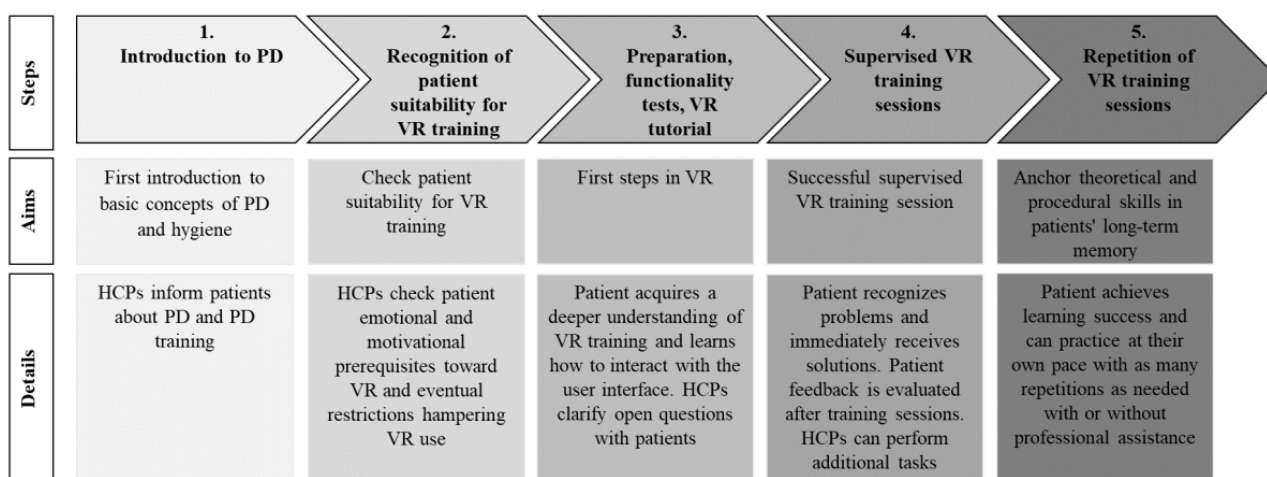

Overall, the collected information indicates that VR implementation into clinical practice may have a profound impact in the PD training scenario. In fact, increasing patients' proficiency in self-management may lead to improved outcomes among patients with CKD [63] and to lower patient concerns related to home dialysis procedures, thereby improving their quality of life. This has a great relevance considering the high burden of anxiety in patients receiving PD [41]. Moreover, the use of VR as a motivational tool during decision-making helps patients in making informed choices and, as a consequence, can promote the uptake of home dialysis over in-center therapies. The use of VR software could similarly improve the educational or training offer because the medical contents can be given in a standardized manner in every dialysis clinic.

On the basis of these observations, we developed a 5-step process proposal that can serve as a guide to implement VR-based PD training within dialysis centers (Figure 2): (1) introduction to PD; (2) recognition of the patient's suitability for VR training; (3) preparation, functionality tests, and VR training tutorial; (4) supervised VR-based PD training sessions; and (5) repetition of VR-based PD training sessions. During the first step, HCPs evaluate patients' psychological, emotional, and physical barriers toward home dialysis to determine whether the patient meets the requirements for PD treatment (step 1, Figure 2). Before starting VR-based training, patients' attitude toward the technology as well as the presence of cognitive or physical disabilities potentially hampering the use of VR must

be thoroughly evaluated (step 2, Figure 2). After checking equipment suitability, pretraining VR tutorials are administered, allowing patients to get familiar with the use of the VR tools (step 3, Figure 2). These preliminary sessions are intended to provide learners with all the instructions necessary to use the devices before starting PD training, with the ultimate goal to reduce patients' cognitive load at later steps. Next, supervised VR-based PD training sessions can be started (step 4, Figure 2). HCPs can check patients' understanding and eventually address any application-oriented questions directly. In addition, professionals evaluate patients' training needs and assess whether obstacles to the learning process are present. This approach enables HCPs to not only customize the information delivery process but also improve patient empowerment and self-confidence. The final step involves the repetition of the learning activities based on individual educational needs (step 5, Figure 2). HCPs can eventually check the acquisition of the procedural skills and provide suggestions to reinforce patient engagement in training activities.

This study has some limitations. One of the limitations is the small sample size, which may limit the generalizability of our findings to a broader population. In addition, while qualitative interviews provide valuable insights and generate working hypotheses, such an approach may introduce potential biases and subjectivity in the data collection process. Furthermore, the study may not have captured the full range of perspectives and experiences. Future research with a larger sample size could provide a more comprehensive understanding about the use of VR training for dialysis.

Figure 2. Process proposal to implement virtual reality (VR)-based peritoneal dialysis (PD) training programs. On the basis of the collected data, we propose a 5-step workflow that can serve as a guide for health care professionals (HCPs) and stakeholders to introduce the VR-based PD training within other dialysis centers: (1) HCPs' assessment of patients' suitability for home dialysis, (2) evaluation of patients' attitude and suitability toward the VR technology, (3) pretraining VR tutorials, (4) supervised VR-based PD training sessions, and (5) repetition of the various activities based on individual educational needs.

Conclusions

In conclusion, VR-based training is intended to facilitate and accelerate patients' skill acquisition required to perform a real PD bag exchange by themselves. Using this innovative technology for PD training is well accepted and feasible and

provides the potential for nephrology HCPs to reach a large population and promote and facilitate home dialysis uptake. Further research is required to investigate the long-term effects of VR training on patient satisfaction, infection rates, and the longevity of PD treatment.

Data Availability

All data generated or analyzed during this study are included in this published article ([Multimedia Appendix 1](#)).

Authors' Contributions

CL contributed to writing the original draft, data visualization, reviewing, and editing. MW contributed to conceptualization, writing–review and editing, data visualization, and project administration. SP and TR contributed to investigation, formal analysis, reviewing, and editing. FK contributed to reviewing and editing. SA contributed to reviewing, editing, and data visualization. UT contributed to conceptualization, reviewing, editing, project administration, and supervision. All authors discussed the results and revised the final version of the manuscript.

Conflicts of Interest

MW, FK, SA, and UT are full-time employees at Fresenius Medical Care. CL provided medical writing services on behalf of Fresenius Medical Care. SP and TR conducted interviews on behalf of Fresenius Medical Care.

Abstract

Background: Virtual reality (VR) is increasingly being used in higher education for clinical skills training and role-playing among health care students. Using 360° videos in VR headsets, followed by peer debrief and group discussions, may strengthen students' social and emotional learning.

Objective: This study aimed to explore student-perceived usability of VR simulation in three health care education programs in Norway.

Methods: Students from one university participated in a VR simulation program. Of these, students in social education (n=74), nursing (n=45), and occupational therapy (n=27) completed a questionnaire asking about their perceptions of the usability of the VR simulation and the related learning activities. Differences between groups of students were examined with Pearson chi-square tests and with 1-way ANOVA. Qualitative content analysis was used to analyze data from open-ended questions.

Results: The nursing students were most satisfied with the usability of the VR simulation, while the occupational therapy students were least satisfied. The nursing students had more often prior experience from using VR technology (60%), while occupational therapy students less often had prior experience (37%). Nevertheless, high mean scores indicated that the students experienced the VR simulation and the related learning activities as very useful. The results also showed that by using realistic scenarios in VR simulation, health care students can be prepared for complex clinical situations in a safe environment. Also, group debriefing sessions are a vital part of the learning process that enhance active involvement with peers.

Conclusions: VR simulation has promise and potential as a pedagogical tool in health care education, especially for training soft skills relevant for clinical practice, such as communication, decision-making, time management, and critical thinking.

Introduction

Background

Virtual reality (VR)-based training has a generally high acceptance amongst trainees, regardless of the technology limitations, usability challenges, and cybersickness [1]. A

systematic review of the effectiveness of VR-based simulation training from the past 30 years showed evidence for VR as useful for training cognitive skills, such as spatial memory, learning and remembering procedures, and psychomotor skills. VR was also found to be a good alternative where regular job training was either impossible or unsafe to implement [1].

Targeted training of health care students is paramount to ensuring the provision of patient-centered care and effective communication with patients and their families. Using 360° videos in VR headsets as a starting point for VR simulation has immense potential for the systematic design of learning experiences and for fostering social and emotional learning through collaborative interactions with students [2-4]. Social and emotional learning concerns the development of emotional intelligence skills, including self-awareness, self-management, social awareness, relationship skills, and responsible decision-making [5]. Further, VR simulation offers an active and engaging approach to learning, which can positively impact the motivation of both teachers and students while enhancing learning opportunities and creativity in the learning process [4,6]. Videos of 360° are prerecorded using an omnidirectional camera that films in every direction. This means that the viewer can look around freely as in other VR experiences, but movement and interaction are limited because the camera only records from one position at a time [4].

To ensure active learning, the vicarious VR learning experiences should be provided with an instructional component of debriefing and peer discussion [7]. According to Biggs et al [8], education is about conceptual change, not just the acquisition of information. Such conceptual change takes place when students work collaboratively and in dialogue with others, both peers and teachers. Good dialogue is an essential element of activities that shape, elaborate, and deepen understanding [8].

VR simulation has the great advantage of facilitating a rich, detailed learning environment through different scenarios that are difficult to replicate in reality (eg, frightening situations) [9]. Considering that most health professions are underpinned by a client-centered philosophy of practice, the use of VR will be more relevant when educators create content that is particularly aligned with each specific education program [10]. Consideration of design issues and student experiences of usability are central for developing VR technologies in medical education programs [11]. According to Nielsen [12], usability is defined by five quality components: (1) how easy it is to accomplish the task, (2) efficiency (when learned), (3) memorability, (4) number of user errors, and (5) satisfaction related to the design. Usability has also been extended to comprise user experience that has a more compelling emotional and motivational effect [13]. We were interested in exploring the usability of a VR simulation program designed for health care students, in particular with a view to perceived learning outcomes and possible enhancement of soft skills such as communication skills and clinical decision making.

Even though recent studies indicate that VR is increasingly being used in higher education for clinical skills training and role-playing among health care students [6,14], there is a research gap concerning the use of VR to facilitate the nontechnical skills inherent in the social and emotional competences [5], such as communication, decision-making, and ethical reflection [15-18]. There is a need for more research on VR simulation in higher education programs within health care [4,19,20]. Further research needs to be directed toward the application of immersive 360° videos and how it is experienced

by students in higher education [4,19,20] and studies that explore the usability of VR simulation [2,19].

A recent review conducted on implementation of VR argued that future studies should explore viable approaches to incorporate VR into health professions education [21]. During the last 2 years, there have been published a few qualitative [22-24] as well as quantitative studies on the usability of VR in nursing education [4]. Literature searches in Google Scholar using the search words *usability AND *virtual reality AND *occupational therapy/social education, published after 2022, revealed 1 mixed methods study on the usability in physical therapy education [25]. This search did not identify any existing publications on usability of VR simulation in occupational therapy or social education programs.

The recommendations from earlier research as well as the scarcity of usability studies concerning VR in health education programs suggest that VR implementation processes and the usability of VR simulation programs should be further explored and evaluated.

Study Aim

This study aimed to explore student-perceived usability of VR simulation in 3 health care education programs in Norway. The research question was: What are the students' perceptions of the usability of the employed VR simulation and related learning activities, and are there differences in perceptions between students in different study programs?

Methods

Design and Study Context

This study is part of a larger interdisciplinary project in a Norwegian university, the Solstien 3 project, with the objective to create a VR simulation that portrays situations future health and social workers might encounter in their professional practice. The purpose was to offer students a safe and controlled environment to practice handling challenging and unexpected scenarios without the risk of compromising the well-being of clients, patients, or themselves. The VR simulation, developed and used for soft skills training, was intended to supplement teaching and field placements [26].

The project has developed a "virtual learning center" accessible on a webpage, featuring portrayals of service recipients (patients or clients) through text and images, along with 360° videos illustrating various scenarios [27]. The design of the VR simulation included scenarios and related discussion tasks based on shared learning outcomes for higher education in Norway [28]. The VR simulation in all education programs commenced with a briefing, followed by students watching the scenario using VR headsets, without any possibility to interact with the actors or the environment. The students subsequently participated in facilitated debrief discussions in groups or conducted planned assignments in groups for peer learning. The debrief was concerned with the ethical issues related to the scenario, as well as communication and interpersonal skills. The VR simulation was conducted as part of the regular curriculum for undergraduate students enrolled in the involved education programs; occupational therapy, social education,

and nursing. After graduation, those who have undergone these education programs with satisfactory results are qualified to work as health care personnel in Norway, provided authorization from The Norwegian Directorate of Health.

In the early development phase of the Solstien 3 project, both faculty members' and students' experience with the prototype 360° video was investigated. The findings showed the importance of VR being contextualized directly in educational programs to create a safe environment for learning [26]. Further, in a pilot study, the students' experience of the VR simulation was explored. Findings showed that students experienced VR simulation as valuable as a space for authentic, engaging, and reflective practice, and therefore the students felt prepared for professional practice [29]. The use of 360° videos in combination with group discussions activates social and emotional learning and appears to be promising for enhancing professional learning [30]. The process and content of the Solstien 3 project are described in detail and are accessible through the aforementioned webpage [27].

Participants

Students from 3 undergraduate health care education programs at the same university were invited to participate in this study. These students, from occupational therapy, social education, and nursing, had VR simulation scenarios that were directly associated with their professional practice (developed by the Solstien 3 project). The VR simulation was therefore carried out in different subject-specific courses in different semesters for these 3 education programs. The data were collected during the academic year of 2022-2023, specifically between October 2022 and May 2023. An overview of the VR simulation and the related learning activities in the 3 education programs are displayed in Table 1, and a description of the scenarios and the students' tasks is displayed in Multimedia Appendix 1. The social education students were in their second semester in their first year of study, while the occupational therapy students were in their fourth semester in their second year of study. The nursing students were in their fifth and sixth semesters in their third year of study.

Table 1. Overview of virtual reality (VR) simulation learning activities in 3 different education programs.

	Occupational therapy	Social education	Nursing
Semester and name of subject	Second year, fourth semester <i>Participation and belonging</i> (15 ECTS ^a)	First year, second semester <i>Social education work processes</i> (10 ECTS)	Third year, fifth and sixth semesters <i>Home nursing care</i> (15 ECTS)
Students in class	38 students	95 students	280 students
Introduction	The simulation started with some initial information in plenum. The students were given a short instruction about the task and shown how to use and adjust the VR headsets	The simulation started with some initial information in plenum. The students were given a short instruction about the task and shown how to use and adjust the VR headsets	The simulation started with some initial information in plenum. The students were given a short instruction about the task and shown how to use and adjust the VR headsets
Group sizes	VR simulation: 12-15 students Discussion groups: 6-7 students	VR simulation: 14-15 students Discussion groups: 6-8 students	VR simulation: 8-9 students Discussion groups: 8-9 students
Organization of the learning activity	The class was divided into 3 VR simulation groups and 6 peer discussion groups. The students spent approximately 3 hours on the whole session.	The class was structured into 3 cohorts for teaching on different days. Each cohort was divided into 2 VR simulation groups and 5 peer discussion groups. The students spent between 2 and 4 hours on the whole session.	The class was structured into 3 cohorts for teaching on different days. The cohort was divided into approximately 11 VR simulation and peer discussion groups. The students spent 1 hour on the whole session (as a part of a full-day health care simulation program).
Peer debrief	After watching the 360° videos, students were organized into peer discussion groups of 6-7 students. Each group had 1 facilitator.	After watching the 360° videos, students were organized into peer discussion groups of 6-8 students. Only 1 facilitator circulated between the groups.	After watching the 360° videos, students stayed in the same peer groups for discussion and debrief. Each group had 1 facilitator.
Learning outcomes	The debrief is concerned with the ethical issues that arise in the situation, as well as communication and interpersonal skills and a discussion on fall prevention.	The students collaborated to discuss and create a written assignment based on their experiences in the situation. The task involved the identification of possible conflicts of values and target behaviors and a discussion on the choice of appropriate mapping tools.	The debrief is concerned with the ethical issues that arise in the situation and the relationship and communication between the nurse and the patient as well as the family.

^aECTS: European Credit Transfer and Accumulation System.

Measurement

To find the most suitable questionnaire for this study, research work with similar objectives was examined. We found 2 relevant studies related to the usability of VR simulation in nursing

education [31,32]. Verkuyl et al [31] developed a questionnaire based on earlier usability testing in the same study context. This questionnaire of 18 items had 2 sections: *perceived ease of use* and *perceived usefulness*. The questionnaire was relevant to our study as items considered whether the students found the VR

simulation easy to use, as well as whether the learning activity would enhance soft skills such as communication skills and clinical decision-making [31]. The questionnaire of Lee et al [32] was a further refinement of the work of Verkuyl et al [31] and consisted of 17 items to be rated and 7 open-ended questions. Based on these 2 studies, a questionnaire was developed by the research group, containing 17 items to be rated and 2 open-ended questions. The questionnaire also included 6 items assessing student characteristics: study program affiliation (social education, occupational therapy, and nursing), gender (male vs female), age (years), current working status in health care or social services (yes vs no), prior experience using VR technology (yes vs no), and attitude toward VR technology in education (sceptical or indifferent vs positive).

In total, 17 statements related to the students' perceptions of the usability of VR simulation and the related learning activities were used. Of the total items, 9 concerned perceived ease of use and 8 items concerned perceived usefulness. The participants were instructed to rate their level of agreement (1=disagree, 2=disagree somewhat, 3=unsure, 4=agree somewhat, and 5=agree). Toward the end of the questionnaire, the participants were also asked to evaluate the VR simulation activity on a 1-5 scale (1=poorest evaluation and 5=best evaluation).

The questionnaire also had 2 open-ended questions: *What specifically did you learn from the learning activity (360° video, group discussions, etc.)* and *Do you have other comments about the 360° videos and the related learning activities? (Improvements? Other ideas?)*

The translation process was first undertaken by one of the research group members before the resulting translations were discussed and adjusted by the team. The students were invited to respond to a digital questionnaire in their native language (Norwegian) shortly after completing the learning activity.

Data Analysis

Differences between students enrolled in different education programs were examined with Pearson chi-square tests for categorical variables, and with 1-way ANOVA for continuous variables. To adjust for inflating type I error rates in the multiple comparisons, Tukey honestly significant difference (HSD) correction was applied to the analysis of variance. To analyze the data from the open-ended questions, we used qualitative content analysis [33]. Initially, the responses were thoroughly read to gain a broad understanding, followed by a systematic categorization into distinct codes. This process helped in identifying similarities and differences in the responses. Subsequently, these codes were grouped into 2 relevant categories, which facilitated the identification of recurring patterns focusing on students' experiences of the usability aspect of the VR simulation.

Ethical Considerations

This study is registered with the Norwegian Centre for Research Data (protocol code 423788). Research ethics were strictly adhered to throughout the study. The learning activity was conducted as a mandatory activity as part of the curriculum for all students in the relevant study programs (n=413). After having conducted the learning activity, the students were invited to complete the questionnaire, which was provided by a QR code in the classroom or a link sent by email. On the first page of the questionnaire, the students received information about the study's purpose and procedures, and that participation was voluntary. The students were also informed that they consented to participate in the study by pressing "go to questionnaire". In this way, informed consent was obtained from all participants before their involvement. The questionnaire was anonymous, and data cannot be traced back to individual informants. Moreover, the questionnaire did not ask for any sensitive information.

Results

Student Characteristics

Overall, 146 students responded to the questionnaire out of a total of 413 invited students (35.4% response rate), representing students of social education (n=74, response rate 77.9%), occupational therapy (n=27, response rate 71.1%), and nursing (n=45, response rate 16.1%). The social education students comprised 50.7% of the sample, while the nursing students comprised 30.8% and the occupational therapy students 18.5% of the sample. Most of the students were women (n=117, 80.1%), while 29 (19.9%) were men, with a larger proportion of younger students in the social education program and a larger proportion of older students in the nursing education program. The sample is described in [Table 2](#).

At the time of the data collection, 105 (71.9%) students worked in health care or social services, and half of the students (n=73) had prior experience using VR technology. Statistically significant differences between the groups were found in the "attitude toward VR in education" and the "evaluation of the VR simulation learning activity." A larger proportion of nursing students were positive toward VR technology in their education program (n=42, 93.3%), compared with occupational therapy students (n=21, 77.8%) and social education students (n=56, 75.7%). Among the nursing students, 26 (72.2%) gave the highest possible rating (5) when evaluating the VR simulation learning activity. In contrast, this rating was given by 7 (33.3%) of the occupational therapy students and 20 (37%) of the social education students.

Table 2. Characteristics of students by study program (N=146)^a.

Characteristics	All, N	Occupational therapy, n (%)	Social education, n (%)	Nursing, n (%)	P value ^b

Perceived Usability of the VR Simulation and Related Learning Activities

In the pairwise comparisons between study programs, using the occupational therapy program as the reference group, the nursing students had the highest mean scores, while the occupational therapy students, for the most part, had the lowest mean scores.

Students' Perceptions of Ease of Use

In the pairwise comparisons, statistically significant differences were found on all items related to the perceived ease of use. The highest mean scores for all students were on the items "the pace and the narrative in the 360° video were good" (mean 4.71, SD 0.64) and "the presented situation was realistic" (mean 4.68, SD 0.64). The lowest mean score was found on the item "the audio quality of the 360° video was good" (mean 3.86, SD 1.41), which was also the lowest mean score for both the occupational therapy students (mean 2.81, SD 1.57) as well as the social

education students (mean 3.72, SD 1.41) throughout the whole questionnaire.

Students' Perceptions of Usefulness

In the pairwise comparisons, statistically significant differences were found on all items related to the perceived usefulness. The highest mean scores for all students were on the item "the 360° video and the related learning activities were useful as a part of my education program" (mean 4.46, SD 0.95). The lowest mean score was found on the item "what I experienced in the 360° video improved my professional competence" (mean 3.93, SD 1.19). The difference between the study programs was rather large, with the occupational therapy students scoring this item on average 1.2 points lower than the nursing students and 0.8 points lower than the social education students. [Table 3](#) displays the total mean scores and the pairwise comparisons of mean scores between study programs.

Table 3. Usability of VR^a simulation and learning activities, N=140-146.

Statements	Total, mean (SD)	Occupational therapy, mean (SD)	Social education, mean (SD)	<i>P</i> ^b value	Nursing, mean (SD)	<i>P</i> ^b value
Ease of use						
The VR ^a headset and the showtime app were easy to use	4.45 (0.97)	3.67 (1.36)	4.57 (0.83)	<.001	4.73 (0.62)	<.001

The 360° video and the related learning activities were useful as a part of my education program	4.46 (0.95)	3.85 (1.29)	4.51 (0.88)	.004	4.75 (0.62)	<.001

^aVR: virtual reality.

^b*P*-values are based on pairwise comparisons between study programs, with 1-way analyses of variance using the Tukey HSD correction. The occupational therapy program is used as reference group.

Open-Ended Questions

Out of 146 participants, 110 answered one or both open questions. There were a total of 135 qualitative responses, which were analyzed. Two categories were created based on the responses, focusing on “perceived learning” and “difficulties and recommendations.”

Perceived Learning

The participants described learning outcomes related to soft skills such as conflict management, reflection, emotion regulation, and non-verbal and verbal skills. Furthermore, they also emphasized professional conduct such as empathy, client-centered practice, and a focus on family involvement. The participants found the following debrief and group

discussion particularly useful in their learning experience. One participant expressed it as follows:

With this type of learning, you are better prepared for clinical practice and the learning curve is steep when we reflect together. It was realistic and touched a lot of emotions. Solutions were discussed together. I think this type of learning is extremely beneficial.

The fact that this learning took place in a safe environment was also highlighted as positive by several of the participants. Several of the participants answered the open-ended questions with few words in a general, but positive, manner. For example, the learning activity was cool, exciting, fun, realistic, and relevant for clinical practice. One participant expressed it as follows:

Being a fly on the wall in such a situation was very enlightening.

Some participants also answered that this learning activity was a new type of learning and that the website was particularly useful for getting to know the material more thoroughly.

Difficulties and Recommendations

The participants' experience of difficulties related to the learning activity mostly concerned either technical or organizational problems. Particularly poor sound quality and the need for noise-reducing headsets were highlighted as technical issues. On the other hand, organizational problems revolved around too many students in the groups and that the preparations could have been more informative, especially for the students with no experience with VR simulation. Two participants reported discomfort related to a rather unpleasant scenario that they found them "in the middle of," and one of them wrote:

...for me, who is a little light sensitive etc., I had great difficulty having the screen so close to my face. The experience was simply quite unpleasant and triggered a headache.

The participants recommended other types of cases and scenarios involving complex choices and interactive roles in the VR simulation, such as:

...options where you can "decide" the actions further.

It was also desirable that the 360° videos would be more available for self-training and that the students could access more VR simulations at their educational program.

Discussion

Overview

This study aimed to explore student-perceived usability of VR simulation, including 360° videos in VR headsets and related learning activities, in 3 health care education programs in Norway. All in all, high mean scores indicate that the students experienced the VR simulation and the related learning activities as very useful. Nevertheless, our findings showed that the nursing students were most satisfied with the usability of the VR simulation, while the occupational therapy students were least satisfied. The qualitative data from the 2 open-ended questions confirmed the findings from the questionnaire, but also illuminated other factors regarding the usability of VR simulation and the related learning activities.

Differences Between the Study Programs

The nursing students in this study were third-year students with previous experience with other simulations, practical skill training, and clinical practice. They had considerably more experience than the first-year social education students. The second-year occupational therapy students had some prior experience with skill training and clinical practice, but not with simulation. Saab et al [22] emphasized in particular that in order to succeed, the key stakeholders, including students and educators, need to be trained in the use of VR prior to implementing VR simulation. The differences in VR experience among the students prior to this learning session may contribute

to explaining why the nursing students scored the usability of the VR simulation significantly higher than students in the other 2 educational programs. They may be due to the novelty effect, where novice VR users tend to focus on managing the hand controllers and exploring the VR environment, rather than focusing on the proposed learning tasks [34].

The key findings in the systematic review of Woon et al [3] illuminate that VR increases nursing students' engagement in the learning experience when allowing them to participate in activities that are close to reality and when implementing an effective training regime consisting of short interval training (≤ 30 min each) for a number of sessions. In our study, the nursing students had this learning activity as part of a larger session with a multiple number of short interval trainings. The larger number of trainings for the nursing students and their embedding the VR simulation into a more comprehensive learning activity may contribute to explaining their higher scores on usability and relevance. Also, the nursing program had the smallest groups in the VR simulation (up to 9 students), while both the social education program and the occupational therapy program reported difficulties with instruction and initiation of VR simulation in somewhat larger student groups (up to 15 students). The occupational therapy program experienced technical problems, particularly with sound control, which may also be reflected in the low mean scores from the survey. Educators at the social education program experienced difficulties with one of the cohorts, due to students having little to no prior experience using VR technology. Noble et al [35] emphasized that one should not take students' knowledge and skills in using VR equipment for granted. However, their study mirrors our results, with approximately half of the students having no experience with VR even though the education program facilitates the use of VR equipment free of charge.

Group differences related to study progression, previous experience with VR simulation, as well as how the learning activity was structured, both according to group size and how many facilitators were available for the students, can partly explain why students scored the usability differently. A valuable recommendation, consistent with previous research [36], is that smaller student cohorts and having a sufficient number of staff available are important so that the students can receive sufficient help at the right time.

Practicing Clinical Skills With Realistic Scenarios in a Safe Learning Environment

Our findings in both qualitative and quantitative data showed that the students perceived the scenarios to be realistic and useful for clinical practice. Also, several students shared in the open-ended responses that they experienced the VR learning activity as a safe way to practice their clinical skills. The sober and realistic nature of the scenarios depicting real-world situations appears to be beneficial for students' skill acquisitions with relevance for clinical practice [14,37-39]. In addition, the open-ended responses indicate that students were emotionally touched and had an increasing engagement with this learning activity. This is beneficial, as increased emotions and engagement in VR simulation can enhance the learning processes [9]. In the development of the prototype for the 360°

videos, students experienced the VR simulation to be genuine and realistic due to actors using direct eye contact with the camera. Furthermore, the importance of having a safe learning environment was highlighted, especially when experiencing strong emotions [26]. Although the learning environment was described as safe by many students, a few of them pointed out that they found the VR simulation uncomfortable. Cybersickness can influence the learners' attitude toward the technology negatively and has been correlated with poorer learning outcomes [40]. For these students in particular, it will be crucial to facilitate the VR simulation to avoid discomfort. To reduce the discomfort among individuals experiencing it, one suggestion is to adapt the VR simulation to a standard desktop [36]. Nevertheless, we have reason to believe that VR simulation with realistic scenarios is an appropriate learning activity to precede clinical practice. Furthermore, this type of teaching has a particular value as students can practice skills needed in a difficult situation but still feel safe in a peer learning process.

Student Active Learning in Peer Debrief and Group Discussions

Our findings based on both qualitative and quantitative data showed that the students perceived the related learning activities useful for their future professional practice. Many students highlighted the group discussions in the debriefing sessions as particularly beneficial, which is consistent with previous research [7,17,26]. These methods are known to enhance learning by allowing students to actively process information, engage in critical thinking, and articulate their understanding or questions [41,42]. Debrief sessions, in particular, offer a reflective space where students can consolidate their learning, address misconceptions, and gain insights from peers and instructors. This discussion contributes to the larger conversation about active learning in education. Active learning, characterized by student participation and engagement, has been increasingly recognized for its effectiveness in promoting deeper understanding and retention of knowledge [43]. However, some of the students remarked that they were passive observers of the 360 video. They suggested including interactivity in the VR simulation for a better learning experience. This aligns with a Canadian study underscoring the benefits of active participation in VR simulation for occupational therapy students [10]. The learning activity in our study still required active involvement in the debrief discussion where students reflected and engaged with the teaching material together with their peers. A suitable alternative could have been active participation in the VR environment, where students would have the opportunity to interact with the virtual environment, make decisions, and influence the outcome of the scenarios. This could lead to a more engaging learning experience, probably more appropriate for training soft skills such as decision-making, time management, and critical thinking.

Our findings have important implications for educational practices. They suggest that incorporating structured group discussions and debriefing sessions can significantly enhance the VR learning experience by allowing students to engage with and process the learning material related to situations they might encounter in a real-world setting. In addition, VR simulations

with the student in an active role will probably increase students' motivation and promote learning.

Study Limitations and Suggestions for Future Research

The study is based on self-report data only. The response rates among both occupational therapy and social education students were high with 71% (n=27) and 78% (n=74). In contrast, the response rate among the nursing students was only 16% (n=45), and, therefore, the findings must be interpreted with caution. Further to this, there may be a response bias, especially among the nursing students, a group possibly consisting of particularly motivated and high-achieving respondents. This may be one important reason why students in this group were more satisfied with the usability of this learning activity. Differences between the student groups may also have been caused by varying levels of VR experience and competence among the faculty facilitating the relevant sessions. While we have the impression that the faculty in the nursing program had more experience with VR compared to their counterparts in the other education programs, we did not collect data from faculty that could support or contradict this view. Thus, we are unable to assess the possible impact of faculty's VR experience and competence on the students' experience, and we suggest that future studies include this information.

Other methodological issues concern that the VR simulation and learning activity was carried out at different year levels among the 3 health care education programs and the presence of age differences between students in the different study programs. Higher age and maturity among the participating nursing students may have resulted in higher levels of satisfaction, while these results may not be representative of differences in the study population. We also note that there might be different "group cultures" related to the evaluation of teaching in different groups of students, essentially meaning that similar experiences are systematically given dissimilar ratings across groups. Thus, there is a possibility that the students' expressed levels of satisfaction differed more than their experienced levels of satisfaction.

Conclusions

In summary, the students in all 3 educational programs perceived the high usability of the VR simulation and the related learning activities. Nevertheless, the nursing students were most satisfied, while the occupational therapy students were somewhat less satisfied. By using realistic scenarios, health care students can be prepared for complex clinical situations in a safe environment. Group discussions in the debriefing sessions are a valuable part of the learning process and enhance active involvement with peers. Particular attention should be given to the organization of the VR simulation with small student groups and a sufficient number of involved educators so that students receive guidance when problems occur. These findings contribute to the overall growing evidence showing that VR simulation has promise and potential as a pedagogical tool in health care education, perhaps particularly for training soft skills such as communication, decision-making, time management, and critical thinking—skills that are unquestionably relevant for clinical practice. However, future studies need to expand

beyond the pilot phase to study if VR simulation exceeds the value of traditional teaching methods.

Acknowledgments

The authors thank the students who volunteered to take part in this study. In addition, we thank our colleagues for conducting the VR simulation and their contribution to the data collection for this study. The larger project was funded by the Norwegian Directorate for Higher Education and Skills and VID Specialized University (project AKTIV-2019/10162).

Data Availability

The datasets used and analyzed during the current study are available from the corresponding author on reasonable request.

Conflicts of Interest

None declared.

Authors' Contributions

GM, TB, and SSL developed the study design. All authors contributed to collecting the data. GM, TB, and SSL conducted the data analyses, but all the authors interpreted the data in light of the learning activities. GM wrote the first manuscript draft. All authors contributed to the editing of the manuscript. Lastly, all authors read and approved the final manuscript.

Multimedia Appendix 1

Descriptions of scenarios and tasks.

Abstract

Background: The use of digital online teaching media in improving the surgical skills of medical students is indispensable, yet it is still not widely explored objectively. The first-person–view online teaching method may be more effective as it provides more realism to surgical clerkship students in achieving basic surgical skills.

Objective: This study aims to objectively assess the effectiveness of the first-person–view live streaming (LS) method using a GoPro camera compared to the standard face-to-face (FTF) teaching method in improving simple wound suturing skills in surgical clerkship students.

Methods: A prospective, parallel, nonblinded, single-center, randomized controlled trial was performed. Between January and April 2023, clerkship students of the Department of Surgery, Pelita Harapan University, were randomly selected and recruited into either the LS or FTF teaching method for simple interrupted suturing skills. All the participants were assessed objectively before and 1 week after training, using the direct observational procedural skills (DOPS) method. DOPS results and poststudy questionnaires were analyzed.

Results: A total of 74 students were included in this study, with 37 (50%) participants in each group. Paired analysis of each participant's pre-experiment and postexperiment DOPS scores revealed that the LS method's outcome is comparable to the FTF method's outcome (LS: mean 27.5, SD 20.6 vs FTF: mean 24.4, SD 16.7; $P=.48$) in improving the students' surgical skills.

Conclusions: First-person–view LS training sessions could enhance students' ability to master simple procedural skills such as simple wound suturing and has comparable results to the current FTF teaching method. Teaching a practical skill using the LS method also gives more confidence for the participants to perform the procedure independently. Other advantages of the LS method, such as the ability to study from outside the sterile environment, are also promising. We recommend improvements in the audiovisual quality of the camera and a stable internet connection before performing the LS teaching method.

Trial Registration: ClinicalTrials.gov NCT06221917; <https://clinicaltrials.gov/study/NCT06221917>

teaching method; live streaming; first-person view; face-to-face; simple wound suturing

Introduction

Using a combination of traditional and online teaching methods in the training of medical students is unavoidable and indispensable in the 21st century, especially in the Education 4.0 framework [1]. Although blended learning methods have been applied in many disciplines, its use in surgical clerkship training has not been thoroughly explored [2,3]. This gap was made obvious during the COVID-19 pandemic, as the training of medical students in various countries was disrupted since digital online tools were not ready to be used in the medical education field [4-6].

Compounding this problem is the discrepancy between the growth rate of new medical students compared to the training rate of certified medical school lecturers [7,8]. The Indonesian Ministry of Education stated that the ideal ratio of lecturers to medical students for effective teaching is 1:5, which is not always achievable [9]. Online teaching methods are also especially useful in the operating theater environment, as the number of personnel in the operating theater must remain as few as possible to decrease the risk of surgical infections [10,11].

A proposed solution for these problems is by teaching procedural skills using live-streamed media with strict quality assurance to ensure the quality of the graduates [12,13]. In this manner, a certified lecturer could educate a number of students simultaneously, while reducing the number of people in the operating theater. While the surgeon is doing the procedure in the operating theater, the students or participants can see and learn the procedural skill in other places simultaneously via the internet [14,15]. Although a previous study by Shikino et al [16] suggested that video training of students are generally better accepted, this may not be applicable in learning a manual dexterity skill such as suturing.

The viewpoint shown in the live stream could also affect the learners' understanding. Typically, live-streamed videos are presented in either first-person or third-person view, where a first-person view simulates the viewer being the person doing the procedure, and a third-person view shows the viewer looking at the surgeon doing the procedure from the side. In the context of surgical skills training, a first-person view could improve the students' skills acquisition, as it provides a more realistic simulation of the procedure performed, especially concerning the hand movements, instrument handling, tissue handling, knot tying, and so on [17-19]. A first-person view could also bring the students' viewpoint closer to the procedure compared to being there in person, as onlookers in the operating theater must maintain their distance due to hygiene and sterility issues [20].

An operator-mounted vlogging camera is also superior compared to fixed operating theater cameras, installed in the light fixtures or dedicated mounts, which require complicated installment, are not readily available in many theaters, and are less cumbersome compared to digital cameras with tripod settings [21-23]. Previous researchers have studied and published procedural learning methods using a minimalist and portable vlogging camera such as a GoPro, which could be easily brought into the operating theater, outpatient clinic, or classrooms

[23-25]. This device is easily mountable and wearable, which also means that surgeons can easily wear it on their heads while operating, and a teaching assistant can help operate it with a simple click [26]. Head-mounted cameras are also easier to use and less intrusive to the operator compared to body mounts [23,27].

Previous studies have researched and published procedural learning methods using digital online platforms [6,13,28-32]. However, to our knowledge, there are still no studies that objectively evaluate the effectiveness of first-person-view live streaming (LS) methods in surgical training such as simple wound suturing, which is unique to this study. The aim of this study is to objectively assess whether performing simple wound sutures via LS using a first-person-view GoPro camera has the same effectiveness as traditional face-to-face (FTF) teaching.

Mastery in suturing skills for simple and clean wounds is a requirement for medical doctors. Simple wound suturing has internationally established techniques and assessment methods [33,34]. The most basic wound closure technique is the simple interrupted suture, which is a required skill for Indonesian medical doctors [35-37]. Objective assessment of this procedural skill is performed using the Objective Structured Clinical Examination (OSCE), which is routinely carried out at the Faculty of Medicine, Pelita Harapan University [32]. To improve participants' skills, the direct observational procedural skills (DOPS) method has been incorporated into the curriculum [38].

Methods

Ethical Considerations

This study was reviewed and approved by the Pelita Harapan University Faculty of Medicine Ethical Board (ethical approval 011/K-LKJ/ETIK/I/2023). This study also has been registered at ClinicalTrials.gov (registration NCT06221917). Details about the study were explained to the participants, and informed consent were obtained from all the participants. All the data were already deidentified. No compensation was given to participants.

Recruitment, Randomization, and Allocation

This study was a prospective, parallel, nonblinded, single-center, randomized controlled trial, conducted between January and April 2023. This study was not funded by any sponsor or institution. This study was conducted and reported in accordance with CONSORT (Consolidated Standards of Reporting Trials) guidelines [39] (Checklist 1).

A total of 74 surgical clerkship students of Pelita Harapan University were recruited as study participants based on a sample calculation from Lemeshow et al [40], from a previous study by Sakurai et al [41]. They were selected from a pool of 254 fifth- and sixth-year active clerkship students using simple computer randomization. They were in the final years of study in the Faculty of Medicine and had just begun their surgical rotation. These students had learned suturing in a clinical skills module during their second year of medical school but had no previous clinical experience of wound suturing in their clinical rotations, such as from a previous obstetrics and gynecology or surgical rotation. Participants who dropped out in the 1-week

period between preintervention and postintervention time points were excluded. It was made clear to the students that their participation in this study would not affect their academic results in any way.

The students were then randomized into 2 groups: of the 74 participants, the first 37 (50%) selected by simple computer randomization were allocated to the FTF group, and the next 37 (50%) were allocated into the LS group. Each recruited participant underwent a pre-experiment simple suturing DOPS assessment with a randomly assigned clinical preceptor from the Department of Surgery. These 8 clinical preceptors are active surgical specialists and subspecialists, with previous experience in DOPS assessment and tutoring medical students. The assessment rubrics used in this study have been reviewed by the Medical Education Unit of Pelita Harapan University and were routinely used in OSCEs ([Multimedia Appendix 1](#)).

The FTF group was taught how to perform simple sutures on a mannequin, and they then watched from the side as a surgeon (FH) performed the simple suturing procedure on a real patient. FH is an assistant professor at the Faculty of Medicine and an active surgeon with more than 10 years of practice. The students were allowed to interact with the operator and ask questions.

The operator simultaneously wore a head-mounted GoPro Hero 8 device, which was performing a LS function. Two assistants, HSK and VSC, helped ensure that the audiovisual quality of the demonstration was adequate. When the visual exposure was not adequate, HSK would help by adjusting the camera [42].

The LS group was taken into a different room, and they watched the live stream from the GoPro on their own devices while being

monitored by HSK or VSC. All participants were instructed to use a university Wi-Fi network to ensure connectivity. LS participants were encouraged to be actively involved in the teaching process, asking questions or giving feedback directly through a speakerphone when they were not clear regarding the demonstration or explanation.

Participants in both groups were allowed to ask the instructor to stop or redo the process. If the audiovisual quality of the live stream was poor, the camera setup was immediately modified, and the instructor would repeat the unclear teaching process to make sure every participant got the same explanation before proceeding to other steps. The live-streamed session was not recorded, and students were not allowed to record it on their device under supervision from HSK or VSC.

One week after the initial training, the participants performed a postexperiment DOPS assessment with the same examiner as the pre-experiment DOPS assessment, using the same rubric to avoid interexaminer bias. Data on the grade point average (GPA) index and frequency of self-training within a 1-week period of both groups were collected.

At the end of the teaching process, we asked both groups using a Likert-scale questionnaire for their opinion regarding the quality of surgical teaching, whether the training enhanced their skill, and the confidence of the participants to do the procedure by themselves. We also asked about the audiovisual quality of the online video as well as the internet connection for the LS group, directly after the training was finished. The participant flow is shown in [Figure 1](#).

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) diagram of participant flow. DOPS: direct observational procedural skills; FTF: face-to-face; LS: live streaming.

Statistical Analysis

Data were analyzed using SPSS (version 23.0; IBM Corp). Paired-samples 1-tailed *t* test was used to determine the difference between the preintervention and postintervention DOPS scores. Fisher exact analysis was used to analyze the subjective evaluation of FTF versus LS effectiveness to enhance participants' skills. Descriptive statistics were used to describe the audiovisual quality and internet connection quality.

The difference between DOPS scores (Δ) was defined as the numerical difference between the scores before and after the teaching process. This numerical difference was calculated from

each participant's preintervention and postintervention scores (paired analysis). By calculating this Δ , we could objectively review the ability of the LS method compared with the traditional FTF method in enhancing suturing skills in this study.

Results

A total of 74 study participants were included in this study, with 37 (50%) participants each in the FTF and LS groups. The characteristics of the study participants are described in [Table 1](#). The mean GPA index of the FTF and LS groups did not show significant differences (mean 3.26, SD 0.21 vs mean 3.20, SD 0.21; $P=.20$).

Table . Study participant characteristics.

Characteristics	Value (N=74)	P value
Sex, n (%)		— ^a
Male	26 (35)	
Female	48 (65)	
Age (years), mean (IQR)	22.4 (21-26)	—
GPA^b index, mean (SD)		.20
FTF ^c	3.26 (0.21)	
LS ^d	3.20 (0.21)	
Overall	3.23 (0.21)	

^aNot applicable.

^bGPA: grade point average.

^cFTF: face-to-face.

^dLS: live streaming.

Table 2 shows the objective evaluation of FTF versus LS effectiveness to enhance participants' skill. There was a significant increase between the preintervention and postintervention DOPS evaluation scores ($P < .001$), and this difference was more apparent in the FTF group. The LS group spent significantly more time performing self-training than the FTF group ($P = .04$).

Table 3 shows the subjective evaluation of teaching method effectiveness. Most students rated the FTF or LS method as

good or very good (FTF: 36/37, 97% and LS: 35/37, 95%). Most students (28/35, 76%) in the FTF group thought that the training improved their skill, while most students (24/37, 65%) in the LS group did not find the training very useful.

Table 4 shows the student assessment of LS method quality. Most students found the first-person-view quality to be good or passable (30/37, 81%). Most students (36/37, 97%) had good or acceptable internet connection, while 1 (3%) student had frequent disconnections.

Table . Objective evaluation of FTF^a versus LS^b effectiveness to enhance participants' skill.

Variable	Value, mean (SD)	Value, range	<i>P</i> value ^c
Overall DOPS^d score			<i><.001</i>

Discussion

Principal Findings

This study aims to prove that first-person-view LS teaching has the same effectiveness compared to traditional FTF teaching in enhancing medical students' practical skills in performing simple wound suturing. As of this writing, no other study has compared these methods before.

We considered these 2 groups to have equal basic abilities prior to their training, as their GPA index and preintervention scores were similar. It is good to see that the overall DOPS scores increased significantly between the preintervention and postintervention periods ($P<.001$), suggesting that the training process generally had good results in enhancing participants' skills regardless of their training method.

However, the posttest scores of the FTF participants were significantly better than those of the LS participants (FTF: mean 86.4, SD 1 vs LS: mean 78.9, SD 15.5; $P=.02$). As seen on the box-plot graph, the data variation in the LS group is wider than that in the FTF group (Figure 2, pink box plot). This wide range of data suggests significant variability in the results in the LS group, ranging from high to poor values (score).

We compared the ability of the LS method to enhance the participants' skills with the FTF method by performing a paired analysis of the numerical differences between each participant's preintervention and postintervention scores (Δ). Based on this analysis, we found that the score increase between the FTF and LS groups was not significantly different (FTF: mean 27.5, SD 20.6 vs LS: mean 24.4, SD 16.7; $P=.48$). Nevertheless, when we observed the data variation as depicted in box-plot graph (Figure 3), we noted that the data spread of the LS group was

narrower in its numerical differences compared to the FTF group, which suggested more limited ability of the LS method to enhance participants' procedural skills compared to the FTF method. The mean score of the 2 groups were 27.5 (SD 20.6) for the FTF group and 24.4 (SD 16.7) for the LS group, which

showed that the FTF group had higher score differences than the LS group. Therefore, we deduced that the LS method was still inferior to the FTF method in enhancing participants' ability to do simple procedural skills.

Figure 2. Box-plot graph of pretest and posttest scores of FTF versus LS group. FTF: face-to-face; LS: live streaming.

Figure 3. Box-plot graph of numerical differences of both groups' scores. FTF: face-to-face; LS: live streaming.

Procedural skills differ from cognitive matters as they need to be mastered and self-trained within some period. We encouraged the participants to train themselves as often as possible in a 1-week period. In an effort to reduce bias, we asked the participants at the end of the 1-week period about their self-training frequency during that period. This analysis showed the LS group had more self-training frequency on average (mean 6.3, SD 3.40 vs mean 4.9, SD 2.3; $P=.048$). It is debatable whether the participants in LS group performed more self-training because they felt compelled to by the LS demonstration as mentioned by Offiah et al [23] or because of something else. It is interesting to see that even though LS participants performed more self-training than FTF participants, they did not acquire the same increase in posttest DOPS scores.

The quality of the instructions given during the FTF and LS methods was also evaluated. Participants were instructed to give feedback regarding the teaching quality, asking if the instructor gave a good, clear demonstration and explanation on the technique. We found that the majority of the FTF group thought that the teaching quality was “very good” (29/37, 78%), but the LS group was dispersed in “very good” (18/37, 49%) and “good” (17/37, 46%) responses. This result may be caused by the FTF group being physically present at the room with the instructor and, therefore, feeling more at ease to ask questions in a natural manner. Although we encouraged the participants in the LS group to actively participate in training sessions, the LS group may have had questions or comments as well but did not express them simply because they felt less engaged in the LS system.

The lack of social interaction, collaborative learning, and teacher-student engagement issues are known to be barriers to online learning [43]. More specifically, the poor engagement between students and instructor in LS settings was also reported in the study of Mill et al [15]. Connectivity problems may also be an issue, as 1 participant in the LS group rated their connectivity as “poor.”

Students were also subjectively asked if their method of training improved their mastery of the skill. In the LS group, most participants (21/37, 57%) said the method did not improve their skills much, while some (3/37, 8%) said it did not improve their skills at all. This contrasted sharply with the perception of the FTF group, where most participants (26/37, 70%) said the method improved their skills a lot. These results are different from the meta-analysis performed by Mao et al [44], which found that skills proficiency improvement was not significantly different between video and conventional methods. Unfortunately, we did not specifically ask which part of the teaching method that the participants were unsatisfied with.

For the LS group, we also inquired about the audiovisual quality of the LS method. Most participants answered with “good” (17/37, 47%) and “passable” (13/37, 36%), reflecting that the quality of the teaching material needed to be enhanced. In the LS method, the participants could not move their viewpoint, head, or body position to get a better picture of what is going on compared to being present in the FTF group. The GoPro itself needed to be adjusted several times during the training due to limited visual ability, causing the participants in the LS group to not see the demonstration clearly. We also thought that the visual exposure in the LS method was still lacking, even when we used the GoPro Hero 8, which came with a 4000-pixel resolution [42,45]. This experience was also noted in LS of neurosurgery cases by Jack et al [46] using the GoPro Hero 5. The LS group also mentioned of an audio delay during the live demonstration, which could be why participants’ opinions of the quality of teaching and the training ability to improve procedural skills were varied. This audio delay is a common problem with the LS method and should be minimized in the future to enhance the effectiveness of LS in teaching procedural skills [47]. Future studies may also consider virtual reality for teaching technical skills, as it is a more immersive experience for the students [48]. Perhaps it is the quality of the teaching materials that needs to be improved to enhance the first-person-view LS method results.

Finally, we asked the participants about their confidence in performing simple wound suturing by themselves after the training. Interestingly, although the majority of both groups are confident, participants of the FTF group were less confident in performing the procedure compared with the LS group (13/37, 35% vs 1/37, 3%). We previously thought that participants of the gold standard FTF teaching method would be more confident in performing the procedure, as this method gives the participant direct visualization of the procedure and better proximity to the instructor to ask questions and, therefore, would impart more

confidence to perform the procedure independently. This finding may be an effect of the first-person-view LS method, since this method puts the viewers directly in the instructor’s field of view, as if they are doing the procedure themselves. This way, the participants felt as if they have done the procedure before and are more confident in performing it independently [19,49]. Another reason may be that the LS group could learn in a more relaxed setting, as they did not have the stress and tension of trying to learn a skill from inside the high-stress environment of an operating theater and, therefore, could enhance their confidence and willingness to practice [50,51].

Limitations

Some methods in this study could be improved. Several confounding factors could not be controlled, such as the exposure of individual students to the practice of suturing when asked to assist their preceptors in surgery during their rotation, or the enthusiasm of some students to perform self-training. As such, we limited the duration between preintervention and postintervention testing to 1 week, to reduce the effects of these factors. The retention of skills over a longer period was not explored here. We were also unable to limit contact and communication between participants from both groups during the 1-week period.

We also noted that 33% (12/37) of the LS participants had a “passable” or “poor” connection when using their own mobile devices, even though the participants were encouraged to use the university internet connection. Connectivity problems need to be more stringently monitored in the future, with all students being required to connect to university Wi-Fi.

We recommend future studies to use higher-quality recording devices to improve the quality of the teaching materials. Each participant has a different learning curve, and therefore, providing a standardized recording of the procedural skill for students would be helpful in giving them a chance to review and gain confidence before they do it independently. Using a prerecorded video to standardize the teaching material could be used, as suggested by Tackett et al [52], although using recorded media will remove the interactive quality of the live-streamed, first-person-view method. The effects of the teaching method on confidence could also be explored, to see if the first-person-view method could independently increase the participants’ confidence.

Conclusions

Using first-person-view LS teaching of simple procedural skills such as simple wound suturing could provide many benefits for the educator, students, and teaching hospital. This method is comparable to standard FTF teaching for improving the students’ skill in performing manual tasks. Teaching a practical skill using the LS method also gives more confidence for the participants to perform the procedure independently. Further improvement to the quality of the recording device, better internet connection, and better teaching materials could improve this method in the future.

Acknowledgments

The authors would like to express our gratitude to Professor Cucunawangsih, PhD, for her help regarding ethical review for this publication; Rhendy Wijayanto, MD; Flora Agustina Situmorang, MD; and Hendry Lie, MD, for their help in conducting the research; Ian Huang, MD, for his help in writing the manuscript; and all surgery clerkship students who were willing to contribute to this research as participants.

Abstract

Background: Generally, cardiopulmonary resuscitation (CPR) skills decline substantially over time. By combining web-based self-regulated learning with hands-on practice, blended training can be a time- and resource-efficient approach enabling individuals to acquire or refresh CPR skills at their convenience. However, few studies have evaluated the effectiveness of blended CPR refresher training compared with that of the traditional method.

Objective: This study investigated and compared the effectiveness of traditional and blended CPR training through 6-month and 12-month refresher sessions with CPR ability indicators.

Methods: This study recruited participants aged ≥ 18 years from the Automated External Defibrillator Donation Project. The participants were divided into 4 groups based on the format of the CPR training and refresher training received: (1) initial traditional training (a 30-minute instructor-led, hands-on session) and 6-month traditional refresher training (Traditional6 group), (2) initial traditional training and 6-month blended refresher training (an 18-minute e-learning module; Mixed6 group), (3) initial traditional training and 12-month blended refresher training (Mixed12 group), and (4) initial blended training and 6-month blended refresher training (Blended6 group). CPR knowledge and performance were evaluated immediately after initial training. For each group, following initial training but before refresher training, a learning effectiveness assessment was conducted at 12 and 24 months. CPR knowledge was assessed using a written test with 15 multiple-choice questions, and CPR performance was assessed through an examiner-rated skill test and objectively through manikin feedback. A generalized estimating equation model was used to analyze changes in CPR ability indicators.

Results: This study recruited 1163 participants (mean age 41.82, SD 11.6 years; $n=725$, 62.3% female), with 332 (28.5%), 270 (23.2%), 258 (22.2%), and 303 (26.1%) participants in the Mixed6, Traditional6, Mixed12, and Blended6 groups, respectively. No significant between-group difference was observed in knowledge acquisition after initial training ($P=.23$). All groups met the

criteria for high-quality CPR skills (ie, average compression depth: 5-6 cm; average compression rate: 100-120 beats/min; chest recoil rate: >80%); however, a higher proportion (98/303, 32.3%) of participants receiving blended training initially demonstrated high-quality CPR skills. At 12 and 24 months, CPR skills had declined in all the groups, but the decline was significantly higher in the Mixed12 group, whereas the differences were not significant between the other groups. This finding indicates that frequent retraining can maintain high-quality CPR skills and that blended refresher training is as effective as traditional refresher training.

Conclusions: Our findings indicate that 6-month refresher training sessions for CPR are more effective for maintaining high-quality CPR skills, and that as refreshers, self-learning e-modules are as effective as instructor-led sessions. Although the blended learning approach is cost and resource effective, factors such as participant demographics, training environment, and level of engagement must be considered to maximize the potential of this approach.

Introduction

Sudden cardiac arrest is a severe condition, particularly when it occurs outside a medical facility, and the corresponding survival rates are very low. In Europe and North America, these survival rates range from 7% to 13%, whereas in Asia, they are even lower at 0.5% to 8.5% [1-3]. Furthermore, these survival rates vary significantly by location and demography. Some countries exhibit higher survival rates, ranging from 20% to 40%. In contrast, according to a database, the survival rate in Taiwan is 8% to 10% [3-6]. Therefore, survival after out-of-hospital cardiac arrest (OHCA) exhibits substantial variability across regions [7].

The survival status for OHCA is closely linked to the Chain of Survival of the American Heart Association (AHA), which emphasizes the early activation of emergency medical services (EMSs), early cardiopulmonary resuscitation (CPR), and early defibrillation as the first 3 critical links [8]. These 3 interventions can be administered in a prehospital setting, and achieving high-quality outcomes following these interventions is pivotal to enhancing OHCA survival rates. Owing to significant disparities in EMSs, bystander CPR rates, and public access to automated external defibrillators (AEDs) in different regions, OHCA survival rates exhibit corresponding variations [7]. However, through CPR training and dispatcher-assisted CPR, the global bystander CPR rate has improved from approximately 20% in 2001 to 40% to 55% in 2023 [9-11]. In Taiwan, the government has implemented legally mandated continuous public CPR education and training programs aimed at improving the response of bystanders to sudden cardiac arrest [12]. This effort has resulted in significant increases in bystander CPR rates and the use of public AEDs [7,13]. Over a decade, 14% and 3.8% increases have been noted in the bystander CPR rate and the use rate of public AEDs, respectively [6,9,14].

Research has demonstrated a significant decline in CPR skills over time, especially regarding chest compression depth and rate [15]. Consequently, maintaining the public's CPR skills and their motivation for learning CPR is challenging. In response to this challenge, the AHA recommended self-directed training

for CPR during the COVID-19 pandemic [16]. Similarly, the European Resuscitation Council recognized blended training models as an alternative to traditional face-to-face teaching models [17,18]. Furthermore, previous studies have indicated that blended training is not inferior to traditional methods and offers advantages such as resource saving and time saving, making it an effective approach for CPR education [15]. By using blended training models, which combine web-based self-guided learning with hands-on practice, individuals can acquire or refresh their CPR skills at their own pace and convenience [15]. Such flexibility fosters increased levels of engagement and enhanced retention of CPR knowledge and thus ultimately enhances the public's preparedness for treating sudden cardiac arrests. Therefore, blended approaches are valuable both during a pandemic and when in-person training cannot be conducted, ensuring widespread CPR education for a broad audience [19].

Limited research has been conducted regarding the effective implementation of relearning stimuli to maintain CPR skills within the framework of blended training. Therefore, the primary objective of this study was to provide relearning stimuli in a blended training setting after using both traditional and blended teaching methods; this study also investigated the effectiveness and most appropriate frequency of blended training. Finally, this study compared learners' performance in 2 educational settings. We hypothesized that using the blended method with 6-month interventions would yield outcomes comparable to those achieved through the traditional method.

Methods

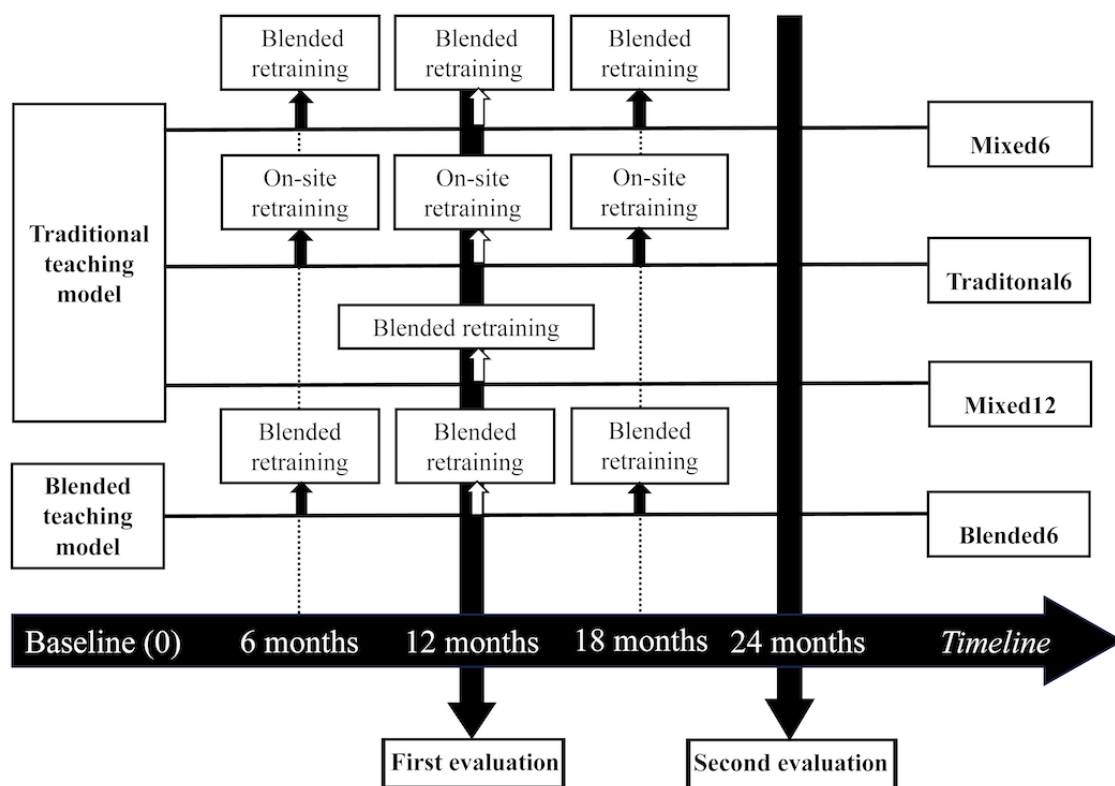

Study Design, Setting, and Participants

This study used a prospective observational design, and participants were recruited from the AED Donation Project, also called the Love GOGO program, implemented by Chang Gung Memorial Hospital, Taiwan. The Love GOGO program aims to establish an educational training system for CPR and build a comprehensive teaching database encompassing participants' attributes, learning models, and CPR parameters. Individuals from government agencies, nonprofit organizations,

schools, and organizations required by current Taiwanese regulations to have AED facilities participate in this education and training program. These include transportation hubs, large long-distance vehicles, tourist spots, schools or large assembly places, large leisure places, large shopping malls, hotels, large public bathhouses, hot springs, and public service sectors such as police stations. These organizations voluntarily participated in the Love GOGO program and proactively contacted the research assistant (YTK) of this study. For this study, participants were enrolled in the Love GOGO program from January to December 2017. Based on our previous study, both traditional and blended teaching models showed a noticeable decline in skill retention after approximately 6 months [12,15]. In this study, mandatory retraining was administered every 6

months or 1 year (Figure 1), spanning a comprehensive training regimen conducted over 2 years. In the initial training phase, the participants were assigned to either traditional teaching or blended teaching modes. Learning effectiveness assessments were conducted every 12 months, with a retraining frequency of 6 or 12 months. Before refresher courses but following initial training, each group underwent evaluation at 12 and 24 months. The results of the 12-month learning effectiveness assessment were disclosed only at 24 months. The research assistants independently allocated training methodologies and the frequencies of subsequent follow-up assessments, using unit convenience and considering the practicalities of the study context. Those responsible for the execution of course training and assessments were not involved in the allocation process.

Figure 1. Schematic diagram illustrating the arrangement of four training courses: Mixed6, Traditional6, Mixed12 and Blended6.

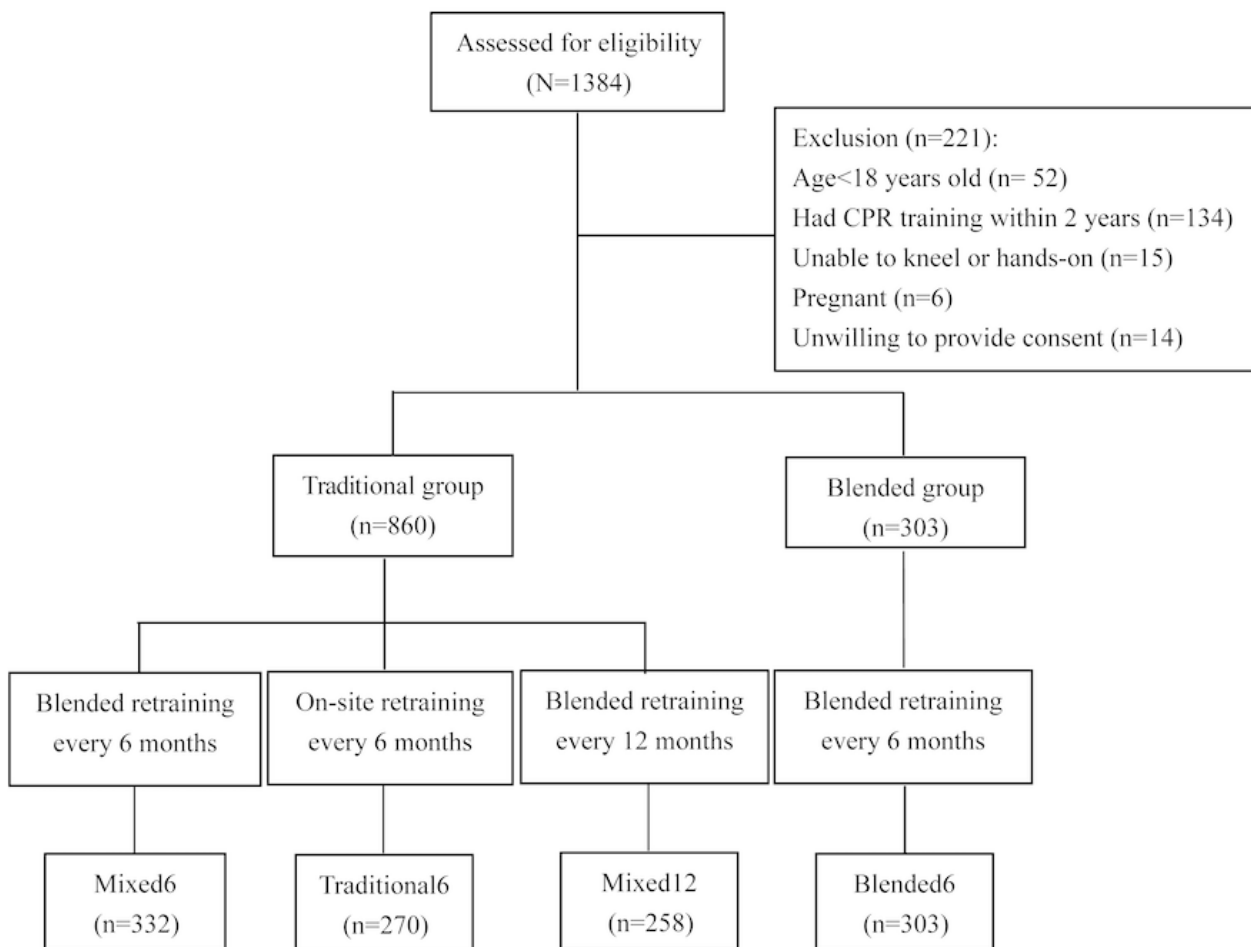

The inclusion criteria are described as follows: (1) aged at least 18 years and (2) not having undergone any CPR training within the preceding 2 years. Individuals who had physical limitations preventing them from kneeling to perform CPR, who were pregnant, or who were unwilling to sign the informed consent form were excluded from this study. Before initial training, the research assistant divided the participants into groups, and their basic characteristics—namely age, sex, educational level, exercise habits, whether they were receiving CPR training for the first time, their most recent CPR training, and their basic life support (BLS) knowledge scores—were collected through a web-based survey. The assessment of CPR learning should encompass the status of both knowledge and skills. After initial training but before refresher training, we collected data regarding BLS knowledge, skill tests, and CPR quality at the scene at 12

and 24 months. The BLS knowledge and skill tests received approval from the Chairman of the Taiwan Society of Emergency Medicine and have also been published in previous studies [12,15] (Multimedia Appendices 1 and 2).

Ethical Considerations

This study was approved by the institutional review board of the Chang Gung Memorial Foundation (approvals: 201600149B0, 201900399B0, 202200559B0, CMRPG1M0081, and CMRPG1N0081), and this study was performed in accordance with relevant guidelines and regulatory requirements. The IGOGO database is anonymized or deidentified, and no type of compensation is provided to participants. Written informed consent was obtained from all the participants (Figure 2).

Figure 2. Flow diagram of participants' inclusion and allocation. CPR: cardiopulmonary resuscitation.

Sample Size

An appropriate sample size for this study was estimated based on a pilot study, in which the expected percentage of correct compression depth was 65.4 (SD 29.5) cm for traditional training. To achieve a statistical power of 90% by using a 2-tailed *t* test with a significance level of $P < .05$, each group was required to have 225 participants. We planned to enroll at least 900 participants in total.

Interventions

The Love GOGO program offers 2 teaching models for CPR training: the traditional instructor-led, classroom-based model and the blended model. In the traditional model, participants undergo a 90-minute session, which includes a 60-minute CPR knowledge education session involving a CPR lecture and demonstration, an AED use demonstration, an introduction to relevant laws, and a 30-minute hands-on practice session focusing on compression-only CPR. The blended program, which was approved by the Chairman of the Taiwan Society of Emergency Medicine in 2016, combines an 18-minute e-learning module with a 30-minute hands-on session for compression-only CPR. The e-learning module comprises a video that covers essential knowledge related to CPR and AEDs, including knowledge related to cardiac arrest scenes, the technique of

compression-only CPR, the benefits of using CPR and AEDs for OHCA treatment, CPR and AED use steps, and an introduction to relevant laws. In this study, the participants assigned to the blended program were granted access to the e-learning video 3 days before the hands-on session. After completing the e-learning module, the participants practiced their skills in a 30-minute instructor-led, hands-on session in a classroom setting. Both CPR training programs were conducted by AHA instructors who were also emergency physicians. For hands-on CPR practice, both groups used sensor-equipped manikins (Resusci Anne with QCPR, Laerdal Medical AS). The participant-to-manikin-to-instructor ratio per class was 6:3:1, involving 4 instructors and 6 examiners. The study team provided different certification learning stimuli (traditional and blended learning) at 2 frequencies: every 6 months (at 6, 12, 18, and 24 months) and every 12 months (at 12 and 24 months). To establish groups with unique frequencies, the research assistant (YTK) conducted allocation during the initial training phase. Therefore, the traditional teaching model was applied for initial training, and certification sessions for retraining occurring every 6 or 12 months were conducted using either the blended retraining model (18-minute e-learning module with self-hands-on practice for compression-only CPR) or the on-site retraining model (30-minute instructor-led, hands-on

session). These groups were called Mixed6 (initial traditional training and 6-month blended refresher training), Traditional6 (initial traditional training and 6-month traditional refresher training), and Mixed12 (initial traditional training and 12-month blended refresher training). For the Blended6 group, initial training was conducted using the blended teaching model, and for certification stimuli every 6 months, the blended retraining model was applied (Figure 1).

Outcome Measures

This study systematically assessed the participants' CPR knowledge and performance at multiple time points. Initially, the CPR knowledge and performance of the participants were assessed immediately after training. Following initial training but before refresher training, subsequent evaluations of knowledge and performance were conducted at 12 and 24 months. CPR knowledge was examined through a written test comprising 15 multiple choice questions, with a maximum total score of 100. CPR performance was assessed through 2 methods: examiner-rated assessment and manikin feedback. Individual examiners meticulously assessed the participants' ability to execute the BLS sequence, encompassing tasks from verifying scene safety to using an AED, with a maximum total score of 40. Objective assessment data regarding CPR quality—including compression depth, compression rate, and full chest recoil—were collected from manikin feedback. The assessment adhered to the 2015 AHA guidelines update for CPR and emergency cardiovascular care; high-quality CPR was characterized by the following three criteria: (1) achieving a compression depth of 5-6 cm, (2) maintaining a compression rate of 100-120 beats per minute (bpm), and (3) facilitating complete chest wall recoil of >80%. Notably, because of the focus on compression-only CPR, ventilation was excluded because it was therefore beyond the scope of the assessment in this study. The primary outcome measure was the comparison of high-quality CPR among the 4 groups. Secondary outcome measures were differences in the percentage of full chest recoil, the percentage of compressions delivered with adequate depth (5-6 cm), the percentage of compressions delivered at an adequate rate (100-120 bpm), written test scores, and examiner-rated skill test scores.

Statistical Methods

Descriptive statistics are expressed as mean (SD) for continuous variables and as counts and percentages for categorical variables. Linear regression analysis was conducted to determine any differences in the mean values of baseline characteristics among the groups, with adjustment for control variables—namely age, sex, educational level, exercise habits, whether CPR training was being received for the first time, most recent CPR training, and pretest BLS knowledge scores, which were based on the significance test result and which were proposed in previous research [12,15,20]. After allocation, differences in characteristics among groups were observed. To mitigate potential biases introduced by this allocation method, we applied multiple linear regression analyses and generalized estimating

equation (GEE) to adjust for these variations when evaluating outcomes (Multimedia Appendices 3 and 4). The chi-square test was used to assess the differences in proportions among the groups, and the general linear model, such as analysis of covariance, was used to test differences among the groups. The control variables—namely age, sex, educational level, exercise habits, whether CPR training was being received for the first time, and pretest BLS knowledge scores—may have influenced skill retention and test scores. Therefore, the model was adjusted for these variables.

We conducted the assessments of the participant's skill levels and BLS knowledge scores at multiple time points. Accordingly, we used a GEE to examine changes over time in CPR ability indicators among the groups. This allows us to comprehend the changes in CPR skills among trainees under different training methods, using a GEE model to analyze the change over time in CPR ability indicators among groups. The GEE analysis was adjusted for the control variables. To ensure fairness, statistical analysis was conducted using data obtained at time points specific to each group. That is, only data from the postinitial training (baseline), 12-month, and 24-month assessments were included in the analysis.

CPR performance is displayed by line charts, bar charts, and radar charts. In particular, we generated radar charts to illustrate the relative CPR performance in each session. The scores were converted using percent ranking, and the average score was then calculated to represent the performance of each skill for each training method. Statistical analysis was conducted using SPSS Statistics (version 26.0; IBM Corp) and STATA (MP 16.0; Stata Corp LLC).

Results

Baseline Characteristics

A total of 1163 participants were recruited for this study, and they were allocated to 4 training groups. The mean age of the participants was 41.82 (SD 11.6) years, and 62.3% (n=725) of participants were female. In this study, 332 (28.5%), 270 (23.2%), 258 (22.2%), and 303 (26.1%) participants were placed in the Mixed6, Traditional6, Mixed12, and Blended6 groups, respectively. Table 1 displays the baseline characteristics of these 4 training groups. As this study was observational rather than randomized, significant differences were observed among the 4 training groups in terms of age ($P<.001$), sex ($P=.008$), educational level ($P=.006$), and CPR training experience ($P<.001$; Table 1). Notably, the Traditional6 group had the highest average age (45.30, SD 11.39 years) and consisted of 68.9% (186/270) female participants. Additionally, this group had the highest proportion of individuals receiving CPR training for the first time (92/270, 34.1%). However, no statistically significant difference was observed in the BLS pretest knowledge score ($P=.11$), with an overall mean score of 67.96 (SD 15.08); this finding indicated similar baseline performance across the groups before BLS training.

Table 1. Baseline characteristics of the 4 training groups.

Variables	Mixed6 (n=332)	Traditional6 (n=270)	Mixed12 (n=258)	Blended6 (n=303)	<i>P</i> value
Age (years), mean (SD)	40.78 (9.97)	45.30 (11.39)	40.72 (12.34)	40.78 (12.28)	<.001 ^a
Sex, n (%)					.008

^cBLS: basic life support.

Posttraining Assessment

According to the results of the objective assessment after the first training session, significant differences were found among the 4 groups in skill tests ($P=.002$), average chest compression depth ($P<.001$), and average compression rate ($P<.001$; [Table 2](#)) after adjustment for the control variables in the multivariate analysis ([Multimedia Appendix 5](#)). In the multivariate analysis, higher skill test scores were associated with younger age ($P=.003$), higher educational level ($P<.001$), more previous CPR training experience ($P=.04$), and higher BLS pretest scores ($P=.004$). Furthermore, the average compression depth was significantly associated with age ($P=.02$) and sex ($P<.001$), and

the average compression rate was significantly associated with educational level ($P=.04$) and CPR training experience ($P=.02$). Although the mean chest compression depths differed among the 4 groups, the proportion of participants achieving the correct chest compression depth did not differ on average ($P=.11$). For the overall performance assessment, the proportion of participants achieving high-quality CPR ranged from 27.4% (91/332) to 32.3% (98/303). The lowest proportion was observed in the Mixed6 group, and the highest proportion was found in the Blended6 group. In the multivariate analysis, high-quality CPR was negatively correlated with the Mixed12 training method (adjusted odds ratio 0.65, 95% CI 0.45-0.93; $P=.02$; [Multimedia Appendix 6](#)).

Table 2. Postinitial training evaluation (baseline) for the 4 training groups.

Variables	Mixed6 (n=332)	Traditional6 (n=270)	Mixed12 (n=258)	Blended6 (n=303)	<i>P</i> value ^a
BLS ^b knowledge score, mean (SD)	86.05 (11.38)	84.61 (12.96)	86.76 (11.79)	84.10 (11.19)	.23
Skill test, mean (SD)	35.09 (3.26)	35.81 (2.78)	35.73 (3.76)	35.26 (4.05)	.002 ^c
Average chest compression depth (cm), mean (SD)	5.07 (0.74)	5.01 (0.73)	5.23 (0.43)	5.33 (0.57)	<.001
Average chest compression rate (times per minute), mean (SD)	113.88 (13.87)	110.56 (14.34)	116.07 (11.33)	116.65 (10.28)	<.001
Correct compression depth, mean (SD)	70.79 (32.83)	71.24 (30.55)	74.75 (32.21)	75.88 (33.31)	.11
Correct compression rate, mean (SD)	61.14 (31.87)	66.16 (30.57)	68.61 (34.15)	61.98 (34.94)	.01
Correct recoil, mean (SD)	84.39 (35.29)	87.16 (30.32)	79.72 (37.57)	80.35 (35.65)	.20
High-quality CPR ^{d,e} , n (%)	91 (27.4)	86 (31.8)	77 (29.8)	98 (32.3)	.52

^aThe *P* value was obtained from the general linear regression model adjusted for age, sex, educational level, exercise habits, whether CPR training was being received for the first time, and BLS pretest knowledge score.

^dCPR: cardiopulmonary resuscitation.

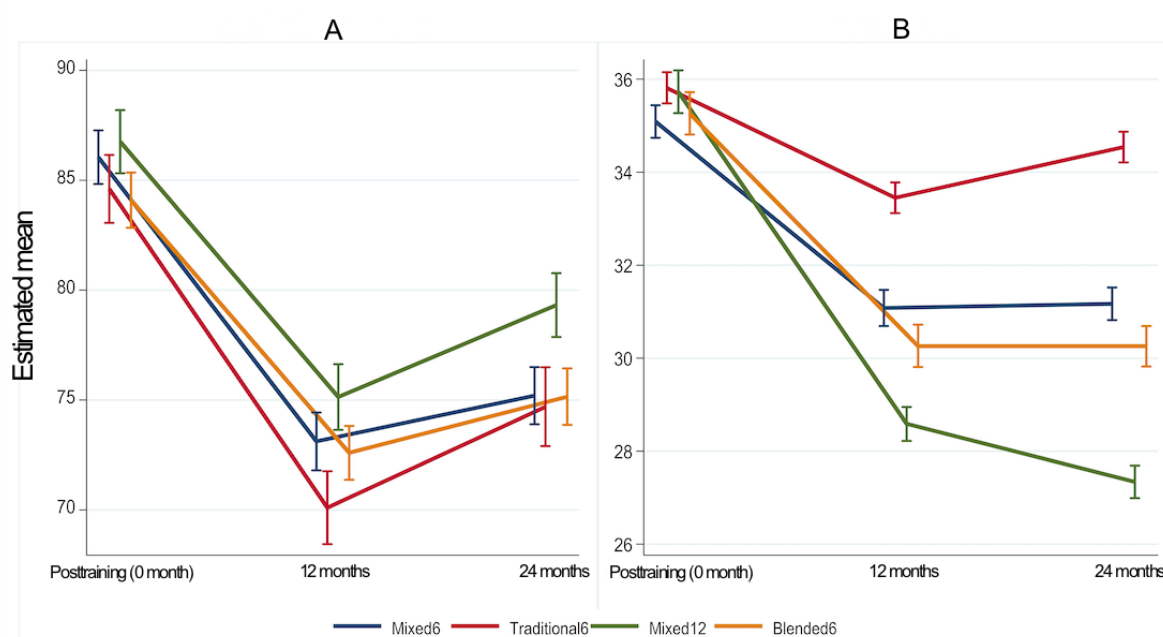

^e*P* values obtained from the chi-square test. High-quality CPR was denoted by an average compression depth between 5 and 6 cm, an average compression rate of 100-120 beats per minute, and 80% chest recoil.

Posttraining Follow-Up and Maintenance

Multimedia Appendix 7 provides the descriptive statistics for the posttraining follow-up data. The results revealed that the Mixed12 group exhibited consistent BLS knowledge scores at baseline (postinitial training), with the highest average scores observed at 12 and 24 months after training. The Traditional6 group exhibited the highest average scores on the skill test at all 3 measurement time points. Figure 3 illustrates the estimated

mean scores of BLS knowledge and skill tests for each group, as assessed over time using GEE models. At 12 months after initial training, the Traditional6 group had the lowest average BLS knowledge score (mean 70.10, SE 0.854), which was significantly different from that of the Mixed12 group (mean 75.14, SE 0.762; Figure 3A presents a nonoverlapping 95% CI). Subsequently, at 24 months following initial training, the Mixed12 group exhibited significantly higher scores (mean 79.32, SE 0.741) compared with the other groups.

Figure 3. Estimated mean scores with 95% CI for (A) BLS knowledge and (B) skill tests in different training courses by generalized estimating equation models. BLS: basic life support.

Furthermore, at baseline, a notable difference was observed in the average scores of the skill tests between the Mixed6 and Traditional6 groups ($P=.003$; Figure 3B shows a nonoverlapping 95% CI). Moreover, in the follow-up assessment, the Traditional6 group exhibited significantly higher scores than the other groups. Table 3 presents the proportion in each group for the achievement of high-quality CPR. At 12 and 24 months after initial training, this proportion in the Mixed12 group exhibited the most substantial decrease compared with those at

12 and 24 months after training. At baseline, no substantial differences were observed in these proportions among the 4 groups. However, no substantial differences were observed among these proportions among the Blend6, Mixed6, and Traditional6 groups at 12 or 24 months after initial training. We concurrently used multiple linear regression and GEE models to examine the performance indicators; the corresponding results are provided in Multimedia Appendices 5, 6, 8, and 9.

Table 3. Proportions of the achievement of high-quality CPRa at 0, 12, and 24 months after training for the different training courses.

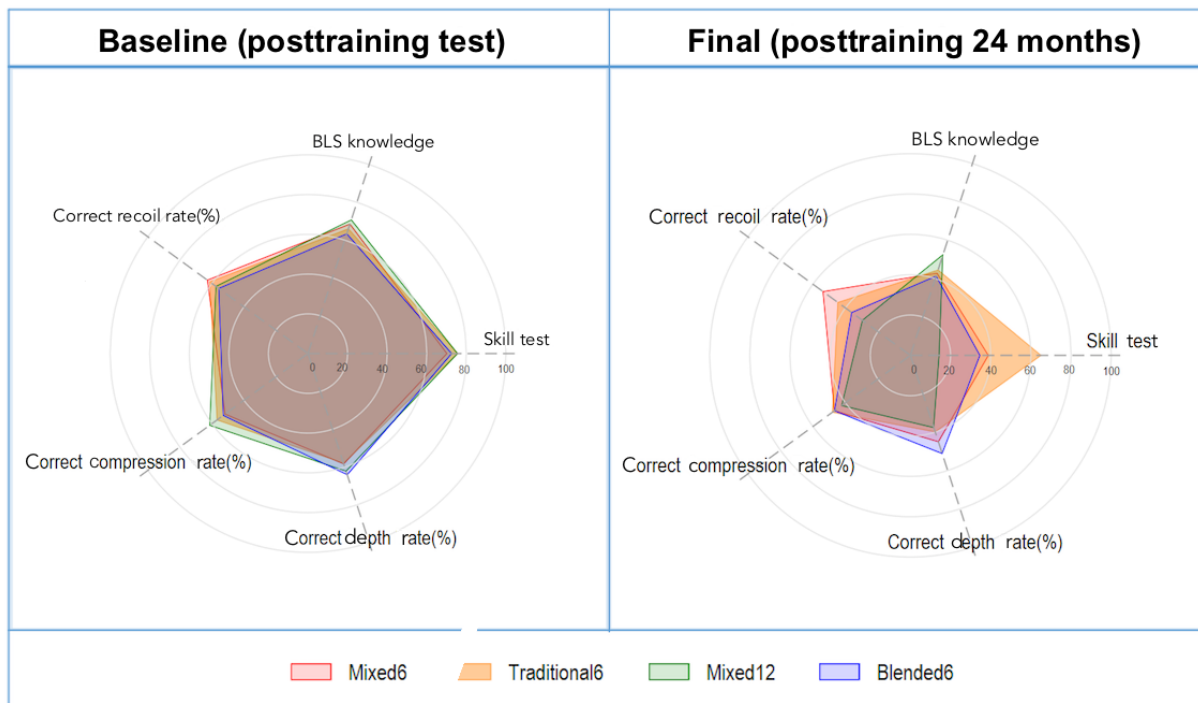

Variables	Mixed6 (n=332), n (%)	Traditional6(n=270), n (%)	Mixed12 (n=258), n (%)	Blended6 (n=303), n (%)
Posttraining (0 month)	91 (27.4)	86 (31.9)	79 (30.6)	98 (32.3)
Posttraining (12 months)	83 (25)	61 (22.6)	2 (0.8)	63 (20.8)
Posttraining (24 months)	79 (23.8)	53 (19.6)	7 (2.7)	84 (27.7)

^aCPR: cardiopulmonary resuscitation.

We used an alternative method to rank the 4 training methods based on objectively evaluated items. The scores were converted using percent ranking, and the average score was then calculated to represent the performance of each skill in each training method. Subsequently, we visualized the results as a radar chart (Figure 4). Overall, the 4 groups exhibited comparable average performance in the tests after the first training session. However, in the follow-up assessment (ie, 12 and 24 months after training), differences emerged among the groups (Multimedia Appendix

10). The Traditional6 group exhibited outstanding performance in the skill test and correct recoil rate. The Blended6 group demonstrated superiority in correct depth rate, whereas no significant difference was observed between the Blended6 and Traditional6 groups in terms of correct compression rate or high-quality CPR achievement. The Mixed12 group exhibited a lower correct recoil rate, compression rate, depth rate, and skill test performance compared with the other 3 groups.

Figure 4. Radar charts for posttraining evaluation at baseline and final visit (posttraining 24 months). BLS: basic life support.

Discussion

Principal Findings

This study provides 3 major findings regarding the effectiveness of traditional and blended training methods for CPR education. First, no significant difference was observed in knowledge

acquisition after initial training, and all the training groups exhibited proficient CPR skills that met the requirements for high-quality CPR. However, a higher proportion of participants receiving blended training initially achieved high-quality CPR; this finding served as the basis for our comparative analysis. The second major finding highlights the importance of timely

retraining. When retraining was conducted 12 months after initial training, significant decreases were observed in the proficiency of CPR skills and the proportion of participants achieving high-quality CPR. Our third major finding suggests that more frequent retraining could maintain CPR skills more effectively. The participants who underwent retraining every 6 months exhibited slight decreases in their proficiency in CPR skills and their achievement of high-quality CPR. Additionally, we explored the potential of web-based self-directed learning as an alternative, and this learning method demonstrated effectiveness for skill retention regardless of the initial training method (traditional or blended), with no significant difference observed between the 2 methods.

Research has demonstrated that blended learning and traditional CPR methods [19,21,22] are practical and reasonably effective alternatives to traditional CPR training; however, large-scale comparisons of these methods or the integration of these instructional methods into CPR education have not been conducted. To the best of our knowledge, this study was the first study to demonstrate that blended learning and retraining stimuli are not inferior to traditional methods when it comes to CPR performance. Chien et al [15] found that blended learning for CPR training does not have inferior learning outcomes relative to traditional methods but that CPR skills at 6 months did not meet the AHA's CPR guidelines. This finding was consistent with our findings. Although traditional instruction may lead to slightly more favorable performance initially, providing self-directed blended learning stimuli every 6 months is effective for maintaining CPR skills. We found that among learners who received CPR training every 12 months, the performance of high-quality CPR decreased by 35% more than that of those retrained every 6 months. Therefore, consistent with previous research recommendations, stimulating learning every 6 months appears to be favorable to doing so every 12 months. This observation aligns with the AHA's 2020 guidelines, which suggest that for the general public, the use of convenient learning methods alongside retraining is a viable alternative to traditional face-to-face CPR training.

The blended learning method used in this study offers considerable economic benefits and is time saving for both learners and instructors. By incorporating 18 minutes of web-based learning and self-training into a course, the face-to-face instruction and relearning time were collectively shortened by approximately 72 minutes initially and by 12 minutes in subsequent training. These decreases reduced the expenditure, human resources, and time requirements for learners and instructors in CPR training courses [21]. One study investigated the cost-effectiveness of blended learning for CPR training; the results revealed that blended learning decreased training costs while achieving similar maintenance of CPR skills relative to the traditional method [23]. However, some researchers have indicated that despite the costs and time reductions offered by blended learning, such learning does not ensure that participants will acquire further professional knowledge and proficiency in a demanding training environment [22]. The maintenance of CPR skills contributes to the willingness of the public to perform CPR. When EMSs are activated, guiding individuals to identify cardiac arrest and to

implement CPR with dispatcher assistance is challenging as is ensuring that members of the public are able to perform high-quality CPR [24]. Accordingly, blended teaching and retraining models, which appear to be as effective as traditional learning models, can address the challenge of instructing individuals during emergency calls. The characteristics of blended teaching models, including time saving and environmental efficiency, can be beneficial for promoting CPR education among the public and for addressing challenges in maintaining CPR skills among the public.

In this study, 95.1% (1106/1163) of the participants were high school graduates who were approximately 40 years old and who exhibited higher learning and web-based operating abilities. This demographic advantage likely contributed to the success of blended learning in this study. Moreover, this study used a participant-to-manikin ratio of 2-3:1, leading to higher costs compared with the traditional method (1 manikin to 6 students). The increased investment in training infrastructure may affect the overall cost-effectiveness of blended learning in various settings. The study did not record the frequency of learners' usage of blended relearning stimuli; the effectiveness of self-paced web-based learning may be related to the time spent engaging with the material. Nevertheless, the primary objective of blended web-based learning is to enable individuals to learn at their convenience. In contrast to traditional face-to-face classroom learning, in blended learning, participants have the flexibility to arrange their web-based and in-class training according to their convenience and location. Accordingly, this learner-centric approach can lead to an environment that is more conducive to the maintenance of CPR skills.

In this study, favorable exercise habits and previous CPR learning experiences enhanced the effectiveness of CPR training. Even if learning had occurred more than 2 years previously, blended CPR training could effectively maintain CPR skills. Ettl et al [20] found that incorporating CPR learning into fitness exercise training increased learners' motivation and confidence in performing CPR. Therefore, establishing exercise habits helps maintain CPR skills and for fostering rescue skills.

Finally, although blended learning with a retraining frequency of 6 months demonstrated significant economic benefits and time-saving ability in this study, its cost-effectiveness depended on factors such as participant demographics, the training environment, and the level of engagement with web-based learning opportunities. Accordingly, consideration of these factors could maximize the potential of blended learning in various CPR training scenarios.

Limitations

This study had some limitations. First, in observational studies, the random allocation of samples is infeasible and could result in disparities between groups. Consequently, we used a multivariate regression model to mitigate the impact of variables; thus, we impartially assessed the differences between the groups. Moreover, this study involved tracking the training status of each group to understand the importance of the interval between retraining sessions and whether the given training method was appropriate. Second, we collected demographic data from a subset of learners, but our comprehension of these

learners' economic backgrounds and technology use was limited; consequently, whether blended learning is effective among individuals with relatively low socioeconomic status should be further explored. Third, our research cohort lacked the representation of older adults. As a result, uncertainties persist regarding the applicability of blended training for this demographic; accordingly, future studies are recommended to address this crucial gap. Finally, the absence of an analysis of the participants' willingness to perform CPR leaves a significant

gap in our understanding. Accordingly, individuals' willingness to administer CPR after blended retraining should be investigated in future research.

Conclusions

Blended learning for CPR with a retraining frequency of 6 months provides higher retention of high-quality CPR skills than does retraining every 12 months. Notably, the blended method demonstrated effects similar to those of traditional relearning methods.

KEYWORDS

AI; artificial intelligence; ChatGPT; medical education

The editorial *ChatGPT in Medical Education: A Precursor for Automation Bias?* by Nguyen [1] is very timely, appropriate, and informative. Being a medical student myself, I find that it gives a balanced view on the use of ChatGPT, which is sweeping across the globe at a spectacular pace. One of the hallmarks of this tool is that it is almost universally accessible, even in parts of the world where there may be limited access to quality medical education. As authors have rightly pointed out, ChatGPT is useful for summarizing information, generating practice questions, and giving instantaneous feedback [2-4], and it could serve as an effective personalized tutor. It provides high-quality scientific text gleaned from a quick and comprehensive review of the literature and presents text in an efficient, readable, and versatile style [1]. It is no wonder that it is gaining immense popularity among students, including medical students, who are “burdened with the impossible task of balancing the need to continuously learn and retain competencies and the need to provide compassionate patient care,” as aptly underscored in the editorial [1].

The downside of this powerful tool has also been well portrayed. There is a very real risk of automation bias, especially among medical students in the younger generation, who are digitally savvy but often lack experience and confidence in their clinical skills. The blind dependence on ChatGPT and other artificial intelligence (AI) tools could corrode their thinking and decision-making skills and lead to erroneous medical outcomes. The clinical setting is undoubtedly the best classroom for

students to develop the skills for understanding and accommodating the needs, expectations, and values of patients and their caregivers in the real-world scenario, as well as cultivate leadership qualities and work in a team. It is vital for us students to retain our originality, identity, and critical analytical skills to avoid falling into the trap of AI solutionism.

The need for AI education at this crucial juncture has been well brought out. At present, only a minority of students have received AI education [5]. Incorporating it into the medical curriculum is a challenging, multidisciplinary endeavor. Knowing how and when to use this powerful tool in a responsible manner, without clouding clinical judgment and in keeping with the tenets of medical ethics, is paramount. I agree with Nguyen's [1] view that ChatGPT should be used as a supplementary tool rather than as the default resource for medical education. There is a need to exercise vigilance in the utilization of this tool right from the formative years of medical professionals.

AI is here to stay, and ChatGPT will undoubtedly have an all-pervading influence on medical education and the practice of medicine itself. Therefore, its optimal utilization is the need of the hour. Imparting AI education would help unleash the power of ChatGPT, but appropriate pre-emptive measures to keep its disruptive potential in check are needed to pave the way for an AI-savvy generation of medical professionals with sound clinical judgment and skills.

digital competence; telehealth; nursing; health care workforce; health care professionals; informatics; education; curriculum; interdisciplinary education; health care education

We read with great interest the article by Rettinger et al [1], "Telehealth education in allied health care and nursing: web-based cross-sectional survey of students' perceived knowledge, skills, attitudes, and experience," recently published in *JMIR Medical Education*.

The authors, addressing an extremely current topic, highlight the need to integrate telehealth into health care education curricula. More generally, we think that the development of digital competence is essential for all health care professionals. The digitalization of care processes requires ever-greater digital skills to ensure high-level care suited to current knowledge. Another recent investigation [2] summarizes the educational intervention methods that have been implemented to develop digital competence and the effects of these educational interventions on health care workforce; this study suggests the best method for enhancing the digital skills of nurses and allied professionals in the context of continuing professional education. This research turned attention to the active workforce, who need to adapt their knowledge to renewed working contexts where digital technology is forcefully entering. However, we must note, as emphasized by Rettinger et al [1], that our curricula often neglect the need to equip health care degree students with adequate digital skills. We observe that few of our students are keeping up with the development of technology. Digital skills

can range from the simplest to the most sophisticated technological applications commonly used in a hospital environment, including the use of virtual simulators and extending to artificial intelligence, which, especially in the coming years, will become a precious tool for improving care processes [3]. Even for delivering high-quality care in digitally enabled health care environments, nursing informatics competency is a required core competency [4]. In light of this, it would be necessary to introduce programs dedicated to the acquisition of these skills into our study courses; these programs could be spread across all curricular disciplines. To achieve these objectives, it is necessary to ensure that teachers have the necessary skills in this field or have the ability to acquire them to pass them on to their students. We are well aware that the nursing profession is going through a period of crisis and that it is essential to implement all available forces and strategies to renew it, making it attractive and satisfying again [5]. There are numerous proposals for this renewal, and they must also address the active workforce; however, the updating of the study contents for degree courses in health professions must be one of the first and fundamental steps to achieve these results. The acquisition of adequate digital skills is a necessity that can no longer be postponed to train professionals capable of providing the best levels of care possible today.

ChatGPT; undergraduate medical education; large language models

We thank the authors for their thoughtful comments on our paper titled, "Anki Tagger: A Generative AI Tool for Aligning Third-Party Resources to Preclinical Curriculum" [1,2]. The authors' discussion of the ethical issues and limitations of generative artificial intelligence is both timely and important. As the capabilities of ChatGPT and other similar tools evolve, so must our conversations about the use of generative artificial intelligence in medicine and medical education.

With respect to the production of educational materials for medical trainees, ChatGPT's ability to "hallucinate" and thereby provide misinformation should be of particular concern to educators. For example, when asked to summarize the research output of 50 scientists and cite relevant literature related to Chagas disease, ChatGPT made a major error in 86.7% of its outputs [3]. The problem of hallucination is more pronounced with smaller training data sets and may therefore disproportionately affect medical education content related to rare diseases, which are emphasized in licensing examinations. The problem of hallucination remains a substantial barrier to the widespread use of generative artificial intelligence in medical education.

We circumvented the issue of hallucination by embedding existing Anki flashcard decks in a large language model, rather than prompting ChatGPT to generate flashcards de novo from

scientific literature [1]. Anki flashcard decks are among the third-party resources used by medical students to bridge perceived gaps in school curricula, especially regarding preparation for the USMLE (United States Medical Licensing Examination). Medical students report feeling overwhelmed with the number of third-party resources at their disposal and experience tension between these resources and their in-house curricula [4]. Their educators experience tension among different domains of responsibility including clinical practice, research, professional development, and education [5]. Therefore, it is beneficial to both teachers and students for medical education to be as efficient as possible. To this end, ChatGPT can organize and stratify third-party learning resources by relevance to lectures and other curricular elements [1].

While the integration of third-party resources into lesson plans for undergraduate medical education may be controversial, it is important to note that medical students are already using third-party resources instead of lectures by clinical educators [4]. Instead of viewing these learning materials as competition, our application of ChatGPT suggests the possibility of integrating third-party resources into existing medical curricula. Future studies should examine the impact of such an intervention on medical students' academic performance and satisfaction as well as medical educator burnout.

A recent study explored the novel application of generative artificial intelligence's (GAI's) capabilities with regard to Anki using a new methodology ("Anki Tagger"), leveraging OpenAI's ChatGPT-3.5 to tag and stratify flashcards from the AnKing deck, which are most aligned with a medical school's curriculum and involve a minimal cost and time expenditure [1]. To the best of our knowledge, their work represents the first publication demonstrating early proof of concept of GAI applied to Anki, a spaced repetition flashcard application designed to promote long-term retention of learned content. A major benefit of their approach is the ability to streamline and automate the otherwise time-consuming and resource-intensive process of manually comparing medical school curricula against the widely used and crowdsourced AnKing deck.

Medical students who use Anki may use decks prepared by more senior students at their medical school, the AnKing deck (a reputable and comprehensive set of >35,000 flashcards and growing daily, collaboratively maintained largely by current and graduated medical students), or a combination thereof. Research indicates that daily Anki use is associated with increased USMLE (United States Medical Licensing Examination) Step 1 scores and higher sleep quality—indicators of academic performance and personal well-being, respectively [2]. Given the prevalent usage and growing adoption of Anki among medical students, applications of GAI and large language

models (LLMs) to Anki workflows may be beneficial. Even considering their present shortcomings, LLMs may provide a unique opportunity to significantly impact medical education in the intermediate term, especially given the propensity of contemporary medical students to supplement didactic learning with web-based learning resources [3].

Furthermore, LLMs with GAI capabilities, such as ChatGPT and Med-PaLM, have the potential to answer medically related questions [4] and—intriguingly for the medical education community—can pass the USMLE [5]. Such a notable feat by LLMs necessitates reevaluation of the future of medical training and practice while carefully considering the relevant ethical issues and current limitations of GAI, such as their susceptibility for generating misinformation through a process known as "hallucination." As GAI and LLMs become increasingly integrated in daily practice, similar and iteratively improved methodologies represent a way for educators and learners alike to benefit considerably by better aligning flashcards from the comprehensive AnKing deck with in-house curricula in preparation for medical licensing examinations such as USMLE Step 1. Future applications of GAI in undergraduate medical education may involve the implementation of AI-assisted features directly built into preferred educational tools and resources, allowing students increased customization with options for multimodal output beyond solely text.

Abstract

Background: Previous studies have predominantly measured e-professionalism through perceptions or attitudes, yet there exists no validated measure specifically targeting the actual behaviors of health care professionals (HCPs) in this realm. This study addresses this gap by constructing a normative framework, drawing from 3 primary sources to define e-professional behavior across 6 domains. Four domains pertain to the dangers of social networking sites (SNSs), encompassing confidentiality, privacy, patient interaction, and equitable resource allocation. Meanwhile, 2 domains focus on the opportunities of SNSs, namely, the proactive dissemination of public health information and maintaining scientific integrity.

Objective: This study aims to develop and validate 2 new measures assessing the e-professional behavior of doctors of medicine (MDs) and doctors of dental medicine (DMDs), focusing on both the dangers and opportunities associated with SNSs.

Methods: The study used a purposive sample of MDs and DMDs in Croatia who were users of at least one SNS. Data collection took place in 2021 through an online survey. Validation of both indexes used a formative approach, which involved a 5-step methodology: content specification, indicators definition with instructions for item coding and index construction, indicators collinearity check using the variance inflation factor (VIF), external validity test using multiple indicators multiple causes (MIMIC) model, and external validity test by checking the relationships of the indexes with the scale of attitude toward SNSs using Pearson correlation coefficients.

Results: A total of 753 responses were included in the analysis. The first e-professionalism index, assessing the dangers associated with SNSs, comprises 14 items. During the indicators collinearity check, all indicators displayed acceptable VIF values below 2.5. The MIMIC model showed good fit ($\chi^2_{13}=9.4$, $P=.742$; $\chi^2/df=0.723$; root-mean-square error of approximation<.001; goodness-of-fit index=0.998; comparative fit index=1.000). The external validity of the index is supported by a statistically significant negative correlation with the scale measuring attitudes toward SNSs ($r=-0.225$, $P<.001$). Following the removal of 1 item, the second e-professionalism index, focusing on the opportunities associated with SNSs, comprises 5 items. During the indicators collinearity check, all indicators exhibited acceptable VIF values below 2.5. Additionally, the MIMIC model demonstrated a good fit ($\chi^2_4=2.5$, $P=.718$; $\chi^2/df=0.637$; root-mean-square error of approximation<.001; goodness-of-fit index=0.999; comparative fit index=1.000). The external validity of the index is supported by a statistically significant positive correlation with the scale of attitude toward SNSs ($r=0.338$; $P<.001$).

Conclusions: Following the validation process, the instrument designed for gauging the e-professional behavior of MDs and DMDs consists of 19 items, which contribute to the formation of 2 distinct indexes: the e-professionalism index, focusing on the dangers associated with SNSs, comprising 14 items, and the e-professionalism index, highlighting the opportunities offered by

SNSs, consisting of 5 items. These indexes serve as valid measures of the e-professional behavior of MDs and DMDs, with the potential for further refinement to encompass emerging forms of unprofessional behavior that may arise over time.

Introduction

Background

The development of social networking sites (SNSs) as a new form of media and communication channel has brought many changes to the health care system [1]. The widespread use of SNSs affects what we perceive as the professional behavior of health care professionals (HCPs) [2].

The rise in SNS users has sparked a growing interest in comprehending e-professionalism, particularly concerning SNSs. This specific facet of e-professionalism is becoming increasingly important. Over the past few years, numerous studies on the e-professionalism of HCPs have emerged [3,4], indicating a sustained momentum in generating scientific insights into e-professionalism.

Defining and Measuring e-Professionalism

The American Board of Internal Medicine (ABIM) guidelines on medical professionalism define 3 fundamental principles and a set of 10 professional responsibilities (or commitments). Fundamental principles are the importance of patient welfare, the principle of patient autonomy, and the principle of social justice. Professional responsibilities are commitments to professional competence, honesty with patients, patient confidentiality, maintaining appropriate relations with patients, improving the quality of care, improving access to care, a just distribution of finite resources, scientific knowledge, maintaining trust by managing conflicts of interest, and commitment to professional responsibilities [5].

E-professionalism is a specific type of professionalism. Cain and Romanelli [6] defined e-professionalism as the attitudes and behaviors (some of which may occur in private settings) reflecting traditional professionalism paradigms that are manifested through digital media.

A large number of previous research around e-professionalism measured the perception of e-professionalism [7-11] and attitude toward e-professionalism [12-18]. Through cross-validation, Kelley et al [19] created an instrument for measuring professional behaviors in pharmacy students, and even though there are some thematic overlaps, it is not suitable for measuring online behavior.

E-professionalism is often defined as a value which justifies the operationalization that directs the measurement of professionalism toward the measure of attitude. Nevertheless, from the perspective of the professions themselves, although professionalism is taught and transferred through socialization into the profession as a value, for assessing the level of e-professionalism of doctors of medicine (MDs) and doctors of dental medicine (DMDs) the behavioral component is of greater

interest. Professional behavior, rather than just attitude, constitutes a visible aspect of professionalism. It is through professional behavior that not only patients and colleagues perceive a doctor's professionalism, but also it is subject to internal control according to Freidsonian principles [20], enabling the profession to enforce sanctions on the professional. Professionalism is a behavior rather than an attitude because it should not be a hypothetical or idealized concept, as Evans [21] writes, but should be perceived as a reality—an actual entity. However, it is a real entity only if it is operational. To be real, professionalism must be something that people—professionals—actually “do,” not just something that the government or any other agency wants them to do, or wrongly imagines them to be doing [21]. The disconnection between behavior and attitude is termed “cognitive dissonance” [22], a phenomenon already acknowledged as a threat to the e-professionalism of HCPs on SNSs [4].

The research focused on the medical and dental professions as the target populations. These 2 fields were chosen due to their fundamental similarities, enabling comparisons, as well as their differences, suggesting potential variations in e-professionalism. Both medical and dental professions are sociologically recognized as professions [20] and share the commonality of providing health services. This entails a significant patient-practitioner relationship in both disciplines. Comparing various health professions is a valuable approach, and existing literature has already established overlaps in core competencies [23].

The primary distinction driving the selection of these 2 professions is the orientation of MDs, particularly in the Croatian context, toward the public sector, whereas DMDs are oriented toward the private sector.

This paper seeks to develop a reliable and valid instrument for assessing the e-professional behavior of both MDs and DMDs.

Normative Framework for Defining e-Professional Behavior

Overview

To define and measure e-professional behavior effectively, it is crucial to differentiate between professional and unprofessional behaviors. In our case, the primary objective of the normative framework is to delineate the content specifications, specifically the domains of instruments used to measure e-professional behavior.

The normative framework for assessing e-professionalism among MDs and DMDs draws upon 3 primary sources. While none of these sources alone is adequate for defining a comprehensive normative framework, each provides essential information crucial for its development. Some aspects of these

sources overlap conceptually, while others offer unique insights necessary for crafting the framework.

The first source comprises the e-professional conduct guidelines established by the ABIM [5]. These guidelines, among the earliest to be published, were developed through an international collaboration involving multiple institutions. They address the fundamental principles of professionalism and outline the professional responsibilities expected of MDs.

The second source consists of guidelines aimed at fostering e-professional behavior among medical and dental students [24]. While initially targeted at this specific demographic, a significant portion of the recommendations is applicable to the e-professionalism of MDs and DMDs. Consequently, these guidelines serve as a valuable resource for “reconstructing” the components of a normative framework for e-professionalism. They aid in delineating acceptable and unacceptable behaviors on SNSs within the context of medical and dental professions.

The third source is Julie Skrabal’s research [9], where she used the grounded theory method to develop a theoretical framework for e-professionalism. Her study empirically demonstrated which behaviors on SNSs are perceived as unprofessional. While the research focused on nursing students, the identification of key domains and indicators comprising professional behavior on SNSs holds significant value and applicability to MDs, DMDs, and all HCPs.

Based on the analysis of these 3 sources, e-professionalism, or e-professional behavior, can be categorized into 6 domains. Four of these domains pertain to the dangers associated with SNSs: confidentiality, privacy, contact with patients, and fair distribution of resources. The remaining 2 domains concern the opportunities afforded by SNSs: proactive dissemination of information relevant to public health and maintaining scientific objectivity. Each of these 6 domains is elaborated upon below.

Confidentiality

Confidentiality encompasses behaviors that primarily contravene the Health Insurance Portability and Accountability Act (HIPAA) of 1996. It entails safeguarding patient confidentiality to ensure that information regarding the patient is not disclosed, even to the patient’s relatives, without the patient’s explicit consent.

Concerning behavior on SNSs, HIPAA violations predominantly involve the unauthorized publication of photos or confidential patient information [9]. Additionally, adopting fake names (pseudonyms) to share posts containing medical or dental information constitutes another unprofessional behavior [24].

Privacy

This domain pertains to profile privacy settings and the management of post visibility. Barlow et al [25] established a correlation between privacy settings and unprofessional behavior, particularly among medical students. Consequently, they recommended the adoption of “private visibility settings” to mitigate such behaviors. Monitoring privacy settings [24], controlling post visibility [9,24], and seeking permission before tagging colleagues in posts to safeguard their privacy [24] are advocated practices. Furthermore, it is advisable to refrain from

publishing professionally inappropriate content on SNSs, including posts containing curses, vulgar expressions, inappropriate attire, or behavior [9,24].

Contact With Patients

This domain encompasses direct contact with patients via SNSs. Inappropriate expressions, political incorrectness, or derogatory remarks toward patients or any individual or group can severely tarnish the public’s perception of doctors’ professional conduct [24]. Additionally, using unofficial channels, such as SNSs, to communicate sensitive professional information is considered unprofessional behavior within this domain [9].

Fair Distribution of Resources

Fair distribution of resources, as acknowledged in the ABIM guidelines, is considered an essential aspect of professional responsibility. While the ABIM guidelines emphasize the avoidance of unnecessary interventions and examinations, resource distribution also extends to SNSs. Time, a valuable resource allocated by MDs and DMDs to their patients, is particularly relevant in this context. Derived from the fundamental principle of professionalism known as the “Principle of Social Justice,” striving for a fair distribution of health care resources is imperative [5]. Communication with patients via SNSs typically requires the doctor’s time, often during their free time since it is an informal communication channel. According to the principle of fairness, it would be considered unprofessional behavior if a doctor selectively chooses which patients they are willing to communicate with on SNS and which they are not.

Proactive Publication of Information of Public Health Interest

The dimension of proactive publication of professional information of public health interest is one of the recognized aspects of e-professionalism that highlights the opportunity aspect of using SNSs. These behaviors are not deemed unprofessional when avoided; however, they can significantly contribute to e-professionalism when practiced by MDs and DMDs. While Skrabal [9] emphasizes creating positive postings as the absence of criticism and negative comments, proactive posting as a deliberate action toward e-professionalism is acknowledged in another research [26].

Scientific Objectivity

Sharing knowledge on SNSs is indeed desirable and constitutes professional behavior. However, it is essential to clearly differentiate between personal or subjective medical opinions and scientifically based facts [24].

Formative Approach in Measuring e-Professionalism

Most latent variables used in the social sciences are measured using reflective (effect) indicators [27,28]. According to a prevailing convention, indicators are seen as functions of the latent variable, whereby changes in the latent variable are reflected in changes in the observable indicators [27]. This is often true regarding constructs such as personality or attitude [28]. For example, attitude about SNSs affects respondents’ responses to the items posed to them. If someone has a negative attitude about SNSs, that attitude “guides” their responses.

However, in the case where the direction of “influence” is reversed, and where the indicators are “causing” the latent variable instead of “being caused by it,” then we can talk about formative measures [28].

Index construction focuses on explaining the abstract (unobserved) variance, considers multicollinearity among indicators, and emphasizes the role of an indicator as a “predictor” (latent variable) rather than “a predicted variable” [27].

The choice of approach (reflexive vs formative) stems from the concept, that is, from the relationship between variables and constructs [29]. Jarvis et al [30] stated 4 conditions that can help discern whether a reflective or a formative model is appropriate: (1) the direction of causality between the construct and the indicator, (2) the interchangeability of the indicators, (3) covariance between indicators, and (4) the nomological network of construct indicators.

The first argument presented by Jarvis et al [30] is valid for our research because, unlike attitude, e-professional behavior stems from specific actions and decisions on SNSs. If someone refrains from posting pictures of patients, seeks permission from a colleague before mentioning them on SNS, actively controls the visibility of their posts, and takes similar actions, then these decisions contribute to their e-professional behavior.

For the second argument, e-professional behavior indicators are not interchangeable, even though they all measure e-professionalism. Posting a picture of a patient on an SNS is considered unprofessional behavior, but so is posting pictures from parties at work. Both behaviors are unprofessional, although they are not interchangeable in measurement (someone may frequently post photos of patients but rarely post workplace-related images).

The third argument states that covariance among indicators is unnecessary [30]. It is neither expected nor needed here because recognized behaviors within the normative framework can be entirely unrelated but still measure e-professional behavior (eg, sending a friend request to a patient and asking a colleague to mention them in a post).

The fourth argument suggests that the nomological network in the formative model can have different antecedents and consequences [30]. Indicators of e-professional behavior do not need to share the same antecedents because they can be driven by different motivations. A doctor may post pictures of patients because they believe it raises awareness about a particular illness (even though this act is unprofessional), while the motivation for unprofessional behavior, such as posting pictures from workplace parties, does not stem from the same motivation.

Based on these arguments, the behavioral component of e-professionalism measured in this paper conceptually corresponds to the formative approach.

We presume that other research in this area has not applied a formative approach in measuring e-professionalism because they have yet to define e-professionalism as a behavior.

Diamantopoulos and Winklhofer [28] proposed 4 key steps for validating indexes with formative indicators. The first step,

content specification, refers to specifying the scope of the latent variable; in the second step, it is necessary to define the indicators; the third step refers to checking the collinearity of the indicators using the variance inflation factor (VIF) [28]. The fourth step is to assess the external validity of the index. Verification of the external validity of formative indices is often carried out by checking the relationship of the index with other measures and variables (as cited in [28]).

Although these 4 steps are sufficient for constructing and validating the index, it is possible to make an additional check of the external validity proposed by Diamantopoulos and Winklhofer [28]. This requires creating a model in which some reflective indicators are included (Diamantopoulos and Winklhofer [28] use 2) in the same model as the formative indicators. This model is called the multiple indicators multiple causes (MIMIC) model [28]. Acceptable overall model fit suggests retention of items in the formative model. If the exclusion of some items can significantly increase the model fit under the very strict condition that not a single exclusion would violate the content validity of the formative model, only then can the items be excluded.

In this paper, we have followed these 4 key steps for validating indexes with formative indicators. An additional step (the MIMIC model) was conducted before assessing the external validity of the index.

Methods

Sample

Quantitative survey data were collected using an online survey questionnaire. The Checklist for Reporting Results of Internet E-Surveys (CHERRIES) [31] is available in [Multimedia Appendix 1](#). The required sample size was defined according to a conservative estimate often used for multivariate analyses, corresponding to a 10:1 ratio between the number of observations and the number of variables used in the questionnaire’s largest instrument [32]. In our case, that is a sample size of 280 (140 MDs and 140 DMDs). The type of sample was a nonprobabilistic purposive sample.

The study was a part of a long-term research project funded by the Croatian Science Foundation, UIP-05-2017 “Dangers and Benefits of Social Networks: E-Professionalism of Health Care Professionals – SMePROF” [33].

The mailing lists used to distribute the survey were the official full membership emailing lists of the Croatian Medical Chamber (CMC) and Croatian Chamber of Dental Medicine (CCDM). At the time of the survey, the CMC’s emailing list contained 15,562 email addresses of MDs, and the CCDM’s email list contained 7616 email addresses of DMDs. The email included a brief text about the study’s objective, the expected time to complete the survey, and the person and university responsible for conducting the study.

Participation in the survey was voluntary; there was no form of incentive to complete the survey. To ensure anonymity, no identification data were collected. Data were collected from February to July 2021, with 2 reminders sent in that period.

Ethics Approval

Both the study and the questionnaire were approved by the ethical boards of the University of Zagreb School of Medicine (641-01/18-02/01) and the University of Zagreb School of Dental Medicine (05-PA-24-2/2018). In addition, formal approval was obtained from the governing bodies of both the CMC and CCDM for the use of the complete mailing lists of MDs and DMDs who are members of the CMC (900-06/20-01/11) and CCDM (900-01/21-01/02).

Measures

The instrument for measuring the e-professional behavior of MDs and DMDs, presented in this study, is part of a more extensive questionnaire called SMePROF Project Survey Questionnaire on Social Media Usage, Attitudes, Ethical Values and E-professional Behaviour of Doctors of Medicine and Doctors of Dental Medicine, available at Viskić et al [34]. Although the questionnaire contained multiple instruments partially derived from previous studies [10,34,35], the instrument for measuring the e-professional behavior of MDs and DMDs is a novel instrument created by the authors. The instrument contains 20 items measured using the self-reporting approach, used to create 2 e-professionalism indexes, and the process is explained in the following parts of this paper. In validating indexes, a MIMIC model was used, which required 4 reflexive variables (y_1 - y_4) measuring attitude toward e-professionalism. These items were taken from a validated instrument for measuring attitudes toward e-professionalism [35]. Descriptives of these 4 reflexive variables are shown in [Multimedia Appendix 2](#). The MIMIC model was exclusively used as a method for validating the external validity of the indexes, and not for theory development.

The associations of indexes with theoretically related constructs were tested to assess the external validity. For this purpose, we used a validated instrument for measuring attitudes toward SNSs [36]. The instrument was translated into the Croatian language, and after additional reliability checks, 1 item was removed from the scale ("Potential and/or existing employers may use the information found on SNS to make decisions about prospective and/or existing employees"). The final instrument used had 12 items and Cronbach α =.70.

Analytical Methods

A descriptive analysis of frequencies and percentage of responses was carried out, and distribution measures such as mean, range, SDs, and α_3 measure of asymmetry were determined depending on appropriateness. Correlations between quantitative variables were tested with the Pearson correlation coefficient and phi coefficients of associations. The multicollinearity of the instruments was tested with the VIF. The MIMIC model was used to check the external validity of

instruments with formative indicators. Data analysis was performed using IBM SPSS Statistics 26. IBM SPSS Amos 22 was used to test the MIMIC model.

Results

Survey Responses

A total of 1013 responses were collected. The response rate was 4.37% (1013/23,178). The final realized sample of the entire research contained the answers of 999 respondents, of which 75.4% (753/999) use at least one SNS, 67.3% (507/753) of the respondents were MDs and 32.7% (246/753) were DMDs. The sample was predominantly female (558/753, 74.1%) with an average age of 38 (SD 10.99) years. Most respondents worked in a public health institution (412/753, 54.7%), and the second most frequent type of workplace was a private institution with a contract with the Croatian Health Insurance Fund (CHIF; 148/753, 19.7%).

Previous research on the same sample [34] showed a significant difference in age, where MDs were older than DMDs with an average age of 39.26 years as opposed to 36.58 years, respectively, and in the type of employment, with more than two-thirds of DMDs (168/246, 68.2%) being employed in the private sector compared with only 20.5% (104/507) of MDs. All specialization status levels are included in the sample ([Multimedia Appendix 3](#)).

The Construction of the e-Professionalism Index—The Danger Aspect of SNSs

Following the first step in creating the index, according to Diamantopoulos and Winklhofer [28], the content for the latent variable is specified below. In the second step, e-professional behaviors described in the normative framework were operationalized into an instrument for measuring the aspect of e-professionalism related to the dangers of SNSs ([Table 1](#)). The identified indicators are grouped into 4 domains: confidentiality, privacy, contact with patients, and fair distribution of resources. Items were evaluated on a frequency rating scale: 0=Never, 1=Rarely, 2=Occasionally, 3=Often; and the option "I have never been in a situation where this could happen" was added. It was essential to distinguish behaviors that could have happened but did not from those for which the respondent was not even in a situation to practice them. Depending on the direction and content of the items, the difference between the opportunity to behave in a certain way and the frequency of that behavior can mean the difference between professional and unprofessional behavior. In the case of items formulated in a positive direction (marked +), a higher frequency measures a higher level of e-professionalism. In the case of items formulated in a negative direction (marked -), higher frequency measures a lower level of e-professionalism.

Table 1. Domains, indicators, and items for the instrument of e-professionalism—the danger aspect of SNSs^a.

Domain and indicator	Item	Direction ^b
Confidentiality		
Disclosure of patient information.	I published some information about my patient.	–
Publication of photographs of the patient without their consent.	I posted a photo of my patient without their knowledge.	–
Hiding behind false names when posting online or anonymously posting medical information.	I shared medical/dental advice on SNS without my name being visible.	–
Confidentiality of communication also applies to SNS.	I shared some information about the patient I received through SNS with others.	–
Privacy of MDs and DMDs profiles		
Active management of the visibility of posts depending on their content.	Depending on the appropriateness of the content of my posts, I determine to whom they will be visible.	+
Controlling the visibility of other people's posts that include you, depending on their content.	If I notice that someone else has published something about me (eg, my picture, location, or similar), I control who will see it.	+
Seeking prior approval from colleagues to publish information about them.	I asked a colleague's permission to mention them in the post.	+
Appropriate behavior on published content from a professional context.	I have posted content that shows informal situations at my workplace (eg, drinks with colleagues or parties at work).	–
The use of profanity and other vulgar expressions in posts.	A curse word or some different vulgar expression occasionally slips out in my posts.	–
Contact with patients		
Inappropriate expression in posts.	In my posts, I am cautious that my expression is entirely professional.	+
Separation of professional and private communication.	I communicate with patients regarding medical/dental problems and treatment from a private profile.	–
Inclusion of patient data obtained at SNS in the medical documentation without the patient's consent.	I included information about the patient I found through SNS in the medical documentation without their knowledge.	–
Sending a friend request to a patient or a patient's family member.	Have you ever sent a "friend request" to a patient or a member of the patient's family from a private profile on an SNS?	–
Fair distribution of resources		
Communication with patients via SNS and outside working hours is selective (the doctor chooses whom they respond to; patients without SNS cannot reach them)	On SNS, I choose which patients I will make contact with and which I will not.	–

^aSNS: social networking site.

^bFor items formulated in a positive direction (marked +), a higher frequency measures a higher level of e-professionalism. In the case of items formulated in a negative direction (marked –), a higher frequency measures a lower level of e-professionalism.

The indicator "Sending a friend request to a patient or a member of the patient's family" was not measured as frequency. Instead, the 4 offered answers were as follows: Yes, to the patient; Yes, to a family member; Yes, both; and No. The negative response is considered professional, while all other responses indicate unprofessional behavior.

The descriptive results for the items that measure the aspect of e-professionalism related to the dangers of SNSs are shown in [Table 2](#). The items that measure e-professional behavior are marked with a "b." All other items measure e-unprofessional behavior.

Table 2. E-professionalism (the dangers aspect of SNSs^a) descriptives (N=753).

Danger aspects	Never, n (%)	Rarely, n (%)	Occasionally, n (%)	Often, n (%)	I have never been in a situation where this could happen, n (%)
1. I asked a colleague's permission to mention them in the post. ^b	170 (22.6)	117 (15.5)	71 (9.4)	50 (6.6) ^c	345 (45.8) ^c
2. I shared some information about the patient that I received through SNS with other people.	368 (48.9) ^c	61 (8.1)	26 (3.5)	3 (0.4)	295 (39.2) ^c
3. I posted a photo of my patient without their knowledge.	492 (65.3) ^c	14 (1.9)	7 (0.9)	2 (0.3)	238 (31.6) ^c
4. I included information about the patient I found through SNS in the medical documentation without their knowledge.	484 (64.3) ^c	3 (0.4)	2 (0.3)	0 (0.0)	264 (35.1) ^c
5. I shared medical/dental advice on SNS without my name being visible.	503 (66.8) ^c	39 (5.2)	6 (0.8)	4 (0.5)	201 (26.7) ^c
6. Depending on the appropriateness of the content of my posts, I determine to whom they will be visible. ^b	295 (39.2)	99 (13.1)	93 (12.4)	71 (9.4) ^c	195 (25.9) ^c
7. If I notice that someone else has published something about me (eg, my picture, location, or similar), I control who will see it. ^b	209 (27.8)	106 (14.1)	104 (13.8)	177 (23.5) ^c	157 (20.8) ^c
8. I have published content that shows informal situations at my workplace (eg, drinks with colleagues or parties at work).	354 (47.0) ^c	181 (24.0)	84 (11.2)	17 (2.3)	114 (15.1) ^c

^aSNS: social networking site.

^bItem represents professional behavior on SNS.

^cResponse represents professional behavior on SNS.

^dThe options were "no," "yes, to a patient," "yes, to a family member," and "yes, both," respectively.

^eN/A: not applicable.

The answer "I have never been in a situation where this could happen" is not a missing value, but it carries a conceptual meaning that must be distinguished from the answer "Never." The assessment of whether that answer is professional or unprofessional depends on the content and direction of the item. Respondents who have never engaged in unprofessional behavior are professional, but so are those who never had an opportunity to act unprofessionally. Respondents who often practice behaviors on items marked with "b" are professional, and so are those who have never been in a situation to practice

these behaviors because they have not been in a situation to behave unprofessionally.

For example, in the case of positive items (those representing professional behavior), such as "I asked a colleague's permission to mention him/her in the post," professional behavior is defined as a situation where the individual has never violated this rule because they have never mentioned colleagues in their posts or seek permission each time they mention them. Any other frequency level implies that, at some point, the person has posted about colleagues without their consent, which constitutes unprofessional behavior on SNS.

It is crucial here to differentiate between the absence of behavior of interest (requesting permission from colleagues when mentioning them in posts) in situations where it should have been sought (if mentioning them in posts) from the situations where it should not have been sought (because they never mention colleagues).

By contrast, for negative items (those representing unprofessional behavior), such as “I shared some information about the patient that I received through SNS with other people,” professional behavior is defined as situations where the individual has never engaged in such behavior or has not even been in a situation where they could engage in such behavior (eg, they do not communicate with patients via SNS, so they cannot receive patient information through this channel).

Therefore, the context of the absence of specific behaviors plays a pivotal role in distinguishing between professional and unprofessional behaviors. It is essential to combine the response “I have never been in a situation where this could happen” with the level of behavior frequency.

To construct the index, the frequency of behavior on each indicator was not graded but only considered as a binary value (professional vs unprofessional).

For items that measure unprofessional behavior, any degree of frequency other than “never” was considered unprofessional behavior. For items that measure professional behavior (eg, asking a colleague’s permission to mention them in a post), all those who did this never, rarely, or occasionally were considered unprofessional on that indicator, because this is the behavior they are expected to do always (or often in our scale).

The Validation Process of the e-Professionalism Index—The Danger Aspect of SNSs

After specifying the scope and defining the indicators, the third step, according to Diamantopoulos and Winklhofer [28], refers to checking the collinearity of the indicators. Intercorrelations of the items in the e-professionalism instrument—the danger aspect of SNSs are shown in [Multimedia Appendix 4](#). Given that these are binary variables, phi coefficients of associations were used. The correlation between the variables “On SNS, I choose with which patients I will make contact with and which I will not.” and “From a private profile, I communicate with patients regarding medical/dental problems and treatment.” ($r=0.568$) represents a moderate correlation and evokes the need to investigate potential multicollinearity. This suggests that those who communicated with patients via SNSs also chose with whom (patients) they would establish communication. As a formative approach is used, special care is needed before excluding indicators to preserve the instrument’s validity. Therefore, the VIF and MIMIC model were calculated. Multicollinearity was tested using a VIF with an additive index of e-professionalism, an aspect of the danger of SNS that was constructed as the sum of values on binary indicators. According

to the conservative threshold [37], VIF values on all indicators were below the value of 2.5, which suggests that multicollinearity is not an issue.

The MIMIC model was implemented to check the external validity of the instrument. The path diagram of the MIMIC model is shown in [Multimedia Appendix 5](#). Variables x_1 - x_{14} correspond to the items from [Table 2](#). Items y_1 (Communication with a patient through social media can be achieved without compromising doctor-patient confidentiality) and y_2 (Social media have the potential to improve communication between a doctor and a patient) were chosen as reflective indicators.

The model showed good fit ($\chi^2_{13}=9.4$, $P=.742$; $\chi^2/df=.723$; root-mean-square error of approximation<0.001; goodness-of-fit index=0.998; comparative fit index=1.000). However, 7 of the 14 items (x_1 , x_2 , x_3 , x_6 , x_7 , x_8 , and x_{13}) did not have significant regression coefficients (γ) that can also be interpreted as validity coefficients [28]. The probable reason is that the measured reflective indicators did not measure the same domains as e-professional behavior; instead, they measured an attitude toward e-professionalism. Both items 11 ($P<.001$) and 12 ($P=.02$), which were investigated as potential problems of multicollinearity, have significant validity coefficients. Considering that, as well as an acceptable VIF, they were retained in the index to preserve the content validity to which formative models are particularly sensitive.

A higher value on the index means a higher degree of e-professionalism, that is, a lower incidence of unprofessional behavior on SNSs. The index results ranged from 0 to 14, and the average value in our sample was 10.60 (SD 2.173). The distribution of the index was skewed toward higher values ($\alpha_3=-.44$, $P=.09$), that is, toward the professional behavior of our respondents on SNSs.

The external validity of the index is supported by the correlation with other measured constructs. There was a statistically significant negative correlation between the index of e-professionalism (aspects of the danger of SNSs) and the scale of attitude toward SNSs ($r=-0.225$, $P<.001$).

The Construction of the e-Professionalism Index—The Opportunity Aspect of SNSs

The construction of the e-professionalism index—the opportunity aspect of SNSs follows the same validation steps as the aspect of the dangers of SNSs [28].

E-professional behaviors described in the normative framework were operationalized into an instrument for measuring e-professionalism through the opportunity aspect of SNSs. The instrument contains 2 domains, measured by 6 items. All items are formulated in the same direction so a higher frequency measures a higher level of e-professionalism ([Table 3](#)).

Table 3. Domains, indicators, and items for the instrument of e-professionalism—opportunity aspect of SNSs^a.

Domain and indicator	Item	Direction ^b
Proactive posting of expert information of public health interest		
Sharing posts that contain general medical advice	I share posts on social media that contain general medical/dental advice.	+
Sharing new scientific knowledge in the field of medicine	I use my profile to share information about new scientific knowledge in the field of medicine/dental medicine.	+
Debunking medical myths and misinformation	I debunk medical/dental myths and misinformation by posting on SNS.	+
Calling for public health actions	I use SNS to raise public awareness of public health actions.	+
Encouraging responsible behavior	I create posts on SNS that call for responsible health behavior.	+
Scientific objectivity		
Emphasis on distinguishing personal medical opinions from facts	In the posts, I clearly separate my personal opinion on a medical/dental issue from scientifically confirmed facts.	+

^aSNS: social networking site.

^bAll items are formulated in the same direction so a higher frequency measures a higher level of e-professionalism.

The descriptive results for the items that measure the opportunity aspect of SNSs are shown in Table 4. While measuring the danger aspect of SNSs focused on occurrence, not on the frequency of occurrence, the frequency of each behavior is relevant with this instrument. All behaviors in this instrument have the characteristic of being desirable, but the absence of

such behaviors is not unprofessional. If an MD or DMD practices these behaviors, they use opportunities of SNSs and contribute to their professionalism. However, if they do not practice any of these behaviors, or have never been in a situation where they can behave like that, it is not unprofessional, but misses the opportunity to use the advantages of SNSs.

Table 4. E-professionalism—opportunity aspect of SNSs^a—descriptives (N=753).

	Never, n (%)	Rarely, n (%)	Occasionally, n (%)	Often, n (%)	I have never been in a situation where this could happen, n (%)
1. I debunk medical/dental myths and misinformation by posting on SNS.	355 (47.1)	130 (17.3)	87 (11.6)	16 (2.1)	165 (21.9)
2. I share posts on social media that contain general medical/dental advice.	312 (41.4)	167 (22.2)	128 (17.0)	28 (3.7)	118 (15.7)
3. I use SNS to raise public awareness of public health actions.	185 (24.6)	191 (25.4)	224 (29.7)	84 (11.2)	69 (9.2)
4. I use my profile to share information about new scientific knowledge in the field of medicine/dental medicine.	248 (32.9)	183 (24.3)	184 (24.4)	54 (7.2)	84 (11.2)
5. I create posts on SNS that call for responsible health behavior.	186 (24.7)	196 (26.0)	212 (28.2)	81 (10.8)	78 (10.4)
6. In the posts, I clearly separate my personal opinion on a medical/dental issue from scientifically confirmed facts.	170 (22.6)	49 (6.5)	77 (10.2)	149 (19.8)	371 (49.3)

^aSNS: social networking site.

To construct an index reflecting the degree of e-professionalism in utilizing social networking opportunities, responses marked as “Never” or “I have never been in a situation where this could happen” are not considered contributions to e-professionalism and are coded as 0. Conversely, responses categorized as “Rarely,” “Occasionally,” and “Often” contribute to e-professionalism, representing 3 levels of engagement with the benefits of social networks and are coded as 1, 2, and 3 respectively.

The Validation Process of the e-Professionalism Index—Opportunity Aspect of SNSs

The correlations between the items that constitute this index have higher values than those in the aspect of dangers of the SNS index (Multimedia Appendix 6). The item “I create posts on SNS that call for responsible health behavior” moderately correlates with several items (from $r=0.418$ to 0.714). To check

if multicollinearity is present in this instrument, paying attention to the VIF is necessary.

VIF was calculated with an additive index of e-professionalism—opportunity aspect of SNSs. VIF values on all indicators are below the value of 2.5, which suggests no risk of multicollinearity, even according to a conservative interpretation.

Before excluding the item “I create posts on SNS that call for responsible health behavior,” an MIMIC model was created with all the items included, and a second model without that item was created to check for any changes in the model fit. The diagram of the MIMIC model is shown in [Multimedia Appendix 5](#). Variables x_1 - x_6 correspond to the items from [Table 4](#). Items y_3 (As MD/DMD, it is my duty to keep abreast of current trends in the use of SNS) and y_4 (Guiding patients to online information is a new responsibility of MDs/DMDs in the digital age) were chosen as 2 reflective indicators.

The MIMIC model with all 6 items showed good fit characteristics ($\chi^2_5=2.880$, $P=.718$; $\chi^2/df = 0.576$; root-mean-square error of approximation $<.001$; goodness-of-fit index=0.999; comparative fit index=1.000). However, 3 items (x_1 , x_3 , and x_5) did not have significant regression coefficients (γ ; $P=.14$, $P=.44$, and $P=.19$, respectively).

Considering the high correlations with other items, the VIF value that exceeds the limit of 2.5, and the regression coefficient γ that is not statistically significant ($P=.19$), item x_5 was excluded from the e-professionalism index—opportunity aspect of SNSs. After excluding item x_5 , the fit of the MIMIC model did not change significantly ($\Delta\chi^2_1=0.336$, $P=.56$) and the fit of the model was $\chi^2_4=2.544$, $P=.718$; $\chi^2/df = 0.637$; root-mean-square error of approximation $<.001$; goodness-of-fit index=0.999; comparative fit index=1.000.

The index of e-professionalism—opportunity aspect of SNSs was created as the sum of the values of the remaining 5 recoded variables. A higher value on the e-professionalism index means a higher degree of e-professionalism. The index results ranged from 0 to 15 (mean 4.13, SD 3.712). The distribution of the index was skewed toward lower values ($\alpha_3=0.67$, $P=.09$), showing that 24% (181/753) of respondents do not take advantage of SNSs at all.

The external validity of the index of e-professionalism—opportunity aspect of SNSs is supported by the correlation with other measured constructs. There was a statistically significant positive correlation between the index and the scale of attitude toward SNSs ($r=0.338$, $P<.001$).

Discussion

Principal Findings

As far as the authors are aware, this is the first measure constructed to measure the e-professional behavior of MDs and DMDs, with the created indexes of opportunity and the danger aspects of SNSs being the first attempt at using a formative approach in the research of professionalism in general and in

e-professionalism. The final instrument for measuring the e-professional behavior of MDs and DMDs consists of 19 items that form 2 indexes. Index of e-professionalism—the danger aspect of SNS, which is formed by 14 items, and the index of e-professionalism—opportunity aspect of SNS, which is formed by 5 items.

These novel indexes can be used to measure the level of e-professional behavior among MDs and DMDs, which can have potential real-world applications. The main implications can be utilized in education for young medical and dental professionals and the development of guidelines for improving e-professionalism. If the instrument were applied on a representative sample, it could yield valuable data to enable the implementation of data-based policies with specific behaviors of interest. Investigation of the external validity of both e-professionalisms showed acceptable results. There was a statistically significant negative correlation between the index of e-professionalism—the danger aspect of SNSs and the scale of attitude toward SNSs ($r=-0.225$, $P<.001$). This is the theoretically expected direction of the correlation because the more positive attitude the respondents have about SNSs, the more inclined they are to use them when working with patients, which according to the normative framework, represents unprofessional behavior. The statistically significant positive correlation between the index of e-professionalism—opportunity aspect of SNSs and the scale of attitude toward SNSs ($r=0.338$, $P<.001$) is also theoretically expected because the more positive attitude toward SNSs doctors have, the more likely they will take advantage of the benefits of SNSs.

In the index of e-professionalism—the danger aspect of SNSs, all initially operationalized indicators were retained. In the index of e-professionalism—the opportunity aspect of SNSs, item x_5 (I create posts on SNS that call for responsible health behavior) measuring the indicator “Encouraging responsible behavior” was excluded. The formative approach suggests cautious consideration of managing the content validity of the model. It seems that respondents understood item x_5 very similarly to item x_3 (I use SNS to raise public awareness of public health actions.). After testing the indicators in the MIMIC model, the authors concurred that the content validity is not threatened by excluding this item, and multicollinearity would pose a more significant problem than losing a very subtle difference in the contents of these items.

Comparison With Prior Work

Conceptual domains recognized in this study only partially overlap with domains in the instrument of (offline) professional behavior [19] and the instrument for measuring attitudes toward e-professionalism [35]. Kelley et al [19] recognized a domain called “Upholding principles of integrity and respect,” which corresponds to the domain “Confidentiality” in this study, as well as “Citizenship and professional engagement” [19], which corresponds to “Proactive posting of expert information of public health interest.” In an instrument for measuring attitudes toward e-professionalism, Marelić et al [35] recognized the domain “Ethical aspects” that theoretically includes HIPAA violations and therefore corresponds to the domain “Confidentiality” in this study, and the domain “Physicians in

the digital age” that corresponds to “Contact with patients”. However, the instrument of (offline) professional behavior contains domains that are not comparable to e-professional behavior, and the instrument for measuring attitudes toward e-professionalism contains domains that are not applicable for behavior measurement, and because of potential cognitive dissonance, measuring attitude is not a replacement for behavior measurement.

Limitations

The first limitation of this study is the low response rate (1013/23,178, 4.37%). Previous research has indicated that these professions have low survey response rates, especially in e-mailing surveys using web-based formats [38-42]. Time, confidentiality concerns, and topic relevance are some of the main reasons for their low survey participation [40]. Previous research has indicated that declining response rates among HCPs may be attributed to various factors, including heightened requests to participate in surveys and increased workloads. This increase in workload encompasses both the rising number of patients and administrative responsibilities [38,39].

One factor likely contributing to the low response rate in this study is the demanding schedule of MDs and DMDs. The estimated time required to complete our survey was lengthy, ranging from 10 to 15 minutes, due to the inclusion of a complex and comprehensive questionnaire containing 40 questions. Moreover, the survey was conducted during the COVID-19 pandemic (February to July 2021), a period marked by heightened strain on the health care system. MDs, especially those in Croatia, were confronted with extreme workloads and specific working conditions during this time. Additionally, MDs received numerous invitations to participate in web-based surveys, particularly regarding the impact of the COVID-19 pandemic on their physical or mental health. Given these circumstances, our study’s focus on e-professionalism may have been perceived as of lower interest, potentially further reducing doctors’ willingness to participate in research.

However, our objective in creating and validating new indexes did not prioritize achieving representativeness in our sample or generalizing our findings to the entire population of MDs and DMDs in Croatia. Instead, our focus was on assessing the suitability of the developed measurement instruments across various medical professions, using a nonprobabilistic purposive sample. Our final sample comprised responses obtained from the population of interest for this study, specifically MDs and DMDs who use at least one SNS. It is worth noting that the number of responses received in our survey (507 MDs and 246 DMDs) exceeded the initially planned sample size (140 MDs and 140 DMDs) by a considerable margin.

The second limitation concerns a relatively large proportion of respondents (ranging from 69/753, 9.2%, to 371/753, 49.3%) who selected the option “I have never been in a situation where this could happen” for certain items. It remains unclear why they did not simply respond with “Never.” The reasons behind this choice are ambiguous. It is possible that some respondents are passive users of SNSs, thus not engaging in any content publication and consequently unable to exhibit unprofessional behavior. Alternatively, it could be that these respondents do

not work directly with patients, rendering items related to violations of the HIPAA irrelevant to them. Another possibility is that they perceive their standards of professionalism to be exceptionally high, leading them to believe they would never engage in such behavior. While this issue does not affect the measurement of the occurrence of e-(un)professional behavior, it does impede a detailed understanding of the frequency of e-unprofessional behavior. Addressing this limitation could be a focus of future research and modifications to the measurement instrument, but this should be preceded by gaining new insights into the e-professional behaviors of MDs and DMDs.

The third limitation involves the potential for bias associated with using a self-reporting approach to measurement. Similar to other self-report measures in medicine, 2 key biases often arise: recall bias and social desirability bias [43]. Recall bias in our study could be attributed to the lack of a specified timeframe, such as “during the last year.” We chose this approach because it represents the initial assessment of such behaviors, and we faced a scarcity of existing data on this subject. Introducing a specific timeframe in future research could aid in mitigating potential recall bias. The potential for social desirability bias stems from 2 sources. First, the nature of the measurement itself requires HCP respondents to self-report potentially unprofessional behaviors, including some that may constitute violations of HIPAA. The other factor to consider is that respondents were contacted to participate in our research through the same institutions responsible for granting and revoking licenses to practice medicine/dental medicine. Despite our assurance of anonymity in the study, respondents may have felt compelled to provide socially desirable answers on certain items. One method to mitigate or control social desirability bias is to include positive items, such as those measuring professional behaviors, alongside other items. An additional approach to address both biases, which could serve as a recommendation for future research, involves further refinement and validation of the instrument. This could be achieved by comparing self-reported data with information obtained through web scraping of respondents’ SNS profiles, particularly focusing on visible behaviors.

The fourth limitation arises from the potential mismatch between the use of reflective indicators y_1 - y_4 in the MIMIC model and the nature of the created indexes, which are intended to measure e-professionalism as behavior. However, the reflective variables used in the model measure attitude. While this approach was necessary for creating the MIMIC model in this study, there is a possibility that cognitive dissonance [4,21] may compromise the fit of the model.

The fifth limitation to note is that the sources used to establish a normative framework were relevant to the time and location of this research. However, their applicability to other countries and populations of HCPs, or their accuracy over time, may be limited. For example, the ABIM e-professional conduct guidelines [5] are relatively dated, and while they represent fundamental values of professionalism, they may not fully encompass changes in societal values that have occurred since the emergence of SNSs. Specific behaviors measured in these indexes may require revision or supplementation in the future.

Moreover, additional studies conducted after the development of this index may offer new insights into creating a normative framework for defining e-professional behaviors [44].

Future Directions

In considering avenues for enhancing both the instruments used in this study and future research directions, it becomes apparent that there are opportunities for improvement and deeper exploration. One potential extension of this study, which could lead to a more thorough understanding of the topic, involves testing the indexes on specific subsamples, particularly within specialties such as dermatology and reconstructive and cosmetic surgery. These specialties may involve visual representations of procedures, such as “before and after” images [34], which could pose potential threats to e-professionalism.

Improving the quality of external validity assessment can be achieved by incorporating self-evaluation of e-professionalism into the MIMIC model. This addition would enhance the content validity of the model by supplementing existing reflective indicators used in the research. Furthermore, self-evaluation of e-professionalism would serve as a valuable tool for evaluating the nomological network of the instrument. It would provide insights into the direction and strength of correlation among individual indicators of e-professionalism, the e-professionalism indices themselves, and potential predictors for model creation.

Future attempts aimed at measuring e-professionalism could focus on investigating the underlying reasons behind responses such as “I have never been in a situation where this could happen.” It is plausible that a more precise definition of items or the inclusion of specific examples could serve as mechanisms to help respondents differentiate between behaviors they never engage in and those they may never encounter. By refining the

clarity and specificity of survey items, researchers can facilitate a more accurate assessment of respondents’ experiences and perceptions related to e-professional behavior. This approach could lead to a deeper understanding of the nuances involved in professional conduct within the context of SNSs.

Conclusions

In this paper, an instrument for measuring the e-professional behavior of MDs and DMDs was developed and validated using the formative approach. Following the validation process, the instrument comprises 19 items, which contribute to the formation of 2 indexes. The first index, focusing on the danger aspect of SNSs, is composed of 14 items that were dichotomized before index construction. The second index, which examines the opportunity aspect of SNSs, is composed of 5 items that were recoded as 4-point items before index construction.

These innovative indexes offer a means to gauge the level of e-professional behavior among MDs and DMDs. This marks the first measure specifically designed to assess the e-professional behavior of MDs and DMDs. The paper demonstrates the feasibility of investigating e-professional behavior using a formative approach, representing an advancement over existing measuring instruments. This approach provides a means to mitigate the impact of cognitive dissonance between attitudes and the actual behavior of MDs and DMDs.

The validation process confirmed that these indexes serve as a robust measure of e-professional behavior. Nevertheless, the instrument has been scrutinized for potential areas of enhancement, and suggestions for improvements have been proposed for future iterations of the instrument.

Acknowledgments

This study was funded by the Croatian Science Foundation under project UIP-05-2017 “Dangers and Benefits of Social Networks: E-Professionalism of Health Care Professionals – SMePROF”. Generative AI was not used in any portion of the manuscript writing.

Abstract

Background: Health care professionals must learn continuously as a core part of their work. As the rate of knowledge production in biomedicine increases, better support for health care professionals' continuous learning is needed. In health systems, feedback is pervasive and is widely considered to be essential for learning that drives improvement. Clinical quality dashboards are one widely deployed approach to delivering feedback, but engagement with these systems is commonly low, reflecting a limited understanding of how to improve the effectiveness of feedback about health care. When coaches and facilitators deliver feedback for improving performance, they aim to be responsive to the recipient's motivations, information needs, and preferences. However, such functionality is largely missing from dashboards and feedback reports. Precision feedback is the delivery of high-value, motivating performance information that is prioritized based on its motivational potential for a specific recipient, including their needs and preferences. Anesthesia care offers a clinical domain with high-quality performance data and an abundance of evidence-based quality metrics.

Objective: The objective of this study is to explore anesthesia provider preferences for precision feedback.

Methods: We developed a test set of precision feedback messages with balanced characteristics across 4 performance scenarios. We created an experimental design to expose participants to contrasting message versions. We recruited anesthesia providers and elicited their preferences through analysis of the content of preferred messages. Participants additionally rated their perceived benefit of preferred messages to clinical practice on a 5-point Likert scale.

Results: We elicited preferences and feedback message benefit ratings from 35 participants. Preferences were diverse across participants but largely consistent within participants. Participants' preferences were consistent for message temporality ($\alpha=.85$) and display format ($\alpha=.80$). Ratings of participants' perceived benefit to clinical practice of preferred messages were high (mean rating 4.27, SD 0.77).

Conclusions: Health care professionals exhibited diverse yet internally consistent preferences for precision feedback across a set of performance scenarios, while also giving messages high ratings of perceived benefit. A "one-size-fits-most approach" to performance feedback delivery would not appear to satisfy these preferences. Precision feedback systems may hold potential to improve support for health care professionals' continuous learning by accommodating feedback preferences.

Introduction

Health care professionals must learn continuously as a core part of their work. As the rate of knowledge production in biomedicine increases, better support for continuous learning is needed [1]. Feedback about care quality and outcomes is pervasive in health systems and widely considered to be essential for learning that drives improvement. Clinical performance

feedback is one form of feedback that is commonly delivered to health care professionals in clinical quality dashboards and reports. However, engagement with these resources is generally low, and their impact has been less than optimal [2-5], resulting in missed opportunities to improve the quality and safety of care. A large proportion of randomized controlled trials of feedback interventions (also known as *audit and feedback*) show limited influence on clinical practice [5]. Moreover, what is

considered as best practice for feedback interventions has not changed meaningfully for decades, even after hundreds of trials and repeated calls for new approaches to feedback interventions [6-8].

To our knowledge, most clinical performance feedback interventions use a “one-size-fits-most” approach to both the prioritization of performance information and its visual display as feedback, with the same metrics and visualizations being sent to all recipients. One-size-fits-most feedback may not be effective due to a host of characteristics such as individuals’ knowledge, skills, and motivational orientation to their work [2,3,9-11]. Methods used by coaches, educators, and quality improvement facilitators to deliver feedback suggest that these factors are important [2,12,13]. Furthermore, in the context of routine feedback interventions (eg, with monthly or quarterly measurement cycles), the value of performance information [14-16] may be reduced when performance is stable, but feedback interventions are not commonly prioritized accordingly. Given the increasing use and digitization of performance measures and clinical quality dashboards [17,18], health care systems need to understand how to better accommodate health care professionals’ feedback preferences and the corresponding value of performance information.

Precision feedback is feedback that has been prioritized based on its motivational potential for a specific recipient [19-23]. Using this approach, high-value feedback messages can be selected to enhance reports and emails, such as “You reached the top performer benchmark” and “Your performance dropped below the peer average.” The potential impact of precision feedback increases with greater variability and differences in individuals’ knowledge, skills, and motivational orientation, but these differences and their interactions are not well understood, as studies of health care professionals’ feedback preferences appear to be scarce. Qualitative studies have explored feedback preferences by asking participants to discuss their experiences with prior feedback; for example, they can be prompted by a published feedback report [24] or a performance report belonging to the participant or their organization [25]. Quantitative preference elicitation methods have been used extensively in health decision-making [26,27], but uncertainty about the measurement properties of preferences contributes to controversy around their use [28]. To our knowledge, no instruments of health care professional feedback preferences with validity evidence have been developed. To begin to explore and understand these differences, we designed a preference elicitation study for motivating performance information and its display format.

We conducted this study in the context of anesthesia care quality improvement. In this context, data generated about care processes are produced primarily by anesthesia machines that report the administration of anesthetics and the patient’s corresponding state with relatively high accuracy and reliability. Attribution of performance to individual anesthesia providers is feasible due to their authenticated use of an anesthesia machine for each operative case. A national-scale quality improvement consortium, the Multicenter Perioperative Outcomes Group (MPOG) [29,30], has developed approximately 70 performance measures for anesthesia care quality and outcomes. Feedback is delivered through its infrastructure via monthly emails and a clinical quality dashboard to more than 8000 health care professionals in more than 20 US states. Thus, a relatively large set of measures are routinely assessed using high-quality clinical data, representing performance information that health care professionals have limited natural sources for across their patient populations.

Multiple types of motivation are recognized as mechanisms through which feedback influences performance [2,10,11,31-33]. These various types of motivation can be understood as a consequence of the cognitive processing of performance information. We use the term *motivating performance information* to mean performance information that has the potential to motivate a feedback recipient through a known mechanism of action (Table 1). A key type of motivating performance information is a *comparison* that represents a discrepancy between the performance level of a feedback recipient and some *comparator* [22]. There are multiple types of comparators, including *benchmarks* having a performance level that is determined by a population-based analysis. Benchmarks are commonly calculated as a summary statistic of top performers, such as choosing the performance level for a population that occurs at the 90th percentile, or the achievable benchmark of care (ABC) method [34]. Another type of comparator is an *explicit target*, including goals or standards that set expectations for attaining a specific performance level that is not necessarily dependent upon peers or another reference group’s performance [35]. The choice of comparators can result in the use of alternate mechanisms of motivation, such as motivation related to social norms versus personal goal-setting. Another key type of motivating information is *trends* that represent change in performance (getting better or worse) [22]. Comparisons and trends may co-occur in performance data to represent an *achievement*, such as reaching a goal, or a *loss*, such as losing top-performer status [22].

Table . Glossary.

Term	Description	Source
Performance information	Information about measures, levels, time intervals, comparators, and feedback recipient	[20,22]
Feedback	Information about performance that can guide future action	[36]
Feedback recipient	A person, team, or organization to whom a feedback intervention is directed	[22]
Precision feedback	Feedback that is prioritized according to its motivational potential for a specific recipient	[23]
Motivating performance information	Performance information that holds motivational potential	[23]
Comparison	Motivating performance information that is about a discrepancy between the performance levels of a feedback recipient and a comparator	[22]
Trend	Motivating performance information that is about a change in performance	[22]
Achievement	Motivating performance information that is about a change from a negative comparison to a positive comparison	[22]
Loss	Motivating performance information that is about a change from a positive comparison to a negative comparison	[22]
Comparator	Information that is used to identify a discrepancy with the performance level of a feedback recipient	[22]
Benchmark	A comparator with a performance level that is calculated from the performance of other health professionals or peers	[22,35]
Explicit target	A comparator with a performance level that is explicitly expected	[22,35]
Time point information	Performance information that is about a single time interval	— ^a
Time series information	Performance information that is about multiple time intervals	— ^a
Causal pathway model	A specification of influential elements in a causal process, including preconditions, mechanisms, moderators, and outcomes	[37]

^aNot available.

Comparisons and trends are represented using a wide range of visualizations in clinical quality dashboards and feedback reports [20]. These visualizations vary both in their content, such as the use of measures, comparators, and duration of time intervals, as well as the display format, such as bar charts, line charts, and tables to represent performance data. A review of published displays from feedback reports and dashboards identified 6 unique combinations of visualized performance information content [20]. For example, feedback displays vary in the number of performance measures, time intervals, and comparators that they visualize.

The display of feedback is theorized as one of many factors affecting the success of clinical performance feedback in Clinical Performance Feedback Intervention Theory (CP-FIT) [38], a leading theory of audit and feedback. Motivating performance information in clinical performance data concerns

configurations of types of feedback display, but is also closely related to CP-FIT's *goal* construct, which concerns the importance and relevance of feedback to health care professionals. Precision feedback may contribute to additional CP-FIT constructs, including health professional characteristics (knowledge and skills in quality improvement), feedback delivery (function), and implementation process (adaptability and ownership).

To understand anesthesia provider preferences for motivating performance information and feedback display format, we investigated the following four research questions:

1. To what extent do anesthesia providers' selected messages reveal an overall preference for
 - a. messages containing time series versus time point information (temporality)?

- b. messages relative to benchmarks versus explicit performance targets (basis of comparison)?
 - c. messages formatted as bar charts versus line charts and text only (display format)?
2. How consistent are individual anesthesia provider preferences?
3. To what extent do anesthesia provider preferences depend on performance level, trend, and their professional background?
4. To what extent are preferred feedback messages perceived to hold potential to improve future clinical practice?

Methods

Overview

To address these questions, we developed a test set of feedback messages that a software application could generate. We formatted these as brief email messages, but designed them as “least common denominator” content that could also be delivered via other channels for feedback, such as clinical quality dashboards.

In the absence of instruments with validity evidence for assessing health care professional feedback preferences, we

created an experimental design to elicit preferences that would expose participants, who were anesthesia providers, to contrasting message versions. To enable measurement validity assessment, we developed performance scenarios in which the same motivating performance information and display characteristics could be repeated in contrasting messages.

Ethical Considerations

This study was approved by the University of Michigan Health Sciences and Behavioral Sciences Institutional Review Board (IRB-HSBS HUM00167426). All participants provided consent to participate and were informed about the ability to opt out of the study. No participant identifiers were collected with the research data for this study, preventing the linking of participants’ responses with their identities. No incentives for participation were provided. We offered participants an opportunity to receive a copy of the study results upon completion.

Email Test Set Development

We developed the email message test set iteratively in three phases: (1) knowledge modeling, (2) display format development, and (3) message set development ([Figure 1](#)).

Figure 1. Development of a precision feedback email test set.

Phase 1: Knowledge Modeling

In the first phase we modeled knowledge about the elements of performance information, types of motivating information, and the influence of motivating performance information (Figure 1). We iteratively refined a model of the elements of performance information through an analysis of published feedback reports [20], resulting in the identification of 5 key elements: measures, recipients, comparators, performance levels, and time intervals. We developed a model of motivating information that combined the 5 elements of performance information into types of motivating information, including comparisons, trends, achievement, and loss. Each type of motivating information was defined using the elements of

performance information. For example, a comparison (a kind of motivating performance information) was defined as a discrepancy between the performance levels of a feedback recipient and a comparator.

Through modeling types of motivating performance information, we recognized that the choice of comparator could affect which type of motivation was used to influence a recipient. For example, choosing a 90th-percentile peer benchmark as a comparator does not necessarily leverage motivation from goal-setting when recipients do not form an intention to reach the benchmark as their personal goal. By inviting anesthesia providers to set goals, feedback that shows performance improving toward a goal may leverage motivation arising from a desire for growth and achievement, rather than a desire for

safety and avoidance of harm. These sources of motivation can differentially interact with the feedback sign (ie, valence) to have counterintuitive effects, such as goal abandonment, relaxation, or the delivery of low-value feedback [2,10].

To understand how different types of motivating performance information might relate to theoretical mechanisms of influence, we created causal pathway models [37] for each type of motivating information with benchmark and explicit target comparators (Multimedia Appendix 1). For example, in one causal pathway we modeled the expected influence of a feedback intervention that combines three elements of a recipient's performance: (1) performance below a comparator (low performance level), (2) a benchmark (such as a peer average), and (3) performance getting better (improving trend). This pathway could represent the influence of precision feedback emails that show performance approaching a peer average, which could indicate to recipients that efforts to improve performance appear to be succeeding. Based on the theoretical construct of *positive velocity* [31] (ie, showing performance improvement), this causal pathway (which we named *social approach* due to the recipient reducing a performance gap with a peer benchmark) uses motivation as a mechanism of action, through which a feedback recipient may decide to increase or sustain effort to improve performance.

We drafted and refined example messages for each type of motivating information. For the causal pathway *social approach*, an example message is "Your performance is approaching the benchmark." We implemented the causal pathway models in computer-interpretable form in a knowledge base to enable

automation of the processing of performance information to identify motivating information in a precision feedback system.

Phase 2: Display Format Development

In the second phase we developed display formats for motivating information in the body of an email message. We selected visualizations (ie, bar charts and line charts) common in health care organizations so that a familiar format would convey the minimal amount of information necessary for each causal pathway. We developed software to generate visualizations within an email message using R (version 4.3.3; R Foundation for Statistical Computing). We included the absence of a visualization (ie, text only) to accommodate recipient preferences for concise, text-based communication (Figure 1).

Phase 3: Message Set Development

In the third and final phase we created a test set of email messages with balanced characteristics of motivating information and display formats. We began by creating four performance scenarios with alternate performance levels (high vs low) and trends (improvement vs worsening vs stable): (1) improvement to a high level, (2) worsening to a low level, (3) consistently high (stable) performance, and (4) consistently low (stable) performance (Table 2). In all scenarios, the recipient's performance could be compared with either the peer average (benchmark comparator) or an organizational goal (explicit target comparator). We set the recipient's performance level to have the same relationship with each comparator (better or worse), enabling either comparator to be displayed while maintaining balance with other elements.

Table . Precision feedback email message test set specification.

Performance data scenario			Motivating information characteristics		Key message	Display format	
Level	Trend	Performance description	Temporality	Comparator		Shown to group A	Shown to group B
High	Improving	Performance level moves above comparators	Time series	Benchmark	You have become a top performer	Line chart	Bar chart
				Explicit target	You reached the goal	Bar chart	Line chart
			Time point	Benchmark	You are a top performer	Bar chart	Text only
				Explicit target	Congratulations on your high performance	Text only	Bar chart
Low	Worsening	Performance level moves below comparators	Time series	Benchmark	You are no longer a top performer	Bar chart	Line chart
				Explicit target	Your performance dropped below the goal	Line chart	Bar chart
			Time point	Benchmark	You are not a top performer	Text only	Bar chart
				Explicit target	You may have an opportunity to improve	Bar chart	Text only
High	No change	Performance level is consistently above comparators	Time series	Benchmark	You are a consistent top performer	Bar chart	Line chart
				Explicit target	Your performance is consistently high	Line chart	Bar chart
			Time point	Benchmark	You are a top performer	Text only	Bar chart
				Explicit target	Congratulations on your high performance	Bar chart	Text only
Low	No change	Performance level is consistently below comparators	Time series	Benchmark	Your performance has remained low	Line chart	Bar chart
				Explicit target	Your performance has not improved	Bar chart	Line chart
			Time point	Benchmark	You are not a top performer	Bar chart	Text only
				Explicit target	You may have an opportunity to improve	Text only	Bar chart

We selected types of motivating information and their example messages across three characteristics: (1) performance temporality (time series vs time point), (2) performance comparison basis (benchmark vs explicit target), and (3) performance display format (bar chart or other). We selected the bar chart format as a key display format because of its common use in health care organizations. We further divided the *other* display format into *line chart* and *text only*. We

composed emails with example messages from each type, based on a single quality measure (Avoiding postoperative nausea and vomiting [PONV-03]) for anesthesia providers. The resulting emails contained information from the same performance scenarios, but not all information from each scenario was provided in each message. For example, of the 4 emails that each participant read in each scenario, 2 messages contained a

goal comparator (explicit target), while the other 2 messages showed a peer benchmark comparator instead.

Study Design

We designed a within-subjects, repeated measures study of anesthesia provider preferences for precision feedback using a test set of prototype email messages printed on paper. We created 2 versions of the test set with alternate display formats for each message (group A vs group B) to enable randomization of the pairing of display format with motivating information. We created a document containing all of the email messages in the test set ([Multimedia Appendix 2](#)). We printed paper copies of the messages and organized them into packets in varying order for a paper card selection task. Based on our experience, we estimated that a sample of more than 30 participants would provide adequate power to detect meaningful differences in summary statistics and internal consistency of preferences.

Population and Setting

We recruited anesthesia providers from a single academic medical center in the midwestern United States. Anesthesiologists (physicians) and certified registered nurse anesthetists (CRNAs) were eligible to participate. A member of the study team recruited anesthesia provider participants by email. All participants received monthly anesthesia provider feedback emails from MPOG.

Data Collection

Upon enrollment, we scheduled a 15-minute proctored video call with each participant and sent them a paper packet with email prototypes before the call. Participants were randomized to receive a paper packet of messages from either group A or group B of the message test set, each of which contained 16 email messages grouped in 4 packets of 4. Each packet of 4 messages contained alternate message formats for 1 of 4 performance scenarios, with balanced message formats and performance information across the 4 scenarios. We created a questionnaire to collect data from participants about their preferred emails using Qualtrics (Qualtrics, Inc). We created 2 versions of the questionnaire (A and B), 1 for each message group to be used based on the participant's random assignment at the time of enrollment. At the time of enrollment, we also instructed participants to have a desk space or table available for placing printed email messages in front of them, and to wait to open the packets until asked to do so during the video call.

Preference Elicitation and Message Usability Assessment

At the start of the proctored video call, a research team member introduced the study, confirmed the participant's preparation, and provided a link to the questionnaire. During the completion of the questionnaire, the participant repeated a preferred email message selection task 4 times, following the instructions in

their packet, once for each performance data scenario. The questionnaire software randomized the scenario presentation order. We described the scenarios as hypothetical performances that the participant could imagine as being their own. At the start of each scenario, participants were asked to find the corresponding set of emails, identified with a cover sheet. Participants were then asked to lay out all 4 of the printed email messages for that scenario in front of them. Next, participants read each message and selected their preferred message. After selecting a preferred message, participants responded to the following statement: "I gained information from this email that would benefit my practice." We adapted this question from an instrument with good validity evidence for assessing the usability of feedback displays [39]. Responses were collected on a 5-point Likert scale, ranging from strongly disagree to strongly agree. The survey questions did not ask directly about preference for information content or display format. Instead, participants' preferences were inferred through the types of content and display format that the selected message contained. After participants completed the questionnaire, we conducted brief interviews and collected qualitative data that were analyzed separately and will be reported elsewhere.

Analysis

To identify preferences, we analyzed 2 characteristics of the selected messages: motivating information (including temporality type and comparator type) and display format. We summed the selected messages with each type of motivating information and display format and calculated descriptive statistics for these sums (Q1). To investigate the consistency of participants' preferences, we calculated the Cronbach α for each preference characteristic in participants' selected messages across the 4 performance scenarios (Q2). We used descriptive statistics to assess relationships between participants' preferences and the characteristics of the 4 performance scenarios, including performance level (high vs low) and trend presence (present vs absent). Similarly, we considered relationships between participants' preferences and their professional background using descriptive statistics (Q3).

To understand participants' perceptions of the potential benefit of precision feedback to their clinical practice, we analyzed ratings of perceived benefit for selected messages using descriptive statistics (Q4). We conducted analyses using R and Google Sheets (Google LLC).

Results

We recruited 35 anesthesia providers, including 18 anesthesiologists and 17 CRNAs ([Table 3](#)). All participants completed all message selection tasks, resulting in the selection of 140 preferred precision feedback messages.

Table . Study participant characteristics (N=35).

Characteristics	Participants, n (%)
Professional role	
Anesthesiologist	18 (51)
Certified registered nurse anesthetist	17 (49)
Race/ethnicity	
African-American	0 (0)
Asian	2 (6)
Hispanic	0 (0)
White	31 (89)
Other	2 (6)
Gender	
Female	19 (54)
Male	16 (46)
Nonbinary/other	0 (0)

To What Extent Do Anesthesia Providers' Selected Messages Reveal an Overall Preference for Temporality (Q1a), Basis of Comparison (Q1b), and Display Format (Q1c)?

An overall preference for multiple time intervals (ie, time series) was apparent, with 110 of 140 (79%) messages being selected over those with a single time interval (ie, time point) (Q1a).

Preferences for display format were highly varied, with selected messages being equally distributed between bar charts versus other formats (Table 4) (Q1c). Preferred messages were also highly varied in their comparators, with 74 of 140 (53%) preferred cards containing explicit target comparators (ie, organizational goals not dependent on population performance) (Q1b), but our assessment of the consistency suggests that the comparator result was not reliable as a preference characteristic (see Q2 below).

Table . Characteristics of preferred precision feedback messages.

Message characteristic and subtype	Preferred messages (n=140), n (%)	Message characteristic preference (n=4), mean (SD)	α
Temporality			.85
Time series	110 (79)	3.14 (1.38)	
Time point	30 (21)	0.86 (1.38)	
Comparators			-.40
Benchmark	66 (47)	1.89 (0.87)	
Explicit target	74 (53)	2.11 (0.87)	
Display format			.80
Bar chart	70 (50)	2.00 (1.61)	
Other display	70 (50)	2.00 (1.61)	

How Consistent Are Individual Anesthesia Provider Preferences (Q2)?

Participants' preferences were consistent for temporality ($\alpha=.85$) and display format ($\alpha=.80$). For performance comparators, participants' selected messages were negatively correlated ($\alpha=-.40$), indicating an absence of consistency, perhaps from an incorrect measurement model [40]. We consider this result to be an artifact of the study design, given that our message test set balanced several characteristics and created opportunities to select them in combination. We anticipate that comparators were not salient for participants, relative to the visual display

and temporality characteristics; therefore, we are unable to draw conclusions about preferences for comparators.

To What Extent Do Anesthesia Provider Preferences Depend on Performance Level and Trend and Their Professional Background (Q3)?

Participant preferences for temporality and display format did not appear to depend on the messages' performance level, with relatively similar means for the selection of each type of message content. Similarly, these preferences did not appear to vary with the presence or absence of performance trends (Table 5).

Table . Precision feedback preferences by performance scenario characteristics.

	Temporality preference, mean (SD)		Comparator preference, mean (SD)		Display format preference, mean (SD)			
	Time series	Time point	Benchmark	Explicit target	Bar chart	Other display	Other display: line chart	Other display: text only
Level: high	1.60 (0.69)	0.40 (0.69)	1.09 (0.56)	0.91 (0.56)	0.94 (0.87)	1.06 (0.87)	0.77 (0.88)	0.29 (0.62)
Level: low	1.54 (0.78)	0.46 (0.78)	0.80 (0.53)	1.20 (0.53)	1.06 (0.87)	0.94 (0.87)	0.66 (0.84)	0.29 (0.62)
Trend present	1.66 (0.68)	0.34 (0.68)	1.06 (0.54)	0.95 (0.54)	1.09 (0.89)	0.91 (0.89)	0.69 (0.83)	0.23 (0.60)
Trend absent	1.49 (0.78)	0.51 (0.78)	0.83 (0.51)	1.17 (0.51)	0.91 (0.85)	1.09 (0.85)	0.74 (0.85)	0.34 (0.64)

Preferences for temporality and display format varied with participants' professional background (Table 6). Some professional role-based differences in means were apparent, such as a higher preference for time point messages among CRNAs than anesthesiologists (mean message characteristics

preference 1.18, SD 1.59 vs mean message characteristic preference 0.56, SD 1.10). However, a majority of CRNAs preferred time series messages, and all message characteristics were repeatedly observed in selections by participants from both professional background-based groups.

Table . Precision feedback preferences by professional background.

	Temporality preference, mean (SD)		Comparator preference, mean (SD)		Display format preference, mean (SD)			
	Time series	Time point	Benchmark	Explicit target	Bar chart	Other display	Other display: line chart	Other display: text only
Anesthesiologist	3.44 (1.10)	0.56 (1.10)	1.83 (0.79)	2.17 (0.79)	2.28 (1.60)	1.72 (1.60)	1.33 (1.68)	0.39 (0.78)
Certified registered nurse anesthetist	2.82 (1.59)	1.18 (1.59)	1.94 (0.97)	2.06 (0.97)	1.71 (1.61)	2.29 (1.61)	1.53 (1.55)	0.76 (1.48)

To What Extent Are Preferred Feedback Messages Perceived to Hold Potential to Improve Future Clinical Practice (Q4)?

Participants' ratings of perceived benefit from all precision feedback messages were positive, with a mean rating of 4.27 (SD 0.77). Although positive overall, the anesthesiologists'

ratings were lower than the CRNAs' ratings (mean rating 4.08, SD 0.85 vs mean rating 4.47, SD 0.61). Ratings for messages did not appear to vary across performance levels or with trends (Table 7). Average ratings of perceived benefit were similar across message content characteristics. One exception to this was for explicit target comparators, which appeared to receive slightly higher ratings (mean rating 4.38, SD 0.7) over benchmark comparators (mean rating 4.15, SD 0.83).

Table . Perceived benefit of selected messages.

Characteristics	Mean rating (SD)
Participant professional background	
Anesthesiologist	4.08 (0.85)
Certified registered nurse anesthetist	4.47 (0.61)
Performance scenario	
Performance level	
High performance	4.23 (0.76)
Low performance	4.31 (0.77)
Performance trend	
Trend present	4.34 (0.72)
Trend absent	4.2 (0.81)
Message content	
Temporality	
Time series	4.27 (0.81)
Time point	4.27 (0.58)
Comparator	
Benchmark	4.15 (0.83)
Explicit target	4.38 (0.7)
Display format	
Bar chart	4.27 (0.76)
Other display	4.27 (0.78)
Other display: Line chart	4.28 (0.83)
Other display: text only	4.25 (0.64)

Discussion

Principal Results

In this study, we found that anesthesia provider preferences for motivating information and display format varied, which suggests that individual difference characteristics may represent a barrier to improving the effectiveness of feedback interventions. Across a set of 4 diverse performance scenarios, we observed preference variability that precision feedback could better address than one-size-fits-most feedback in this anesthesia provider population.

We observed consistency in participant preferences for the temporality of motivating information and for display format. Even though a large majority of participants preferred messages with time-series information, the participants who preferred time-point messages reliably selected them. The consistency of preferences for display format was similar, and also more varied, with exactly half of participants choosing bar charts over other visual displays. We also did not observe differences in preferences associated with performance scenario characteristics or professional background that could be used to design one-size-fits-most feedback interventions.

While participants exhibited diverse preferences, their ratings of the benefit of the messages were consistently high across

performance scenarios. These findings suggest that anesthesia providers would welcome the enhancement of feedback interventions with precision feedback that prioritizes motivating information. These findings are important because they point to a possible approach for improving audit and feedback that can leverage both high and low performance, as well as increasing or decreasing trends, to prioritize performance feedback.

To our knowledge, this is the first quantitative study of preferences for clinical performance feedback. As an exploratory study, the findings primarily demonstrate the existence of differences in preferences for feedback, rather than speaking to the significance of their role in the success of clinical performance feedback. Our findings are related to CP-FIT, which recognizes that health professional knowledge and skills for engaging with feedback can be important factors for the success of feedback [38]. Differences in feedback preferences could be driven by differences in health care professionals' knowledge and skills related to the interpretation of performance data. For example, participants' variable and consistent selection of messages could be related to their graph literacy skills [41,42]. Precision feedback could be used to accommodate these and other individual differences by enabling health professionals to configure their feedback delivery and display, which further holds potential to increase feelings of ownership of feedback.

By prioritizing motivating information according to recipients' preferences, precision feedback could be a strategy for reducing the cognitive load required by health professionals to recognize and assess the priority of learning opportunities. Precision feedback has also potential to improve feedback cycle completion by delivering information that is more likely to be perceived and accepted, resulting in increased formation of intentions to sustain or improve performance. In terms of CP-FIT, precision feedback can be understood as an approach for prioritization of feedback messages that are more likely to result in successful completion of the feedback cycle.

Our findings are aligned with the idea that positive feedback can be effective for learning and improvement [13], as well as sustainment of high performance. It is noteworthy that participants rated precision feedback messages as beneficial even when performance was high, such as the messages "you are a top performer" or "you reached the goal." This finding points to the possibility that a key function of feedback may be to motivate recipients through appreciation of accomplishments [43], including recognition of high performance, in addition to motivating recipients to learn to improve.

Limitations

As an exploratory study for a novel type of feedback intervention, there are several important limitations for this study. The poor consistency of preferences demonstrated for performance comparators suggests that participants did not meaningfully differentiate between peer-based benchmarks and explicit targets, as presented in the message test set. This may be a function of the labels used for the comparators message test set, and during the study we discovered that some of the printed messages contained the abbreviation "ave" instead of "avg" for the peer average comparator. Competing explanations are that (1) anesthesia providers equated the value of both comparator types or did not perceive them as fundamentally different, and (2) that this characteristic was less salient than the others, such that its significance was negligible.

Using performance scenarios based on synthetic performance data may have introduced bias in participants' responses. However, the consistency of participant preferences for temporality of motivating information and display format suggests that this bias was not significant. Nevertheless, our study design assessed preferences within types of motivating information (eg, high and improving performance or low and worsening performance) that were presented with unambiguous motivating information, such as trends showing marked improvement or worsening. As such, our results do not address the appropriateness of using performance scenarios to elicit the strength of anesthesia provider preferences directly; rather, they primarily demonstrate the existence of individual differences as an exploration of factors that may moderate the influence of feedback on health care professional learning and improvement.

We asked participants to rate the perceived benefit of messages that they had already selected as their preferred message, which may have resulted in positively biased ratings. Furthermore, we used a single performance measure for all messages (avoiding postoperative nausea and vomiting) that may not be representative of other performance measures, both in terms of

perceived benefit and preferences for motivating information. We did not evaluate feedback about clinical outcome measures, which may have resulted in a different preference profile across this population. We also did not evaluate participants' skills or knowledge to engage effectively in feedback, which is a recognized factor [38] that may have resulted in further insight into participant preferences.

Additional limitations include the context and nature of the preference elicitation task, which was done in a video call with paper prototypes and thus differed from the context of email use in health care organizations. When designing this study, we chose to use email messages printed on paper because we could not identify a remote, video call-proctored approach that would allow participants to consider 4 different messages types in the same field of view on their personal or work computer without a risk of technical complications from participants' particular computer monitor and device configurations.

Our model of preferences in this study was linear and static and assumed that available information was complete, but anesthesia provider preferences may be nonlinear, dynamic, and depend on missing information that we did not consider. When designing the test set of messages, we paired the text-only display format consistently with time-point information, and line charts with the time-series format. As such, preferences for line charts and text-only display formats were not independent from temporality. We recruited anesthesia providers from a single academic institution whose population is not necessarily representative of other anesthesia provider populations. We did not recruit any anesthesia providers who identified as Black or Hispanic, increasing the likelihood that our results are racially and ethnically biased toward the perspectives of anesthesia providers who identify as White and non-Hispanic. In spite of all of these limitations, we note that the variability that we observed demonstrates that preferences were nonuniform in this small population, which suggests that a one-size-fits-all solution may be inadequate for feedback reporting to anesthesia providers more generally.

Future Studies

We anticipate that preference clusters may exist and may be identifiable in studies that are better powered to detect such differences. Such clusters could be used to develop profiles for precision feedback, such as profiles for anesthesia providers who prefer text-only messages about low performance or those who prefer visualization of performance changes (ie, trends) using time-series displays in line charts. Future studies may be able to detect preference clusters to better understand the diversity of preferences for performance feedback across a larger anesthesia provider population that is more racially, ethnically, and geographically diverse. Furthermore, we would welcome studies that aim to better understand the diversity of anesthesia provider preferences in association with additional anesthesia provider characteristics, such as duration of professional experience, clinical setting, and organization type.

Conclusions

Clinical performance feedback to health care professionals has potential to support continuous learning and influence practice,

but this potential is frequently not achieved. By prioritizing motivating performance information based on the preferences and needs identified for a health care professional population, precision feedback may increase the effectiveness of clinical performance feedback for health care professionals' continuous learning and resulting quality improvement. Among a sample of anesthesia providers, preferences for precision feedback were

varied, yet consistent within participants. Furthermore, participants' perceived benefits of precision feedback messages were observed to be high across a diverse set of performance scenarios. Based on these findings, it appears that precision feedback holds potential to improve support for health care professionals' continuous learning.

Acknowledgments

The authors would like to thank Ms Astrid Fishstrom for contributing to the investigation. We are grateful to Dr Anne Sales, Dr John Rincón-Hekking, Ms Dahee Lee, Mr Cooper Stansbury, and Ms Veena Panicker for their contributions to foundational work for this study. We thank the NIH (National Institutes of Health) National Library of Medicine for funding this research. This study was funded by a grant from the NIH National Library of Medicine (K01LM012528; principal investigator ZLL) paid to the University of Michigan.

Data Availability

Data collected without identifiers are included as a supplementary file ([Multimedia Appendix 3](#)).

Authors' Contributions

ZLL and CPF conceptualized this study. ZLL and NJS contributed to the investigation. Formal analysis of the study was conducted by ZLL, CPF, and CAA. ZLL, NJS, CAG, and CPF contributed to the methodology. CAG developed the software for this study. ZLL and CAG developed the visualizations. ZLL wrote the original draft, and ZLL, CAA, CAG, CPF, and NJS contributed to the review and editing. No generative artificial intelligence was used in any portion of the manuscript writing.

Conflicts of Interest

ZLL has received research support paid to the University of Michigan and related to this work from the National Library of Medicine (K01 LM012528; R01 LM013894). NJS has received research support paid to University of Michigan and unrelated to this work from Merck & Co. NJS received support paid to the University of Michigan for his role as program director of the Anesthesiology Performance Improvement and Reporting Exchange (ASPIRE) Collaborative Quality Initiative, and has received research support from Edwards Lifesciences, Apple Inc, and the National Institute on Aging (R01 AG059607) paid to the University of Michigan and unrelated to this work.

Abstract

Background: Currently, there is a need to optimize knowledge on digital transformation in mental health care, including digital therapeutics (eg, prescription apps), in medical education. However, in Germany, digital health has not yet been systematically integrated into medical curricula and is taught in a relatively small number of electives. Challenges for lecturers include the dynamic field as well as lacking guidance on how to efficiently apply innovative teaching formats for these new digital competencies. Quality improvement projects provide options to pilot-test novel educational offerings, as little is known about the acceptability of participatory approaches in conventional medical education.

Objective: This quality improvement project addressed the gap in medical school electives on digital health literacy by introducing and evaluating an elective scoping study on the systematic development of different health app concepts designed by students to cultivate essential skills for future health care professionals (ie, mobile health [mHealth] competencies).

Methods: This proof-of-concept study describes the development, optimization, implementation, and evaluation of a web-based elective on digital (mental) health competencies in medical education. Implemented as part of a quality improvement project, the elective aimed to guide medical students in developing app concepts applying a design thinking approach at a German medical school from January 2021 to January 2024. Topics included defining digital (mental) health, quality criteria for health apps, user perspective, persuasive design, and critical reflection on digitization in medical practice. The elective was offered 6 times within 36 months, with continuous evaluation and iterative optimization using both process and outcome measures, such as web-based questionnaires. We present examples of app concepts designed by students and summarize the quantitative and qualitative evaluation results.

Results: In total, 60 students completed the elective and developed 25 health app concepts, most commonly targeting stress management and depression. In addition, disease management and prevention apps were designed for various somatic conditions such as diabetes and chronic pain. The results indicated high overall satisfaction across the 6 courses according to the evaluation questionnaire, with lower scores indicating higher satisfaction on a scale ranging from 1 to 6 (mean 1.70, SD 0.68). Students particularly valued the content, flexibility, support, and structure. While improvements in group work, submissions, and information transfer were suggested, the results underscore the usefulness of the web-based elective.

Conclusions: This quality improvement project provides insights into relevant features for the successful user-centered and creative integration of mHealth competencies into medical education. Key factors for the satisfaction of students involved the

participatory mindset, focus on competencies, discussions with app providers, and flexibility. Future efforts should define important learning objectives for digital health literacy and provide recommendations for integration rather than debating the need for digital health integration.

Introduction

Background

Initiated by the slow digital transformation of the German health care system, the German Federal Parliament passed the Digital Healthcare Act in December 2019, which made it possible to prescribe certain medical apps [1]. Since then, topics related to medical informatics, digital health, and telemedicine have started to appear more and more in the curriculum of some German medical schools, although mostly through few electives rather than compulsory subjects [2,3]. As digital health is a highly complex, dynamic field that constantly changes and advances and that has rarely been implemented into medical curricula [4,5], it seems necessary to compile and establish designated novel teaching formats that focus on the different subtopics, such as digital mental health interventions (DMHIs; eg, mobile health apps for dealing with depressive symptoms or managing study-related stress).

Digital mental health literacy, as well as competencies, becomes more and more important for (future) health professionals and medical education. It can be defined as “the degree to which individuals obtain, process, and understand basic mental health information and services needed to aid their recognition, management, or prevention of mental health issues” [6]. Even though younger generations are often supposed to be familiar with digitization and the corresponding competencies, research has shown that medical students do not feel adequately prepared for digitization in their course of study [2,3,7,8].

Previous studies have found that medical students perceive insufficient digital health literacy [9] and know little about available DMHIs [10,11]. At the same time, mental disorders have relatively high prevalence rates among the general population (ie, approximately 27.8% of the general German population have a mental disorder [12], and approximately 20% of the German population have depressive symptoms [13], a general decline in mental health in the last year [14]), and digital interventions could offer additional treatment and prevention options [15]. A systematic review and meta-analysis demonstrated that pooled depression prevalence among medical students worldwide was 37.9% [16]. DMHIs are especially relevant for medical students because, on the one hand, students are less likely to seek psychological help (due to barriers such as fear of stigmatization or lack of awareness) [17]. On the other hand, they themselves will eventually treat patients with (mental) health issues and may prescribe and use telemedicine, including digital health applications (in German: *Digitale Gesundheitsanwendungen* [DiGAs]) as future physicians [18].

Since October 2020, physicians and psychotherapists can prescribe DiGAs that are listed in the DiGA register by the German Federal Institute for Drugs and Medical Devices (Bundesinstitut für Arzneimittel und Medizinprodukte), including different DMHIs for mental disorders, on the expense of statutory health insurance companies [1]. DiGAs are certified medical products mainly based on digital technologies that can be used to detect, surveil, treat, or mitigate diseases, injuries, or disabilities [19]. The goals of DiGAs include the monitoring and improvement of current treatments in patient care. In the face of aging societies and the rise of chronic diseases, high-income industrial nations are confronted with rising health care costs. Therefore, digital health care and digital self-care practices are linked to efforts to better prevent disease, calculate disease risks and life expectancy through algorithm-based personalized medicine, and at the same time delegate clinical treatment responsibilities to the affected individuals themselves [20]. The potential of digital therapeutics or DiGAs in particular to improve the uptake of health care services has not been fully exploited yet, and the uptake is relatively low compared to prevalence rates [21]. In preventive medicine and disease monitoring, digital interventions could improve patients' health and personal motivation [22]. In addition, digital data collection promises to optimize processes and increase the efficiency of the health care system at an institutional level [20].

Studies have shown that physicians are open to the idea of DiGAs [21], but the current prescription rates of DiGAs are low, with approximately 203,000 DiGAs prescribed or granted by health insurances in Germany [23]. Physicians in a mixed methods study described that they were skeptical (eg, due to technical insecurities) and said that they lacked adequate information sources on how to prescribe DiGAs and how to guide and advise patients concerning their use [19]. From a patient perspective, there is a clear interest in digital health as well. A recent German study on health app acceptance found that 76% of participants, including those without previous app experience, expressed willingness to use DiGAs [18]. Information measures can effectively increase acceptance of quality-assured digital health services among health care providers and patients [24]. To address the knowledge gap and enhance digital health competencies, practicing physicians are considering continuing education opportunities [21].

However, digital health literacy and digital competencies, or the acquisition of knowledge on DMHIs, including DiGAs for the treatment of mental disorders and the management of chronic conditions, need to be part of the curriculum, which could be piloted in elective subjects in medical schools. To the best of our knowledge, there are only a few studies concerning the

teaching of digital health and digital competencies in German medical schools. Thus, little is known about strategies to implement such new teaching offerings in medical education. In one study, a total of 16 universities in Germany were identified that had included digital skills in their curricula (17 elective and 8 compulsory courses) [2]. For example, a study investigated the impact of an interdisciplinary and cross-faculty course concerning digital medicine with the help of a web-based questionnaire before and after the course [3]. Aulenkamp et al [2] found a positive impact of such courses on the students' digital competencies and concluded that more efforts to integrate them into the curriculum would be necessary. One comparative study examined the implementation of a module on digital health among undergraduate medical students at a German university, the knowledge gain of students, and their attitudes toward digital health and suggested a firm implementation of digital competencies in medical education [25]. Another German study examined interdisciplinary teaching with the help of teaching teams of medical informatics professionals and physicians. In different academic years, new seminars on digital competencies were designed and implemented, and the usefulness of interdisciplinary teaching teams was demonstrated [26]. Further studies covered the integration of an elective on digital health in diabetes for pharmacy students [27] or the design, implementation, and evaluation of a course with a focus on telemedical components [28].

Overall, it is essential to permanently integrate digital health education into the curricula of medical schools [29,30]. Practical, competence-oriented didactic concepts offer promising strategies to enhance knowledge transfer and enable students to proficiently handle DMHIs and health apps.

Goals of the Quality Improvement Project and the Case Study

The overarching objective of the quality improvement project was to develop and iteratively optimize an innovative learning and teaching offering for medical students based on their preferences and needs in a German medical school. The goals were targeted via an elective subject.

The elective subject in this proof-of-concept study aimed to provide students with basic knowledge and practical skills and promote a comprehensive understanding of designing concepts for digital health interventions in prevention and therapy with the potential user in mind. The focus of the elective was on digital health competencies in the field of mental health; the use of DMHIs in occupational and social medicine, especially in the area of primary prevention (eg, stress management); and DiGAs for somatic and mental diseases based on the students' choices.

Our proof-of-concept study on quality improvement in medical education is meant to provide insights into the piloting of an innovative digital elective subject concerning the development of theoretical prototypes for DMHIs. We aimed to evaluate the implementation and realization of the elective subject using a design thinking process and analyze students' feedback, ideas, and preferences concerning the competence-based education on mental health apps ("learning by doing" and cocreating).

Methods

Setting and Background of Teaching Innovation

The focus of the innovative teaching offering at a German medical school was on digital mental health in areas of application relevant to prevention and health care settings; quality criteria of mobile health apps; legal framework, including structural conditions for telemedicine (eg, the so-called Digital Healthcare Act in Germany and prescription of DiGAs); and user-oriented app design (eg, persuasive design [31]). The elective also aimed to promote knowledge of app development, self-competence, collaborative learning (codevelopment of an app concept in small student groups according to the prominent design thinking approach by the Hasso Plattner Institute [32]) as well as critical reflection on the opportunities and risks of digitalization for health professionals. The main target group were medical students, but due to the interdisciplinary nature of health app development, we allowed a small number of students from other disciplines to also participate.

Quality Improvement Project

The quality improvement project was divided into 2 parts: funding (24 months) and the implementation of the web-based elective into the curriculum after the pilot project (12 months). The quality improvement project took place for 24 months from January 1, 2021, to December 31, 2022, at the Medical Faculty of Heinrich Heine University Düsseldorf (HHU) in Germany. We offered the digital elective 6 times within 3 years. The concept was based on a preceding elective subject involving a co-design workshop on digital mental health literacy in medical studies, which we conducted on campus with 26 medical students in March 2020, as described in sufficient detail by Dederichs et al [8]. In this subject, medical students developed theoretical prototypes of health apps in small groups using appropriate background knowledge and the established 5-step design thinking principle [33]. The students gave us feedback and indicated that they would have liked more flexibility, digital content in ILIAS (Integriertes Lern-, Informations- und Arbeitskooperations-System [German for "Integrated Learning, Information and Work Cooperation System"]), and additional guest lectures, which is why we developed the idea of a digital or hybrid implementation of the seminar (blended learning approach) [8]. The corresponding author conceived the project idea and acquired funding for an innovative educational project by the Commission for Quality Improvement in Teaching and Studies of the Dean's Office of the Medical Faculty in November 2020. In January 2021, we prepared the digital elective "Fit for digitalization and 'apps on prescription'?—Understanding digital health applications and developing digital health offers such as health apps" for the summer semester of 2021. Medical students were able to take the elective subject with 2 semester hours per week. Over time, we also extended the elective to students from other fields if there were enough available openings. This was achieved either in the framework of "studium universale" or as a psychology minor, including credit points for active participation. Finally, the following 12 months (January 2023–January 2024) were used to implement the project into medical education practice without additional staff, which required some adaptations,

including providing a screen cast (ie, video tutorial) on the technical creation of app mock-ups using the collaborative design tool Figma (Figma, Inc) instead of personal assistance for each group.

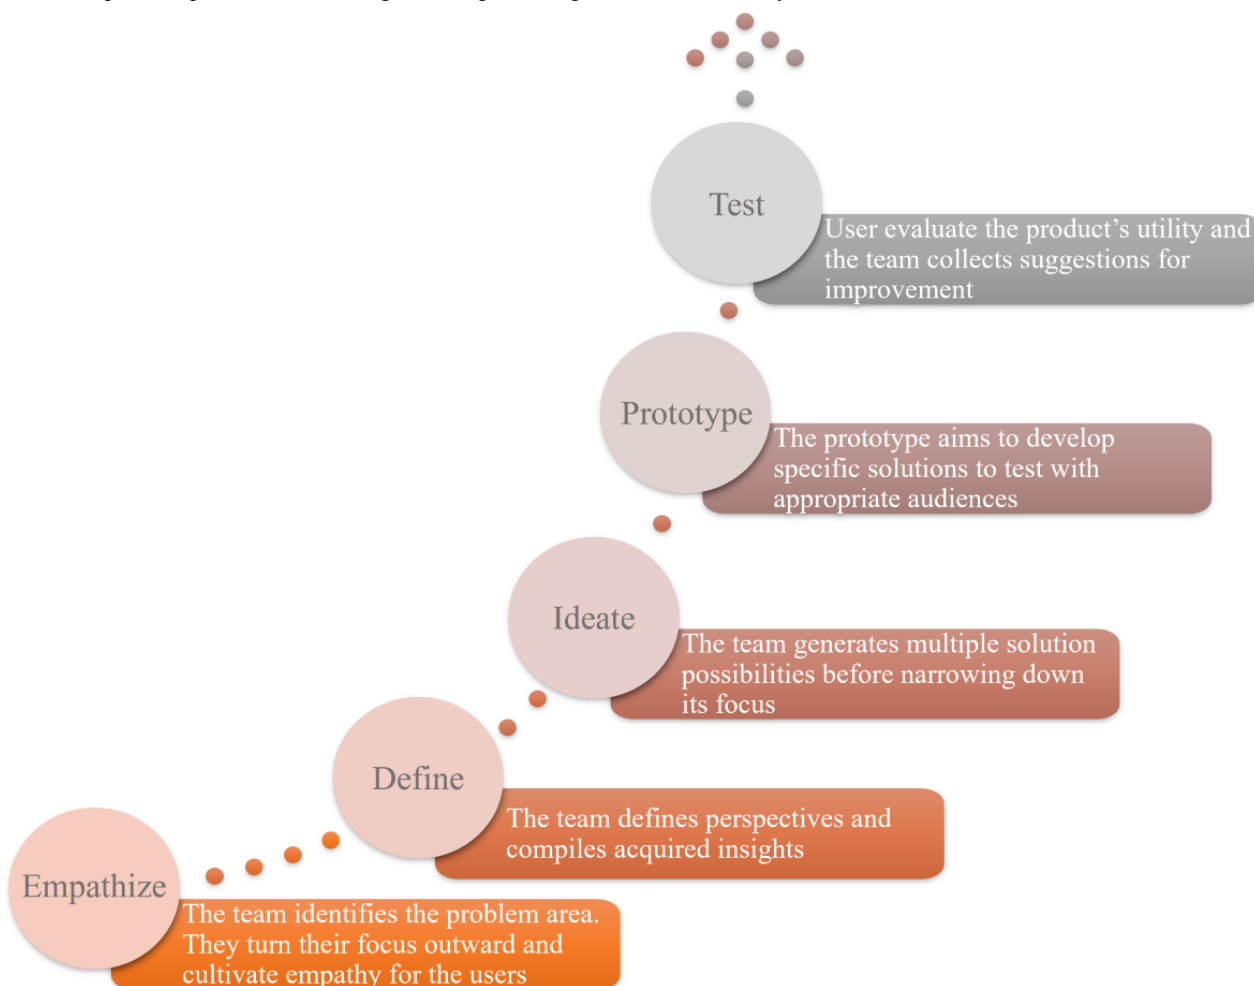

Structure and Composition of the Elective

We varied the elective either as an intensive block course (5 consecutive days, full time during the lecture time, and provided once) or as weekly seminars (7 times, part time during the lecture-free time, and provided 5 times), equating to a time effort of 2 semester hours for both options. For more intensive support, we increased the proportion of synchronous live lectures after the first run in 2021. In addition, students were able to access the content (eg, presentations) and additional material via the web-based learning management system ILIAS (ILIAS open source e-Learning e.V). Students could request feedback

on their group work via ILIAS. We refined the ILIAS environment steadily to ensure its immediacy and to meet students' preferences.

The focus was on competence-oriented learning and participatory design approaches. The acquired knowledge about health apps was directly transferred into a concrete app concept in the group work. In creating the group assignments, we were guided by the concept of design thinking and its phases for developing an app. Design thinking is an iterative, user-centered approach to innovation and problem-solving. This framework emphasizes the comprehensive analysis and understanding of human needs to generate original approaches to solving complex problems [31-33]. The process, which typically involves multiple stages, includes understanding the problem, carefully eliciting user-specific requirements, generating ideas, creating prototypes, and testing solutions (Figure 1 [31]).

Figure 1. A simplified explanation of the 5 stages of design thinking (based on the work by Meinel et al [31]).

The elective included an introductory session at the beginning of the semester, which introduced the procedure, contents, and objectives and brought students together in small groups with different app topics (eg, insomnia). Initial content-related issues were also covered (eg, definitions and fields of application). In lessons 2 to 5, the students were given a group task aligned with

the content of the lessons and a design thinking process, which systematically guided them in the development of a hypothetical app.

A detailed description of the structure of the elective can be found in Table 1.

Table 1. Lessons and main contents of the elective course^a.

Session number	Main topic	Contents
1	Organizational matters and introduction	<ul style="list-style-type: none"> • Overview and examination • Presentation of group results (app concepts) from previous semesters • Introduction—working definition of digital mental health • Areas of application • Support with digital health interventions • Evidence of e-mental health • Telemedicine and digital health in occupational medicine • Division into small groups for the development of own app concepts and introducing tools for group work • First introduction to design thinking • Option of test access to DiGAs^b (GAIA AG)
2	Quality criteria of health apps	<ul style="list-style-type: none"> • Description of quality seals for health apps • Description of quality principles • Presentation of the DiGA register • Quality measurement using the MARS^c [34] (German version [35]) • Presentation of the search for quality-assessed health apps and e-mental health interventions • Presentation of an app (eg, blood pressure app Manoa) • Group work
3	DiGAs—“apps on prescription”	<ul style="list-style-type: none"> • Regulation of the apps listed in the DiGA directory • Acceptance and use of DiGAs • Various guest lectures on mental health DiGAs (eg, Somnio, Deprexis, Elona Therapy Depression, and Velibra DiGAs) • Guest lecture ReHappy (former stroke DiGA), including screencast (ie, video files of recorded lectures) • Group work
4	Design thinking and persuasive design (app development)	<ul style="list-style-type: none"> • Description of the phases of the design thinking process • Presentation of concept mapping • Teaching persuasive design and persuasive design in mental health apps • Discussion on the “ideate” phase in the design thinking cycle and idea generation • Incentives for managing successful apps • Group work
5	Strategies to promote acceptance and adherence	<ul style="list-style-type: none"> • Measures to promote user adherence and motivation by communicating acceptance models, such as the UTAUT^d and UTAUT2^e adapted to digital health [36,37] • Presentation of usability in health apps (eg, via the SUS^f [38]) • Description of gamification approaches for health apps • Presentation on promoting acceptance through information • Description of the distinction between health and medical apps as well as trusted health apps • Group work
6	Finish for the final presentation	<ul style="list-style-type: none"> • Explaining peer feedback • Guest lecture from Startup4MED, HHU^g (each semester) • Tips for the final presentations and peer feedback • Group work
7	Final presentation of the group work	<ul style="list-style-type: none"> • Lecture—summary plus current developments and perspectives • Presentation of the developed app concepts in small groups • Feedback and evaluation of the elective

^aDetailed description of the elective structure (sessions 1 to 7). The contents partly varied across the semesters based on expert availability (digital health app providers) and adaptations made following the evaluation results of the former semester.

^bDiGA: digital health application.

^cMARS: Mobile App Rating Scale.

^dUTAUT: Unified Theory of Acceptance and Use of Technology.

^eUTAUT2: extension of the UTAUT to the consumer context.

^fSUS: System Usability Scale.

[§]HHU: Heinrich Heine University Düsseldorf (Germany).

Practical Transfer Through the Integration of Guest Lectures and Test Access

We provided students with selected guest lectures by experts who created, provided, or presented DiGAs to the professional community (eg, Somnio, Velibra, and Elona Therapy Depression). In addition, at the end of the course, we hosted lectures from staff members of the medical-specific start-up support unit “Startup4MED.” Startup4MED is the internal start-up support unit of the University Medicine Düsseldorf and identifies, promotes, and supports the commercial exploitation of innovative medical projects from the Medical Faculty of HHU and the University Hospital of Düsseldorf. This allowed participants to connect with the start-up support team for extra guidance on their ideas and on how to implement their app concepts in practice.

Each semester, students had the opportunity to attend between 1 and 3 guest lectures, some of which were recorded as screencasts (ie, videos in terms of recorded lectures) and uploaded online. In addition, students were given the chance to try free demonstration versions of various DiGAs through a trial program sponsored by a German company (GAIA AG) in 2021 and 2022.

Student Support and Competence-Oriented Performance Recording

During their elective, students received comprehensive assistance through multiple media and communication channels that aligned with their individual preferences. These channels comprised Rocket.Chat, an open-source team chat platform, as well as Microsoft Teams. To reinforce their learning process, the participants were assigned concise, structured tasks following every session, and the completion of these tasks was monitored by the project team. We also offered personalized feedback and guidance on demand beyond the group feedback each week upon completion of the tasks uploaded using ILIAS. As part of the overall design thinking process, the students were gradually and systematically introduced to the app concept. This was done by providing weekly synchronous web-based lectures in addition to the educational material provided via ILIAS. This approach aimed to promote collaboration, reduce inhibitions to reach out, and provide students with more flexibility. In the last session of the elective, student groups presented their developed app concepts to their instructors and peers and received feedback. Optionally, the assessment could be completed as an exam. Finally, the students were instructed to evaluate the elective through a web-based survey provided via “evasys” (evasys GmbH).

Evaluation

In addition to the oral feedback in the last session, we used a web-based evaluation questionnaire created using templates provided by the Dean’s Office (Department of Evaluation, Medical Faculty). The questionnaire, implemented using “evasys,” included standardized questions on digital teaching offerings and was completed by students online after finishing the course. Participation was voluntary, and thus, we tried to

increase it by sending reminders. In the first part of the questionnaire, we asked students to provide information about their gender and their field of study. In the second part of the questionnaire, we asked students to rate the module through 19 questions. The first 13 were answerable on a 6-point Likert scale ranging from 1 (“completely agree”) to 6 (“do not agree at all”). These questions concerned the content of the elective as well as the visualization and access to ILIAS, such as “The learning module was well structured.” Finally, we assessed the perceived difficulty level of the learning material, overall satisfaction with the elective (both in general and regarding digital implementation), and the students’ own estimated learning gains after completing the elective.

A total of 3 additional questions dealt with the difficulty of the learning content, the scope of the learning and reading material, and the assessment of particularly helpful elements in the course (5 response options, eg, text units and screencasts). The last 3 questions served as feedback and were presented in the form of open questions (eg, what students liked most about the course, which competence area they benefited most from, and which suggestions for improvement they had). The evaluation was centralized and anonymized by the Dean’s Office. Results of the evaluation were provided in an aggregated format by the Dean’s Office if a minimum of 5 completed surveys per elective were available. Following the completion of the elective in the summer semester of 2021, the questionnaire was revised and used in the subsequent courses. We further analyzed quantitative data from the elective descriptively (eg, means and proportions) and summarized qualitative data (comment fields) using Microsoft Excel and SPSS (version 27.0; IBM Corp). Answers to the open-ended questions and comments were analyzed using MAXQDA 2020 (VERBI GmbH). We then formed categories both deductively based on our questionnaire and inductively from the material. The preliminary code system was discussed, revised, and agreed upon.

Ethical Considerations

This proof-of-concept study received an ethics approval for retrospective analyses by the IRB of the Medical Faculty at the Heinrich Heine University Düsseldorf (ref. no. 2024-3033). We obtained informed consent for the publication of mockup figures designed by the student groups. The evaluation in this quality improvement project was conducted in a regular teaching context. The participation in the web-based survey on the subjective evaluation of the elective was voluntarily and conducted anonymously by the central evaluation of the study dean office upon completion of the elective, so that the authors had no access to personal data linking individual survey responses to specific participants. We also had no access to information on individual data such as gender, age, study subject or semester based on the aggregated results of the web-based survey. The web-based survey did not address sensitive topics and the respondents were not considered as a vulnerable group according to the nature of the survey as we only ask for them to indicate their views on the quality of the attended elective and optionally provide suggestions for improvements.

Results

Sample Characteristics

A total of 75 students (women: $n=45$, 60%) from HHU registered for the elective in 6 seminars over 3 years (2021-2024; ie, 5 semesters [no elective in summer 2023 due to parental leave of the project lead]). Of these students, 72% (54/75) were medical students (median 5, range 3-11 semesters), 12% (9/75) were psychology students (bachelor's program; median 7, range 5-21 semesters), and 4% (3/75) were economics students (bachelor's program; median 9, range 7-16 semesters). In addition, 1% (1/75) studied business administration (bachelor's program; semester 1); 5% (4/75) were bachelor's biology students (mean 9.50, SD 2.96 semesters; range 5-13); 1% (1/75) studied art history (semester 17), philosophy (semester 9), or medical physics (semester 7; bachelor's program each case) each; and 1% (1/75) were master's biology students (semester 1). Overall, 20% (15/75) of the students dropped out of the elective, mainly before its start, as they did not attend the first session. The remaining 80% (60/75) of the students successfully finished the elective (including course achievement). Of these 60 students (women: $n=36$, 60%), 77% (46/60) were medical students (median 5, range 3-11 semesters), 15% (9/60) were psychology students (bachelor's program; as mentioned above), and 8% (5/60) studied one of the aforementioned subjects (2/5, 40% studied economics; median 12.5, range 9-16 semesters; and 1/5, 20% studied a bachelor's biology program; semester 13; art history, and a master's biology program).

Insights Into Common Themes and App Development From the Sessions and Group Discussions

According to individual preferences, students focused on both mental health promotion and dealing with mental and somatic diseases in the development of the hypothetical app, but for this case study, we only reported some examples of health apps. After the first round of the elective, the scope was expanded beyond DMHIs in the course description for upcoming electives to better meet the preferences of more medical students. Overall, 25 projects were finished and presented, 10 (40%) of which covered somatic conditions and 15 (60%) of which covered mental health conditions or indications. The students were asked to create a name for their app concept and to check whether this app name exists already. The task was to create a suitable, recognizable name they can explain with respect to the

hypothetical product and target group. However, we did not control each app name in terms of brands or specific products worldwide as this was an elective for educational non-commercial purposes. Table 2 shows an overview of all app concepts developed by the students in the different semesters.

The following main topics emerged in the prototypes of the apps: exam anxiety in students, stress management, resilience, insomnia and sleep disturbances in children and adolescents, and depression in youths and young adults as themes for mental health apps, with some frequently chosen topics (especially stress management). Furthermore, various disease management or prevention apps for somatic conditions were conceptualized (breast cancer, diabetes, stroke and arterial hypertension, reflux disease, musculoskeletal diseases, glioblastoma, skin diseases, and premenstrual syndrome). Recurring app topics among different electives were stress, exam anxiety, and stress-inducing learning behavior regarding procrastination, as well as depression and anxiety.

In the context of app development, the students systematically applied the knowledge they had learned in the elective subject considering various aspects, guided each week on different aspects by the elective's team (5 steps of design thinking [31,33]). The topics that students emphasized most often in their presentations of their app concepts included target group-specific information (eg, prevalence rates and relevance of the app for health care); usability; and features of persuasive design, including gamification, accessibility, and the promotion of adherence (eg, through reward systems, gamification, provision of human support, and cost reimbursement), which we will illustrate with suitable case examples in the following sections. The featured functionalities varied depending on the selected app concept. For apps related to disease management, students often incorporated symptom diaries, reminders about medications or physician's appointments, and educational resources about the corresponding illness. In contrast, apps aimed at stress management during learning focused mainly on structuring daily routines, relaxation, and avoiding procrastinating behaviors. An example of this would be the ability to lock smartphones for a set period. Most app prototypes included considerations for integrating professional guidance (eg, via chat functions). These chat functions either established contact with professionals or facilitated communication among user groups.

Table 2. Overview of the different app concepts in each semester partially translated into English.

Number	Topic or indication of the app	Target group or population	Name of the app concept	Semester
1	Chronic conditions, diabetes	Patients (adults)	My Diabetes Pass	SS ^a 2021
2	Learning support, self-management, stress management	Pupils and students	Studytime	SS 2021
3	Resilience promotion	Young people in education	Mental Power	SS 2021
4	Stress reduction	Students	MeTime	WS ^b 2021-2022
5	Musculoskeletal diseases, pain	Patients (primarily adults)	legLos (“getStarted”)	WS 2021-2022
6	Sleep disturbances, insomnia	Patients (children aged 3-12 years, supported by their parents)	Morpheus goes to sleep	WS 2021-2022
7	Depression, depressive symptoms	Patients (aged 13-25 years)	Dinotherapy	WS 2021-2022
8	Gastroesophageal reflux disease	Patients (aged >40 years)	StopGERD	WS 2021-2022
9	Breast cancer	Patients (adult female individuals)	BRUHNO	WS 2021-2022 intensive block
10	Stress reduction, exam anxiety	Students and trainees (aged 15-30 years)	Companion	WS 2021-2022 intensive block
11	Glioblastoma	Patients (aged 50-70 years)	GlioblAPP	WS 2021-2022 intensive block
12	Stress reduction, stress prevention	Company employees (ie, finance sector)	Stress Cutter	WS 2021-2022 intensive block
13	Back problems, pain	Patients (aged 18-60 years)	Backfit	SS 2022
14	Eating disorders	Patients (ie, anorexia nervosa)	Provida	SS 2022
15	Hypertension, blood pressure problems	Patients (mainly adults aged >50 years)	Eutonia	SS 2022
16	Stress management after rehabilitation	Patients (adults)	iGrow	WS 2022-2023
17	Blood pressure problems, arterial hypertension	Patients and risk groups (adults)	Tonus	WS 2022-2023
18	Sleep disturbance in depression, burnout	Patients (adults aged 35-45 years)	Happy Sleeper	WS 2022-2023
19	Exam anxiety	Students (aged 18-25 years)	Exam Anxiety	WS 2022-2023
20	Skin diseases	Patients (children and adults)	DermaDiary	WS 2023-2024
21	PMS ^c , PMDD ^d , self-management	Patients (mainly female individuals aged 18-30 years)	ZenCycle	WS 2023-2024
22	Self-management, (emotional) self-regulation	Primary school children (their parents or legal guardians)	MaxiKids	WS 2023-2024
23	Stress management	University students	UniRelax	WS 2023-2024
24	Resilience promotion	Health care staff, nurses (aged 16-64 years)	Pflege-Care (ie, care for nurses)	WS 2023-2024
25	Depression, depressive symptoms	Patients (adults)	Livetta	WS 2023-2024

^aSS: summer semester.

^bWS: winter semester.

^cPMS: premenstrual syndrome.

^dPMDD: premenstrual dysphoric disorder.

Case Examples: App Development and Concepts

In this section, several app prototypes that were developed by student groups are presented. All prototypes chosen for this paper serve as comprehensive and visually clear examples of app concepts. All design samples, images, and the creative theoretical work belong to the students and cannot be used without their permission.

Morpheus geht schlafen (Morpheus goes to sleep) is an app for sleep disturbance in children. A group of 2 students (n=2, 100% female) created this app concept to improve sleep hygiene and facilitate falling asleep for children. In [Textbox 1](#), the app and its design and implementation are described in detail. [Figure 2](#) visualizes the app concept.

Figure 2. Mock-ups of the Morpheus geht schlafen (Morpheus goes to sleep) app. Top left: welcome screen. Top right and bottom left: choice of the customizable companion (animal or human). Bottom right: assessment of individual well-being.

Textbox 1. App concept for Morpheus geht schlafen.

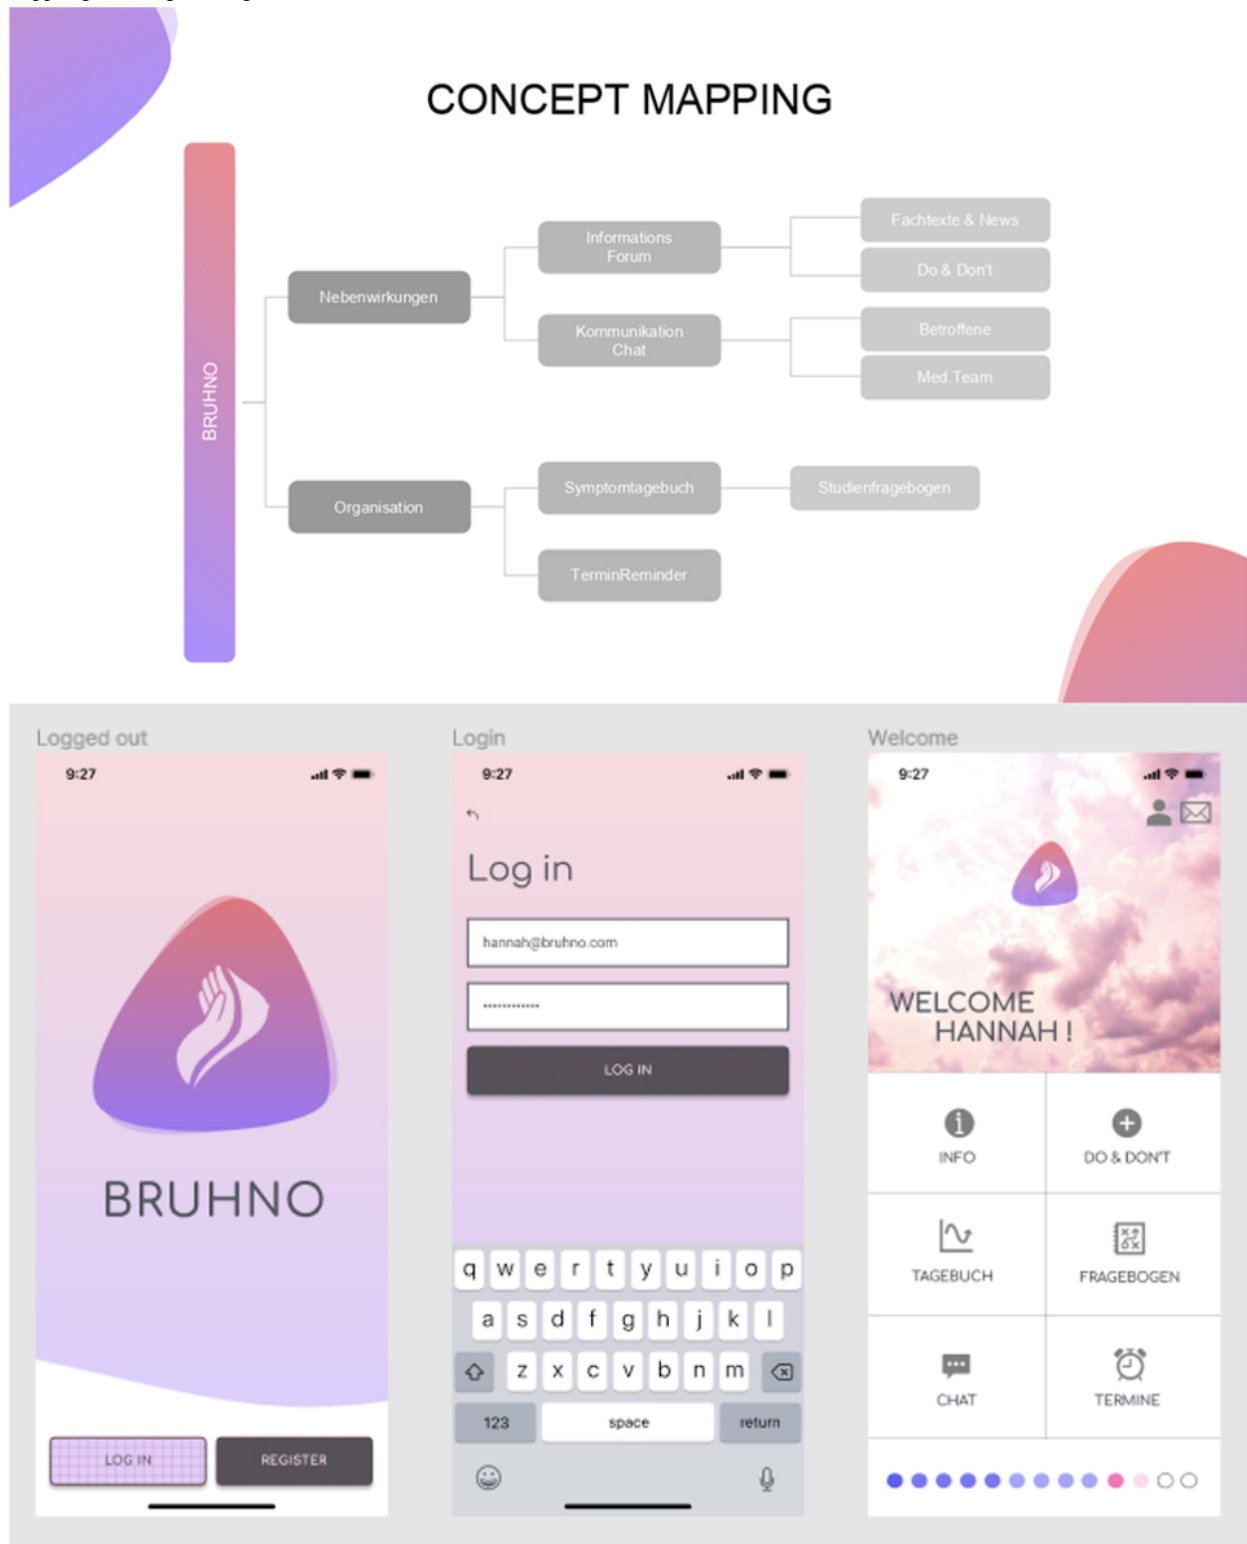

Morpheus geht schlafen (Morpheus goes to sleep) app concept

- Students developed the app for (nonorganic) sleep disturbances in children.
- The selected target group was children aged between 3 and 12 years.
- Concerning design and aesthetics, students chose dark background colors, little movement on screen, a background that remains the same, and a dark color scheme with little white. They also added a customizable companion (human or animal) with rounder body shapes to make it more appealing for children and to present a positive body scheme.
- According to the students, the app can be used to improve sleep hygiene and facilitate falling asleep and could be adapted in relation to the child's level of activity. Methods included exercises concerning movement and relaxation, fantasy journeys with progressive muscle relaxation, bedtime stories with integrated breathing instructions, "sound forests," and lullabies.
- Additional functions covered a link to the app alarm (default setting for when to get up, individualization by parents, and calculation of sleep phases and the ideal sleep time), a sleep tracker, and, optionally, a companion toy with speaker function.
- Students said that parents should be involved via either a separate app or a button for parents. Parents could be supported and informed about sleep hygiene in children (examples concerning a child-oriented evening routine, information on sleep disturbances in children, and a section with frequently asked questions).
- Concerning adherence promotion, students thought of the individualization of the companion, fun facts when brushing teeth, interesting activities, and the collection of stars for every use day. Nonadherence should also be detected (notifications in case of nonactivity).
- Data security was another very important aspect for the students. They explained that the app should include a data privacy statement. In addition, the use of the app is only possible after an active confirmation of informed consent. Data are stored on the device, and data transfer needs are separately authorized (or data can be downloaded as a PDF file).

Bruhno—Brustkrebs Helfer für Nebenwirkungen und Organisation (Breast cancer helper for side effects and organization) is a companion app for female patients with breast cancer. A group of 2 students (n=2, 100% female) created this app concept to support women in systemic therapy and aftercare.

In [Textbox 2](#), the app and its design and implementation are described in detail. [Figure 3](#) visualizes the app concept (for additional prototypes, see [Figures S1 and S2 in Multimedia Appendix 1](#)).

Figure 3. Mock-ups of the Bruhno app. Above: concept mapping for the Bruhno app mock-up as developed by the students. Below: mock-up of the Bruhno app-logo and log-out, log-in, and welcome screens.

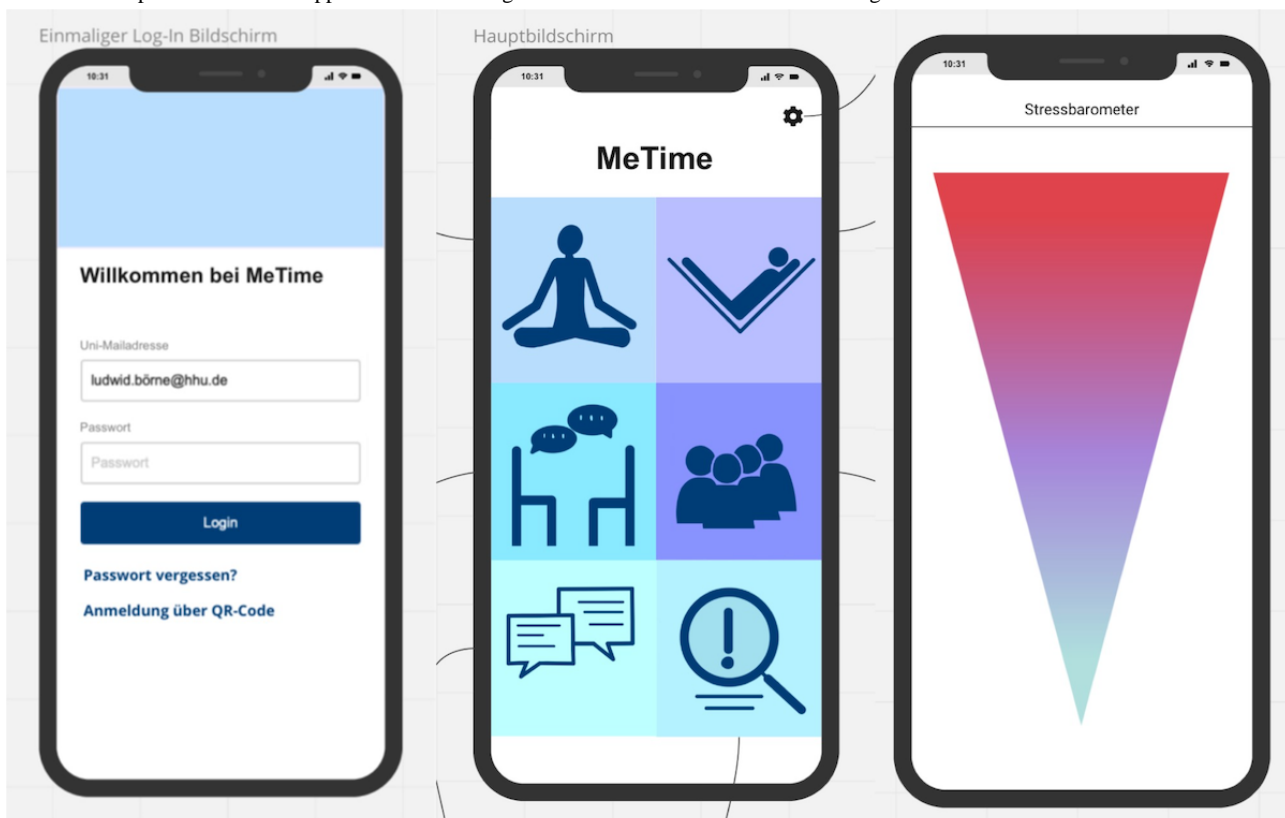

Textbox 2. App concept for Bruhno.**Bruhno app concept**

- Students developed the app as a companion for female patients with breast cancer (support in systemic therapy and aftercare).
- The selected target group was predefined (participants of a clinical study with a diagnosis of breast cancer). Female patients aged ≥ 18 years (mean age 40-65 years) with sufficient technical abilities and equipment (mobile phone and internet access) should use the app.
- The following goals and functions were intended by the student group: reduction of fear (chat with physicians or other persons affected and short explanatory texts or videos), enhancement of well-being (eg, tips to manage side effects), data collection and monitoring (query of side effects, symptom diary, possible evaluation by physician, and questionnaires on life quality), appointment reminders (push notifications, and appointments could be entered by the clinic team or the patient), and an optional intake tracker in case of oral medication.
- Included methods were information, education, data collection, monitoring, tracking, and reminders.
- In the concept of the app, factors to promote adherence were tracking progress using a timeline and maintaining personal motivation through social exchange with other app users via chat.
- The student group also considered technical aspects related to the use of the app. Internet access is vital, and additional web applications would be useful to type longer posts or contributions. In addition, aspects concerning certification, advertisement, and financing were considered (categorization as a medical product and sale to study organizers or sponsors).

MeTime is an app for stress reduction in students. A group of 3 students (n=3, 67% female) created this app concept to promote relaxation in students. In [Textbox 3](#), the app and its design and implementation are described in detail. [Figure 4](#) visualizes the app concept (for additional prototypes, see [Figures S3 and S4](#) in [Multimedia Appendix 1](#)).

Figure 4. Mock-ups of the MeTime app. Left: one-time log-in screen. Middle: welcome screen. Right: visualization of a stress barometer.

Textbox 3. App concept for MeTime.**MeTime app concept**

- The app MeTime was developed by a group of students to reduce stress and promote relaxation for students.
- The relevant target group were students from Heinrich Heine University Düsseldorf in acute phases of stress (eg, exam periods).
- The concept of the app was to provide relaxation exercises and possibilities for networking and social exchange.
- Factors related to the design were also considered by the students. The app should be intuitive and minimalistic. Appealing colors, little text and many symbols, and a stress barometer should also be implemented.
- Students also added a companion, Heinrich, to the app (referring to the first name of a German writer and poet and eponym of the Heinrich Heine University Düsseldorf). This companion supports users, serves as a search engine for the lexicon, reads out instructions and texts, and wears different clothes depending on the context or situation.
- Use options and options to personalize the app were considered. Stress reduction, networking, and education were seen as important. In addition, personal exercises can be created and selected, favorite exercises can be chosen, and an anonymous chat can be used. Color scheme and text size should be customizable, and the user's personal calendar can be accessed. Individual stress levels should be assessed by the user before and after an exercise.
- Concerning app costs, students suggested including the costs in the semester fee. The chosen category for the mHealth app in app stores was lifestyle, health, and fitness.

Dinotherapy is a companion app for depressive episodes in youths and adolescents. A group of 2 students (n=2, 100% male) created this app concept to bridge the time until psychotherapy starts or as a companion during psychotherapy. In [Textbox 4](#),

the app and its design and implementation are described in detail. [Figure 5](#) visualizes the app concept (for additional prototypes, see [Figure S5](#) in [Multimedia Appendix 1](#)).

Figure 5. Mock-ups of the Dinotherapy app. Left: welcome screen (vivid user interface to create a positive user experience). Middle: options for the individual, customizable avatar or companion. Right: questionnaire to assess the user's mood.

Textbox 4. App concept for Dinotherapy.**Dinotherapy app concept**

- Students developed the app as a companion for youths and adolescents who are diagnosed with depression.
- The selected target group were youths aged between 13 and 25 years.
- The app combines interactive provision of psychoeducational content (using gamification elements) with practical tasks and uses dinosaurs as protagonists, identification figures, and “virtual pets.”
- According to the students, the app has different goals: (1) development of knowledge and understanding of the disease—“depression as a disease,” (2) continuous tracking of the course of the depression, (3) establishing activities and fixed rituals that will have a beneficial effect on the course of the depression, and (4) social exchange with other persons affected via the app.
- Students said that a link between the accounts of the patient and physician or psychotherapist responsible can be possible. This way, the attending person could set priorities; assign patients to each other as peers; and specifically be informed if depression values fall below a critical threshold in case, for example, there is a suicide risk.
- To promote adherence, students thought of self-monitoring (tracking using short, daily questions), a visual presentation of the course of depression, tailoring and personalization of tasks and contents, rehearsals or reminders, appraisal and points for each completed task that can be used for the dinosaur (the “virtual pet”), and peer interaction.
- The design of the dinosaurs is also meant to promote adherence and should be appealing for the selected target group.
- The following functions were included by the students: (1) surveys (*TRACK*), (2) comics (*EDUCATE*), (3) tasks (*ACT*), (4) interaction (*EXCHANGE*), and (5) *INTERVENT*.

Companion is an app to reduce stress and exam anxiety and enhance support for students and trainees. A group of 2 students (n=2, 100% female) created this app concept to accompany the target group in the course of the study and in vocational training.

In [Textbox 5](#), the app and its design and implementation are described in detail. [Figure 6](#) visualizes the app concept (for additional prototypes, see [Figures S6 and S7](#) in [Multimedia Appendix 1](#)).

Figure 6. Mock-ups of the Companion app. Left: welcome screen, current level, functions, and the customizable pet. Right: selection of tasks and activities for breaks.

Textbox 5. App concept for Companion.**Companion app concept**

- Students developed the app as a companion for students and trainees. The selected target group were users aged between 15 and 30 years.
- Students introduced an individual pet that accompanies users and explains the handling of the app. They also implemented daily individual and evidence-based hints to reduce stress, exam anxiety, or procrastination.
- In the app, learning plans, to-do lists, and morning and evening routines can be created. In addition, motivating reminders are used. Chatting with the companion (artificial intelligence) is possible. Further functions are structuring, a timer, time management, and the blocking of other apps to work productively.
- To promote adherence, the students implemented progress confirmation, the collection of points for leveling up, and rewards for new levels (eg, unlocking new items for the companion pet) in the app concept. They also paid attention to personalization and adaptation regarding user needs (tailoring).
- To enhance credibility, the students suggested the following: universities should recommend the app, physicians and therapists should test and also recommend it, scientific researchers should be involved in the app development, and the app should receive a seal of approval.
- No data are meant to be given to third parties. If an account is deleted, all individual data are also deleted, and there is anonymous feedback.
- Unique selling points developed by the students were rewards for breaks and not only for work phases (to promote a healthy balance between resting and working), the combination of various functions in 1 app, and evidence-based psychoeducation for users' daily lives.
- The app is meant to be a free app in the app stores or an app with a monthly subscription and a free test version (eg, for 14 days). University licenses and licenses from training facilities should enable use free of charge.

The theoretical prototypes developed as part of the elective course were designed with a strong practical orientation and regard to applicable national requirements for medical devices. This opens up the possibility of using the products designed in the course in the inpatient or outpatient medical sector in the future.

The Bruhno and Dinotherapy student groups approached Startup4MED with their ideas concerning the app concepts. Together with the start-up support unit, the students were given the opportunity to plan and work on the transfer of their theoretical prototypes into practice. For this purpose, next steps, analyses of marketability and customer needs, and financial requirements were examined in individual consultation sessions. To address the financial requirements for further development of the concepts and their implementation into initial prototypes, suitable funding was identified, and the application process was supported. Providing contact with founders of successful medical start-ups, additional team members, and mentors from the Startup4MED network further aimed to achieve translation of theory into practice.

The app concepts developed during the course showed valuable potential for the students to found their own start-ups and

generate future-oriented innovations in the field of mental health. In addition, combining education and training in the field of digital health and the practical application of the designed products can make an important contribution to sustainable benefits in the field of innovation.

Evaluation and Suggestions for Improvement***Quantitative Results: Questionnaires***

Students were asked to complete a questionnaire that had been designed by the research team to assess the elective and receive suggestions for further improvement. To ensure comparability between the individual semesters, a basic average for each semester from all questionnaires submitted per elective was calculated (a total of 6 seminars within 5 semesters). Overall, 73% (44/60) of the students completed the evaluation survey.

Table 3 shows the results of the different items of the questionnaires for each semester. **Figures 7** and **8** display the perceived learning gain and the evaluation of the elective overall (for additional results on the satisfaction with the module as well as the evaluation of the digitalization, see **Figures S8** and **S9** in **Multimedia Appendix 2**).

Table 3. Items from the evaluation questionnaire, including means and SDs per course^a.

Item from the evaluation questionnaire	Course					
	SS ^b 2021 (n=5 ^c), mean (SD)	WS ^d 2021-2022 (n=11), mean (SD)	WS 2021-2022 block seminar (n=9), mean (SD)	SS 2022 (n=5), mean (SD)	WS 2022- 2023 (n=5), mean (SD)	WS 2023- 2024 (n=9), mean (SD)
Overall assessment of the elective	1.50 (0.50)	1.70 (0.80)	2.40 (1.10)	1.30 (0.40)	1.50 (0.50)	1.80 (0.80)
Digital implementation	1.70 (0.80)	1.70 (1.10)	1.80 (0.70)	1.20 (0.30)	1.40 (0.60)	1.60 (0.70)
The learning module was well structured.	1.60 (0.50)	1.50 (0.70)	1.60 (0.70)	1.00 (0.00)	1.00 (0.00)	1.90 (0.90)
The content was made easy to understand.	1.20 (0.40)	1.60 (0.90)	1.80 (0.80)	1.00 (0.00)	1.40 (0.50)	1.30 (0.50)
The distinction between crucial information and insignificant particulars became evident.	2.00 (1.00)	2.10 (1.00)	3.40 (1.60)	1.50 (0.90)	2.00 (0.70)	2.10 (1.10)
The significance of the material instructed for the medical field became evident.	1.00 (1.00)	1.50 (1.00)	2.70 (1.10)	1.40 (0.50)	1.40 (0.50)	1.70 (0.70)
The visuals (such as interactive images and video tutorials) made it easier to grasp the educational material.	1.60 (0.90)	1.40 (0.50)	1.80 (0.80)	1.60 (0.50)	1.20 (0.40)	1.80 (0.80)
The integrated tests (eg, quizzes) were aligned with the learning content.	2.40 (0.80)	— ^e	—	—	—	—
The integrated tests (eg, quizzes) helped me check my understanding of the learning content.	2.40 (1.30)	—	—	—	—	—
Concrete tips were provided for following up on the learning material.	1.20 (0.40)	1.50 (1.20)	1.60 (0.70)	1.20 (0.40)	1.50 (0.50)	1.60 (0.70)
I found it easy to stay motivated throughout the module.	2.20 (1.30)	2.10 (1.50)	2.90 (1.20)	1.00 (0.00)	1.60 (0.90)	1.80 (1.20)
Access to the learning module was successful without any issues.	1.20 (0.40)	1.80 (1.50)	1.30 (0.50)	1.00 (0.00)	1.00 (1.00)	1.20 (0.40)
The learning module was easy to use.	1.20 (0.40)	1.50 (0.70)	1.30 (0.50)	1.00 (0.00)	1.40 (0.90)	1.40 (0.50)
All participants were engaged in the course.	—	1.70 (0.80)	1.80 (1.00)	1.60 (1.30)	1.20 (0.40)	1.80 (1.30)
There were various opportunities available for inquiries and exchanges (eg, through Rocket.Chat, Webex, ILIAS, or email).	—	1.20 (0.60)	1.40 (0.50)	1.40 (0.90)	1.00 (1.00)	1.20 (0.40)

^aWith regard to the first 2 items listed in the table, students were requested to provide an assessment of the elective subject in terms of the German school grades. A 6-point Likert scale ranging from 1 (“completely agree”) to 6 (“do not agree at all”) was used for the subsequent items.

^bSS: summer semester.

^cQuestionnaires submitted per course.

^dWS: winter semester.

^eThese items were subsequently removed from the questionnaire, consequently they were only surveyed for SS 2021.

Figure 7. Assessment of students' perceived learning gain from the elective conducted at the end of each semester. SS: summer semester; WS: winter semester.

Figure 8. Overall evaluation of the elective subjects over 6 courses within 5 semesters. The ratings are based on student ratings in accordance with the German grading system (1=completely agree; 6=do not agree at all), with lower values indicating better ratings. The inversion is intended to improve readability, with higher bars now corresponding to higher satisfaction ratings. The dashed line indicates the average rating across all semesters. SS: summer semester; WS: winter semester.

The general feedback in the different semesters showed that the elective was well received by the students. The relevance of the various contents for their future work life was noticeable for many students, and there were enough opportunities to ask questions and discuss issues. It was also positively mentioned that the contents were explained in a clear and comprehensible way, that the learning module could be accessed easily, and that the elective was well structured. Room for improvement became apparent (eg, with regard to self-motivation, the perceived helpfulness of the integrated tests and quizzes, and the

differentiation between important contents and less important detailed knowledge).

In the winter semester of 2021 to 2022, when the elective was presented as an intensive block seminar on 5 consecutive days, the overall rating and the rating concerning digital implementation were the lowest (Table 3) compared to those in the other semesters. However, the mean score was good in terms of German school grades even in the worst-rated intensive course. Concerning the intensive block seminar, students were less satisfied with the block course but still rated it as good.

They reported having difficulties motivating themselves to do the tasks and complete the module.

Qualitative Results: Open Questions

In the open questions, students could give additional feedback (eg, suggestions for improving the elective) in the form of free text. Overall, many of them seemed to appreciate contents concerning digital health and challenges in implementing digital health offerings and perceived a substantial knowledge gain after taking part in the elective. Students liked the autonomy, flexibility, support from teaching staff, contents, and structure best:

Autonomy and free time management. Interesting content that is otherwise not covered in your studies! I learned a lot. Immediate feedback from the teaching staff, absolutely great! [Summer semester 2021]

The entire elective offered us the opportunity to freely shape our ideas, but it was all within a professional framework. [Winter semester 2021-2022]

Great support! [Summer semester 2022]

Freedom of choice for the app concept. [Winter semester 2023-2024]

Additional factors that were perceived as positive were creativity, the fact that they could always ask questions, the guest lectures, fixed submission dates, and social exchange:

The freedom to design and be creative yourself. [Winter semester 2021-2022]

Plenty of room to ask questions. [Winter semester 2021-2022 intensive block]

Permanent availability of the teaching staff. [Summer semester 2021]

The guest lectures were very interesting. [Winter semester 2023-2024]

When being asked which competence area students benefited most from, several participants mentioned knowledge gain, self-sufficiency, and soft skills. It was also important to assess perceived deficits of the elective and aspects that could be improved. Students mentioned that submissions and arrangements within the work group seemed to be improvable (eg, submission deadlines could have been communicated more clearly right at the beginning, and communication between group members should be enhanced):

Addressing clearer deadlines at the beginning: For me, it was a bit difficult to understand the structure with the respective modules etc. right away. [Summer semester 2021]

Some participants perceived group work as exhausting because of the structure of the groups (ie, group members were determined based on thematic interests and it did not always seem to be clear enough who else was part of the group) and different work attitudes. It was also mentioned that some more face-to-face sessions would have been helpful (eg, to address problems and issues and to get in contact with the other group members). More information on how to realize and implement app ideas and concepts was also desired:

I would have liked more guest lectures to learn more about their experiences in app development. [Winter semester 2022-2023]

How do you actually turn a concept into an app? Who else do you need for this; how do you get the app into the app store when it's nearly finished? [Winter semester 2021-2022]

Some students from the block seminar in February 2022 (winter semester 2021-2022) would have liked to have more time for the contents dealt with as it seemed to be a lot of input in a short period for them:

It's a lot of input for one week. Maybe you can try to skip or cut some parts if possible. [Winter semester 2022-2023]

Furthermore, it was said that the elective would have been preferred as an in-class or face-to-face event to facilitate exchange and discussions:

For me, it would be easier to follow the content of the course in person. Unfortunately, I drifted off a lot of times. [Winter semester 2022-2023]

Concerning missing contents or topics, the following suggestions were made: more economic contents (eg, financial aspects, approaching sponsors, and approaching programmers), more information on how to turn a concept into an actual app or how to publish the app in an app store, and more guest lectures.

In the winter semester of 2023 to 2024, the issue of artificial intelligence (AI) was also brought up:

The topic, or presentation on AI in the medical setting was something new, I would have liked more of that. In general, more variety would be good. [Winter semester 2023-2024]

Discussion

This study describes findings in the piloting and iterative optimization of a new, digitally mediated elective subject in the field of digital health at a German medical school. A central objective was to involve students actively and continuously in the optimization and design of the elective from the beginning onward and successfully convey relevant content.

Principal Findings

Through multiple iterations, a participatory, optimized, innovative teaching offering was developed tailored specifically to the needs and preferences of medical students. The overall implementation, digital execution, knowledge increase, content relevance, and supervision received (very) positive ratings by the students. The overarching goal of acquiring competencies and knowledge in the field of digital health (digital skills) was clearly achieved according to the surveyed participants.

Students considered several important aspects related to digital health (especially health apps, including DiGAs) and implemented them accordingly in their app prototypes. As previous studies have shown, gamification [39], adherence promotion, and an appealing design are important elements for creating a positive user experience [40,41]. These features were

also considered by many student groups in our elective subject. However, it is important to emphasize that one should not only rely on elements of gamification to develop a useful, appealing, and persuasive app [41]. This was also considered by most of the students in their app concepts as they often included background information, useful functions depending on the purpose of the app, and information on data security. As data security concerns are one of the main barriers to the acceptance and broad implementation of mobile health apps, addressing these issues in the process of the app's development is essential [42].

According to the participants, the expansion of their knowledge in the area of mobile health apps was successfully realized as they reported having more information and an improved understanding of digital health after completing the seminar. In particular, the opportunities for independent and creative work seemed to convince the students of our approach to teaching digital health and digital competencies. Examining the mean scores for digital delivery revealed a slight positive trend. The comprehensive ratings of 4 courses ranged from "very good" to "good plus" in terms of overall implementation and digital delivery. Interestingly, the block course (on 5 consecutive days) in the winter semester of 2021 to 2022 received substantially lower ratings than the other courses during the semester despite higher investment in the supervision. Potentially, the intensive course involved a workload perceived as too high with too little time between the sessions to develop the app concepts in a creative process that may benefit from a longer time to discuss the ideas within the group. Feedback regarding improvement suggestions indicated that the content and development of an app concept required more time for processing, which negatively affected student satisfaction with the elective in the form of a block seminar.

We were able to implement the proposed improvements, which proved successful as these suggestions were not mentioned again in subsequent course evaluations. However, it must be noted that there might be other possible reasons for this (eg, students with other needs in the following courses or students with generally lower expectations or previous knowledge). Some students emphasized in their feedback that the topics covered filled a gap in their previous education. This perceived gap aligns with the results of elective subjects in the field of digital health at other universities. Before participating in the digital health elective, a survey was conducted at another German medical school, the Charité–Berlin University Medicine, where >85% of participating students stated that digital medicine was not sufficiently integrated into the current curricula [25]. A further study examining medical students' perspectives indicated their desire for a more robust integration of digital health into the curriculum [43]. While certain German medical faculties have initiated the provision of digital health electives [2], the integration of digital health topics into medical education in Germany and Europe is still not firmly established [9,26,44]. During our last elective course, the topic of AI was suggested for the first time. We had already anticipated this and included it as an excursus, which was well received by the students during the seminar. Current research indicates that most physicians and medical students have a favorable attitude

toward the integration of AI into medical education. Many are already studying AI or intend to do so. The introduction of AI into the curriculum must be carefully planned to ensure that students' education remains up-to-date. The digitalization of the health care system, the use of digital health apps, and AI in medicine are interconnected. Therefore, medical curricula should be adapted to the digital age as soon as possible [45].

However, contrary to expectations, no substantial increase in the number of participants, reflecting the demand for digital health education, was observed. In all semesters, the total number of participants in the elective course remained below the maximum capacity (5 to 17 students who successfully completed the elective). One exception was the winter semester of 2021 to 2022, in which the course was offered both weekly and as a block course during the lecture-free period with 30 course places, which was the upper limit of participants. This could be attributed to the wide range of parallel electives offered at the Medical Faculty at HHU (approximately 150 different electives each semester [46]) as well as the lack of integration of digital health into the National Competence-Based Learning Objectives for Undergraduate Medical Education. Higher registration numbers for other electives indicate that students' interest and focus rather seem to lie on clinical diseases or imaging procedures, possibly due to a supposedly clearer and more tangible practical relevance. Feedback of the students in the final discussions after their app concept presentations also revealed that the content of the elective was considered very important but that there were other decisive factors in course selection, such as the integrability into the rest of their schedule and the expected workload. The number of participants should be further improved in possible subsequent courses after the intended integration of digital competencies into the medical curriculum. It might be beneficial to organize more large-scale courses and interdisciplinary sessions, maybe also in collaboration with other departments in the medical school and beyond (eg, medical informatics) to increase the range and achieve higher participation numbers. In doing so, the relevance of digital health for students' future daily work as physicians could also be highlighted. It is also worth discussing to what extent students' needs regarding organization, amount of work, and implementation could be combined (eg, preferences regarding block seminars in the semester break, face-to-face sessions, or blended learning formats).

The provision of digital health education represents an important step in supporting future practicing physicians who need to be able to use and prescribe digital health interventions. By integrating the elective into medical curricula, the willingness of physicians and psychotherapists to prescribe DiGAs could be increased. In a previous study, 63% of surveyed general practitioners indicated a relatively low willingness to prescribe DiGAs [47]. This could be attributed to concerns about safety, reliability, additional workload [48], personal uncertainty [21], lack of knowledge, lack of reliable information sources [49], and a lack of evidence of effectiveness [19]. The inclusion of digital health education in medical studies could address these concerns and positively influence the already established infrastructure of DiGAs through well-designed and trusted information based on academic training.

Limitations

The limitations of this case study are the small sample sizes and the conduction at only 1 medical school in Germany, which may restrict the generalization of the findings of the evaluation to a broader or more diverse population of medical students (eg, students with different preferences and experiences and students in more advanced semesters). We did also open the elective to further study subjects beyond medicine to broaden the perspectives and capture the interdisciplinary nature of digital health. The integration of a certain proportion of other subjects was also beneficial because there are approximately 150-200 electives per semester at our medical school that the students can freely choose from and we could only conduct the elective with at least 5 students. Nonetheless, we adhered to the requirement that the vast majority of the web-based seminars had to consist of medical students (usually at least two-thirds of the participants).

Furthermore, we did not statistically compare the evaluation outcomes (mean scores) across the semesters as the sample sizes were small and unequal. Instead, initial individual insights can serve as starting points for a broader implementation of digital health in the German curricula for medical students. In addition, there could be a potential bias due to participant self-selection—students chose the elective course themselves. Therefore, it might be possible that they already had a greater interest in the topic or were more familiar with digital health in general, which might have led to more positive evaluations.

Furthermore, the prescription of DiGAs, which was a key topic of the elective, is still unique to the German health care system, making several of the contents of the lectures and ILIAS modules for self-guided learning hardly generalizable to medical education in other countries. However, other aspects are generally important for education on digital health and app development (eg, gamification). In addition, the design thinking approach to develop app concepts is universally adaptable to electives that aim to foster digital competencies in medical education outside the context of Germany.

Another limitation is the fact that the input of lecturers and experts might have had a strong influence on the students' focus on the development of app concepts. This could have led to a potential bias on the part of the students in terms of topics and priorities in the implementation process. However, it was essential to provide sufficient knowledge beforehand, and this enabled students to put special emphasis on factors that were relevant for them (such as gamification, adherence promotion, or data security). Furthermore, the evaluation was based primarily on students' feedback. Thus, the possible gain of knowledge and usefulness for the students cannot really be assessed. In future electives, it could be helpful to assess pre- and postknowledge on digital health topics addressed in the elective in a standardized manner. In this project, we only gathered this information via verbal feedback in the first and last session as well as via 1 item in the anonymized survey (perceived knowledge gains). However, students' presentations and feedback indicated that they seemed to have learned relevant aspects concerning digital health. Finally, there was no feedback from students who started the elective but chose to terminate

participation or from students who did not choose the elective in the first place. These insights could have been useful to further improve the course and find out more about the generally rather low participation rate (eg, whether this was related to the course content or to organizational and time aspects).

Implications

For Medical Schools

Currently, there is a discrepancy between the demand for and the benefits of DMHIs and their integration into medical education. Although medical students acknowledge the importance of digital health in enhancing core skills [50], participation in our elective was rather low. Existing research literature highlights that students and health care providers have a discernible knowledge gap in the domain of digital health. To address this, providing clear information about the benefits of such electives is crucial. A general lack of awareness, compounded by insufficient information from academic faculties, may hinder progress. In Germany, digital health courses are limited, mainly offered as electives [2]. Even though more and more medical schools participate in surveys in which they are asked whether they offer digital health courses, indicating an interest in the topic, the number of courses they actually provide appears to stagnate [51]. This discrepancy highlights the importance of defining standards and providing guidance for digital health education across medical schools. Integrating digital health into curricula has the potential to enhance future physicians' capabilities, but specialized training is vital for navigating the digital age. Introducing digital health competencies equips aspiring clinicians with essential skills. These include fostering positive patient-physician relationships and explaining the risks and benefits. Foundational knowledge can be integrated into standard medical curricula, with electives focusing on specific in-depth knowledge and specializations [30].

For Teaching Staff

To successfully implement and execute courses that focus on digital health and app development, it is useful to provide enough time for the students to take in relevant aspects and knowledge (eg, regular weekly courses instead of block seminars). Regular exchange among students and between students and teaching staff also seems to be important. The use of interactive web-based learning platforms and chat programs can also improve the course (eg, ILIAS and Rocket.Chat). Involving different occupational groups and experts (eg, start-up developers and economists) facilitates networking and allows for the exposure to different perspectives and in-depth knowledge for the students. The concept itself is scalable at a larger level even though it needs staff deployment, and the focus or topics of the elective are interchangeable. Finally, it could be beneficial to collaborate with other institutes or departments to increase the range of courses related to digital health.

For Researchers

Further quantitative and qualitative research methods could be useful to gain more insights into the preferences and needs of medical students with regard to digital health. It might also be beneficial to conduct research concerning outcomes of learning

success that goes beyond individual feedback in the form of questionnaires and open questions. Research among the general population of medical students in Germany is needed to deepen existing knowledge, further adapt elective courses, and prepare the integration of digital health into the medical curricula.

Conclusions and Outlook

A current challenge in health care and prevention is a lack of knowledge and competencies in the field of digital health among

health care providers. To increase the prescription readiness and establish digital health in the everyday lives of patients and physicians, it needs to be implemented in medical education. Further research is needed to define specific learning objectives for digital health competencies and develop detailed recommendations for their integration into medical curricula.

Acknowledgments

First, the authors cordially thank the Dean and the Commission for Quality Improvement (QI) in Teaching and Studies of the Medical Faculty of Heinrich Heine University Düsseldorf (HHU), including the Dean's Office, for supporting their QI project and their helpful advice (e.g., consultation and webinars on ILIAS [Integriertes Lern-, Informations- und Arbeitskooperations-System (German for "Integrated Learning, Information and Work Cooperation System")]). The QI project was funded by decentralized budget means from the Dean's Office of the Medical Faculty of HHU based on the endorsement by the Commission for QI for the first 2 years (QI grant no. 39/21). They would like to express their sincere gratitude to Stefan Stehl (research associate until April 2023) for his valuable support in programming and optimizing additional e-learning material, his excellent contribution to the supervision of the creation of digital mock-ups, and his support in various operative tasks (organization and coordination). His contribution was crucial to the successful completion of this QI project. The authors also thank Dr Thomas Muth for his support in administrative tasks. Furthermore, they thank the Evaluation Department of the Medical Faculty for their support with the web-based evaluation using evasys (evasys GmbH) and for providing them with aggregated evaluation results. The authors thank all students who participated in the elective. In particular, they would like to thank Sophie Smutny, Roxana Hulpoi, Dang Quoc-Dat, Annik Roßberg, Viola Neumann, Jasmin Mirheli, Grit Klöker, and Nils Gerisch, who generously shared their results and provided their prototype pictures, contributing significantly to the depth and quality of this proof-of-concept study. Without their combined efforts and contributions, this work would not have been possible. The authors also thank Professor Dr Nils Hansson, Institute of History, Theory and Ethics in Medicine (HHU), for collaborating with them and sharing ideas on the topic of digital health in medical education. In addition, they thank the DiGA providers for their guest lectures (GAIA AG, Mementor GmbH, and Elona Health GmbH). They also would like to express their gratitude to Büsra Köprücü for her swift assistance with the adapted visualization of the figure of the Dinotherapy app mockups for publication purposes. Finally, the authors thank the Heinrich Heine University Düsseldorf for covering the publication fees (University Library, Open-Access-Funds of the Heinrich Heine University Düsseldorf).

Authors' Contributions

FS contributed significantly to the methodology, conceptualization, formal analysis, software development, visualization, data curation, investigation, and the writing of the original draft. LG was involved in the methodology, conceptualization, formal analysis, data curation, visualization, and contributed to the writing of the original draft. KP participated in the conceptualization, investigation, and visualization, and was responsible for reviewing and editing the manuscript. AS-K was responsible for the software development, investigation, and visualization, and contributed to the review and editing of the manuscript. IE was involved in the conceptualization and contributed to the review and editing of the manuscript. BDS contributed to the conceptualization and was responsible for reviewing and editing the manuscript. JA-H played a key role in conceptualization, funding acquisition, project administration, and methodology. JA-H also contributed to the investigation, data curation, supervision, and was responsible for reviewing and editing the manuscript.

Conflicts of Interest

None declared. DiGA providers held their lectures for free, and the authors did not receive any kind of compensation from them.

Abstract

Background: The deployment of OpenAI's ChatGPT-3.5 and its subsequent versions, ChatGPT-4 and ChatGPT-4 With Vision (4V; also known as "GPT-4 Turbo With Vision"), has notably influenced the medical field. Having demonstrated remarkable performance in medical examinations globally, these models show potential for educational applications. However, their effectiveness in non-English contexts, particularly in Chile's medical licensing examinations—a critical step for medical practitioners in Chile—is less explored. This gap highlights the need to evaluate ChatGPT's adaptability to diverse linguistic and cultural contexts.

Objective: This study aims to evaluate the performance of ChatGPT versions 3.5, 4, and 4V in the EUNACOM (Examen Único Nacional de Conocimientos de Medicina), a major medical examination in Chile.

Methods: Three official practice drills (540 questions) from the University of Chile, mirroring the EUNACOM's structure and difficulty, were used to test ChatGPT versions 3.5, 4, and 4V. The 3 ChatGPT versions were provided 3 attempts for each drill. Responses to questions during each attempt were systematically categorized and analyzed to assess their accuracy rate.

Results: All versions of ChatGPT passed the EUNACOM drills. Specifically, versions 4 and 4V outperformed version 3.5, achieving average accuracy rates of 79.32% and 78.83%, respectively, compared to 57.53% for version 3.5 ($P < .001$). Version 4V, however, did not outperform version 4 ($P = .73$), despite the additional visual capabilities. We also evaluated ChatGPT's performance in different medical areas of the EUNACOM and found that versions 4 and 4V consistently outperformed version 3.5. Across the different medical areas, version 3.5 displayed the highest accuracy in psychiatry (69.84%), while versions 4 and 4V achieved the highest accuracy in surgery (90.00% and 86.11%, respectively). Versions 3.5 and 4 had the lowest performance in internal medicine (52.74% and 75.62%, respectively), while version 4V had the lowest performance in public health (74.07%).

Conclusions: This study reveals ChatGPT's ability to pass the EUNACOM, with distinct proficiencies across versions 3.5, 4, and 4V. Notably, advancements in artificial intelligence (AI) have not significantly led to enhancements in performance on image-based questions. The variations in proficiency across medical fields suggest the need for more nuanced AI training. Additionally, the study underscores the importance of exploring innovative approaches to using AI to augment human cognition and enhance the learning process. Such advancements have the potential to significantly influence medical education, fostering not only knowledge acquisition but also the development of critical thinking and problem-solving skills among health care professionals.

(JMIR Med Educ 2024;10:e55048) doi:[10.2196/55048](https://doi.org/10.2196/55048)

KEYWORDS

Introduction

The launch of OpenAI's ChatGPT-3.5 in November 2022 has impacted various fields, including medical education [1]. On September 25, 2023, OpenAI announced the release of a highly anticipated new functionality, ChatGPT-4 With Vision (4V;

also known as "GPT-4 Turbo With Vision"), to support multimodal interaction and further exploration [2].

ChatGPT has shown promise, or some would argue that it is a threat, for medical education with its outstanding performance in several medical examinations. For example, in the Médicos Internos Residentes examination in Spain [3], ChatGPT

answered 51.4% of the questions correctly [3]. In the United States, different studies have reported an accuracy of 80%-90% on the United States Medical Licensing Examination [4]. These results highlight ChatGPT's potential to impact the future of medical education. However, there is a limited understanding of ChatGPT's performance in non-English examinations in Latin America, such as Chile's EUNACOM (Examen Único Nacional de Conocimientos de Medicina).

The EUNACOM comprises 180 multiple-choice questions from various medical areas such as internal medicine, pediatrics, obstetrics and gynecology, surgery (general surgery and anesthesia, traumatology, and urology), psychiatry, specialties (including dermatology, ophthalmology, and otorhinolaryngology), and public health. The examination assesses topics such as diagnosis, treatment, and follow-up care. Passing the EUNACOM is vital for foreign-trained doctors to practice in Chile and for Chilean medical students to complete their studies and transition to medical practice [5]. This examination, central to Chilean medical education, can potentially pose linguistic, cultural, and contextual challenges to ChatGPT. This study aimed to evaluate the performance of ChatGPT versions 3.5, 4, and the recently released 4V on EUNACOM practice drills, with the intent to guide future improvements—specifically, the integration and use of artificial intelligence (AI) in medical education—across various cultural and linguistic contexts, thereby contributing to the ongoing debate on the role and efficacy of AI as an educational tool in the global medical community.

Methods

Study Design

We adopted a quantitative, descriptive, cross-sectional approach to evaluate ChatGPT's performance in the EUNACOM practice drills. We gathered a data set of EUNACOM practice questions, categorized them, and analyzed the responses of ChatGPT versions 3.5, 4, and 4V.

EUNACOM Data Set

It is challenging to obtain an authentic and representative set of questions from the EUNACOM, as the examination is not publicly accessible for integrity and security reasons. Therefore, we used 3 official practice drills designed by the University of Chile as preparatory material for its students. These drills are not included in the data used to train ChatGPT due to their limited public availability. Each drill consists of 180 multiple-choice questions with 5 options, where only 1 is correct. The number of questions across medical areas in each drill reflects the specifications of the EUNACOM's administrative office (ie, internal medicine, n=67; pediatrics, n=29; obstetrics and gynecology, n=29; surgery, n=20; psychiatry, n=14; specialties, n=12; and public health, n=9).

Classification of Questions

The categorization of EUNACOM's questions in this study is in line with that of Carrasco et al [3] in 2023 on the Médicos

Internos Residentes examination in Spain. Two of our research team members classified the questions as follows:

1. Medical area according to the EUNACOM: internal medicine, pediatrics, obstetrics and gynecology, surgery, psychiatry, specialties, and public health.
2. Category of questions: "clinical case" if they presented a clinical case in the stem of the question, or "medical knowledge" if the question asked for the retrieval of knowledge of medical content.
3. Type of question in clinical case questions: diagnosis, treatment, or follow-up.

Prompting and Application of ChatGPT

We used ChatGPT versions 3.5, 4, and 4V, trained up to January 2022, to respond to the 3 EUNACOM drills in October 2023. Each drill was conducted 3 times with each version of ChatGPT using the prompt, "Which is the correct answer to the following questions?" We excluded "EUNACOM" from the prompt to guarantee ChatGPT's responsiveness to the questions, since, according to OpenAI's policies, the model abstains from taking official assessments. When using version 4V, we prompted questions with images (eg, x-ray) individually, attaching the image to its corresponding question.

The 3 attempts at providing responses in each drill allowed us to address the variability in ChatGPT's answers, attributable to its probabilistic nature, by estimating an average performance.

Data Analysis

Data analysis was conducted using Stata (version 16.0; StataCorp). We computed the percentage of correct responses for each drill and set the passing score at >51% in accordance with the EUNACOM standard [6]. We used a 2-sample test of proportions to test for differences in performance among different versions of ChatGPT [7].

Ethical Considerations

The Human Research Ethics Committee of the Faculty of Medicine at the University of Chile determined that this study presented no ethical concerns that warranted institutional review board oversight. We used EUNACOM drills authorized by the University of Chile's School of Medicine because access to the actual examination is restricted.

Results

The three versions of ChatGPT successfully passed EUNACOM drills on average. Notably, version 4 exhibited superior performance to that of version 3.5 across all drills and attempts, while version 4V did not show a statistically significant advantage over version 4. The only instance of not passing the EUNACOM was observed with version 3.5, specifically during its third attempt at drill 2. Detailed performance metrics for each drill and attempt are provided in Table 1. To assess the robustness of our results, we also compared the performance of ChatGPT by each attempt and by each drill. The results are qualitatively similar.

Table . Correct answers of ChatGPT versions 3.5, 4, and 4 With Vision on each of the EUNACOM^a drills (each with 180 multiple-choice questions) per attempt.

EUNACOM drill and attempt	Correct answers provided by each version of ChatGPT, n (%)		
	3.5 ^b	4 ^c	4 With Vision ^d
Drill 1			
1	105 (58.33)	143 (79.44)	147 (81.67)
2	109 (60.56)	148 (82.22)	149 (82.78)
3	103 (57.22)	146 (81.11)	145 (80.56)
Drill 2			
1	93 (51.67)	138 (76.67)	133 (73.89)
2	94 (52.22)	134 (74.44)	139 (77.22)
3	86 (47.78) ^e	132 (73.33)	137 (76.11)
Drill 3			
1	112 (62.22)	143 (79.44)	142 (78.89)
2	114 (63.33)	150 (83.33)	139 (77.22)
3	116 (64.44)	151 (83.89)	146 (81.11)

^aEUNACOM: Examen Único Nacional de Conocimientos de Medicina.

^bMean accuracy rate 57.53% (95% CI 55.12%-59.94%).

^cMean accuracy rate 79.32% (95% CI 77.35%-81.29%); $z_{3.5 \text{ vs } 4} = -13.34$, $P < .001$ (2-sample test of proportions).

^dMean accuracy rate 78.83% (95% CI 76.84%-80.82%); $z_{4 \text{ vs } 4V} = 0.35$, $P = .73$ (2-sample test of proportions).

^eThis is the only instance of not passing the EUNACOM practice drill.

Across all attempts and the 3 practice drills, we observed a variation in average accuracy rates by both medical area and clinical case question type. In an evaluation across various medical areas, all 3 ChatGPT versions demonstrated distinct high and low performances. For version 3.5, the highest accuracy was observed in psychiatry (average 69.84%), while the lowest accuracy rate was observed in internal medicine (average 52.74%). Version 4 excelled in surgery with a 90.00% average accuracy rate, whereas its weakest performance was observed in internal medicine (average 75.62%). Similarly, version 4V's performance was strongest in surgery (average 86.11%) and weakest in public health (average 74.07%). When analyzing performance across different medical areas, ChatGPT-4 consistently outperformed ChatGPT-3.5. However, ChatGPT-4V did not significantly outperform ChatGPT-4.

The 3 drills included a total of 501 clinical case questions and 39 medical knowledge questions. In answering clinical case questions, the average accuracy rate of ChatGPT across the 3 attempts was as follows: 57.22% for version 3.5, 80.11% for version 4, and 79.71% for version 4V. In answering medical knowledge questions, the average accuracy rate of ChatGPT was as follows: 61.54% for version 3.5, 74.36% for version 4, and 67.52% for version 4V.

Among the clinical case questions, ChatGPT performed best in follow-up questions, with version 4 scoring 88.89%, while the lowest performance was observed in treatment questions, with version 3.5 scoring 48.50%. On analyzing performance over different types of clinical case questions, ChatGPT-4 regularly outperformed ChatGPT-3.5. Nonetheless, ChatGPT-4V showed no significant difference in performance compared to

ChatGPT-4. Comprehensive data on average performances across all medical areas and types of clinical case questions are included in [Multimedia Appendix 1](#).

The 3 drills had a total of 50 questions with images; therein, ChatGPT-4 had an average accuracy rate of 70.67% and version 4V had an average accuracy rate of 70.00% across the 3 attempts.

Discussion

Principal Findings

This study shows that ChatGPT successfully passed the EUNACOM, with version 4 showing a superior performance to that of version 3.5. However, interestingly, version 4V did not significantly outperform version 4 in this examination. All versions demonstrated proficiency in various medical specialties, with version 3.5 excelling in psychiatry and versions 4 and 4V in surgery. However, unexpectedly, version 4V did not outperform the other 2 versions in questions including images. The differences in performance among versions are likely due to continuous enhancements in training and knowledge with each update, which improve the models' grasp of complex medical subjects. Nevertheless, varying success rates in specific medical fields could stem from the complexities of those specialties, unique terminologies, or the specific structure of the questions in those areas, which may align differently with the data the models were trained on.

In particular, when analyzing the question categories, all versions presented a lower accuracy rate in medical knowledge questions than in clinical case questions, indicating a possible

gap in the models' data regarding specific content knowledge. In clinical case questions, versions 4 and 4V consistently outperformed version 3.5, possibly due to the AI's advancement in pattern recognition. Interestingly, each version performed differently across various types of questions in the clinical case category: version 3.5 showed a lower performance on treatment and follow-up questions, whereas versions 4 and 4V performed better on follow-up questions, suggesting an enhanced ability to handle dynamic, evolving clinical scenarios in later versions.

The modest enhancements in visual data interpretation from ChatGPT-4 to ChatGPT-4V indicate that improvements in later versions focused more on specific refinements rather than on broad upgrades to support image processing. This trend is evident in image-based questions, where version 4V did not outperform version 4 in questions including images. For example, while ChatGPT showed improved accuracy in interpreting electrocardiograms, its performance was less consistent with dermatological images. A striking instance was its misdiagnosis of a *Staphylococcus aureus* skin infection in a toddler, where ChatGPT incorrectly identified the condition as Molluscum contagiosum, erroneously attributing significance to an area of the image that was, in fact, the patient's belly button. These variations underscore the intricate challenges AI faces in processing multimodal medical information and suggest that while ChatGPT's textual understanding has advanced, its image processing requires further contextual depth and fine-tuning.

ChatGPT's strong performance on medical licensing examinations from different parts of the world and in different languages demonstrates its adaptability and potential in medical education despite not being specifically designed for such specialized content [3,4,8-10]. However, its varying responses highlight the model's limitations in handling the depth and variability of real-life medical expertise.

This study is one of the first to evaluate ChatGPT-4, including its vision-enhanced iteration, in medical licensing examinations, notably being the first to evaluate its performance in Chile's EUNACOM. The multiple attempts per practice drill approach in our methodology is a significant strength of our study, facilitating a thorough examination of ChatGPT's response consistency. Despite these strengths, the study has some limitations. The reliance on practice drills from the University of Chile may not encompass the full breadth of the

EUNACOM's questions, potentially narrowing the scope of our findings. The focus on specific versions of ChatGPT could also limit the generalizability of our results to other iterations of the model. Inherent biases in the AI's training data pose another challenge, potentially affecting the accuracy of responses.

Future studies should expand AI evaluations in medical training by including diverse medical examinations and question types, assessing adaptability to various contexts. Exploring newer AI models and their performance in practical medical scenarios will also be crucial. This research will enhance the understanding of AI's role in medicine, guiding its effective integration into health care education and practice.

The rise of generative AI in medicine, highlighted by tools such as ChatGPT and upcoming models such as Med-PaLM [11], signals a need to evolve medical education. While these tools provide extensive resources, the essence of medical practice extends beyond simple access to data, necessitating reflective and critical application of this knowledge. Therefore, medical curricula must prioritize critical thinking, enabling future practitioners to discern the quality and relevance of AI-generated information. Similarly, reflective practices are crucial, promoting continuous self-assessment and adaptation in a rapidly advancing technological landscape. As AI becomes integral, especially in diagnostics, professionals must merge AI insights with human-centric care, underscoring that medical expertise is not only about accessing information but also involves deep understanding and evaluation of that information, empathy, and ethical judgment.

Conclusions

In conclusion, this study shows the performance of ChatGPT versions 3.5, 4, and 4V in successfully passing the EUNACOM, underscoring the evolving role of AI in the field of medicine and its potential in medical education. Future studies should encompass a wider array of AI models and diverse question types, contributing to a deeper understanding of how AI can enhance medical education. Moreover, it is imperative to explore innovative directions in the application of AI, such as leveraging AI to augment human cognition and optimize the learning process. Embracing these possibilities can lead to a more profound impact on medical education, fostering not only knowledge acquisition but also critical thinking and problem-solving skills among future health care practitioners.

Abstract

Background: Text-generating artificial intelligence (AI) such as ChatGPT offers many opportunities and challenges in medical education. Acquiring practical skills necessary for using AI in a clinical context is crucial, especially for medical education.

Objective: This explorative study aimed to investigate the feasibility of integrating ChatGPT into teaching units and to evaluate the course and the importance of AI-related competencies for medical students. Since a possible application of ChatGPT in the medical field could be the generation of information for patients, we further investigated how such information is perceived by students in terms of persuasiveness and quality.

Methods: ChatGPT was integrated into 3 different teaching units of a blended learning course for medical students. Using a mixed methods approach, quantitative and qualitative data were collected. As baseline data, we assessed students' characteristics, including their openness to digital innovation. The students evaluated the integration of ChatGPT into the course and shared their thoughts regarding the future of text-generating AI in medical education. The course was evaluated based on the Kirkpatrick Model, with satisfaction, learning progress, and applicable knowledge considered as key assessment levels. In ChatGPT-integrating teaching units, students evaluated videos featuring information for patients regarding their persuasiveness on treatment expectations in a self-experience experiment and critically reviewed information for patients written using ChatGPT 3.5 based on different prompts.

Results: A total of 52 medical students participated in the study. The comprehensive evaluation of the course revealed elevated levels of satisfaction, learning progress, and applicability specifically in relation to the ChatGPT-integrating teaching units. Furthermore, all evaluation levels demonstrated an association with each other. Higher openness to digital innovation was associated with higher satisfaction and, to a lesser extent, with higher applicability. AI-related competencies in other courses of the medical curriculum were perceived as highly important by medical students. Qualitative analysis highlighted potential use cases of ChatGPT in teaching and learning. In ChatGPT-integrating teaching units, students rated information for patients generated using a basic ChatGPT prompt as "moderate" in terms of comprehensibility, patient safety, and the correct application of communication rules taught during the course. The students' ratings were considerably improved using an extended prompt. The same text, however, showed the smallest increase in treatment expectations when compared with information provided by humans (patient, clinician, and expert) via videos.

Conclusions: This study offers valuable insights into integrating the development of AI competencies into a blended learning course. Integration of ChatGPT enhanced learning experiences for medical students.

KEYWORDS

medical education; ChatGPT; artificial intelligence; information for patients; critical appraisal; evaluation; blended learning; AI; digital skills; teaching

Introduction

Since its public launch in November 2022, ChatGPT (OpenAI), as a text-generating artificial intelligence (AI), has garnered significant attention in academic education overall and particularly in the field of medical education. Besides endeavors such as exams in the field of medicine [1,2], there are many

other opportunities to implement ChatGPT in medical education [3,4]. However, these opportunities also have certain challenges such as overreliance, plagiarism, and privacy concerns [5]. Previous research has suggested the need for the advancement of knowledge, interpretation, and application of AI in the context of medical education [6], thereby underscoring the importance of acquiring practical skills essential for using AI in one's future

professional career. The lack of integrating AI into medical education has been described [7,8]. Up to now, there are, however, few specific proposals on how to implement text-generating AI into existing courses. Recent studies exemplify the integration of ChatGPT primarily as a tool for training communication skills among medical students [9,10] or as a supporting tool in problem-based learning scenarios [11].

In our elective course, “Placebo and Nocebo,” which was offered to medical students at the University of Zurich, we integrated content generated with ChatGPT into various teaching units by using different learning scenarios. The overall aim of this course was to teach medical students concepts related to the topic of placebo and nocebo.

Within the course, the importance of expectations regarding medical treatment, as raised by specific information and the corresponding impacts on treatment outcomes, were presented. Methods for phrasing information for patients concerning medical treatment, including benefits and potential side effects, was another key topic of this course. One possible application of ChatGPT in the clinical context could be to support the writing of information for patients in order to educate or prepare patients for upcoming treatments [12,13]. Such information must be clear and safe. Clarity includes readability and understandability of the presented information [14]. With regard to safety, information should present concerning potential side effects in a correct but layperson-friendly way, and the positive framing of side effects is encouraged [15,16].

In this explorative study, we wanted to investigate how medical students evaluate the integration of ChatGPT teaching units into the course and their perceived importance of text-generating AI-related competencies during their studies. Furthermore, we wanted to explore how personal characteristics such as sex and openness to digital innovation are related to these outcomes. By using information for patients written using ChatGPT, we wanted to further explore how medical students in this course assess the use of ChatGPT-created content as a source of information for patients and its respective persuasiveness.

Methods

Procedure

Medical students (third bachelor and first master) were invited to enrol themselves in the elective course “Placebo and Nocebo” at the University of Zurich in spring 2023. The course comprised 28 teaching units (45 min each), 3 of which integrated ChatGPT. The course was set up as a blended learning course combining 13 teaching units delivered as e-learning and 15 teaching units delivered as in-person lectures. The course description was available to students before enrollment and indicated that the course would include a scientific evaluation and that the results would be published. All interaction with ChatGPT was performed on a personalized teacher’s account (AT) rather than by students due to data privacy issues.

The teaching units of the course and the corresponding insights gained into ChatGPT application as well as the data gathered are summarized in [Figure 1](#).

Figure 1. Integration of ChatGPT into different teaching units during the “Placebo and Nocebo” course taught at the University of Zurich.

Baseline and additional data, along with the overall course evaluation data, were collected via web both before and after the course.

In the teaching unit “Placebo control condition,” the students were divided into working groups. They developed a placebo control condition for a clinical trial using a checklist in a problem-based learning scenario. Subsequently, the students presented their results in the plenary. These results were compared with suggestions from ChatGPT and discussed in the plenary, emphasizing a critical appraisal of the ChatGPT-generated solution.

In the teaching unit “Expectations,” the students participated in an experiment. Through web-based questionnaires, they were

asked about their individual outcome expectations regarding an acupuncture treatment for headaches. This specific symptom and treatment were selected due to the likelihood that students may have familiarity with both. We created 4 different videos that were 60 to 80 seconds in length, which were presented sequentially over 4 weeks (1 video per week). The videos were animated voice-overs. Each video delivered supportive information regarding the treatment of acute headaches using acupuncture, but different protagonists and different information were used (expert opinion, clinician opinion, patient experience, and general information from the internet). For example, the expert opinion focused on the evidence, whereas the patient reported on her own experience. The video transcripts in English are presented in [Multimedia Appendix 1](#). Directly before and

after each video, the medical students answered 5 questions regarding their own expectations concerning acupuncture within the e-learning of the course. This pre-post-measurement provided an opportunity to assess the extent to which each video impacted the expectations of the students. The persuasiveness of text written using ChatGPT was compared with text provided by human beings. The information written using ChatGPT 3.5 was labeled as “general information from the internet.” The same text was used in the subsequent teaching unit “Information for patients” using the extended prompt from that unit.

Before the teaching unit “Information for patients,” students learned and practiced the rules for developing content intended for patients, along with the criteria used to review such information [15,16]. During the lecture, students were divided into 9 groups containing 4 to 6 students each. They applied these criteria within their groups to review 2 different pieces of information for patients written with ChatGPT 3.5 using digital whiteboards. Aiming to provide insight into the importance of prompt quality, the first information for patients was written with a rather basic prompt (“Can you please write a patient information about the effectiveness of acupuncture for tension headaches. The text should be no longer than 180 words.”), whereas the second extended prompt included the review criteria (“Can you please change this text so that it is generally understandable for patients? Please formulate statements about effects and side effects in the sense of positive framing. Also make sure that patient safety is guaranteed. The text should be no longer than 180 words”). The students also marked content in each of the descriptions which they found “problematic” within the information for patients (eg, terminology). The review decisions and the rationale behind each group’s choices were discussed in the plenary. The prompts and corresponding answers written with ChatGPT 3.5 as well as the content labeled as “problematic” by the groups are shown in [Multimedia Appendix 1](#).

Outcomes

Treatment Expectations

During the experiment in the teaching unit “Expectation,” students’ expectations concerning acupuncture treatment for headaches were assessed using the Expectation for Treatment Scale [17] before and after the students watched the information provided in the video. The Expectation for Treatment Scale contains 5 items assessing the individual expectations regarding the effectiveness of a specific treatment. Total scores could range from 5 to 20, with higher values indicating higher expectations concerning acupuncture treatment.

Quality of Information for Patients

During the teaching unit “patient information,” in 9 subgroups, students reviewed the quality of information for patients written with ChatGPT in terms of three criteria: (1) comprehensibility (lay language), (2) patient safety, and (3) correct application of communication rules taught in the course (positive framing). The categories for these judgments were “Fully met,” “Partly met,” and “Not met.” Furthermore, the medical students were instructed to mark unclear, ambiguous, and critical content in the information for patients.

Evaluation

The integration of ChatGPT into different teaching units of the course was evaluated based on the Kirkpatrick Model [18,19], encompassing 3 levels: satisfaction, learning progress, and application. Ratings were assigned on a scale ranging from 1 (no agreement) to 6 (full agreement). We built aggregated scores for satisfaction (Cronbach $\alpha=.90$), learning progress (Cronbach $\alpha=.80$), and application (Cronbach $\alpha=.72$) with good to excellent internal consistency based on 4 items per level. The results regarding single items are reported in [Multimedia Appendix 1](#).

Additional Data

Baseline information of the students (age, sex, and previous experience with text-generating AI) was collected anonymously via the web. Openness to digital innovation was assessed using 4 items that have a similar phrasing to that used in the NeoFFI (NEO Five Factors Inventory) for assessing openness to experience [20]. Each item was assessed on a scale ranging from 1 (no agreement) to 6 (full agreement). The aggregated score ranged from 1 to 6, and the four items had excellent internal validity (Cronbach $\alpha=.95$). Furthermore, medical students were asked about the potential of AI in medical education and medicine in general. The students evaluated the importance of 5 AI competencies in medical education on a scale ranging from 1 (no agreement) to 6 (full agreement). Competencies were selected based on the proposal of Caliskan et al [21]. Additionally, students shared their thoughts concerning the potential use of text-generating AI in medical education in response to an open question.

Data Analysis

Baseline data are summarized as median and IQR. Data from the teaching unit “Expectations,” were analyzed using paired *t* tests to explore pre-post differences in expectations. The magnitude of the effect is expressed as mean difference with the respective 95% CI and as effect size. Data drawn from the teaching unit “Information for patients,” are described as counts on group level. Data drawn from the overall evaluation are presented as median and IQR for the 3 evaluation levels due to the skewed data distribution. Spearman correlations between openness and the 3 evaluation levels were calculated for the total group and stratified by sex. The quantitative results concerning competencies are reported in a descriptive way. Quantitative analyses were conducted using IBM SPSS Statistics (Version 29). All analyses must be considered as exploratory.

We conducted a thematic analysis of the qualitative data using MAXQDA Software (release 20.4.2; Verbi) [22]. A team of 6 researchers created themes based on the answers provided by the students in 3 subgroups and coded the answers accordingly. The themes and codings associated with the subgroups were then harmonized through discussion, rearrangement, and intersubjective validation within the whole group.

Ethical Considerations

We submitted the study synopsis to the Ethics Committee of Zurich, Switzerland, and, after review, they stated that the study did not fall under the regulations of the Human Research Act of Switzerland (BASEC-Nr. Req-2023 - 00400).

Results

Study Participants

In total, 52 medical students (19 male and 33 female) participated in the “Placebo and Nocebo” course. The median age of the participants was 23 (IQR 22 - 25) years. Of the 40 students who completed the overall evaluation, 43% (n=17) of participants reported having never or rarely used text-generating AI before. A third (14/40, 35%) of participants had used text-generating AI occasionally before, and 23% (n=9) participants reported frequent or very frequent previous use of text-generating AI.

Overall Evaluation

Overall, the integration of ChatGPT into different teaching units of the course was evaluated very positively with high satisfaction scores (median 5.12, IQR 4.31 - 5.75), high perceived learning progress (median 4.37, IQR 3.75 - 5.25) due to the course and high applicability of the knowledge (median 4.75, IQR 4.25 - 5.25). The results regarding single items are reported in [Multimedia Appendix 1](#).

The 3 levels of satisfaction, progress, and applicability were correlated by approximately 0.50 to 0.60, thus indicating rather strong associations among all 3 learning levels ([Table 1](#)). More interestingly, the associations between the overall evaluation outcomes and participants’ sex and their openness to digital innovation are presented in the first 2 lines of [Table 1](#). Sex was not associated with the evaluation outcomes of the course, but openness was strongly associated with satisfaction and to a lesser extent with applicability. No association between openness and progress was found.

Since the male sex was associated with higher openness, the associations for females and males were analyzed separately. There were no major differences between sex strata in the association of openness with satisfaction (female 0.500; male 0.652). However, the association of openness with progress (female: 0.150; male: 0.419) and applicability (female: 0.317; male: 0.783) differed between sexes. Male students with high openness also indicated higher learning progress and a higher applicability of the course content than female students.

Table . Associations of openness, sex, and the evaluation of the course (satisfaction, progress, and application).

	Sex	Openness	Satisfaction	Progress	Application
Sex^a					
Spearman correlation	1	0.462	0.037	-0.121	0.073
P value	— ^b	.003	.82	.46	.65
Openness					
Spearman correlation	0.462	1	0.483	0.119	0.399
P value	.003	—	.002	.47	.01
Satisfaction					
Spearman correlation	0.037	0.483	1	0.585	0.584
P value	.82	.002	—	<.001	<.001
Progress					
Spearman correlation	-0.121	0.119	0.585	1	0.622
P value	.46	.47	<.001	—	<.001
Application					
Spearman correlation	0.073	0.399	0.584	0.622	1
P value	.65	.01	<.001	<.001	—

^aFemale sex was coded as 1 and male sex as 2.

^bNot applicable.

Potential of AI in Medical Education and Medicine in General

As shown in [Table 2](#), the perceived importance of AI-related competencies in other courses of the medical curriculum is high for the students. Among the suggested competencies, the

assessment of the opportunities and limitations of text-generating AI received the highest rating, while competencies for basic understanding of how AI functions received the lowest rating but are still regarded as important.

Qualitative analysis of the open-ended question revealed areas in teaching and learning for which students see potential uses

of ChatGPT. The themes identified and example quotations are shown in Table 3. Furthermore, students identified other potential uses of ChatGPT, namely, supporting clinical practice (eg, the use of ChatGPT in the context of documentation/patient reports, administrative work and support as a second opinion)

and serving as a general information source. In addition, students made several statements regarding their opinions and values, such as the perceived lack of empathy in ChatGPT and the necessity for human supervision.

Table . Students' perceived importance^a of artificial intelligence (AI)-related competencies in other courses.

AI-related competencies	Median (IQR)
Competencies for assessing the opportunities and limitations of text-generating AI	5.0 (5.00 - 6.00)
Competencies for combining text-generating AI with professional knowledge	5.0 (4.00 - 5.75)
Competencies for assessing the value of text-generating AI in teaching, care and research	5.0 (4.00 - 5.75)
Competencies for the efficient and effective use of text-generating AI in patient care	5.0 (4.00 - 6.00)
Competencies pertaining to a basic understanding of how text-generating AI functions	4.0 (4.00 - 5.00)

^aEach item was evaluated on a scale ranging from 1 (no agreement) to 6 (full agreement).

Table . Students' ideas concerning the potential use of ChatGPT to support teaching and learning: Themes and quotations.

Themes	Quotations ^a (representative examples)
General support for teaching and learning	<ul style="list-style-type: none"> • <i>To generate good summaries of the learning material</i> (student 15) • <i>Instead of emailing lecturers to clarify ambiguities regarding lecture content, ask ChatGPT</i> (student 37) • <i>As exam preparation</i> (student 21)
ChatGPT as a form of writing support	<ul style="list-style-type: none"> • <i>Maybe ChatGPT could be used to optimize one's own texts</i> (student 13) • <i>As a form of support, workload relief and the acceleration of processes</i> (student 38)
ChatGPT for patient case simulation	<ul style="list-style-type: none"> • <i>ChatGPT could be used to simulate patients and thus practice what has been learned</i> (student 13)
Learning how to use ChatGPT	<ul style="list-style-type: none"> • <i>We could learn in the context of these courses how we could use ChatGPT optimally for learning, for research</i> (student 13) • <i>Assess the possibilities and limitations of such tools in a medical context</i> (student 22)

^aThese quotations were originally in German and were translated into English by the authors.

Results Regarding Specific Teaching Units

Change in Treatment Expectations by Different Information

Expectations regarding treatment showed an increase after each of the 4 information videos was presented (Table 4). The

strongest increase was observed for the video that shared patient experiences, whereas the video containing the ChatGPT content did not change expectations substantially. Information presented by a clinician or the expert opinion changed expectations moderately.

Table . Changes in treatment expectations by information presented as 4 videos (expert, clinician, patient, and ChatGPT).

	Expectation, mean difference (95% CI)	<i>t</i> test (<i>df</i>)	<i>P</i> value	Effect size
Expert (n=50)	0.649 (0.102 - 1.178)	2.391 (49)	.021	0.338
Clinician (n=51)	0.941 (0.324 - 1.558)	3.063 (50)	.004	0.429
Patient (n=51)	1.431 (0.746 - 2.116)	4.198 (50)	<.001	0.588
ChatGPT (n=49)	0.449 (0.002 - 0.896)	2.021 (48)	.049	0.289

Quality of Information for Patients

The students reviewed the information for patients written using ChatGPT using a basic prompt and judged the text most often as partially comprehensive, safe, and appropriate in terms of communication rules (Table 5). The students identified many terms and phrases that they deemed problematic for use in information for patients. Reasons mentioned by students in group discussion included, for instance, the use of too specific

terminology with low readability and poor understandability (Multimedia Appendix 1). The information for patients written using ChatGPT using an extended prompt was reviewed very positively. Only a minority of the student groups indicated after the review that the criteria of comprehensibility, safety, and communication rules were only partly met or not met. The number of problematic terms identified by the students was much lower than the number of such terms in the first text.

Table . Students' judgments (group decision counts) regarding the information for patients generated using ChatGPT using a basic or an extended prompt.

Review criteria	Basic prompt ^a			Extended prompt ^b		
	Fully met ^c	Partly met ^c	Not met ^c	Fully met ^c	Partly met ^c	Not met ^c
Comprehensibility	0	5	3	8	0	1
Safety	1	6	2	8	1	0
Communication rules	1	5	2	7	1	1

^aBasic prompt: "Can you please write a patient information about the effectiveness of acupuncture for tension headaches? The text should be no longer than 180 words."

^bExtended prompt: "Can you please change this text so that it is generally understandable for patients? Please formulate statements about effects and side effects in the sense of positive framing. Also make sure that patient safety is guaranteed. The text should be no longer than 180 words."

^cFully met: Rules are applied throughout the whole text; partly met: rules are sometimes applied, but not consistently throughout the whole text; not met: rules were not applied within the text.

Discussion

Principal Findings

Our study showed that integrating ChatGPT into medical courses is feasible, although the majority of the students had no or only limited experience using ChatGPT. The ChatGPT-enriched teaching units were highly appreciated by medical students, and this approach can be used as a stimulating teaching tool. Text generated using ChatGPT in a persuasion experiment (ie, information for patients to change treatment outcome expectations), a practical review exercise focusing on information for patients, and a problem-based learning scenario were suitable formats for our teaching units. All 3 formats used in this course were closely related to possible scenarios that may be relevant for medical students in their later professional careers. Medical students consider the acquisition of competencies related to text-generating AI to be highly important during their studies.

To support constructive learning for the students, the ChatGPT-enriched scenarios addressed different teaching strategies, namely, problem-solving, self-experience, and evaluation. The respective teaching units were embedded into the framework of the course rather than merely added, as also suggested by McCoy et al [23]. This goal was achieved by using ChatGPT directly to revisit or deepen teaching content drawn from other teaching units of the course. In general, the integration of ChatGPT in education demonstrated superiority in both evaluation results and knowledge outcomes. The findings from a medical communication course incorporating ChatGPT revealed positive student evaluations [24]. Direct comparisons of dental students' knowledge after a ChatGPT-integrated teaching scenario with an AI-free scenario showed better

learning progress [11]. Our course evaluation was based on the Kirkpatrick Model considering satisfaction, learning progress, and applicable knowledge as key assessment levels [18,19,25]. Based on the subjective assessment of the students, the evaluation results show that our approach can facilitate students' understanding of the course content and allow them to explore the possibilities and limitations of text-generating AI.

Although nearly half of the students had no or only limited experience using text-generating AI, the evaluation was very positive. Hence, students' previous experience with or interest in innovative technologies does not seem to be a necessary prerequisite for the introduction of such technologies into medical teaching. This confirms the findings of Weidener and Fischer from a survey of medical students across Germany, Austria, and Switzerland. In this study, less than half of the students had prior experience with ChatGPT or other AI-based chat applications but indicated a need for AI in medical education [7].

For the successful integration of AI into teaching modules, facilitating and impeding factors among students should be investigated. Openness to digital innovations might be an asset to facilitate learning with AI tools. It has been demonstrated in adults in the United States that users' trust impacts both the intention to use and the actual use of ChatGPT [26]. Here, we showed that students with lower openness to digital innovation reported less satisfaction and lower applicability in our evaluations, which may be a result of their lower motivation to engage in teaching units with ChatGPT content. Consequently, less open students may also lack knowledge regarding the limitations of ChatGPT since they may avoid this technology in general. Sex is another factor that could lead to different receptions of AI-enriched courses. Higher use of AI tools in

male persons has also been shown in students from different fields in Germany [27], possibly reflecting a higher openness to digital innovations. In our study, we also found similar associations of openness to digital innovations, progress, and applicability for male students. However, for female students, other factors beyond openness might affect progress and applicability.

Our evaluation results showed that the perceived importance of AI-related competencies for students is rated very high in general and covers a wide range of different competencies. The chosen competencies are similar to the categories of knowledge, interpretation, and application of AI that were revealed by teaching experts [6]. Some of these competencies were addressed in our teaching units. For example, the teaching unit "Information for patients," illustrated the need to use a meaningful prompt and the importance of choosing relevant criteria when using ChatGPT to create information for patients. During the course, the quality of this information written using ChatGPT has been improved by incorporating important criteria for the text into the prompt. Students found information written using the extended prompt to be of higher quality, providing insights into the importance of prompt quality for the generated text. Several studies have investigated the application of ChatGPT and other large language models as tools for providing patient material, yielding promising results. According to Ayers et al [12], AI-generated text messages on health-related patient questions in a social media forum were superior to physician responses as rated by health care professionals. Tangadulrat et al [28] showed that both medical students and graduated doctors positively perceived using ChatGPT for creating patient educational materials. Patient material readability scores were considerably improved by the large language model as demonstrated by Rouhi et al [29]. Interestingly, the ChatGPT generated text using the extended prompt, was found to be the least persuasive within the expectation experiment. It did not change students' expectations regarding a specific treatment substantially compared with information provided by humans (especially when compared with a patient statement). As the information written using ChatGPT was read by an artificial voice, while the other information was read by humans, the lower persuasiveness might be due to a lower acceptance of the

artificial voice. A preference for human voices has been shown in other research [30].

Open-ended questions revealed misleading concepts, such as the use of text-generating AI to support patient documentation, a potential concern due to data protection issues as discussed by Eggmann et al [31]. Particularly, to circumvent problematic applications of text-generating AI in physicians' later professional careers, the systematic integration of AI-related competencies into medical curricula is critical.

Limitations

Our results lack generalizability with respect to the use of ChatGPT in other learning environments (eg, larger groups). Furthermore, the results cannot be generalized to the use of other generative AI (such as image-generating AI).

The evaluation items were based on the Kirkpatrick Model. However, all items were self-reported. Ideally, learning progress and application would be assessed with objective indicators, eg, based on progress tests and performance evaluations. Learning effects, especially at the level of application, would be larger if students used ChatGPT on their own, entering their own prompts rather than using answers written using ChatGPT based on teachers' prompts. However, this scenario would cause problems with students' data privacy and would be a course on its own.

Given the predefined structure and learning objectives of the course, it was unfortunately not possible to explore further the use of AI in generating information for patients and its respective change in expectation. Additionally, it would have been of advantage to reflect these questions not only with medical students but with patients as actual target groups of such information.

Conclusions

According to the evaluation of medical students, integration of ChatGPT into an existing course is highly appreciated and enhances the learning experience. The development of AI-related competencies, including the phrasing of meaningful prompts during medical education, was perceived as very important by these medical students. The ability to critically appraise AI-generated information is also an important competency for medical students.

Acknowledgments

We would like to acknowledge Yuqian Yan, Institute for Complementary and Integrative Medicine, University Hospital Zurich, Switzerland, for her help in the data analysis of the expected results. We would like to acknowledge Manuela Oehler, Institute for Complementary and Integrative Medicine, University Hospital Zurich, Switzerland, for her work in setting up the expectation experiment. We would like to express our special thanks to Claudia Canella for her support during the qualitative analyses. Finally, we are grateful to Casey Murphy for conducting literature update searches and editing the manuscript.

Abstract

Medical advice is key to the relationship between doctor and patient. The question I will address is “how may chatbots affect the interaction between patients and doctors in regards to medical advice?” I describe what lies ahead when using chatbots and identify questions galore for the daily work of doctors. I conclude with a gloomy outlook, expectations for the urgently needed ethical discourse, and a hope in relation to humans and machines.

(*JMIR Med Educ* 2024;10:e50869) doi:[10.2196/50869](https://doi.org/10.2196/50869)

KEYWORDS

chatbot; ChatGPT; medical advice; ethics; patients; doctors

Introduction

While I strive to provide accurate and helpful information, I am not a substitute for medical advice or professional judgment, and it's always important for patients and healthcare providers to work together to develop a personalized treatment plan that takes into account a patient's individual needs and circumstances. [ChatGPT, 2023]

Medical advice (MA) is key to the relationship between doctor and patient. The question I will address is “how may chatbots affect the interaction between patients and doctors in regards to medical advice?” To this end, I shall consider—and go beyond—what was recently outlined regarding MA in “A Conversation With ChatGPT” [1].

Advances in artificial intelligence (AI) and chatbots are changing the world, including medicine [2-4]. ChatGPT is a generative pretrained transformer model based on GPT-3 from OpenAI. Based on word correlations in its 175 billion-parameter database, ChatGPT floods us with meaningful but also nonsensical information.

Concerning the interaction between patients, doctors, and chatbots, I describe what lies ahead when using chatbots and identify many questions for the daily work of doctors. I conclude with a gloomy outlook, expectations for urgently needed ethical discourse [5,6], and a hope in relation to humans and machines [3,7].

Weighing ChatGPT's Quote

How ChatGPT describes its role [1]—“I am not a substitute for medical advice”—should be a fact. Doctors, as the only authoritative providers of professional MA, must always be in the driver's seat. Chatbots have the potential to help with the task of contributing general information to an information chain. Importantly, doctors need to review and question all AI output and see if and how it contributes to a patient's understanding and fits within MA. Depending on the expectations and hopes that ChatGPT raises in patients, this task could become an unprecedented challenge.

With their up-to-date knowledge and medical experience and expertise, doctors need to integrate personal, specific, and general information into their comprehensive MA to the patients. Chatbots are limited to general information stored in databases. Concerningly, ChatGPT invents facts, called a hallucination in

AI [3]. Moreover, ChatGPT can produce nonsensical or “bullshit” [8] information, nicely worded and seemingly justified but disregarding truth and facts—disconcertingly, we do not readily know how often and when ChatGPT offers “bullshit” or nonsense responses.

The Daily Work of Doctors: Question Galore

Nevertheless, ChatGPT will be used by many simply because it is there and seemingly easy and, importantly, free to use.

Is it, therefore, likely that we can do without chatbots? No, because society will not abandon ChatGPT or other advanced chatbot tools [3]. The sooner we understand chatbot information for patients, the better. Realistically, ChatGPT is just the tip of an AI iceberg. The “Godfather of AI” [9] Hinton and OpenAI’s chief executive officer Altman [10] have warned forcefully about the speed, impact, and inevitability of AI developments.

Doctors routinely deal with both informed and misinformed patients, fuelled by online health searches (eg, “Dr Google” [11]). Indeed, the internet has become the starting point for many to ask questions about health, disrupting traditional doctor-patient relationships [12] and leading to potential harm from online misinformation [11]. Importantly, neither patients nor doctors should give away too much information when using AI. Even if MA could get better with more details, can we know if this information is being used beyond MA? Indeed, to what extent may creating MA be used as an AI Trojan horse to extract information for other purposes, including business benefits? Which biases go into AI-based medical information, for instance, through training data that neither represent the ethnicity nor the financial options of diverse patients? That medically advanced AI may become expensive raises questions of equity: who will have access to these technologies?

What knowledge do doctors need to understand medical AI advice? How can AI-based medical information be used [13], and how do you deal with medical information that AI cannot explain [14]? Could doctors working with chatbot-provided diagnoses and AI-recommended treatments miss the true picture and become overreliant on AI? Who is liable when doctors use AI medical information, and to come full circle, who is liable when they do not [2,15]? Could there come a time when not considering AI such as ChatGPT constitutes less than adequate advice and nonstandard care [15]? Doctors should ask their liability insurer how (ie, under what conditions) and to what extent the insurer covers the use, or nonuse, of AI in practice [15].

Key orientation for interactions between patients, doctors, and chatbots regarding MA can come from physicians’ professional organizations and the US Food and Drug Administration. Similar to practice guidelines [15], recommendations and guardrails for practice-specific medical information via chatbots may have to be developed.

A Gloomy Outlook, Expectations From Much-Needed Ethical Discourse, and a Hope in Relation to Humans and Machines

That ChatGPT “strive(s) to provide accurate and helpful information” [1] has a stale empirical aftertaste. In fact, according to OpenAI, advanced AI [16] will make reviewing chatbot information even more difficult. GPT-4 (eg, in Microsoft Bing and ChatGPT Plus), with 571 times as many learned parameters as GPT-3, has “learned” to deliver incorrect work more convincingly than earlier models. Such mistakes will pose severe problems even if “[ChatGPT] admits these when challenged” [1].

PubMed-listed comparisons between GPT-3 and GPT-4 suggest that the latter may provide more accurate patient information in nuclear medicine [17]. Another study suggested that both free and paid versions of ChatGPT risk providing misleading responses when used without expert MA [18]. Chatbot medical information written at a college reading level suggested that such AI devices may be used supplementarily but not as a primary source for medical information [19], emphasizing the doctor’s key role in MA. More research is needed on MA in numerous medical fields and settings, for numerous applications, and for various populations.

Overall, when AI experts at the University of California, Berkeley explored and discussed the implications of ChatGPT and AI and future challenges in the spring of 2023, there was an explicit call for more ethical considerations [6,20]. Priority safety measures include strict regulations for patient privacy and ethical practices [21]. While the questions above are not exhaustive, it is time to systematically answer them regarding MA and the unavoidable interaction of patients, doctors, and chatbots.

Ultimately, we can only hope that the boundaries between humans and machines [3] will never become so blurred that patients cannot distinguish the MA of a human doctor from the general information provided by ChatGPT [22] or other AI.

Abstract

Patients' online record access (ORA) is growing worldwide. In some countries, including the United States and Sweden, access is advanced with patients obtaining rapid access to their full records on the web including laboratory and test results, lists of prescribed medications, vaccinations, and even the very narrative reports written by clinicians (the latter, commonly referred to as "open notes"). In the United States, patient's ORA is also available in a downloadable form for use with other apps. While survey studies have shown that some patients report many benefits from ORA, there remain challenges with implementation around writing clinical documentation that patients may now read. With ORA, the functionality of the record is evolving; it is no longer only an aide memoire for doctors but also a communication tool for patients. Studies suggest that clinicians are changing how they write documentation, inviting worries about accuracy and completeness. Other concerns include work burdens; while few objective studies have examined the impact of ORA on workload, some research suggests that clinicians are spending more time writing notes and answering queries related to patients' records. Aimed at addressing some of these concerns, clinician and patient education strategies have been proposed. In this viewpoint paper, we explore these approaches and suggest another longer-term strategy: the use of generative artificial intelligence (AI) to support clinicians in documenting narrative summaries that patients will find easier to understand. Applied to narrative clinical documentation, we suggest that such approaches may significantly help preserve the accuracy of notes, strengthen writing clarity and signals of empathy and patient-centered care, and serve as a buffer against documentation work burdens. However, we also consider the current risks associated with existing generative AI. We emphasize that for this innovation to play a key role in ORA, the cocreation of clinical notes will be imperative. We also caution that clinicians will need to be supported in how to work alongside generative AI to optimize its considerable potential.

Introduction

Patient online record access (ORA) is growing globally [1]. Access includes test and laboratory results, secondary or hospital

care letters, lists of prescribed medications, and the narrative reports written by clinicians after visits (the latter referred to as "open notes"). Already, patients across an estimated 30 countries can access some of their records via secure web portals including

health apps. In some countries, this innovation is advanced [1]. Since 2021, the federally enacted 21st Century Cures Act in the United States mandated that providers offer all patients access to download their electronic health records without charge [2]. In the Nordic countries, ORA has been implemented incrementally, starting around 2010 [3]. The Finnish patient portal OmaKanta was rolled out with stepwise implementation of functionality between 2010 and 2015 [4]. Patients in Sweden first obtained ORA in one of 21 regions in 2012 [5] with nationwide implementation achieved by 2018. Implementation in Norway began in 2015, reaching patients in 3 out of 4 regions by 2019 [6]. In England, from October 31, 2023, it is mandatory for general practitioners to offer ORA to their adult patients, albeit on a prospective basis [7].

Patients with access to their records report using them to become more involved in their care, to follow up on doctors' visits, and to obtain an overview of their test results and treatment history [3,8,9]. Multiple surveys show that patients using ORA are positive about the experience after reading their notes. They report many benefits including understanding their care plans better [9], improved communication with and greater trust in their provider [10], and feeling more in control of their health and care [6,8], including doing a better job taking their medications [11,12].

Despite the patient benefits with ORA, challenges with their implementation in clinical practice remain. In this viewpoint paper, we identify outstanding concerns with ORA, which encompass a range of unintended consequences for clinician work burdens, and for the substantial task of conveying bespoke, compassionate, and understandable information to each unique patient who accesses their records. Currently, it has been proposed that a range of targeted patient training and medical education strategies may be sufficient to resolve at least some of these challenges [13-17]. We believe that such interventions are valuable; however, in this viewpoint paper, we explain why the ambitions of such training interventions may be limited.

As a solution, we explain why the use of generative artificial intelligence (AI) may offer more tangible long-term promise than clinician training alone in helping to resolve problems with ORA implementation. While generative AI itself is not new, recent technical advances and the increased accessibility of large language models (LLMs; GPT-4 by OpenAI, LLaMA by Meta, and PaLM2 by Google) have made clinical use increasingly feasible. LLMs are an application of generative AI technology, often defined as machine learning algorithms that can recognize, summarize, and generate content based on training on large data sets. Unlike search engines, which offer pages of internet links in response to typed queries, generative LLMs such as GPT-4 simulate well-reasoned answers couched as conversations. In addition, these models can "remember" previous prompts, helping to build up the perception of dialogic exchange. We review the strengths and limitations of generative AI and emphasize that for this innovation to play a key role in ORA, it will be imperative for humans to be involved as overseers of computer input.

Current Challenges With Open Notes

Evolving Functionality of Records

Guidelines, such as those issued by the British General Medical Council, state that clinicians should keep clear, accurate, contemporaneous records that include "...any minor concerns, and the details of any action you have taken, information you have shared and decisions you have made relating to those concerns" [18]. In the era of ORA, clinicians will also need to consider if what they write will be understandable, accessible, and supportive for patients [19]. With the knowledge that patients will read what they write, the functionality of the record is evolving, and this incurs changes with respect to how clinical information is documented [20,21]. Clinicians must uphold the original functionality of the record—documenting the patient's medical information in clinical detail, but also communicating this information to the patient. With respect to the latter function, it is argued that for records to be understandable and acceptable to a lay audience, clinicians should ideally remove or explain medical acronyms, omit medical vernacular that may be perceived as offensive (such as "patient denies" or "patient complains of"), and strive to convey information in a manner that it is straightforward, comprehensive, and empathic in tone [14]. This is not an easy undertaking for clinicians tasked with pitching information at a literacy level that accommodates diverse patient populations while maintaining the clinical utility of records and adequately serving their medicolegal functions. Indeed, whether such dual functionality is even possible has been questioned [22].

Documentation Changes

To date, it is unclear whether ORA diminishes the clinical value of documentation [19,23]. However, there is evidence that clinicians may be undermining the accuracy or completeness (or both) of their records, perhaps in attempts to reduce patient anxieties, minimize follow-up contact, or reduce the likelihood of potential complaints [24,25]. For example, in the largest study conducted on clinicians' experiences of open notes, a 3-center study at 3 diverse health systems in the United States (1628 of 6054, 27% clinicians responded), DesRoches et al [26] found that around 1 in 4 physicians admitted that they changed how they wrote differential diagnoses (23%, n=176), though the nature of these changes is not understood. More worryingly, more than 1 in 5 physicians (22%, n=168) believed that their notes were now less valuable for other clinicians [26].

Conceivably, other changes following implementation of ORA might be more positive. In the study by DesRoches et al [26], 22% (n=166) of physicians reported changes to the use of a partnering language, and 18% (n=139) of them reported changes to how they used medical jargon or acronyms. However, it remains unknown whether such changes improve the comprehensibility of clinical records among patients or whether amendments come with a trade-off in terms of documentation quality.

With ORA, there is also the potential for notes to convey bias of stigmatizing language. For example, in the United States, recent linguistic analysis studies have shown that negative patient descriptors in notes are considerably more common for

non-Hispanic black patients and for patients with diabetes, those with substance use disorders, and those with chronic pain [27,28]. It is unclear whether with the knowledge patients may now read what they write, the use of stigmatizing language among these patient populations is being effectively omitted and “cleaned up” by clinicians.

Work Burdens

Time spent on documentation and patient portal messages remains a growing cause of clinician dissatisfaction and burnout [29]. The impact is exacerbated for clinicians with lower levels of digital competencies, and this “technostress” has been found to directly correlate with burnout [30]. Even tech-savvy young resident physicians have reported the use of the electronic health record as a leading cause of burnout [31]. In the United States, the study by DesRoches et al [26] on clinicians’ experiences, 37% (n=292) of physicians reported spending more time writing notes after patient access was enabled.

Few studies have explored objective measures of the impact of ORA, however, where these measures have been implemented, some of them signal potential for increased patient contact. For example, Mold et al [32] found that the provision of ORA in primary care settings resulted in a moderate increase in email traffic from patients, with no change in telephone contact and variable changes to face-to-face contact. A recent Canadian study found that registration with a primary care web-based portal was associated with an increase in the number of visits to physicians, calls to practice triage nurses, and an increase in clerical workload [33]. Another recent study at an academic medical center in the United States reported a doubling in the number of messages sent by patients within 6 hours after ORA was implemented [34]. It seems reasonable to postulate that at least some of this increased contact may be driven by patients who desire clarifications about diagnoses, results, or other information that is documented in their records.

Currently Proposed Solutions

To encourage confidence with ORA and to overcome some of these challenges, targeted educational programs have been proposed. Among them are short lists of tips and advice to clinicians, and brief web-based training interventions [13,14,24]. More recently, some medical schools have taken this further. For example, Harvard Medical School has embedded within its curriculum practical training in how to write notes that patients will read [16], and similar work is underway in England [35]. The expressed aim of such training programs is to support physicians in writing notes efficiently and clearly, preserving the necessary clinical details. These programs also encourage students and clinicians to write sensitively and empathically, removing loaded jargon or acronyms that may be perceived as offensive (eg, “follow-up” instead of “F/U,” or “shortness of breath” instead of “SOB”) [14,16]. Notably, however, calls for curricular adaptations are isolated, perhaps reflecting wider uncertainty about ORA among the medical community and the perception that the innovation has been foisted on them.

Similarly, interventions to advise patients about how to engage with ORA appear limited [14,36]. This may be owed to a fear
