Members of the research team were involved in the development of ECHO programs at the institution (CW-B) or in the coordination of the research project (AT, RK, ÉD, and MGP). They come from the disciplines of medicine (AT and CW-B), social science (ÉD), environmental and occupational health (RK), and psychology (MGP). Team members directly involved in the execution of the research project and analysis (MGP and ÉD) engaged in reflexivity throughout the project, but most intensely during the elaboration of the study material (ie, development of interview guide), throughout data collection, and during the analysis, with the intent of reflecting on how our perspectives and experiences within the institution but also with regards to the research topic, influenced the orientation of the project, our understanding of the data, and how it shaped the findings. Reflexivity involved individual reflections through memos and note-taking as well as collaborative meetings.

Results

Overview

We generated themes based on available data pertaining to Project ECHO's acceptability, appropriateness, cost and trialability, and feasibility (refer to Textbox 1 for a summary of the themes).

Textbox 1. Summary of domains and themes.

Acceptability

- Knowledge transfer as a core value in line with the institution's academic and public health mission
- Innovation as an institutional pillar
- Institutional benefits—optimizing the patient flow in a 2-way stream

Appropriateness

- Versatility and structure of the ECHO (Extension for Community Healthcare Outcomes) model
- Meeting a growing need for education on rapidly evolving complex health conditions
- Rapid growth of ECHO programs

Cost and trialability

- Institutional sources of funding and human resources that benefit the outside community
- Lack of an easily measurable performance indicator
- Lack of recognition for time and resources invested

Feasibility

- Decentralized management structure
- Ministerial and academic characteristics of the outer setting bolstering the institution's innovative educational practices

Acceptability

The perceived acceptability of the Project ECHO programs was influenced by cultural aspects specific to the institution and its role within the larger health care network. The structure of this innovative program also contributed to increasing its acceptability.

Knowledge Transfer as a Core Value in Line With the Institution's Academic and Public Health Mission

The institutional support for Project ECHO stemmed in part from the program's fit with the institution's academic mission. Being a university health network institution, its mandate beyond patient care involves knowledge transfer and supporting the wider health care community. From that perspective, Project ECHO uses an innovative continuous education model that enables expertise within the university health network and academic workforce to be shared with the broader medical community, which facilitates the execution of the institution's academic mission as a center of expertise.

> *I'd say that we have a great deal of specific expertise at the [institution], and our challenge is to share this expertise with partners who could benefit from it. Projects ECHO are in line with this and at the [institution], we try to generate knowledge, and from that knowledge we generated, how can we play our role as a member of a university health network within our network and how can we maybe support teams within this network. It builds pride in what they do, what they achieve, so I would say that there are not super demanding activities, not overly costly, but so worth it on multiple fronts. You cannot not support these initiatives and encourage them.* [P4, Director]

Innovation as an Institutional Pillar

The Project ECHO distinguishes itself from other more conventional learning modalities, as it is based on ongoing real clinical cases and offers adaptability to have participants' questions answered by a panel of clinical experts, using personalized solutions in an "all teach, all learn" approach. This leads to rich exchanges, making it possible for participants to have access to the experts' reflections and decision-making processes that led to the proposed treatment path. Those components were identified as central to the success of such a learning model. Comments from managers and stakeholders underlined that one of the institutions' characteristics that facilitated the deployment of those programs was the crucial importance given to innovative practices. This implied an agility to recognize innovative approaches and to maximize existing resources to bring them to life.

> *However, to be an innovative institution, its also to see things differently, you know to have other ways of doing things. And so it was that, another way of looking at this and to say well, we have given a lot of training, of information, but telementoring, we had never done it. So, the openness that this brings…* [P1, Director]

The emphasis put on innovative practices not only facilitated the implementation of the programs, but it also improved the likelihood of successful sustainability. Justifying the financial expenses and required resources for running Project ECHO was facilitated by a good comprehension of the project's fit within the larger institutional academic mission and its core value of innovative practices.

Institutional Benefits-Optimizing the Patient Flow in a 2-Way Stream

Stakeholders described perceiving important institutional benefits from the Project ECHO programs in place. The projects were in line with the institution's vision of patients receiving the right treatment at the right place at the right time. By helping health care providers within the broader health care system to care for their patients with complex health conditions, the institution contributed to facilitating optimal patient flow. This ensured that specialized services were used for the most complex cases, while less complex patients could access the right care in their community.

> *Well, I think that it's the main strength because otherwise our institution has 772 beds, not all of them are open, we cannot admit all of the patients so we must develop knowledge and expertise about specific clienteles and after that, help our network partners to care for these clienteles. With Projects ECHO, it helps do that. So, I would say that the strength of such programs is that it reinforces education, it reinforces partnership, it helps reinforcing multidisciplinary work and also the actors from different sectors.* [P4, Director]

One way that Project ECHO facilitated this was through connecting and empowering first-line health care providers to treat more complex cases.

> *We make sure that patients who are physically coming to the CHUM really need to be here, that they are the ones that fit with our mission. Because each time we accept a patient that could have been treated elsewhere, well we worsen access for another patient who probably must be seen at the CHUM. So I see a clear impact in terms of access, the famous "the right patient at the right place," there really is an impact at that level. So for the CHUM, to allow the institution to recenter itself on its tertiary and quaternary mission, well it's always a good thing that there are activities targeting primary and secondary care, we are after all a teaching institution.* [P2, Director]

In addition, the experiences of clinical experts within the program benefited not only participants but the experts themselves. Through the constructive discussions taking place on complex cases, experts gained a better understanding of constraints other health care professionals are confronted with in their practice. These were perceived as factors enhancing the acceptability of the program by directors, managers, and stakeholders.

> *Well those who do it, the team in fact, it helps them rethink, and then hearing, listening to what people working in primary and secondary care have to say, well it helps them too to discover other aspects that perhaps they might not have focused on previously. And I think that it brings the team closer because they to do that together. So even if these are people who work together, well in this case we can be a microbiologist who comes on board and the pharmacists is there… and that, that brings a lot.* [P1, Director]

Appropriateness

Appropriateness of Project ECHO fluctuated based on the structure of its delivery and on its fit with the outer setting.

Versatility and Structure of the ECHO Model

Project ECHO was perceived as attractive by managerial instances because of its operationalized structure that demonstrated effectiveness across various chronic health conditions and settings. This prestigious program's history and the standardization of its delivery facilitated buy-in from various instances as little investment was needed to deploy the programs.

> *Also, it's a proven program, so it's not just us, it's elsewhere in the world… in Canada, in the United States, it's well implemented. So, it's had already proven its worth before we imported it here. That's an important aspect.*
>
> *[FG7, Director]*

On the other hand, the rigidity around the delivery of Project ECHO turned out in some instances to be an obstacle to its spread within the institution. This was either because it was perceived as less suitable for some pathologies since associated with higher costs than other telementoring alternatives, or because it lacked flexibility to use other technological platforms approved by ministerial instances.

> *I don't know if the ministerial position about the use of TEAMS, with for example teleconsultations, if that can be an obstacle. Well yes and no, maybe not. But if we would arrive at the conclusion that the two technologies do exactly the same thing, but with ECHO we must work with Zoom… I'll give you an example. We are involved in the First Nations dossier. If we would realize that using Zoom for Project ECHO® is technologically not feasible in this setting… well I think it would be a strong enough justification to use another model. I mean, the first priority, is to meet the needs. Then, if we can answer those needs through a standardized approach, it accelerates things, its more efficient in terms of deployment, maintenance, putting resources in common, etc. But it must meet the needs, otherwise we must find something else that will.* [P2, Director]

Meeting a Growing Need for Education on Rapidly Evolving Complex Health Conditions

Successful implementation of the program depended in part on the adequacy between what was being offered and the need for such services within the broader medical community. In recent years, the increased complexity observed in various patient populations, the rapid evolution of therapeutic approaches, and the lack of educational resources targeting multiple concurrent diseases appeared to positively impact enrollment of participants in the program.

> *For us, we have a large number of participants, but I think it answered a need, that people were a bit lost,*

> *people were helpless to know what to do with this clientele that is complex. So, I think that when they saw this, they jumped on it because there were no other services that provided this… It's really difficult to be able to solve the problems this clientele has. So, to know that in one place, at the same time, many professionals from different disciplines. I think it was very tempting to have enrollees.* [FG6, Coordinator]

By palliating gaps in the health care system and facilitating patient care within the network, this program was also perceived as indirectly benefiting the institution. This was perceived as one of the main advantages of Project ECHO from stakeholders' perspectives.

> *It is part of our mandate, so the admission to the institution, the return back to the network, all of that is part of the big network umbrella. So, it's a bit for that reason that I was interested in Projects ECHO, because for us, obviously, we aim to optimize healthcare trajectory of patients who must come to our center or return to the network… So it is in this context that Projects ECHO are really interesting for our mission, because we have realized, us, while working with many clinical teams, that very often, a medical care is offered in our institution to compensate for a discomfort from certain partners in the network. And also, there are other ways of responding to this than having patients come here. So that's how Projects ECHO fall in part within our institutional mission.* [P3, Director]

Project ECHO was viewed as a valuable addition to the institutional service offerings because it had the potential to reach individuals beyond the actual participants and clinical experts involved in these sessions. In fact, the knowledge sharing that occurred between participants and their peers, as well as with other tertiary care centers, was significant. Several health care managers and stakeholders noted the snowball effects associated with the visibility of Project ECHO and the improvement of clinical practices within the network.

> *So, to have a platform where when we do an intervention, we reach well 50, 70 other professionals, but in fact we maybe reach much more, because when the social worker from the team of first psychotic episodes in a clinic, often this person will talk to others during team meetings of 20 other professionals, and all of that. So, we reach a very large proportion of people.* [FG5, Medical lead]

Rapid Growth of ECHO Programs

There has been a rapid growth within all 3 Project ECHOs over time. All 3 programs were implemented by individual medical leaders within an 18-month period with a rate of participation rapidly increasing over time. This rapid growth could be accommodated by the institution from a technology support standpoint. This expansion raised both awareness and interest within the institution and also within the broader medical community and other provincial health care networks.

> *We always say that the CHUM is there for all individuals in Quebec, so ECHO is one way to help people from outside… The idea is to know, if you tell me tomorrow morning "we will go from 3 to 10 [programs]," well then we would need to assess the technical needs, how many times per week [technicians] need to be there, what this represents so that we can do this work together, so that it is a collaboration that works well. Because the idea is to support but we must plan well.* [P3, Director]

Cost and Trialability

Alongside the elements that impact acceptability and appropriateness of the programs, the absence of a long-term source of funding and the lack of easily measurable performance indicators remained important barriers to further program expansion and long-term sustainability of the existing programs.

Institutional Sources of Funding and Human Resources That Benefit the Outside Community

Basic costs of these programs involve access to telediffusion material such as webcams, screens, and computers, along with an available technology staff to troubleshoot any problems that can arise during live sessions. Considering the material and conference room being shared by the 3 programs, investments were optimized over the years.

Unlike other programs elsewhere in the country or in other countries, there was minimal funding from public sources to set up these 3 projects within the institution. The in-kind services offered by the institution, such as access to technology material and services, were made possible because of the fit between Project ECHO and the institutional mission. However, the absence of a permanent program coordinator position and of a dedicated paid medical lead posed a threat to the sustainability of the projects.

> *In the United States, they often finance it, but in Toronto as well, they have a pretty big team compared to what we had. In terms of researchers, there are two doctors who are paid to do only ECHO with one salary. So, there is a really big paradigm between what is being asked here. And the risk is that it gets off track, and then stops, or the quality decreases, meaning that I can make recommendations in 15 minutes, but it won't be of the same quality as if I were taking longer to write them. So, there is that organizational, financial aspect.* [FG5, Medical lead]

Despite the recognized adequation between Project ECHO and the institutional mission, the lack of a permanent source of funding was identified as a constant threat to their survival.

> *And let me tell you, I consider that it is not going fast enough, we should have more [programs], but we always hit the same problem when we say "I will need a budget to do that.*" [P1, Director]

This instability might be due in part to the dual mission of the project, which is at the crossroads between educational and health care mandates. This overlap can generate confusion and a lack of accountability among funding bodies, who may assume

that the program falls under the responsibility and the funding of other authorities.

> *You know, its complex Project ECHO. There are multiple aspects. But at some level, it's clear that after the meeting, at least from what I understood, there is an intention to help a patient from the start, which motivates, there is a discussion of real cases that will influence medical acts eventually. But in addition, in parallel, there is knowledge that people acquire more and more to become independent. So, there are these two aspects. One is clinical and one integrates knowledge transfer. And that, this aspect, is really novel.* [FG7, Director]

Lack of an Easily Measurable Performance Indicator

Project ECHO programs are innovative educational models that benefit health care professionals within the community and patients. Currently, there are no easily accessible measurement metrics or dedicated resources to collect performance outcomes within the network. This poses a barrier to the long-term sustainability of the program. For example, it is difficult to document the exact number of patients that benefited from recommendations made within the ECHO sessions, or to estimate the number of patients who were not referred to specialized centers because of the knowledge and expertise gained by their primary health care provider. Given the very low budget allocated to Project ECHO, it became difficult for individual projects to collect empirical data to demonstrate their effectiveness. Because the data are limited, providing a strong rationale to maintain and expand the ECHO model within the institution was challenging. Such an issue is being recognized and must be addressed.

> *We are going to have to think about how we will measure outputs from this process… and what is reasonable to invest considering the population gains in the end, but also for the knowledge development of our professionals. And… we cannot forget our professionals, our researchers, our experts, who learn a lot from people in the different regions, and not to remain disconnected from reality, it is important that communication goes in both directions. So, this has a worth. In my opinion, we probably do not measure it enough, and we probably don't have enough indicators from a managerial standpoint to advertise the program to the level of the real impact it has for the population and for clinicians.* [FG7, Manager]

Lack of Recognition for Time and Resources Invested

Despite the enthusiasm reported above, the time required to set up Project ECHO programs and maintain them reduced its acceptability. Such programs require leadership and skills to offer a high-quality experience. The tasks are often complex, including within and outside of the institution, to finalize the program logistics, create a cohesive hub team, recruit participants from the community, and carry out direct and indirect tasks related to the program. There was often a lack of recognition for the efforts invested. Beyond the actual time spent in an ECHO session, there was significant legwork required behind the scenes, which was not recognized financially.

> *But Projects ECHO raise a lot of small questions, that are not evident from the start. And people think we put on a show you know, that it's fun to do that, … but there is the visible side, but also the invisible side of ECHO. You know, there is the show, but after that, well you have to take care of it after. So it's not that simple, when there is an investment from so many people. I think there are a lot of people who work for nothing in this program. We always work more than what we get paid for I think. And, that's a reality for people who innovate, I think not necessarily the responsibility, but the impact that it has on each person. So, that's what innovation looks like in [region], we never receive anything for the efforts that we put in.* [FG5, Coordinator]

Feasibility

Feasibility was enhanced by the managerial structure in place and also by the ministerial and academic characteristics of the outer setting that supported the institution's innovative educational practices.

Decentralized Management Structure

The institution's managerial structure is to assign a manager for each group of clientele, favoring, as a result, proximity management. This was identified as an organizational characteristic of the inner setting that facilitated the deployment of the Project ECHO model but also made it more difficult.

On the one hand, the decentralized management structure allowed each service to provide authorization for their staff to free up clinical and medico-administrative time to participate in the program, without needing approval from higher-level managers.

> *Yes, the decentralized management structure in the patient populations I think is favorable because it is medical co-management and medico-administrative and proximity management so near sectors of care.* [P4, Director]

On the other hand, however, decentralization increased the reliance on medical leaders to ensure the deployment and maintenance of programs over time. Project ECHO relied on the leadership of specific clinicians within each of the programs to set them up, mobilize their clinical teams, and obtain support from managers and stakeholders to access resources and disseminate the program within and outside of the institution. While there was an overwhelming institutional buy-in, the concrete steps to make this happen relied solely on those medical leaders.

For many participants, the existing structure, which provided a high level of autonomy within each clinical service, was a barrier to adequate communication within different levels of management about Project ECHO being put in place. Each of the 3 programs was developed through individual leaders' initiatives, and as such, they were less visible within the hospital's ecosystem. This led to suboptimal sharing of resources

that could have accelerated the implementation of each program, had an institutional vision been in place earlier. For example, not all of the managers interviewed were aware of the different programs operating within the institution more than 3 years after their launch.

> *I don't know to what extent the Projects ECHOs are known from the larger CHUM community. Me I know them because they operate in sectors within my responsibility so we discuss them regularly. Do we hear about them more broadly, is everyone aware that we have initiatives such as Projects ECHO in other sectors? I have the impression that it's less known and can be a barrier to further deployment of these programs.* [P4, Director]

Ministerial and Academic Characteristics of the Outer Setting Bolstering the Institution's Innovative Educational Practices

The institution was the first in the province to implement Project ECHO programs, so that their success depended on the support received at the ministerial and the integrated university network for health and social services (Réseau universitaire intégré de santé et de services sociaux de l'Université de Montréal [RUISSS]) levels. The RUISSS mission is to federate the university and its affiliated health and social services institutions to facilitate collaborations and set up special projects in line with its ministerial education and health mission. Project ECHO, being at the intersection of teaching and clinical practices, was a perfect fit with this mission. While the process took a few months to target the appropriate type and level of resources needed to implement the first program and required initial funding from pharmaceutical sponsors, the subsequent Project ECHO programs deployed benefited from the already established corridor.

> *So there has really been a year and a half of processes, finding a key person at the RUISSS level has been key, because that person believed in the project from the start and helped me and the manager working there, who knew that person well, to meet the dean of pharmacy, make those connections for us…* [FG5, Medical lead]

This collaboration between the RUISSS and the institution, early in the implementation phase, helped increase visibility of the projects within the medical community, which facilitated recruitment of participants and also increased awareness at the ministerial level of this type of program. The notoriety of Project ECHO worldwide, and the fact that the institution was the first university academic center to offer Project ECHO in French, highlights and contributes to the institution's and the province's visibility in innovative practices. Such progress could potentially lead to additional deployment of projects within the institution and within the province and play a role at the international level with the deployment of French-speaking Project ECHO programs.

> *Let's not forget that if we look at the strategic planning from the ministry for 2019-2023, there is an item about access to specialized care. But this type of ECHO, it's exactly about making a specialty accessible in regions. So it could fall under that mandate…. Because it has been a while since we went to the ministry about that. But let's not forget also that there is some pride. These are the first francophone ECHOs. We can rely on that. We can be francophone leaders for ECHOs.* [FG7, Director]

Discussion

Overview

This study highlighted the rarely reported perspectives of executives and institutional partners, shedding light on the organizational components that are essential to the implementation and sustainability of Project ECHO. Results reflect the intricate balance between institutional resources and its broader mission within a provincial, public health care system. In terms of acceptability, the fit between the projects and the institution's values of innovation, contribution to the broader community, and improving patient trajectory was central from the organizational leaders' standpoint. The structure of the projects and their rapid growth within the institution confirmed an adequate fit with the organization. Initially, the projects benefited from temporary funds, but the absence of easily measurable performance indicators and a lack of recognition for clinicians' invested time posed barriers to progress toward sustainability. Organizational characteristics, including a decentralized management structure and ministerial support for innovative educational practices, increased the perceived feasibility of implementing and maintaining these programs.

These results are in coherence with Mintzberg's *Professional Bureaucracy* structural configuration of the institution under study [33,34], which is characterized by a strong focus on professionals placed as the operating core within the organization, standardization of skills to coordinate the different mechanisms, and the use of both vertical and horizontal decentralization so that professionals can benefit from a high degree of autonomy. Goals of such a professional bureaucracy structure are typically to innovate and provide high-quality health care services within a large, complex yet stable environment [33,34]. These key characteristics of the organization's structure facilitate but also hinder the deployment and sustainability of initiatives like Project ECHO.

Principal Results

The 3 initial Project ECHO programs launched at the institution were initiated by local experts who aimed to meet various needs, including building a stronger primary care network to reduce referrals to their specialized clinics and contribute to knowledge diffusion. In this context, the organization had little involvement in the initial setup of these programs, but its endorsement was essential to the sustainability and growth of the ECHO model within the institution. This is worrisome considering that a recent survey showed that across more than 1000 Project ECHO programs in 68 different countries, funding was temporary at the start [35]. The public health mission of this tertiary and quaternary care center and the potential disruptive nature and value creation associated with these projects were central to

obtaining this endorsement, which enabled the launch of 3 additional Project ECHO programs since the completion of this study.

Considering Mintzberg's organizational structures [33,34] can help understand how the inner setting (structural characteristics, culture, and mission alignment) and outer setting (financing, local conditions, and external pressure) characteristics highlighted in the CFIR framework can guide the development of an implementation strategy for Project ECHO. In this case, for example, professionals' autonomy has been central to setting up the first operational year for each of these 3 projects, with little direct involvement from higher-level governance. This might not be possible in all organizations, especially if the organizational structure is less focused on professional autonomy, in which case the initial implementation strategy might need to include more rapid institutional leads.

Coherent with the professional bureaucracy organization structure, the executives also highly valued innovation in all of its forms. Project ECHO represented new ways within the province to train clinicians that showed promising results for both the recipients (primary care providers) and the deliverers (hub experts) and the institution. The benefits perceived by the participants of the 3 projects have been previously reported [27]. These bidirectional benefits were highly valued and helped the organization set up an infrastructure that would be able to maintain some growth of the innovation. These findings are similar to those reported in Australia, where executives highlighted key elements of Project ECHO that facilitated its deployment, including the alignment with the institution's strategic priorities, innovative potential, and potential for integrated care [36].

The Project ECHO programs are highly standardized, including how sessions are carried out and the telehealth services needed for the sessions (Zoom). This had significant advantages as it minimized the program development required to launch a program, keeping it simple to generate the didactic content specific to each project. Conversely, some of these standardized procedures were incompatible with governmental commendations for the platforms to use for telehealth, which did not include Zoom. At the same time, it was possible for the 3 projects to share the room and licenses to deliver the sessions.

Even after the pandemic, Canada remains largely behind Commonwealth countries in terms of scheduling appointments online (22% in 2019 and 38% in 2022 in Canada compared with 56% in 2019 and 57% in 2022 in the Commonwealth countries), but the use of technology has been improving, particularly for the use of electronic medical records which increased by 20% from 2019 to 2022 [37]. It is likely that the initial technological barriers discussed in this study during the implementation of the ECHO programs before the pandemic have widely decreased by now.

The complexity of the health care ecosystem in the province made it difficult to collect performance indicators that are directly associated with health care performance. For example, the institution executives would like to understand how many patients are not referred to the institution because they received care from their provider locally. However, not all participants in the program would refer to this institution, as they might be living in a geographical region that is under the authority of a different tertiary care center. This lack of a direct performance indicator represents an important barrier to the sustainability of these programs. This difficulty in assessing the impact of the model on a population level is well-recognized [38]. A recent scoping review of patient and community health outcomes associated with Project ECHO showed that out of the 15 studies included, only 1 provided data on outcomes changed at the community level [38].

Finally, results highlighted some possible barriers to sustainability, namely, regarding the availability of human resources, such as dedicated time and funding for hub members to participate in sessions and write recommendations, as well as funding to cover operational costs. A 2023 review of financial structures of North American Project ECHO programs highlights that while many programs initially start up using institutional funds, those are rarely renewed in time, and finding permanent sources of funding becomes crucial [39]. There is a diversity of successful strategies that have been put in place, including aligning the program with state, provincial, or federal health priorities or finding external partners (eg, practice-based networks and translational institutes) [39].

Limitations

This study provides the unique perspectives of organizational executives and leads as their institution implemented 3 different Project ECHO programs. Results are relevant to those institutions operating within public health care systems and want to implement and maintain these programs. Notwithstanding, this study has limitations. Results were collected in a single institution, and it would be important to validate these findings in other provinces and countries with a similar health care structure. Interviews took place after the implementation of the 3 projects, and thus, there might be a recall bias around questions pertaining to the early phases of implementation.

Conclusions

This qualitative study, focusing on institution leaders and directors, highlighted the challenges and facilitators to the deployment of ECHO projects aiming at building capacity in the community for the management of various health conditions. Despite temporary initial funding, challenges in collecting performance indicators most valued, and perceived rigidity of the projects' structure, our results show many characteristics (innovative model, alignment with the institution's mission, and simplicity of its deployment) that helped move these projects toward sustainability within the institution. These learning experiences will be relevant to other institutions evolving within a similar public health care system, wishing to implement this model.

This study focused on the identification of factors at various levels that can influence the readiness for implementation but also the sustainability of an innovation and used the CFIR as a determinant framework for this purpose [40]. The CFIR is less adapted, however, to the collection of quantitative measures of implementation success [41]. It might be helpful for future

studies to combine this model with other models, such as Proctor's taxonomy of outcomes, to also document implementation outcomes.

Abstract

Background: The increasing prevalence of dermatological diseases will pose a growing challenge to the health care system and, in particular, to general practitioners (GPs) as the first point of contact for these patients. In many countries, primary care physicians are supported by teledermatology services.

Objective: The aim of this study was to detect learning effects and gains among GPs through teledermatology consultations (TCs) in daily practice.

Methods: As part of a mixed methods study embedded in a cluster-randomized controlled trial (TeleDerm), a full survey and semiguided face-to-face interviews were conducted among GPs of participating intervention practices using the telemedicine approach. A TC assessment tool (TC-AT) was developed to evaluate the quality of clinical data and images of TCs conducted during the run-in and intervention phases, with a score ranging from 0 (lowest quality) to 10 (highest quality). Mixed methods analysis triangulated qualitative content analysis, survey data with a growth curve model calculated from TC-AT data, comparing subjective experiences of GPs with objective process data.

Results: A total of 487 TCs of 33 practices were analyzed. Questionnaires from n=46 GPs (practice-level response rate: 69.9%) were included in the quantitative analysis. Two-thirds of the GPs (n=31; 67.4%) in the written survey rated the TCs as helpful for differential diagnosis and treatment management. Improved self-reported confidence in diagnosing skin diseases due to the timely clinical feedback from dermatologists was reported by more than half of the responding GPs (n=25; 54.3%). In the interviews (n=13), teleconsultations were mainly seen as a learning opportunity by the GPs. Regarding the quality of TCs, a mean TC-AT score of 7.4 (SD 1.7, range 0 - 10) was observed. In the growth curve model, a simple linear time trend provided the best fit to the TC-AT score trajectory across the observed study period. A significant time * TC-AT start score interaction was found (F_{452}=30.66, P<.001). While regardless of the initial TC-AT score, repeated TCs lead to process quality improvements over time, post hoc probing of the TC-AT start score as a moderator of the learning effect over time revealed the highest improvements among GP practices with a lower initial TC-AT score (−1 SD: standardized slope=0.59, P<.001; mean: standardized slope=0.38, P<.001; +1 SD: standardized slope=0.18, P<.001).

Conclusions: TCs have been shown to be an effective method of education for GPs in terms of “learning on the job” in daily practice. The telemedicine approach seems to be an easily implementable and effective tool to support continuing medical education in the field of dermatology. Strategies could be developed to train GPs and medical students in the use of TC to adequately prepare them for the increasing technological demands of their future profession in primary care.

Introduction

Background

Demographic and environmental factors, climate-related health risks, and lifestyle changes will contribute to a significant increase in skin diseases in the near future, placing a particular burden on health care systems [1-7]. General practitioners (GPs) as the first point of contact for patients with skin conditions play a crucial role in the early detection, accurate diagnosis, and effective management of skin diseases [8]. The care of patients with skin lesions is becoming increasingly difficult due to the growing shortage of specialists, especially in underserved areas.

Teledermatology consultations (TCs) offer an opportunity to alleviate the escalating demand for dermatology services [9-11]. International studies have shown that the telemedicine approach is as effective as traditional medical referrals in reducing costs, enhancing care coordination, and improving patients' quality of life [12-21].

In addition to the aforementioned benefits of TC for patient care, international studies have reported an increase in confidence and learning effects among GPs through TC with their dermatology colleagues [8,15,18,22-28]. Learning effects were achieved, for example, by refreshing old knowledge, sharing new therapeutic concepts, or exchanging difficult cases that were considered essential for their daily work [15,29]. It has been shown that the percentage of correctly prediagnosed cases by GPs increased through TC [8].

Studies have demonstrated teledermatology (TD) to be an effective educational method and an opportunity for dermatologists' and medical students' professional development [30-34]. Lee et al [10] recommended TD as an educational tool for health care providers to interact with for diagnostic support and guidance, especially if they lack specialized dermatology training. In a systematic scoping review of educational programs on melanoma diagnosis for GPs, only 16 of 31 educational interventions included training in dermoscopic diagnosis. Hereof, only one RCT study included TD feedback [35]. To date, little is known about the competence gains, learning effects, and skills acquired by GPs through TC in general practice.

Among these competencies, communication between specialists and primary care is of paramount importance [36]. In a cross-sectional survey by Scaioli et al [37] of more than 7100 GPs in 34 OECD (Organisation for Economic Co-operation and Development) countries on GP-specialist communication in the referral process, the extent and intensity of communication between GPs and medical specialists in a country where a gatekeeping system exists is associated with the organization of the primary health care system. Especially in societies without a mandatory gatekeeping system, as in Germany, there is a higher risk of poor communication between different levels of care [36,37]. In addition, the high workload, the shortage of doctors, and the associated time pressure on doctors may also have a negative impact on communication behavior. According to OECD statistics, Germany had an average of 9.8 doctor-patient contacts per capita in 2019, compared with an OECD average of 6.8 doctor contacts per capita [38].

Despite the need for a more direct exchange between specialists and GPs, written communication still remains the most common form of interdisciplinary exchange between specialists and primary care [36]. Rübsam et al [] [39] identified a need for optimization of interdisciplinary exchange with dermatologists among German GPs, mainly because written feedback from dermatologists was often missing or incomplete, which led to poor communication with dermatology colleagues and also made it very difficult for GPs to pursue or even effectively implement appropriate diagnoses and therapies and deprived them of the opportunity to receive further training based on written feedback 39.

The use of health information technology and a closer collaboration between GPs and specialists have been shown to improve communication [36]. For example, teledermatology has proven to be a useful tool to support direct communication between dermatologists and GPs [23].

While communication via telemedicine was already an integral part of patient care in many European countries, in Germany, liability, professional and data protection regulations, a heterogeneous organization of regional health care due to federalism, and a rather conservative attitude of users have made it difficult to introduce health technology on a large scale [40-43]. It was not until the amendment of the Medical Practitioners' Code (MBO-Ä) in 2017 and the new regulation of exclusive telemedical treatment in the Professional Code of the Medical Association of Baden-Württemberg in June 2020 that the way was paved for the implementation of telemedicine services beyond pilot projects in Baden-Württemberg, about 20 years later than in other European countries [42,44].

Apart from the regulatory framework, it has been proven that adequate reimbursement for teledermatology services plays a critical role in provider participation and the sustainability of such programs [45]. With the amendment of the reimbursement regulation in the statutory insurance on October 1, 2020, a TC request as well as the evaluation of the TC by a medical specialist from then on can be reimbursed [46]. The latter includes not only the assessment of the medical problem, but also a written report to the GP who requested the TC.

Given the persistent deficiencies in interdisciplinary communication, the integration of asynchronous store-and-forward (SaF) TC approach seems to be a promising way to close this communication gap, while at the same time providing German GPs with an on-the-job learning opportunity.

Research Aim and Questions

There is little evidence that TCs lead to learning effects in "real-world" GP settings. The aim of our substudy within the randomized controlled TeleDerm trial was thus to identify learning effects in GPs, defined as subjective reporting of competency gains in combination with objective improvement in process quality. The accompanying mixed methods process evaluation addressed the following research questions: (1) to what extent can the SaF approach be considered an effective training tool for GPs in daily practice in the sense of "learning

on the job", (2) what is the impact of case-based interdisciplinary communication through direct feedback using the SaF approach on the competence and confidence of GPs in the diagnosis of patients with skin complaints and in the assessment of dermatologic diseases, and (3) does the frequency of TC requests in combination with direct feedback from dermatologists support an improvement in the process quality improvement in TCs of GPs over time, indicating competency gains? Based on the results, strategies for the use of TC in GP training and medical education, and for the implementation in primary health care can be derived. The results from this study may benefit health care researchers and persons involved in the continuous professional development of GPs, especially in training scenarios in the context of day-to-day clinical practice.

Methods

Setting and Study Design

TeleDerm was designed as a 2-arm, cluster-randomized confirmatory trial with an accompanying mixed methods process evaluation. It was conducted from 2017 to 2020 in 4 rural and semirural intervention counties in the German federal state of Baden-Württemberg [42,47]. Inclusion criterion for all GP intervention practices (IPs) and patients with skin complaints aged 18 years and older was their participation within the GP-centered health care program of the General Local Health Insurance Fund Baden-Württemberg (AOK-BW). All patients who gave written consent to participate in the TeleDerm trial underwent TC, while patients who refused TC were treated as usual. Based on standardized case documentation, the TC system within our study provided asynchronous (SaF) recording, transmission, and reporting of the patient history (eg, medical history, differential diagnosis, medications, therapy, information on complaints, duration, and changes in shape, color, or size of the lesion). In addition, images of the affected skin area were taken by the primary care physician using a digital camera. The assessment of the TC was to be completed within 48 hours. Via a secure web interface, the dermatologists provided direct, timely, and comprehensive case-based feedback including *ICD-10* (*International Statistical Classification of Diseases and Related Health Problems, 10th Revision*) code and management advice in free text to the requesting GP. In case of further questions from either the GP or the dermatologist, a one-time "question loop" was set up. This meant that when a TC request was made, either the GP or the dermatologist had a one-off opportunity to communicate directly with their medical colleague via a secure web interface to discuss and clarify any outstanding issues relating to the specific TC request. Multimedia Appendix 1 shows the detailed SaF process steps for TC requests in the TeleDerm study. Further information on the study design can be found in the peer-reviewed TeleDerm study protocol [47]. A detailed overview of the mixed methods flow chart within our study is depicted in Figure 1.

Figure 1. Mixed methods study flow chart. GP: general practitioner; TC: teledermatology consultations; TC-AT: teledermatology consultation assessment tool.

Survey

The paper-based questionnaire was developed based on literature and informal interdisciplinary exchange during the preparatory phase of the study and covers the categories of learning effects and competence gain with 9 questions. Additional free text entries were permitted in the questionnaire. In February 2019, the questionnaire was piloted (n=5) with representatives of the target groups using the think-aloud method, and between May and June 2019, the survey was conducted in the participating GP practices (n=46 IP). During its development, the questionnaire was presented several times in an interprofessional plenary session at the Quantitative Methods Research Workshop at the University Hospital of Tübingen and discussed methodologically. Descriptive statistics were calculated by AP using SPSS Statistics version 28.0.0.0 (IBM Corp.). Categorical variables were expressed as frequencies and percentages. A chi-square test (χ^2) was performed to compare user behavior (frequent users vs infrequent users) and learning effect. Free text responses were categorized thematically, using the categories and subcategories developed in 2.3 as a template. Quotes from the free text fields of the survey in the article are marked with the abbreviation "QuesTC." Missing values are excluded from further analysis.

Interviews

Semistructured face-to-face interviews with GPs explored both the impact on interprofessional collaboration and communication between GPs and dermatologists, as well as the competence gain of GPs through feedback from dermatologists. Before piloting the interview guideline with representatives of the target group, the guideline was presented and methodologically discussed in an interprofessional plenary session at the Qualitative Methods Research Workshop at the University Hospital of Tübingen. The interview guideline was piloted by AP in February 2019 (n=5) using the think-aloud method [48]. The participants were asked to give their interpretation of the questions and to explain their answers. According to their feedback, no changes to the interview guideline were necessary.

A stratified selection of interviewees was made according to age (young, middle-aged, and older), gender (male, female), county of origin, and TC use behavior (nonresponder, occasional user, and frequent user). An initial sample size of n=20 interviews with GPs was determined using Malterud 5-dimensional approach of "information power". The dimensions comprise study aim (exploratory), sample specificity (high), established theory (experiential learning [49]), quality of dialogue (expected: mediocre, which means low information density in the transcripts), and analysis strategy [50]. Should the estimated sample size prove insufficient during the analysis, we reserve the right to recruit additional participants. Within the mixed methods evaluation, semistructured face-to-face interviews (AP and EF) were conducted starting March 2019, after informed consent to participate was obtained. Digital recordings of the interviews were transcribed verbatim.

Analysis started with an initial reading of the transcripts in April 2019 to get to know the material and assess the quality of dialogue. Based on this initial reading, we determined in May 2015 that no further information would be obtained through additional interviews due to a high degree of repetition in the interview transcripts and a better dialogue quality than expected. At that point, recruitment to additional interviews was stopped at 13 interviews, and we began with the qualitative analysis.

For qualitative analysis, we assumed a constructivist paradigm that individuals make sense of their subjective reality through narration [51]. Health care professionals learn continuously based on concrete experience [49,52-55]. Qualitative analysis was performed with software support using MaxQDA (VERBI Software GmbH; version 20.1.0) according to Mayring and Fenzl [56]. First, an initial coding frame was built deductively based on the questions of the interview guideline. Both authors (AP and EF) independently applied the coding frame to the same 3 transcripts to assess consistency and reach a shared understanding of how the codes were to be applied. According to the principles of qualitative content analysis, the coding frame was organized into main and subcategories and inductively extended by systematically paraphrasing and generalizing text segments, followed by the formulation of new categories based on recurring content and consensus between coders. Under the supervision of RK, the researchers (AP and EF) iteratively compared new data against existing codes or categories. This ongoing process allowed us to refine and validate the coding frame, ensuring it reflects the evolving understanding of the data. The refined coding frame was then used by AP and EF to code the remaining transcripts, adding and refining categories whenever new information had to be integrated. The coding frame and initial results were also presented and discussed in an interprofessional plenary session at the Qualitative Methods Research Workshop at the University Hospital of Tübingen, in an initial stage as well as the final frame with its detailed categories and subcategories. Quotes from the interviews in the article are marked with the abbreviation "Int."

Development and Reliability of a TC Assessment Tool

Dermatologists need comprehensive clinical data and high-quality images for effective, efficient TC. Especially image quality is crucial for ensuring the same quality of care as a face-to-face consultation [57-59]. A TC assessment tool (TC-AT) was developed to provide a retrospective evaluation of the quality of the TC process. In addition to assessing the quality of the uploaded images, the tool was designed to assess whether the dermatologist was provided with all of the patient information necessary for diagnosis, a detailed description of the dermatologic changes, and the diagnostic question. The results of the AC-TC assessments should show the extent to which the participating GPs were able to perform the relevant process steps in the same way throughout the study and to "deliver" the information relevant to the dermatologist's diagnosis with regard to improvement over time.

Referring to the training concept developed for the participating GPs in the TeleDerm study and the recommendations of the TC guidelines of the German Dermatological Society (DDG) and the Federal Association of German Dermatologists (BVDD) [60], 2 of the authors (AP and RK) developed an assessment tool focusing on the process quality of clinical data and images for SaF TC. Based on the evaluation of randomly selected TCs by 2 raters (AP and RK), the TC-AT was developed and

evaluated within a 2-step process. To ensure the uniformity of the raters' evaluation and to guarantee the simplicity of the criteria catalog, it was streamlined after the first evaluation and the criteria were formulated more specifically (Step 1). Both the pairwise Cohen kappa statistic for single item TC assessment scores (κ=0.852; 95% CI 0.776 - 0.928) as well as the intraclass correlation coefficient (ICC) for overall item TC assessment scores (ICC=0.871; 95% CI 0.697 - 0.945) based on a final assessment of randomly selected TCs (n=24) showed a very good test-retest reliability (Step 2).

Whereas the interrater reliability calculation for assessment of randomly selected TCs (n=24) for single scores was carried out by means of the pairwise Cohen kappa statistic, the reliability concerning the overall TC assessment scores was analyzed by using ICC estimates and their 95% CIs based on a mean-rating (k=2), absolute-agreement, 2-way random-effects model, both times using SPSS Statistics (IBM Corp.; version 28.0.0.0).

The adjusted and finalized qualitative evaluation criteria covered the following aspects: patient history, description of skin area, dynamics of changes, therapy, and medical assessment, as well as the quality of images regarding exposure, contrast, and acuity (Table 1). Each item with respect to clinical data was scored with either 0 (quality criterion not fulfilled) or 1 point (fulfilled). To appropriately weight the importance of the image quality in the evaluation process, image quality was scored from a minimum of 0 to a maximum of 5 points. Item scores were summed up, resulting in an overall TC-AT score range from 0 (poorest quality) to 10 points (highest quality) per TC.

Table . Teledermatology consultation assessment tool (TC-AT).

Item number	Item name	Criteria	Points
A. Clinical data			
A.1	Patient history[a]	Symptoms and duration of complaints	1
A.2.	Skin area[b]	Description of localization, size, and color	1
A.3.	Dynamic[c]	Changes in size, shape, and color of the affected skin area	1
A.4.	Therapy	Information on medical treatment so far	1
A.5.	Medical assessment	Formulation of a presumptive diagnosis or question for the dermatologist	1
B. Images			
B.1.	Quality of images[d]	Exposure, contrast, and acuity	5
Overall TC assessment score		Maximum points	10

[a]Patient history: at least 1 out of 2 listed criteria is to be specified

[b]Skin area: at least 2 out of 3 listed criteria are to be specified, otherwise the item is scored 0 points

[c]Dynamic: at least 1 out of 3 listed criteria is to be specified

[d]Quality of images: 3 out of 3 criteria: 5 points (all fulfilled); 2 out of 3 criteria: 4 points (exposure, contrast); 1 of 3 criteria: 3 points (exposure); 0 of 3 criteria: 0 points (nothing fulfilled, not usable)

Statistical Analysis of TC-AT Score Time Trend

To explore the evolution of TC quality over time, a mixed model was fitted to the TC-AT data. As the total number of TCs per GP practice differed and time points of TCs were unevenly spaced, time was introduced as a continuous variable. In the model building process, linear and quadratic time terms were introduced as fixed effects. Furthermore, the interaction between the starting TC-AT score at baseline and time was assessed. In addition, we investigated whether introducing the overall number of TCs per GP practice as a covariate added significantly to the improvement in model fit. A random intercept and slope for GP practices were added to account for cluster effects. Due to convergence problems, a simple diagonal covariance structure for random effects was chosen. For the residuals, an autoregressive error structure AR(1) was assumed. Model selection was achieved by forward selection: terms were only added when the model significantly improved, as tested with a log-likelihood ratio test. In addition, the Akaike information criterion and Bayesian information criterion were evaluated, deeming models with lower fit criteria as more appropriate.

The final mixed model included time (linear) and a time*baseline TC-AT start score interaction as fixed effects and a random intercept for GP practices. Simple slopes analysis as post hoc probing was conducted to determine the nature of the interaction. We furthermore applied the Johnson-Neyman technique to identify the region of significance. Model assumptions were checked visually and found adequate. A *P* value <.05 (2-sided) was considered statistically significant and adjusted for multiple testing with Bonferroni correction where necessary. All data analyses were implemented in R (version 4.1.3; R Core Team) and R Studio (version 2022.02.1; Posit Software, PBC). Linear mixed models were fitted using the *lme4* [61] and *nlme* [62] packages.

To assess whether the frequency of TC also impacted the subjective impression of competency and confidence gain, the GPs' user behavior was categorized into frequent users (≥11 TC) or low users (≤10 TC) on the practice level. The cutoff value was based on the median number of teleconsultations per practice. A chi-square test was used to compare the GPs' user behavior and their subjective learning effect. No expected cell frequencies were below 5.

Ethical Considerations

The TeleDerm study was approved by the Ethics Review Board of the Eberhard Karls University of Tübingen (Ref. No. 395/2017BO1). Participation in the study was voluntary. Participants were informed of the study's purpose and their right to withdraw and prohibit the use of their data at any time. They gave written consent to participate in the study, and to collect and to use their data for the study's purposes.

Results

Characteristics of Participants

A total of n=49 GPs participated in the full survey. One GP was excluded from further analysis of the survey because this IP did not conduct any TC. In addition, 2 other GPs were excluded from further analysis because they did not respond to the questions on learning effects and competence gain. Thus, questionnaires from n=46 GPs (response rate of 69.6% on practice level) were included in the further quantitative evaluation.

Table 2 summarizes the main characteristics of the study population at the level of GP practices and health care providers in the full survey of GP intervention practices and in the semistructured interviews with GPs.

Table . Practice and provider-level characteristics of the study population.

Characteristics	Survey	Semistructured interviews
GPs in total, n (% on GP-practice level)	46 (69.6)	13 (28.3)
Male, n (%)	33 (71.7)	8 (61.5)
Age (years), mean (SD, range)	56.87 (7.963, 37 - 75)	59.0 (8.617, 40 - 75)
Job experience (years), mean (SD, range)	22.09[a] (9.273, 1 - 38)	Not recorded

[a]n=1 missing

Educational Value of TCs

According to the survey, 9 out of 10 GPs stated that they learn more about skin conditions through TC than by regular referrals, of which 20 GPs (43.4%) strongly agreed with this item (Figure 2, item C5).

In the interviews, several GPs elaborated that in contrast to normal referrals, TC offers a direct, case-based exchange between specialist and GP:

> *In the past, patients were sent to the dermatologist, who examined them and wrote a letter. Today, this feedback from dermatologists is almost non-existent. And that's a pity because in the meantime we no longer know whether the tentative diagnosis was correct or not, what the dermatologist is doing. So, this learning effect, which we used to have automatically through the report of the specialist, has largely disappeared in the meantime. And this would now be an opportunity to reconnect with this learning effect that we used to have automatically.* [(IntA3-29)]

The GPs emphasized the benefit of a timely, direct reporting from the dermatologist for their learning effect, as opposed to regular referrals

> *For me, the learning effect is good, simply also because of the quick feedback* [(IntA12-64)]

and their therapy recommendations for the further treatment of the GP patients

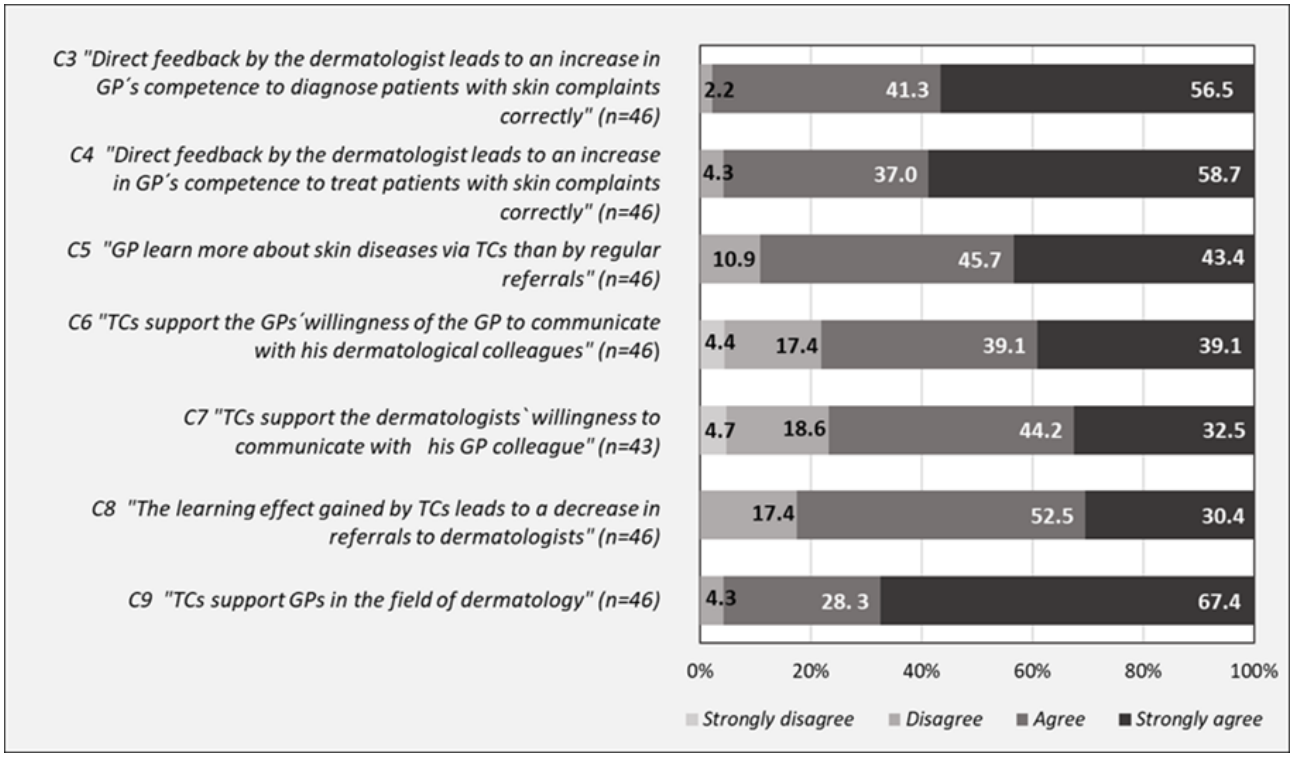
> *We started the therapy on the recommendation of the dermatologists, and it was quite successful.* [(IntA5-24)]

In addition, interviewees indicated that personal feedback helps physicians to validate their own findings and thus actively provides an educational impetus for the primary care physicians:

> *Sometimes you are confirmed, and sometimes new aspects are added, which you nevertheless include and perhaps treat.* [(IntA7-38)]

Despite the many positive effects of direct and personal interaction between GPs and their dermatology colleagues, some respondents were skeptical about the use of telemedicine for communication between the 2 groups. According to the survey results, more than 1 in 5 physicians disagreed with the statement that TCs promote GPs' willingness to communicate with dermatologists, while 39.1% strongly agreed with this point (item C6). GPs were even more skeptical about the willingness of dermatologists to communicate with GPs via TC. Only one-third (32.5%) of GPs strongly agreed that telemedicine increased dermatologists' willingness to communicate with GP colleagues, while 23.3% disagreed, including 4.7% who strongly disagreed (Figure 2, item C7).

Figure 2. Learning effect (Survey).



When asked about the support of GPs by TCs in the field of dermatology, the survey revealed an agreement among the participating physicians about the benefits for their daily practice. Using a 4-point Likert scale, two-thirds of the respondents (67.4%) strongly agreed that TCs support them, while only a small number of respondents (4.3%) strongly disagreed with their colleagues in this regard (Figure 2, item C9).

Increase in Confidence of Diagnostic and Management Skills in GPs

The GPs were asked about their feeling of learning and competence gain during the TeleDerm project. On a 3-point Likert scale, 54.3% of the GPs reported an improvement in their ability to correctly diagnose patients with skin diseases (item C1). In total, 47.8% of the respondents stated that their competence in performing and assessing dermoscopy in patients with skin diseases had increased during the TeleDerm study (item C2), 77.3% of them were male GPs. One in 2 GPs had not noticed any change in either of these areas.

Interview participants reported that direct interaction between GPs and dermatologists has a positive impact on physicians' confidence and acquisition of dermatologic knowledge regarding the treatment and management of common skin diseases and lesions.

> *You have a tentative diagnosis and now, through the TC, you have the possibility to get confirmation. You gain confidence and that is of course an enormous learning effect.* [(IntA3-29)]

In the survey, almost all GPs agreed that the direct feedback from the dermatologists leads to an increase in GPs' competence to correctly diagnose (Figure 2, item C3) and treat (Figure 2, item C4) patients with skin complaints.

Physicians also see qualitative potential in the learning effect in terms of increased treatment safety, strengthening of their role, and simplification of processes in the care system:

> *[The learning effect] of course also offers a safety factor that can be gained for oneself as a therapist and makes many steps simply unnecessary* [(IntA10-34)]

This statement was further substantiated by a GP, especially regarding a possible relief of the dermatologists as well as an extension of the approach to other areas of work in family medicine:

> *TeleDerm-approach is a good introduction to further telemedicine applications in the classic family doctor/specialist division of labor. There is thus a possibility of avoiding the clogging of the specialist's schedule with unnecessary consultations* [(QuesTC43-04)]

While GPs were overall very positive about the previous items presented, the respondents seemed to be more cautious about the statement that the learning effect gained by TC will lead to a decrease in referrals of patients with skin complaints to dermatologists. Only 30.4% of GPs strongly agreed with this statement, while almost 1 in 5 GPs (17.4%) disagreed with their colleagues (Figure 2, item C8).

Learning Curve Through Iterative Processes

The number of TC requests during our study had a positive effect on GPs' subjective competence gain in frequent users. Among GPs who frequently used the service, 64.3% (n=18) reported an increase. The findings of this study, as evidenced by the results of the survey, demonstrated a significance between user behavior and competence in performing and assessing

dermoscopy in patients with skin disease, as indicated by the following statistical analysis: χ^2 (1)=7.769, *P*=.005, ϕ=0.411.

Interview participants also reflected on the association between the frequency of TC and GPs' professional expertise in the field of diagnostic and therapy of patients with skin diseases:

> *I would have liked it better if we could have presented many more patients, because the knowledge gain for each of us would have been correspondingly higher.* [(IntA4-27)]

Next to repetitive TCs, the use of a dermascope was associated with learning from the GP's perspective:

> *By [.] working with the dermascope, you look at it even more closely [.] and when you get the feedback, you've already learned something from it - in case of a repetition, it's easier to recognize what it was*
>
> *(IntA1-47)*

TC Data Flow

Of the 568 TC datasets, 71 TCs had to be excluded due to GP dropouts, duplicates, TC sham datasets, or non-compliance with inclusion criteria.

In addition, 5 nonresponding practices did not conduct any TCs. So far, there is no evidence of when a learning effect can be expected from repeated TC requests. However, since curve fitting requires at least 3 points to derive a trend, only IPs with more than 2 TCs were included in the further analysis of the learning effect. Therefore, n=8 practices with less than 3 TCs per practice during the run-in and intervention phases were excluded, for a total of n=10 TCs. Finally, a total of 33 practices with 487 TCs were included in the subsequent statistical analysis to examine the learning effect over time.

Learning Effects

The median number of TCs on the practice level was 10 (IQR 6, range 3 - 75), and the mean assessment TC-AT score evaluated by both raters reached a value of 7.44 (SD 1.68; median 8, IQR 2, range 0 - 10). It has to be pointed out that 3 "*power-user*" IPs were responsible for more than one-third (n=174; 35.72%) of all TC requests during the run-in and the intervention phase. The last TC was conducted 426 days after baseline (ie, after the first TC of the respective IP).

Results of the final linear mixed model are given in Table 3. A statistically significant time * TC-AT start score interaction was found (F_{452}=30.663, *P*<.001), indicating that progression of TC quality over time was influenced by the initial TC-AT score. In Figure 3, post hoc probing of the interaction is displayed by simple slopes at the mean (=average TC start score; dashed line) and 1 SD below (=low start score; dotted line) and above the mean TC-AT score level (=high start score; solid line). At all 3 moderator levels, there was a statistically significant positive effect of time on the improvement in TC quality (*P*<.001). The learning process over time was strongest for GPs with a lower-than-average TC-AT start score (standardized slope=0.590) and less pronounced for GP practices starting with a higher-than-average TC-AT start score (standardized slope=0.179). The Johnson-Neyman plot (Multimedia Appendix 2) revealed that the interaction was statistically significant below 249 days.

Table . Linear mixed model results for the evolvement of the teledermatology consultation assessment tool score over time.

Discussion

Principal Results

Our findings show subjective improvements in GPs' competency paired with observable improvement in TC process quality over time assessed through the TC-AT score. The mixed methods analysis revealed that 2 main aspects contribute to these learning effects: interdisciplinary communication and learning on the job. Both aspects will be discussed in the context of the current research situation in the following section.

Interdisciplinary Communication Increases GP Expertise

According to our study, timely feedback and direct exchange with specialists on diagnosis, therapy, and treatment options seem to promote learning by validating the GP's own findings. Thus, it may increase the confidence of physicians in treating patients with skin diseases in daily practice.

As with TeleDerm, German GPs in the study by Rübsam et al [39] criticized the communication with the dermatologists and the lack of written feedback, which meant that the learning effects that GPs had previously gained from the specialists' reports were lost, making it difficult for GPs to understand and effectively implement an appropriate diagnosis or treatment. Apart from a few critical voices, the majority of our GPs were of the opinion that the TC approach was a supporting tool and a very good opportunity to increase the willingness to communicate and thus to improve the interdisciplinary exchange on both sides in the future. Also, based on the findings of van den Akker et al [23], TC is viewed as a useful tool for interpersonal communication between GPs and dermatologists.

The standardization of TC web templates to ensure the collection of necessary information not only promotes their structured implementation but also provides guidelines for structured interdisciplinary communication between GPs and dermatologists, thus increasing diagnostic and management concordance [25]. This process is particularly supported by the provision of good diagnostic images. According to the results of our main article on the TeleDerm study, 79.8% of the specialists stated that the image quality provided by the GPs during the intervention phase was sufficient for the diagnosis, underlining the importance of this approach [42].

By supporting this interdisciplinary exchange with specialists, the telemedicine approach proves to be a helpful training tool for physicians that can be used in daily practice and at the same time offers the opportunity to close the lamented communication gap between German GPs and dermatologists. Especially the recent changes in the framework conditions in Germany (changes in data protection and the medical code of conduct and the possibility of billing for teleconsultations) may contribute to a sustainable change in communication behavior and stimulate direct exchange not only between GPs and dermatologists but also with other disciplines. Although practitioners frequently perceive standardized forms as a source of double work, this study indicates that structured data

processing through such tools may enhance the quality of care by organizing relevant information more effectively.

On-the-Job Learning in Daily Practice

Practices with initially low TC-AT scores showed the steepest improvement in the quality of TC requests over time, indicating a stronger learning effect in inexperienced practices. The improvement in the process quality of TC requests over time can be explained as a result of this on-the-job learning among GPs [42]. Mohan et al [24] also demonstrated a statistically significant improvement in dermatological knowledge among frequent users of SaF TC among GPs. An effect between the time factor and the frequency of use and repetition in everyday practice is to be expected, especially if the TC requests are also used repeatedly by both sides for refresher and training purposes, for example by discussing differential diagnoses, exchanging alternative treatment approaches, or also in the case of reasons for differences of opinion [15,26]. Frequent use appears to be the most effective way for GPs to build competence with the tools. Educational formats should therefore aim to support the initial adoption phase and help overcome early barriers to use.

Based on the Kolb experiential learning cycle, our results show that frequent use of TC and access to an expert opinion on skin complaints help GPs to reflect on their daily practice. International research supports that TC is a time-saving and effective training tool for GPs and supports continuous learning [15,18,33,34]. The interdisciplinary exchange and communication between GPs and dermatologists could promote the continuous and experiential learning process on many medically relevant aspects—therapy, diagnostics, lesion description, and image quality. This low-level implementation facilitates sustainable and continuous medical education for generalists. The integration of TC into the daily clinical practice of GPs appears to have a positive impact on both perceived and self-reported gains in dermatological knowledge, as well as confidence in diagnostic skills and care management. Furthermore, the feedback and self-assessment by GPs participating in the study indicated that the adoption of TC seems to support improvements in GPs' professional competence, particularly in the assessment of patients with dermatologic complaints. Our results thus follow the findings of international studies that direct and case-based exchange with specialists provides an educational impetus for GPs by refreshing previously acquired knowledge, but also by sharing new therapeutic concepts, especially when used to discuss differential diagnoses, alternative treatment strategies, or even reasons for disagreement [15,18,25,26]. GP's reflective practice is supported by iterative, direct feedback by specialists.

In Germany, telemedicine was opened about 2 decades later than in many other European countries. In order to cope with the increasing digitalization of health care, today's medical students must be prepared for the complex challenges of their future professional life [63]. For this reason, the necessary practice-oriented approaches to digitalization and the teaching of interdisciplinary and intersectoral skills should be included in the compulsory curriculum of medical faculties as a useful combination and should be taught there at an early stage [63,64]. By introducing TC early in medical education, the next generation of practitioners will have already navigated the initial challenges, allowing them to focus more effectively on "learning on the job."

Strengths and Limitations

The TeleDerm study is one of the first studies to investigate the effects of "learning on the job" among primary care physicians in the context of dermatology teleconsultations. It should be emphasized that the mixed methods process evaluation is based on 3 different qualitative and quantitative data sources. While the process data collected at the practice level from teleconsultation requests provided a large amount of objectively evaluable data from the "real world" to answer the research question, the full survey allowed a representative assessment of the GPs. The interviews also supported an in-depth qualitative investigation of individual experiences and self-assessment of learning effects and perceived competence gains in relation to dermatological expertise of the target group under investigation. The triangulation of the different data sources thus allowed for a comprehensive analysis and a multifaceted consideration of the research questions from the perspective of the GPs at both group and individual levels.

The operationalization of learning effects as subjective competency gains in combination with objective improvements in process quality is limited. A randomized controlled trial design with the main focus on these learning effects with a stronger emphasis on clinical aspects (eg, by issuing a test of dermatologic skills) would have been preferable but was effectively impossible to implement into the main study.

The TC-AT was developed and tested to evaluate the TCs conducted. All TCs included in the evaluation were assessed and objectively evaluated on the basis of these quality criteria. As a limiting factor in the process evaluation, it should be noted that the evaluation matrix on which the qualitative assessment was based was developed post hoc by the authors. Another limiting factor is that only the formal process indicators collected during the study period were evaluated. A professional evaluation of the medical plausibility, such as a professional evaluation of the diagnosis, therapy, or even the treatment success of the teleconsultations, was not provided for in the study design and was therefore not carried out. Nevertheless, the matrix tool allowed a continuous recording of process and data quality over time, and we were able to describe central aspects of GP's education through TC based on real-world data.

Conclusions

The telemedicine approach proves to be an effective training tool for enhancing the diagnostic and therapeutic skills of GPs. The positive learning effects are enabled by direct and timely interprofessional exchange. With the increasing digitalization of our health care system, telemedicine has the potential to enrich medical education as well as training of GPs or specialists. Furthermore, incorporating telemedicine into medical education will ensure that future health care professionals are equipped to meet the evolving needs of modern health care delivery.

Acknowledgments

TeleDerm was funded by the Innovation Fund at the Federal Joint Committee (Innovationsausschuss beim Gemeinsamen Bundesausschuss (G-BA)), Berlin, Germany (grant number 01NVF16012). We thank all the GPs and dermatologists involved in the study for their support and cooperation. We acknowledge the support from the Open Access Publication Fund of the University of Tübingen.

Abstract

Background: Effective diabetes management requires behavioral change support from primary care providers. However, general practitioners (GPs) often lack training in patient-centered communication methods such as motivational interviewing (MI), especially in time-constrained settings. While brief MI offers a practical alternative, evidence on its impact among GPs and patient outcomes remains limited.

Objective: This study aimed to evaluate the effectiveness of a structured MI educational program for GPs and GP trainees on their MI knowledge and confidence, and its impact on clinical outcomes among patients with type 2 diabetes in primary care settings.

Methods: A mixed methods study was conducted using a before-and-after two-group design with quantitative assessments of GPs' knowledge and patients' biomarkers, supplemented by qualitative interviews. The intervention group (n=35) received a 4-hour interactive MI workshop, optional web-based modules, and brief MI guides. The control group received standard care. A total of 149 and 167 patients with diabetes were included in the study and control groups, respectively.

Results: A paired-sample *t* test was conducted to evaluate the impact of the MI course on the learners' knowledge. There was a statistically significant difference in the knowledge test scores from Time 1 (mean 11.46, SD 3.48) to Time 2 (mean 15.04, SD 2.35), t_{28}= –7.74; *P*<.001 (2-tailed). The mean increase in knowledge score was 3.57 (SD 2.44), with a 95% CI of 2.62 to 4.52, indicating a large and statistically significant effect. The eta-squared statistic indicated a large effect size (eta-squared=0.85). Patients in the intervention group had greater improvements in HbA_{1c} (mean difference= −0.50, 95% CI −0.91 to −0.09; *P*=.02) and diastolic blood pressure (mean difference= −5.96 mmHg, 95% CI −8.66 to −3.25; *P*<.001) compared to controls. Qualitative feedback highlighted the usefulness of brief MI, along with challenges in mastering advanced techniques and time constraints.

Conclusions: The MI educational program improved GP trainees' MI knowledge and patient outcomes. Brief MI appears feasible in primary care but requires ongoing support for skill development and implementation.

Introduction

Diabetes is a chronic illness with a rising prevalence worldwide [1]. Over the past two decades, the global prevalence of diabetes has significantly increased. In 2021, it was estimated that 536.6 million people were living with diabetes [1]. This number is projected to rise to 642.7 million (11.3%) by 2030 and 783.2 million (12.2%) by 2045 [1]. Furthermore, 3 out of 4 adults with diabetes reside in low- and middle-income countries [1]. Approximately 240 million people are living with undiagnosed diabetes globally, with 90% of these individuals residing in low- and middle-income countries [1]. Diabetes and its complications, such as heart disease, stroke, and chronic kidney

disease, are pressing public health challenges that are expected to worsen globally [2,3].

Patients with diabetes often face significant challenges in adopting and maintaining healthy lifestyle changes, which can hinder blood sugar control and increase the risk of complications. Research and systematic reviews have highlighted multiple barriers to sustained behavioral change, including low motivation, insufficient self-discipline, and limited adherence to recommended lifestyle practices [4-7]. These challenges are often compounded by a lack of personalized guidance and support for self-management from health care providers [8], as well as systemic constraints such as limited consultation time for effective behavioral counseling [9,10]. Many providers report difficulty engaging patients in meaningful discussions about lifestyle modification due to limited training in behavioral change techniques and patient-centered communication [9]. Addressing these issues requires strategies that not only convey information but also actively enhance patient motivation, strengthen self-efficacy, and support the development of sustainable health behaviors within routine care.

Motivational interviewing (MI), a counseling method widely recognized and developed by Miller and Rollnick [11], is a patient-centered approach [12]. MI focuses on the client's perspective, allowing them to express their feelings and motivations for change [12]. It empowers clients to take ownership of their change process, thereby reducing defensiveness and resistance [12]. MI consists of 4 key processes: engaging, focusing, evoking, and planning [11]. The foundational skills of MI—open-ended questions, affirmations, reflections, and summaries—are used to improve engagement and facilitate change talk [11]. Focusing is the process of finding or discussing a common interest topic for behavioral change between the client and counselor [11]. In the evoking process, the counselor aligns with the patient's talk (change vs sustain talk) to encourage change. The more the patient makes change talk, the closer she or he is to the change. Patients were guided, invited, and responded toward change talk, such as reflecting on past successes, envisioning future benefits, considering consequences, exploring extreme scenarios, identifying personal values, and addressing ambivalence [11]. During the planning process, the patient expresses more change talk and less sustain talk. In this process, potential obstacles to change and strategies to overcome them are explored [11]. This approach has been successfully applied to various lifestyle challenges and medical conditions [12,13]. Systematic reviews and meta-analyses have demonstrated efficacy of MI in addressing various health behaviors, including alcohol abuse, increasing physical activity, smoking cessation, pain management, and improving body weight and blood sugar control [14-17]. The application of MI varies across health care settings and among different clinicians. Reviews continue to support the positive impact of MI across diverse diseases, settings, and delivery modes, effectively delivered by various health care professionals [12,16,18].

General practitioners (GPs) or family physicians play a pivotal role in diabetes management [19]. Their involvement is essential for improving health outcomes, particularly by facilitating behavioral changes [20]. GPs are uniquely positioned to promote health and prevent disease through lifestyle counseling and guidance on managing risk factors [21,22]. However, previous studies have found that patient-centered, motivational techniques aimed at behavioral change are not routinely used during diabetes consultations [23,24].

Given their central role in supporting behavioral change, GPs are well-positioned to apply MI to promote lifestyle modification and improve outcomes in patients with type 2 diabetes. Previous studies have shown that MI delivered by health care professionals in primary care can improve diabetes management outcomes, including glycemic control, weight loss, and self-management [12,15,18,25,26]. When delivered specifically by GPs, a systematic review reported that MI may enhance patient outcomes; however, the effects are often modest and inconsistent, with variable results observed for HbA_{1c}, cholesterol levels, and physical activity [17,27]. In addition, a significant research gap remains regarding MI's impact on GPs themselves, particularly in terms of their knowledge, competencies, and barriers to implementation in routine diabetes care [17].

Despite its feasibility in daily general practice, the uptake of MI remains inconsistent. Common barriers include time constraints—especially in managing complex conditions like diabetes, which require detailed behavioral counseling—and the difficulty of balancing MI principles with competing clinical priorities during a single consultation [12,17]. Brief interventions have been suggested for use in routine diabetes care; however, these often lack the patient-centered techniques central to MI [20,28]. To address this, brief MI has been developed as an adapted form of MI for high-volume clinical settings [29]. It emphasizes core processes such as engaging and evoking within a condensed interaction, making it feasible within standard consultation times [29]. This adaptation enables GPs to facilitate patient-centered behavioral change without conducting a full-length MI session.

Brief MI may be a more practical approach for busy GPs in managing diabetes. Despite its potential, there is a notable lack of rigorous studies evaluating the effectiveness of brief MI in diabetes care. For instance, a study implemented brief MI but involved only 4 patients with diabetes and was delivered by providers who were not exclusively GPs [30]. Another study found that training brief MI for family medicine residents can enhance their counseling skills and improve patient self-management, as evidenced by the increased use of MI-adherent approaches and improved clinical outcomes [31]. Additional challenges to implementing brief MI include the complexity of the technique, which demands that GPs develop advanced clinical skills to apply MI effectively, and the lack of ongoing support systems to sustain and enhance these skills over time [17]. Addressing these barriers is critical for optimizing the feasibility and impact of brief MI in primary care settings.

Continuing medical education (CME) or the broader concept of continuing professional development (CPD) is widely used to maintain the quality of GPs' clinical practice [32] and for GP diabetes education [33]. Multifaceted educational approaches, such as interactive workshops, small-group discussions, outreach visits, audits and feedback, and reminders, have been shown to

effectively improve physician practices and clinical outcomes [34,35]. In contrast, traditional CME methods, such as lectures and educational material distribution, have a limited impact on behavioral change [34,35].

Web-based educational methods are increasingly popular due to their flexibility, convenience, and reduced travel costs, offering similar effectiveness to traditional methods [36,37]. While web-based CME methods may not replace traditional approaches, they can serve as complementary tools to enhance learning outcomes [36,38]. Previous studies have examined the effectiveness of web-based MI training across diverse diseases, settings, and health care professional groups [29,39-43]. These studies have shown the potential of web-based MI training to improve learners' knowledge, skills [39,40], and confidence [29,42]. However, evidence on its impact on clinical practice or patient outcomes is scarce [39]. In addition, the role of web-based educational methods in supporting MI skill development for GPs managing diabetes has not been rigorously tested.

This study addresses existing gaps by implementing a comprehensive educational program for GPs, combining an interactive workshop, structured web-based learning, and practical guides for brief MI. The primary research question was whether this multifaceted MI educational approach could improve GPs' learning and patient clinical outcomes. Therefore, this study aimed to evaluate the effectiveness of a structured educational program on MI for GPs and GP trainees in primary care settings. Specifically, it assessed whether a combination of interactive workshop training, web-based modules, and practical brief MI guides could improve participants' MI-related knowledge and confidence, and whether this translated into improved clinical outcomes among patients with type 2 diabetes in pilot communities, and exploring GPs' experiences, perceptions of the MI training, and their implementation of MI in routine consultations.

Methods

Study Components and Research Design

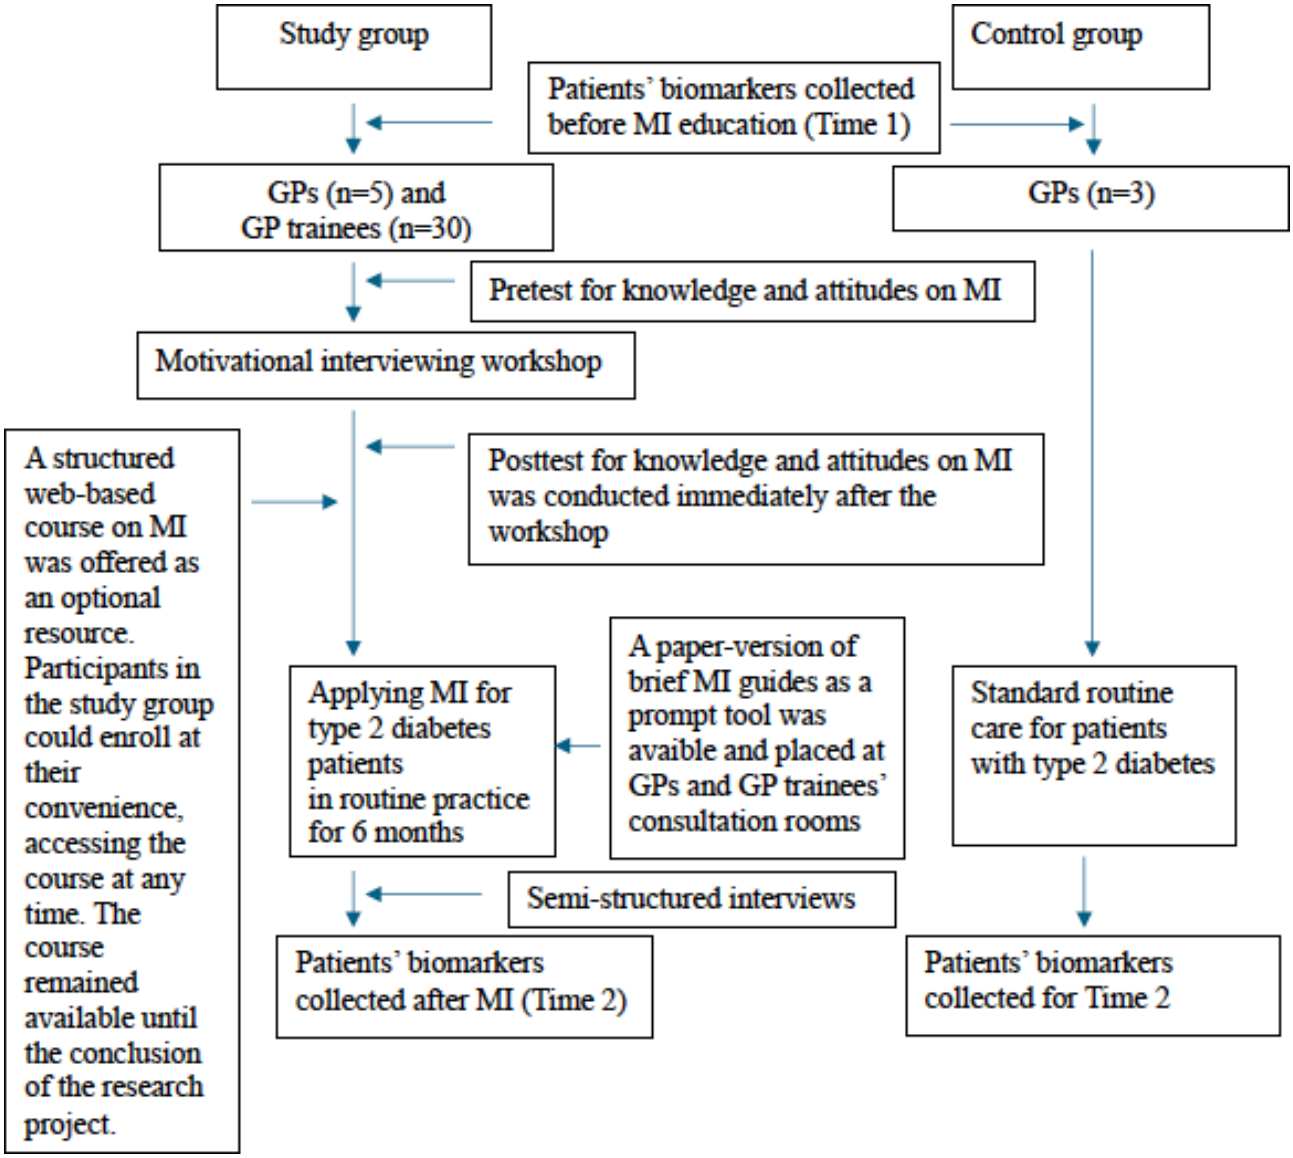
To address the overarching aim of evaluating the effectiveness and feasibility of MI training in primary care, this study used a mixed methods design composed of three components: (1) Evaluation of GP learning outcomes: A before-and-after study assessed changes in GPs' and GP trainees' knowledge and confidence related to MI through pre- and posttests; (2) Assessment of patient clinical outcomes: A quasi-experimental, nonrandomized 2-group design compared biomarker changes in patients with diabetes from intervention (MI-trained) and control (routine care) sites; and (3) Qualitative exploration of GP experiences: A descriptive qualitative study using semistructured interviews explored GPs' experiences in applying MI in routine consultations after training and their experiences in the MI education. GP interviewees were selected based on their confidence in applying MI in routine consultation after their completion of the MI courses. This integrated structure is justified by the implementation nature of the study, aiming to evaluate not only educational effects but also practical application and outcome relevance. The integration is intentional and appropriate for a pragmatic, real-world educational intervention. Improving GP knowledge without understanding its translation into patient care would offer limited insights. Conversely, changes in patient biomarkers without a provider perspective could misattribute causality. Including qualitative data allowed us to contextualize the quantitative results, explain variability in outcomes, and identify barriers and facilitators to implementation.

The sample size was calculated separately for the two primary components of the study: (1) the before-and-after evaluation of GPs' knowledge and (2) the comparison of patient biomarker outcomes between the intervention and control groups. For the knowledge assessment, the sample size was calculated using the G*Power (version 3.1.9.7; Heinrich-Heine-Universität Düsseldorf) based on the proportion of GP trainees enrolled in diabetes CME [44]. Assuming a power of 80%, a significance level of 0.05, and an effect size of 0.6, a total of 24 participants was sufficient to detect a significant difference in knowledge scores before and after completing the CME courses. For the patient outcome component, the sample size estimation was based on previously published research in which patients with diabetes received MI-guided behavioral change counseling [26]. To detect a 10% effect size with an alpha of .05 and a power of 80%, a total of 241 participants was required. This meant that 121 patients were needed for each of the study and control groups.

Participants and Recruitment

Figure 1 shows the flow of participant recruitment for the study. The study was conducted from January 2024 to January 2025.

Figure 1. Flow of recruitment. GP: general practitioner; MI: motivational interviewing.



GPs and GP trainees' recruitment

Study and control groups were recruited by convenience from primary care units, which had family doctors working full-time. Notably, in Thailand, the majority of family or primary care doctors work in the hospitals, some work part-time at primary care units, and the majority of primary care units do not have doctors but are operated by nurse practitioners.

For the study group, a primary care unit affiliated with a medical school was selected. Doctors working at this unit included 5 full-time GPs and 2 to 3 GP trainees rotating in each month (the total number of GPs was 5, and the number of GP trainees was 30). For GP trainees, each would rotate at this primary care unit for at least 3 months per year. This primary care unit covered the care of 10 communities with a total population of approximately 13,000. For the control group, 3 primary care units were selected. These units served 4 communities with a combined population of approximately 10,897 and were staffed by 3 family doctors. Notably, the study and control areas are located approximately 300 km apart.

Patients' Recruitment

The study used primary care catchment areas as the unit of allocation and analysis. This enabled the impact of the interventions to be examined at the population level and allowed the outcomes related to diabetes care for individuals to be examined, regardless of whether care was sought from a single or multiple GPs within their community. All patients with diabetes under care of the selected primary care units were included in the analysis as a unit of analysis. Therefore, 149 patients with diabetes in the study areas and 167 patients with diabetes in the control areas were included.

Educational Interventions

An interactive 4-hour workshop on MI was offered to GPs and GP trainees who worked at the primary care unit of the study group. The instructors (IT and PN) attended several MI web-based courses provided by William Miller, Stephen Rollnick, and Theresa Moyers. The GPs and GP trainees voluntarily attended the workshop. The content of the workshop included human behavior, introduction to MI, roles of GPs in MI technique, MI spirit, 4 processes of MI, brief MI for busy

GPs caring for people with diabetes, MI vs stage of change, and case studies using MI in each stage of change.

An additional educational course on MI was offered to GPs and GP trainees to self-study at their convenience. A structured web-based course on MI and stage of change was designed and developed to provide the foundation for GPs using MI in their routine consultations. The web-based course was developed and designed by incorporating several steps to create effective web-based learning activities, as recommended in a previous study [45]. The intervention, designed to provide GPs with knowledge of MI, was offered for a period of study. The content was designed as text-based plus interaction with text, that is, knowledge-based quizzes, self-practice, and self-reflection activities. The course comprised approximately 4 hours of learning activities for individuals to complete. The course content was developed in a manner similar to the workshop. Notably, participants could access other forms of MI education during the study period. The content of this course could be accessed through our medical school web-based platform free of charge.

A paper version of brief MI guides as a prompt tool for GPs to help people with diabetes change their behavior was available and placed in the GP consultation room at the primary care unit. These guides were developed based on "A Taste of MI" Exercise from the Motivational Interviewing–Foundational web-based course by William Miller, Stephen Rollnick, and Theresa Moyers (see the English translated version of brief MI guides in Multimedia Appendix 1).

Quantitative Component

Data Collection: GPs and GP Trainees

A before-and-after design was used to compare the knowledge and attitudes of the GPs and GP trainees who completed the MI workshop. The GPs and GP trainees self-selected by voluntarily choosing to enroll in the workshop and the web-based course and participating in the before-and-after study. The questionnaires were developed by the authors (IT and RM) based on the literature [17] and inputs from academic GPs and experts in the field. Each item was assessed thoroughly regarding the intention of the measurement, relevance, ambiguity, understandability, and necessity by 3 independent experts in medical education and academic GPs at our medical school to ensure the face and content validity of the questionnaires. The tests were conducted on the web and divided into 2 phases: pre- and postsurveys. These tests included questions in the form of multiple-choice, yes-no, open-ended, attitudinal, and knowledge questions. The questionnaires were piloted with 30 GPs and were revised accordingly. Cronbach α coefficient of the questionnaire was 0.95.

Data Collection: Patient Outcomes

Data on patients with diabetes were collected twice from the patient data records. First, before the GPs and GP trainees attended the MI workshop. Second, 6 months after the workshop completion. This means that GPs and GP trainees had time to apply MI for their patients for at least 6 months. Patients' biomarker data were obtained from the patients' medical records for the latest values collected for each patient, according to the routine collection of the primary care units. Patient data included blood pressure, body weight, and HbA_{1c} and lipid levels.

Qualitative Component—Data Collection: Interviews With GPs and GP Trainees

Semistructured interviews were also conducted. The GPs and GP trainees who completed the pretest were invited to participate in semistructured interviews. A small sample of 10 GPs and GP trainees was sought for convenience. A total of 5 GPs or GP trainees from each of the following groups were sought: GPs and GP trainees who reported having less confidence in applying MI in their routine consultation and those who reported having confidence in applying MI in their routine consultation. The interviews were conducted in September 2024 via Zoom (Zoom Communications) and were recorded for documentation. Each session lasted approximately 15 minutes. The audio recordings were transferred to a computer for repeated listening and detailed content review. The recordings were transcribed into Microsoft Word documents, and they were confirmed with participants to ensure accuracy and for further analysis.

Quantitative Analysis

IBM SPSS 19 for Windows (version 20.0) was used for statistical analysis, and a pairwise deletion strategy was applied to handle missing data. Paired-sample *t* tests were applied to assess within-group differences between pre- and postintervention measurements, and independent-sample *t* tests were used to compare outcomes between the study and control groups. Baseline characteristics were descriptively compared across study and control groups; however, formal statistical adjustments for potential confounders (eg, baseline differences in patient demographics or clinical characteristics) were not performed. This decision was based on the study's design focus on population-level comparisons and the available sample size, which limited the feasibility of multivariable analyses. Descriptive statistics were used to describe demographic data. The participants' responses on Likert scales to a 10-item questionnaire on their confidence in applying MI for diabetes management were tallied, creating a confidence score range of 10 to 50. A paired-samples *t* test was used to compare the mean differences in the knowledge scores between the two tests.

Qualitative Analysis

Interview transcripts were analyzed using conventional content analysis. An inductive coding approach was applied, whereby initial codes were generated from repeated reading of transcripts. These codes were then grouped into categories, and overarching themes were derived by identifying recurring patterns and relationships among the data. Coding and analysis were conducted manually by a single trained coder (IT). Although intercoder reliability was not assessed, the coding process was reviewed by members of the research team to enhance consistency and credibility. The codes were then organized into themes, identifying the relationships and connections between them.

Integration of Quantitative and Qualitative Data

The quantitative and qualitative findings were synthesized during the interpretation phase to provide a comprehensive

understanding of the intervention's impact. Quantitative data provided objective evidence of improvements in knowledge and patient outcomes, while qualitative insights offered contextual understanding of how GPs applied MI, the challenges encountered, and their suggestions for improvement. This integration supported triangulation of results and enhanced the depth and relevance of the study's conclusions.

Ethical Considerations

This study was approved by the Human Research Ethics Committee of Khon Kaen University (project HE631031). GPs and GP trainees were recruited through the researcher's assistant, who invited volunteers to participate. Before completing the questionnaires, participants were informed that participation was voluntary and that they could drop out of the study at any time. They were informed that their opinions were important for enhancing diabetes practice in primary care and were therefore encouraged to express them. All GPs and GP trainees voluntarily agreed to participate without receiving compensation. The participants' privacy and identity were protected, and confidentiality was assured. Informed consent was obtained from each participant who participated in the semi-structured interviews. The study objectives were explained to the participants and the study was conducted according to the academic ethical code.

For patients, individual consent was not required because all clinical outcome data were extracted from anonymized, routinely collected health records, in accordance with institutional ethical guidelines. No experimental procedures or additional data collection were imposed on patients. After the study concluded, the brief MI materials and web-based MI course were shared and offered to clinicians in the control group as part of standard CPD dissemination. This approach ensured that no participants were denied care and aligns with accepted ethical principles for real-world implementation research.

Results

Participants' Characteristics

The MI workshop was attended by 32 GPs and GP trainees out of a total 35 participants (91%). A total of 2 participants out of 38 had previous training in MI (n=2, 5%). While both GPs and GP trainees participated in the educational interventions (n=32), only 28 GP trainees (87%) completed the pre- and posttests to assess their knowledge, and later 10 GP trainees provided feedback through semistructured interviews, whereas no GPs participated in these assessments (see Table 1).

Table . Participating general practitioners (GPs) and GP trainees' demographic data.

Demographic data (N=38)[a]	Results
Sex, n (%)	
Males	18 (47)
Females	20 (53)
Age (years)	
Mean (SD)	28.5 (7.85)
Median (range)	28 (25-62)
Previous web-based learning, n (%)	
Yes	25 (66)
No	13 (34)
Previous web-based course completion	
Mean (SD)	0.86 (1.15)
Median (range)	1 (0-4)
Previous motivational interviewing course completion, n (%)	
Yes	2 (5)[b]
No	36 (95)
Diabetes patients in the catchment areas, n (%)	
Study areas (N=13,000)	149 (1.14)
Control areas (N=10,897)	167 (1.53)

[a]A total of 35 GPs and GP trainees participated in the study group, while 3 were from the control group.

[b]The general practitioners in the study group.

Data from the web-based learning management system (LMS; (updated on January 21, 2025) showed that there were 35 GPs and GP trainees (100%) enrolled in the structured web-based MI courses, 14/35 (40%) completed the courses, 5/35 (14%) had not yet started the lesson, and 16/35 (46%) had started but had not yet completed. The course had 21 lessons. Participants'

enrollment time in the course was a median of 3 minutes (range 0-416 min), with a mean of 68.54 (SD 108.82). The number of completed lessons by participants was a median of 2 lessons (range 0-21), with a mean of 6.46 (SD 8.79).

Changes in MI Knowledge and Confidence

A paired-sample *t* test was conducted to evaluate the impact of the MI course on learners' knowledge. There was a statistically significant improvement in knowledge test scores from Time 1 (mean 11.46, SD 3.48) to Time 2 (mean 15.04, SD 2.35), t_{28}=7.74; *P*<.001 (2-tailed). The mean increase in knowledge test score was 3.57 (SD 2.44), 95% CI 2.62-4.52. Notably, overlapping pre- and postintervention CIs do not invalidate the finding, as this was a within-subjects comparison. The eta-squared statistic indicated a large effect size (eta-squared=0.85). Table 2 shows participants' confidence levels in applying MI techniques after completing the course. The highest confidence was reported for the focusing process (mean 3.86, SD 0.65) and using affirmations (mean 3.79, SD 0.63). Other skills, such as using open-ended questions, planning, and inviting change talks, scored slightly lower but consistently reflected moderate to high confidence levels, indicating the course's effectiveness in enhancing practical MI skills.

Table . After the course completion, participants' level of confidence in applying motivational interviewing (MI) with patients (n=28).

Participants' level of confidence in applying MI with patients	Mean[a] (SD)
Focusing process	3.86 (0.65)
Using affirmation	3.79 (0.63)
Using open-ended questions	3.71 (0.76)
Planning process	3.71 (0.66)
Inviting change talks	3.68 (0.61)
Using summary	3.68 (0.67)
Using MI with stage of change	3.68 (0.61)
Using reflection	3.61 (0.63)
Responding to change talks	3.61 (0.74)
Recognizing change talks and sustain talks	3.57 (0.63)

[a]Mean was calculated using a 5-point Likert scale ranging from 1 (not at all confident), 2 (somewhat not confident), 3 (neutral), 4 (confident), and 5 (very confident).

Changes in Patient's Outcomes

Table 3 provides biomarker outcomes for patients with diabetes over 6 months after GP trainees completed the MI workshop. In the study group, there were significant improvements, including reductions in HbA_{1c} (mean difference 0.35, 95% CI 0.03-0.66; *P*=.03), body weight (mean difference 1.11, 95% CI 0.27-1.95; *P*=.01), triglyceride (mean difference 14.18, 95% CI 1.69-26.67; *P*=.02), systolic blood pressure (mean difference 5.14, 95% CI 1.06-9.03; *P*=.01) and diastolic blood pressure (mean difference 3.82, 95% CI 1.66-5.99; *P*=.001). Between-group analysis showed that the study group had significantly better outcomes for HbA_{1c} (mean difference −0.50, 95% CI −0.91 to −0.09; *P*=.02) and diastolic blood pressure levels (mean difference −5.96, 95% CI −8.66 to −3.25; *P*<.001) compared to the control group.

Table . The patients' biomarkers before and after 6 months of GPs and GP trainees' enrollment in the motivational interviewing (MI) workshop. The number of cases used in each calculation varies slightly across variables.

Patient outcomes	Study group (n=149)					Control group (n=167)					Between group			
	Pre-MI mean (SD)	Post-MI mean (SD)	Mean difference (SD)	95% CI	*P* value (within group)[a]	Time 1 mean (SD)	Time 2 mean (SD)	Mean difference (SD)	95% CI	*P* value (within group)[a]	Pre-MI		Post-MI	
											Mean difference (95% CI)	*P* value[b]	Mean difference (95% CI)	*P* value[b]
HbA_{1c}	8.07 (1.59)	7.71 (1.53)	0.35 (1.88)	0.03-0.66	.03	8.38 (1.97)	8.23 (2.10)	0.16 (1.74)	−.11 to .42	.25	−0.30 (−0.70 to 0.11)	.11	−0.50 (−0.91 to −0.09)	.02
Body weight	63.55 (12.33)	62.44 (12.89)	1.11 (4.70)	0.27-1.95	.01	59.83 (11.51)	58.41 (11.71)	1.42 (5.08)	0.64-2.20	<.001	3.08 (0.49-5.68)	.02	4.03 (1.16-6.89)	.006

[a]Data were analyzed using paired-samples *t* test.

[b]Data were analyzed using independent-samples *t* test.

[c]LDL: low-density lipoprotein.

[d]HDL: high-density lipoprotein.

Learners' Experiences and Perceived Impact of the Course

Table 4 summarizes the participants' expectations before enrolling in the MI workshop and how these expectations were met after the workshop. Participants reported improvement in skills and knowledge about MI, with mean scores increasing from 3.96 to 4.07 and from 3.93 to 4.14, respectively. In addition, the learning methods, venue, and learning period received positive ratings postcourse, highlighting the course's effectiveness in meeting expectations.

Table . Expectations for learning in this motivational interviewing (MI) course before and how they were met after the participants' enrollment in the MI workshop (n=28).

Participants' expectations before enrolling in MI courses and reported their expectations were met after the course completion	Mean[a] (SD)	
	Before enrollment in the course	After the course completion
Having skills in MI	3.96 (0.69)	4.07 (0.86)
Having knowledge about MI	3.93 (0.60)	4.14 (0.80)
Promptly applying MI techniques with patients	3.64 (0.83)	3.79 (0.79)
After applying MI with patients, the patients can control their diseases	3.93 (0.77)	—[b]
After applying MI with patients, the patients can change their behaviors	3.96 (0.79)	—
Teaching and learning methods for MI	—	3.93 (0.77)
Place or venue for learning	—	3.96 (0.88)
Period of learning	—	3.86 (0.89)

[a]Mean was calculated using a 5-point Likert scale ranging from 1 (strongly disagree), 2 (disagree), 3 (neutral), 4 (agree), and 5 (strongly agree).

[b]Not available.

Insights From Participant Interviews

Table 5 summarizes the interviews with participating GP trainees regarding their experience in implementing MI during their routine consultation. The GP trainees found MI useful for engaging patients with diabetes, especially in brief MI formats. All participants reported that MI techniques were used in patient interactions, particularly in cases of diabetes, hypertension, and dyslipidemia. The engaging and evoking processes were most frequently used, while planning and responding to sustain talk were less commonly applied.

Table . General practitioner (GP) trainees' experiences and challenges in implementing motivational interviewing (MI) in their routine consultation.

General practice trainees' experiences in and perceptions toward the use of MI with patients	Comments
Experience with applying MI in practice. Contexts and types of cases where MI is used.	
• All participants reported using MI techniques in their patient interactions. They primarily applied MI in cases involving noncommunicable diseases, such as diabetes, hypertension, and dyslipidemia. In addition, all participants attempted to use brief MI, particularly in diabetes cases (T1-T5[a] and P1-P5[b]).	• "Most of the cases I applied MI are NCDs" (T3). • "I tried to apply MI with my patients to help them with lifestyle modification, including for NCDs, diabetes, hypertension, dyslipidemia, but just some processes of MI such as empathic listening" (P5). • "I have only experienced using brief MI as a guide for approaching patients, and all the cases were diabetes, so I have not applied the full MI process with my patients" (T5). • "While I was rotating in Internal Medicine, I applied MI with patients to help them lose weight and with the issues of nutrition management. During my rotation at primary care practice, I used brief MI for only diabetes patients" (T1).
Most frequently used MI processes (eg, engaging, focusing, evoking, and planning)	
• For full MI, the majority of participants most frequently used the engaging process, as they were familiar with its fundamental skills, such as open-ended questions, affirmations, reflections, and summaries (T2-T3 and P2-P5). A participant reported primarily using the focusing process (T5), while others frequently applied the evoking process (T1, T4, and P1). • For those using brief MI, all MI processes were experienced; however, they might not have explicitly recognized the distinct processes involved (T1-T5 and P1-P5).	• "Engaging is easy to use. It is like a small talk before starting the consultation. I used open-ended questions quite often as well as reflection" (P3). • "I used only brief MI with all diabetes cases,… engaging with fundamental skills and evoking with important ruler" (P2). • "Evoking with important ruler is easy to use" (T1). • "Engaging since it is like we are getting to know the patient like a small talk before starting consultation, so I'm familiar with OARS and open-ended questions were used the most" (P4).
Least used MI processes and reasons behind it.	
• The evoking process (T3, T5, and P2-P5) and the planning process (T1, T2, and T4) were reported as the least frequently used by participants. The primary reasons included not yet reaching these stages in their patient interactions, uncertainty about how to transition to these processes, or a lack of opportunity to follow-up with patients until the final stage of MI due to rotations in their training programs.	• "I am not yet good at using evoking and also planning since I have not yet took the patient to this process yet and I did not have a chance to follow-up the same patient because of changing rotation" (T3). • "Planning process was used the least since I have not reached this process yet and sometimes was not sure how to go next" (T1). • "I have not reached this process yet and I am not familiar of how to use it" (T2). • "Evoking is the least. I tried to use important ruler to invite change talks however, it seemed like patient did not understand particularly those aged above 60." (T5). • "I tried to all the processes, but each was like little here and there" (P1) • "I'm not yet familiar with evoking. To start evoking, you may need to have good relationship with patients and important ruler is hard to understand" (P4).
Challenges faced when applying specific MI processes	
• All the participants reported that evoking process is the most difficult to use in all aspects of evoking including recognizing, inviting, and responding to change talks (T1-T5 and P1-P5).	• "To deal with sustain talk, how to respond to sustain talk is the most difficult for me" (T1). • "Evoking, particularly inviting patient for change talk, it is difficult to do" (P1). • "In inviting change talks, patient did not understand the question, particularly using important rulers and it felt like it was not flow naturally" (T3). • "Evoking is difficult particularly, recognizing and inviting change talks since I do not have much experience in applying full MI sessions but for brief MI, there is check lists to help how to proceed" (P2). • "Recognizing change talk is the hardest part because it's difficult to identify which statements are actually change talk. In some cases, patients didn't say much, and when they did, their speech was not sequential, making it hard to distinguish between change talk and sustain talk" (P4).
Obstacles encountered during the use of MI in routine consultations	

General practice trainees' experiences in and perceptions toward the use of MI with patients	Comments
• All participants (T1-T5 and P1-P5) agreed that incorporating MI into routine consultations adds extra time to each patient encounter. They noted that if the daily patient load were lower, MI could be applied more comfortably. While brief MI may offer a practical solution, participants acknowledged the need to first master the technique to use it effectively without extending consultation time. • Another challenge is limited experience, which hinders skill development and prevents MI from becoming a natural part of routine practice. In addition, for GP trainees, structured training rotations often limit their ability to follow-up with patients through the full MI process.	• "Time and number of patients seeing in routing consultation per day. If small number of patients like if less than 60 a day, MI can be used but if not, it would increase time for each case and ended up with delay waiting time for the next patient" (P2). • "Elderly patients do not understand the questions may be because doctor could not make the question flow naturally or even do not know how to make it easy to answer. I, myself, not yet good at execute MI" (P2). • "MI takes longer consultation time. It matches with the setting that have a smaller number of patients or have many doctors in the same practice or it needs to separate MI session out of routine consultation, but this would be solved with brief MI" (T4). • "I used brief MI, it helps a lot but since I' m not yet mastered the whole processes of MI, so it is not yet felt naturally in applying it routinely" (P5). • "Because of trainee rotation, I cannot follow the same patient till the final process of MI" (T1). • "I have less experience in using MI but when start using it I feel good and better when dealing with patient's lifestyle modification, so I need to practice more" (T1). • "In the form of brief MI, it helps shorten the time but overall, still adds time to the consultation and my MI skills are not yet ready" (T3). • "MI needs time to explore patients to get to know them and sometimes they did not know how to respond or say, so it takes time" (P3). • "Spending longer time and together with "I'm not yet good at using MI," sometimes I need to stop thinking what is next because this also adds up time" (P4).
Perceived benefits of using MI in routine consultations	
• All participants (T1-T5 and P1-P5) highlighted the advantages of MI, emphasizing its foundation in the patient-centered approach. They noted that MI empowers patients to decide what and how to change, while the doctor provides guidance and support to help them achieve their goals.	• "Patient selects by themselves what they want to change so this will eventually lead to actual change" (T2). • "Concepts and principles of MI are great, unlike the traditional approach of ordering or telling patients to change but MI is to guide and help them change with the direction" (T3). • "We as a doctor understand patient more and respect them for whom they are" (T4). • "There is a direction in MI, making it like a framework that guides us toward the goal. The process consists of steps or pathways that help us navigate patient interactions and continue follow-ups from where we left off in the last visit. Otherwise, we would end up repeating the same advice at each visit, providing a generic package of behavior change recommendations, which would ultimately lead to unsuccessful outcomes." (P2).
Potential drawbacks or limitations of using MI in consultations	
• Participants identified several limitations in implementing MI in routine consultations. The primary challenge was a lack of skill, largely due to limited experience in applying MI in daily practice (P1-P3). While brief MI offers a promising approach, it still requires practice to master and integrate naturally into consultations without extending their duration (T1, T4, and T5). Since participants had not yet fully mastered MI, their consultations often took longer than usual (P1 and P2).	• "Full MI taking long time and may not suit particularly in the setting of outpatients where each doctor needs to see 100 cases a day" (T5) • "If you are not familiar or not good at it, it will take more time in consultation. In some cases, we cannot use this method such as dementia" (P2). • "I'm not yet confident in using the MI process. Those who want to apply MI should have adequate knowledge and skills, become familiar with the process, and integrate it into their routine practice" (P3). • "I could not yet find any limitation or disadvantage" (T3) • "Take longer time in consultation and need to be cautious using some questions which may affect the doctor-patient relationship" (P4).
Areas for further development in MI	

General practice trainees' experiences in and perceptions toward the use of MI with patients	Comments
• Some participants need to improve all knowledge and skills to gain their confidence in using MI (T2-T5, P4, and P5). Some mentioned have sufficient knowledge but need more practice to improve skills and particularly for evoking process (P1-P3).	• "I feel a lack of knowledge and skills in MI. I think I know and can do only 50%. Brief MI works for me — no need for more time in consultation. It is practical, easy to use, and can be applied in real practice" (Participant 5). • "Knowledge and skills in evoking are still limited, and I also have little experience using MI. Sometimes I have to focus too much when using MI, as I need to practice empathic listening, be able to reflect back what the patient is saying, and also summarize parts of the conversation" (P4). • "Since I have not yet become good at using MI and do not use it regularly, only with some diabetes patients using brief MI, I need more practice to build my confidence" (P3). • "My knowledge is ok but I need to improve my skills, particularly for evoking process" (P2). • "I am not yet confident in my overall MI knowledge and skills, so I can not apply them naturally in practice. In the evoking process, for inviting change talk, there are plenty of ways to do it, so I need to go back and practice more of those options" (T5). • "I need to update all MI knowledge and skills" (T4).
Need for additional training or support in MI techniques	
• Majority of the participants need more observations to become experts in using MI in routine practice and, if possible, need coaching (T1, T3-T5, and P2-P5). One mentioned role-play sessions with colleagues will also help to gain more confidence in applying MI in their routine consultation (P1). Additional video clips would also help in self-learning (P1). Others needed to practice brief MI more (T2 and P2).	• "I need to keep practicing using MI in my routine consultations, and share cases that were successful after using MI. I also need observation sessions with experts or supervisors, as well as coaching" (P4). • "I need more observation sessions to see experts using this technique in real practice, followed by coaching to get feedback on whether I'm doing it right" (P3). • "I need more role plays in class so all my colleagues can practice together and learn which parts we do right or wrong, and practice the whole process step by step. Other helpful methods would be coaching or observation in real practice settings. Video clips of different situations applying MI in routine consultations would also be great" (P1). • "I want more observation from expert or coaching" (T3) • "I need to practice brief MI more and use more" (T2) • "I need more examples of how to use MI in a variety of situations—what to say and how to say it, and how to apply MI in each situation. These would help me get a clearer picture of applying MI in real consultations. Brief MI is great and I can use it in my routine, but I need more observation classes to use it naturally rather than relying on checklists or guidelines all the time" (P2).
Impact of MI on practice and likelihood of continued use	

General practice trainees' experiences in and perceptions toward the use of MI with patients	Comments
• Initially, MI has changed their practice, getting to know more for their own patients. All participants mentioned further practice in MI and will continue using it in their routine consultation (T1-T5, P1-P5).	• "I will definitely continue to use MI in my routine practice, particularly brief MI, as it does not take more time than a regular consultation. I will use it as part of my routine work because even when there are many patients, brief MI can still be applied within 5 - 6 minutes as part of usual care" (P2). • "There are many advantages to applying MI in routine consultations, particularly for DM and CKD patients, since these techniques can be used before they become sick, while they are sick, and also in the process of tertiary prevention for disease complications" (T5). • "I will definitely continue practicing until I master MI and will integrate it into my routine practice" (P5). • "The process of MI is very interesting; it helps you have something to talk about with patients and understand them more. I need more practice to become good at it and use it in my routine practice" (T4). • "Empathic listening and important rulers help you get clear answers and lead to change" (T2). • "I will use it more, since if the patient selects the option themselves—what and how to change—it is much better than having someone else tell them what to change" (T1). • "I will definitely continue using MI so the way I help my patient with their lifestyle change is now not the same" (T3).

[a]T: Participants who reported having confidence in applying MI in routine consultations, based on pretest survey data.

[b]P: Participants who reported having less confidence in applying MI in routine consultations.

> *I feel confident using open-ended questions and affirmations because they make patients open up more, and I can understand their situation better.* [P3]
>
> *Even with brief MI, I tried to engage and ask about their goals… patients seem more open, and it helps me decide what to suggest next.* [T2]

However, many participants noted difficulty in applying the evoking and planning processes.

> *I know the steps of MI, but the evoking part—like using importance rulers or asking about change—is really hard to apply when the patient doesn't understand the question.* [T4]
>
> *Planning is hard when we don't see the patient again. During rotations, we only see them once, so it's difficult to finish the full MI cycle.* [P5]

Challenges also included time constraints and unfamiliarity with the MI approach.

> *MI takes longer time in consultation and my skills are not yet good enough, so I need to stop and think before responding.* [P1]

Despite these obstacles, participants valued the patient-centered nature of MI.

> *Using MI makes me feel like I really listen to my patients. They appreciate it more, and some of them even said they feel more motivated to change.* [T1.]
>
> *Brief MI is a practical tool I can use in real life—it gives structure to the conversation without taking too much time.* [P2.]

Discussion

Principal Findings

This study evaluated the implementation of a combined educational intervention on MI for GPs and GP trainees involved in type 2 diabetes care. The findings revealed significant improvements in participants' MI knowledge, confidence, and related patient outcomes. Furthermore, participants reported positive experiences with the training and perceived enhancements in their communication skills and patient care practices.

All GPs and GP trainees in the study group completed the interactive MI workshop, but only GP trainees participated in knowledge pre- and posttests, and the latter half of GP trainees completed the structured web-based courses. The study demonstrated that MI education provided for GPs and GP trainees in interactive workshop formats significantly improved their knowledge, and together with additional self-learning through structured web-based courses and brief MI guides, had a measurable impact on the patient outcomes. In terms of patient outcomes, the MI-trained group showed improvements in key health metrics, such as HbA_{1c} and diastolic blood pressure, compared to the control group, emphasizing the practical benefits of MI training in clinical settings. Semistructured interviews revealed that GP trainees valued MI for its patient-centered approach but faced challenges related to its time demands and their own proficiency in its processes. However, this study was conducted in a single study area; therefore, the results should be interpreted with caution.

This study contributes to the literature on CME and the application of behavioral science in clinical practice. It addresses the gap between theoretical knowledge of MI and its practical application by GPs and trainees in routine care. Through the

design of a structured, multifaceted CME intervention—comprising an interactive workshop, web-based learning, and practical tools—this study illustrates how behavioral science principles can be effectively translated into real-world practice. The findings may also guide the development of future training programs to enhance patient-centered communication among healthcare providers.

Effects of MI Training on GP Trainees' Knowledge and Confidence

GP trainees who underwent MI training demonstrated a significant improvement in their knowledge scores. The educational program successfully met its objective of enhancing knowledge among GP participants, aligning with previous studies that highlight the potential of MI education to improve both knowledge and confidence in delivering behavior-change interventions [17,31].

Knowledge assessments were conducted before and immediately after the workshop, indicating an immediate knowledge gain. This finding is consistent with previous studies on the effectiveness of MI training in primary care, which have demonstrated improvements in both knowledge acquisition and skill application [17,46,47]. Given that knowledge was assessed immediately after the workshop, the observed improvement could be attributed primarily to the interactive workshop component. However, following the workshop, participants also had access to web-based resources and MI guides. The combination of these educational methods aligns with existing evidence demonstrating that multifaceted educational interventions effectively enhance not only knowledge but also clinical practices and patient outcomes [34,35].

The educational content covered MI processes and their practical application through case studies in accordance with the frameworks established by Miller and Rollnick [11]. Notably, all participants who took the knowledge pre- and posttests had no previous MI training, which aligned with their self-reported learning expectations from the pretraining questionnaire. This targeted approach contributed to the successful development and implementation of an effective educational program as it addressed learners' specific needs [44].

Participants' feedback indicated that fundamental MI processes such as engaging, evoking, and planning were effectively taught. However, more advanced skills, particularly responding to change talk, remain challenging, an issue frequently noted in MI training [30,48]. Participants also reported that this was their first exposure to MI, and that the combination of workshop-based learning, structured web-based modules, and brief MI guides was sufficient for acquiring foundational MI knowledge.

In addition to knowledge acquisition, the training significantly enhanced participants' confidence in applying MI techniques, particularly in the practical aspects of brief MI. As shown in Table 3, participants reported the highest confidence in performing the focusing process and using affirmations, both essential elements of patient-centered communication. Other MI skills—including open-ended questioning, planning, and inviting change talks—also received moderate to high confidence ratings. These findings support the effectiveness of the combined educational interventions in building participants' self-efficacy for using MI in clinical practice. The pattern of reported confidence aligns with the stages of skill development, where foundational processes such as engaging and focusing are typically mastered earlier, while more advanced tasks like evoking and planning require further practice and reinforcement. This confidence boost is crucial, as self-efficacy is strongly linked to successful behavioral change counseling and continued use of MI techniques in routine care.

Impact of MI Training on the Patient Outcomes

Patient outcomes in this study were analyzed at the unit level. Patients with diabetes treated by MI-trained GPs and GP trainees demonstrated significant improvements in HbA_{1c} levels, body weight, triglyceride levels, systolic blood pressure, and diastolic blood pressure when comparing pre- and posteducational interventions and MI implementation. However, only HbA_{1c} levels and diastolic blood pressure showed statistically significant differences between the study and control groups after the educational interventions and MI implementation. Notably, although the study was powered to detect a 10% change in key clinical outcomes, the observed changes in most patient biomarkers—including HbA_{1c}, blood pressure, and lipid levels—were smaller than this threshold. While some changes reached statistical significance, the study may have been underpowered to detect modest effects, and tests of significance should be interpreted with caution. These findings suggest that knowledge gained from a single training session, supplemented by self-learning through the provided resources, can be effectively applied in clinical practice, leading to measurable improvements in diabetes patient outcomes.

Although few studies have examined MI delivered by GPs for diabetes patient outcomes, this study aligns with previous research demonstrating MI's mixed but promising efficacy in GP-led diabetes management [17]. Similar to the current findings, previous studies have reported improvements in HbA_{1c} levels between the study and control groups [49,50], and reductions in diastolic blood pressure [49].

This study found improvements in systolic blood pressure within both groups, but no statistically significant difference between them, which is consistent with previous findings [51]. A similar pattern was observed for triglyceride levels [51]. Notably, the study also found a positive effect on body weight in both groups; however, the control group showed a statistically greater reduction than the study group. In contrast, a previous study reported no significant impact on body weight [52]. Despite the variability in effects of MI on patient outcomes, these findings contribute to a growing body of evidence supporting the potential of MI when implemented by GPs in diabetes care.

Semistructured interviews with GP trainees in this study reinforced the quantitative findings, as participants reported that MI facilitated better patient engagement and empowered individuals to make sustainable behavioral changes. Although many GP trainees did not complete all 4 MI processes with patients, the majority implemented brief MI guides during diabetes consultations. Participants most frequently applied the

engaging and evoking processes, which may help explain the observed improvements in HbA_{1c} and diastolic blood pressure—both outcomes known to be influenced by enhanced patient motivation and communication. Even limited MI skills, such as empathic listening and goal-focused dialog, have been perceived as effective in fostering patient engagement, supporting the feasibility of brief MI formats in high-volume primary care settings. However, some clinical metrics, such as triglyceride levels and systolic blood pressure, have shown mixed results, highlighting the need for further research on MI uptake and its long-term impact, particularly regarding the sustained effects of brief interventions. This variability aligns with a systematic review that identified mixed yet promising results in MI interventions, underscoring the importance of more consistent training and implementation to improve outcomes [17].

While the observed improvements in HbA_{1c} and diastolic blood pressure among patients in the MI-trained group are promising, it is important to interpret these findings with caution. HbA_{1c} is a valid and widely used clinical outcome; however, it can be influenced by a variety of factors beyond the educational intervention, such as medication adherence, lifestyle changes, appointment attendance, or changes in health service delivery. Since we did not measure intermediate outcomes such as patient adherence, satisfaction, or visit frequency, the attribution of clinical improvements solely to MI training may be limited. Future studies should incorporate additional process measures to more fully explore the mechanisms by which MI training may impact patient outcomes. We also acknowledge limitations related to the interpretation of lipid profile outcomes. Variability in LDL and total cholesterol levels across groups may reflect unmeasured factors such as baseline statin use, medication adherence, and dietary or genetic differences. These variables were not adjusted for in this analysis. We recommend that future research include medication adherence monitoring and baseline lipid-lowering therapy documentation to better account for such confounders in lipid-related outcomes.

In addition to statistical significance, the improvements observed in certain outcomes appear to be clinically meaningful. Patients managed by MI-trained GPs and GP trainees demonstrated significant reductions in HbA_{1c} and diastolic blood pressure compared to the control group. These changes are important in diabetes management, as even modest reductions in HbA_{1c} and blood pressure have been linked to decreased risk of microvascular and cardiovascular complications. While improvements in other parameters, such as systolic blood pressure and triglycerides, were mixed or nonsignificant between groups, the observed HbA_{1c} and diastolic blood pressure reductions suggest that gains in MI-related knowledge and confidence may have translated into tangible patient benefits. This underscores the potential for brief MI training, when implemented in routine primary care, to yield clinically relevant outcomes.

GP Trainees' Perspectives and Experiencers Implementing MI

MI requires complex skills [53]. Effective MI implementation necessitates comprehensive training programs that integrate didactic presentations, experiential exercises, and role-playing to develop both basic and advanced MI skills. This study used these combined educational methods. In addition, these educational methods encourage practitioners to progress toward becoming trainers themselves [54]. Evidence suggests that practical applications and expert feedback are crucial for developing MI proficiency [46]. Participants in this study expressed a strong need for coaching or observational support from experts who could demonstrate MI in real consultations, aligning with research indicating that mentorship significantly enhances MI skills [55].

The GPs and GP trainees in this study were trained in the full MI process for comprehensive consultations. However, time constraints in Thai primary care settings make full-session MI difficult to implement. This issue has been noted in other health care settings, where time limitations hinder MI adoption [17]. To address this, brief MI guides were introduced, enabling GPs and GP trainees to apply MI techniques to patients with diabetes within typical consultation durations. Previous studies have suggested that brief MI can be an effective alternative in high-volume practices while maintaining its patient-centered benefits [30]. Participants from this study who had foundational MI knowledge from the workshop found brief MI guides particularly useful for integrating MI into clinical practice, aligning with research that highlights the importance of initial training before adopting streamlined approaches [26].

Qualitative data revealed mixed experiences with the implementation of MI. While GP trainees valued MI's structured, patient-centered approach, they faced barriers such as time constraints, difficulty in mastering advanced techniques, and limited follow-up opportunities due to rotational training schedules. The engaging and evoking phases were widely used, but many GP trainees struggled with the planning phase, a challenge documented in previous MI research [17]. Participants also noted that MI's emphasis on empathic listening and reflective questioning extended consultation times, making it difficult to sustain in high-volume clinical settings [30]. Although brief MI guides were designed to fit within standard consultation durations, some GP trainees reported that a lack of confidence in advanced MI techniques and incomplete mastery of MI skills could inadvertently prolong consultations. This aligns with findings from previous studies, which highlight that practitioners in the early MI training phases may take longer to implement MI effectively [47,56].

Despite these challenges, all participants acknowledged the benefits of MI, particularly brief MI, which they found more manageable within their workloads. Most reported using brief MI in nearly all encounters with patients with diabetes, while recognizing the need for continued practice to enhance their confidence and further refine their skills.

Our findings align with previous literature that supports the potential of MI to improve clinical outcomes in patients with type 2 diabetes when delivered by primary care providers

[17,49,50]. Similar to previous studies, we observed a significant reduction in HbA_{1c} and diastolic blood pressure following MI training [17,49], reinforcing the value of even brief MI interventions when embedded in routine consultations. However, as reported in earlier work [17,30,48], our participants also faced challenges in mastering advanced MI processes such as evoking and planning. This underscores the need for structured, staged training that starts with foundational MI concepts and provides opportunities for progressive skill development.

In line with recommendations from systematic reviews on effective MI training [13,53,55], our study supports the implementation of multifaceted educational strategies. These include combining in-person workshops with asynchronous web-based learning, distributing practical tools (eg, brief MI guides), and offering ongoing peer coaching or expert feedback. Such approaches help accommodate varying learning styles and time constraints, particularly in high-volume clinical settings. Based on our findings, we recommend that MI training programs for GPs incorporate brief MI frameworks early in the training, followed by reinforcement through mentorship, peer observation, or reflective practice sessions to sustain skill application over time. Tailoring training to local practice constraints—such as patient volume, consultation duration, and provider rotation—can enhance feasibility and long-term adoption.

Strengths and Weaknesses

This study has several strengths and limitations. The study design combining quantitative and qualitative approaches enriched the understanding of MI's implementation in real-world practice and its impact on GPs and their patients, offering both measurable outcomes and contextual insights. The study's focus on routine practice settings enhances the relevance and applicability of the findings to primary care environments. In addition, the pre- and posttraining assessments provided robust evidence of the effectiveness of training in improving knowledge of GPs.

While this study incorporated a control group to compare patient outcomes, we acknowledge that the nonrandomized design limits the ability to draw strong causal inferences regarding the effectiveness of the MI intervention. The control group consisted of primary care units in another province where GPs did not receive MI training and thus served as a comparator for usual care. Although this allowed for between-group comparisons, differences in context, provider characteristics, or patient demographics may have introduced selection bias or residual confounding. To minimize these biases, control sites were selected based on similarities in service structure, population size, and staffing (ie, family doctors in community-based settings). In addition, the use of population-level data from primary care catchment areas helped reduce provider-specific effects and reflect routine care delivery more accurately. However, unmeasured differences—such as provider motivation, local health system factors, or patient case mix—may have influenced the results. Therefore, findings should be interpreted with caution and viewed as indicative of association rather than definitive evidence of causality. Future studies employing randomized controlled designs or matched comparison groups with standardized training exposures and comparing the observed changes with broader regional trends in diabetes outcomes are recommended to strengthen causal conclusions and improve generalizability.

This study has many limitations. First, the study did not include a control group among GPs or GP trainees for the educational intervention, limiting our ability to attribute changes in learning outcomes solely to the MI training. Comparisons were made only within the intervention group before and after the training. Second, the sample size of GP trainees who completed both pre- and postassessments was modest, which may affect statistical power and limit the robustness of subgroup analyses. Third, the use of self-reported measures for MI confidence and qualitative interviews introduces potential bias, as participants may have overestimated their skills or provided socially desirable responses. Fourth, the relatively short follow-up period of 6 months for assessing clinical outcomes such as HbA_{1c} and blood pressure. While this timeframe allowed us to evaluate initial effects of MI training and implementation, it may be insufficient to capture longer-term behavioral change and sustained clinical benefits. In addition, while the study demonstrated statistically significant improvements in certain diabetes outcomes (eg, HbA_{1c} and diastolic blood pressure), the magnitude of these changes was modest. This may be due in part to the relatively short duration and intensity of the MI training provided. A single 4-hour workshop, even when supplemented by optional web-based modules, may not be sufficient to fully develop and sustain advanced MI competencies. Furthermore, qualitative findings indicated that GPs and trainees faced several implementation barriers, including time constraints, limited patient continuity, and lack of confidence in using more advanced MI processes such as evoking and planning. These challenges likely impacted the consistency and depth of MI delivery. Fifth, despite having a control group of patients with diabetes, the study sample consisted of a homogeneous group of GPs, GP trainees, and patients from a single area, potentially limiting the generalizability of the findings to broader populations. Another limitation is that no formal statistical adjustments were made for potential confounders, such as baseline differences in patient characteristics between the study and control groups. Although descriptive comparisons were conducted, the absence of adjusted analyses means residual confounding cannot be ruled out. Future studies using larger sample sizes and multivariable analytical approaches are warranted to strengthen the robustness of causal inferences. Another limitation is the absence of data on intermediate behavioral indicators—such as patient adherence to lifestyle recommendations, medication compliance, frequency of follow-up visits, or satisfaction with care—which may mediate or moderate the observed effects on HbA_{1c} and blood pressure. Including such measures in future studies would provide a more comprehensive understanding of the impact and mechanisms of MI in real-world primary care settings. Sixth, a further limitation relates to the qualitative analysis process. Thematic derivation was based on conventional content analysis using an inductive coding approach, whereby initial codes were generated from repeated readings of the transcripts and subsequently organized into categories and overarching themes.

However, coding was undertaken by a single trained coder, and intercoder reliability was not formally assessed. Although the coding process followed established qualitative research methods and was reviewed for internal consistency by members of the research team, the absence of formal intercoder reliability testing may have introduced subjectivity in theme interpretation. Finally, GP trainees' inability to follow-up with the same patients owing to rotational schedules reduced the opportunity to apply MI processes comprehensively.

Implications of Findings for Practice

MI may assist in addressing behavioral and relational barriers to diabetes care—such as patient ambivalence, low motivation, or resistance to change—we acknowledge that MI alone cannot resolve the full range of complex challenges associated with chronic disease management. Structural issues, resource constraints, and system-level determinants also contribute significantly to outcomes. Thus, MI should be viewed as a single component of a broader multifaceted strategy aimed at enhancing communication, empowering patients, and supporting behavioral change.

While MI is often perceived as time-consuming, the use of brief MI, as emphasized in our training, can actually help structure consultations more efficiently. Several participants reported that once familiar with brief MI, they were able to guide patient discussions more purposefully, avoid redundant advice-giving, and promote greater patient involvement in setting goals. Over time, this may reduce the burden on clinicians by improving communication flow and minimizing repeated discussions of unresolved issues in future visits. Thus, brief MI may mitigate, rather than exacerbate, the challenges posed by time-limited practice environments. The development of brief MI protocols tailored to high-volume clinical settings could enhance feasibility without compromising effectiveness. MI's emphasis on patient autonomy and behavioral change aligns with modern health care priorities, making it a valuable tool in chronic disease management. To support GPs in integrating MI into their daily practices, it is essential to provide continued education, peer coaching, and expert supervision. Policymakers should consider supporting MI training as part of CPD programs, given its demonstrated benefits in improving patient outcomes.

Further studies should explore the key components of brief MI that can retain the effectiveness of full-process MI while remaining practical in busy clinical environments. In addition, future studies should include longer follow-up periods to assess the sustained impact of MI on both GPs' skills retention and patient outcomes over time. Research should also focus on optimizing MI training approaches by identifying effective educational methods suited to GPs, as well as strategies to increase uptake and sustained implementation of MI in routine practice. The potential of digital tools, such as mobile apps or web-based coaching platforms, to support MI training and delivery warrants further exploration to enhance accessibility and long-term integration into primary care.

Conclusions

This study underscores the transformative potential of MI in primary care, particularly in diabetes management. MI training not only enhanced GP trainees' knowledge, but also translated into tangible improvements in patient health metrics. Brief MI is an alternative if one cannot perform a full session of MI and better suits the busy schedule of GPs. However, challenges such as time demands, skill mastery, and patient continuity must be addressed to maximize its usability. By refining training methods, supporting GPs in their implementation efforts, and exploring innovative applications of MI, health care systems can better harness its benefits to improve patient outcomes and advance the quality of care.

Acknowledgments

We sincerely thank the Production House teams at our school for their invaluable support in developing and producing a structured web-based course on MI and stage of change. This study was supported by the Faculty of Medicine, Khon Kaen University, Thailand, under grant IN63237.

Abstract

Background: Alzheimer disease (AD) presents significant challenges to health care systems worldwide. Early and accurate diagnosis of AD is crucial for effective management and care to enable timely treatment interventions that can preserve cognitive function and improve patient quality of life. However, there are often significant delays in diagnosis. Continuing medical education (CME) has enhanced physician knowledge and confidence in various medical fields, including AD. Notably, web-based CME has been shown to positively influence physician confidence, which can lead to changes in practice and increased adoption of evidence-based treatment selection.

Objective: This study investigated the impact of a targeted, web-based CME intervention on health care providers' confidence, competence, and real-world outcomes in diagnosing early AD.

Methods: The study employed a 2-phase design. Phase I used a pre-post assessment to evaluate immediate changes in knowledge and confidence before and after CME participation. Phase II involved a retrospective, matched case-control study to examine the impact of CME on AD diagnoses in claims data.

Results: A 1-way ANOVA showed a significant effect of CME regarding change in the volume of AD diagnoses (F_{1900}=5.50; P=.02). Compared to controls, CME learners were 1.6 times more likely to diagnose AD, resulting in an estimated net increase of 7939 new diagnoses annually. Post-CME confidence was associated with a greater likelihood of diagnosing AD (odds ratio 1.64; 95% CI 0.92-2.92; P=.09; n=219).

Conclusions: Web-based CME participation is associated with increased real-world AD diagnoses. Findings offer a mechanism to explain the changes in clinical practice seen as a result of the CME intervention, which improves skills and confidence.

KEYWORDS

Alzheimer disease diagnosis; continuing medical education; real-world outcomes; physician confidence; web-based CME; CME; self-efficacy

Introduction

Alzheimer disease (AD) is a progressive neurodegenerative disorder that poses significant challenges to health care systems worldwide. AD affects more than 6.0 million persons in the United States, 7.9 million in Europe, and at least 50 million people worldwide [1,2]. The risk of AD increases with age. By 2050, the number of affected persons 65 years and older is expected to reach 12.7 million in the United States and over 152 million worldwide [1]. As the global population ages, the prevalence of AD has risen dramatically and will continue to rise, bringing new urgency to addressing the widespread lags in diagnosis that impede effective patient management and care.

Early diagnosis is vital for maintaining quality of life, delaying institutionalization, and improving treatment outcomes. Monoclonal antibodies that target plaque work best in the early stages of AD when pathologic changes are still relatively mild [3,4]. Early diagnosis allows for early initiation of treatment, which can help preserve patients' functional abilities and cognitive function, thereby improving quality of life [5]. Early diagnosis can also reduce caregiver burden by helping patients and caregivers access culturally competent care and support services to improve quality of life [6].

Significant delays are common in the diagnosis and management of patients with AD. Physician practice patterns across several countries, including the United States, reveal that while approximately half of patients globally receive an AD diagnosis

within 6 months of initial presentation, a significant number of patients remain undiagnosed for several months after initially presenting to a physician [7-9]. Misdiagnosis of AD in primary care settings is exceptionally high, with as many as two-thirds of patients being misdiagnosed [6]. While primary care physicians (PCPs) are typically first to see patients with mild cognitive impairment (MCI) and early AD [10], physician suspicion accounts for only 20% of AD diagnoses globally, with caregivers often serving as the primary impetus for seeking medical attention [8]. Overall, referral rates for specialist care are also low (14% - 23%) [8].

Recent updates to diagnostic and staging criteria for AD are based on biological indicators versus clinical syndrome [11]. In practice, AD is often diagnosed through the evaluation of cognitive symptoms, which is highly dependent on a clinician's experience and skill [6]. In the absence of a single diagnostic test for AD, physicians rely on physical and neurological examination, mental status tests, imaging, and biomarkers for diagnostic purposes [12]. However, by the time a patient starts showing signs of cognitive impairment, underlying pathologic changes have likely been happening for a decade or longer [13].

Gaps in physician knowledge and insufficient specialized training partly drive challenges in the diagnostic process [12]. Physicians often struggle to distinguish normal aging from dementia, and between various types of dementia [14], and demonstrate limited awareness of early cognitive impairment indicators [8]. Notably, many physicians lack self-efficacy in diagnostic abilities, including their skills to detect signs of MCI and differentiate MCI from AD [12]. Physicians also lack self-efficacy to use and interpret cognitive testing and neuroimaging [5]. While specialists are more likely to use magnetic resonance imaging, PCPs often rely on computed tomography scans, which are less informative [12]. This lack of self-efficacy can lead to delayed diagnoses, hindering timely interventions and optimal patient outcomes.

Continuing medical education (CME), including web-based CME, has shown promise in improving physician knowledge and self-efficacy across various medical domains, including in AD diagnosis [15-17]. However, the relationship between improving knowledge, competence, self-efficacy, and real-world outcomes (RWOs) in AD diagnosis remains understudied [10,16-18]. Improving knowledge does not guarantee its application in practice. Rather, improving self-efficacy is an essential intermediary between knowledge and practice change. Self-efficacy, a motivational construct also known as confidence, empowers physicians to act upon their knowledge and implement learned skills (also known as competence) [19]. However, the relationship is not strictly linear. Improvements in and reinforcement of knowledge and competence can also increase self-efficacy, which in turn influences practice change [20,21]. These relationships suggest that clinicians with a greater sense of self-efficacy following CME activities demonstrate a stronger intention to change their practice, regardless of whether they improved their knowledge [22,23].

This study investigates whether a targeted, web-based CME intervention can improve physicians' self-efficacy, competence, and RWOs in diagnosing early AD. The study addressed the following hypotheses: (1) competency scores for HCPs will increase; (2) the proportion of HCPs who are confident will increase; and (3) the volume of new AD diagnoses will increase for the CME group compared with the matched control group.

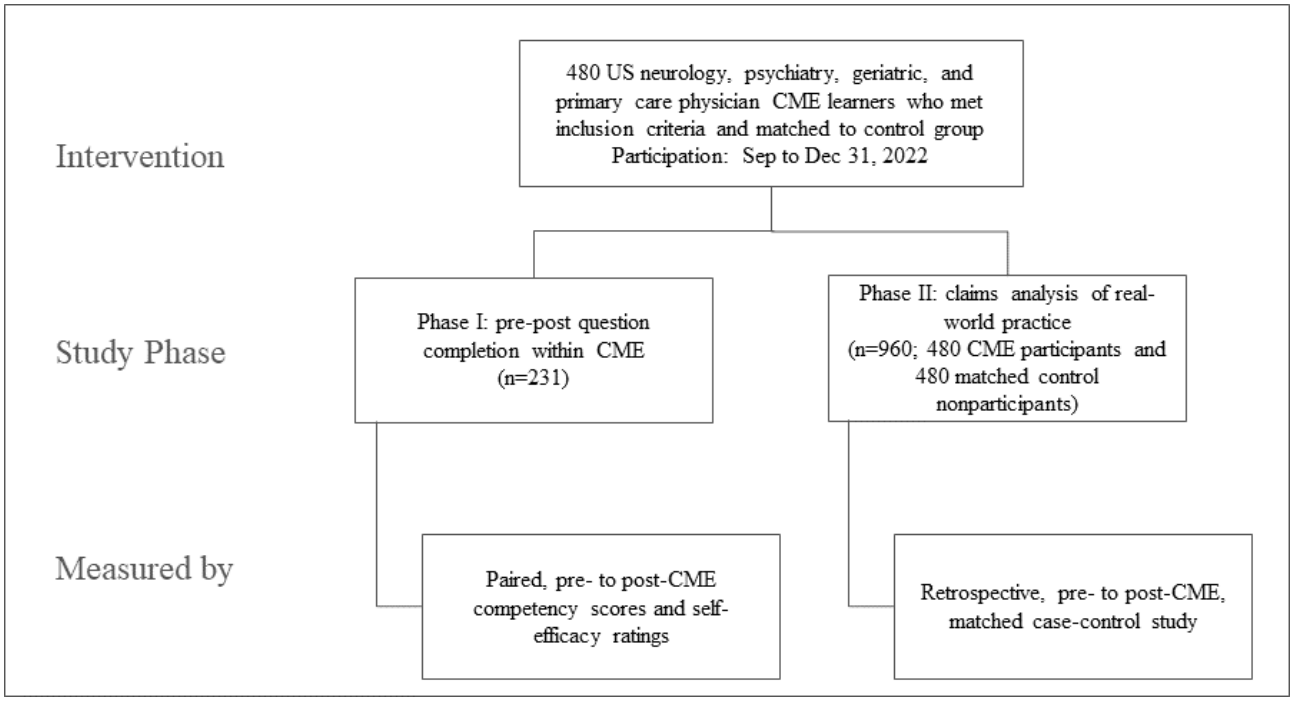
Methods

Study Design

Overview

We conducted 2 study phases using the outcomes assessment framework by Moore et al [24] to assess leading indicators (changes in competency scores and confidence ratings) and lagging indicators of success (changes in real-world performance, specifically the volume of new AD diagnoses). Phase I focused on AD diagnosis within CME activities. Phase II focused on AD diagnosis in the real world (Figure 1).

Figure 1. Study design. CME: continuing medical education.



Phase I: Educational Assessment

We employed a paired, pre-post design to assess the impact of CME activities on knowledge and competency scores and confidence ratings immediately before and after the point of learning in the activity for learners from September 13 to December 31, 2022.

Phase II: Real-World Outcomes

We conducted a retrospective, matched case-control study from March 2022 to June 2023 to evaluate the impact of CME activities on diagnosing patients with AD. The intervention period spanned from September 13 to December 31, 2022, with data collection extending from March 2022 to June 2023, assessing practice 6 months before and 6 months after the CME participation date (“index date”).

CME Intervention

The intervention consisted of a web-based CME initiative for PCPs and neurologists designed to improve competence and confidence in early recognition and diagnosis of AD. The first activity focused on best practices in delivering care for patients with AD in primary care and neurology (released September 13, 2022, through September 13, 2023) [25]. The activity was valid for a maximum of 0.50 American Medical Association Physician Recognition Award (AMA PRA) Category 1 Credit. Topics included triaging and assessing patients with cognitive impairment in primary care, coordinating with neurologists, and treatment goals. A subsequent series of 3 simulated online office visits focused on increasing clinicians’ ability to identify and communicate with patients experiencing early cognitive impairment (released October 14, 2022, through October 14, 2023, valid for a maximum of 0.25 AMA PRA Category 1 Credit) [26]. Each office visit centered around an interactive patient-physician vignette for which a decision on screening and evaluation was required. Vignettes included White and Black patients with cognitive impairment due to MCI, cognitive impairment due to early AD, and cognitive impairment not due to dementia. Participants previewed the chief concern for each patient vignette via a landing page with an interactive, graphic table of contents. The activity required participants to investigate cognitive complaints and select diagnostic tests. Faculty feedback was included in each activity.

Inclusion Criteria

Physicians were included if they participated (that is, viewed the content, after the front matter and disclosures) in at least 1 activity in the study period, practiced in the United States, had at least 1 patient who met the inclusion criteria, and had complete claims data available for the study period. Patients were included if they were at least 60 years of age and saw the learner during the study period as evidenced by at least 1 *International Statistical Classification of Diseases and Related Health Problems, Tenth Revision* (*ICD-10*) code or prescription by the learner.

Sample

Medscape member registration provides the country of residence, profession, specialty, and National Provider Identifier (NPI; if applicable) number for health care providers (HCPs). A total of 1725 US physicians in the target specialties with a valid NPI were learners between September 13 and December 31, 2022. Of these, 1310 had matches with claims data with at least 1 patient who met the inclusion criteria. The RWO intervention group (RWO learners) comprised 480 physicians who met the full inclusion criteria, participated in the CME activities during the intervention period, and were matched to a nonparticipant control (287/480, 60% PCPs; 100/480, 21% neurologists; 71/480, 15% psychiatrists; and 22/480, 5% geriatric specialists). Of the 480, 231 fully completed an activity.

Matching Process

An equal number of 480 HCPs who did not participate in CME served as the control group. We used a 1:1 matching ratio to pair cases with controls. The matching criteria included: (1) number of patients with AD, (2) number of patients diagnosed with AD by the HCP, (3) profession, (4) specialty, and (5) the first 2 digits of the HCP's ZIP code. Match-It in R was used to match the propensity score by the number of patients with AD and the number of patients diagnosed with AD by the HCP. Exact matching was used for profession, specialty, and the first 2 digits of the ZIP code. An independent samples *t* test showed no statistically significant difference in the number of patients with AD seen in the preperiod by the CME and matched control groups (t=−0.24; P=.81).

Real-World Data Collection

We sourced real-world data from Medscape licensed claims data, accessed in November 2023. This dataset provided comprehensive information on patient visits, diagnoses, and procedures performed by the participating HCPs. Data were aggregated at the patient level, and patient counts were aggregated at the HCP level. See Multimedia Appendix 1 for the codes accepted as indicators of diagnosis.

Measures

Three primary outcome measures assessed the effectiveness of the CME intervention: (1) competency score, (2) confidence rating, and (3) number of patients newly diagnosed with AD by the HCP. Additionally, we examined whether there was an association between being confident following CME and real-world diagnoses.

Competency Score

Competency scores were assessed by asking 3 case-based vignette questions pre- and postpoint of learning in the CME activity. Scores were aggregated at either the learning topic or activity level and then to the HCP. Scores ranged from 0% to 100%. Questions were developed to assess learning against learning objectives related to cognitive assessment or differentiation between MCI and AD. Questions were developed by content experts and reviewed by an expert AD HCP, an outcomes assessment specialist, and a copyeditor.

Self-Efficacy Rating

A question assessed self-efficacy on a 5-point Likert-type scale, with higher scores indicating greater self-efficacy (eg, "How confident are you right now in your ability to assess patients for cognitive impairment?"). Learners were deemed "confident" if they rated themselves as a 4 or 5. We used the term "confident" because it is more easily understood by the respondent than self-efficacy and use "confident" in the methodology and results for ease of interpretation when referring to those who select a 4 or 5.

New AD Diagnoses

New AD diagnoses were assessed by examining patient-level *ICD-10* data. Patients with an AD *ICD-10* code by the HCP of interest in the timeframe of interest were identified. Then, the patient's history 2.5 years prior was examined to assess whether they had previously received any AD *ICD-10* codes by any HCP. If there was no history of receiving an AD *ICD-10* code previously, the patient's *ICD-10* code was considered a new AD diagnosis by the HCP of interest. The count of patients who met these criteria was aggregated at the HCP level.

Statistical Analysis

Phase I: Educational Assessment

We assessed immediate changes in learner competency scores and confidence via 4 matched pair questions before and after CME participation. The McNemar test evaluated change in the proportion of learners who rate themselves as confident. The McNemar test was chosen because it measures differences in paired proportions against the null hypothesis. A paired samples *t* test was conducted to measure mean differences in paired samples. Overall competency changes were assessed using paired samples *t* tests. Statistical significance was set at P<.05 for all tests.

Phase II: Real-World Outcomes

The relationship between CME participation and the postintervention volume of new AD diagnoses was assessed with a 1-way ANOVA. One-way ANOVA was chosen because we wanted to examine the change in volume of AD diagnosis from pre– to post–index date (dependent variable) and whether being a learner was associated with this change (independent variable with 2 independent groups). The dependent variable was the change in the volume of AD diagnoses from pre– to post–index date, and the independent variable was CME participation (versus control). In a secondary analysis, we explored the association between postintervention confidence (confident=1, not confident=0) and AD diagnosis (diagnoser=1, nondiagnoser=0) via logistic regression.

The association between being confident and diagnosing AD was explored because the more we know about mechanisms for change that we can immediately measure at scale within a web-based CME activity, the more effective our education can be. A dichotomous independent variable and dichotomous dependent variable were selected because the research question focused on whether confidence predicts being a diagnoser. More confidence should not equate to diagnosing more because how many patients get diagnosed depends on the types of patients an HCP sees. Previous research used this same dichotomy and found similar results [25].

Statistical significance was set at P<.05 for all tests, and analyses were performed using SAS version 9.4 (SAS Institute).

Ethical Considerations

The Sterling Institutional Review Board deemed this study exempt under the terms of the US Department of Health and Human Service's Policy for Protection of Human Research Subjects at 45 CFR §46.104(d) [27]. The ethical standards of the Declaration of Helsinki were applied to all research procedures. As the study was exempt, there was no requirement for informed consent. The institutional review board approval covered secondary analysis without additional consent. The data were deidentified prior to analysis to safeguard participant information. No compensation was provided to participants.

Results

Phase I: Competency and Confidence

"Completers" answered all linked questions within at least 1 of the CME activities, representing 48% (231/480) of the larger learner population. After participation, RWO learners demonstrated a 34 percentage point increase in correct answers for competency in the diagnosis of AD (33% prescore to 67% postscore; *P*=.008) and a 16 percentage point pre- to postactivity increase in the proportion of those who were confident in assessing cognitive function and diagnosing AD (75/231 preactivity to 99/231 postactivity; *P*<.001).

Phase II: New AD Diagnoses

ANOVA showed a significant effect of CME regarding change in the volume of AD diagnoses (F_{1900}=5.50; *P*=.02). The 6-month postactivity increase in new AD diagnoses was 160% greater for the CME group than the control group, as verified by claims data. RWO learners diagnosed 239 more patients after education (487 diagnoses pre-education vs 726 diagnoses posteducation). Control-group learners diagnosed 91 more patients after education (517 diagnoses pre-education vs 608 diagnoses posteducation). Neurologists had the highest increase in new AD diagnoses (1.58 per neurologist), while psychiatrists had the lowest (0.10 per psychiatrist). The logistic regression model showed a trend within the CME group toward a significant positive relationship between being confident in AD assessment post-CME and diagnosing AD in the real world in the 6 months following CME (odds ratio [OR] 1.64, 95% CI 0.92-2.92; *P*=.09; n=219). Table 1 summarizes the RWO learners and the matched control group on key outcomes from claims data.

Table . Number of patients with Alzheimer disease (AD) and number of patients newly diagnosed with AD before and 6 months after the activity.

	Patients with AD, mean (SD)		Patients newly diagnosed with AD, mean (SD)	
	Pre	Post	Pre	Post
CME[a] (n=480)	2.16 (7.51)	2.33 (8.35)	1.01 (3.60)	1.51 (5.59)
Geriatric specialists (n=22)	2.27 (5.23)	2.64 (5.95)	1.41 (2.92)	2.05 (4.36)
Neurologists (n=100)	6.50 (15.03)	7.14 (16.79)	3.04 (7.17)	4.62 (11.29)
PCPs[b] (n=287)	1.12 (2.38)	1.14 (2.43)	0.51 (1.14)	0.71 (1.52)
Psychiatrists (n=71)	0.20 (0.60)	0.27 (0.81)	0.10 (0.38)	0.20 (0.62)
Control (n=480)	2.05 (6.27)	1.92 (6.03)	1.08 (3.33)	1.27 (4.07)
Geriatric specialists (n=22)	1.95 (4.36)	1.86 (2.92)	0.82 (1.62)	1.00 (1.69)
Neurologists (n=100)	5.94 (12.11)	5.50 (11.40)	3.24 (6.40)	3.71 (7.46)
PCPs (n=287)	1.15 (2.56)	1.08 (3.03)	0.57 (1.42)	0.68 (2.31)
Psychiatrists (n=71)	0.24 (0.60)	0.31 (1.04)	0.17 (0.48)	0.27 (1.03)

[a]CME: continuing medical education.

[b]PCP: primary care physician.

Discussion

Principal Findings

This matched case-control study examined the impact of a web-based, vignette-based CME on participants' knowledge, competence, self-efficacy, and RWOs in diagnosing early AD. Participation in CME was associated with a significant (*P*=.02) increase in the diagnosis of early AD. RWO learners were more likely to be diagnosers than control-group physicians, with a magnitude of increase in AD diagnoses that was 1.6 times higher for RWO learners than control-group physicians. The estimated net increase of 7939 in new AD diagnoses in the year following participation for CME learners through the expiration of the activities for credit indicates a substantial positive impact of education on AD diagnosis rates. RWO learners also improved their confidence in identifying early forms of AD (*P*<.001). When HCPs were confident after CME, they had a 1.64 greater odds of diagnosing AD.

Comparison with Prior Work

Research suggests that CME can effectively improve physician knowledge, self-efficacy, and competence regarding dementia care in general. A large study in Australia evaluated an accredited CME program on the diagnosis and management of dementia in primary care. Participants who completed the program reported feeling significantly more confident in their knowledge, skills, and ability to provide care for people with dementia [15,16]. Our study not only affirms the impact of CME on real-world AD diagnoses but also offers a mechanism to explain the changes in real-world practice seen as a result of the CME intervention. Previous research shows that improvements in knowledge and competence following CME participation are associated with increased self-efficacy, and posteducation self-efficacy mediates the relationship between knowledge and competence and intention to change [20,21]. A recent secondary analysis of knowledge, competency, self-efficacy, and clinical practice using pre- and postparticipation data from web-based CME interventions in 3

different therapeutic areas combined with medical claims data examined the relationship between knowledge, competency, self-efficacy, and real-world clinical practice [23]. Knowledge and competency (P=.08; OR 1.515, 95% CI 0.953-2.410) and self-efficacy (P<.001; OR 2.768, 95% CI 1.705-4.492) were significant predictors of clinical practice. However, the effect size for self-efficacy was larger, suggesting that clinicians confident in their abilities were more likely to utilize evidence-based treatments. These results suggest that self-efficacy plays a significant mediating role in influencing clinical practice.

Reinforcement of existing knowledge also appears to influence clinical practice. A study that examined the relationships among knowledge, competence, self-efficacy, and intention to change across 57 online oncology-certified education programs published from 2018 to 2020 found that both improvements in and reinforcement of knowledge and competence are significant predictors of changes in self-efficacy [20]. Lucero et al [28] supported this finding. They found that participants who reinforced their knowledge had higher posteducation confidence ratings than participants who improved their knowledge after controlling for posteducation scores. Reinforcement of knowledge also likely explains why neurologists demonstrated the most significant increase in the number of new AD diagnoses.

Limitations

Potential confounding factors could affect the relationship between CME participation and increased AD diagnoses. Physicians who participated in CME may have been more motivated to improve their practice, potentially leading to increased diagnoses regardless of the CME content. Three activities were case-based simulated patient visits and 1 was a video-based discussion on cases. We did not tease out which activities might have been more or less impactful and whether participation in multiple activities was associated with practice change. Concurrent initiatives, such as other AD awareness campaigns or participation in non–study-related CME activities focused on AD or cognitive disorders during the study period, could also have confounded results. The control group also saw an increase of 91 more diagnoses postintervention, suggesting some external factors may have influenced diagnosis rates. Professional learning occurs in many places, given the demands of clinical practice and the requirement to maintain licensure. While changes for the control group were anticipated, matching based on demographic and practice factors helps reduce biases associated with those factors such as opportunity to diagnose, training, types of patients seen, and environment in which one practices.

Despite these limitations, the comprehensive matching strategy minimizes potential confounding factors and ensures group comparability. By matching profession, specialty, and ZIP code, the study controls for some differences in baseline knowledge, experience, and practice patterns associated with different medical specialties, as well as variations in patient demographics and health care access. Matching based on the number of patients with AD controlled for differences in patient population and exposure to AD cases. Using a time-aligned control group helped to control temporal factors, such as concurrent initiatives, that would affect both groups equally. Results were assessed by counting claims nested in patients to better tease out patients with their first AD diagnosis from a learner versus a nonlearner physician. Using paired pre- and postintervention data for individual learners enhances the statistical precision of the analysis, reducing sampling error and providing a robust assessment of the education's impact. Including the matched control group at follow-up increases confidence that changes are associated with education. Future research should explicitly examine how CME interventions affect AD diagnosis rates across different racial and ethnic groups and identify with more detail the mechanisms for change. We identified self-efficacy as a mechanism for practice change, but we should further understand which components in the CME influenced self-efficacy.

Conclusion and Significance

Diagnostic delays contribute to suboptimal patient outcomes in AD. By using a matched case-control design and assessing both immediate educational outcomes and subsequent changes in diagnostic behavior, this study provides evidence for the potential of CME as a tool to increase AD diagnosis. This web-based CME intervention increased participant likelihood of diagnosing AD, led to a greater number of new AD diagnoses than the control group, and fostered a positive relationship between postintervention confidence and diagnosis rates. Building self-efficacy should be a key objective in education interventions with practice-changing potential, alongside improving, reinforcing, and validating existing knowledge. Overall, this study shows the power of real-world data in demonstrating the impact of CME on clinical behavior and offers a first step in identifying CME's impact on dementia care. We are currently conducting a second phase of this initiative. Future directions could include a breakdown of CME engagement levels and learning outcomes by specialty to clarify which provider groups benefit most from this intervention.

Acknowledgments

We thank Garimesh Kumar for his work on pulling and analyzing data; to continuing medical education content faculty Charles Vega, MD; SB; Frances McFarland, MA, PhD; and Sharon Cohen, MD; and Alexandra Howson, PhD, for written contributions. Abstract

Background: Health care professionals often face challenges in providing affirming and culturally competent care to transgender, nonbinary, and intersex (TNBI) patients due to a lack of understanding and training in TNBI health care. This gap highlights the opportunity for tailored educational resources to enhance health care professionals' interactions with TNBI individuals.

Objective: This study aimed to explore health care professionals' perspectives on education and awareness of health issues related to TNBI individuals. Specifically, it aimed to identify their needs, challenges, and preferences in accessing and using digital educational resources to enhance their knowledge and competence in providing inclusive and effective care for this population.

Methods: A qualitative research approach was used in this study. In total, 15 health care professionals were recruited via convenience sampling to participate in semistructured interviews. Thematic analysis was applied to identify recurring codes and themes.

Results: The study identified several themes and subthemes related to gender diversity awareness, inclusive communication and understanding the needs of TNBI individuals, societal and structural challenges, regulatory gaps in training and support infrastructure, education and training needs for health care professionals on TNBI care, educational resources and training tools for TNBI care, challenges and design considerations for eHealth tools integrations, and evaluating eHealth impact. Participants identified communication barriers, the need for health care providers to use inclusive language, and gaps in both health care system infrastructure and specialized training for gender-affirming care. In addition, participants expressed a need for comprehensive education on transgender and nonbinary health issues, resources for mental health professionals, user-friendly design, and accessibility features in eHealth tools.

Conclusions: The study revealed substantial deficiencies in health care professionals' knowledge of gender diversity, cultural competency, and the importance of inclusive communication. Addressing the identified barriers and challenges through targeted interventions, such as providing training and support for health care professionals, investing in user-friendly design and data security, and promoting cultural competence in TNBI health care, is essential. Despite integration challenges, eHealth tools have the potential to improve patient–health care professional relationships and access to care.

health care professionals; transgender, nonbinary, and intersex; communication challenges; systematic barriers; information and communication technology

Introduction

Background

The term transgender refers to individuals whose gender identity or expression differs from the sex they were assigned at birth [1]. The concept has expanded over time to include a wide range of gender identities, such as transmen, transwomen, nonbinary individuals, and those who are gender nonconforming [2,3]. Nonbinary individuals may not exclusively identify as male or female. Their gender identity can be fluid, agender, or fall outside the binary spectrum [1,4]. The transgender community is highly diverse, and the understanding of transgender identity varies across different cultures [2]. Intersex individuals are those whose physical sex characteristics do not conform to the traditional binary classification of bodies as strictly male or female [4]. Previous epidemiological and clinic-based investigations have suggested that approximately 0.1% to 2% of the population identifies as transgender or with other noncisgender identities [5-7].

The literature reveals that transgender, nonbinary, and intersex (TNBI) individuals experience disproportionate levels of human rights violations and adverse health outcomes, largely attributed to intersecting forms of social marginalization and legal exclusion. Particularly transgender individuals, especially those from minority ethnic groups, are disproportionately impacted by gender-based hate crimes [8]. In addition, TNBI individuals face multiple challenges in accessing adequate health care services [9-12]. The challenges faced by TNBI individuals in accessing health care services are often rooted in systemic barriers that perpetuate stigma, discrimination, and lack of understanding. These systemic barriers contribute to disparities in health care access, quality, and outcomes for these individuals [9-12]. These barriers may include policies that fail to recognize their gender identity and social factors such as discrimination and stigma from health care providers [9-13]. TNBI individuals often face a range of health disparities, largely driven by a lack of awareness regarding their unique health needs. These disparities manifest in higher rates of mental health issues, such as depression and anxiety, as well as increased risks of sexually transmitted infections, including HIV, and other diseases such as cancer, smoking-related conditions, and cardiovascular disease [14,15]. The elevated risk of acquiring sexually transmitted infections among TNBI individuals is influenced by factors such as limited access to comprehensive sexual health education, prevention measures, and adequate preventive care [16]. Furthermore, TNBI individuals often face significant barriers to accessing gender-affirming health care, which can lead to poorer overall health outcomes [13].

In addition to these health care challenges, TNBI individuals frequently experience widespread stigma, discrimination, and prejudice in various facets of life, including employment, education, housing, and health care. This systemic stigma surrounding gender diversity and nonconformity creates a hostile environment for TNBI individuals even within health care systems [6,17-20]. In a sexual health seminar held in Minnesota, a sample of 181 transgender participants revealed that 66% reported experiencing discrimination based on their gender identity or presentation [21]. Consequently, the denial of essential health care services can intensify feelings of dysphoria and distress among transgender individuals. While TNBI individuals face significant challenges in accessing care, health care professionals also encounter numerous obstacles that hinder their ability to provide effective support and services to these individuals.

Challenges Faced by Health Care Professionals

Health care professionals play a crucial role in caring for patients, acting as key facilitators of essential health care services and resources. This highlights the responsibility of health care providers to promote the health and overall welfare of the populations including TNBI [22]. However, health care professionals face challenges in treating and communicating with TNBI individuals, as many of them receive minimal or no training during their medical education and professional development regarding hormone therapy, gender-affirming surgeries, and mental health support—key aspects that are aimed at aligning an individual's physical appearance and gender identity with their affirmed gender during medical education and professional development [10,23].

In addition, health care professionals often encounter challenges when interacting with TNBI individuals, including issues related to cultural competency, communication barriers, and a lack of knowledge about appropriate care practices [24]. These challenges can result in disparities in health care access and quality for TNBI individuals, leading to negative health outcomes and experiences of discrimination [25]. Without adequate training, health care professionals may lack the necessary knowledge and skills to provide competent and affirming care to TNBI patients. This can result in misdiagnosis and inappropriate treatment for patients [26]. Moreover, health care professionals who are unfamiliar with the specific health needs of TNBI individuals may inadvertently overlook important aspects of care and may fail to provide appropriate interventions. Increasing awareness and understanding of TNBI health issues through education, professional development, and exposure to diverse patient populations can help health care professionals better meet the needs of their TNBI patients [27].

In this study, we focused on 4 countries—Sweden, India, the United Kingdom, and the United States—due to their diverse sociocultural context, legal frameworks, and health care systems. This selection provides valuable insights into the varying approaches to TNBI health care and medical education within each country, which allows for a broad examination of how medical education on TNBI individuals can be improved globally. Sweden's progressive health care policies and a strong emphasis on human rights, including TNBI rights, make it an ideal setting to explore advanced practices and identify areas

for improvement. India, with a complex sociocultural landscape and a vast and diverse population, presents unique challenges and opportunities in providing health care to TNBI individuals. Understanding health care professionals' perspectives in India can reveal the specific needs and barriers faced by TNBI individuals in a resource-limited setting. The United Kingdom has recently experienced significant sociopolitical changes affecting health care policies for TNBI individuals. The United States' diverse health care environment regarding TNBI care, with some states enacting progressive policies and others imposing restrictions on gender-affirming treatments, offers insights into the challenges and successes in providing care to TNBI individuals in such varied regulatory settings. By understanding these varied contexts, we aimed to identify gaps in education and awareness as well as potential best practices to address health care professionals' needs, challenges, and preferences in accessing and using educational resources. This insight will help enhance their knowledge and competence in providing inclusive and effective care for TNBI individuals. The medical education systems in each of these countries present unique structures but share a common challenge: a lack of formal education on TNBI health care needs. In Sweden, despite its progressive stance on gender equality, medical curricula still rarely address the specific health care concerns of gender-diverse individuals. India's medical education, influenced by traditional values and diverse cultural perspectives, similarly lacks comprehensive training on gender diversity, despite growing awareness of TNBI rights [28]. The United Kingdom and the United States have made strides in addressing health care inequalities, yet many health care professionals report limited exposure to TNBI health topics during their training [29,30].

The Importance of Educational Tools and the Role of Information and Communication Technology

Lack of necessary training can result in misunderstandings, misgendering, and insensitive or inappropriate interactions that undermine trust and rapport between patients and health care professionals [31]. To address these challenges, it is essential to explore and develop tailored educational resources and interventions that provide health care professionals with the knowledge and skills needed to interact effectively with TNBI individuals [32]. Promoting equitable health care access for all individuals requires innovative solutions that empower health care professionals to provide supportive and inclusive care to TNBI patients [32-36]. Incorporating information and communication technology (ICT) into training and education has proven highly beneficial, as it enhances learning opportunities, improves communication, and increases accessibility to educational resources [37]. While there are other strategies for training and education, ICT offers unique advantages such as personalized learning, interactive content, and the ability to reach a wider audience [38]. These benefits make ICT a more effective approach for improving various aspects of education and training. ICT plays a transforming role in health education by providing innovative and accessible solutions to train health care professionals effectively. It also enhances learning flexibility, promotes collaborative opportunities, and ensures scalability to meet diverse educational needs in health care settings [39].

In health care, ICT can be leveraged through digital tools to support training by providing diverse and interactive educational resources, facilitating remote learning, and enabling real-time access to up-to-date medical information and best practices. The World Health Organization defines eHealth as the "cost-effective and secure use of information and communications technologies in support of health and health-related fields, including health-care services, health surveillance, health literature, and health education, knowledge and research" [40]. In this study, eHealth tools refer specifically to the digital health tools (eg, mobile apps and web-based platforms) used by health care professionals for health education purposes. By fostering inclusive practices, these tools can enhance patient trust, reduce discrimination, and ultimately lead to better health outcomes for these populations. Given the limited research on this topic for health care professionals [41], understanding health care professionals' needs, challenges, and preferences is vital for developing effective, targeted educational resources that promote more inclusive and effective care for TNBI individuals.

Aim of the Study

This study aimed to explore health care professionals' perspectives on education and awareness of health issues related to TNBI individuals. Specifically, it aimed to identify their needs, challenges, and preferences in accessing and using digital educational resources to enhance their knowledge and competence in providing inclusive and effective care for this population.

Methods

Study Design

A qualitative research approach was chosen to investigate health care professionals' perspectives on education, awareness, and preferences for digital educational resources to support TNBI care. This method aligns with the study's aim by comprehensively understanding their experiences, needs, and challenges in accessing and using educational resources. To further enrich this exploration, a sociotechnical framework [42] was applied, as it provides a structured perspective to examine how social, cultural, and technological factors intersect and influence the delivery of inclusive and effective care for TNBI populations. This framework has been applied to examine how health care professionals engage with TNBI individuals and the potential of eHealth educational tools to enhance these interactions. The strengths of qualitative research lie in the ability to gain profound insights into a problem or necessity by directly engaging with individuals and their contexts where the issue arises [43].

Study Setting and Participants

In total, 15 health care professionals with various health care backgrounds were recruited to participate in this study. The data were collected in Stockholm County, Sweden. While most participant interviews were held via Zoom (Zoom Video Communications), 2 were conducted in person at the participants' workplaces. The participants were selected through convenience sampling, primarily via social media platforms.

The inclusion criteria required participants to be health care professionals with experience in using digital tools in their practice, aged ≥18 years, and proficient in written and spoken English. To capture diverse perspectives, we included professionals across 9 disciplines (physiotherapy, dentistry, pediatrics, general practice, general surgery, gynecology, oncology, psychology, and cosmetic surgery), representing a broad spectrum of patient care. Recruiting participants from different disciplines and countries with varying acceptance, health care system diversity, legal recognition, and social and cultural attitudes toward TNBI individuals enabled us to gather varied insights on the challenges that health care professionals face in interacting with TNBI individuals. Each group of health care professionals in this study plays a crucial role in different aspects of health care, from initial assessments and referrals to specialized care, ongoing support, and mental health services. The inclusion of these varied perspectives was essential for capturing the complexity of care required for TNBI individuals. However, the diversity in the respondent pool also presents challenges, as it can make it more difficult to maintain focused discussions and reach consensus. The exclusion criteria were non–English-speaking health care professionals and individuals without any health care background. These criteria ensured that participants had relevant and thorough experiences, insights, and recommendations related to the research topic, thereby preserving the quality and validity of the study's findings.

In qualitative research, the number of participants is typically determined by reaching data saturation, meaning that further data collection does not yield new insights [44]. In this study, participants were interviewed until no new insights were generated from the interviews. The participants' characteristics are presented in Table 1. The participants had a mean age of 40 (SD 7.3) years and worked in various fields within the health care sector. The study included 4 participants from Sweden, 5 participants from India, and 3 participants each from the United States and the United Kingdom. The variation in participant numbers across countries was due to the use of convenience sampling and the differing availability of health care professionals in each discipline and location. Among the 15 participants, 8 (53%) were female, 6 (40%) were male, and 1 (6%) participant did not disclose their sex. In total, 6 (40%) out of 15 participants had no prior experience working with TNBI individuals.

Table 1. Participants' characteristics.

Participant ID	Age range (y)	Geographic location	Occupation	Experience in health care (y)	Experience working with TNBI[a] individuals
Participant 1	35-45	Sweden	Physiotherapist	5-10	No
Participant 2	30-40	Sweden	Dentist	1-5	No
Participant 3	30-40	Sweden	Pediatrician	5-10	No
Participant 4	30-40	Sweden	Dentist	1-5	Yes
Participant 5	30-40	India	General physician	5-10	Yes
Participant 6	40-50	India	General surgeon	10-15	Yes
Participant 7	50-60	India	Gynecologist	15-20	Yes
Participant 8	50-60	India	Oncologist	1-5	Yes
Participant 9	30-40	India	General practitioner	5-10	No
Participant 10	40-50	United Kingdom	General practitioner	5-10	Yes
Participant 11	30-40	United Kingdom	General surgeon	1-5	No
Participant 12	25-35	United Kingdom	Surgical intern	1-5	No
Participant 13	30-40	United States	Psychologist	5-10	Yes
Participant 14	35-45	United States	General practitioner	5-10	Yes
Participant 15	40-50	United States	Cosmetic surgeon	10-15	Yes

[a]TNBI: transgender, nonbinary, and intersex.

The selected professions were included because they are likely to engage TNBI individuals in their practice. This diversity allows us to capture a wide range of insights and experiences, which are crucial for understanding the multifaceted needs of these patients. Although 6 (40%) out of 15 participants had no prior experience working with TNBI individuals, their contributions were insightful and added significant value to the findings. By including a variety of roles, we aimed to identify common themes and differences across different medical specialties, which can inform more inclusive health care practices.

Data Collection

Overview

Data were collected through semistructured interviews. To formulate our interview script, we followed a systematic approach grounded in the sociotechnical framework by Sittig and Singh [42]. This framework ensures that we comprehensively address the intersection of social, cultural, and technical factors and their impact on providing inclusive and effective care for the TNBI population.

Development of the Interview Schedule

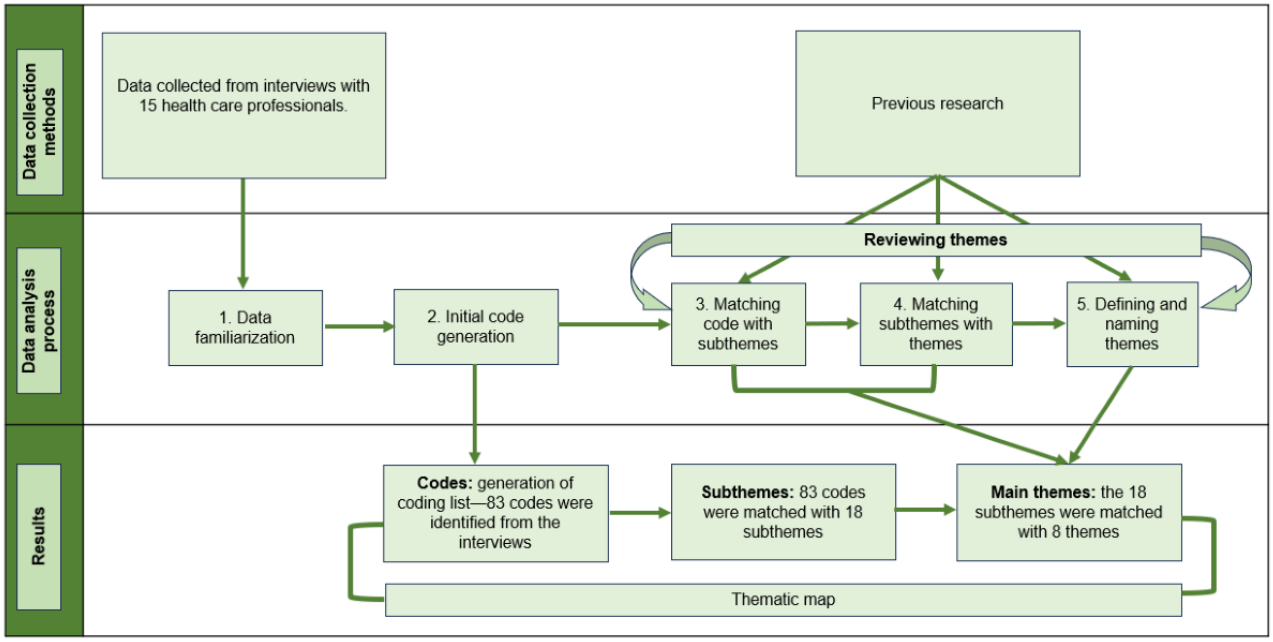
The interview schedule (Multimedia Appendix 1) was developed based on the 8 key dimensions of the sociotechnical framework: hardware and software; clinical content; human-computer interface; people; workflow and communication; internal policies, procedures, and culture; external rules and regulations; and measurement and monitoring [42]. We mapped the objectives of our study to the relevant dimensions of the framework to ensure comprehensive coverage: understanding current interactions and challenges (people and workflow and communication), identifying gaps in resources and training (internal policies, procedures, and culture and clinical content), exploring the potential of eHealth tools (hardware and software and human-computer interface), ensuring usability and integration (human-computer interface and communication), considering regulatory and organizational factors (external rules and regulations and internal policies, procedures, and culture), and evaluating effectiveness and feedback mechanisms (measurement and monitoring). We then continued with developing specific questions. For each dimension, we developed specific questions that align with our research objectives. The final interview script was designed to comprehensively address all aspects of the sociotechnical framework, ensuring the collection of detailed data on health care professionals' perspectives regarding education and awareness of health issues related to TNBI individuals and the potential of digital educational resources to enhance their care delivery. The interview guide was iteratively refined during early interviews to ensure its validity and relevance to the study's aim.

By using semistructured interviews, we could get a deeper understanding of what the participants had experienced during their clinical practice and their thoughts and feelings related to the need for digital educational resources. Semistructured interviews also allowed for follow-up questions to further deepen the understanding of their thoughts. Each interview lasted between 40 and 60 minutes. All the interviews were conducted in English.

Data Analysis

The interviews were audio recorded, transcribed, and analyzed using thematic analysis according to the guidelines by Braun and Clarke [45]. The audio recordings were transcribed verbatim using Microsoft Word and then reviewed for accuracy. The transcribed data were first thoroughly reviewed to gain a comprehensive understanding of the data. The next phase involved coding the text where codes are segments of the text that are linked by content and context, allowing a deeper exploration of the underlying themes and concepts. Descriptive coding was used to capture and summarize the main topics of the text. To build on this, pattern coding was applied to condense meaning units into overarching patterns, grouping the initial codes into broader themes. This approach facilitated the identification and understanding of larger patterns and relationships within the data [46]. SK conducted the initial coding by identifying meaning units, condensing them, and assigning relevant codes. Both authors reviewed the initial codes and grouped them into clusters reflecting emerging subthemes and then examined the relationships between the subthemes. They identified patterns and combined related subthemes into broader themes. The data analysis process was an iterative process in which discrepancies were resolved through several meetings and discussions. The authors analyzed the collected data and continuously revisited and refined the codes, subthemes, and themes as needed to ensure a comprehensive understanding of the data. The data analysis process is presented in Figure 1.

Figure 1. Data analysis process.



Ethical Considerations

This research was conducted in Sweden. According to the Swedish Ethical Review Act, this study does not require ethics approval as it does not handle sensitive personal information (as defined by the European General Data Protection Regulation). However, ethical requirements still apply. Participants were recruited from Sweden, India, the United States, and the United Kingdom. No sensitive personal information (eg, health status, political opinion, or racial or ethnic background) was collected. Prospective study participants were provided with comprehensive information regarding the study's objectives, methodologies, potential risks and benefits, and their right to withdraw at any time. This information was conveyed through both a written consent form, which participants were required to sign, as well as verbal explanations provided by the first author. To maintain confidentiality and privacy, the collected data were anonymized. In addition, any personal or sensitive information shared by participants was excluded from the study. The participants were guaranteed confidentiality and informed about how their data would be handled. Although the study was conducted in Sweden, ethical principles such as confidentiality and respect for participants' autonomy were upheld in line with international research standards, including those applicable in the United States (eg, Common Rule) [47], the United Kingdom (eg, Health Research Authority guidelines) [48], and India (eg, Indian Council of Medical Research guidelines) [49]. These measures ensured the ethical integrity of the research across all participant demographics.

Results

Overview

The analysis of the interviews resulted in 8 themes: gender diversity awareness, inclusive communication and understanding of the needs of TNBI individuals, societal structural challenges, regulatory gaps in training and support infrastructure, education and training needs for health care professionals on TNBI care, educational resources and training tools for TNBI care, challenges and design considerations for eHealth tools integration, and evaluating eHealth impact. In addition to the 8 themes, 18 subthemes and 83 codes were formulated. An overview of the sociotechnical aspects, themes, and subthemes is presented in Table 2.

In this study, the participants predominantly used the term *transgender* as an umbrella term to refer broadly to TNBI individuals.

Table 2. An overview of the subthemes and themes.

Sociotechnical aspects	Subthemes	Themes
People	• Limited understanding of gender diversity	Gender diversity awareness
Workflow and communication	• Acknowledgment of communication barriers and the need for inclusive language • Lack of understanding of TNBI[a] individuals' needs	Inclusive communication and understanding of the needs of TNBI individuals
Internal organizational policies, procedures, and culture	• Suppression of identity due to societal stigma, cultural norms, and societal pressures • Vulnerability arising from societal and political oppression • Limited research on TNBI health issues	Societal and structural challenges
External rules and regulations and pressures	• Lack of awareness among health care professionals and inadequate mental health support • Gaps in specialized training and guidelines for gender-affirming care • Weakness in health care infrastructure for TNBI individuals	Regulatory gaps in training and support infrastructure
Clinical content	• Inadequate training in cultural competency regarding gender diversity • Importance of education on TNBI health issues for health care professionals • Need for tailored resources and training modules designed for mental health professionals	Education and training needs for health care professionals on TNBI care
Hardware and software	• Interactive case studies and peer support forums • Comprehensive training modules workshops and web-based courses • Resources about gender-affirming therapy, trauma, and intersectionality	Educational resources and training tools for TNBI care
Human-computer interface	• Challenges in integrating eHealth tools into regular health care practice, including time constraints and cultural change • Emphasis on user-friendly design, accessibility features, and data security in health care tools	Challenges and design considerations for eHealth tools integration
System measurement and monitoring	• Expectations of improved patient–health care professional relationships using eHealth tools	Evaluating eHealth impact

[a]TNBI: transgender, nonbinary, and intersex.

Sociotechnical Aspect: People (Theme 1: Gender Diversity Awareness, Subtheme: Limited Understanding of Gender Diversity)

A hierarchical structure with the themes at the top, subthemes in the middle, and the corresponding codes at the base is illustrated in Figure 2.

A limited understanding of gender diversity may result in inadequate screening and assessment practices for TNBI patients' health care needs. Health care professionals discussed misunderstanding the unique health risks and concerns facing TNBI individuals, leading to delays in diagnosis, inappropriate treatment recommendations, or suboptimal care outcomes:

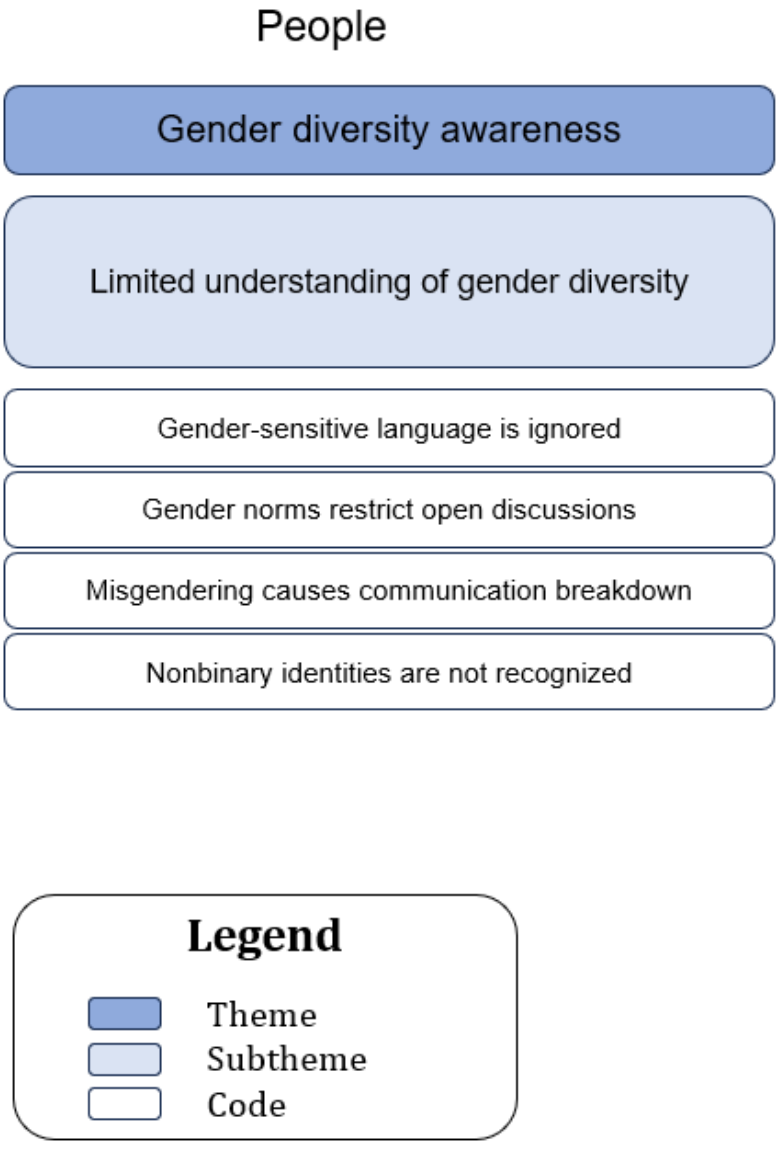
> *When I worked as an intern, we usually strengthened the biological sex or gender, ignoring the psychological stuff, because most of us in our education, are taught to learn the difference between male and female.* [Participant 10]

Some participants expressed that a limited understanding of gender diversity could create institutional barriers to accessing gender-affirming care, further exacerbating disparities in health care access and outcomes for TNBI individuals:

> *From my clinical work, outdated regulations often obstruct the care of transgender patients, a sign of the healthcare system's failure to fully grasp the nuances of gender diversity.* [Participant 11]

> *In my clinical experience, I've observed bureaucratic hurdles, such as outdated policies and procedures that fail to accommodate the unique needs of transgender individuals. These stemmed from a limited understanding of gender diversity.* [Participant 6]

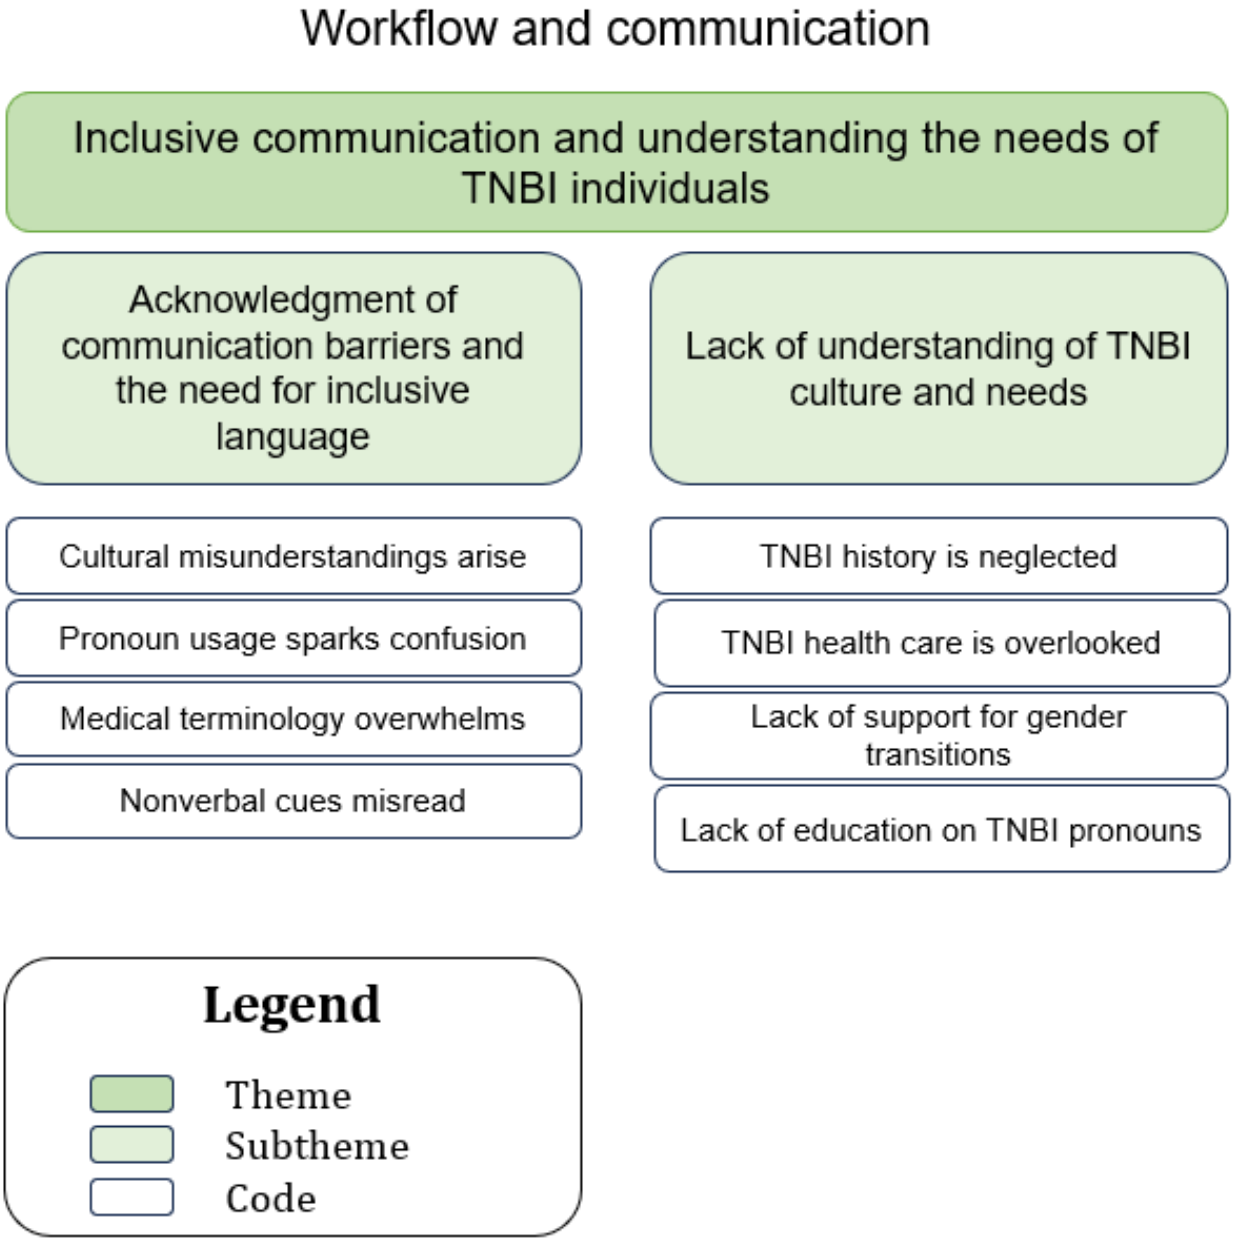
Figure 2. The relationship between the codes and subthemes for theme 1—gender diversity awareness.



Sociotechnical Aspect: Workflow and Communication (Theme 2: Inclusive Communication and Understanding the Needs of TNBI Individuals)

A hierarchical structure with the themes at the top, subthemes in the middle, and the corresponding codes at the base is illustrated in Figure 3.

Figure 3. The relationship between the codes and subthemes for theme 2—inclusive communication and understanding the needs of transgender, nonbinary, and intersex (TNBI) individuals.



Acknowledgment of Communication Barriers and the Need for Inclusive Language

Participants felt an existing lack of awareness about TNBI health issues, including appropriate language and communication strategies. They also stated that without adequate education on TNBI terminology and cultural competency, they may unintentionally use insensitive or outdated language, leading to misunderstandings and discomfort for TNBI patients:

> *I used inappropriate language for communication with transgender patients and they felt bad for that and some of them were even frustrated for not having adequate knowledge of terms that should be used.* [Participant 7]

> *I've unintentionally used terms that were not affirming, which caused discomfort for my transgender patients, and this has shown me the urgent need for proper education on inclusive language.* [Participant 5]

Most of the participants presented fear of inadvertently misgendering them. This fear of causing harm or disrespect can lead to hesitation or avoidance of discussions related to gender identity, which can hinder effective communication and rapport building with TNBI patients:

Sometimes I did avoid discussions regarding gender identity, as I was not sure about it, due to which rapport with the patients was not constructive. [Participant 4]

Some of the participants mentioned that there are limited resources and guidelines available to health care professionals on best practices for communication with TNBI patients. In the absence of clear guidance, they may struggle to navigate conversations about gender identity and may rely on personal assumptions or biases, which can contribute to communication barriers and misunderstandings:

There were moments when my judgment was clouded by my assumptions leading to uncomfortable situations. It is a mistake I have learned from. [Participant 15]

Struggled a lot and also felt embarrassed due to my personal assumptions that led to misunderstandings in a peculiar situation and never did it again. [Participant 6]

Lack of Understanding of TNBI Culture and Needs

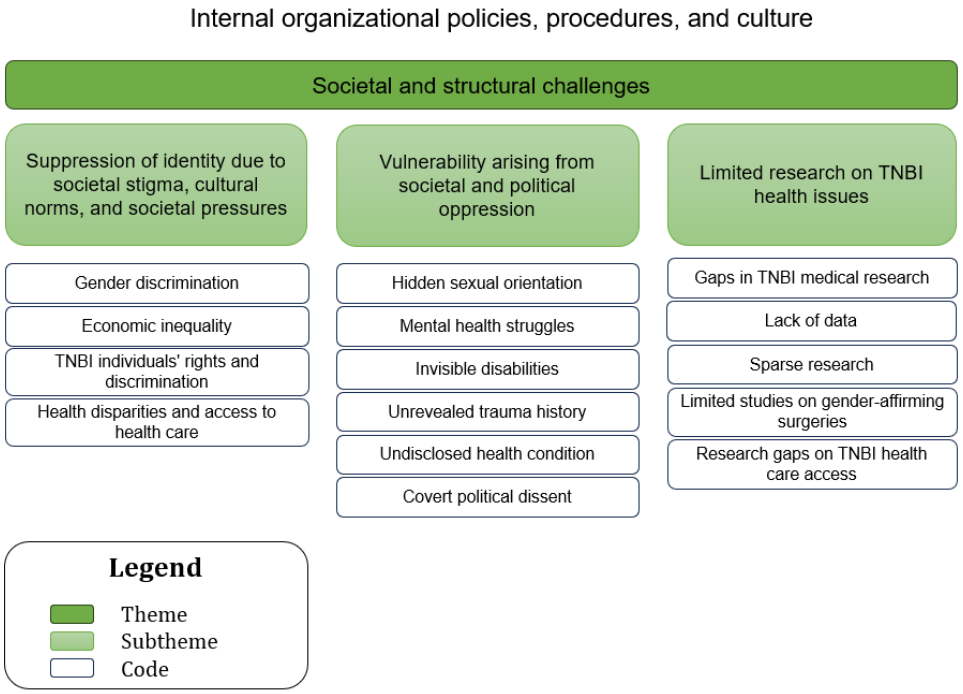
Participants also expressed that they struggled to establish trusting relationships due to a lack of understanding regarding their cultural identities and needs. Therefore, they observed a hindrance in disclosing patient's gender identity, expressing their health care concerns, and seeking support for their health and well-being:

In fact, I have no experience of working with transgender, hence building rapport with these patients is tough for me as I don't have a proper idea regarding their needs. [Participant 2]

Sociotechnical Aspect: Internal Organizational Policies, Procedures, and Culture (Theme 3: Societal and Structural Challenges)

A hierarchical structure with the themes at the top, subthemes in the middle, and the corresponding codes at the base is illustrated in Figure 4.

Figure 4. The relationship between the codes and subthemes for theme 3—societal and structural challenges. TNBI: transgender, nonbinary, and intersex.



Suppression of Identity Due to Societal Stigma, Cultural Norms, and Societal Pressures

Participants highlighted that experiences of discrimination, prejudice, and social rejection increased the vulnerability of TNBI individuals to mental health conditions, such as depression, anxiety, and posttraumatic stress disorder. They also believe that internalizing negative stereotypes and beliefs about their identity can further exacerbate mental health issues, causing feelings of shame, self-doubt, and identity concealment:

During my experiences in clinical practice, I have encountered transgender patients who have expressed fear, shame, and hesitation in disclosing their gender identity to healthcare providers. [Participant 10]

One of the participants said that traumatic experiences such as hate crimes, physical violence, or verbal abuse based on gender identity can lead to symptoms of posttraumatic stress disorder, including intrusive thoughts, hypervigilance, and avoidance behaviors:

They cannot say how they recognize themselves as transgender or non-binary in the workplace or even to their families. It's a kind of a secret for them. So, they are emotionally vulnerable and sensitive at the same time. [Participant 13]

Many transgender individuals feel they must conceal their identities both professionally and personally,

> *which places them under immense emotional strain and leaves them feeling isolated.* [Participant 2]

In addition to that, they also focused on the barriers to accessing health care faced by TNBI individuals because of societal stigma. Participants also revealed that past negative experiences or stories of discrimination within health care settings may lead to mistrust and reluctance to seek medical care.

Another point they mentioned is that the fear of being misgendered, invalidated, or subjected to invasive questioning can create significant barriers to accessing necessary health care services. In addition to that, internalized stigma and shame may also contribute to reluctance to seek health care services, as TNBI individuals may feel unworthy of receiving care or fear being perceived as *different*:

> *The first I think is the culture because trans people and also non-binary people, have their own culture, different than the majority culture and we, health care professionals didn't know that.* [Participant 5]

Some of the participants mentioned that using correct pronouns and respecting chosen names can help mitigate the effects of societal stigma and foster a sense of validation and belonging for TNBI patients:

> *It reminds me of a transgender patient, who did not behave like the gender that person looked like and that causes some confusion. So, it's necessary to ask them first how you recognize yourself and respect their social gender identification.* [Participant 5]

> *Gender identity is personal, and as clinicians, we should always lead with questions, not assumptions to ensure we are providing care that respects who they are.* [Participant 8]

Vulnerability Arising From Societal and Political Oppression

For TNBI individuals, intersectionality exacerbates vulnerability, particularly for those who belong to marginalized racial, ethnic, or socioeconomic groups. This means that TNBI individuals may face compounded discrimination and barriers to health care access due to overlapping forms of oppression:

> *I have seen many cases, who faced added discrimination to healthcare access due to political oppression...I believe that it's crucial to understand how multiple forms of discrimination intersect for transgender people, making access to healthcare even more challenging.* [Participant 6]

> *Political and social discrimination compounds the barriers transgender individuals face in accessing care, highlighting the need to address overlapping layers of bias in healthcare systems.* [Participant 11]

Limited Research on TNBI Health Issues

Participants said that they rely on evidence-based practices to guide their clinical decision-making and provide quality care to patients. The limited research on TNBI health issues means that there may be a lack of robust evidence to inform best practices in the diagnosis, treatment, and management of health conditions:

> *Without sufficient research, we are not only constrained in delivering optimal care, but it is also difficult to fully trust the treatments we prescribe to our patients.* [Participant 9]

> *Lack of research not only hampers our ability to deliver effective care but also undermines our confidence in the treatments and interventions we provide [...] As a result, we often find ourselves relying on anecdotal evidence, expert opinions, and extrapolations from related fields to inform our clinical decisions.* [Participant 4]

They also reported the lack of data on prevalence, risk factors, and outcomes of health conditions within these populations as a hindrance to their ability to assess and address their health care needs accurately. Without this information, it is challenging to determine the scope and magnitude of health disparities and to allocate resources effectively to address them:

> *Without accurate data, it's challenging to develop informed strategies for promoting the health and well-being of transgender and non-binary communities.* [Participant 3]

> *The absence of prevalence data makes it difficult to gauge the extent of health disparities within transgender and non-binary populations.* [Participant 13]

In addition, the lack of data on risk factors means that health care professionals may struggle to identify and mitigate factors that contribute to adverse health outcomes among TNBI individuals. Furthermore, the absence of data on outcomes of health conditions within TNBI populations hampers efforts to evaluate the effectiveness of interventions and treatments. Without data on treatment outcomes, health care professionals may be limited in their ability to tailor interventions to the unique needs of TNBI individuals and to optimize their health outcomes:

> *We struggle to allocate resources effectively and prioritize interventions without a clear understanding of the prevalence and severity of health conditions among transgender and non-binary individuals.* [Participant 5]

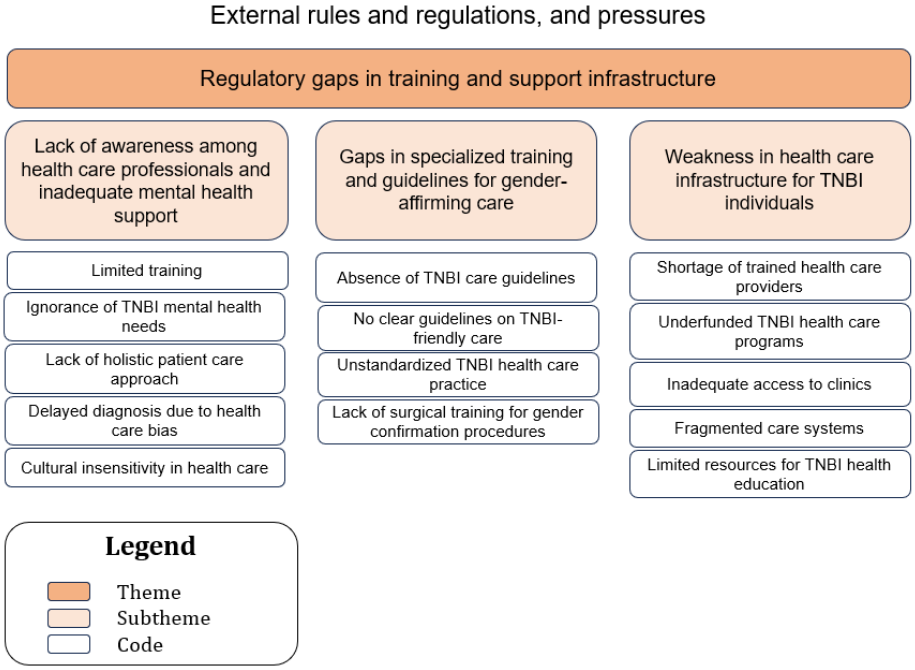
Participants also recognized the importance of investing in research initiatives focused on TNBI health to fill existing knowledge gaps and improve health care delivery:

> *It's necessary that we prioritize funding and resources for research aimed at filling existing knowledge gaps, addressing disparities, and promoting health equity among transgender and non-binary populations in transgender and non-binary healthcare.* [Participant 4]

Sociotechnical Aspect: External Rules and Regulations and Pressures (Theme 4: Regulatory Gaps in Training and Support Infrastructure)

A hierarchical structure with the themes at the top, subthemes in the middle, and the corresponding codes at the base is illustrated in Figure 5.

Figure 5. The relationship between the codes and subthemes for theme 4—regulatory gaps in training and support infrastructure. TNBI: transgender, nonbinary, and intersex.



Lack of Awareness Among Health Care Professionals and Inadequate Mental Health Support

Significant gaps discussed by the participants include a lack of awareness and understanding of TNBI health issues. They also expressed feelings of being frustrated by the systemic gaps in education and training on TNBI health issues within their profession. They were also concerned about the limited availability of culturally competent and affirming mental health services for TNBI patients, recognizing the detrimental impact of untreated mental health conditions on their overall well-being:

> *I feel ill-equipped to address their unique healthcare needs, leading to challenges in providing culturally competent and affirming care.* [Participant 3]

Gaps in Specialized Training and Guidelines for Gender-Affirming Care

The participants' identification of gaps in specialized training and guidelines for gender-affirming care highlights a critical challenge within health care systems. These gaps stem from limited education and training on transgender health issues and gender-affirming care during both formal education and professional training programs. They also expressed concerns about the lack of comprehensive education and training on transgender health topics throughout their academic and professional journeys:

> *I feel the lack of preparation and education on transgender health issues is a systemic issue that requires immediate attention and action from healthcare institutions and educational programs.* [Participant 3]

Many reported minimal exposure to transgender health issues and gender-affirming care protocols during their formal education, which left them feeling ill-prepared to provide culturally competent and affirming care to transgender patients.

In contrast, they expressed that they are encountering inconsistencies in clinical protocols, treatment approaches, and referral criteria for TNBI patients, resulting in variations in care quality and patient experiences due to the lack of standardized guidelines within health care institutions and disciplines.

Even though some of the participants were interested in specializing in transgender health, they said that they were facing challenges in accessing advanced training opportunities to develop expertise in this area, leading to a scarcity of trained specialists within the health care workforce:

> *Even with a strong interest in transgender healthcare, I'm struggling to access the specialized training necessary to develop my skills in this field.* [Participant 12]

> *Despite my interest in specializing in transgender health, I am encountering challenges in accessing advanced training opportunities.* [Participant 13]

Weaknesses in Health Care Infrastructure for TNBI Individuals

The participants also stated that they observed a lack of specialized health care facilities equipped to provide gender-affirming care for TNBI individuals. In addition, they also reported the absence of dedicated clinics or centers specializing in transgender health, which limits access to competent care and contributes to disparities in health outcomes:

> *There's a noticeable absence of dedicated clinics specializing in transgender health within our healthcare system, due to which patients are facing difficulties in receiving the affirming care they need.* [Participant 6]

> *The scarcity of transgender-focused healthcare facilities means many patients struggle to find affirming care, which compromises their overall well-being.* [Participant 4]

They have also mentioned the challenges they were facing in accessing gender-affirming treatments, such as hormone therapy and gender-affirming surgeries, for TNBI individuals, including a shortage of trained health care providers and long waiting times for appointments. Apart from the aforementioned challenges, they also recognized the need for expanded access to mental health support services for TNBI individuals:

> *The limited availability of trained providers is impeding my ability to provide timely and comprehensive gender-affirming care.* [Participant 4]

> *The shortage of providers skilled in transgender care significantly delays access to the affirming treatments many patients require.* [Participant 8]

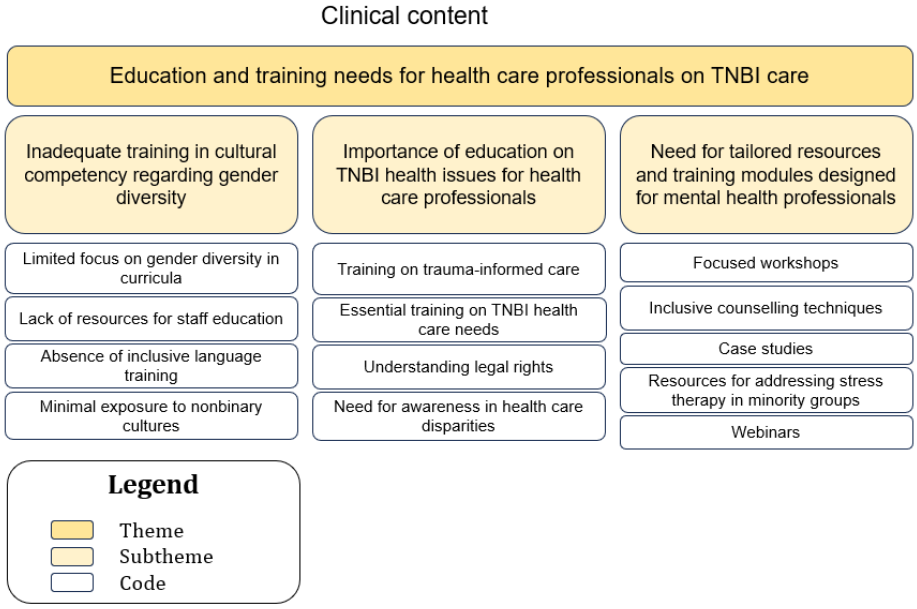
> *For transgender individuals, mental health support is essential for comprehensive care, yet it remains frustratingly inadequate in many healthcare settings.* [Participant 9]

> *Access to mental health support services is crucial for the holistic well-being of transgender individuals, yet it remains limited in many healthcare settings.* [Participant 6]

Sociotechnical Aspect: Clinical Content (Theme 5: Education and Training Needs for Health Care Professionals on TNBI Care)

A hierarchical structure with the themes at the top, subthemes in the middle, and the corresponding codes at the base is illustrated in Figure 6.

Figure 6. The relationship between the codes and subthemes for theme 5—education and training needs for health care professionals on transgender, nonbinary, and intersex (TNBI) care.



Inadequate Training in Cultural Competency Regarding Gender Diversity

Participants reported a lack of comprehensive instructions on gender diversity and cultural competency during their formal education and professional training. Many indicated that TNBI health topics were either inadequately covered or entirely omitted from their curriculum. Without proper education and training in this area, health care professionals find themselves inadequately prepared to navigate the complex landscape of gender identity and expression:

> *Without adequate training in transgender health, many of us enter practice unsure of how to approach the nuanced aspects of gender identity and provide affirming care to all patients.* [Participant 9]

> *The limited coverage of transgender health topics in our curriculum left us feeling ill-equipped to navigate the nuances of gender identity and expression in clinical practice.* [Participant 4]

> *Our training offered minimal focus on transgender health, leaving us underprepared to address the complexities of gender identity in practice.* [Participant 5]

Participants also expressed their struggles to provide patient-centered care that respects and affirms the diverse identities and needs of transgender patients, resulting in disparities in health care access, quality, and satisfaction:

> *I can say that I have experienced difficulties in tailoring care approaches to align with the diverse identities and needs of transgender patients. My*

> *attempts to provide affirming care to transgender patients have revealed gaps in my understanding and implementation of patient-centered principles.* [Participant 6]

Importance of Education on TNBI Health Issues for Health Care Professionals

Participants felt that education on TNBI health fosters the creation of inclusive health care environments where all patients feel respected, affirmed, and understood. Health care professionals who received training on transgender health issues are better equipped to provide culturally competent care, use affirming language, and create safe spaces for transgender patients to access health care without fear of discrimination or mistreatment:

> *I strongly believe education on transgender health is a crucial step towards building a healthcare system that is truly inclusive and affirming of all gender identities.* [Participant 5]

> *I assume by investing in education on transgender health, healthcare institutions can promote inclusivity and reduce disparities in healthcare access and outcomes for transgender individuals.* [Participant 7]

> *Investing in education about transgender health is a critical step toward fostering inclusivity and addressing disparities in care outcomes.* [Participant 9]

They also felt that education regarding TNBI health issues empowers them to recognize and address barriers, including delayed diagnosis and inappropriate treatment, ensuring that TNBI individuals receive timely, appropriate, and affirming health care services that meet their unique needs:

> *By educating ourselves on transgender health issues, we can break down barriers and create more inclusive healthcare environments and we can also work towards reducing disparities in healthcare access and outcomes for transgender individuals.* [Participant 10]

> *Through education on transgender health issues, we can eliminate obstacles to care and strive to reduce healthcare disparities for transgender individuals, ensuring better outcomes for all.* [Participant 12]

Participants were also interested in learning about the specific health care needs of TNBI patients, including hormone therapy, gender-affirming surgeries, preventive care, and mental health support, enabling them to deliver comprehensive and evidence-based care:

> *At least, I am eager to gain insights into the unique healthcare needs of transgender patients, including understanding nuances of hormone therapy and this interest in learning about the healthcare needs of transgender patients reflects our commitment to providing inclusive and affirming care within our practice.* [Participant 4]

Need for Tailored Resources and Training Modules Specifically Designed for Mental Health Professionals

The need for specialized training for mental health professionals to understand the unique mental health challenges faced by TNBI individuals has been observed by some participants, as these individuals are at increased risk of mental health disorders such as depression, anxiety, suicidality, and gender dysphoria due to societal stigma, discrimination, and identity-related stressors.

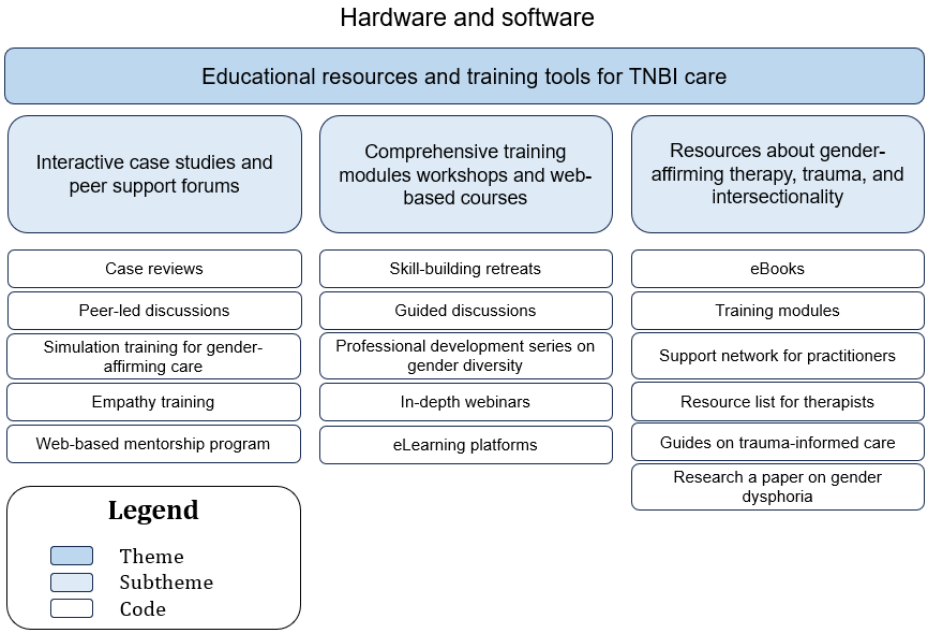
One of the participants, who was a mental health professional, was also expecting training in gender-affirming care principles to provide affirming and culturally competent mental health services to transgender and gender-diverse clients. The participant feels that tailored resources and training modules equip mental health professionals with strategies for creating affirming therapeutic environments and implementing gender-affirming interventions:

> *As per my observation, through education and training, mental health professionals can gain the knowledge and skills needed to provide competent and compassionate care to transgender and gender-diverse clients.* [Participant 13]

Sociotechnical Aspect: Hardware and Software (Theme 6: Educational Resources and Training Tools for TNBI Care)

A hierarchical structure with the themes at the top, subthemes in the middle, and the corresponding codes at the base is illustrated in Figure 7.

Figure 7. The relationship between the codes and subthemes for theme 6—educational resources and training tools for transgender, nonbinary, and intersex (TNBI) care.



Interactive Case Studies and Peer Support Forums

The participants generally perceived interactive case studies and peer support forums as valuable educational resources that promote active learning, cultural competency, professional networking, and skill development in transgender health.

Some of them felt that interactive case studies allow them to engage actively in the learning process by analyzing real-life scenarios, making decisions, and receiving immediate feedback:

> *My personal preference is to have interactive case studies, as they enable active participation and engagement in the learning process.* [Participant 7]

Others were interested in peer support forums that provide opportunities to learn from each other's experiences, perspectives, and insights, fostering a collaborative learning environment. They strongly believed that peer support forums facilitate knowledge sharing, discussion of clinical challenges, and exchange of best practices among peers, leading to enhanced learning outcomes and professional development.

They also felt that they could access these resources at their convenience to refresh their knowledge, stay updated on emerging practices, and enhance their clinical competencies in transgender health:

> *I agree that these resources encourage reflection, critical thinking, and dialogue among health care professionals, promoting continuous improvement in transgender healthcare delivery.* [Participant 3]

Comprehensive Training Modules, Workshops, and Web-Based Courses Focusing on Gender Diversity

To have an in-depth understanding of gender diversity, including the spectrum of gender identities and expressions, health care professionals were in favor of comprehensive training modules, workshops, and web-based courses.

They expect the training modules, workshops, and web-based courses to facilitate interdisciplinary collaboration among themselves from different specialties and disciplines, leading them to work collaboratively as part of multidisciplinary care teams to address the complex health care needs of transgender and gender-diverse patients, promoting coordinated and holistic care approaches:

> *The opportunity to exchange knowledge and best practices among health care professionals is vital for advancing our shared understanding of transgender health issues.* [Participant 11]

Some participants felt that training modules, workshops, and web-based courses focusing on gender diversity contribute to advancing health equity and social justice for transgender and nonbinary gender-diverse individuals. On the contrary, one of the participants expressed concern regarding time management:

> *In my opinion, it's essential to tackle issues regarding time management and resource allocation to ensure health care professionals can actively participate in gender diversity training and play their part in promoting health equity and social justice.* [Participant 2]

Resources About Gender-Affirming Therapy, Trauma, and Intersectionality

Health care professionals are expected to have resources that cover principles and practices of gender-affirming care, including approaches to hormone therapy, gender-affirming surgeries, and psychotherapy, enabling them to support transgender patients in aligning their bodies with their gender identities:

> *I expect to have access to resources on gender-affirming care will equip us with the knowledge and skills needed to navigate complex healthcare decisions and provide holistic support to*

> *transgender patients throughout their transition journey.* [Participant 3]

In addition, they were willing to have and learn about trauma-sensitive approaches to care delivery, recognizing the impact of past traumas on patients' mental health and well-being and creating safe and supportive environments for survivors of trauma to access health care services:

> *I am open to learning and implementing trauma-sensitive approaches into our practice, as I believe they are essential for providing patient-centered and holistic care to individuals affected by trauma.* [Participant 13]

> *As health care professionals, we recognize the importance of ongoing education and training in trauma-sensitive care to ensure that we can effectively meet the needs of patients who have experienced trauma.* [Participant 10]

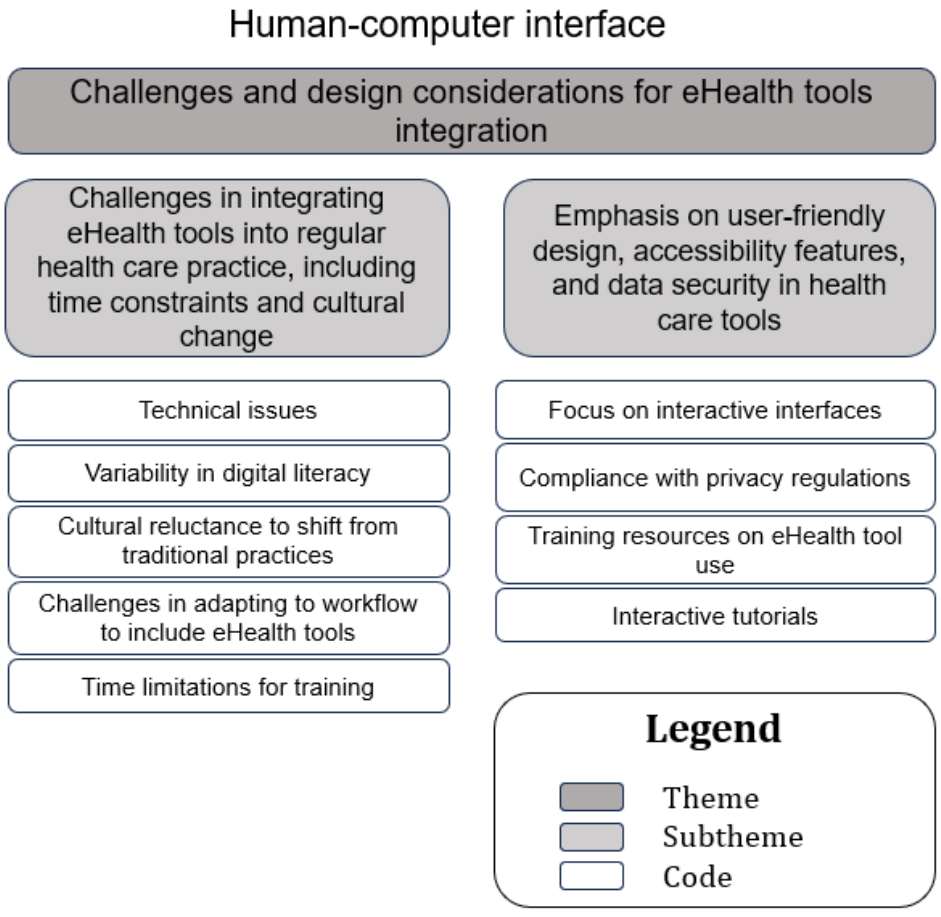
Health care professionals were interested in gaining an understanding of how multiple intersecting identities influence individuals' experiences of discrimination, access to health care, and health outcomes, enabling them to provide more nuanced and inclusive care to diverse transgender communities:

> *My priority is having education about intersectionality to work towards creating more equitable and inclusive healthcare systems that address the complex needs of all patients.* [Participant 13]

Sociotechnical Aspect: Human-Computer Interface (Theme 7: Challenges and Design Considerations for eHealth Tools Integration)

A hierarchical structure with the themes at the top, subthemes in the middle, and the corresponding codes at the base is illustrated in Figure 8.

Figure 8. The relationship between the codes and subthemes for theme 7—challenges and design considerations for eHealth tools integration.



Challenges in Integrating eHealth Tools Into Regular Health Care Practice, Including Time Constraints and Cultural Change

Several challenges were recognized in integrating eHealth tools into regular health care practice, including time constraints and cultural change. Participants said that they often face time constraints due to busy schedules, heavy workloads, and competing priorities in clinical practice.

They recognized that integrating eHealth tools could require additional time for training, learning new technologies, documentation, and troubleshooting technical issues. This demand may strain already limited time resources and disrupt workflow efficiency. Participants acknowledged that integrating eHealth tools requires a cultural shift in attitudes, behaviors, and practices within health care organizations and among health care professionals:

> *With our heavy workloads, it can be challenging to dedicate time to training and troubleshooting the technical issues that arise with eHealth tools.* [Participant 14]

> *Require additional time for documentation and adapting to new workflows, which can strain our already limited time resources.* [Participant 7]

They recognized that resistance to change, skepticism about technology, and concerns about the impact on traditional care delivery models may impede the adoption and acceptance of eHealth tools, necessitating cultural change initiatives, leadership support, and stakeholder engagement to foster a culture of innovation and digital transformation:

> *In the place I work, to overcome resistance to change, proactive efforts are required to educate, train, and support healthcare staff in adopting new technologies and workflows.* [Participant 7]

One participant anticipated that integrating eHealth tools into regular health care practice may disrupt existing workflows and processes, leading to initial challenges in adaptation and implementation. They expressed concerns about potential workflow inefficiencies, disruptions in patient flow, and coordination issues among health care team members, particularly during the transition phase, when adapting to new technologies and integrating them into clinical routines:

> *It would be difficult for most of us during the transition phase, as there may be a need for additional training, support, and resources to help us navigate the changes and overcome implementation barriers.* [Participant 13]

Participants expressed that they even encounter technical and logistical barriers, such as inadequate infrastructure, limited access to technology, interoperability challenges, and data security concerns, which hinder the seamless integration of eHealth tools into regular health care practice. They recognized the need for investment in IT infrastructure, resources for training and support, and adherence to regulatory requirements and standards to address these barriers effectively and ensure the successful implementation and use of eHealth tools:

> *Inadequate infrastructure and limited access to technology might hinder the seamless integration of eHealth tools into our practice.* [Participant 3]

They recognized that patients may have varying levels of comfort, literacy, and access to technology, which can influence their willingness and ability to engage with eHealth tools. Health care professionals emphasized the need for patient education, support, and empowerment to promote successful integration and use of eHealth tools in regular health care practice:

> *As health care professionals, we play a critical role in facilitating patient engagement and empowerment in the use of eHealth tools by providing guidance, encouragement, and ongoing support.* [Participant 15]

Emphasis on User-Friendly Design, Accessibility Features, and Data Security in eHealth Tools

Health care professionals prioritized user-friendly design in eHealth tools to ensure ease of use, intuitive navigation, and efficient workflow integration. They recognize that user-friendly interfaces enhance usability, minimize user errors, and promote acceptance and adoption among health care professionals, ultimately improving efficiency and productivity in clinical practice.

Health care professionals prioritized data security and privacy in eHealth tools to protect sensitive patient information, maintain confidentiality, and comply with regulatory requirements:

> *I prefer the user-friendly design of eHealth tools to ensure that we can easily navigate and utilize these technologies in our daily practice.* [Participant 4]

Health care professionals recognized that user-friendly design and accessibility features in eHealth tools contribute to patient engagement and empowerment. They believed that tools that are easy to use, accessible across devices, and customizable to individual preferences encourage active participation, self-management, and shared decision-making among patients, leading to improved health outcomes and patient satisfaction. Health care professionals' confidence and satisfaction with eHealth tools are influenced by the design, usability, and security features of these tools.

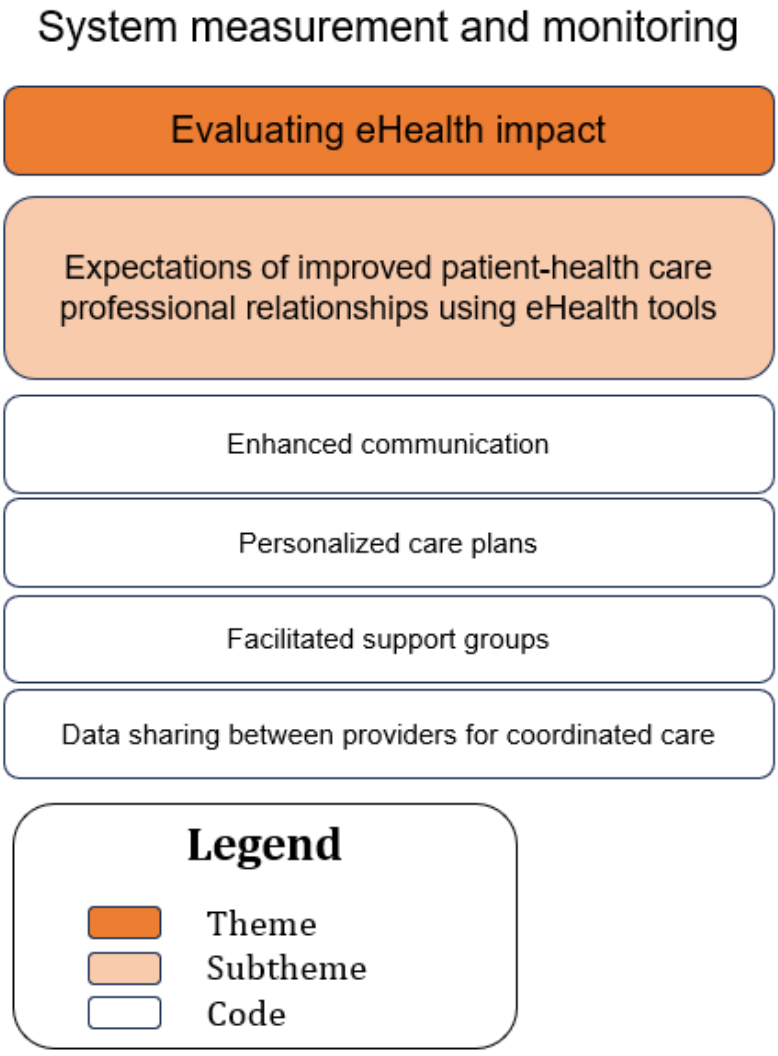
They expressed a preference for tools that are intuitive, reliable, and secure, enabling them to focus on patient care rather than technical frustrations or concerns about data integrity, thereby enhancing their overall professional experience and job satisfaction:

> *I believe that patient-centric design principles, such as intuitive interfaces and clear navigation, are essential for promoting patient autonomy and engagement in their healthcare.* [Participant 2]

Sociotechnical Aspect: System Measurement and Monitoring (Theme 8: Evaluating eHealth Impact, Subtheme: Expectations of Improved Patient–Health Care Professional Relationships Using eHealth Tools)

A hierarchical structure with the themes at the top, subthemes in the middle, and the corresponding codes at the base is illustrated in Figure 9.

Figure 9. The relationship between the codes and subthemes for theme 8—evaluating eHealth impact.



Health care professionals anticipated that eHealth tools would enhance communication, enabling more frequent and accessible contact with patients. This, in turn, could strengthen the patient–health care professional relationship by fostering trust, engagement, and continuity of care:

> *I still work in a healthcare setting, where there is no eHealth tools included in the regular practice. Through the integration of eHealth tools into our practice, we aim to create a healthcare environment that values transparency, accessibility, and patient engagement.* [Participant 7]

Discussion

Principal Findings and Comparison With Prior Work

Overview

The overall theme of this study is enhancing health care professionals' education and awareness of inclusive TNBI care. The analysis of health care professionals' interviews revealed significant insights into the challenges they face in providing care to TNBI individuals and the gaps in health care systems regarding these individuals' health. The analysis also highlighted the pivotal role of eHealth educational tools in addressing various challenges faced by health care professionals in providing inclusive and affirming care to transgender and gender-diverse individuals. Through its features and functionalities, an educational tool aims to bridge gaps in knowledge, communication, and access to resources, ultimately enhancing health care delivery and patient outcomes. In total, 8 themes were identified, highlighting the multifaceted nature of TNBI health care and the complex interplay among societal, cultural, regulations, institutional, technical, and individual factors.

Societal stigma and structural challenges emerged as a pervasive issue affecting the health and well-being of TNBI individuals. Participants highlighted the detrimental effects of discrimination, prejudice, and social rejection on mental health, emphasizing the need for culturally competent and affirming care to mitigate these challenges. In countries such as the United Kingdom and the United States, social acceptance and legal protections for TNBI individuals have progressed significantly, with antidiscrimination laws and health care rights actively supporting gender diversity. However, unlike in India, where acceptance remains complex due to strong cultural and religious norms, participants from these Western countries still reported that many patients experience fear, shame, and hesitation when disclosing their gender identity—whether to health care

professionals, in the workplace, or even within their families. The fear of being misgendered or invalidated, coupled with past traumas and societal pressures, creates significant barriers to accessing health care services, underscoring the importance of creating safe and supportive environments within health care settings.

Regarding external rules and regulatory gaps, although the United Kingdom and the United States are generally more open in terms of social and cultural norms, the recent sociopolitical shift in both countries has negatively affected TNBI care. For example, the United Kingdom has recently removed gender-affirming care with puberty blockers for those aged <18 years [50]. In the United States, >20 states have aimed to limit or ban access to gender-affirming care, especially for minors. These measures also included restrictions on access to mental health support and educational resources for TNBI individuals. Such policies reflect a growing sociopolitical climate that not only affects the patients directly but also impacts the engagement of health care professionals in providing gender-affirming care. These changes can lead to decreased accessibility to necessary treatments and negatively affect health outcomes for TNBI individuals [51].

Gender diversity awareness, inclusive communication, and understanding the needs of TNBI individuals have revealed a lack of awareness and understanding of TNBI health issues among health care professionals. Communication barriers, limited education on transgender and nonbinary terminology, and inadequate training in cultural competency contribute to misunderstandings and discomfort for these individuals. In addition, the limited understanding of gender diversity and institutional barriers further hinder effective care delivery, highlighting the need for comprehensive education and training on transgender and nonbinary health topics. Participants in this study noted that despite social acceptance, a lack of clear guidance and limited resources leaves them struggling with issues around gender identity. They expressed a fear of misgendering individuals and often avoided discussions on gender identity. Participants mentioned that their training has emphasized focusing on biological sex in treatment, often overlooking the psychological aspects of gender identity.

Various systemic issues, including the lack of awareness among health care professionals, limited mental health support, and gaps in research and specialized training for gender-affirming care, were identified as substantial barriers to providing comprehensive care for TNBI individuals. All participants emphasized the need for increased awareness, research, and resources to address these gaps and promote health equity and social justice for TNBI individuals.

Education and training needs for health care professionals on TNBI care highlighted the importance of comprehensive education on gender diversity and transgender and nonbinary health issues for health care professionals. Participants from all 4 countries expressed a desire for tailored resources and training modules specifically designed to enhance cultural competency and provide gender-affirming care. Moreover, the lack of specialized training and guidelines for gender-affirming care underscores the need for systemic changes within health care institutions to support the professional development of health care professionals in this area.

Educational resources and training tools for TNBI care identified interactive case studies, peer support forums, and comprehensive training modules as valuable tools for promoting active learning and skill development in transgender and nonbinary health. These resources facilitate knowledge sharing, collaboration, and reflection among health care professionals, ultimately enhancing the quality of care for these individuals.

Challenges and design considerations for eHealth tools integration and evaluating eHealth impact presented both opportunities and challenges in health care delivery. While eHealth tools have the potential to streamline communication and improve patient–health care professional relationships, participants identified various barriers, including time constraints, cultural change, and technical issues. Overcoming these barriers requires proactive efforts to address resistance to change, invest in IT infrastructure, and prioritize user-friendly design and data security.

Subanalysis of Participants With Experience in Providing Health Care to TNBI Individuals and Those Without Such Experience

Most of the participants without experience in working with TNBI individuals felt ill-equipped to address their unique health care needs. They struggled to build trusting relationships due to a limited understanding of cultural identities and health care requirements, citing that their education focused solely on binary male and female individuals' perspectives. Participants from Sweden noted that, despite living in an open society, gaps in transgender and nonbinary-specific training persist.

Both groups emphasized that delivering trustworthy care requires sufficient research and evidence-based practice to guide clinical decisions. There was no perceived difference in mental health support for TNBI individuals across Sweden, India, the United States, and the United Kingdom. All participants—regardless of prior experience—reported a lack of comprehensive training and instructions on TNBI health, with a shared belief that education is crucial for fostering an inclusive and affirming health care system. Participants across countries agreed that exchanging knowledge, ongoing training, and access to gender-affirming resources are essential for equipping health care professionals. While many were optimistic about eHealth tools improving communication with patients and continued education, they noted challenges such as additional training requirements, adapting to new workflows, and the importance of user-friendly designs.

The findings of this study align with and extend upon existing research in the field of health care education, particularly regarding the communication needs of health care professionals when interacting with TNBI individuals.

Hughto et al [33] highlighted the importance of addressing societal stigma and vulnerability in health care settings, particularly for TNBI individuals. Similarly, our research underscores the detrimental effects of societal stigma and cultural norms on TNBI mental health and well-being, as well

as the barriers to accessing health care services due to fear of discrimination and misgendering.

Furthermore, our study supports previous research conducted by Grant et al [22] on the challenges faced by health care professionals in delivering inclusive and affirming care to transgender patients. Consistent with these findings, our participants expressed concerns about communication barriers, limited understanding of gender diversity, and gaps in specialized training and guidelines for gender-affirming care. These challenges highlight the need for comprehensive education and training initiatives to enhance health care professionals' cultural competency and sensitivity to transgender and nonbinary health issues.

A scoping review of transgender health training in internal medicine and subspecialty residency programs identified significant gaps in medical education, emphasizing the need for clearly defined objectives to prepare health care professionals for competent and affirming transgender care [52]. Similarly, a systematic review of educational interventions for medical students and residents working with sexual and gender-minority patients demonstrated the effectiveness of structured programs in improving knowledge, attitudes, confidence, and skills, highlighting the importance of implementing comprehensive training to bridge these gaps [53]. Davidge-Pitts et al [54] studied the importance of comprehensive training and educational resources to address the gaps in health care professional's knowledge and skills related to TNBI health issues. Similarly, our study underscores the significance of tailored educational tools in enhancing health care professional's understanding and competency in providing gender-affirming care. In addition, the Transgender Education for Affirmative and Competent HIV and Healthcare Program further highlights the impact of structured educational initiatives in fostering gender-affirming knowledge, perceived competency, and inclusive practice behaviors among health care providers [55]. These findings align with our study's recommendation for interactive, solution-oriented tools to promote ongoing skill development and professional collaboration. In addition, research on barriers to transgender and gender-diverse care highlights several challenges, including the absence of clear guidelines; extended waiting times; a shortage of specialist centers; insufficient training in transgender and gender-diverse health; and technical, cultural, and social obstacles [26]. These findings align with and reinforce the results of our study.

Our study supports the notion that interactive case studies and peer support forums, integrated within an educational tool, promote active learning, cultural competency, and professional networking among health care professionals. These features facilitate ongoing learning and skill development, fostering a collaborative environment conducive to improving TNBI health care delivery. Moreover, the challenges identified in the integration and use of eHealth tools, as discussed in our study, echo the findings of previous research by Light et al [56]. Time constraints, cultural barriers, and technical issues have consistently been recognized as barriers to the adoption of digital health technologies in clinical practice by the participants.

In contrast to earlier studies conducted by Mansh et al [57], which primarily focused on identifying gaps and challenges in TNBI health care education, our study advances the field by proposing a solution-oriented approach. This study provides actionable recommendations for improving TNBI health care education and training initiatives. This shift toward solution-focused research aligns with the broader goal of enhancing health care delivery and patient outcomes through innovative educational interventions. The findings of this study contribute to the growing body of literature on educational interventions for health care professionals and their implications for TNBI health.

Strengths and Limitations of the Study

The main strength of this study is the use of a qualitative research approach, which allowed for an in-depth exploration of the challenges faced by health care professionals when communicating with TNBI individuals, facilitating a comprehensive understanding of the nuances and complexities surrounding this topic.

In addition, the study included participants from various health care backgrounds and geographic locations, enhancing the richness and diversity of perspectives gathered. This diversity contributed to a more comprehensive analysis of the educational eHealth tools' requirements and potential impact across different health care contexts. The diverse backgrounds of the participants offered a wide range of experiences and provided a more comprehensive understanding of the issues. While our study provides a broad overview of the needs across different medical professions, we recognize the importance of conducting more in-depth studies for each profession. Future research should focus on the specific needs and challenges faced by each medical specialty when working with TNBI individuals. As qualitative studies do not guarantee the generalizability of the results, we argue that the results of our study are transferable to other contexts.

We believe that the number of interviews conducted with health care professionals was sufficient to achieve data saturation across the overall sample. This indicates that we obtained a sufficient breadth and depth of information to address the research objectives. This ensured that a thorough exploration of the topic was achieved without the need for additional participants [37]. It is also important to note that due to the diversity of countries and health care professions in the sample, combined with the relatively low number of participants from each profession and country, data saturation specific to each subgroup may not have been fully achieved. This limitation could affect the transferability of our findings, particularly for specific roles or cultural contexts. Future research could benefit from a more focused examination of these subgroups to deepen the understanding of context-specific nuances. In addition, conducting additional interviews with health care professionals from settings not represented in this study could enrich findings within the subject.

Another limitation of the study is that the interview guide was not pilot-tested. However, the authors carefully designed the guide and conducted multiple meetings to review and refine it. In addition, during the interviews, we maintained a flexible and

adaptive approach, making minor adjustments needed to better capture health care professionals' experiences.

Conclusions

The study aimed to explore health care professionals' perspectives on education, awareness, and preferences for digital educational resources to support TNBI care. The results provided valuable insights into the barriers health care professionals encounter when providing care to TNBI. The study identified key gaps in health care professionals' understanding of gender diversity, cultural competency, and the need for inclusive communication. In addition, the study emphasized the importance of specialized training and the integration of user-friendly eHealth tools to improve the relationships between health care professionals with TNBI individuals.

eHealth tools play a significant role in enhancing patient–health care professional relationships, improving access to care, and promoting patient engagement in health care. Despite the challenges associated with their integration, health care professionals acknowledged their potential to facilitate more efficient, patient-centered care delivery.

Addressing the identified barriers and challenges through targeted interventions, such as providing training and support for health care professionals, investing in user-friendly design and data security, and promoting cultural competence in providing health care for TNBI individuals, is essential.

In conclusion, this study contributes to the growing literature on eHealth interventions in TNBI health care and sets the stage for future research and practice initiatives aimed at leveraging technology to improve health outcomes and reduce health disparities for these individuals.

Acknowledgments

The authors would like to thank all the study participants for their time and valuable contributions to this study. The authors received no specific funding for this work.

Generative artificial intelligence technologies, including Grammarly [58] and OpenAI's ChatGPT 3.5 [59], were used during manuscript preparation to improve grammatical accuracy and enhance clarity in the text. These tools were not used to refine or alter the original qualitative data or inform the thematic analysis. The qualitative data were analyzed in their original form, ensuring accuracy and consistency with participants' responses. The authors reviewed and edited all aspects related to grammatical accuracy and textual clarity to ensure alignment with the study's objectives and maintain content integrity, taking full responsibility for the content of the publication.

Authors' Contributions

Both SK and ND were involved in the study design. SK conducted the data collection and performed the initial data analysis, which was subsequently reviewed and refined by ND. Both the authors were actively involved in writing and reviewing the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Recruitment to cancer clinical trials (CCTs) is low, particularly for underrepresented groups such as uninsured patients, those with low-income status, and racial and ethnic minoritized individuals. A significant barrier is that treating oncologists often fail to inform patients about the possibility of CCT participation as an option for quality cancer care. Therefore, patient inquiries about trials before starting treatment should be normalized and encouraged, particularly for underrepresented groups. Primary care providers (PCPs) are uniquely suited to do this because they interact with patients at the time of cancer diagnosis, provide ongoing care, and are trusted sources of information.

Objective: This study was designed to pilot an innovative web-based CCT training intervention for PCPs, including practicing clinicians and trainees, to increase their ability to prepare patients for cancer treatment decisions and conversations with oncologists about clinical trials.

Methods: We conducted an evaluation of a pilot study using a self-guided, 1-hour web-based training intervention for PCPs with survey assessments before the intervention, immediately after the intervention, and at the 3-month follow-up. We used a mixed methods approach, incorporating quantitative and qualitative data collection and analysis. The evaluation was guided by the Kirkpatrick evaluation model, focusing on levels 1 (reaction), 2 (learning), and 3 (behavior).

Results: A total of 29 PCPs completed the intervention and pre- and postintervention measures, with 28 (97%) PCPs completing the 3-month follow-up assessment. Of these 28 PCPs, 8 (29%) participated in a qualitative interview after the 3-month follow-up assessment. Participants reported high levels of satisfaction with the course. CCT knowledge, as well as attitudes and beliefs, improved after the course and were sustained at the 3-month follow-up. PCPs reported willingness to communicate with patients about cancer treatment options, including CCTs, and willingness to talk with their colleagues about potential changes in referral practices. However, fewer PCPs had actually engaged in these conversations by the 3-month follow-up. In the interviews, PCPs cited limited interprofessional knowledge sharing and organizational constraints as barriers. Notably, PCPs reported changes in their communication behavior with patients: a higher proportion reported communicating with patients at the time of referral about cancer treatment options and clinical trials at the 3-month follow-up than at baseline. In the interviews, PCPs reported that they felt more comfortable and empowered to have these conversations.

Conclusions: This pilot study found that a self-guided, 1-hour web-based training intervention for PCPs resulted in improved knowledge, attitudes, and beliefs, as well as improved communication with patients, to prepare them for discussions with oncologists about cancer treatment and CCTs. Future dissemination of this course has the potential to make an impact on CCT accrual.

Introduction

Background

Cancer clinical trials (CCTs) are essential for advancing cancer treatment and ensuring quality of care for patients [1]. However, for cancer research to benefit all patients, it is critical to include participants who represent the diversity of the American population. Unfortunately, participation in cancer treatment trials remains low, with an overall accrual rate of only 7.1% [2]. Moreover, only approximately 5% of trial participants are Black or Hispanic, although these groups represent 15% and 13%, respectively, of people with cancer [3]. The ongoing underrepresentation of minoritized populations in CCTs not only raises concerns about equitable access to care but also limits the generalizability of the findings across diverse patient groups.

Various barriers at the system, institutional, clinician and research team, and patient levels contribute to low CCT enrollment [4-11]. One significant barrier is that a substantial portion of eligible patients are not approached about the possibility of receiving treatment through clinical trials [12]. This issue is especially pronounced for patients from demographic groups who are typically underrepresented in trials (eg, uninsured individuals, members of racial and ethnic minoritized groups, and people living in rural areas) [12-19] and who experience higher cancer mortality rates [20]. Even when the option of clinical trials is discussed with eligible patients, the communication is frequently unclear or inequitable, often reflecting racial disparities in how comprehensively information about CCTs is conveyed [21].

Research has shown that educating patients before their first oncologist visit can improve their knowledge, attitudes, and readiness for treatment decision-making, as well as increase their willingness to ask about and consider cancer treatment trials [22]. Therefore, it is important to normalize receiving treatment through clinical trials and encourage patient inquiries about trials before starting treatment, particularly for underrepresented groups. To effectively inquire about clinical trials, patients need to understand that quality care can be provided through CCTs, that asking about CCTs is encouraged and supported, that their participation in treatment decisions is encouraged [23,24], and that they are capable of fulfilling this role [8-10]. Patient education can start with the patient's trusted primary care provider (PCP).

PCPs are a potential gateway facilitating access to CCTs because they interact with patients at the time of cancer diagnosis, provide ongoing care, and are trusted sources of information [25,26]. PCPs also report believing that they play an important role in patient care across the cancer continuum, including being actively involved during treatment [27]. Moreover, studies have shown that a trusted physician's recommendation is a primary factor influencing patients' decisions to enroll in clinical trials when offered [5,10,28-34] and that this influence may even be more acute for minoritized populations [35]. Therefore, improving PCPs' attitudes, beliefs, and behaviors around CCTs may significantly influence patients' attitudes and openness toward participation [36-39].

Although PCPs have expressed a desire for more of their patients with cancer to participate in CCTs, they often feel inadequately prepared to discuss trials due to their own limited understanding of CCTs as a high-quality treatment option [40,41]. In addition, they need guidance on effectively communicating with patients about potential trial participation. This gap in knowledge and skills presents a significant opportunity to educate PCPs about CCTs and their role in preparing patients for the oncology referral. These new skills can potentially improve trial accrual and patient access, especially for underrepresented groups.

Previous research, including our own, has demonstrated that conducting education with PCPs who serve underrepresented populations can contribute to breaking down key barriers to trial participation [42-44]. This can be achieved by improving PCPs' capacity to both (1) educate recently diagnosed patients about the possibility of trial participation at the time of treatment referral to cancer care and (2) provide decision-making support

to patients if advice is sought about trial participation after the patient has already met with the oncologist.

Objectives

The purpose of this study was to pilot-test an innovative web-based training intervention for PCPs, including both practicing clinicians and trainees, designed to help them prepare patients for discussions about cancer treatment and CCTs. There are several types of CCTs, including prevention, screening, behavioral, and supportive care trials. However, for the purpose of this training, we focused specifically on treatment trials (eg, those involving chemotherapy or immunotherapy). We aimed to evaluate (1) PCPs' general impressions of the training intervention and how the intervention impacted (2) their knowledge about CCTs, (3) their perceptions of their roles in caring for patients with cancer, (4) their approach toward and communication with patients, and (5) their willingness and behaviors in enacting practice-level changes.

Methods

Study Design

A 1-hour web-based training intervention for PCPs was developed and evaluated in a single-arm pilot study with assessments conducted before the intervention, immediately after the intervention, and at 3-month follow-up. We used a mixed methods approach, using quantitative and qualitative data collection and analysis to evaluate the training intervention [45]. We used the Kirkpatrick model to guide our evaluation [46]. The Kirkpatrick model proposes 4 sequential levels of training evaluation that become progressively more distal from the original training. In this study, we focused on levels 1 (reaction), 2 (learning), and 3 (behavior).

After conducting separate analyses, we integrated the results to allow the qualitative data to enhance and provide context for the quantitative data [47,48]. This approach integrates the data for triangulation, which strengthens the validity of the findings and allows for a more comprehensive understanding of the data [49-51]. This study followed the SQUIRE 2.0 (Standards for Quality Improvement Reporting Excellence) guidelines for assessing quality and reporting results [52].

Training Intervention

We collaborated with instructional designers (DD and JA) from the University of Florida's E-Learning, Technology, and Communications department to develop a 1-hour web-based training intervention for PCPs titled "Preparing Patients for Cancer Treatment Decisions: The Critical Role of Primary Care Providers in Facilitating Equitable Access to Care and Clinical Trials." The content of the intervention was based on the authors' collective research on the topic [40-43,53] as well as current literature on the role of PCPs in cancer treatment and referral, barriers to CCTs, patient activation, and best practices in medical education.

The asynchronous training intervention was hosted by a PCP (AN-P) and a radiation oncologist (RMV) who introduced content through engaging conversations and videos. Using a model of cognitive dissonance, the course introduced new information about CCTs, with the intent of helping providers realize inaccuracies in their knowledge, attitudes, and behaviors around CCTs and the referral to cancer treatment [54,55]. A clinical trials content expert (MM) additionally provided facts about CCTs, cancer care disparities, barriers to CCT participation, and the role of PCPs in cancer care. The 4 intervention modules covered content to enhance PCPs' knowledge and communication skills surrounding cancer treatment discussions, including clinical trials and strengthening preparation related to the oncology referral process. The communication skills taught in the curriculum centered on the 5 E's communication model (ie, explore, educate, encourage, engage in planning, and emphasize partnership), a framework designed to support patients in becoming more active participants in cancer treatment decision-making. Informed by principles of patient activation, treatment decision support, shared decision-making, and patient-centered communication, the model provides a simple mnemonic that clinicians can use to educate patients; prepare them for oncology referrals; and encourage inquiry about treatment options, including cancer treatment trials [56-59]. The learning objectives for each of the 4 modules are displayed in Table 1.

Table 1. Intervention modules and learning objectives.

Module	Learning focus	Learning objectives
1	Disparities in cancer care and clinical trial participation	• List the reasons why cancer treatment trials are defined as quality cancer care • Describe disparities in cancer care and in cancer treatment trial participation
2	Importance of strong PCP[a] role in referrals to cancer treatment	• Assess the critical role of the PCP in the referral process • Assess the PCP's role in preparing patients around treatment decision-making with the specialist
3	Communication skills to foster patient engagement in cancer treatment	• Apply a 5-step communication approach to prepare patients for the specialist referral and their engagement in treatment planning
4	Needed changes with colleagues in the referral process	• Evaluate the need to refine organizational procedures to improve one's own referral practices for patients recently diagnosed with cancer

[a]PCP: primary care provider.

Throughout the modules, video vignettes featuring actors as patients and physicians further illustrate the 5E's communication model. The modules also include case studies where participants can explore patients' disease histories, backgrounds, and cancer diagnoses. Participants complete each module at their own pace.

Evaluation of the Training Intervention: Quantitative Assessments

Participants and Recruitment

We recruited PCPs to complete a web-based training intervention, pre- and postintervention surveys, and a postintervention interview. Recruitment was based on the following inclusion criteria: (1) being a PCP, including a physician (with MD or DO degrees), nurse practitioner (NP), physician assistant, or trainee (specifically postgraduate year [PGY] 2 or above in a family or internal medicine residency program) with at least 3 months of outpatient primary care experience; (2) working in an outpatient setting; (3) having made patient referrals to specialists for cancer treatment in the past year; and (4) speaking English and residing in the United States or its territories. Between July and December 2023, we emailed invitations that included a study description and instructions for those interested to contact a research coordinator. The invitations were distributed through email lists provided by three partner organizations: (1) the Clinical Directors Network, a national not-for-profit practice-based research network and clinician training organization; (2) Penn Medicine, an academic health system; and (3) the University of Florida's Department of Community Health and Family Medicine and its family medicine and internal medicine residency programs, which are based in a large public academic health system. Once enrolled in the study, participants had up to 4 weeks to complete the training intervention.

Procedure

Participants completed a pretraining survey, an immediate posttraining survey, and a 3-month follow-up survey. Data were collected on the web via QualtricsXM (Qualtrics International Inc) [60]. The quantitative and qualitative phases of data collection and descriptions of each method are presented in Table 2.

Table 2. Descriptions of data collection measures and timeline.

Measures	Description	Before the training	After the training	3-mo follow-up
Participant characteristics	A 10-item survey that asks about participants' demographics, professional background, and current professional setting	✓		
Knowledge of CCTs[a]	A 7-item measure comprising true or false statements about CCTs	✓	✓	✓
CCT attitudes and beliefs	A 4-item Likert-type measure that assesses attitudes, beliefs, and behavioral intentions related to CCTs	✓	✓	✓
Patient communication and referral practices	A 14-item measure that assesses the communication and referral behaviors of PCPs[b] before (7 questions) and after (7 questions) returning patients' initial referral to a cancer specialist to discuss treatment options	✓		✓
Willingness to change	A 3-item Likert-type measure that focuses on PCPs' willingness to make changes in their practice	✓	✓	✓
Willingness to communicate	A 6-item Likert-type measure that focuses on PCPs' willingness to engage with patients who have a cancer diagnosis	✓	✓	✓
Intervention usability	A 5-item survey that asks about participants' device (eg, tablet computer), browser type, and whether they encountered any technical issues while taking the web-based course		✓	
Overall course satisfaction	A 10-item Likert-type measure where participants evaluate their training experience (eg, content and logistics) and intervention acceptability, along with 2 open-ended questions for additional feedback		✓	
Interview	A semistructured interview based on the quantitative survey measures, with an emphasis on exploring PCPs' experiences with the course			✓

[a]CCT: cancer clinical trial.

[b]PCP: primary care provider.

Before beginning the training intervention and after providing informed consent, participants were asked to complete a 44-item web-based survey. The preintervention survey included 5 measures—knowledge of CCTs, CCT attitudes and beliefs, patient communication and referral practices, willingness to communicate, and willingness to change—all of which were informed by our previous work [40,41,43,53]. The preintervention survey also collected participant characteristics, including demographics and professional background. Immediately after the intervention, participants were asked to complete a 35-item web-based survey that included the knowledge of CCTs, CCT attitudes and beliefs, willingness to communicate, and willingness to change measures. In addition, they were asked about intervention usability and overall course satisfaction. Completing the intervention and the pre- and postintervention surveys fulfilled participants' training requirements, at which point they were compensated US $150 for their participation.

Three months after the intervention, participants were asked to compete an additional 34-item web-based survey that included the knowledge of CCTs, CCT attitudes and beliefs, patient communication and referral practices, willingness to communicate, and willingness to change measures. After completing the 3-month follow-up survey, participants were compensated an additional US $45 for their participation. All surveys are shown in Multimedia Appendix 1.

Statistical Analysis

Descriptive statistics were used to analyze participants' demographic characteristics. The data were analyzed using R software (version 4.4.0; R Foundation for Statistical Computing) [61]. Cronbach α values were used to measure the internal consistency among the CCT attitudes and beliefs, willingness to communicate, and willingness to change measures, and we report both individual item means and aggregated means for these measures. Frequencies (%) and mean (SD) scores for all survey measures were reported. The McNemar chi-square test and the Wilcoxon signed rank test were used to compare the results of the preintervention and postintervention surveys, including the 3-month follow-up survey. Due to the exploratory nature of this pilot study, adjustments for multiple comparisons were not made.

Evaluation of the Training Intervention: Qualitative Phase

To gain further insights into the survey results, we conducted follow-up interviews with PCPs who completed the 3-month follow-up survey.

Participants and Recruitment

At the end of the 3-month follow-up survey, interested PCPs were invited to participate in a brief web-based interview to discuss their experience with the course. Between December 2023 and February 2024, members of the research team (A Crowe and NDP) contacted interested PCPs to confirm their participation and to schedule the interviews.

Interview Procedure

Between December 2023 and February 2024, two authors (NDP and A Crowe) interviewed PCPs via Zoom (Zoom Video Communications, Inc). The semistructured interview guide was designed based on the quantitative survey measures, with an emphasis on exploring PCPs' experiences with the course. Participants were asked to share their impressions of the training intervention, their attitudes and beliefs regarding the role of PCPs, and to describe any changes they had made to their practice since taking the course. The interviews were audio recorded and professionally transcribed verbatim before analysis. Participants who completed the interview received an additional US $50 in compensation.

Qualitative Analysis

The interview data and analysis were managed using ATLAS.ti software (version 24.1.1; ATLAS.ti Scientific Software Development GmbH) [62]. Data collection and analysis were conducted concurrently, enabling an initial rapid analysis to capture and categorize data into broad themes [63,64]. Subsequently, a comprehensive thematic analysis was conducted by the first author (NDP), using both deductive and inductive coding strategies guided by the constant comparative method [65,66]. Throughout the analysis, 2 authors (NDP and CLF) met to review and discuss codes and emerging themes and to develop a codebook that guided the full thematic analysis [65,67]. Similar codes identified across all transcripts were collapsed into overarching themes, followed by axial coding to further characterize thematic properties [67].

Data Integration

After conducting individual quantitative and qualitative analyses, we jointly interpreted the findings from both phases to enhance reporting. We report quantitative data first, which are then elaborated with the qualitative findings. When appropriate, we created joint displays to illustrate this data integration and to organize the results [48,68].

Ethical Considerations

The study procedures were approved by the University of Florida Institutional Review Board (202200894). Before the PCPs participated in the surveys and interviews, they were provided a statement of participant rights and responsibilities and given the option to withdraw from the study at any time. All survey participants checked a box agreeing to participate before taking the survey. All interview participants verbally confirmed their willingness to participate, had the opportunity to ask questions before the interview, and were informed that interview data would be transcribed for analysis but only available to members of the research team. All data were deidentified before reporting in this study. Participants who completed the intervention and the pre- and postintervention surveys were compensated US $150. Participants who completed the 3-month follow-up survey were compensated an additional US $45.

Results

Overview

A total of 29 PCPs completed the study and preintervention and postintervention surveys; the sample included 15 (52%) women and 14 (48%) men. Of the 29 PCPs, 28 (97%) completed the 3-month follow-up survey (Figure 1). Of these 28 participants, 8 (29%) took part in the interviews. Of the 29 participants, 26 (90%) had MD degrees, 2 (7%) were NPs, and 1 (3%) had a DO degree. More than half were physicians in training, with 17 (59%) describing themselves as residents or fellows in PGY2 (n=7, 41%), PGY3 (n=9, 53%), or PGY4 (n=1, 6%). Participants described their practice areas as internal medicine (16/29, 55%), family practice (11/29, 38%), or other (2/29, 7%). Most reported that their practice or training setting was an academic-affiliated hospital (17/29, 59%) or community-based and owned by an academic medical center (7/29, 24%). Complete demographic and professional characteristics of both survey and interview participants are shown in Table 3.

Figure 1. Flow diagram depicting study enrollment and participation.

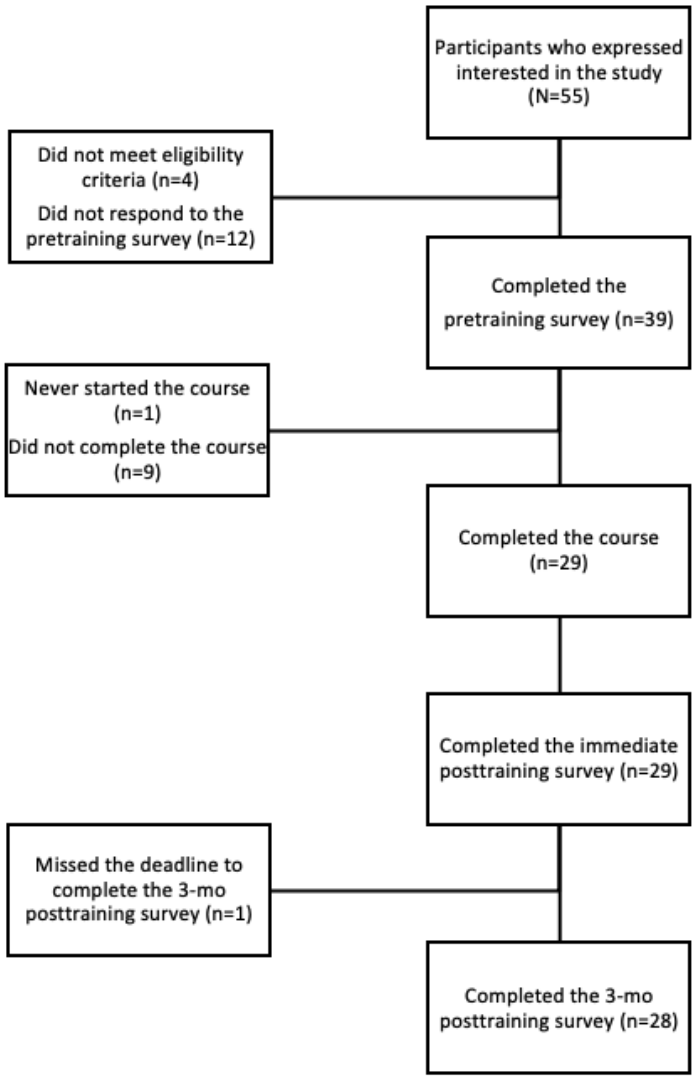

Table 3. Characteristics of surveyed and interviewed participants[a].

Characteristics	Survey (n=29), n (%)	Interview (n=8), n (%)

The mixed methods findings were used to (1) characterize PCPs' general impressions of the training intervention; in addition, we used these evaluation findings to capture how the training intervention impacted their (2) knowledge, (3) perceptions of their roles in caring for patients with cancer, (4) communication with their patients, and (5) practice-level change willingness and behaviors. The quantitative results are reported first and then elaborated upon with the qualitative findings within each of the 5 areas of impact.

General Impressions of the Course

Both survey and interview findings illustrated PCPs' positive impressions of, and high satisfaction with, the course. Specifically, PCPs expressed satisfaction with the course content, design and functionality, course elements, and course length. Their general impressions are presented in a joint display (Table 4) to depict the mixed methods results comprehensively.

Table 4. Primary care providers' impressions of the course.

Course characteristics and quantitative measures	Survey question ratings[a], mean (SD)	Illustrative quotes from the interviews
Content		
"Course content was relevant to my work."	4.6 (0.5)	"The content was excellent, and the way that it was provided was also very good. I found it very useful to learn information that I didn't know before." [P1]
"The course provided an adequate evidence base to support the content."	4.5 (0.6)	"I thought it was kind of helpful...I'd never looked into discrepancies in cancer care. I probably could've suspected but didn't know that was a fact." [P8]
"The right amount of information was provided."	4.6 (0.5)	"I felt [the course was] kind of straight to the point, and the topic was well laid out." [P2]
Design and functionality		
"The course presented information in a clear and organized manner."	4.7 (0.5)	"From an educational perspective, I thought it was designed pretty well. It was logical in the way that the modules flowed from one to the next." [P3]
"The graphics (graphs, pictures, illustrations) added to the effectiveness of the presentation."	4.5 (0.6)	"I thought [the course] was really well organized and laid out, and it had a nice, I guess, sequence of training." [P4]
Course elements		
"The course scenarios facilitated my understanding."	4.6 (0.5)	"I really enjoyed the videos, the examples, and the quiz questions...[and the] summary at the end, which I felt was helpful." [P1]
"The interactive features in the course activities helped me learn."	4.4 (0.8)	"I liked the different scenarios, and the short videos that you could engage with, and then immediately afterwards, trying to apply that to some questions." [P3]
"The clinical interactions shown in the course felt authentic."	4.3 (0.8)	"I really liked the case scenarios where it gave you different options for how you would respond to a patient. I thought that gave really valuable feedback in how we phrase some of the topics that we bring up." [P4]
"The clinical interactions shown in the course were relatable to me."	4.4 (0.6)	"I think, even as a primary care doctor who sees a lot of patients and who does diagnose cancer sometimes...It was really good content to push me to be more hands-on in my patients' cancer care process." [P3]
Length of course		
"The length of the course was appropriate."	4.7 (0.5)	"I thought that [the course] was educational and informative, and it was fairly straightforward and quick." [P8]

[a]Survey questions were scored on a 5-point scale ranging from 1=strongly disagree to 5=strongly agree.

CCT Knowledge

PCPs' positive feedback about the course aligns with their significant improvement in CCT knowledge after participating in the course. The survey results (Table 5) indicated that PCPs' knowledge of CCTs was low before the training, with a mean score of 55% (SD 17.9%) across all 7 CCT knowledge items. Immediately after the training, PCPs' knowledge of CCTs improved significantly to a mean score of 81% (SD 12.1%; $P<.001$). This improvement from before the training was sustained at the 3-month follow-up, with a mean score of 73% (SD 18.4%; $P=.005$).

Table 5. Comparison of correct responses on the pretraining and posttraining knowledge of cancer clinical trials (CCTs) survey[a].

True or false CCT knowledge questions	Before the training (n=29), n (%)	After the training (n=29), n (%)	3-mo follow-up (n=28), n (%)	*P* value[b] (before the training vs after the training)	*P* value[b] (before the training vs 3-mo follow-up)
"In a cancer treatment trial, patients will receive a placebo alone or the new treatment being tested."	19 (66)	26 (90)	21 (75)	*.046* [c]	.70
"While about 25% of U.S. adults with cancer are eligible to participate in cancer treatment trials, only about 8% participate."	20 (69)	29 (100)	27 (96)	*.008*	*.046*
"Patients determined to be eligible for cancer treatment trials are usually offered the opportunity to participate."	14 (48)	23 (79)	22 (79)	*.04*	.06
"Patients from racial and ethnic minority groups eligible to participate in cancer treatment trials tend to be offered the opportunity to participate less frequently than are white patients."	19 (66)	25 (86)	21 (75)	.15	.60
"When offered the opportunity to participate in a cancer treatment trial, patients from racial and ethnic minority groups agree to participate at about the same rate as do white patients."	0 (0)	5 (17)	5 (18)	.07	.07
"Recommendation by a trusted physician is a primary factor influencing a patient's decision to enroll in a cancer treatment trial."	28 (97)	29 (100)	27 (96)	1	1
"Federal law now requires private insurers, Medicare and Medicaid to cover routine patient care costs in most cancer treatment trials."	11 (38)	28 (97)	20 (71)	*<.001*	*.03*

[a]Percentage of aggregated correct responses: before the training, n=55 (18%); after the training, n=81 (12%); 3-mo follow-up, n=73 (18%); before the training versus after the training *P*<.001*;* before the training versus 3-mo follow-up *P*=.005.

[c]Italicization indicates a statistically significant *P* value.

PCPs' Perceptions of Their Roles in Caring for Patients With Cancer

Overview

The findings demonstrated that the training intervention was effective in changing PCPs' attitudes and beliefs about their role in caring for patients with cancer, which was sustained at the 3-month follow-up. As shown in Table 6, the scores across all 4 items increased significantly from before the training (mean 4.2, SD 0.6) to after the training (mean 4.6, SD 0.4; *P*<.001), as PCPs agreed that they play a role in their patients' cancer care. This change was sustained at the 3-month follow-up (mean 4.5, SD 0.5; *P*=.004). Most significantly, PCPs were more likely to agree that they "have an important role in educating patients about the possibility of receiving cancer treatment through a clinical trial, before the referral to a specialist" immediately after the training (mean 4.5, SD 0.6; *P*<.001) compared to before the training (mean 3.6, SD 1.0). This individual item improvement was also sustained at the 3-month follow-up (mean 4.4, SD 0.6; *P*<.001).

Table 6. Comparison of pretraining and posttraining scores on the cancer clinical trial attitudes and beliefs survey[a].

Questions[b]	Before the training (n=29), mean (SD)	After the training (n=29), mean (SD)	3-mo follow-up (n=28), mean (SD)	*P* value[c] (before the training vs after the training)	*P* value[c] (before the training vs 3-mo follow-up)
"Health care providers like me have an important role in educating patients that there is often more than one option for treatment, before the referral to a specialist."	4.2 (0.8)	4.6 (0.5)	4.5 (0.6)	*.008* [d]	.07
"Health care providers like me have an important role in educating patients about the possibility of receiving cancer treatment through a clinical trial, before the referral to a specialist."	3.6 (1.0)	4.5 (0.6)	4.4 (0.6)	*<.001*	*<.001*
"Health care providers like me have an important role in supporting patients' decision to participate in a cancer treatment trial."	4.4 (0.7)	4.7 (0.5)	4.6 (0.6)	.07	.30
"Health care providers like me can make a difference in the quality of cancer care our patients receive."	4.6 (0.6)	4.7 (0.5)	4.5 (0.6)	.11	.80

[a]Mean of aggregated CCT attitudes and beliefs questions: before the training, mean 4.2 (SD 0.6); after the training, mean 4.6 (SD 0.4); 3-mo follow-up, mean 4.5 (SD 0.5); before the training versus after the training *P*<.001*;* before the training versus 3-mo follow-up *P*=.004. Survey questions were scored on a 5-point scale ranging from 1=strongly disagree to 5=strongly agree.

[b]Cronbach α value for the 4 CCT attitudes and beliefs questions was 0.82.

[c]*P* values were calculated using the Wilcoxon signed rank test with continuity correction, including only the participants who completed both pre- and posttraining surveys.

[d]Italicization indicates a statistically significant *P* value.

The qualitative findings shed light on these results by illustrating PCPs' perceived role in caring for patients with cancer. After the 3-month follow-up, PCPs described fulfilling three key roles: (1) *partner*, (2) *educator*, and (3) *interpreter.* However, they also acknowledged struggling or feeling restricted in these roles due to *expertise boundaries*.

PCP as Partner

PCPs explained how they can fulfill roles beyond offering medical expertise by being partners. They emphasized the importance of *being a consistent source of support* by remaining involved in patients' cancer journeys:

> *As a primary doctor, you really want to make your patient feel that you're there. You're not leaving...You still want to be a part of whatever plan is going to occur.* [P2]

Another PCP highlighted the collaborative nature of this ongoing support:

> *You have to look forward and make a plan, let [patients] know that they take one step, I take one step forward, and we're kind of in tandem.* [P7]

PCPs also discussed *providing emotional support*, including helping patients manage their emotions and "the mental health issues that come along with [a] cancer diagnosis and cancer treatment, in general" (PCP1). Another PCP explained as follows:

> *When you initially tell the patient, they're kind of like flabbergasted, and they're in a state of shock...They're just thinking "I'm going to die," so I...try to help the patient get through the emotions, that initial shock.* [P6]

PCP as Educator

PCPs also discussed having roles as educators, where they focused on preparing patients for consultations with specialists by *discussing treatment options*, including introducing the possibility of receiving care through a CCT. PCPs emphasized being more proactive after the training intervention in ensuring that their patients were adequately informed to engage with specialists:

> *[The course] helped me to focus more on general treatment ideas, like radiation, surgery, chemotherapy, and sort of introduce them to those different treatment options so that then they could take that information and ask their oncologist and oncology surgeons about what is truly available to them, including clinical trials.* [P4]

A PCP additionally described *exploring patients' understanding* of their treatment options, including clarifying misconceptions:

> *Whether it's clinical trials or normal treatment, it's important to explore [the patient's] understanding of what's going on, then you can kind of course correct, educate them on what actually might be happening and maybe where there'd be misconceptions.* [P7]

PCP as Interpreter

PCPs described taking on an interpreter role that centered on enhancing patients' comprehension of medical information. PCPs described being a "go-between" (ie, a bridge) by acting as intermediaries who can interpret information provided to patients by oncologists and other cancer specialists:

> *[Patients] should come to me if they have questions, concerns, don't understand something, because I am great at being a go-between in terms of reading notes and/or contacting oncologists, surgeons, interpreting things for them...and analyzing their options with them in ways that they understand.* [P5]

PCPs also recognized their role in *translating medical information*, such as information related to medications and laboratory results, to "kind of frame [the information] in terms the patient may know, just because some of the language isn't as clear all the time" (PCP8). They recognized the value of making information more accessible for patients, although they were not cancer specialists themselves:

> *As a patient, it's very overwhelming...but that's kind of like why I'm here. I can try to interpret, maybe, better what's going on...Like medications. What is it? What does it do? I mean, obviously, I'm not a specialist. I don't know the ins and outs of everything, but I think kind of interpreting labs, a patient, a lot of times, they don't [understand]...Just maybe a more kind of hands-on understanding for the patient.* [P2]

PCPs Navigating Expertise Boundaries

Finally, despite completing the training intervention, PCPs emphasized that they were still struggling with expertise boundaries. They admitted that their *lack of specialized knowledge* in oncology made them cautious about discussing cancer-related topics in detail:

> *I think the challenges as just a PCP...is that I just don't have that knowledge of oncology, in specific. I don't know enough about that specific clinical trial or that specific diagnosis, the prognosis, and things like that...Due to the lack of expertise, it makes it hard to communicate.* [P1]

PCPs further highlighted feeling the constraints of *role limitations* in guiding patients through complex cancer treatment decisions:

> *Oftentimes the questions [that patients are] asking about the treatments are very nuanced...I think there's only so much that the primary care doctor can answer.* [P7]

Communication About Treatment Options

Overview

The survey findings demonstrated that the training intervention enhanced PCPs' *willingness to communicate* with their patients about cancer treatment options in general, including CCTs (Table 7). Mean scores across the 6 items increased significantly from before the training (mean 4.4, SD 0.5) to immediately after the training (mean 4.7, SD 0.5; P=.007). This improvement was not sustained at the 3-month follow-up. However, 1 item—PCPs' willingness to "educate these patients about the possibility of receiving treatment within a cancer clinical trial"—showed significant improvement at the 3-month follow-up (mean 4.4, SD 0.6; P=.04) compared to before the training (mean 4.0, SD 0.8).

Table 7. Comparison of pretraining and posttraining scores on the willingness to communicate survey[a].

Questions[b]	Before the training (n=29), mean (SD)	After the training (n=29), mean (SD)	3-mo follow-up (n=28), mean (SD)	*P* value[c] (before the training vs after the training)	*P* value[c] (before the training vs 3-mo follow-up)
"I am willing to explore patients' concerns about cancer treatment."	4.4 (0.5)	4.7 (0.5)	4.5 (0.5)	*.01* [d]	.60
"I am willing to educate these patients that there is often more than one option for treatment."	4.4 (0.7)	4.7 (0.6)	4.5 (0.6)	*.04*	.70
"I am willing to educate these patients about the possibility of receiving treatment within a cancer clinical trial."	4.0 (0.8)	4.6 (0.6)	4.4 (0.6)	*.003*	*.04*
"I am willing to encourage these patients to ask questions of the specialist about different treatment options."	4.6 (0.6)	4.7 (0.5)	4.4 (0.7)	.30	.30
"I am willing to encourage these patients to ask questions of the specialist about receiving treatment within a cancer clinical trial."	4.4 (0.6)	4.7 (0.5)	4.5 (0.5)	.14	.60
"I am willing to emphasize my role as a partner throughout these patients' cancer care."	4.6 (0.5)	4.7 (0.5)	4.6 (0.6)	.20	.80
Mean of aggregated willingness to communicate questions	4.4 (0.5)	4.7 (0.5)	4.5 (0.5)	*.007*	.50

[a]Mean of aggregated willingness to communicate questions: before the training, mean 4.4 (SD 0.5); after the training, mean 4.7 (SD 0.5); 3-mo follow-up, mean 4.5 (SD 0.5); before the training versus after the training *P*=.007*;* before the training versus 3-mo follow-up *P*=.50. Survey questions were scored on a 5-point scale ranging from 1=*strongly disagree* to 5=*strongly agree*.

[b]Cronbach α value for the 6 willingness to communicate questions was 0.91.

[c]*P* values were calculated using the Wilcoxon signed rank test with continuity correction, including only the participants who completed both pre- and posttraining surveys.

[d]Italicization indicates a statistically significant *P* value.

The survey results also showed that the training intervention influenced PCPs' self-reported *patient communication and referral practices* immediately after the training and at the 3-month follow-up. As shown in Table 8, seven items on the patient communication and referral practices measure focused on the 5Es model from the curriculum (ie, explore, educate, encourage, engage in planning, and emphasize partnership). We asked PCPs about their communication in two different contexts of seeing patients: (1) before making an initial patient referral and (2) after patients returned following their referral appointment. After the training, PCPs reported improvements in both contexts. Specifically, they reported discussing cancer treatment options with a higher percentage of patients in the "before making a referral" context (ie, context 1). Overall, 6 (86%) of the 7 items showed improvement, with the most significant changes seen on the 2 items focusing specifically on CCTs. PCPs reported educating a higher percentage of patients "about receiving treatment with a cancer clinical trial" 3 months after completing the training intervention (before the training: mean 15%, SD 20.2%; 3-mo follow-up: mean 48%, SD 30.5%; *P*<.001). They also reported educating a higher percentage of patients to "encourage inquiry about receiving treatment through a cancer clinical trial" (before the training: mean 22%, SD 29.4%; 3-mo follow-up: mean 62%, SD 34.9%; *P*<.001). When surveyed about their behaviors after patients returned following their referral appointment (ie, context 2), these same 2 items were the only ones that showed significant improvement.

Table 8. Comparison of pretraining and 3-month follow-up scores on the patient communication and referral practices survey.

Questions (regarding patients diagnosed with cancer in the past 3 mo)	Before the training (n=29), mean (SD)	3-mo follow-up (n=28), mean (SD)	*P* value[a]	Illustrative quotes
"**Prior to making a referral, approx. what percentage of patients did you:"**[b]				
"Explore concerns about cancer treatment in general"	59.8 (35.9)	75.4 (27.1)	*.03* [c]	"[The course] reaffirmed the importance of leveraging the primary care relationship...A lot of my patients circle back to ask about my opinions before starting a specific type of cancer treatment." [P3]
"Educate about cancer treatment in general"	54.8 (32.7)	73.4 (34.2)	*.006*	"[Patients are] meeting these oncologists for the first time and...these are people I've known for years, so it makes sense that I also still have a role in making sure that they understand clinical trials, but also the treatment options that have been made available to them by the oncologist." [P7]
"Educate about receiving treatment with a cancer clinical trial"	15.2 (20.2)	47.9 (30.5)	*<.001*	"[Before the course] I didn't realize that PCPs can also play a role and influence patient decisions [about clinical trials]." [P1]
"Encourage inquiry about treatment options"	68.8 (37.6)	83.8 (28.0)	*.04*	"The important role of the PCP, that was interesting to me. I thought...the oncologist probably had more impact. But I can see that if you have a good relationship with your patient, then you can also encourage them one way or the other, or maybe as a second opinion, to help them figure out what they want for their treatment plan." [P1]
"Encourage inquiry about receiving treatment through a cancer clinical trial"	21.7 (29.4)	61.6 (34.9)	*<.001*	"[I now remember] to emphasize and mention the possibility of clinical trials when they see their specialists, particularly when I'm working with minority patients to...remind them to consider [clinical trials] and to ask" [P5]
"Engage in helping patients plan these inquiries with a specialist"	48.3 (37.2)	70.2 (30.2)	*.007*	"Putting on people's radars...the availability of trials and asking patients to talk to specialists about the potential to participate in trial was valuable." [P5]
"Emphasize partnership as patients go through cancer care"	80.7 (32.6)	83.6 (29.4)	.60	"I kind of felt like I needed to do a better job on being more intentional about the follow-ups...Maybe having more check-ins to see how the treatment is going, how their mental health is doing and stuff like that is important. So that was one thing I've been trying to do is schedule more follow-ups during their active cancer treatment." [P3]
"**After patients returned following their initial referral, approx. what percentage did you:"**[b]				
"Explore concerns about cancer treatment in general"	62.3 (38.6)	53.4 (44.3)	.40	"What I've noticed is a patient will get diagnosed with something...then they'll come to us as a primary care doctor and sort of ask questions, like, they want us to help guide them through the decision-making process, which is great." [P7]
"Educate about cancer treatment in general"	56.9 (35.0)	58.1 (42.6)	.60	"In a couple of cases [my patient] point blank said, 'You've explained my diagnosis and my treatment options better than the other people that I talked to...I felt very prepared with asking [my oncologist] about specific treatment options.'" [P4]
"Educate about receiving treatment with a cancer clinical trial"	23.3 (32.4)	50.4 (40.7)	*.003*	"[A takeaway for me was] the involvement of a PCP in helping make some of those decisions and helping patients feel open to [cancer clinical trials]. I do get the sense of encouraging the patient or empowering them a little bit and supporting them in terms of whatever their [treatment] decision might be. It was helpful to see that there is a true role for that." [P8]
"Encourage inquiry about treatment options"	59.6 (37.8)	64.4 (41.5)	.70	"I think...just presenting the different treatment options for the patients really got them to feel more comfortable asking questions when they were ready to see their oncologist." [P4]
"Encourage inquiry about receiving treatment through a cancer clinical trial"	19.6 (25.9)	55.9 (43.1)	*<.001*	"I actually encourage [my patients] to ask more treatment discussion and decision-making questions with their oncologist. I just explain to them that, you should write [questions] down in ways that they'll remember, right?" [P7]
"Engage in helping patients plan these inquiries with a specialist"	47.8 (40.2)	61.0 (42.7)	.13	"I try to use that connection and that existing relationship to help patients feel comfortable in the decisions they're making and then also to support the specialists in our academic institution to try to help them also build confidence in the new specialists that they're seeing." [P3]

Questions (regarding patients diagnosed with cancer in the past 3 mo)	Before the training (n=29), mean (SD)	3-mo follow-up (n=28), mean (SD)	*P* value[a]	Illustrative quotes
"Emphasize partnership as patients go through cancer care"	73.2 (36.0)	69.5 (41.4)	.70	"I think what stood out to me is there's an emphasis on making sure patients understand their diagnosis...and the importance of following up...and [that] the oncologist is meeting them probably for the first or second time when you're talking about clinical trials and cancer treatments." [P7]

[a]*P* values were calculated using the Wilcoxon signed rank test with continuity correction, including only the participants who completed both pre- and posttraining surveys.

[b]Each question was answered as a percentage, ranging from 0 to 100.

[c]Italicization indicates a statistically significant *P* value.

The findings from the interviews expand on these results by illustrating how PCPs' approach to patient communication evolved after the course. Collectively, they reported an increased sense of self-efficacy, feeling more comfortable and empowered in discussing cancer treatment options with patients. PCPs emphasized the importance of three goals in their approach: (1) engage patients, (2) empower patients, and (3) promote equity. PCPs described using specific communication approaches to achieve each of these goals.

Engage Patients

First, PCPs described a shift in practice after taking the course, working to engage patients in informed discussions about treatment options, including CCTs, rather than deferring these conversations to oncologists. They emphasized taking a proactive approach by initiating discussions about treatment options:

> *[The course] helped me to be more aware [of treatment options], so I can at least have that conversation with the patient.* [P2]

> *[The course] certainly opened my eyes to the fact that [treatment options] should be mentioned, something I would not have previously done.* [P8]

PCPs also highlighted encouraging consideration of clinical trials when communicating with patients about their cancer treatment options:

> *After the course, I'm just more likely to bring up clinical trials, whether there's a clinical trial [available] or not.* [P7]

> *My approach, it changed a little bit, to the point that I'm more willing to talk to [patients] a little bit more about [CCTs], rather than just immediately just defer everything to oncology.* [P1]

Empower Patients

Next, PCPs highlighted their efforts in empowering patients to "take ownership of their own health care" (PCP4). PCPs discussed prompting patients to thoroughly *explore treatment options*, ensuring that they are aware of the possibilities available to them:

> *I...either encourage them to at least take a look at what that [treatment] option is for them or encourage them to deep-dive into that option.* [P1]

Moreover, PCPs emphasized encouraging their patients to *ask specialists questions about treatment options*:

> *[I tell patients] "I can answer as many questions as I can, but the ones that I can't...you can go back to the oncologist and ask them." So, I encourage them to ask more treatment discussion and decision-making questions with their oncologist.* [P7]

Promote Equity

Finally, PCPs discussed being more aware of the importance of promoting equity when discussing cancer treatment options. PCPs described *tailoring patient communication* to incorporate patients' diverse needs and to actively engage those who are part of groups who are underrepresented in clinical trials:

> *[Before the course] I didn't realize...that there is a discrepancy on, for example, race, and those that participate in clinical trials...When I see that patient, I now know that I should actively engage them and talk to them about clinical trials and prime them before they go in to see the oncologist, for example...If you know where...the lack of utilization is, you can kind of intervene and make it more of an active conversation with the patients.* [P7]

PCPs also highlighted being "far more cognizant" (PCP5) after the course about *facilitating patients' access* to treatment options to ensure "patients are getting offered the same [care] as everyone else" (PCP2). A PCP emphasized as follows:

> *I was appreciative that the [course] modules focused on [disparities in CCT participation], and I am trying to be more equitable in the care that I provide to my patients as well, by being sure that I offer all the treatment options...You never know how much that could change someone's life.* [P4]

PCPs' Practice-Level Changes

Overview

We also examined PCPs' willingness or ability to enact practice-level changes when referring patients to cancer specialists (Table 9). At the posttest assessment, PCPs reported high levels of willingness to enact these changes (mean 4.3, SD 0.6). However, at the 3-month follow-up, PCPs reported lower levels of agreement, although still above midpoint, with statements indicating that they had had these conversations (mean 3.7, SD 0.8). Notably, although 24 (83%) of the 29

participating PCPs completed the course's interactive action plan, none of those interviewed reported printing the plan for future reference, which was provided as a direction in the course. Of the 8 PCPs who were interviewed, 5 (63%) stated that they did not have access to a printer, 2 (25%) mentioned being too busy, and 1 (12%) did not provide an answer.

Table 9. Comparison of pretraining and posttraining and 3-month follow-up scores on the willingness to change survey[a].

Assessments and questions[b]	Scores, mean (SD)
Posttraining survey (n=29)[c]	
"I am willing to make needed changes to whom I refer my patients for cancer care, in order to improve their access to cancer treatment trials."	4.3 (0.7)
"I am willing to talk with colleagues in my practice about needed changes in how we educate our patients with cancer prior to referral."	4.3 (0.7)
"I am willing to talk with colleagues in my practice about needed changes to whom we refer our patients for cancer care, in order to improve their access to cancer treatment trials."	4.3 (0.6)
3-mo follow-up survey (n=28)[d]	
"I have made changes to whom I refer my patients for cancer care, in order to improve their access to cancer treatment trials."	3.9 (1.0)
"I have talked with colleagues in my practice about needed changes in how we educate our patients with cancer prior to referral."	3.7 (1.0)
"I have talked with colleagues in my practice about needed changes to whom we refer our patients for cancer care, in order to improve their access to cancer treatment trials."	3.5 (0.9)

[a]Survey questions were scored on a 5-point scale ranging from 1=strongly disagree to 5=strongly agree.

[b]Cronbach α values for the 3 willingness to change questions was 0.9.

[c]Mean of aggregated willingness to change questions=4.3 (SD 0.6).

[d]Mean of aggregated willingness to change questions=3.7 (SD 0.8).

The qualitative findings further illuminate the underlying factors contributing to PCPs' hesitancy or unwillingness to implement practice-level changes. Most PCPs reported facing systemic barriers, specifically highlighting (1) *limited interprofessional knowledge sharing* and (2) *organizational constraints*.

Limited Interprofessional Knowledge Sharing

First, PCPs cited how limited interprofessional knowledge sharing within their practice environments was a barrier to discussing and enacting change for improving cancer care and referral practices. Instead, PCPs shared, "we kind of just do our own thing" (PCP2). PCPs emphasized that a *lack of collaboration opportunities* made informal or formal discussions within their practice settings scarce:

> *Part of the course involved talking with colleagues about best ways to advocate for our patients and potentially system-change stuff for advising patients about clinical trials...Loved the idea, but...We typically work at our individual desks through lunch and rarely get together and talk...When we do have staff meetings, they are typically putting out the biggest fires then the smallest fires, rather than things that would address this particular topic.* [P5]

This challenge was compounded by *time constraints* as PCPs noted the difficulty in finding moments amid busy schedules to discuss referral practices or share insights from training:

> *In clinic we're just always so busy. There aren't really many opportunities for any major interprofessional collaboration. I mean, if you have a medical question or something, of course, yes, you can ask your colleague, but as far as just sharing information, usually the days are pretty jam-packed.* [P6]

Organizational Constraints

Second, PCPs described being limited by *organizational constraints*, particularly within large institutions where high specialization diminishes the perceived need to refine referral practices:

> *We're at a large academic institution, things are so specialized that we just assume our patients are going to get very high-quality cancer care...often our main objective is to get our patients to the oncologist as quickly as possible.* [P3]

Institutional policies such as set referral practices further reduce the flexibility needed to refine these processes:

> *We do get pretty stuck here with referring. We have oncologists at [my institution] that we refer to and then if they feel they don't have adequate options available, the oncologist usually refers the patient out [to another institution] which is right across the street from us. So, it is sort of a closed community.* [P4]

PCPs further expressed having *limited power* to make changes within their current roles, pointing to obstacles such as systemic barriers and hierarchical structures:

> *The health care system and the clinic schedule, in general, are very overwhelming, and there are a lot of burdens, as the PCP...So, I think it's the system structure, in general, makes it difficult to make the*

> *changes, and it's just not encouraging enough to really motivate me to make the changes.* [P1]

Another PCP cited hierarchical barriers as limiting their ability to effect change:

> *Because I'm a resident, this is a little bit trickier, honestly. I think when I'm attending, I'll have more structural influence on how things are practiced.* [P7]

Finally, *fiscal policies* impacted PCPs' ability to refine their referral practices:

> *Some of our referral practices are going to be based off what type of insurance [a patient has]. Or for us, like I mentioned at [my institution], our clinical decision-making is oftentimes within the realm of what [our institution] is willing to cover.* [P4]

Discussion

Principal Findings

This mixed methods pilot study provides a comprehensive evaluation of an innovative web-based training intervention aimed at enhancing PCPs' knowledge, attitudes, communication, and practices regarding referrals to cancer care and CCTs. The Kirkpatrick evaluation model [46] provided a helpful framework for these evaluation findings. It is widely used in medical education to assess the outcomes of training and learning programs.

Level 1 of the Kirkpatrick evaluation model focuses on user reaction to the training intervention. Participants had high levels of satisfaction with the training intervention and reported high scores and positive comments about various aspects. Although satisfaction is important for participant engagement, it is not necessarily sufficient to produce desired changes.

Kirkpatrick level 2 focuses on learning as the next important outcome. Before the intervention, PCPs demonstrated relatively low levels of CCT knowledge, with a mean score of 55% (SD 17.9%) across 7 knowledge items, consistent with our earlier assessments of PCPs' understanding of clinical trial concepts [40]. We found that PCPs' knowledge about CCTs improved significantly after the intervention and was sustained at the 3-month follow-up, replicating what our team found in a prior study of PCPs in the New York City area [40]. This improvement is particularly important given PCPs' previously self-identified limitations in cancer-specific knowledge [33,41]. Our evaluation also found an improvement in PCPs' self-reported attitudes and beliefs about their role in working with patients with cancer, which was sustained at the 3-month follow-up, as well as willingness to communicate with their patients about CCTs, although this willingness to communicate was not sustained at the 3-month follow-up. However, willingness may be less important than actual behaviors.

With a foundation of change in knowledge, attitudes, and behavioral intentions, Kirkpatrick level 3 examines the impact of the educational intervention on behavior. According to our survey data, PCPs reported using the communication skills taught in the course with a higher percentage of patients about cancer treatment and CCTs at the 3-month follow-up than they did before the training within the context of making an initial referral for cancer care. Of the 7 communication items on the PRCP, only 1 (14%)—*emphasize partnership as patients go through cancer care*—did not show an improvement in scores. There may have been a ceiling effect on this item because the baseline score was already high. With respect to communication skills with patients who had already met with an oncologist, only 2 (29%) of the 7 items on the PRCP saw significant increases, and these 2 items focused specifically on the discussion of CCTs as a potential treatment option. It may be that the other items are not as relevant for a patient who has already had their initial meeting with the oncologist.

Another type of behavior we assessed was participants' willingness to change their referral behavior after the training and the reports of these behavior changes at the 3-month follow-up. As these are slightly different concepts, we did not compare them; however, it was not unexpected to see lower scores on actual behavior change than intention.

Overall, the qualitative data underscored the positive impact that the training intervention had on the participating PCPs in terms of their evaluation of the intervention, their learning, and their behavior change. The qualitative data highlighted ways in which the intervention facilitated a more informed and patient-centered approach to care by increasing PCPs' self-efficacy and confidence.

In addition to these positive outcomes, PCPs expressed some barriers to changing their CCT communication behaviors. They voiced concerns about their perceived lack of cancer expertise despite the course addressing the boundary of what PCPs should be expected to discuss. In our prior work, PCPs expressed a similar reluctance to discuss cancer treatments with patients [40], further highlighting a need to expand education regarding the role of PCPs in encouraging patients to engage in decision-making about their cancer treatment, including the consideration of CCTs. Importantly, the training does not suggest that PCPs determine patient eligibility for specific trials but rather prepares them to initiate supportive, patient-centered conversations that help patients feel empowered to ask questions and engage in screening discussions with their oncology team. PCPs can also support patients by reviewing laboratory or imaging results, helping to translate complex findings into accessible language, and explaining how these may relate to cancer treatment decisions or clinical trial eligibility without making determinations about eligibility themselves.

PCPs also relayed broader systemic challenges in their work settings that hindered making behavioral changes. The interview data helped to explain the lower scores on the willingness to change referral practices, as PCPs discussed the systematic barriers hindering collaborative efforts among health care professionals; these barriers in turn hindered their ability to integrate new knowledge and practices into their clinical settings.

Implications for Practice

Our findings underscore the need for ongoing education to address gaps in the PCPs' knowledge and skills needed to effectively communicate with patients about the potential of

participating in CCTs as a high-quality treatment option. The evaluation of this educational intervention suggests that sustained change in knowledge, attitudes, and behavior can be achieved through an engaging, self-directed web-based intervention. As this training intervention is easily scalable, further dissemination may be able to positively impact quality of care and participation in clinical trials.

Limitations and Future Research

As this was a pilot study, the sample size was small, although not too small to have enough power to detect significant results. Notably, the majority of the participants (n=17, 59%) were trainees working in academic settings, which may influence the generalizability of findings to the broader population of practicing PCPs. Furthermore, their receptiveness to the training and self-reported outcomes may not fully reflect the attitudes and behaviors of more experienced PCPs. Future research using a larger and more diverse sample of practitioners, including both trainees and practicing PCPs, would allow us to look for differences in evaluation metrics among different types of PCPs (residents, practicing physicians, physician assistants, and NPs). This study is also limited by its reliance on self-reported measures. Future research could incorporate patient interviews to provide additional insights into the effectiveness of the intervention from the patients' perspectives. Using larger, more diverse samples to validate the intervention's effectiveness across different practice settings and demographics is also recommended. Furthermore, including more follow-up surveys (eg, at 6 mo and 12 mo) could evaluate the sustained impact of educational interventions on PCPs' knowledge retention and clinical practices over time. While this study identified several systemic barriers that may hinder CCT recruitment, addressing these challenges was beyond the scope of this pilot intervention. Future research should explore multilevel strategies to overcome these barriers and support sustained changes in clinical practice. This study, while focused on oncology referrals, is intended to be proof of concept for an intervention that can be adapted for other disease areas requiring specialist referrals, such as cardiology, rheumatology, and gastroenterology.

Conclusions

This pilot study found that a self-guided, 1-hour web-based training intervention for PCPs improved their knowledge about CCTs as well as their attitudes and beliefs regarding their role in discussing treatment options with patients. The intervention also enhanced PCPs' ability to communicate with patients about CCTs and prepare them for subsequent steps in the referral process, including discussions with specialists. Further testing of the training intervention in a larger sample can lead to future dissemination, with the potential to improve CCT accrual, especially among underrepresented groups. Furthermore, this study underscores the effectiveness of targeted educational interventions in equipping PCPs with the knowledge and confidence to communicate with patients about the potential of trial participation as a high-quality treatment option.

Acknowledgments

This research study was sponsored in part by the Leukemia & Lymphoma Society, AbbVie Inc, Amgen Inc, AstraZeneca Pharmaceuticals LP, and Bristol Myers Squibb.

Authors' Contributions

CLB, MM, ESW, and MS-H conceptualized the study. NDP and A Crowe curated the data. NDP, CLF, CLB, JHL, and ZZ were responsible for formal analysis. CLB, ESW, and MS-H were responsible for funding acquisition. A Crowe was responsible for investigation. CLB, MM, A Crowe, ESW, MS-H, JA, DD, RMV, AN-P, and TSV were responsible for methodology. CLB, A Crowe, and A Cassells were responsible for project administration. CLB was responsible for supervision. NDP and ZZ were responsible for visualization. NDP, CLF, CLB, and A Crowe wrote the original draft. All authors reviewed and edited the manuscript.

Abstract

Background: The evolution of the health care landscape necessitates expanding the roles of pharmacists in patient-centered care to encompass direct patient management, collaborative practice, and preventive service. These responsibilities can be fulfilled by pharmacists through ongoing professional development, in which continuing education (CE) is instrumental to career advancement and improved patient care.

Objective: This cross-sectional study aimed to assess Vietnamese pharmacists' attitudes, perceptions, and preferences regarding CE.

Methods: Participants were recruited via convenience and snowball sampling, after which a validated 42-item questionnaire was administered to them through online and offline channels from December 2024 to February 2025. The data were examined via descriptive statistical analysis using SPSS (version 26.0; IBM Corp). The associations between participant characteristics and attitudinal or perception scores (P<.05) were assessed using 1-way ANOVA with 1000 bootstrap samples.

Results: This study involved 508 pharmacists, most of whom were aged 25 to 30 years (n=197, 38.8%), and the majority held university degrees (n=360, 70.9%). Their mean attitudinal score was 44.4 (SD 5.5), reflecting generally positive attitudes toward CE. However, significant differences in mean attitudinal scores were found across groups categorized by education level, job position, and frequency of overtime (P<.05). More than half of the participants derived good scores on their perceptions of CE, with their preferred CE formats including computer- and internet-based learning, as well as the use of medical search engines. Finally, the pharmacists expressed a strong preference for CE topics focusing on skill development.

Conclusions: The Vietnamese pharmacists exhibited positive attitudes toward CE, favoring flexible learning formats and practical topics. These insights can inform the efforts of policymakers and educators to enhance CE accessibility, improve pharmacists' competencies, and, ultimately, advance patient care.

KEYWORDS

attitudes; continuing education; pharmacist; perception; preferences; Vietnam

Introduction

Continuing education (CE) is defined by the World Health Organization (WHO) as the process of updating professional knowledge after the completion of formal education, enabling health care professionals to maintain and enhance their clinical practice [1]. In 2015, the Accreditation Council for Pharmacy Education expanded its CE framework by introducing the concept of continuing professional development (CPD), which is characterized as a self-directed, ongoing, systematic, and goal-oriented learning process embedded within professional practice [2]. CPD is to describe the broader, holistic process by which health professionals maintain and enhance their knowledge, skills, and performance throughout their careers [2]. This encompasses not only formal learning activities but also self-directed learning, quality improvement initiatives, and mentorship. CE, in contrast, refers specifically to structured, formal educational activities, such as courses, workshops, and conferences, which are a subset of CPD [2,3]. In Vietnam, the Ministry of Health has enacted CE policies since 2013 through

Circular No. 22/2013/TT-BYT, later amended through Circular No. 26/2020/TT-BYT [4]. The Vietnamese primary framework for lifelong learning is designated as CE, which includes various short-term training programs such as professional development courses, continuing medical education, and technology transfer training [5]. From a broader international perspective, this CE framework constitutes a central component of CPD, which encompasses a wider range of formal and informal learning activities. Circular No. 32/2023/TT-BYT requires a minimum of 120 CE credit hours over 5 years from the medical practitioners [6], while Decree No. 163/2025/NĐ-CP, which amends the Law on Pharmacy No. 105/2016/QH13 [7], mandates the completion of at least 8 credit hours every three years by pharmacists [8]. These regulatory distinctions reflect a progressive shift toward role-specific CE requirements for different health care professionals. However, the absence of a globally standardized definition of CE brings about variations in CE awareness, structural implementation, and regulatory frameworks across countries. While the policy framework is being constructed, there is a striking lack of empirical research into how Vietnamese pharmacists themselves perceive and experience this evolving CE system.

CE is pivotal in ensuring the continued competence of health care professionals, ultimately contributing to improved patient care and efficiency in health care systems. Among such professionals, pharmacists need to take on roles that go beyond traditional dispensing duties to include direct patient care, collaborative practice, comprehensive medication management, and preventive care service [9]. This means that CE is essential to updating clinical knowledge and skills. CE is critical for maintaining excellent pharmacy practice and optimizing health care outcomes. Its importance grows as technology advances, evidence-based medicine expands, and health care becomes increasingly globalized. CE is also a prerequisite for the renewal of pharmacist licenses, with specific credit requirements enforced in jurisdictions such as France and the United States. Similarly, the United Kingdom and Canada implement a mandatory CPD approach [10]; European countries, such as Belgium and Norway, link CE completion to salary increments; and the Netherlands, Austria, Switzerland, Spain, Hungary, and Italy treat CE as compulsory for health care professionals [11]. The same holds true for Vietnam, where pharmacists must fulfill CE requirements within 3 years of obtaining their practice certificates to maintain licensure [7].

Accordingly, assessing pharmacists' attitudes, perceptions, and preferences regarding CE is crucial for optimizing training programs and ensuring their relevance to professional practice. In this context, identifying cognitive gaps—defined as the discrepancies between pharmacists' current knowledge, skills, or perceptions and the expected competencies—serves a dual role. First, it enhances the evaluation of attitudes by revealing potential misconceptions or underrecognized needs that may influence learning motivation. Second, it informs how CE programs are designed and delivered. This ensures content and instructional strategies match real-world professional demands and learners' expectations. Several studies have examined these variables in relation to CE participation, particularly in Gulf and Middle Eastern countries [12-18]. These studies demonstrated that most pharmacists recognize CE as essential for professional development. Research in Kuwait indicated that over 60% of pharmacists exhibit positive attitudes toward CE, with workshops being the most preferred modality [16]. Enhancing pharmacists' engagement with CE requires the provision of educational content in preferred formats, such as interactive workshops or structured discussions, to improve knowledge retention and application [12]. Meanwhile, a study in Ethiopia found that 56.5% of pharmacists are unfamiliar with the concept of CE, highlighting regional disparities in CE awareness and accessibility [19].

Despite the growing importance of CE, limited evidence has been derived as to Vietnamese pharmacists' attitudes, perceptions, and preferences regarding CE. To address this deficiency, this study evaluated the aforementioned variables to contribute to essential endeavors to strengthen the national CE system in the country and improve pharmacists' access to CE opportunities. The findings will provide the first crucial evidence to inform the effective development of the national CE system, ensuring it is responsive to its end users. From a global perspective, this research offers a valuable case study of CE implementation in a developing country, contributing comparative insights into how regulatory evolution interacts with professional motivation in a unique Southeast Asian context.

Methods

Study Design

This cross-sectional study involved the distribution of a self-administered questionnaire online and offline from December 2024 to February 2025 to evaluate the attitudes, perceptions, and preferences regarding CE of pharmacists in southeastern Vietnam.

Eligibility and Sample Size

The inclusion criteria were (1) pharmacists employed in both the government and the private sector in the southeastern region of Vietnam, covering the provinces of Binh Phuoc, Binh Duong, Ba Ria-Vung Tau, Dong Nai, and Tay Ninh as well as Ho Chi Minh City, and (2) those proficient in reading and comprehending Vietnamese. Pharmacists who submitted incomplete questionnaires or provided the same answer (eg, only "A") throughout the questionnaire were excluded.

The minimum sample size was determined using the formula used by the WHO [20]:

$$N=(Z\alpha/2)2\times P(1-P)d2$$

where $Z_{\alpha/2}$ denotes normal distribution with a 95% CI ($Z_{\alpha/2}$=1.96), d is an error margin of 0.05, and P denotes the proportion of pharmacists with positive attitudes toward CE (P=.7, based on the pilot study). To account for potential exclusions, an additional 10% was incorporated into the sample size, resulting in a minimum requirement of 355 participants.

Data Collection

Questionnaire Development

A questionnaire was developed following a comprehensive review of the literature [12,13,15,16,19,21,22], after which it was translated on the basis of conceptual equivalence using a four-step process adapted from the WHO [23]: (1) two independent forward translations, of which the initial translation from the original English version into Vietnamese was performed by a professional translator, (2) a review of the first draft by an expert panel comprising five pharmacists operating in different fields relevant to the study, (3) cognitive interviews performed by 25 pharmacists who did not participate in the main research, and (4) revision based on feedback and suggestions. Face and content validity were determined in steps 2 and 3.

A pilot study was performed on a convenience sample of 30 pharmacists to identify ambiguities and ensure that the questionnaire items would yield reliable data. Revisions were made on the grounds of feedback derived during the pilot study. The data collected during this phase were excluded from the analyses carried out in the main research. The reliability of the questionnaire's subcomponents was assessed. The Cronbach α coefficients of the subscales on attitudes toward CE (14 items), perceptions regarding CE (4 items), and satisfaction with CE activities (8 items) were 0.841, 0.821, and 0.897, respectively. These values indicate good internal consistency.

Questionnaire

The final questionnaire comprised 4 sections (42 items): demographic characteristics (10 items), attitudes toward CE (14 items), perceptions regarding CE (4 items), and preferences for CE types and topics (14 items; Multimedia Appendix 1).

The demographics section was intended to assess sex, year of birth, marital status, education level, years of experience, ethnicity, organizational type, job position, frequency of overtime, and number of CE courses attended. The section on attitudes toward CE was adapted from the Jefferson Scale of Physician Lifelong Learning (JSPLL) [16]. The 14 items were ranked using a 4-point Likert scale ranging from 1=*strongly disagree* to 4=*strongly agree*. The sum of the item scores was used to compute the total attitudinal score, which was interpreted and categorized as follows: a total score ranging from 14 to 28 was regarded as indicative of poor attitudes, a score of 29 to 42 was a reflection of fair attitudes, and a score of 43 to 56 represented good attitudes.

In the section on perceptions regarding CE, statements were rated on a 5-point Likert scale ranging from 1=*strongly disagree* to 5=*strongly agree*. The sum of the item scores was used to compute the total perception score, which was interpreted and categorized into 3 levels: a total score ranging from 5 to 10 denoted poor perceptions, a score of 11 to 15 reflected fair perceptions, and a score of 16 to 20 represented good perceptions.

The section on CE preferences covered pharmacists' satisfaction with CE activities (8 items) and their interest in CE topics (6 items), as well as the perceived impact of such education on professional practice and knowledge. The items were rated on a 5-point Likert scale (*strongly disagree*, *disagree*, *neutral*, *agree*, and *strongly agree*).

Measures

Data were collected using both paper-based and online questionnaires. A combination of convenience and snowball sampling was used. Participant recruitment was conducted systematically through multiple channels to enhance sample diversity:

1. On-site recruitment: research team members directly approached pharmacists at a selected variety of community pharmacies and hospitals across the urban and suburban areas of Ho Chi Minh City and the neighboring provinces of Dong Nai and Binh Duong. At these sites, pharmacists were informed about the study and could immediately participate by scanning a QR code to access the online questionnaire or by completing a paper version.
2. Digital outreach: the survey was disseminated through closed professional social media groups and forums dedicated to Vietnamese pharmacists, accompanied by a post explaining the study's purpose.
3. Institutional distribution: the questionnaire was distributed via the official mailing lists of partner universities and professional pharmacist associations in the region. The online questionnaire was administered using Google Forms, with access provided via a QR code and a direct link. To maintain data integrity, the platform was configured to prevent multiple submissions from the same device. As part of the snowball sampling approach, all participants, regardless of recruitment channel, were explicitly encouraged to share the survey link with their pharmacist colleagues.

Data Processing and Statistical Analyses

The initial sample consisted of 550 pharmacists, among whom 42 were excluded because they provided the same response across the questionnaire. The final sample consisted of 508 pharmacists who satisfied the inclusion criteria. The data were entered directly into Microsoft Excel 2019 for cleaning and checking for missing answers.

The SPSS software (IBM Corp) was used to analyze the data. More specifically, descriptive analysis was conducted to determine frequencies and percentages for categorical variables, while means and SDs were calculated for continuous variables. A one-way ANOVA with 1000 bootstrap resamples was carried out to assess differences in the mean attitudinal and perception scores of two or more unrelated groups based on the same continuous dependent variable, with a $P<.05$ considered indicative of statistical significance.

Ethical Considerations

This study adhered to the ethical principles outlined in the Declaration of Helsinki [24] and received approval from the Scientific Research Ethics Committee at Pham Ngoc Thach University of Medicine (1237/TĐHYKPNT-HĐĐĐ). Informed consent was obtained from all participants prior to enrollment. Participants were informed of their right to withdraw at any

time without consequence. Participants did not receive any compensation for their involvement in the study. To ensure confidentiality in the online survey, the study was designed to be fully anonymous; no personally identifiable information (eg, names and IP addresses) was collected. Data were collected via a secure platform with encrypted transmission and stored on a password-protected, encrypted server accessible only to the principal investigators. In compliance with institutional data governance policy, the anonymized dataset will be retained for a period of 5 years following study completion, after which it will be permanently deleted.

Risk of Bias Assessment

A risk of bias assessment was conducted using the Appraisal Tool for Cross-Sectional Studies (AXIS; Checklist 1) [25] to determine whether bias mitigation strategies were implemented in this study rather than the provision of a numerical rating of bias risk. The assessment consisted of 20 questions directed toward the study's design, analysis, and reporting processes, with the response options available being "yes," "no," or "don't know." To enhance objectivity and reduce potential bias, 2 authors independently conducted the assessment.

Results

Sociodemographic Characteristics

Table 1 summarizes the sociodemographic characteristics of pharmacists. The majority of the 508 respondents were female (331/508, 65.2%). The most prevalent age group was 25 to 30 years, who accounted for 38.8% (197/508) of the sample. More than half of the pharmacists were employed in enterprises operating in the private sector (339/508, 66.7%). A substantial proportion of them were single (318/508, 62.6%) and had less than 5 years of professional experience (311/508, 61.2%). Most of the pharmacists attended at least 1 CE course (458/508, 90.2%).

Table . Demographic characteristics (N=508).

	Value, n (%)
Sex	
Male	177 (34.8)
Female	331 (65.2)
Age (y)	
21-24	109 (21.4)
25-29	197 (38.8)
30-34	76 (15)
≥35	126 (24.8)
Marital status	
Single	318 (62.6)
Married	190 (37.4)
Highest level of education	
Elementary or intermediate or college[a]	108 (21.2)
University	360 (70.9)

Never	50 (9.8)
At least 1 course	458 (90.2)

[a]Educational levels in the Vietnamese context: elementary=vocational secondary training; intermediate=technical diploma; and college=3-year college degree.

[b]CE: continuing education.

Attitudes Toward CE

As shown in Table 2, participants generally held positive attitudes toward CE, with a majority (311/508, 61.2%) demonstrating good attitudes and a mean score of 44.4 (SD 5.5). There was a near-universal agreement (457/508, 89.9% combined) with the statement “I take every opportunity to gain new knowledge/skills.” A notable proportion of respondents reported disengaging from routine professional activities, with 25.2% (128/508) disagreeing that they “routinely attend meetings of pharmacy organizations” and 31.9% (162/508)

disagreeing that they “read professional journals at least once every week.”

Table . Attitudes toward continuing education (CE)[a].

Item	Pharmacists' attitude	Likert scale, n (%)				Value, mean (SD)
		1[b]	2[c]	3[d]	4[e]	
A1	Searching for the answer to a question is in and by itself rewarding.	2 (0.4)	33 (6.5)	271 (53.3)	202 (39.8)	3.3 (0.6)
A2	CE is a professional responsibility of all pharmacists.	4 (0.8)	46 (9.1)	263 (51.8)	195 (38.3)	3.3 (0.7)
A3	I enjoy reading articles in which issues of pharmacy are discussed.	2 (0.4)	56 (11.0)	310 (61.0)	140 (27.6)	3.2 (0.6)
A4	I routinely attend meetings of pharmacy organizations.	11 (2.2)	128 (25.2)	267 (52.6)	102 (20.0)	2.9 (0.7)
A5	I read professional journals at least once every week.	26 (5.1)	162 (31.9)	246 (48.4)	74 (14.6)	2.7 (0.8)
A6	I routinely search for computer databases to find out about new developments in my specialty.	11 (2.2)	60 (11.8)	297 (58.4)	140 (27.6)	3.1 (0.7)
A7	I believe that I would fall behind if I stopped learning about new developments in pharmacy.	2 (0.4)	16 (3.2)	251 (49.4)	239 (47.0)	3.4 (0.6)
A8	One of the important goals of Faculties of Pharmacy is to develop students' lifelong learning skills.	3 (0.6)	32 (6.3)	258 (50.8)	215 (42.3)	3.3 (0.6)
A9	Rapid changes in therapeutics require constant updating of knowledge and the development of new professional skills.	2 (0.4)	13 (2.6)	256 (50.4)	237 (46.6)	3.4 (0.6)
A10	I always make time for self-directed learning, even when I have a busy work schedule and other obligations.	7 (1.4)	89 (17.5)	306 (60.2)	106 (20.9)	3.0 (0.7)
A11	I recognize my need to constantly acquire new professional knowledge.	3 (0.6)	24 (4.7)	269 (53.0)	212 (41.7)	3.4 (0.6)
A12	I routinely attend CE courses to improve patient care.	14 (2.7)	121 (23.8)	263 (51.8)	110 (21.7)	2.9 (0.7)

Item	Pharmacists' attitude	Likert scale, n (%)				Value, mean (SD)
		1[b]	2[c]	3[d]	4[e]	
A13	I take every opportunity to gain new knowledge/skills that are important.	5 (1.0)	46 (9.1)	321 (63.1)	136 (26.8)	3.2 (0.6)
A14	My preferred approach in finding an answer to a question is to search for the appropriate computer databases.	6 (1.2)	47 (9.3)	285 (56.0)	170 (33.5)	3.2 (0.7)

[a]Poor attitude: 4/508 (0.8%); fair attitude: 193/508 (38%); and good attitude: 311/508 (61.2%). The average total score using bootstrap (1000 times) was 44.4 (SD 5.5).

[b]1: strongly disagree.

[c]2: disagree.

[d]3: agree.

[e]4: strongly agree.

Perceptions Regarding CE

Table 3 shows the findings related to the participants' perceptions regarding CE. More than half (288/508, 56.7%) held good perceptions, 39.4% (200/508) exhibited fair perceptions, and 3.9% (20/508) showed poor perceptions. Their mean perception score was 15.6 (SD 2.7). The majority of the pharmacists agreed and strongly agreed with the assertion that CE helps increase knowledge (434/508, 85.4%). Over 60% of the respondents agreed or strongly agreed with the remaining statements.

Table . Perceptions regarding continuing education (CE)[a].

Item	Pharmacist's perception	Likert scale					Value, mean (SD)
		1[b]	2[c]	3[d]	4[e]	5[f]	
P1	The value of the employer places on his participation in CE	8 (1.6)	41 (8.1)	136 (26.8)	235 (46.2)	88 (17.3)	3.7 (0.9)
P2	Your interest in/value of CE	6 (1.2)	12 (2.4)	110 (21.6)	283 (55.7)	97 (19.1)	3.9 (0.8)
P3	CE affects the way you practice	9 (1.8)	40 (7.9)	124 (24.4)	239 (47.0)	96 (18.9)	3.7 (0.9)
P4	CE helps increase your knowledge	5 (1.0)	3 (0.6)	66 (13.0)	230 (45.3)	204 (40.1)	4.2 (0.8)

[a]Poor perception: 20/508 (3.9%); fair perception: 200/508 (39.4%); and good perception: 288/508 (56.7%). The average total score using bootstrap (1000 times) was 15.6 (SD 2.7).

[b]1: strongly disagree.

[c]2: disagree.

[d]3: neutral.

[e]4: agree.

[f]5: strongly agree.

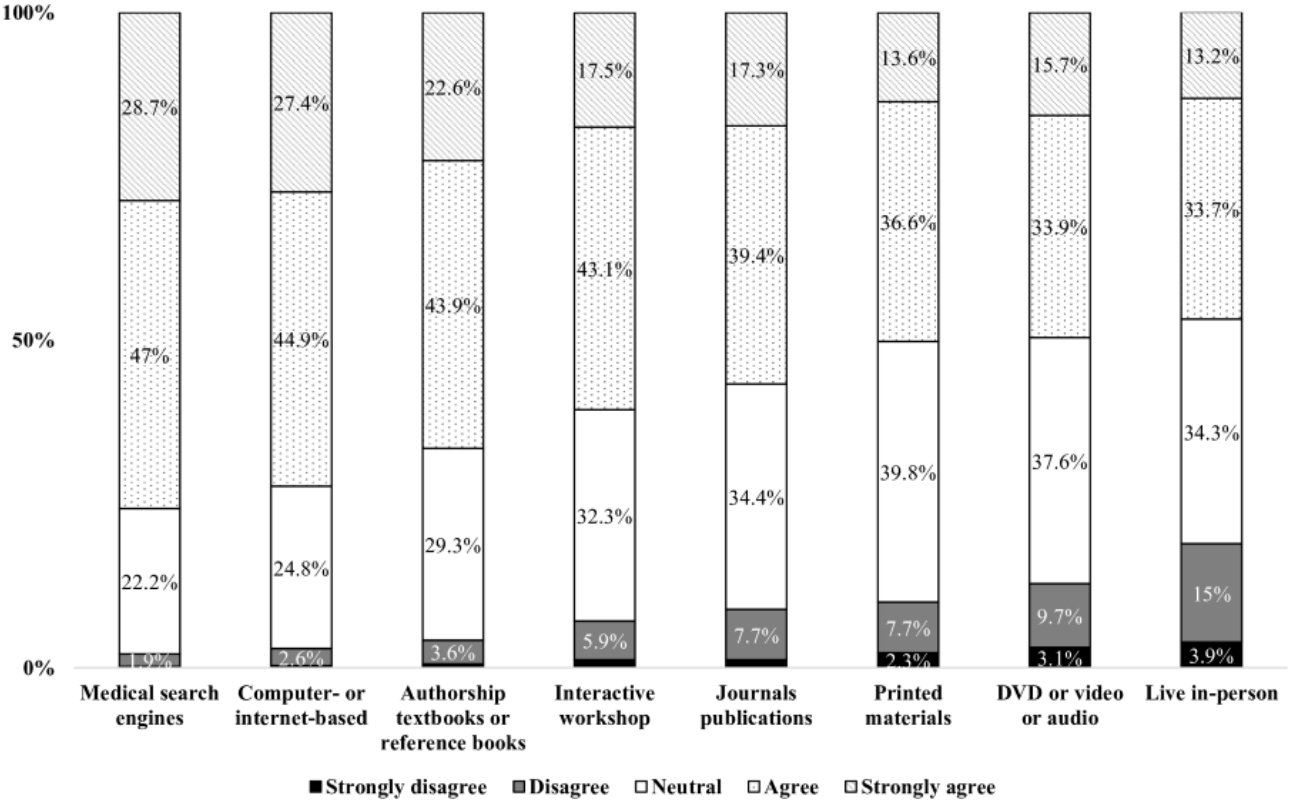
Preferences Regarding CE

Figure 1 illustrates the participants' levels of satisfaction with CE activities. The majority preferred computer- or internet-based CE (367/508, 72.2% agreed or strongly agreed with this option) and medical search engines (385/508, 75.7% agreed or strongly agreed with this option). The option of live in-person learning received mixed feedback from participants: 15% (76/508) of the respondents disagreed with the aforementioned options, 34.3% (174/508) exhibited neutrality, and 46.9% (238/508) expressed agreement. The pharmacists showed little preference for DVD- or video- or audio-based learning, with 9.7% (49/508) disagreeing and 37.6% (191/508) showing neutrality with

respect to this option. Textbooks or reference books were well received, with 43.9% (223/508) indicating preference and 22.6% (115/508) showing a strong preference for these materials.

Pharmacists' preferences for CE topics were assessed, with the most favored issue being results on skill development (415/508, 81.7% agreed or strongly agreed with this option), followed by innovations in pharmacy practice (399/508, 78.5% agreed or strongly agreed with this option), pharmacy management concepts (398/508, 78.3% agreed or strongly agreed with this option), and innovations in disease management (397/508, 78.1% agreed or strongly agreed with this option). The least preferred topic was innovations in pharmaceutical manufacturing (303/508, 59.6% agreed or strongly agreed with this option).

Figure 1. Pharmacists' level of satisfaction with continuing education activities.



Evaluation of Mean Scores for Perceptions, Attitudes, and Impact in Relation to Sociodemographic and Professional Characteristics

The mean attitudinal and perception scores of the pharmacists pointed to significant differences between groups with varying levels of education (43.3, SD 5.4 vs 44.6, SD 5.4 or 45.3, SD 6.0 for mean attitudinal score, *P*=.048 and 15.1, SD 2.6 vs 15.7, SD 2.8 or 15.6, SD 2.5 for mean perception score, *P*=.046; Table 4). Significant differences in mean attitudinal scores were found between respondents categorized by job positions (44.2, SD 5.3 vs 45.7, SD 6.2; *P*=.04) and frequency of overtime (44.2, SD 5.5 vs 45.9, SD 5.0; *P*=.03).

Table . Comparison of mean attitudinal and perception scores in relation to sociodemographic and professional characteristics.

	Attitude		Perception	
	Mean (SD)	*P* value[a]	Mean (SD)	*P* value[b]
Age (y)		.59		.46
21-24	44.9 (5.9)		15.9 (2.4)	
25-29	44.1 (5.1)		15.6 (2.7)	
30-34	44.7 (5.9)		15.3 (2.7)	
≥35	44.3 (5.3)		15.4 (2.9)	
Gender		.74		.14[c]

[a]The italicized *P* values are used to denote statistical significance, following conventional academic practice. A *P* value <.05 indicates that the observed difference between groups is statistically significant.

[b]ANOVA test.

[c]Welch test.

[d]Educational levels in the Vietnamese context: elementary=vocational secondary training; intermediate=technical diploma; and college=3-year college degree.

[e]CE: continuing education.

Risk of Bias Assessment

The risk of bias assessment indicated a low risk across all evaluated domains (Checklist 1). The study had clearly defined objectives, an appropriate design and sampling strategy, and robust data analysis methods, although potential nonresponse bias was noted.

Discussion

Main Findings

This study evaluated the attitudes, perceptions, and preferences of 508 southern Vietnamese pharmacists regarding CE. Most of the respondents reported participation in at least 1 CE course. The majority demonstrated positive attitudes and considerably favorable perceptions of CE. Computer- or internet-based CE and the use of medical search engines were the preferred learning methods of the participants. The mean attitudinal scores varied significantly depending on education level, job position, and overtime frequency. Significant differences in the mean perception scores were found across groups with varying education levels.

Sociodemographic Characteristics

Most of the pharmacists were aged between 25 and 30 years (197/508, 38.8%), followed by those >35 years (126/508, 24.8%). The mixed methods approach to data collection, that is, the administration of both online and offline surveys, was intended to achieve an age-balanced sample. The online survey streamlined questionnaire distribution, facilitated data management, and enhanced engagement by allowing the respondents to conveniently complete the survey on their phones or computers from various locations. However, online surveys are often more accessible to younger individuals, potentially leading to an age imbalance due to sampling bias, low response rates, and data quality concerns [26,27]. To mitigate these limitations, we administered the survey offline, which also enabled direct interaction with the participants [26] and the provision of clarifications, thereby improving response accuracy and increasing participation among older pharmacists. Combining these methods enabled us to maximize data collection efficiency while ensuring a more representative age distribution.

The majority of the pharmacists hold university degrees. Similarly, Adhikari et al [28] reported that 60% of their pharmacist participants completed university education, whereas Poudel et al [29] indicated that 70% of their respondents acquired college diplomas or equivalents. According to Circular No. 22/2011/TT-BYT in Vietnam Law, most of the main divisions in the pharmacy departments of special-, first-, and second-grade hospitals require pharmacists to have a university degree or higher to practice [30]. Most of the pharmacists in the current work have attended at least 1 CE course, while the remaining individuals may have been newly graduating pharmacists who had not obtained a practicing certificate or taken CE classes. As the field of pharmacy continues to advance globally, pharmacy practitioners feel the need to keep in step with innovations to improve their skills in providing better care to patients [28]. Without CE engagement, pharmacists risk falling behind with regard to new drug developments, treatment protocols, and safety guidelines. This knowledge gap can directly impact the quality of patient care, leading to inaccurate medication counseling, increased potential for prescription errors, and compromised treatment outcomes. High-income countries require pharmacists to pursue CPD to maintain licensure and ensure exceptional patient care—this means frequent and regular participation in CE. As shown by Tjin et al [31], Dutch pharmacists participate in CE for an average of 27.0 hours over 11 months and prefer face-to-face learning (85.5%) over e-learning (13.8%).

Attitudes Toward CE

The questionnaire used in the present research included closed-ended items taken from the JSPLL [32], which has been used in similar studies conducted in Saudi Arabia [16] and Nigeria [21]. The JSPLL is the first instrument intended specifically to measure lifelong learning among health care providers with supporting psychometric evidence [32]. The majority demonstrated positive attitudes, aligning with the findings of Aldosari et al [16]. Specifically, 61.2% showed good attitudes regarding CE, 38% had fair attitudes, and only 0.8% indicated poor attitudes. These findings are consistent with those of Aldosari et al [16], who reported that 60%, 39%, and 1% of the pharmacists participating in their study showed good, fair, and poor attitudes, respectively [16]. The mean score of 44.4 in the present research pointed to overall good attitudes toward CE among the Vietnamese pharmacists. Specifically, most of them agreed that CE is an essential professional commitment for all pharmacists and that failing to keep up with pharmaceutical advancements could hinder their professional growth. Although the attitudinal distribution was similar to the findings of Aldosari et al [16], the underlying drivers for these attitudes are likely fundamentally different, highlighting the influence of the national context. The Vietnamese context lacks a fully institutionalized framework [3]. Therefore, the similarly favorable attitudes observed among pharmacists in this study are arguably more indicative of a strong intrinsic motivation for professional development. This suggests that, even in the absence of a coercive system, Vietnamese pharmacists personally value lifelong learning. This intrinsic drive is a response to the pressures and opportunities within an evolving national health care system, where rapid advancements and increasing patient expectations create a professional imperative to stay current. This finding underscores that the Vietnamese pharmacist workforce possesses a foundational readiness for CE, which could be powerfully leveraged as the formal system continues to develop. However, the greater proportion of them neither routinely participated in pharmacy organizational meetings nor engaged in weekly readings of professional journals. These results are consistent with the findings of Aldosari et al [16]. Acknowledging the responsibility to engage

in CE and lifelong learning is essential for pharmacists to maintain professional competence and deliver outstanding patient care as part of a patient-centered approach. The limited participation of pharmacists in professional organizational meetings and the low frequency of reading professional journals may be attributed to time and cost constraints. In addition, these types of CE may be less prevalent due to the increasing preference for internet-based resources. To solve these issues, professional meetings should be widely promoted at pharmacists' workplaces and scheduled with suitable time and cost considerations. The availability of professional journals should also be increased to enhance attitudes. In fact, increasing access to professional journals enhances attitudes by providing up-to-date research and expert insights that shape a deeper understanding of the field [33]. This exposure encourages critical thinking and helps professionals refine their practices, fostering more informed and positive attitudes.

Pharmacists with advanced degrees are often exposed to academic environments that promote evidence-based practice, critical thinking, and reflective learning, which enhance their appreciation of CE as an essential component of professional competence [34,35]. They also tend to possess stronger career motivation and clearer professional development goals, fostering a greater intrinsic drive for lifelong learning [36,37]. Their advanced level of education may also provide a stronger knowledge base, reducing uncertainty and fostering a more positive attitude of CE participation as a marker of professional identity and responsibility [38]. Consequently, pharmacists with high educational attainment tend to demonstrate stronger commitment to continuous learning than those with low qualifications [39]. The favorable attitudes among pharmacists in managerial positions align with the findings of Darwish et al [17], who reported greater awareness among pharmacist managers in Jordan. Managers often bear supervisory and decision-making responsibilities, which enhance their recognition of CE as essential for maintaining professional competence and ensuring the quality of pharmaceutical services [35,40]. Moreover, such positions may cultivate stronger intrinsic motivation toward continuous learning, as these individuals perceive CE as a pathway for leadership development and professional recognition [38]. Their access to institutional resources and professional networks could also facilitate participation in CE activities. These findings suggest that interventions to improve attitudes may need to be tailored, for instance, by emphasizing practical benefits for frontline staff and leveraging the advocacy of managerial and postgraduate champions.

Perceptions Regarding CE

The study found that Vietnamese pharmacists held considerably favorable perceptions of CE, with most agreeing that it increases their knowledge. This aligns with global trends observed in studies from Saudi Arabia [15] and Lebanon [22], suggesting a universal recognition of CE's core purpose among pharmacists. A notable point of divergence, however, lies in the perceived institutional support. While only 63.5% of the respondents agreed that their employers fully recognize the value of CE, this rate is substantially higher than the rates reported in the earlier international studies [15,22]. This divergence cannot be explained by regulatory mandate alone, as CE is compulsory in all three contexts. Instead, it likely reflects the unique and evolving state of Vietnam's CE landscape. Unlike the more established systems in other countries, Vietnam's framework has undergone significant recent reforms aimed at enhancing regulatory enforcement and accessibility [4,14]. This period of active development and the concurrent national focus on upgrading health care professional competency have created a distinctive environment. This has potentially fostered a stronger, more tangible sense among Vietnamese pharmacists that CE is becoming increasingly relevant and valued within their specific professional ecosystem, even if employer recognition is not yet universal.

In Vietnam, most pharmacists recognize CE activities as essential for enhancing their professional knowledge and skills [41]. Similarly, in their identification of pharmacists' professional learning needs in support of expanded roles in practice, Schindel et al [42] discovered that most of the respondents participate in CE activities out of personal interest or due to job requirements. Interestingly, we found that a considerable number of pharmacists disagreed with the idea that CE affects the way in which these professionals practice. This suggests that pharmacists pursue CE to maintain licensure rather than educate themselves on topics that can be applied to their current work. Therefore, understanding pharmacists' preferences and ensuring that CE topics align with their practice is a critical mission for policy makers and health care institutions.

A critical finding of this study is the apparent discrepancy between the broadly positive attitudes toward CE and the reported low engagement in specific activities like routine journal reading or organizational meeting attendance. This reflects the practical barriers within the Vietnamese context. The positive attitudes likely capture a genuine desire for knowledge and professional growth. However, the translation of this desire into consistent action may be hindered by significant systemic and personal obstacles. These could include overwhelming clinical workloads and limited paid leave, which restrict time for self-directed learning; financial constraints, where the cost of journal subscriptions or conference fees is prohibitive; a perceived lack of immediate relevance of available content to daily practice challenges; or limited access to resources, particularly for pharmacists in rural or community settings. This gap highlights that fostering positive attitudes is only the first step. For CE to be truly effective, systemic changes, such as providing protected time for learning, subsidizing costs, and ensuring the practical relevance of content, are necessary to enable pharmacists to convert their positive attitudes into consistent professional development behaviors.

Preferences Regarding CE

Computer- or internet-based and medical search engines were the preferred methods of learning by the Vietnamese pharmacists, as with other studies [16,21]. However, the mean scores for these resources were higher than those derived by Alharthi et al [15], suggesting that pharmacists in Vietnam prefer participating in online CE programs. This preference, in

turn, may be attributed to the flexibility of online offerings, allowing pharmacists to complete lessons at their convenience. They also reduce or eliminate program and travel costs, making them more accessible options [41,43]. Economic and financial factors may significantly influence the strong preference for online CE among pharmacists in this study. In resource-constrained settings like Vietnam, traditional in-person CE often entails direct costs such as travel, accommodation, registration fees, and indirect costs related to time away from work. For many pharmacists—particularly those working in rural or underfunded health facilities—these costs can be prohibitive. Online CE offers a cost-effective alternative, eliminating travel expenses and reducing opportunity costs, thereby making professional development more financially accessible. In addition, the increasing availability of free or low-cost online CE programs offered by hospitals, universities, and professional associations further reduces financial barriers. This shift in learning modality can also be interpreted as a response to broader economic pressures. Health care professionals, especially in low- and middle-income countries, often face modest salaries and must finance their own continuing education. These findings contribute to the growing body of literature on digital health education by emphasizing the role of economic factors in shaping learning preferences. From a policy perspective, this highlights the need for targeted investment in digital infrastructure and the subsidization of online CE initiatives. Such measures would not only improve access to education but also help build a more resilient and up-to-date health care workforce. In contrast, Al-Kubaisi et al[12] and other researchers [18,28,44] found that live in-person CE is favored over online learning. This preference stems from the fact that face-to-face classes allow for peer discussions, direct interactions with instructors, and the immediate clarification of questions, which enhance understanding and knowledge retention [28,45].

Most of the pharmacists in our study preferred topics related to skill development, innovations in pharmacy practice, and pharmacy management. These findings are consistent with Iskandar et al.'s study, which showed greater interest in pharmaceutical management than in any other matters [22]. In Dai et al's research [41], the majority of the participants were inclined to learn about regulations related to drug business operations (75.8%) and pharmaceutical practice (73.5%).

A larger proportion of pharmacists agreed that obtaining certification for a job and commitment to lifelong learning were important reasons for engaging with CE courses. Al-Kubaisi et al [12] found that the main motivation for CE participation among pharmacists is the relevance of a given topic. Therefore, incorporating more engaging and relevant subjects into CE programs can encourage greater participation. The development of future CE programs should focus on comprehensiveness and effectiveness in bridging the divide between theoretical learning and real-world application. CE topics must help pharmacists improve their competencies and abilities as they carry on with their practice. The applicability of what they learn from CE to their work would increase their interest in and motivation for such training. The organization of CE courses must also align with pharmacists' interests, especially those offered on the web. This goal can be achieved by enhancing engagement and support from employers and by advancing collaborative work between pharmacy regulators and CE providers, which can define the skills and competencies that need to be reinforced and offer CE programs intended for self-directed, lifelong learning.

Strengths of the Study

This study has several notable strengths. As the first study in Vietnam to explore pharmacists' attitudes, perceptions, and preferences regarding CE, it addresses a substantial gap in research and delivers novel insights into an underexamined aspect of pharmacy practice. By identifying the key attitudes, perceptions, and preferences that influence pharmacists' participation in CE, the study derives evidence that policymakers and health care institutions can use to design targeted CE programs that align with pharmacists' needs and preferences, ultimately enhancing participation rates and improving professional competencies. By offering evidence-based recommendations, this study contributes to the development of more effective CE initiatives, ensuring that they are accessible, relevant, and promotive of pharmacists' professional growth. Overall, the implication is support for improvements in pharmacy practice and health care quality in Vietnam.

Limitations

The limitations of this research are likewise worth discussing. First, the use of the JSPLL, which was originally designed to assess physicians' attitudes toward CE in the United States, may not have fully captured the perspectives of the Vietnamese pharmacists. Although the questionnaire has been validated and culturally adapted for Vietnamese people, the tool may not have reflected unique local professional development needs and contextual factors. The potential impact of this is a measurement bias that could have led to an underestimation of certain attitudes or perceptions highly specific to the Vietnamese pharmacy context. Consequently, some of the nuanced barriers or motivators for CE in Vietnam might remain unidentified. Second, the structure of the questionnaire may have limited the scope of responses, particularly in sections where predefined answer options were provided for CE preferences (eg, reading journal articles, and attending conferences or seminars). This limitation could have constrained the depth of insights into preferred learning methods and emerging CE trends. Third, since the study used a self-administered questionnaire, there was potential for response bias, wherein the participants may have tended to agree with the statements because this was expected or favorable rather than reflecting their true attitudes and behaviors. The likely impact is an inflation of positive scores on attitudinal items, and the prevalence of negative or ambivalent attitudes is likely underreported. Fourth, the study used a web-based questionnaire, which could not ensure that responses were exclusively from the target population, as anyone could access the QR code and complete the form. To address this limitation, a screening question was included to confirm whether the respondent was a pharmacist. The primary mode of data collection was a web-based questionnaire, which, even when combined with paper-based options and on-site recruitment, poses a potential risk of selection bias. The risk of selection bias arises from the fact that internet access is unevenly

distributed over the population [46]. Under-coverage occurs because people without internet access are excluded from the survey. It is possible that the sample may still be somewhat skewed toward younger, more technology-comfortable pharmacists who are inherently more receptive to digital surveys. While the mixed mode approach, particularly the on-site paper-based option, was implemented to counter this effect, it cannot be ruled out entirely. Therefore, the generalizability of the findings, especially regarding attitudes toward digital CE, should be interpreted with this potential bias in mind. Fifth, this study was based on quantitative survey methodology. While this approach was effective for identifying and statistically analyzing trends, attitudes, and perceptions across our sample, the closed-ended nature of the questions (including Likert scales and multiple-choice formats) inherently limits the depth of exploration into the underlying motivations, personal narratives, and nuanced contextual factors behind the responses. A qualitative research design would be necessary to provide that deeper layer of understanding. Finally, this study did not examine differences among pharmacists working in various practice settings (eg, community, hospital, and industry). By treating pharmacists as a homogeneous group, it may have obscured significant variations in learning needs, motivations, and perceived barriers. This limits the practical use of the findings for designing targeted CE programs, as the specific, setting-dependent drivers of engagement remain unexplored.

Future Research

Future research can expand this work by recruiting a nationally representative sample, including pharmacists from various regions of Vietnam, to better capture geographic and demographic differences in CE participation and preferences. Qualitative methods, such as in-depth interviews or focus group discussions, can help researchers more exhaustively illuminate the barriers to and motivators of engagement in CE. Studies should also focus on evaluating the effectiveness of different CE methods, identifying the most impactful learning formats so that they enhance pharmacists' knowledge, skills, and professional practice. Future studies should investigate the factors that influence these preferences to enable the design of more targeted and effective CE programs. Conducting subgroup analyses across different practice settings is necessary. Investigating the specific CE needs and preferences of pharmacists in community, hospital, industrial, and regulatory roles would provide invaluable data for designing highly targeted and effective CE programs that are responsive to the unique demands of each sector. Finally, longitudinal studies assessing the long-term impact of CE on pharmacists' career progression, clinical decision-making, and patient outcomes would be valuable in shaping future CE policies and programs.

The findings of this study offer clear, actionable guidance for optimizing CE in Vietnam. While the policies mandate CE, understanding the pharmacists' views and attitudes toward it is essential for improving both compliance and voluntary participation. For policymakers, the results underscore the need to move beyond a one-size-fits-all regulatory approach. The strong preference for digital and self-directed learning modalities supports the strategic expansion and accreditation of high-quality online CE platforms, which can improve accessibility for pharmacists across diverse geographic and practice settings. For pharmacy educators and training institutions, the high demand for topics in skill development, pharmacy management, and innovative practice indicates a critical need to shift content away from purely theoretical knowledge toward applied, practical competencies. Curricula should be co-designed with practicing pharmacists to ensure relevance. Furthermore, the significant intrinsic motivation observed suggests that promotional campaigns should frame CE not just as a mandatory requirement, but as a valuable tool for career advancement and professional excellence. By aligning program design with these evidence-based preferences, stakeholders can significantly enhance engagement and the overall impact of continuing professional development in Vietnam.

Conclusions

This study found that although most of the pharmacists exhibited positive attitudes and perceptions regarding CE, a substantial proportion had not participated in CE activities, indicating a gap between awareness and engagement. Variations in preferences for CE formats and topics underscore the need for tailored programs. Addressing participation barriers and aligning CE initiatives with pharmacists' professional needs may enhance engagement, support professional development, and improve patient care in Vietnam.

Abstract

Background: Learning health systems (LHS) have the potential to use health data in real time through rapid and continuous cycles of data interrogation, implementing insights to practice, feedback, and practice change. However, there is a lack of an appropriately skilled interprofessional informatics workforce that can leverage knowledge to design innovative solutions. Therefore, there is a need to develop tailored professional development training in digital health, to foster skilled interprofessional learning communities in the health care workforce in Australia.

Objective: This study aimed to explore participants' experiences and perspectives of participating in an interprofessional education program over 13 weeks. The evaluation also aimed to assess the benefits, barriers, and opportunities for improvements and identify future applications of the course materials.

Methods: We developed a wholly online short course open to interdisciplinary professionals working in digital health in the health care sector. In a flipped classroom model, participants (n=400) undertook 2 hours of preclass learning online and then attended 2.5 hours of live synchronous learning in interactive weekly Zoom workshops for 13 weeks. Throughout the course, they collaborated in small, simulated learning communities (n=5 to 8), engaging in various activities and problem-solving exercises, contributing their unique perspectives and diverse expertise. The course covered a number of topics including background on LHS, establishing learning communities, the design thinking process, data preparation and machine learning analysis, process modeling, clinical decision support, remote patient monitoring, evaluation, implementation, and digital transformation. To evaluate the purpose of the program, we undertook a mixed methods evaluation consisting of pre- and postsurveys rating scales for usefulness, engagement, value, and applicability for various aspects of the course. Participants also completed identical measures of self-efficacy before and after (n=200), with scales mapped to specific skills and tasks that should have been achievable following each of the topics covered. Further, they undertook voluntary weekly surveys to provide feedback on which aspects to continue and recommendations for improvements, via free-text responses.

Results: From the evaluation, it was evident that participants found the teaching model engaging, useful, valuable, and applicable to their work. In the self-efficacy component, we observed a significant increase (P<.001) in perceived confidence for all topics, when comparing pre- and postcourse ratings. Overall, it was evident that the program gave participants a framework to organize their knowledge and a common understanding and shared language to converse with other disciplines, changed the way they perceived their role and the possibilities of data and technologies, and provided a toolkit through the LHS framework that they could apply in their workplaces.

Conclusions: We present a program to educate the health workforce on integrating the LHS model into standard practice. Interprofessional collaborative learning was a major component of the value of the program. This evaluation shed light on the multifaceted challenges and expectations of individuals embarking on a digital health program. Understanding the barriers and facilitators of the audience is crucial for creating an inclusive and supportive learning environment. Addressing these challenges will not only enhance participant engagement but also contribute to the overall success of the program and, by extension, the broader integration of digital health solutions into health care practice and, ultimately, patient outcomes.

Introduction

As health care delivery evolves in complexity and scope, the need for systems that promote continuous learning and adaptation is paramount. The learning health systems (LHS) concept has emerged as a transformative framework that bridges clinical practice with ongoing research, ensuring that health care institutions remain at the forefront of scientific and patient-centered care advancements [1,2]. Central to the LHS paradigm is the notion that data contribute to a broader system of knowledge and is used to refine care practices in real time [1,3]. Achieving this idea requires an interdisciplinary workforce adept in information systems, informatics, data interrogation, quality improvement and implementation methods, and system-based practice, to be able to use the existing data to inform future care [3]. Moreover, health care transformation such as this requires the skills of various professions working together towards solving these complex problems [4,5].

While there are previous studies that have described their LHS-focused programs, few have robustly evaluated the purpose of their implementations. Furthermore, other programs have focused on specific cohorts of participants such as PhD students [6], postdoctoral students [7,8], and clinical fellows [9-11] in the United States [6,9-11] and Canada [7]. Our study adds new insights to the literature given the interprofessional nature of the program, as well as its design (flipped classroom, working groups) and delivery (wholly online). To our knowledge, few programs have involved teaching a structured curriculum [8,12], while other programs have involved mainly project-based work and on-the job learning [7,10,13,14].

For such a dynamic and integrated approach to take root, educating the next generation of health care professionals about LHS principles is crucial. While the theoretical foundation of LHS has been well established, there has been a paucity of research evaluating the efficacy and impact of educational interventions centered on LHS. We developed a 13-week short course called Applied Learning Health Systems, which commenced in September 2021 and has now been running for 2 years [15]. The program is open to all professionals working in the health care setting—clinical and nonclinical—and focuses on interdisciplinary work; the LHS concept can be taught to both digital health and informatics generalists and specialists, clinicians and nonclinicians, front-line workers, and upper management [15].

As institutions increasingly incorporate LHS into their curricula, understanding the nuances of its educational translation becomes vital. This research aims to evaluate the motivations, experiences, and perceptions of participants learning in a collaborative learning environment, as well as the effectiveness, confidence, applicability, challenges, and outcomes of LHS education, providing insights that will shape pedagogical strategies and potentially influence the future of health care education.

The purpose of this paper is to explore participants' experiences and perspectives of participating in a wholly online interprofessional education program. This evaluation also aimed to assess the benefits, barriers, and opportunities for improvements, and identify future applications of the course materials to the participants' workplace endeavors. We will also discuss the implementation, feasibility, and outcomes of the program which aimed to foster LHS skills in the Australian health care workforce through didactic coursework, interactive workshops, and collaborative learning. By describing our program and its 2-year evaluation, we believe that current and future educators can learn from our experience when building their own programs. Additionally, our paper will contribute to the emerging education literature on how to foster LHS through workforce development and education. Compared to previous publications on LHS education programs, we are contributing novel insights to this literature through new perspectives based on our location (ie, Australia), the health system data infrastructure (ie, recent electronic medical record [EMR] implementations and digital immaturity), and our participants (ie, diverse interprofessionals). While we have had early successes, we also wish to highlight the obstacles we encountered and how we refined our approach in response. Our results will be valuable to other educators as they consider similar endeavors.

Methods

Study Design and Recruitment

We undertook a mixed methods study consisting of both quantitative and qualitative data collection methods. Surveys were conducted precourse, throughout teaching, and postcourse. The surveys consisted of metric scales, qualitative scales, and open free-text boxes. Participation in the research project was via opt-out. Therefore, all enrolled participants were eligible to participate in the project voluntarily, unless they chose not to. There were several modes of recruitment for the course itself. These included reaching out to existing precinct partners who undertook internal expression of interest recruitment processes to sponsor a number of places, social media advertising on X and LinkedIn, Google search search engine optimization, and university students undertaking electives or formal university-accredited certificates.

Ethical Considerations

This study was approved by the University of Melbourne ethics committee (project ID 22641). In certain parts of the study, participants had the option to opt out (eg, surveys) or provide consent to participate (eg, interviews). In terms of informed consent, participants were provided with a plain language statement describing the purpose and design of the study.

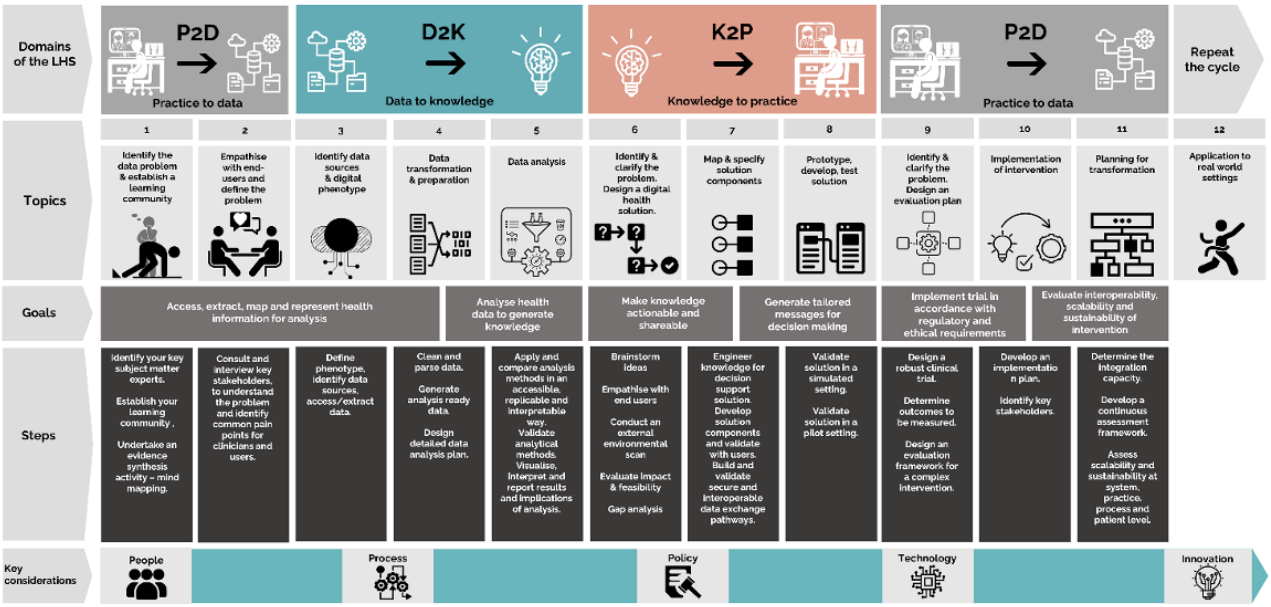
Participants were notified that participation was voluntary and were given the option to opt out. For privacy and confidentiality, data were completely deidentified and only aggregate data were analyzed and presented. Data were housed on secure University of Melbourne single sign-on Qualtrics servers and restricted access to OneDrive servers. As participation was completely voluntary, no compensation was provided to participants; however, participants in the pilot version of the course were given free scholarship admission in return for their feedback.

The Program

The LHS short course was created by the University of Melbourne Centre for Digital Transformation of Health, a high-research academic institution with existing partnerships with local and regional hospitals and primary care networks. The course has been delivered 5 times to 400 participants. Each iteration of the short course involved a 13-week online course revolving around LHS and was delivered wholly online, by diverse instructors, in a flipped classroom learning format. Participants were from a range of backgrounds, including working professionals in health care, PhD research students, masters-level university students, and consumers. The course structure involves 3 hours of weekly individual asynchronous prereadings, followed by 2.5 hours of weekly workshops. Each week participants work through activities associated with a threaded diabetes case scenario, in their assigned interprofessional working group [15].

We mapped the stages of the LHS system onto a swim lane diagram and created specific learning objectives for skills and knowledge at each stage, which were then operationalized into the diabetes scenario. Filling in this swim lane and competency map required knowledge from many disciplines, including data science and biostatistics, standards, user-centered design, change management, workflow mapping, app development, implementation science, and evaluation as well as expertise in the clinical domain and in how the Australian health system works. No single person could effectively design the course we developed, which posed challenges and opportunities for curriculum development. Using the LHS cycle enabled curriculum designers to join the varied subject matter expertise, by mapping it to an agreed framework. Details of the full course design, development, and curriculum outline are published elsewhere (Figure 1) [16].

Figure 1. The Applied Learning Health Systems short course curriculum [16].



Evaluation Framework

We used the Kirkpatrick model of evaluation [17] to map out our measurements (Table 1). This model is a widely used evaluation framework in education and is used to shift researchers away from simply measuring perceptions and satisfaction. We examined whether participants' attitudes, knowledge, behavior, and professional practice changed as a result. Additionally, we applied a mixed methods approach that included pre- and postsurveys, weekly surveys, and postinterviews.

Table . Application of the Kirkpatrick model of evaluation, adapted from Barr et al [18], to this project.

Level	Details	Evaluation measures and data sources in this project
1	Perception of training among subjects	Pre-, weekly, and postsurveys; postcourse participant interviews
2a	Change in the attitudes of subjects	Pre- and postchange in digital health interest and identity
2b	Change in the knowledge and/or skills of subjects	Pre- and post-self-efficacy changes in specific LHS[a] concepts (skills); pre- and postconcept maps (knowledge; out of scope for this paper)
3	Changes in the behavior of subjects	Postcourse participant interviews (will follow up in 1 year with participant interviews)
4a	Change in professional practice	Postcourse participant interviews (will follow up in 1 year with participant interviews)
4b	Changes in patients' condition	Not applicable

[a]LHS: learning health system.

Pre- and Postcourse Surveys

The pre- and postcourse surveys were developed by using a combination of psychological scales and open-ended questions. The pre- and postcourse surveys included the same self-efficacy scale (100 points; cannot do at all to highly certain can do) [19] which has significant evidence of reliability and validity. We choose to evaluate self-efficacy as it is one of the strongest proxy measures in education to predict actual and future performance, which are more difficult and take longer to measure [20]. The 10 items on the self-efficacy scale were adapted from the material taught in the LHS course and language from the LHS literature (eg, use machine learning algorithms to create a model for predicting a health outcome) [21,22]. The open-ended questions included demographic questions (eg, job title) and questions related to digital health identity development, course benefits, course barriers, what to keep, what to improve, and other suggestions or comments.

Surveys were designed and distributed via Qualtrics. Participants were invited to complete the surveys through emails and the learning management system. Responses to open-ended survey questions were also analyzed through qualitative content analysis. Two coders independently coded the text responses using NVivo (Lumivero) software. Coders met to resolve discrepancies and solidify themes and categories under each research question. The self-efficacy scales were analyzed using a 2-tailed, unpaired *t* test in GraphPad Prism to determine whether there was an improvement in self-efficacy across the 13 LHS concepts.

Weekly Surveys

Over the 12 weeks, participants had the opportunity to provide feedback on the level of engagement, usefulness, value, satisfaction, and areas for improvement in the course content, through participation in weekly surveys. These surveys contained scales (strongly disagree to strongly agree) and ask questions such as "how useful did you find this topic" and "how engaged did you feel" and open boxes for free-text responses. Descriptive statistics such as frequency, mean, and standard deviation will be used to summarize the data from these questions. Completion of these weekly surveys ranged from 2530 participants each week.

Qualitative Coding of Free-Text Responses

To analyze the text response according to our research questions, we first deidentify the transcripts for participant and institution names. The transcripts will be uploaded to NVivo software for qualitative content analysis [23]. A codebook was developed deductively from the literature and inductively from the research data. Two coders independently analyzed the transcripts according to the codebook. The 2 coders met to calculate an interrater agreement rate and resolve any discrepancies. The final codes were synthesized by creating summaries, narratives, and matrices. The final results included coding frequencies, themes, and categories according to the research questions.

Quantitative Statistical Analysis

For descriptive statistics, number of participants and proportion of participants are shown. For rating scales, frequency and proportion are shown. Pre- and postcourse self-efficacy comparisons were undertaken using a 2-tailed, unpaired *t* test. Incomplete or missing data were excluded from the analysis.

Results

Demographics

Thus far, the Applied Learning Health Systems program has had approximately 400 participants from various organizations (health care, government, research or university, industry) and job roles (clinician, researcher, data or information technology [IT], health services management, allied health, EMR implementation, health administration, consumer advocacy) (Table 2). Of the 400 participants, 343 (85.8%) completed the presurvey (week 0) and 200 (50%) completed the postsurvey (week 12). A few participants were lost to follow-up during the final week because they were ill, dropped out due to overcommitment, or did not respond to requests.

Table . Demographics shared by participants in the Applied Learning Health Systems program.

Characteristic		Participants, n (%)
Professional background (n=399)		
	Primary health care	44 (11)
	Tertiary health care	141 (35.3)
	Health services management	29 (7.3)
	Allied health	48 (12)
	Government	10 (2.5)
	Academia or research	73 (18.3)
	Business, IT[a], tech or data analytics	47 (11.8)
	Other	7 (1.8)
Role type (n=343)		
	Clinician (medical)	67 (17)
	Clinician (nursing)	25 (6.4)
	Clinical informatician	22 (5.6)
	Researcher (health services research or public health)	68 (17.3)
	Data analyst	28 (7.1)
	Allied health professional	58 (14.8)
	Health services manager	36 (9.2)
	Quality improvement lead	24 (6.1)
	Consultant or IT professional	19 (4.8)
	EMR[b] implementation team	18 (4.6)
	Health administration	8 (2)
	Consumer advocate	20 (5.1)

[a]IT: information technology.

[b]EMR: electronic medical record.

What Were Participants' Previous Encounters With the LHS Framework?

At the beginning of the course, participants were asked if they had any previous exposure to the LHS framework. Almost one-third of the participants had no previous experience with the LHS concept or any digital health concepts (121/343, 35.3%). Some participants stated that they had previous exposure to digital health and informatics concepts (50/343, 14.6%) through other courses and certifications (27/343, 7.8%), as well as through work-based activities, for example, EMR implementation and optimization (47/343, 13.1%), quality improvement, data interrogation (56/343, 16.3%), and various other health services projects (45/343, 13.1%). Others stated that they had no previous exposure to digital health or LHS concepts (49/343, 14.2%).

What Type of Teaching Approaches Did Participants Perceive as Effective?

Participants were asked to rate the usefulness and engagement of the topic's preclass learning and in-class sessions. In terms of usefulness, the majority found the preclass materials useful (880/956, 92.1%—"the preclass material was excellent and really helped to clarify many of the terms that I had heard people say but not truly understood") and in-class sessions useful (902/955, 94.5%—"analyzing the data during the class was useful and to see it connect with prelearning materials was good"). When asked to rate engagement, the majority found the preclass (881/954, 92.3%) and in-class activities engaging (881/955, 92.3%) (Tables 3-6).

Table . Ratings of usefulness and engagement with preclass learning materials and in-class Zoom sessions. Participants were asked to rate the agreement for usefulness (extremely useless to extremely useful) and engagement (extremely unengaged to engaged), weekly for each topic (1-13).

Questions	Rating							Total, n
	Extremely useless, n (%)	Moderately useless, n (%)	Slightly useless, n (%)	Neither useful nor useless, n (%)	Slightly useful, n (%)	Moderately useful, n (%)	Extremely useful, n (%)	
I found this topic's preclass learning useful (13 topics)	5 (0.5)	39 (4.1)	13 (1.4)	20 (2.1)	210 (22.0)	265 (27.7)	404 (42.3)	956
I found this topic's in-class session useful (13 topics)	2 (0.2)	13 (1.4)	9 (0.9)	28 (2.9)	103 (10.8)	360 (37.7)	440 (46.0)	955
I felt engaged when completing the preclass learning for this topic (13 topics)	5 (0.5)	9 (0.9)	29 (3.0)	30 (3.1)	127 (13.3)	428 (44.9)	326 (34.2)	954
I felt engaged when participating in the topic's in-class session (13 topics)	10 (1.0)	13 (1.4)	17 (1.8)	33 (3.5)	104 (10.9)	349 (36.5)	429 (44.9)	955

Table . Participants' ratings of value pertaining to overall value to personal career development for all topics.

Question	Rating					Total, n
	Highly unvaluable, n (%)	Unvaluable, n (%)	Neutral, n (%)	Valuable, n (%)	Highly valuable, n (%)	
Valuable to your personal career development (13 topics, n=189)	12 (0.6)	13 (0.6)	251 (12.3)	989 (48.5)	776 (38.0)	2041

Table . Participants' ratings of value pertaining to applicability to current workplace role for all topics.

Question	Rating					Total, n
	Highly not applicable, n (%)	Not applicable, n (%)	Neutral, n (%)	Applicable, n (%)	Highly applicable, n (%)	
Applicability to your current workplace role (13 topics, n=189)	64 (3.1)	154 (7.5)	325 (15.9)	837 (41.0)	661 (32.4)	2041

Table . Participants' ratings of value pertaining to overall satisfaction with the quality of the course, recommendation, instructors, and choice to revisit, as well as the value of educational activities (instructors, Zoom workshops, Canvas preclass activities, collaborative learning, the diabetes case scenario, Jupyter Notebooks, and discussion boards).

Questions	Rating							Total, n
	Extremely valueless, n (%)	Moderately valueless, n (%)	Slightly valueless, n (%)	Neither valuable nor valueless, n (%)	Slightly valuable, n (%)	Moderately valuable, n (%)	Extremely valuable, n (%)	
Collaborative learning in the working groups	1 (0.5)	6 (3.3)	3 (1.6)	5 (2.7)	29 (15.9)	63 (34.6)	75 (41.2)	182
Preclass learning activities on Canvas	0 (0)	3 (1.6)	2 (1.1)	2 (1.1)	21 (11.5)	77 (42.3)	77 (42.3)	182
In-class learning (Zoom) sessions	1 (0.5)	2 (1.1)	1 (0.5)	6 (3.3)	17 (9.3)	74 (40.7)	81 (44.5)	182
The diabetes case scenario	1 (0.5)	4 (2.2)	3 (1.6)	10 (5.5)	30 (16.5)	70 (38.5)	64 (35.2)	182
Jupyter Notebooks	0 (0)	11 (6.0)	11 (6.0)	20 (11.0)	53 (29.1)	55 (30.2)	32 (17.6)	182
Canvas learning management system	0 (0)	1 (0.5)	3 (1.6)	12 (6.6)	30 (16.5)	83 (45.6)	53 (29.1)	182
Discussion boards	5 (2.7)	10 (5.5)	10 (5.5)	43 (23.6)	62 (34.1)	39 (21.4)	13 (7.1)	182
The instructors	0 (0)	1 (0.5)	0 (0)	4 (2.2)	8 (4.4)	49 (26.9)	120 (65.9)	182

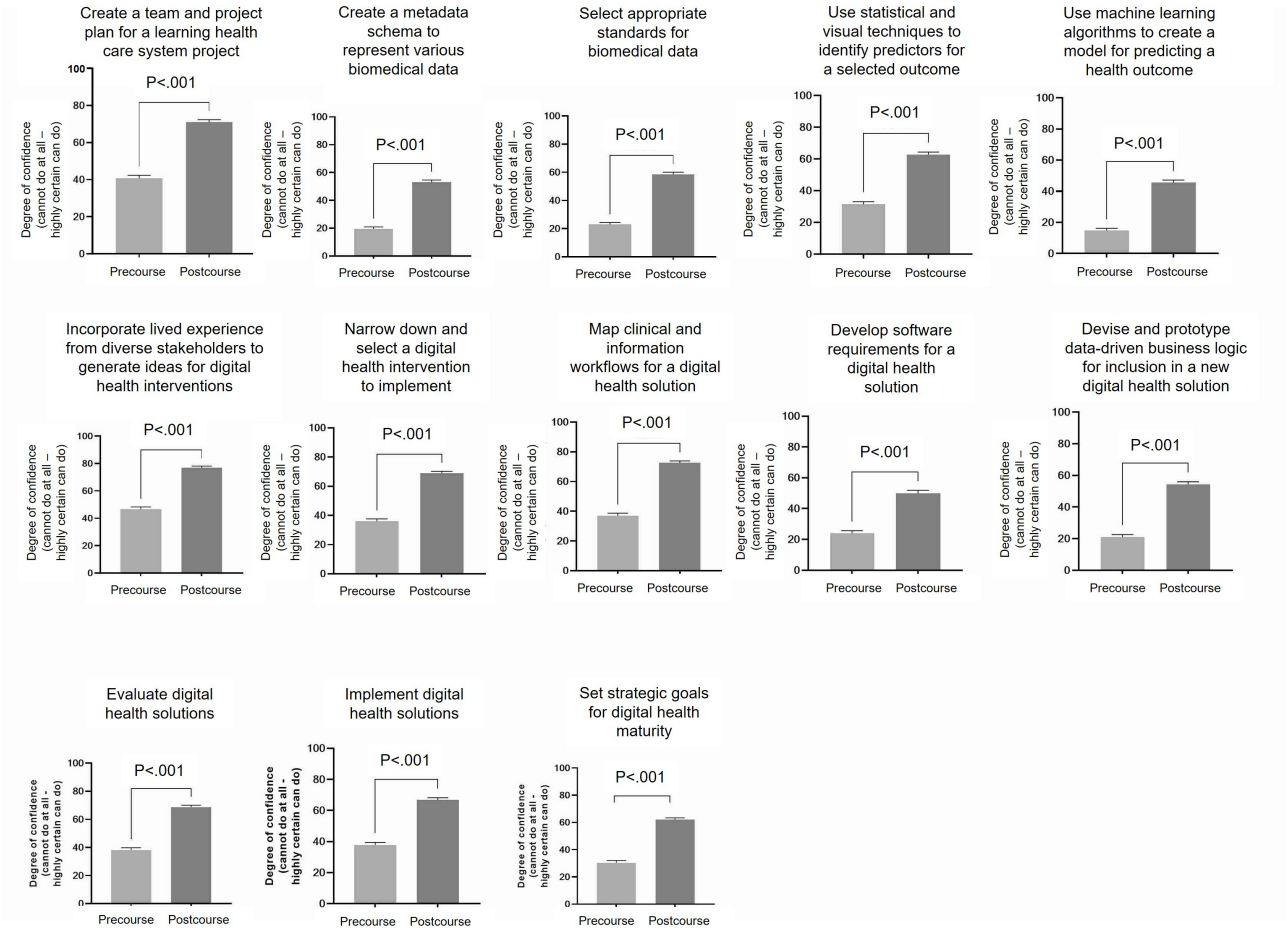
Responses to the question of satisfaction also yielded highly positive results. For the overall quality of the short course, most agreed that it was of a high standard (178/182, 97.8%), including the instructor quality (175 /182, 96.2%). When asked if they would recommend the short course to a colleague, 89.5% (163/182) said they would. In terms of revisiting the decision to complete it again, 85.1% (154/182) still said they would choose to take the course. When rating the value of the course to their personal career development, a majority found the course valuable (173/200, 86.5%). Participants were also asked to rate the applicability of the course to their day-to-day work, where 73.4% (134/182) found it applicable.

Given the number of facets implemented in the course, we asked participants to rate the value of these various elements. The most highly rated was the instructors: "the speakers were great, and the structure of having a short lecture and then doing an activity then coming back and having another lecture was good," with 92.8% (169/182) finding them moderately or extremely valuable. Next, in-class learning (155/182, 85.2%), preclass learning (154/182, 84.6%), collaborative learning (138/182, 75.8%), the diabetes case scenario (134/182, 73.7%), and the Canvas learning management system platform (136/182, 74.7%) rated similarly. The use of Jupyter Notebooks (87/182, 47.8%), and the discussion boards (52/182, 28.6%) rated lower (Table 6).

How Did Participants' Self-Efficacy for Digital Health Topics Change After the Course?

To explore the change in self-confidence levels pre- and postcourse, participants were surveyed on the key competencies for the 13 topics. Participants completed the same set of ratings at the beginning and at the end of the course, following completion of all the material. For all 13 learning outcomes, there was a statistically significant increase in self-efficacy (n=200, $P<.001$) (Figure 2).

Figure 2. Pre- and postcourse self-efficacy in LHS concepts. Participants rated confidence on a scale of 0 - 100 (0=cannot do at all to 100=highly certain can do). Two-tailed, unpaired *t* test was undertaken (n=296 precourse, n=200 postcourse). Changes from baseline to postcourse confidence are shown for each LHS concept. LHS: learning health system.



How Did Participants' Self-Perceived Role in Digital Health Change?

In the pre- and postsurvey, participants were asked to respond to the open-ended question of "What do you see as your role in digital health?" There were several types of roles that participants perceived themselves embodying postcourse. These included users of digital health or learners; champions, advocates, or change agents; researchers, innovators, or entrepreneurs; leaders, managers, strategic planners, or decision makers; educators or mentors; specialists or implementers; community builders, connectors, facilitators, collaborators, or translators (Table 7).

After the course, there was an increase in participants who viewed their role as an end user or learner and a community builder or facilitator, whereas there was a decrease in those who viewed their role as a champion or advocate and leader in digital health.

Table . Participants' perceived roles in digital health pre- and postcourse (qualitative themes).

	Precourse responses (n=274), n (%)	Postcourse responses (n=228), n (%)
End user of digital health or learner	41 (15.0)	54 (23.7)
Champion, advocate, or change agent	62 (22.6)	37 (16.2)
Researcher, innovator, or entrepreneur	32 (11.7)	30 (13.2)
Leader, manager, strategic planner, or decision maker	38 (13.9)	22 (9.6)
Educators or mentors	13 (4.7)	6 (2.6)
Specialist or implementer	57 (20.8)	41 (18.0)
Community builder, connector, facilitator, collaborator, or translator	31 (11.3)	38 (16.7)

What Did Participants Perceive as the Applications of the Learning in Their Workplace?

There were five main themes that arose for the types of applications that participants foresaw themselves using the course learnings: (1) learning and professional development: "upskilling in the current role, more understanding of the roles of my team members"; (2) using data and undertaking data analysis more effectively: "data mining and improving processes at work"; (3) implementing the LHS framework for digital health interventions: "we are embarking on establishing a data and analytics 3-year plan and we intend to incorporate LHS principals into this strategy"; (4) for undertaking research and quality improvement activities: "I now play a role in learning health networks for Safer Care Victoria, where I believe I could encourage digital health projects focused on quality improvement and patient safety"; and (5) collaborating and sharing knowledge and learnings with colleagues: "I intend to instill the LHS framework into my role, the work that I do and share it with my team" (Table 8).

Table . Participants' anticipated applications of learning in the workplace (qualitative themes).

	Precourse responses (n=338), n (%)	Postcourse responses (n=231), n (%)
Learning and professional development	74 (21.9)	47 (20.4)
Using data and undertaking data analysis	54 (16.0)	43 (18.6)
Implementing digital health solutions with the LHS[a] framework	63 (18.6)	52 (22.5)
Researching and quality improvement	82 (24.3)	62 (26.8)
Collaborating and knowledge sharing	65 (19.2)	27 (11.7)

[a]LHS: learning health system.

What Were the Perceived Benefits of the Program?

Participants were asked to state the benefits of the program. The major themes that arose were learning and knowledge acquisition: "the course material was presented well on Canvas and had a good mix of different learning resources to use," value of collaboration: "the course has been extremely eye-opening and has led me to begin collaborations on digital health projects through contacts made through the course," participant diversity and group work : "being in a group of people with all different work backgrounds and skills coming together with a common interest was really good for tackling the problems to solve in the class," beneficial course structure and content delivery (preclass: "the course material was presented well on Canvas and had a good mix of different learning resources to use" and in-class: "beneficial to be in a diverse group of other health care professionals - I learnt a lot from the robust and engaging discussions on Zoom)," and learning tools, importance of real-world applications: case study and personal work: "applying course concepts to this real-world scenario was instrumental in reinforcing their understanding," appreciation for instructors' diversity, expertise, engagement, and quality: "the instructors were very engaged and passionate about their topics," consumer focus, and focus on data analytics (Table 9).

Table . Beneficial elements of the course.

Theme	Responses (n=295), n (%)
Collaborative group work, diversity, or multidisciplinary approach	63 (21.4)
Course structure and content delivery or pre- and in-class material	54 (18.3)
Learning and knowledge acquisition	53 (18.0)
Real-world scenarios or real-world applicability	44 (14.9)
Exposure to tools and techniques	28 (9.5)
Appreciation for instructors	25 (8.5)
Exposure to complexity and challenges	14 (4.7)
Focus on consumers	14 (4.7)

What Were Participants' Barriers to Engaging With the Program?

When asked regarding barriers to participating in the course, participants' responses formed the following major categories: time constraints due to work, family, and other social commitments: "time constraints, balancing clinical work, other non-clinical work and home life," a lack of knowledge, terminology, and experience: "limited coal-face/frontline exposure and visibility of emerging frontline issues. I work at a more systems-based level and am not involved in interacting with patients day-to-day," technical challenges: "I found using so many new platforms eg Jupyter notebooks, BPMN so quickly challenging...," content complexity, and limited interactions online (Table 10).

Table . Barriers to effective participation.

Theme	Responses (n=259), n (%)
Time constraints or keeping up with materials	109 (42.1)
Lack of knowledge and experience	56 (21.6)
Family and personal commitments	37 (14.3)
Technical challenges	23 (8.9)
Health care terminology and clinical knowledge	14 (5.4)
Work commitments	14 (5.4)
Course structure and content	6 (2.3)

What Changes or Improvements Would Participants Suggest to the Short LHS Coursework?

While the majority of participants found beneficial elements to the course, there are always improvements that can be made. Areas in which changes were suggested were course structure, duration, and timing, suggesting concerns around the pace of the course and the amount of information and breadth covered: "it feels like a lot of materials are being cramped into 1 session and it was hard to appreciate the differences between the models" and the timing of delivery after a long work day; the usability of some learning tools, such as Jupyter Notebooks, difficulties with learning management platform navigation, more revision activities to reinforce learning and a desire for more printable or downloadable resources; questionable benefit of group work and collaborative work where students wanted more support and time to hear instructor expertise: "I feel there was too much reliance on group work and not enough input and guidance from the experts"; course delivery—online format, questioning whether networking opportunities were lost online; prerequisite skills required, given the difficulty of some content (Table 11).

Table . Participants suggested improvements to the course.

Theme	Responses (n=158), n (%)
Course content and structure—curriculum, quality, volume of material, level of complexity, clarity, usefulness, effectiveness, engagement, and applicability	64 (40.5)
Course logistics and administration—course duration, pace, delivery modality, pre-requisites, and learning platforms	37 (23.4)
Learning tools and materials—usability and accessibility	15 (9.5)
Group work and collaboration activities—diversity, effectiveness, and interaction	30 (19.0)
Instructor interactions in-class—interaction, engagement, and support	12 (7.6)

Discussion

Principal Findings

Despite the concept originating in 2007 [24], there is a lack of reports evaluating LHS education programs. In this evaluation, we discuss the findings of 2 years of implementation and iteration of an interdisciplinary Applied LHS professional development course (343/400, 85.8%, presurvey respondents; 200/400, 50%, postsurvey respondents), to a diverse range of professionals working and studying in health care, with an interest in digital health. Most of our participants were from Australia, where LHS was a novel but emerging concept [15,25-27]. The participants found the course engaging and relevant to their work. Participants highlighted specific benefits, barriers, and applications to this course and the LHS framework on their work.

Most health systems are actively seeking to increase the use of data and digital technology to drive improved health care delivery and health outcomes. A major ingredient needed to achieve that lofty goal is a workforce that knows how to not only thrive within the rapidly digitizing world but also how to innovate to improve value-driven care. Training a diverse workforce in the digital transformation of health poses an overwhelming number of choices about the most important learning objectives, competencies, and skills. The LHS framework [16] placed boundaries around the grand vision and enabled us to concretely tell a story that resonated with the goals of potential learners while lending itself to hands-on activities that invite learners to be part of that story.

In addition to the advantages of multidisciplinary curriculum development, the LHS framework was also a key part of the value of the course to interdisciplinary learners. We launched this course as a pilot and hand-selected 50 participants from a much larger pool of applicants with the aim of multidisciplinary involvement and of creating buzz around the course to encourage enrolment for a fee-paying version of the course. Medical directors, research leads, clinicians, and managers brought learnings from the course to hallway discussions and team meetings in their workplaces about how they could apply the LHS framework in specific projects. In addition to a better

understanding of how a project could go from idea to implementation and evaluation using the LHS principles, the framework provided a shared lexicon, a set of approaches like the creation of a learning community, and a toolkit of methods that learners could envision being used in their work. Their excitement was contagious, and a large proportion of our enrolees have come from organizations who continue to sponsor entire interdisciplinary teams of people to take the course together, because they see the value of the framework as a connector across disparate teams, such as clinicians, IT or EMR analysts, and health intelligence units, seeking to work toward a shared goal.

Overall, the course attracted a wide range of professionals at different levels (eg, medical students to directors of emergency departments), professions (eg, nursing and social work), consumers, researchers, and disciplines (eg, IT professionals). In this study, participants highly valued the interdisciplinary nature and collaborative learning activities in the course. Based on previous educational research, we purposefully sorted the groups for a diversity of professions and kept the participants within the same groups for the majority of the course to encourage relationship building. The interdisciplinary aspect of this course was a strength of our education model as it mimics the type of interdisciplinary practice required for complex LHS and digital health initiatives [28].

From several written comments and weekly surveys, we found that different disciplines struggled at different points within the course. For example, people without a research background found the data analysis topic and using Jupyter Notebooks the most challenging aspect of the course, whereas those with a nonclinical background struggled the most with mapping clinical workflows and implementation. Although we used these struggles as teaching moments to demonstrate the need for an interdisciplinary team in LHS, our experience indicates the need to improve our interdisciplinary education model. Previous education researchers and motivational theorists have established that optimal challenge is a key ingredient for engagement and learning [29]. If the material is too easy or too difficult, then learners disengage and, thus, do not learn the material. Many educators have described the challenge of designing a course for optimal challenge among a large cohort of uniprofessional courses [30]. However, our experience is that this challenge is even more dramatic in a one-size-fits-all model in an interdisciplinary course. The content we taught is still appropriate for all audiences, but each person may require more or less self-directed preparatory work as part of the flipped classroom model. Future researchers and educators should investigate how to continue serving an interdisciplinary audience while creating optimal challenges for all participants. For example, in future iterations, we will explore the use of generative artificial intelligence tools to personalize the self-directed online modules for participants' previous knowledge and professional context.

The participants' self-described digital health roles before and after the course only went through minor changes. There was a small conversion in participants who started out seeing themselves as leaders and then later described their roles as connectors. This phenomenon may have been due to instructors telling participants about the importance of connector roles within the LHS framework. Another reason for this effect may be the Dunning-Kruger effect [31]. The Dunning-Kruger effect is when individuals with low exposure to a topic often overestimate their abilities due to a lack of metacognitive awareness. As they gain more knowledge, they become more aware of the limitations. Despite the potential for the Dunning-Kruger effect, the lack of significant changes in participant digital health identity was in contrast to a similar evaluation of our parallel LHS education offering—a 1-year LHS fellowship program for clinicians [15]. In the fellowship program, half of the participants began the program by describing their role as champions and leaders, and then, by the middle of the program, all of the participants described their role as champions and leaders. This potential effect may be due to the benefits of the fellowship program; the fellowship is more experiential, project based, and explicitly focused on leadership development. Since self-identities are an important mediator of future performance [32], future educators and researchers should continue to investigate how LHS educational programs influence participants' self-described roles in the LHS framework and digital health.

Strengths, Limitations, and Future Directions

Overall, we achieved commendable survey response rates, suggesting a high level of engagement from participants. This study uniquely contributes to the existing literature by evaluating an interdisciplinary LHS education program—a domain previously underexplored. Our comprehensive approach encompassed both pre- and postcourse survey data, leveraging learning theories such as self-efficacy theory and the Kirkpatrick evaluation framework to inform our evaluation. Moreover, our qualitative analysis offers valuable insights into participants' perceptions, enriching our understanding of their experiences. However, a limitation is our current inability to capture the upper levels of the Kirkpatrick model, specifically how the LHS course may have influenced participants' workplace behaviors and the subsequent outcomes of those behaviors. In the long term, we aim to evaluate the impact this course and other LHS education offerings have had on individuals and their health organizations' journeys toward a learning health system and individual's career progression. We aim to do this by conducting follow-up, in-depth interviews with participants and organizational sponsors and thematically analyzing the changes that have occurred over time.

Achieving an LHS requires a symbiotic partnership between researchers and health services—by bridging theory and real-world application, future innovations emerging from an LHS will be evidence based and clinically relevant. To increase academic-practice collaboration, our LHS educational offerings aim to grow the understanding of LHS principles and skills in our health services partners and to provide insight into the enablers and barriers for their digital transformation. The shared LHS framework and increased mutual understanding from these programs are increasing trust and collaborative opportunities, leading toward joint translational LHS innovation programs within the health services. We hope that future educators and academic leaders see promise in our emerging LHS education evaluation work [15], other descriptions of LHS education

initiatives [6-11], and the success of LHS initiatives in health care practice [33-35].

By providing a professional development short course, we were able to serve a large market of health professionals who would not otherwise have participated in an expensive university degree. While some professionals like medical specialists receive a continuing medical education fund, most other disciplines are not provided with funding for professional development. Additionally, a major source of participants was partner organizations supporting and sending groups of staff through the program, to learn together as cohorts to develop communities of practice. In this scenario, enrollment was funded by their employers. This is crucial, as at the national and international level, we require a critical mass of appropriately skilled workforce to leverage LHS principles in improving the quality and value of health care delivery.

An interdisciplinary LHS short course has also provided a testbed for applying new technologies to learning. For instance, in the last iteration of the course, we experimented with generative AI feedback on the participants' learning. In their working groups, participants developed an evaluation plan. They fed their plans into ChatGPT, which we provided with structured, custom prompts to provide feedback and rate the quality of the plans. Although some students found the feedback to be generic, the depth of the feedback was dependent upon the richness of the data initially fed to the machine. In large group settings, where there are limited instructors and limited time to provide in-depth feedback to each interdisciplinary group or participant, ChatGPT may be a useful tool to assist with providing formative feedback. The use of this will be further explored in future iterations of the course.

Conclusions

Overall, the Applied Learning Health Systems course received significant positive feedback from interdisciplinary learners. They found the course to be well structured, engaging, and a valuable learning experience. The qualitative comments emphasized the importance of delivering courses that not only provide knowledge but also inspire and motivate learners, and provide concrete tools to apply in their workplaces. A significant number of participants expressed interest in future courses and opportunities for further learning, underscoring the potential for expanding and diversifying course offerings in the future. There is still a great deal of education that needs to be provided to upskill the workforce adequately enough to undertake digital health transformation, but it begins with a shared vision, a common language, and a mutual framework to follow.

Acknowledgments

We are grateful for the dedication of several instructors and contributors to the Applied Learning Health Systems program: Dr Mahima Kalla, Dr Kara Burns, Dr Chris McMaster, Associate Professor Brian Chapman, Dr Douglas Capurro, Reuben Daniels, Jennifer Morris, Dr Vlada Rozova, Anna Fedyukova, Dr Kit Huckvale, Professor Kathleen Gray, Associate Professor Graeme Hart, and Dr Debbie Passey.

Data Availability

All relevant data generated or analyzed during this study are included in this published article. The raw data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

SD played a key role in data curation, formal analysis, investigation, project administration, and visualization, and wrote the original draft, contributing to its review and editing. NZ focused on formal analysis. DC contributed by reviewing and editing the manuscript, ensuring its quality and coherence. WC conceptualized the project and also participated in the review and editing process. KL contributed to the investigation, methodology, supervision, writing the original draft, as well as reviewing and editing the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Information security is a critical challenge in the digital age, especially for hospitals, which are prime targets for cyberattacks due to the monetary worth of sensitive medical data. Given the distinctive security risks faced by health care professionals, tailored Security Education, Training, and Awareness (SETA) programs are needed to increase both their ability and willingness to integrate security practices into their workflows.

Objective: This study investigates the effectiveness of a video-based security training, which was customized for hospital settings and enriched with motivational framing strategies to build information security skills among health care professionals. The training stands out from conventional interventions in this context, particularly by incorporating a dual-motive model to differentiate between self- and other-oriented goals as stimuli for skill acquisition. The appeal to the professional values of responsible health care work, whether absent or present, facilitates a nuanced examination of differential framing effects on training outcomes.

Methods: A randomized controlled trial was conducted with 130 health care professionals from 3 German university hospitals. Participants within 2 intervention groups received either a self-oriented framing (focused on personal data protection) or an other-oriented framing (focused on patient data protection) at the beginning of a security training video. A control group watched the same video without any framing. Skill assessments using situational judgment tests before and after the training served to evaluate skill growth in all 3 groups.

Results: Members of the other-oriented intervention group, who were motivated to protect patients, exhibited the highest increase in security skills (ΔM=+1.13, 95% CI 0.82-1.45), outperforming both the self-oriented intervention group (ΔM=+0.55, 95% CI 0.24-0.86; *P*=.04) and the control group (ΔM=+0.40, 95% CI 0.10-0.70; *P*=.004). Conversely, the self-oriented framing of the training content, which placed emphasis on personal privacy, did not yield significantly greater improvements in security skills over the control group (mean difference=+0.15, 95% CI –0.69 to 0.38; *P*>.99). Further exploratory analyses suggest that the other-oriented framing was particularly impactful among participants who often interact with patients personally, indicating that a higher frequency of direct patient contact may increase receptiveness to this framing strategy.

Conclusions: This study underscores the importance of aligning SETA programs with the professional values of target groups, in addition to adapting these programs to specific contexts of professional action. In the investigated hospital setting, a motivational framing that resonates with health care professionals' sense of responsibility for patient safety has proven to be effective in promoting skill growth. The findings offer a pragmatic pathway with a theoretical foundation for implementing beneficial motivational framing strategies in SETA programs within the health care sector.

Introduction

Background

In the digital era, information security has emerged as a pivotal challenge for a wide array of industries, most notably for critical infrastructure, where interruptions can exert detrimental impacts on public safety, the economy, and the daily lives of individuals [1]. Hospitals have become a primary target for cyberattacks due to the substantial financial value of sensitive medical data [2]. The *Ponemon Healthcare Cybersecurity Report 2023* indicates that 88% of health care organizations experienced an average of 40 cyberattacks in the past 12 months, significantly impacting patient care and causing financial losses amounting to millions of dollars [3]. The prevalence of incidents underscores the need to enhance measures of information security protection [4]. However, technological vulnerabilities are not the sole source of threat. The human factor frequently serves as a crucial gateway for criminals. Errors, negligence, and inadequate knowledge about countermeasures all contribute to successful cyberattacks [5]. In particular, a lack of security awareness encourages noncompliance with organizational security policies, thus leading to risky workplace behaviors such as using weak passwords and unsecured devices [6]. As a consequence, hospital staff unknowingly create vulnerabilities that can be exploited by attackers [7]. This problem is exacerbated by hospitals' increasing reliance on interconnected digital systems [2,8], including IoT-based health care solutions [9], and the high-pressure environment of health care work, which often prioritizes rapid patient care over rigorous security measures [10].

In response, health care organizations are expanding the implementation of Security Education, Training, and Awareness (SETA) programs to improve their employees' information security skills [11]. Despite these efforts, many SETA programs have proven ineffective in fostering secure working practices over the long term by focusing on formal regulatory requirements without addressing the work processes of health care professionals and, thus, the application contexts of users [12-15]. Adapting SETA programs to the tasks and inherent security threats that health care professionals face every day seems imperative [16]. However, this target group rarely perceives information security as part of their primary job responsibilities [17]. Despite the provision of domain- and context-specific knowledge through training, health care professionals may still rate the importance of safeguarding medical data in their daily workflows as low [18]. A substantial proportion of professionals even demonstrate a flawed understanding of the consequences of inadequate security practices, including ransomware attacks that access electronic health records or data manipulations that lead to treatment errors [5]. This inner devaluation of risky behaviors and their consequences threatens the confidentiality, availability, and integrity of sensitive patient data. In essence, motivational deficits on the part of the professionals can be a serious barrier for acquiring skills that are necessary to act in accordance with security policies at work—even if training content is adequately customized to match their daily professional activities.

Enhancing Training Engagement Through Motivational Framing Strategies

A recognized method of invigorating involvement in training and promoting compliance with information security policies at work applies *fear appeals*, which raise awareness of the *personal relevance* of counteracting security threats [19,20]. As Johnston et al [21] point out with reference to protection motivation theory (PMT), powerful fear appeals address both formal sanctions (eg, punishment and loss of valuable information) and informal consequences (eg, social disapproval and reputational damage) in future cases of noncompliance. Nevertheless, an exclusive emphasis on avoiding unfavorable outcomes may not be the most effective strategy to encourage engagement with training content, as evident in research on controlled versus autonomous motivation of learning [22]. Research based on self-determination theory [23] shows that controlled motivation, such as compliance driven by external pressure, often leads to superficial learning. By contrast, training approaches that cultivate autonomous motivation by connecting to individual goals or professional purpose are more likely to elicit deeper engagement and enduring behavioral change [24]. Moreover, where consequences for unnoticed violations are missing, there may be little long-term motivation to follow information security rules in daily work [19].

Motivational framing offers a promising alternative for establishing the personal relevance of secure workplace behaviors and encouraging their acceptance as an integral part of one's professional practice. It aligns the content and structure of a message or topic with the motivational states, pursued goals, or cherished values of the target audience, thereby increasing the topic's subjectively assessed importance [25]. Joyal-Desmarais et al [26] report that motivational framing has a strong impact when the message aligns specifically with the individual's intrinsic motivation or core values. Their meta-analysis of 702 experimental studies highlights how messages that are tailored to resonate with such personal reference points of the recipients can significantly increase the persuasiveness of provided information, thus contributing to marked changes in attitudes, intentions, and behaviors. This raises the question of which core values a security training in hospitals should best appeal to.

Since hospital staff provide assistance to others, their professional activities can most generally be termed prosocial [27]. According to the *dual-motives model*, however, prosocial behavior can be driven either by self-serving (self-oriented) or by altruistic (other-oriented) motives [28]. While the former focus on personal benefits, such as enhancing one's reputation, gaining recognition, or fulfilling job-specific duties as part of

one's paid employment, the latter prioritize the needs and well-being of others, such as ensuring the safety and dignity of patients [29]. A closer investigation of the *core professional values* endorsed by health care professionals strongly suggests that an other-oriented (ie, patient-oriented) framing of training content on information security could indeed function as the most effective prompt to encourage attention and engagement—an assumption that will be further elaborated in subsequent sections.

At this point, we can conclude that the "personal relevance" of averting security threats as a health care professional could become more of a voluntary activity in accordance with one's professional values than merely a pointless duty imposed by regulatory bodies if training participants are prompted to detect this accordance. The general idea of addressing a professional commitment as a motivational stimulus is also fully compatible with the Fogg Behavior Model (FBM). The FBM posits that the performance of a target behavior is contingent upon 3 factors: sufficient motivation, the capacity to execute this behavior, and an adept cue that prompts its execution. The occurrence of these factors must be simultaneous for the behavior to manifest [30]. A training program that incorporates appeals to those salient values that generally drive professional action and, thus, enriches practical applicability with targeted messages or cues, therefore, seems particularly adept for building individual capacities for secure workplace behaviors.

Against this background, this study seeks to determine whether a motivational framing of information security training content, which varies in its alignment with the professional values of the target audience, impacts the acquisition of information security skills to varying degrees.

Hypotheses Development

The training for health care professionals has been meticulously developed, integrating problem-solving approaches to learning and recommended features for video formats while delivering domain-specific, contextualized content (see section on Instructional and Assessment Design for details). Therefore, the investigated hypotheses focus on the "dual" strategies of motivational framing and their potential to establish a connection between the adoption of information security practices and the commitment to professional values.

Since core professional values form the foundation of health care practices and the inner ethical obligations of health care staff [31], appeals to these values should promote engagement with learning material in an effort to expand one's repertoire of security skills [32]. Among these values, patient-centered care stands out as a primary commitment, emphasizing the safety, dignity, and well-being of patients. Professional integrity, another critical value, entails adherence to ethical standards and accountability, particularly in safeguarding sensitive patient information. Altruism and compassion further underscore the motivation of health care professionals to prioritize patient needs, often going beyond contractual obligations to act in the best interest of those they serve [33]. Consequently, an *other-oriented* framing of training content, which directs the participants toward *protecting information of and about their patients*, should be most adept to foster the acquisition of information security skills. In support of this idea, White and Peloza [34] report that people are more likely to respond to other-oriented appeals in contexts where social responsibility is emphasized.

Nevertheless, self-oriented appeals, emphasizing the individual benefits of protecting personalized data, should not be without any effects. Support for this perspective comes from PMT [35], which argues that individuals are most likely to engage in protective behavior when they anticipate being affected individually by the consequences of successful threat aversion or their failure to do so, while concurrently believing that they possess the knowledge and tools to respond adequately. Self-oriented framing consequently stresses these personal risks and the importance of self-protection. It makes consequences, such as service disruption or privacy loss, more immediate. Research supports the notion that perceived personal vulnerability drives individuals to adhere to safety measures. AlSobeh and colleagues' [36] findings suggest that adolescents who perceive cybersecurity risks to impact their personal quality of life demonstrated a heightened level of security awareness. In accordance with this line of thinking, self-oriented framing is appealing to defenses of one's own (informational) integrity.

Therefore, we expect an other-oriented framing of information security training, accentuating patient protection, to promote greater skill acquisition than delivering the training without any framing. It should also be superior to self-protection appeals, which should again be more effective than no framing at all. This leads to the following hypotheses:

- Hypothesis 1: Participants who receive a self-oriented framing of training content will demonstrate higher levels of skill acquisition compared to a control group without any framing.
- Hypothesis 2: Participants who receive an other- (ie, patient-) oriented framing will demonstrate higher levels of skill acquisition compared to those with a self-oriented framing.

Methods

Instructional and Assessment Design

Enhancing Information Security Skills Through Job-Specific, Problem-Oriented, Video-Based Training

In determining the relevant skillset to be acquired, we drew on a framework that was developed specifically for information-secure workplace behaviors [37,38]. The model proposes professional activity to be targeted, knowledgeable, justifiable, and responsible [39,40]. It further aligns with models of (expert) problem-solving [41,42] by positing that a proficient handling of security threats spans a comprehensive cycle of reasoned action. This cycle starts with an early detection of risky situations within one's own working environment and extends up to the execution of follow-up procedures that are beneficial for the whole team or organization. Thus, the skillset comprises seven elements. (1) *Threat awareness* emphasizes the ability to recognize potential security threats and remain vigilant, distinguishing between threatening and nonthreatening work situations. (2) *Threat identification* focuses on accurately

identifying the presence of a security threat and understanding its specific nature. (3) *Threat impact assessment* ensures that individuals understand the consequences of not addressing current security threats. (4) *Tactic choice* enables individuals to select appropriate measures by aligning their actions with prevailing best practices and established rules of information security while tailoring those actions to the specific threat scenario they face. (5) *Tactic justification* emphasizes the importance of a structured, goal-oriented approach in which individuals can justify their actions based on relevance, effectiveness, and superiority. With (6) *tactic mastery,* individuals can effectively implement the security measure of choice. Finally, (7) *tactic check and follow-up* involves evaluating the effectiveness of implemented measures and, where possible, taking follow-up actions to further improve the organization's security.

A critical evaluation of the strengths and limitations of various training methods (for an overview, see [43]) revealed that video-based training offers a promising solution for the health care sector. First, it provides a largely visual presentation of content, thereby facilitating the acquisition of knowledge and skills regardless of the learners' literacy [44,45]. Second, health care professionals often have unpredictable schedules and limited time for instructor-led classroom training. In such circumstances, training videos provide a convenient and accessible learning route, ensuring the delivery of essential strategies and reasoning in a clear, concise, and engaging manner [46]. Third, the standardization and repeatability of video-based training material fosters the dissemination of consistent, high-quality information to all employees, enabling them to progress through the material at their own pace [47].

Several research-based recommendations were implemented in the video production. Given the condensed information typically conveyed in this format, empirical studies suggest limiting the duration of training videos to no more than 6 minutes to maintain attention and engagement [48,49]. Storytelling and sensory activation [50,51] appeal to different learning styles [52] and promote information retention. At the beginning of each training video, participants are presented with general orienting information, including the learning objectives to be achieved, the approximate completion time, and an explanation of the badges to be earned [53]. These badges provide transparency of individual learning progression (beginner, advanced, or expert), thereby contributing to learner motivation and self-directed learning [54]. Upon completion, participants have mastered all training content for analyzing and averting security threats. Figure 1 illustrates these design principles as a multipanel overview covering the key visual elements of the training: (A) introduction, (B) learning objectives and badges, (C) other-oriented nudge, and (D) the "tactic justification" dimension.

Figure 1. Design highlights from the training module "handling sensitive and critical information on social networks.".

In line with the general objective of SETA programs described in the introduction, the training aimed to develop the ability to select and implement safe behaviors that are compatible with the respective employee's daily work and that are particularly relevant to the risk factors present there. Based on a comprehensive analysis of information security behavior in the health care sector [16], different *threat vectors* have been identified for typical *job profiles*. These job profiles differ in their levels of interaction with patients and their reliance on IT systems, which directly influence their exposure to information security risks.

Physicians interact with patients frequently and use IT systems moderately to extensively, depending on their responsibilities for diagnosis, treatment planning, and documentation. Common

threats they face include the *inadvertent disclosure* of sensitive information, for example, by forwarding patient-related data via private messaging services, as well as *spear phishing*, where attackers send personalized emails designed to appear legitimate.

Nurses typically have the most frequent patient contact but rely on IT systems only to a limited extent, mainly for tasks such as documentation and medication administration. They, too, are particularly vulnerable to *inadvertent disclosure* of sensitive information, such as through social networking or the use of private messaging services, which could be used for expeditious communication.

Administrative staff rarely interact directly with patients but rely heavily on IT systems. Tasked with the critical function of managing both digital and physical (patient) data, scheduling, and billing, they are frequent targets of *phishing attacks*, such as fake websites. Additionally, a disorganized workspace increases the probability of sensitive information being exposed on desks or computer screens. Failure to comply with the hospital's *clean desk policy* thus increases their risk of granting unauthorized access and violating data confidentiality.

By assessing the criticality and phenomenology of these threat vectors through expert interviews [16], we designed customized training videos that specifically address these prevalent and consequential security threats of different job profiles. In line with the problem-solving skills model described above, the videos take the occurrence of threat vectors as the starting point of a problem-solving process in a prototypical workplace scene. Thus, each video begins with visual or auditory stimuli that represent variants of an authentic workplace situation that could pose an information security threat, encouraging employees to assess associated risks and participate in finding a solution [55].

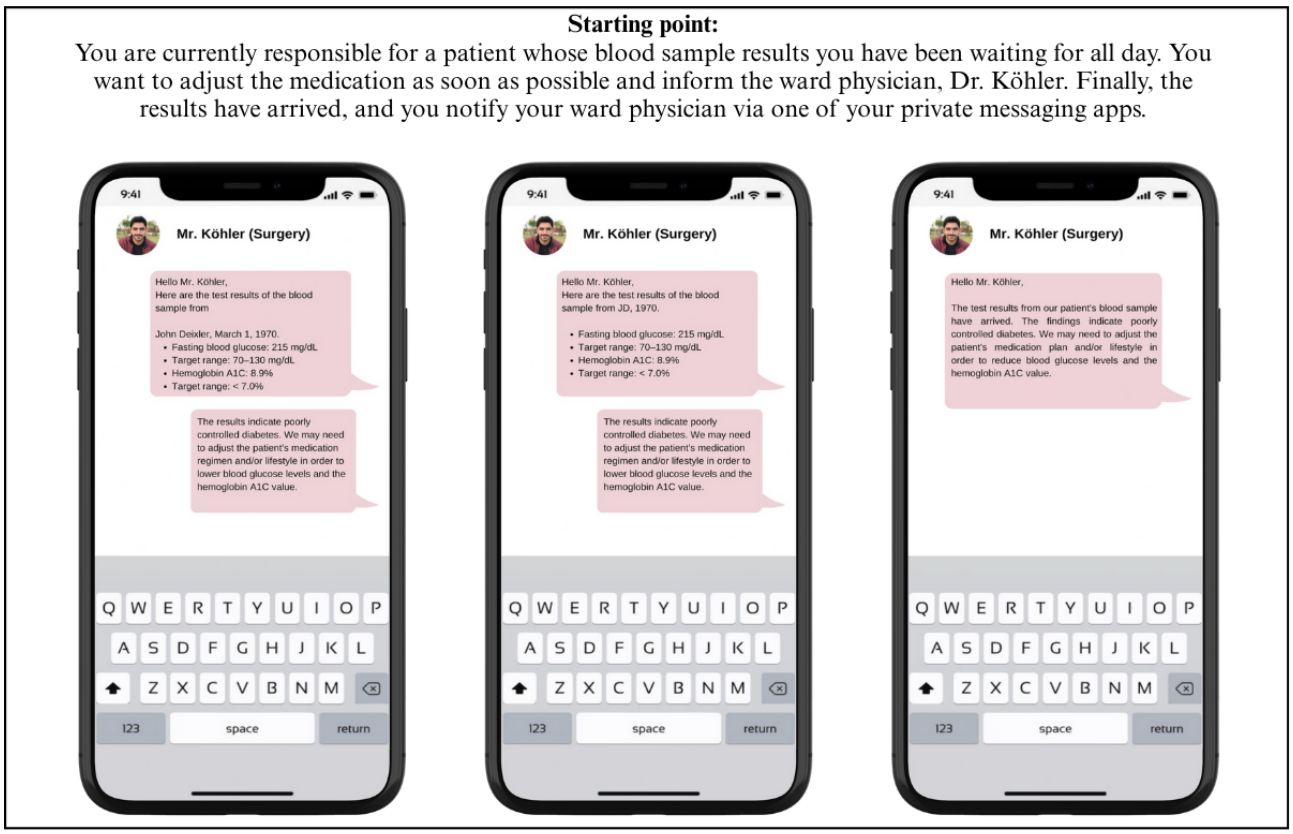
Creating Authentic Learning Assessments Through Situational Judgment Tests

Situational judgment tests (SJTs) provide a robust approach to assessing general and job-specific procedural knowledge in an authentic environment. They are applicable to a wide range of fields, including personnel selection and development, medical licensing and certification, education, and psychological assessment (eg, personality) [56-58]. Moreover, they hold significant potential for expanding into emerging applications, including health behavior and interpersonal skills [59]. SJTs are characterized by a strong intuitive prompt that asks test takers to place themselves in specific situations [60]. In this study, participants face a security threat scenario. Their task is then to select the most adept judgments and the most effective actions from several alternative responses, which are presented hereafter. In accord with the problem-solving cycle delineated above, which guided the participants through the training videos, the test items for evaluating their skill gains cover 7 dimensions, ranging from *threat awareness* to *tactic check and follow-up*. Each of these dimensions was represented by one test item within a thematically coherent testlet based on a realistic threat scenario.

Thus, the central tenets of the developed SJTs lie in their contextualization and authenticity. By immersing participants in a fictional university hospital and presenting prototypical threat scenarios through authentic image and video stimuli, these SJTs provide a cost-effective and valid method to assess employees' capabilities to manage these threats without the need to simulate factual security incidents. This approach is particularly salient in professional contexts where interruptions pose a significant threat to patient health and, in extreme cases, patient lives. The impracticality, cost, and ethical challenges associated with extensive simulations of, for example, data breaches render SJTs a compelling alternative. An example of such a scenario is shown in Figure 2, illustrating the *threat awareness* dimension of the SJT. Participants were asked to evaluate the relative severity of various messaging behaviors that could lead to the inadvertent disclosure of sensitive patient data via private messaging apps, and to rank them using the following scale: 1=most threatening, 2=less threatening, and 3=least threatening.

In several workshops, we not only developed problem-based threat scenarios but also professionally grounded response options for information-secure actions. The scenarios and response options were iteratively revised in close collaboration with information security experts and test developers, who paid particular attention to their alignment with the respective skill dimensions and security policies. To allow for a differentiated assessment of both high and low levels of the targeted construct, the number of response options per item was limited to 4 to 6. The tests used a forced response format with different response types, including single choice, multiple choice, and rating, to enable a nuanced assessment of decision-making and judgment in information security contexts. To examine the quality of the testlets, we conducted a pretest with 100 physicians (37 female, 63 male; mean age 34.73, SD 10.95 years), 101 nurses (41 female, 60 male; mean age 41.40, SD 9.85 years), and 102 administrative staff (24 female, 76 male, 2 diverse; mean age 28.26, SD 7.29 years). The results indicate an acceptable level of difficulty for the target population, as reflected in the range of the item difficulty index (0.71-0.78). In addition, key metrics such as variance and discrimination index confirmed that the test items effectively detect interindividual differences in test performance. Consistently positive feedback on the usability and authenticity of the test underscored its acceptance among the target groups [37].

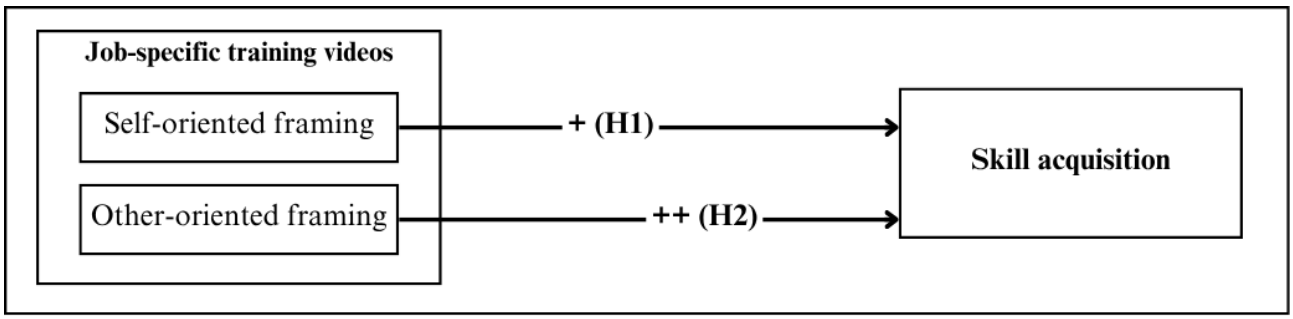
Figure 2. Example item from the situational judgment test targeting the dimension "threat awareness.".



Intervention Implementation

To test our hypotheses and proposed research model (Figure 3), we conducted a randomized controlled trial with hospital staff of 3 German university hospitals in late 2023. Data were collected via the online platform Qualtrics. The participating organizations were free to decide whether to share the link to this platform in their intranet or via newsletter, sent from either their marketing or their information security department. The training phase was open for 2 weeks, during which time participants could schedule the training at their convenience. At the beginning, participants were asked to indicate their job profile. Based on this information, participants were assigned a job-specific training video and corresponding pre- and posttests, each tailored to the demands and risks associated with their professional role. An attention check in the form of a single content-related question was included after the video, without revealing or overlapping with any later test content. All participants correctly answered the attention check question, indicating continuous attention to the video content. Additionally, the time participants spent on the training page was recorded as an indicator of intervention exposure. To ensure standardization and minimize external influences, all participants completed the baseline-skill assessment (pretest), the video intervention with or without motivational framing, and the achieved-skill assessment (posttest) in immediate succession on the platform.

Figure 3. Conceptual model illustrating the hypothesized effects of self-oriented and other-oriented motivational framing of job-specific training videos on skill acquisition.



Randomization and Blinding

Within each job profile, participants were randomly assigned to either the treatment or control condition. The allocation was conducted using simple randomization through the online platform at the start of the study. This automated process was embedded in the predefined succession of tests and training (see above) to ensure allocation concealment and prevent any influence from the researchers or participants on group assignment. Professionals in the control group were provided

only with their respective job-specific training videos. Those in the two intervention groups watched the same videos (for their profile) with an additional motivational framing at the beginning that was either self-oriented or other-oriented (Table 1). The total length of the training videos was approximately 5 minutes of pure information security content and an additional 30 seconds for a motivational framing. Participants were unaware that different motivational framings were used in the training materials and assumed that all participants received the same intervention. Skill assessment in both the pre- and the posttests was fully automated through a predefined scoring algorithm. No manual input or subjectively biased coding influenced the outcome data, ensuring objectivity and consistency.

Table 1. Overview of motivational framing strategies in the intervention groups.

Group	Motivational framing
Other-oriented framing (n=43)	The dangers posed by incorrect IT security behavior are very high and can lead to the interruption of services or the disclosure of sensitive data. Therefore, it is important that you are able to protect your patients. The content from this training will help you build the skills necessary to protect your patients and their privacy.
Self-oriented framing (n=43)	The dangers posed by incorrect IT security behavior are very high and can lead to the interruption of services or the disclosure of sensitive data. Therefore, it is important that you are able to protect yourself. The content from this video will help you build the skills necessary to protect yourself and your privacy.
Control (n=44)	No motivational framing.

Measures

The intervention's efficacy was evaluated using SJTs, which were developed to assess information security skills. To serve the purpose of pre- and posttraining assessments, these SJTs used 2 threat vectors from the same risk category for each job profile. For physicians and nurses, the risk category of inadvertently disclosing sensitive information was operationalized in two ways: (1) disclosing sensitive patient data via private messenger services and (2) publishing images via social networks. For administrative staff, two threat vectors were developed to reflect noncompliance with the clean desk policy: (1) leaving confidential documents openly visible on the desk and (2) leaving sensitive electronic data accessible by failing to lock the computer when unattended. Therefore, the pre- and posttest scenarios and their related items were not identical, although they followed the same structure and belonged to the same risk category. Nonetheless, the SJTs were presented in a randomized order to minimize potential biases arising from test familiarity. Each participant was randomly assigned 1 of the 2 SJTs corresponding to their job profile for the baseline assessment. The other test served to measure posttraining skill levels. Each test item, corresponding to 1 of the 7 information security skill dimensions, was scored from 0 to a maximum of 2 points, resulting in a total score of up to 14 points per testlet. Age and gender were included as control variables to account for potential demographic influences on skill gains.

Participants

A total of 130 participants were included in the study, with a balanced gender distribution (53.8% male and 46.2% female). Their age ranged from 18 to 71 years (mean 42.6, SD 12.21 years). Regarding job profiles within the health care sector, 50% of the participants primarily fulfilled administrative tasks in their respective hospitals, 30.8% were occupied as nurses, and another 19.2% as physicians. This diverse sample composition allows for a comprehensive analysis of the effects of the intervention across different job profiles.

Power Calculation

A power analysis was conducted using the R package pwr [61] to determine the necessary sample size for a 1-way ANOVA with 3 groups. Assuming a medium effect size (f=0.30 [62]), an alpha level of .05, and a desired statistical power of 0.80, at least 37 participants would be needed per group, which was exceeded in the present sample. The underlying assumption was supported by effect sizes reported in comparable studies on motivational framing and message matching, which demonstrated moderate effects on attitude and behavior change [26].

Data Analysis

Before running the main analysis, we compared the baseline characteristics of the experimental groups to ensure group equivalence at the beginning of the study. Categorical variables were analyzed using chi-square tests, while age was examined using 1-way ANOVA. Baseline skill levels (pretest scores) were compared using Kruskal-Wallis tests to account for potential violations of normality. No significant differences were found between groups with respect to age (P=.39), gender (P=.95), or job profile (P=.91). However, baseline skill levels differed significantly between groups, as indicated by the Kruskal-Wallis test (χ^2_2=9.4, P=.009). Therefore, the baseline skill level was included as a covariate in subsequent analytical steps. This allowed us to adjust for initial differences in participants' prior knowledge and to isolate the effect of motivational framing on skill gain with greater precision.

Before testing hypotheses of motivational framing, exploratory paired-samples t tests within each job profile were conducted. This step established the training intervention's baseline efficacy, allowing the interpretation of any estimated framing effects as modulators of learning processes. Its outcome is reported in the descriptive results below.

Building on this, we examined the expected differential extents of skill acquisition yielded by the applied types of motivational framing. An analysis of covariance (ANCOVA) was performed with skill acquisition (measured by the difference between posttest and pretest scores) serving as the dependent variable

and the experimental condition (control, self-oriented, or other-oriented) representing the independent variable. The requirements for applying ANCOVA are fulfilled. Observations were independent by design, as each participant was assigned to only one experimental condition. The assumption of homogeneity of variances was met, as indicated by the Levene test ($F_{2,127}$=0.37; P=.69). To detect potential outliers in skill acquisition within each experimental group, we calculated z scores separately for each group. No outliers were identified based on this criterion, suggesting that extreme values in skill acquisition were not present within any experimental condition. Although the Shapiro-Wilk test (W=0.967; P=.003) indicated a slight deviation from normality, given the sample size and the demonstrable absence of extreme outliers, the ANCOVA can be considered to deliver robust estimations [63]. The assumption of homogeneity of regression slopes was also fulfilled, as the interaction between group and pretest score was not significant ($F_{2,124}$=0.30; P=.74). All statistical analyses were conducted using R version 4.3.2 (October 31, 2023; R Core Team).

Ethical Considerations

The study was reviewed by the ethics committee of the Georg-August University of Göttingen, Germany (approval issued May 8, 2023). In an official statement issued in May 2023, the committee raised no ethical concerns about implementing the project as long as all applicable data protection regulations were followed. All participants were informed of the purpose of the training and how the tests would be used to evaluate its effectiveness. Participation was voluntary, and informed consent was obtained beforehand. Data handling complied with the General Data Protection Regulation and institutional data protection policies. No financial or material compensation was provided to participants.

Results

Descriptive Results

Building on the sample description above, Figure 4 depicts the flow of participants through recruitment, allocation, and analysis in accordance with the CONSORT (Consolidated Standards of Reporting Trials) guidelines [64] (checklist in Multimedia Appendix 1). Table 2 shows the descriptive study results for the 3 job profiles sorted by the experimental groups. Paired-samples t tests (2-tailed) indicate significant gains in information security skills in all job profiles following the training intervention. For administrative staff, the analysis reveals a significant improvement from pretest scores to posttest scores (t_{64}=3.30; P=.002) with a mean difference of 0.51 (95% CI 0.20-0.81) and an effect size of Cohen d=0.41. Similarly, a significant increase was observed for nurses (t_{39}=2.63; P=.01), with a mean difference of 0.65 (95% CI 0.15-1.15) and an effect size of d=0.48. The greatest improvement was found among physicians (t_{24}=4.11; P<.001), with a mean increase of 1.24 (95% CI 0.62-1.86) and an effect size of d=1.21. Taking an average across all job profiles, information security skills reached significantly higher levels after the training compared to before the training, with a mean difference of 0.69 (95% CI 0.45-0.94; t_{129}=5.58; P<.001), and an overall effect size of d=0.52, indicating a medium effect. These findings document that skill gains were not limited to an average value for the entire sample, but were consistently observed within each job profile.

Figure 4. CONSORT flow diagram illustrating the progression of participants through the randomized controlled trial. CONSORT: Consolidated Standards of Reporting Trials.

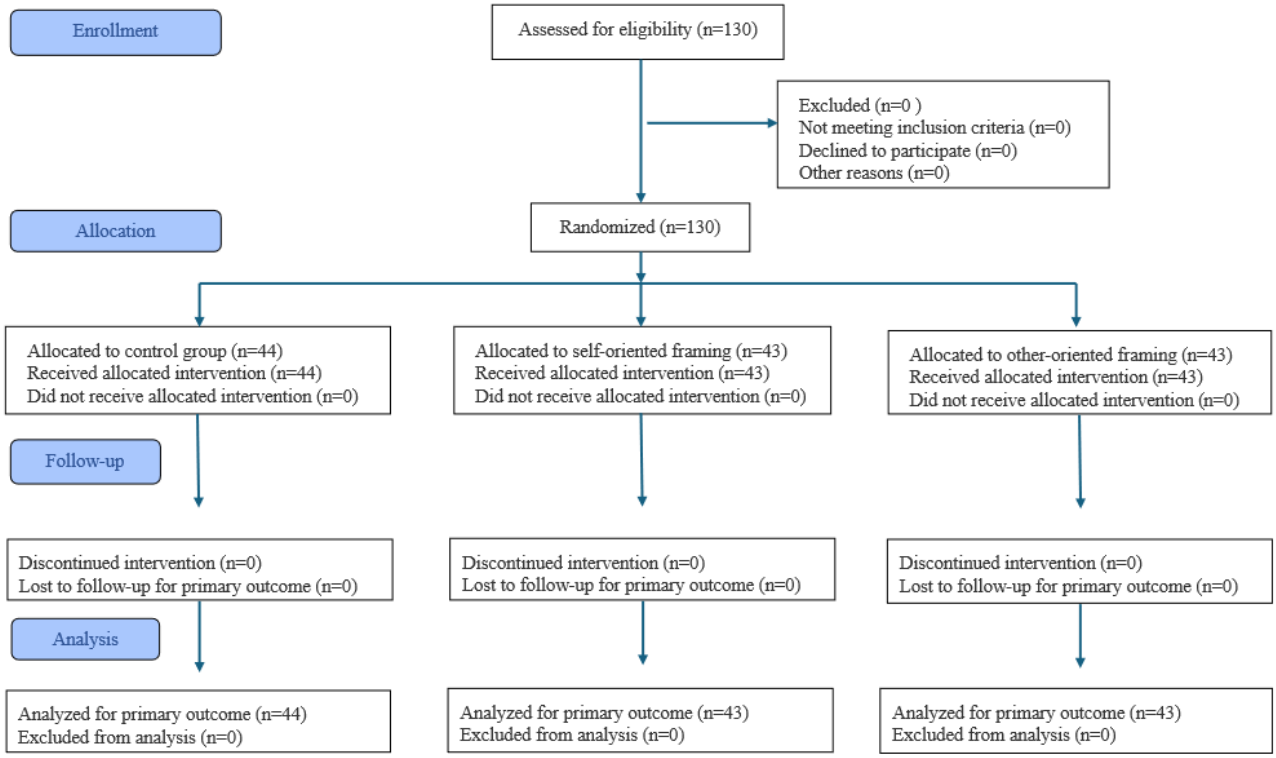


Table 2. Pretest, posttest, and skill acquisition scores by experimental group and job profile.

Intervention condition and job profile	Control group (n=44), mean (SD)	Self-oriented framing (n=43), mean (SD)	Other-oriented framing (n=43), mean (SD)
Administrative staff (n=65)			
Pretest	12.42 (1.25)	12.81 (1.33)	12.05 (1.28)
Posttest	12.67 (1.20)	13.00 (1.22)	13.20 (1.06)
Skill acquisition	+0.25 (1.33)	+0.19 (1.12)	+1.15 (1.04)
Nurses (n=40)			
Pretest	10.92 (1.66)	12.07 (1.27)	10.77 (1.54)
Posttest	11.54 (1.13)	12.07 (1.07)	12.15 (0.99)
Skill acquisition	+0.62 (1.66)	0.00 (1.36)	+1.38 (1.45)
Physicians (n=25)			
Pretest	12.86 (0.69)	12.13 (1.13)	11.20 (1.32)
Posttest	13.14 (0.69)	13.13 (0.83)	13.30 (0.67)
Skill acquisition	+0.29 (0.76)	+1.00 (1.31)	+2.10 (1.66)

Impact of Motivational Framing Strategies on Skill Acquisition

While overall improvements in information security skills are evident, the question remains whether the specific type of motivational framing influenced their magnitude. To address this, we tested hypotheses 1 and 2 using an ANCOVA procedure. The results reveal a significant main effect of motivational framing on skill acquisition, controlling for initial skill level ($F_{2,126}$=5.92; P=.004; partial η^2=0.09). Post hoc pairwise comparisons with Bonferroni adjustment across all job profiles indicate that the other-oriented framing group achieved significantly greater skill growth (mean +1.133, SD 0.159) compared to the control group (mean +0.400, SD 0.154; t_{126}=3.30; P=.004), as well as to the self-oriented framing group (mean +0.551, SD 0.158; t_{126}=2.54; P=.04). No significant differences were found between the control and self-oriented framing groups (t_{126}=0.687, P>.99). In addition to the effect of the framing strategy, a substantial portion of the variance in skill growth can be attributed to each participant's baseline skills ($F_{1,126}$=86.88; P<.001; partial η^2=0.41). Participants who started at a higher skill level demonstrated smaller gains from the training videos than those who started at lower or even rudimentary skill levels. These findings offer substantial evidence for hypothesis 2, which predicted the other-oriented framing of training content to be superior to a self-oriented framing in the studied target audience of health care professionals. Contradicting hypothesis 1, however, self-oriented framing did not yield greater enhancements of information security skills than no framing at all.

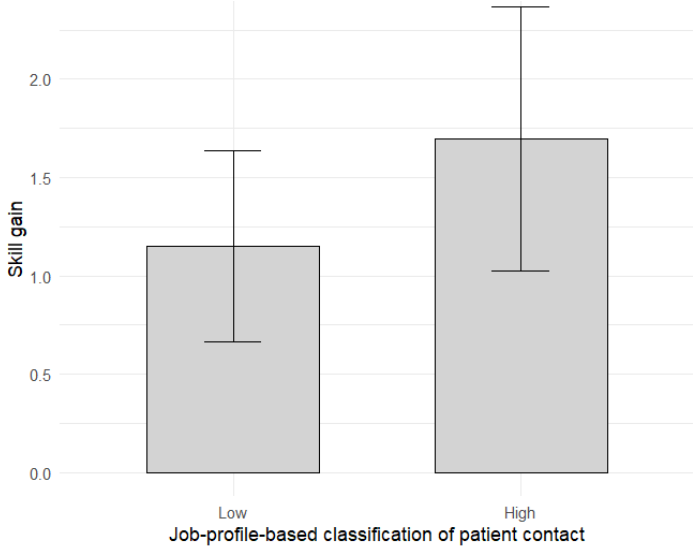
Furthermore, a closer inspection of the descriptive means presented in Table 2 suggests that the generally superior effectiveness of the other-oriented framing (see hypothesis 2 above, comparing intervention and control groups) appears to resonate more strongly with certain job profiles than with others. Physicians demonstrated the largest improvement (mean increase +2.10), followed by nurses (mean increase +1.38), and administrative staff (mean increase +1.15), whose gains, although statistically significant, were markedly smaller. This variability suggests that although all professional sectors within hospitals responded to an other-oriented motivational framing of training content, the extent of responsiveness may be influenced by individual or contextual characteristics. Drawing on models of social responsibility and professional identity [31,32], the degree of personal and direct patient contact may influence how strongly hospital staff respond to other-oriented appeals. Specifically, the frequency with which one engages personally and directly in medical and care work, as well as ethically charged decision-making, may further increase the salience of other-oriented appeals, thereby enhancing their persuasive potency.

A rigorous moderation analysis examining other-oriented framing effects contingent on contact frequency was not feasible, as a direct and isolated measure of individual patient contact was unavailable in this study. However, contact frequency is typically, although not deterministically, higher for certain job profiles than for others (see profile descriptions above). Consequently, we grouped nurses and physicians to compare them to the administrative staff. Nurses and physicians are embedded in the core clinical care process. They operate in close proximity to patients and often form interprofessional treatment teams within inpatient settings. Both focus on health-related goals and are most immediately responsible for the well-being of vulnerable individuals. Administrative staff primarily perform organizational and procedural tasks that serve patients' best interests, such as ensuring they receive swift treatment and proper accommodations. However, most of these tasks are structurally removed from the clinical care environment.

Therefore, we conducted a descriptive subgroup analysis restricted to participants who received the other-oriented framing. Specifically, we compared skill gains between roles involving high (n=23) and low (n=20) frequencies of direct patient contact. We applied the Welch t test, which yields robust

estimates. While the high-contact group showed greater skill gains (mean increase 1.70, SD 0.150) than the low-contact group (mean increase 1.15, SD 0.104), this difference did not reach statistical significance, $t_{38.67}$=1.37, *P*=.18, 95% CI –1.35 to 0.26. Figure 5 illustrates this descriptive pattern, showing that when receiving training content that is framed toward patient protection, participants whose professional roles typically involve frequent direct patient contact experience an even stronger increase in skill gain than those in lower contact-frequency roles. However, this observation is limited to the present sample.

Figure 5. Mean skill gain by the "profile-typical" frequency of patient contact within the other-oriented framing condition.



Discussion

Principal Findings

This study sheds new light on the effectiveness of motivational framing strategies in information security training for health care professionals. Participants of a video-based, job-specific training demonstrated significant improvements in information security skills. These improvements were observed across all job profiles, including administrative staff, nurses, and physicians. While empirical evidence that a contextualized and psychologically grounded content increases the effectiveness of security training has already been provided by previous studies [65], our randomized controlled trial with 130 participants demonstrates that the targeted activation of professional values can further enhance skill acquisition.

In particular, our results underscore the widely recognized limitations of traditional SETA programs, which focus on formal content and guidelines without addressing motivational aspects [66]. In this study, both the control group and the group that received a self-oriented motivational framing achieved comparably small skill gains. This indicates that appeals to individual protection or self-interest do not prompt heightened engagement with training content on information-secure workplace behaviors in professions with high levels of social responsibility, even if this content is well tailored to their daily tasks. Therefore, hypothesis 1 was not supported. This finding contrasts with studies from other professional sectors that used self-oriented *fear* appeals to promote secure behavior [67,68]. While self-oriented motivational framings have proven effective in private settings, such as protecting personal data, they appear to be less effective in clinical settings where the exertion of professional roles is strongly guided by professional-ethical values. As set out in the introduction, patient-centered care represents a primary commitment of health care professionals, which prioritizes the safety, dignity, and well-being of patients. Such concepts are integral to professional identity in the health care sector [33].

Consequently, and in accordance with hypothesis 2, framing security training content in an other-oriented way, thereby highlighting the protection of patients through information-secure workplace behaviors, proved to be the superior strategy. Participants in this intervention group demonstrated significantly greater improvements in information security skills compared to those in the control and self-oriented intervention groups. These results underscore the importance of aligning the messages that precede and accompany a training program with the core professional values of the target audience. The principle of value congruence [69], which posits that individuals respond more positively to messages that resonate with their core values, further substantiates this interpretation. Similar effects have been demonstrated in prosocial messaging research, where other-oriented appeals have a markedly stronger impact than self-oriented ones when applied in morally salient contexts [34]. Our findings extend this body of work to cybersecurity education, suggesting that value congruence can increase the effectiveness of SETA programs in socially responsible professions.

Supplementary exploratory examinations of subgroups indicate that certain variations in individual skill gains within the (generally superior) other-oriented framing condition might depend on the frequency of patient interaction. Participants whose job profiles typically require frequent direct and personal contact with patients, that is, physicians and nurses, displayed even greater increases in information security skills when the

training content was framed in an other-oriented manner than administrative staff participants did. This (merely descriptive) pattern is consistent with identity-based motivation theory [70], which posits that individuals are more likely to respond to messages that activate their specific role characteristics in a social or professional community. Thus, it provides initial support for the idea that the frequency of patient interactions (as an individual feature of participants) may further enhance the general responsiveness of health care professionals to other-oriented approaches.

Taken together, the findings highlight the importance of value-based design in SETA programs. Aligning training content with the core professional values of health care workers, such as patient protection and social responsibility, can help interventions achieve better learning outcomes. This interdisciplinary approach is a promising avenue for future research and practice on cybersecurity education.

Practical Implications

Not only the obtained empirical results but also the applied instructional and assessment design provide practical implications for the construction of SETA training and the implementation of motivational framing strategies. Structuring information security content around a substantiated skill model and tailoring it to employees' specific tasks and demands can arguably promote attention and engagement levels throughout the training. Put simply, professionals are more encouraged to extend their skill repertoire when the content is directly applicable to their daily work routines. Furthermore, tailored training programs are effective in reducing the duration of the program by eliminating irrelevant information. This approach prevents participants from feeling either overwhelmed by abstract input or overlooked as an agentic professional. Moreover, it facilitates an efficient use of training resources.

Explaining the repercussions and rationales for security-compliant conduct to participants is another important feature of effective training programs. Employees who comprehend the potential consequences of noncompliance, including data breaches and compromised patient safety, are more inclined to adopt secure practices (“threat impact assessment” according to the skill model in the present training design). The articulation of the reasons underlying particular security measures ensures that employees not only adhere to the prescribed procedures blindly (if at all) but also discern their significance (“tactic justification” according to the skill model in the present training design). In the long run, this can foster a culture of accountability and vigilance within the organization by promoting consistent and deliberate practice of safe behaviors.

Our empirical findings emphasize that a motivational framing of information security training should align with employees' professional values to maximize its impact. In the context of health care, patient protection was identified as a core value that can demonstrably be addressed through appropriate framing strategies. In other professional fields, formulating an adequate motivational framing necessitates a thorough understanding of the professional values advocated by the respective workforce.

Another recommendation is to introduce the topic of information security early in a professional’s development. This can be done through customized, easily accessible videos, such as those used in this study, or even through playful formats. Addressing this topic during the initial phases of formal vocational education can foster the understanding that information security is an integral part of responsible health care work. Initial vocational education provides more time for reflection on the compatibility of professional values and the protection of sensitive data than short-term pedagogical interventions that accompany daily professional routines and must therefore rely on short framing messages.

From an evaluative perspective, the study underscores the importance of accounting for baseline skills, particularly in light of ceiling effects, where participants with higher pre-training skill levels tend to show less growth. This underlines the need for adaptive and personalized training interventions that can optimize learning outcomes across various starting points [71]. By assessing skill levels across a range of skill sets prior to an intervention, organizations can more effectively target their training efforts to focus on areas where improvement is truly needed. Resources can be allocated to address individual skill gaps rather than providing redundant and one-size-fits-all training to the entire workforce. In the long run, this allows each employee to experience individual skill development throughout the training process, but also facilitates meaningful evaluation of the training program.

Limitations and Future Research

The study has several limitations that must be acknowledged. First, the investigation was conducted in German university hospitals with a sample of 130 health care professionals, which restricts the generalizability of the findings to other national, cultural, and organizational contexts. While patient protection served as a powerful motivator in the investigated health care context, other professional fields (eg, finance, public administration, and manufacturing) may be guided by entirely different core values, such as diligence, transparency, or efficiency. Further efforts are therefore required to develop problem-oriented, context-sensitive, and profession-specific training content for other occupational fields, as information security demands and role-related responsibilities differ substantially across sectors. In particular, the successful design of motivational framing strategies in these sectors requires a deep understanding of their respective professional ethos.

Second, the study examines short-term effects on skill acquisition, leaving open the question of long-term retention. Future research should focus on the long-term effects of information security interventions, ideally by using follow-up assessments weeks or months after the initial training. This would allow researchers to determine whether the training effects are stable, fade over time, or possibly even increase through continued application in practice.

Another limitation concerns potential self-selection bias. As participation in the study was voluntary and recruitment was conducted via internal channels, such as newsletters and hospital intranet systems, individuals with a stronger interest in information security, greater intrinsic motivation, or a higher

sense of professional responsibility were likely to be overrepresented. This may have led to an overestimation of intervention effects. It certainly helps to explain the relatively high baseline skill levels observed across the sample. Participants with advanced prior knowledge may be overrepresented compared to the general hospital workforce. Incorporating random sampling procedures or mandatory participation (in addition to the reported random assignment to framing conditions) could help to ensure a more representative selection of participants.

Results from exploratory subgroup comparisons for the generally beneficial other-oriented framing condition should encourage future investigations into moderator variables that capture individual features of health care professionals. In this study, a grouping approach to contrast job profiles that typically involve high versus low personal contact with patients (physicians and nurses versus administrative staff) provides preliminary support of the assumption that individual interaction frequency with patients might further enhance the impact of patient-oriented appeals. However, this pattern should be interpreted with caution, as the grouping by job profiles offers only a rough approximation of the psychological conditions that may shape responsiveness to value-based framings. Though commonly used to classify professional functions, job profiles often conceal variability within these profiles. For instance, not all physicians are equally involved in direct patient interaction, while certain administrative staff, such as case managers or receptionists, may routinely interact with patients. To specify features that further enhance or reduce the effectiveness of other-oriented framings in the health care sector, future research should therefore consider direct and controllable measures of individual-level moderators. This approach may also include individual assessments of empathy, moral sensitivity, or motivational regulation styles [72,73]. On a contextual level, variables such as organizational culture or leadership commitment to cybersecurity might also be considered as moderating the perceived relevance of information-secure behavior, engagement with training content, or responsiveness to different motivational framing strategies [74].

Finally, this study has put forth several didactical arguments to substantiate that demonstrable skill gains occur because instructional design elements and, in particular, motivational framing strategies encourage deeper engagement with the training content. Studies in other educational contexts have already established the mediating role of learning-process characteristics such as cognitive elaboration and engagement [75]. For information security training in health care settings, statistical evidence of the mediated learning path is still pending.

Conclusions

The increasing prevalence of cyberattacks and data breaches, particularly in the health care sector, underscores the need to enhance the information security skills of health care professionals through SETA programs. This experimental study highlights the effectiveness of customized security training videos with strategically framed motivational prompts in improving related skills, as assessed by elaborated SJTs. A key aspect of promoting skill acquisition of professionals is to elucidate that compliance with security policies can be fully compatible with their core professional values and that mastering information secure workplace behaviors contributes to enacting these values.

At least in the health care sector studied, where information security breaches have been documented to jeopardize patient safety, this alignment appears to be beneficial. By establishing a link between internalized professional responsibilities to protect patients and methods to ensure the confidentiality, availability, and integrity of sensitive patient data, employees develop a deeper commitment to security policies and to acquiring the necessary skills. In the long run, motivational framing strategies in information security training can become an important tenet in building organizational resilience to cyberattacks. They can not only raise awareness of security-related issues in day-to-day operations but also cultivate the deliberate and regular use of information-secure behaviors.

Acknowledgments

This research paper has been developed as part of the research project “KISK: Kompetenzbasierte Entwicklung von ITS-Trainingsangeboten in Krankenhäusern,” funded by the German Federal Ministry of Health. We gratefully acknowledge the support of the Federal Ministry of Health and all other project members, especially Dr. Kristin Masuch, Florian Schütz, and Florian Rampold. We would also like to thank the Chief Information Security Officers of the participating hospitals, whose cooperation made this research possible. Abstract

Background: Virtual simulated patients (VSPs) powered by generative artificial intelligence (GAI) offer a promising tool for training clinical interviewing skills; yet, little is known about how different system- and user-level variables shape students' perceptions of these interactions.

Objective: We aim to study psychology students' perceptions of GAI-driven VSPs and examine how demographic factors, system parameters, and interaction characteristics influence such perceptions.

Methods: We conducted a total of 1832 recorded interactions involving 156 psychology students with 13 GAI-generated VSPs configured with varying temperature settings (0.1, 0.5, 0.9). For each student, we collected age and sex; for each interview, we recorded interview length (total number of question–answer turns), number of connectivity failures, the specific VSP consulted, and the model temperature. After every interview, students provided a 1-10 global rating and open-ended comments regarding strengths and areas for improvement. At the end of the training sequence, they also reported perceived improvement in diagnostic ability. Statistical analyses assessed the influence of different variables on global ratings: demographics, interaction-level data, and GAI temperature setting. Sentiment analysis was conducted to evaluate the VSPs' clinical realism.

Results: Statistical analysis showed that female students rated the tool significantly higher (mean rating 9.25/10) than male students (mean rating 8.94/10; Kruskal-Wallis test, H=8.7; P=.003). On the other side, no significant correlation was found between global rating and age (r=0.02, 95% CI –0.03 to 0.06; P=.42), interview length (r=0.04, 95% CI –0.2 to 0.10; P=.18), or frequency of participation (Kruskal-Wallis test, H=4.62; P=.20). A moderate negative correlation emerged between connectivity failures and ratings (r=–0.26, 95% CI –0.41 to –0.10; P=.002). Temperature settings significantly influenced ratings (Kruskal-Wallis test, H=6.93; P=.03; η^2=0.02), with higher scores at temperature 0.9 compared with 0.1 (Dunn's test, P=.04). Concerning learning outcomes, self-perceived improvement in diagnostic ability was reported by 94% (94/100) of students; however, final practical examination scores (mean 6.67, SD 1.42) did not differ significantly from those of the previous cohort without VSP training (mean 6.42, SD 1.56). Sentiment analysis indicated predominantly negative sentiment in GAI responses (median negativity 0.8903, IQR 0.306-0.961), consistent with clinical realism.

Conclusions: GAI-driven VSPs were well-received by psychology students, with student gender and system-level variables (particularly temperature settings and connection stability) shaping user evaluations. Although participants perceived the training as beneficial for their diagnostic skills, objective examination performance did not significantly differ from the previous cohort. However, lack of randomization limits the generalization of the results obtained, and further experiments are required.

Introduction

In health education, the development of clinical reasoning is fundamental for preparing competent professionals capable of making accurate diagnostic and therapeutic decisions. However, formal instruction in clinical reasoning remains limited within many curricula, often due to time constraints and the lack of targeted pedagogical approaches. As a result, recent graduates frequently report feeling inadequately prepared to manage the ambiguity and complexity inherent in real-world clinical practice, particularly in clinical psychology, where effective diagnostic formulation requires integrating diverse, nuanced patient information [1,2].

Clinical skill development in psychology education, particularly in subjects such as psychopathology, presents a significant challenge for university programs. Successful clinical training necessitates the integration of theoretical knowledge—such as diagnostic criteria—and practical skills, such as conducting clinical interviews. Acquiring competencies such as symptom identification, differential diagnosis, clinical reasoning, and empathic communication extends beyond theoretical understanding. These competencies are deeply intertwined with practical experience, decision-making in uncertain contexts, and sustained exposure to complex clinical situations. Unfortunately, traditional teaching methods, such as paper-based clinical cases, offer limited opportunities for students to actively and progressively develop these skills, negatively affecting their confidence and preparedness.

To address these limitations, the use of virtual patients has increasingly emerged as an effective pedagogical strategy [3,4], offering simulations of realistic clinical encounters in a risk-free environment. These simulations allow students to practice crucial skills such as history taking, hypothesis formulation, and diagnostic reasoning without risking patient safety [5,6]. Virtual patient technologies have evolved considerably—from initial static textual cases to sophisticated interactive simulations powered by generative artificial intelligence (GAI) and natural language processing (NLP) technologies [3].

The integration of GAIs based on large language models (LLMs), such as ChatGPT into virtual patient platforms represents a significant advancement in educational simulations. These models facilitate realistic, responsive interactions that closely resemble genuine clinical dialogues, thereby increasing learner engagement and immersion [7]. Recent studies, including a systematic review, have shown that GAI-powered conversational virtual patients (virtual simulated patients [VSPs]) significantly enhance clinical reasoning skills and student satisfaction, especially when the interactions are perceived as authentic and dynamic [8].

Concerning authenticity, LLMs are parameterizable in different ways to adjust their behavior. In particular, the temperature parameter controls how random or deterministic LLMs' choices are: low temperature values produce more predictable and less spontaneous answers, whereas high temperature values produce more creative and natural-sounding answers (although less consistent). This effect is discussed in detail in the report presented by Peeperkorn et al [9]. Temperature control is thus relevant in a VSP, where natural-sounding answers are preferable, but consistency is also a requirement.

Despite the promising literature on VSPs, existing research has predominantly focused on medical education (eg, Peralta Ramírez et al [10] or Borg et al [11]) and nursing education (eg, Padilha et al [12] or Hu et al [13]). There remains a gap regarding their effectiveness in psychology education, particularly in the field of psychopathology. A complete review of VSP applications in psychology can be found in Imam Hossain et al [14]. Among the few previous studies in this field, the work by Lan et al [15] proposes an alternative to objective structured clinical examinations in psychology based on VSPs, which, however, are not powered by GAI. Another study from Walkiewicz et al [16] compares actors or standardized patients with VSPs, the main conclusion being that standardized patients were more effective for interview skills and VSPs were most effective for clinical reasoning skills. Also in this case, the VSP platform used was not powered by a GAI.

This study evaluates the students' perceptions of GAI-based VSPs for practical psychopathology training in an undergraduate psychology course of a public Spanish University.

Methods

Experimental Design

This study used a cross-sectional observational design to evaluate the effectiveness of GAI-based VSPs in training psychological diagnostic skills.

Every student-VSP session followed a similar schedule: the student started with no prior knowledge about the case, except from the name and age of the patient (eg, a session may start with a heading like "Simon, a 12-year-old boy, is your new patient"). With only this limited information, the student had to start the interview with the patient and ask all questions she or he found necessary to reach a conclusion about a diagnosis for the patient. When the student had gathered all information needed, she or he ended the interview and filled out a report specifying the diagnose and, depending on the patient, answering a set of extra questions related to the case.

Apart from that, the student also rated the tool after each session and evaluated self-perceived learning improvement. All sessions ended through 2 web-based questionnaires. Both questionnaires adhere to the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) guidelines [17] (Multimedia Appendix 1).

The first questionnaire (student satisfaction, completed after each interview) consisted of 3 items, distributed across a single screen (page). The second questionnaire (learning improvement,

completed only once after all practice sessions) had 14 questions distributed across 5 screens (pages), although only one of these items is included in this study. The project team was multidisciplinary: the psychologists designed both questionnaires, and the engineers designed the responsive web application following this design and assuring correct behavior on different screen sizes.

The study was conducted as a "closed survey," requiring participants to log in via the university's virtual campus with their unique student credentials. Once the questionnaire had been submitted, the students could check their answers and the conversation with the VSP, but the submit button was disabled to prevent duplicate entries. Furthermore, the application only allowed the submission of fully completed questionnaires. To remove nonmeaningful interactions from the dataset, sessions with fewer than 3 questions in the conversation between student and VSP were excluded from analysis.

In selected sessions, the GAI model's temperature parameter was fixed randomly at one of 3 different levels: 0.1, 0.5, and 0.9. This setting was unknown to the students in all cases. As outlined in the Introduction section, temperature controls the degree of randomness in the model's responses: lower values (eg, 0.1) produce more deterministic and structured replies, while higher values (eg, 0.9) allow for more varied and unpredictable outputs. The study explored whether this parameter influenced students' perceptions of the tool (tool rating), as well as the length of the interviews (number of questions asked by the student).

The platform recorded the complete interaction history, including both student inputs and GAI responses. The length of each interview was measured in terms of the number of questions asked by the student and answered by the VSP. We also explored whether this parameter influenced students' ratings of the tool.

Due to internet connectivity issues, the GAI model was occasionally unreachable, and certain student questions were not answered by the VSP. In these cases, the message received by the student was "Connection error, please repeat your question." Interview length did not account such failed interactions. We recorded separately the number of these connectivity failures in every interview to evaluate their possible influence on student ratings.

Platform Development

The starting point for platform development was 13 cases of different psychopathologies described in terms of (1) symptoms, clinical history, and familial or social context; and (2) questions to be answered by the students, including a proposal of the correct diagnosis for the patient.

The desired final result was 13 GAI-based VSPs behaving accordingly to each of the 13 cases. The VSPs did not offer any initial information about their diseases, and the students were responsible for gathering all information by interviewing them. An important requirement was to allow interaction using unlimited natural language (ie, free text instead of selection from predefined questions). After the interviews, the software had to ask the students the questions related to the case, including the proposal of a correct diagnosis. The complete interview (student questions and VSP answers) had to be registered for further analysis.

Other goals to be fulfilled by the VSP platform included:

- It should enable health care educators without programming expertise to modify and adjust the VSPs.
- The reliability of the GAI responses had to be assured, to avoid hallucinations or incorrect VSP answers to student questions.
- It should allow an easy customization of key GAI parameters—such as temperature (controlling response randomness) and top_p (influencing response diversity).
- It should facilitate user satisfaction assessment by collecting qualitative feedback and improvement suggestions.

The tools selected for VSP development were the PHP programming language and 2 different GAI models (OpenAI and Mistral AI) accessed through their public APIs.

The platform was designed by a multidisciplinary team involving software engineers, psychologists, and docents. We followed a collaborative approach similar to that presented in Fernández et al [18], under an incremental and iterative software development life cycle [19], in which, for each added functionality, we carried out successive steps of development, revision by the complete team, redesign if needed, and validation. This incremental scheme aimed at 6 different development steps:

- Step 1: Working VSP for the first clinical case: must answer all student questions correctly, according to the patient symptoms and expected behavior in terms of expressiveness and feelings.
- Step 2: Working VSP for the first clinical case with adjustable temperature and top_p parameters for answer randomness control.
- Step 3: Working VSP for the first clinical case with closed-loop supervision by a secondary GAI model and temperature or top_p automatic adjustment.
- Step 4: Working VSP for the first clinical case integrated in a teaching and evaluation environment with access control, final questionnaire for students, and practice registration in the database.
- Step 5: Docent tool for creation and edition of VSPs. This tool will further be used to create the 13 required VSPs for each of the 13 cases.
- Step 6: VSPs created for all 13 cases.

A final validation step was carried out, with exhaustive tests performed by the psychologists and docents for each of the 13 VSPs developed, prior to the start of training sessions with the students.

Recruitment of Participants and Demographic Data Registered

Participants were recruited from second-year undergraduate psychology students enrolled in the psychopathology course at Miguel Hernández University (UMH), Elche, Spain. This mandatory course, part of the second year of the psychology degree program, was delivered during the first semester (October

2024 to January 2025) of the 2024-2025 academic year and carried a workload of 7.5 credits, according to the European Credit Transfer and Accumulation System. All enrolled students were invited to participate in the study, with no exclusion criteria applied. Participation in the study required attendance at least one of the 6 training sessions scheduled, each one involving interaction with 1-3 different VSPs (globally, 13 VSPs distributed across 6 training sessions; more details can be found on the website [20]).

The only demographic data registered for participants were age and gender.

Student Satisfaction

Upon completion of each session, participants rated their experience on a 1-10 scale. Ratings of exactly 5 were excluded from the analysis, as this value appeared as the default option on the evaluation form. Because it could not be determined whether these responses were selected intentionally or by omission, their inclusion was considered potentially biased. Therefore, they were removed to preserve the validity of the statistical analysis.

Each student was also encouraged to write 2 open-ended comments: the first detailing the positive aspects found in the tool and the second providing improvement suggestions. Multimedia Appendix 2 shows the structure of the questionnaire.

Student satisfaction was analyzed for relationships with frequency of participation (number of interviews carried out by each student), age and gender of the student, length of interviews, VSP interviewed, number of connectivity failures, GAI temperature parameter, and gender pairing. Gender pairing refers to the possible influence on the tool rating of the VSP and the student having the same or different genders. In other words, the goal is to check whether male or female students rated male or female VSPs differently.

Learning Improvement

Learning improvement was measured both in terms of perceived improvement and in terms of marks obtained by the students, compared to previous years.

For perceived learning improvement, a final questionnaire was completed (optionally) by the students after all VSP sessions had ended. The only item related to learning improvement was: “Do you consider that interacting with virtual patients helped you improve your ability to identify relevant symptoms during the clinical interview?”

The final questionnaire included other items that are out of scope of this study; more details can be found in Morales et al [21]. Multimedia Appendix 3 shows the structure of the questionnaire.

For mark comparison, the marks obtained by the students in courses 2023/2024 and 2024/2025 were compared. Two items were analyzed: the marks obtained by the students in the practice sessions (reflecting how challenging the practices were) and the marks obtained by the students in the final practice examination (reflecting the competencies they acquired). The final practical examination was a paper-based examination in both courses. The training was also similar in both courses, covering the same 13 clinical cases; however, this training was paper-based in course 2023/2024 and VSP-based in course 2024/2025. For the analysis of average session grades, students with zero attendance were excluded, and the mean was calculated using only attended practices, ensuring that absences did not function as “zero” scores and skew the results.

Sentiment Analysis

A sentiment analysis was performed on both student questions and GAI-generated responses using a Python script [22] and an NLP library, *Pysentimiento* [23]. This analysis classified the emotional tone of the interactions as positive, neutral, or negative, both at the individual exchange level and for the entire conversation.

Content Analysis

Regarding open-ended comments, an automated content analysis was carried out to extract the most repeated topics from all user comments, both in the set of positive comments (ie, positive aspects found in the tool) and in the set of critical comments (ie, improvement suggestions). The analysis was automated through GAI to extract the most repeated topics and their repetition counts. Similar automations have been tested in Prescott et al [24], with results comparable to those obtained by human coders, particularly in inductive analyses like the one carried out in this study.

Statistical Details

Excel (version 16.101.3 for MacOS; Microsoft Corp) was used for data storage. Data processing and analysis were conducted using R (version 4.4.2; R Core Team).

Measures of central tendency and dispersion were calculated for quantitative variables, while frequency distributions were computed for categorical variables. Group comparisons were performed using parametric tests when the assumptions of normality were met and nonparametric alternatives when those assumptions could not be satisfied.

To examine the relationship between students’ ratings of the tool and other quantitative variables, Pearson correlation analyses were conducted.

Ethical Considerations

This study was approved by the Research Ethics Office of UMH (code DPS.CFP.250116). According to the limited personal data registered (only age and gender), the Research Ethics Office considered the study anonymous, that is, it is not possible to identify a participant from these data. Multimedia Appendix 4 shows the ethical approval record.

Results were stored in a password-protected database whose access was restricted to the researchers taking part in the project.

All students accepted an informed consent prior to every VSP session. The conversation with a VSP did not start unless the student read and accepted the terms. The text of the informed consent was made intentionally clear and concise: “The conversation held with the virtual patient, as well as the answers given in the further questionnaire, will be analyzed in aggregated terms, ensuring privacy and anonymity, as part of a research

study whose goal is to improve the use of virtual patients for psychology education. Please confirm that you accept the treatment of your conversation and answers under these conditions."

After all practice sessions ended, a final, global questionnaire was also presented to the students, who were also required to accept a similar informed consent, with the text: "The results obtained in this questionnaire will be analyzed in aggregated terms, ensuring privacy and anonymity, as part of a research study whose goal is to improve the use of virtual patients for psychology education. By sending the questionnaire you accept the treatment of your answers under these conditions."

Students received no financial compensation for their participation in the study.

Results

Platform Developed

According to the incremental and iterative software development life cycle described in the Methods section, different versions of the application were developed, tested, and validated before proceeding to the next development step. Table 1 shows the development process followed, including development and validation dates.

Table 1. Incremental development steps for the virtual simulated patient (VSP) platform.

Step	Developed	Validated
Step 1: Working VSP for first case	April 15, 2024	May 9, 2024
Step 2: VSP with temperature and top_p control	May 15, 2024	May 21, 2024
Step 3: VSP with closed loop supervision	June 19, 2024	June 25, 2024
Step 4: VSP integrated in learning environment	July 3, 2024	July 9, 2014
Step 5: Tool for creating and editing VSPs	July 12, 2024	July 24, 2024
Step 6: VSPs created for each of the 13 cases	September 12, 2024	September 25, 2024

The platform was developed as a responsive web application, optimized for seamless use across desktops, tablets, and smartphones, and programmed using PHP [25].

Figure 1 shows the flowchart of a practice session, which required initial informed consent. The main screen of the application is the dialogue or interview with the VSP, which can be as complete as the students require (in terms of number of questions asked to the VSP). The students can also check extra information during the practice session, specifically a manual with information on how to diagnose a patient. Once the students access the practice questionnaire, it is allowed to return to the interview screen (to revise the conversation), but it is not allowed to ask new questions to the VSP. After sending the questionnaire with all items fulfilled, the practice session ends.

Figure 2 provides example screenshots of a generated VSP interaction: the left-hand image shows the ongoing text-based patient dialogue (ie, interview screen), while the right-hand image presents sample assessment questions provided to the student postinteraction (ie, questionnaire screen).

Figure 1. Flowchart of a practice session with a virtual simulated patient (VSP).

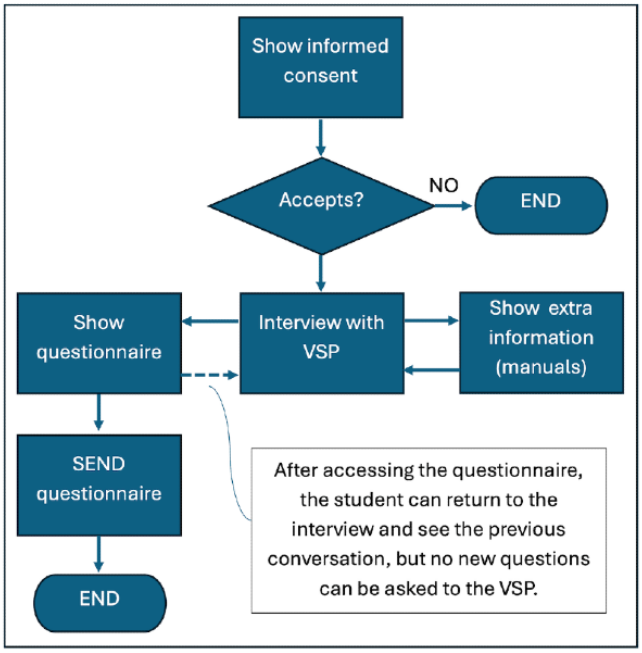

Figure 2. Example screenshots from the virtual simulated patient (VSP) application.

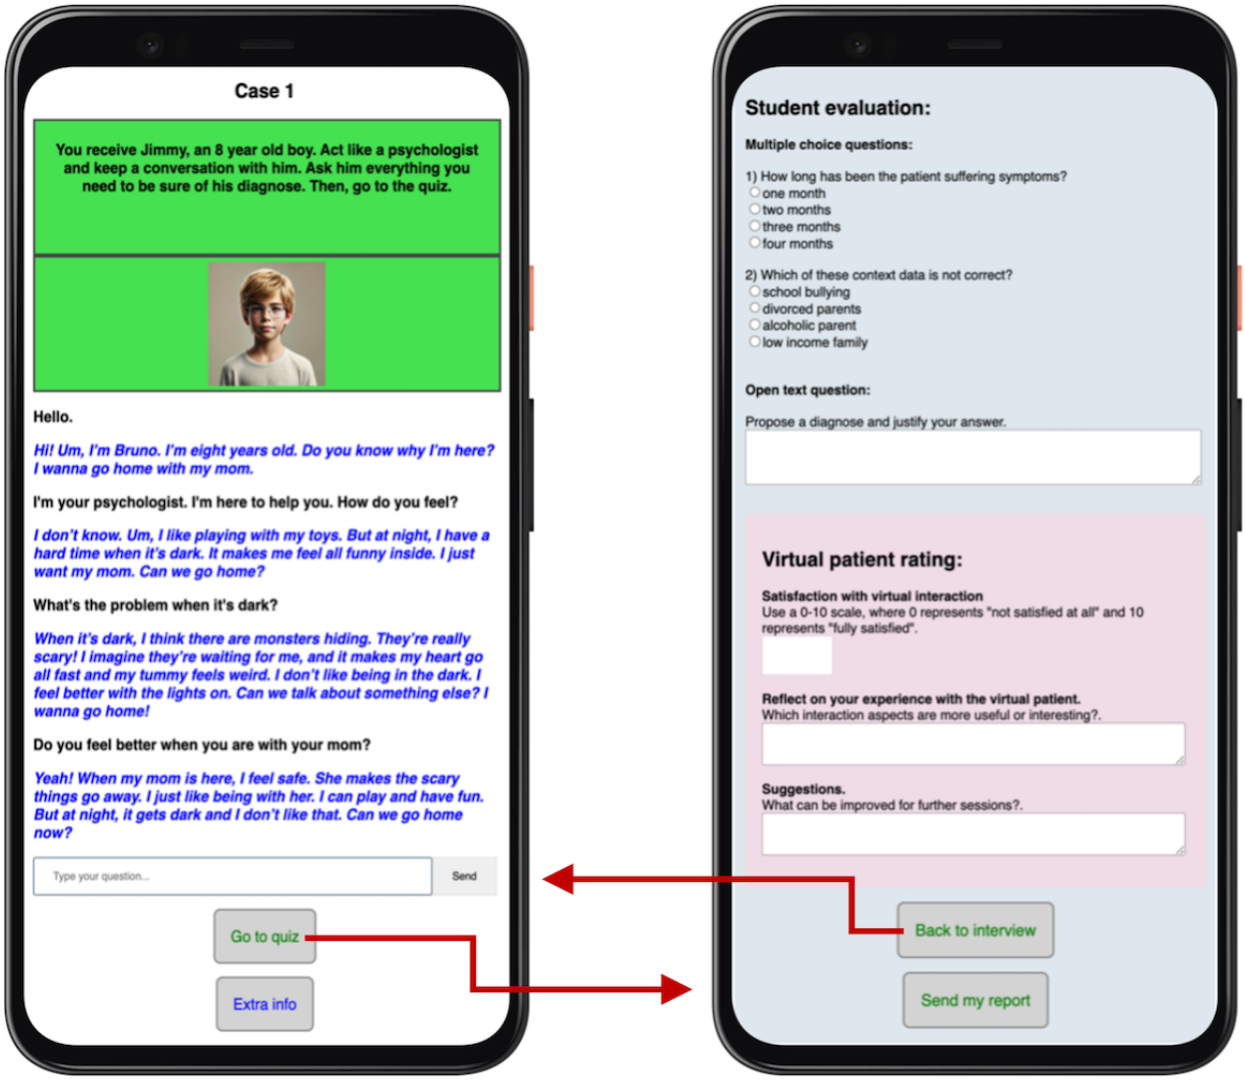


More details about the VSP platform developed, namely software architecture and the VSP generator for docents, are available in Multimedia Appendix 5.

Participant Demographics

A total of 156 unique participants took part in the study, carrying out 1832 interviews with VSPs (13 different VSPs). Most of the participants were aged 18-22 years, with a limited number of older participants (3 participants did not provide their ages). Table 2 shows the number of interviews carried out (frequency) per participant age range, among the 153 participants who provided age data.

The sample showed a marked gender imbalance, consisting mostly of female students (127/153, 83%), with male students representing 17% (26/153) of the total sample. Table 2 shows the complete age and gender distribution, which reflects the current trend in Spain, where the number of women enrolled in psychology degree programs significantly exceed that of men, a pattern observed in higher education statistics nationwide (77.2% of female psychology students as of the course 2022/2023 [26], and 79.9% of female psychology graduates [27], preliminary report for the course 2024/2025).

Table 2. Frequency and percentage distribution of participants by age range and gender.

Age range (years)	Men, n (%)	Women, n (%)	Total n (%)
18	0 (0)	8 (5.2)	8 (5.2)
19	14 (9.2)	86 (56.2)	100 (65.4)
20	4 (2.6)	10 (6.5)	14 (9.2)
21-25	5 (3.3)	10 (6.5)	15 (9.8)
26-30	1 (0.7)	5 (3.3)	6 (3.9)
31-35	1 (0.7)	4 (2.6)	5 (3.3)
36-40	0 (0)	1 (0.7)	1 (0.7)
41-45	0 (0)	2 (1.3)	2 (1.3)
46-50	1 (0.7)	0 (0)	1 (0.7)
51-55	0 (0)	1 (0.7)	1 (0.7)
Total	26 (17)	127 (83)	153 (100)

Student Satisfaction

Student Satisfaction Versus Demographics and Interview Length

Overall, high ratings (medians close to 10) remained consistent across different demographic groups and interaction levels.

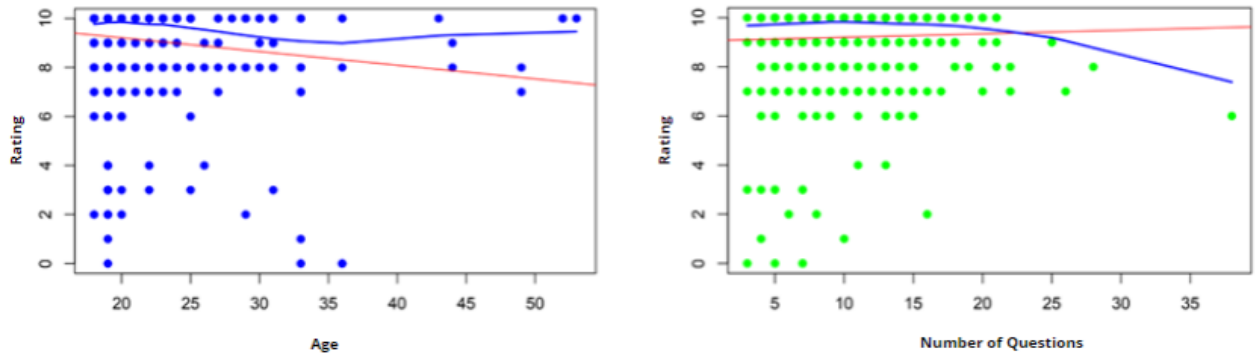
Female students rated the tool significantly higher (mean rating 9.25/10) than male students (mean rating 8.94/10; Kruskal-Wallis test, H=8.7; *P*=.003).

Concerning age, no significant correlation was found between participants' age and their overall rating of the tool (*r*=0.02, 95% CI –0.03 to 0.06; *P*=.42).

Similar results were obtained for interview length (number of questions posed by participants), with no significant correlation against the overall rating of the tool (*r*=0.04, 95% CI –0.2 to –0.10; *P*=.18). This indicates that the quantity of interaction did not notably influence students' evaluation of the platform.

Participants age and interview length are plotted against overall ratings in Figure 3. In interpreting these trends, no meaningful association emerged between participants' age and their rating of the tool: students of different ages consistently evaluated the tool positively, with only minimal variation across the age range. Likewise, although interviews involving a higher number of questions tended to show slightly lower ratings, this pattern was weak and did not indicate a substantial change in students' perceptions of the tool.

Figure 3. Relationship between participants' age and their rating of the tool (left panel) and between the number of questions posed and the rating provided (right panel).



Student Satisfaction Versus Frequency of Participation

On average, students rated the tool highly, with minor variations related to their frequency of participation. However, a modest positive trend in average ratings was observed, suggesting that increased exposure might slightly enhance perceptions of the platform's effectiveness (Table 3). To analyze this relationship between students' frequency of participation and their average ratings, Shapiro-Wilk tests indicated that ratings did not follow a normal distribution in any of the participation groups (*P*<.001 in all cases). To evaluate whether parametric methods could nevertheless be applied, several common transformations were tested (logarithmic, square root, Box-Cox, and Yeo-Johnson). Although the Yeo-Johnson transformation provided some improvement (eg, W=0.775; *P*<.001 for "Participated once"; W=0.911; *P*=.005 for "6-10 times"), none of the groups achieved normality. Consequently, a nonparametric Kruskal-Wallis test was used as the most appropriate analytic strategy. The results of this test showed that the effect of frequency of participation was not statistically significant (H=4.62, *P*=.20; Table 3).

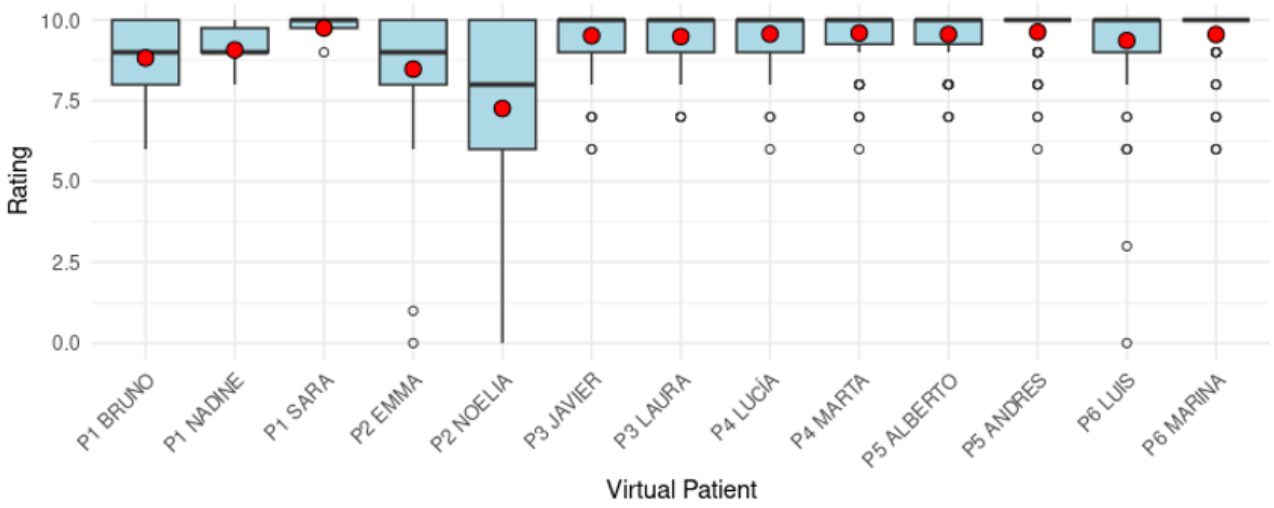
Table 3. Mean ratings of the platform based on student participation frequency (Kruskal-Wallis test, *P*=.20).

Participation frequency	Participants, n	Mean rating (95% CI)
Participated once	16	8.8 (7.3-9.6)
Participated 2-5 times	21	8.9 (8.3-9.4)
Participated 6-10 times	48	9.0 (8.6-9.4)
Participated >10 times	75	9.3 (9.1-9.6)

Student Satisfaction Versus VSP Interviewed and Connectivity Failures

When analyzing ratings by VSP, overall scores remained high, with most VSPs receiving median values near 10. However, some variation was observed, with median ratings ranging from approximately 8 to 10 across the 13 VSPs (Figure 4). Notably, Emma and Noelia received comparatively lower ratings. These 2 VSPs were involved in a session affected by a higher incidence of internet connectivity issues, which likely contributed to the reduced participant evaluations.

Figure 4. Distribution of participant ratings for each virtual simulated patient (VSP). The red dots represent the mean rating for each VSP. The label "P" indicates the practice session in which each VSP was used (eg, P1=Practice 1).



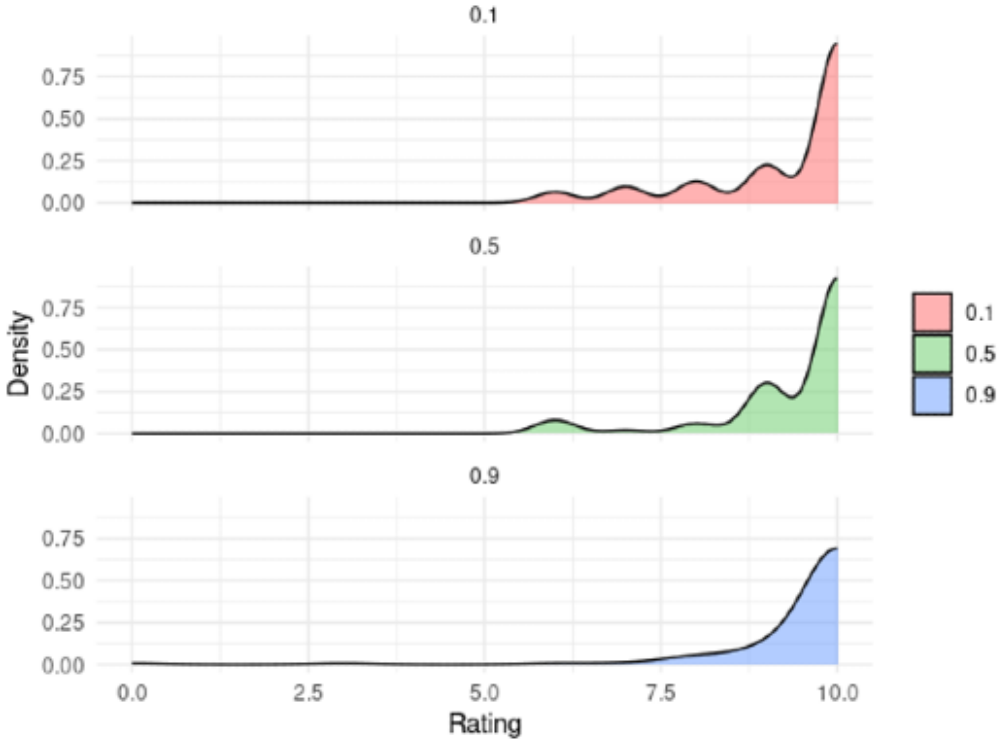
This finding aligns with a moderate negative correlation between the number of internet connectivity issues and participant ratings (r=–0.26, 95% CI –0.41 to –0.10; P=.002). This suggests that a higher number of connectivity failures was associated with lower ratings from students.

Student Satisfaction Versus GAI Temperature Parameter

Shapiro-Wilk tests conducted for each temperature level (0.1, 0.5, and 0.9) indicated strong departures from normality (P<.001 in all cases). Attempts to normalize the data through logarithmic and square root transformations were unsuccessful. The Box-Cox procedure suggested a transformation parameter far from 1, while the Yeo-Johnson approach estimated an extreme λ value ($\lambda \approx 11.2$), confirming severe nonnormality. Given these results, nonparametric Kruskal-Wallis tests were again retained as the most suitable analytic approach, revealing a statistically significant difference between them (H=6.93; P=.03). The effect size was small (η^2=0.02, 95% CI –0.00 to 0.07), suggesting that temperature explained only about 2% of the variance in ratings.

Post hoc comparisons using Dunn's test with Holm correction showed no significant difference between temperature levels 0.1 and 0.5 (P=0.62) nor between 0.5 and 0.9 (P=.14). However, a significant difference was found between 0.1 and 0.9 (P=.04), suggesting that higher ratings were associated with the 0.9 temperature condition (Figure 5).

Figure 5. Density plot showing the distribution of tool ratings across different temperature settings (0.1, 0.5, and 0.9).

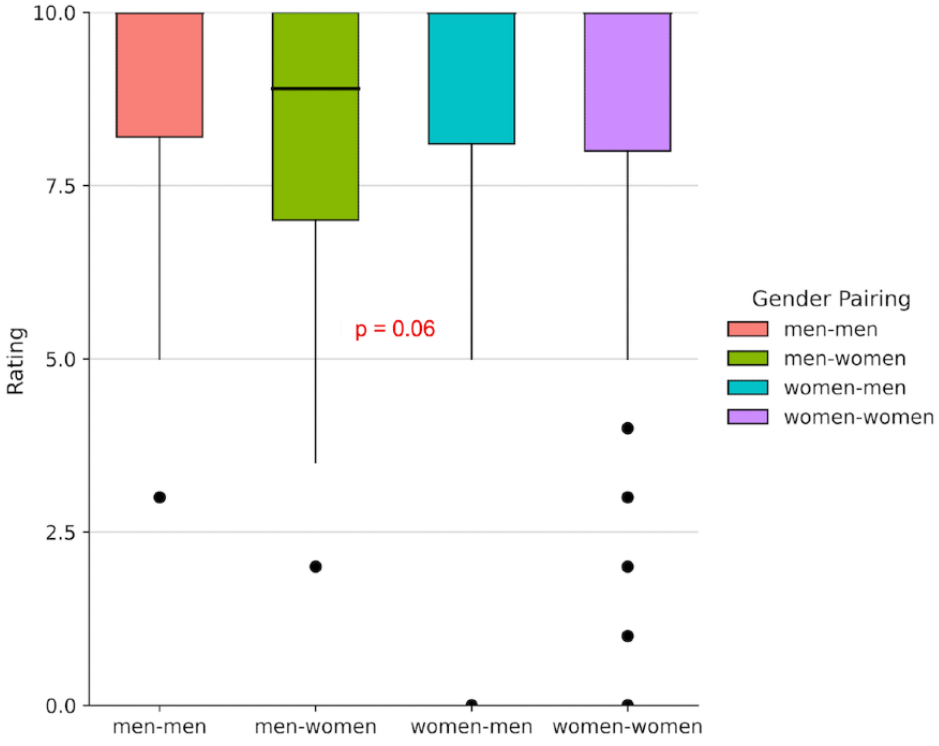


Student Satisfaction Versus Gender Pairing

Regarding the gender pairing between students and VSPs (Figure 6), the Kruskal-Wallis test revealed no statistically significant differences between groups (H=7.41, *P*=.06). Post hoc comparisons using Dunn's test with Bonferroni correction also showed no significant differences across any of the gender combinations evaluated. These results suggest that neither the participant's gender nor that of the VSP had a meaningful impact on how the tool was rated.

However, given that the *P* value was close to the conventional threshold for significance, it would be advisable to include a larger sample in future studies to more accurately assess whether gender pairing influences students' evaluations of the tool.

Figure 6. Boxplot showing the distribution of tool ratings by gender pairing between the participant and the virtual simulated patient (VSP).



Learning Improvement

A total of 100 students completed the optional final questionnaire. Table 4 shows the results obtained the question related to learning improvement.

According to the results obtained, the ability to identify relevant symptoms was mostly agreed (94/100, 94% of students found their ability had increased “a great deal” or “quite a lot”).

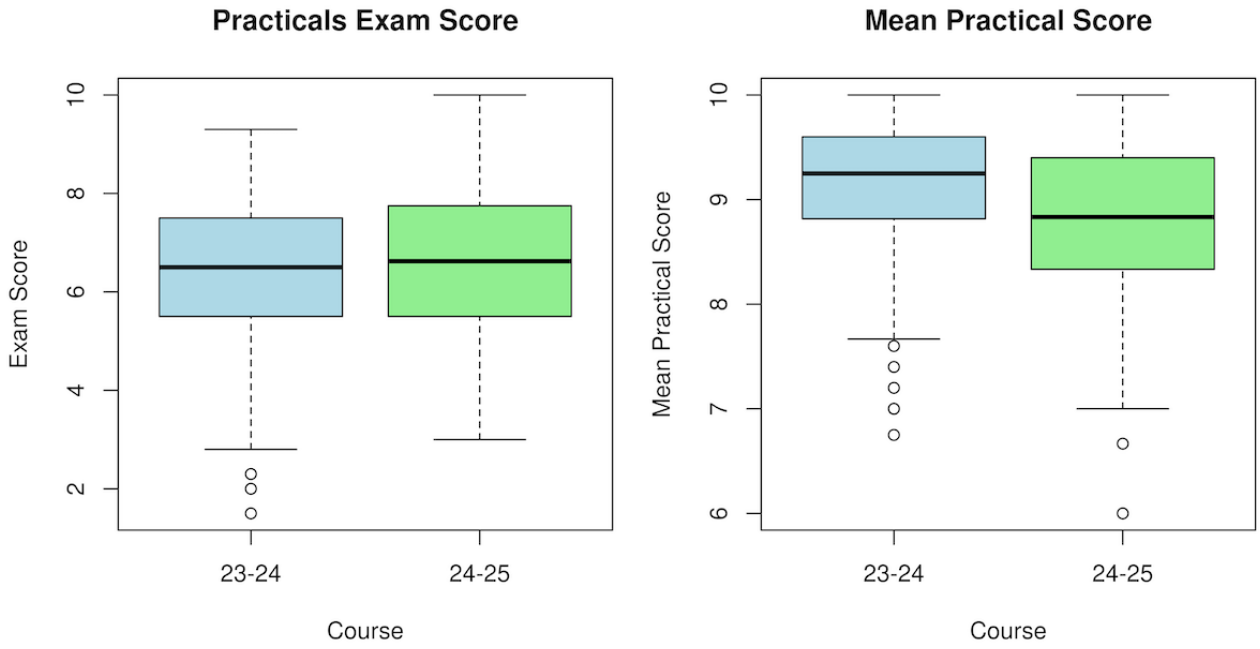
Table 4. Final questionnaire, item related to learning improvement.

Question: Do you consider that interacting with virtual patients helped you improve your ability to identify relevant symptoms during the clinical interview?	Answers, n (%)
A great deal	43 (43)
Quite a lot	51 (51)
Somewhat	5 (5)
A little	1 (1)
Not at all	0 (0)

The analysis of the final practical examination (Figure 7) showed that the mean score obtained in course 2024/2025 (mean 6.67, SD 1.42) was slightly higher than that of course 2023/2024 (mean 6.42, SD 1.56). However, this difference was not statistically significant (W=9297; *P*=.46).

Conversely, the analysis of the average practical session grades revealed that the scores from the 2024/2025 course (VSP-based; mean 8.8, SD 0.77) were significantly lower than those from the 2023/2024 course (paper-based; mean 9.14, SD 0.74; W=12,428; *P*<.001).

Figure 7. Mark comparison against previous course. Exam: examination.



Sentiment Analysis

All interactions with the platform (either student questions or GAI answers) were recorded and further processed using NLP, with the help of the *pysentimiento* library[23]. The output of the library rates the positive, neutral, and negative sentiments of each sentence, normalized so that positiveness + negativeness + neutralness = 1.

The first analysis carried out tried to explore whether the emotional tone of the GAI responses was influenced by the temperature parameter of the GAI model. We only show positiveness and negativeness results, since neutralness can be obtained from them. Figure 8 displays the total positive sentiment in responses (median 0.008, IQR 0.003-0.079). The results show a striking concentration of low positive sentiment across all temperature levels, especially at 0.1 and 0.5. Interestingly, temperature 0.9 shows slightly more dispersion, possibly due to more expressive or varied GAI outputs under higher randomness. Despite this, positivity in responses remains generally low, consistent with the structured, clinical nature of the interactions.

Figure 9 presents the total negative sentiment in responses, where a clear concentration of high negativity scores was observed across all temperature levels (median 0.890, IQR 0.306-0.961). This was particularly noticeable at temperatures 0.1 and 0.5. These findings may reflect the emotional content

inherent in the psychological case scenarios, in which patients often express distressing or symptomatic narratives.

Figure 8. Density plot of total positive sentiment in generative artificial intelligence (GAI) responses, grouped by model temperature (0.1, 0.5, and 0.9).

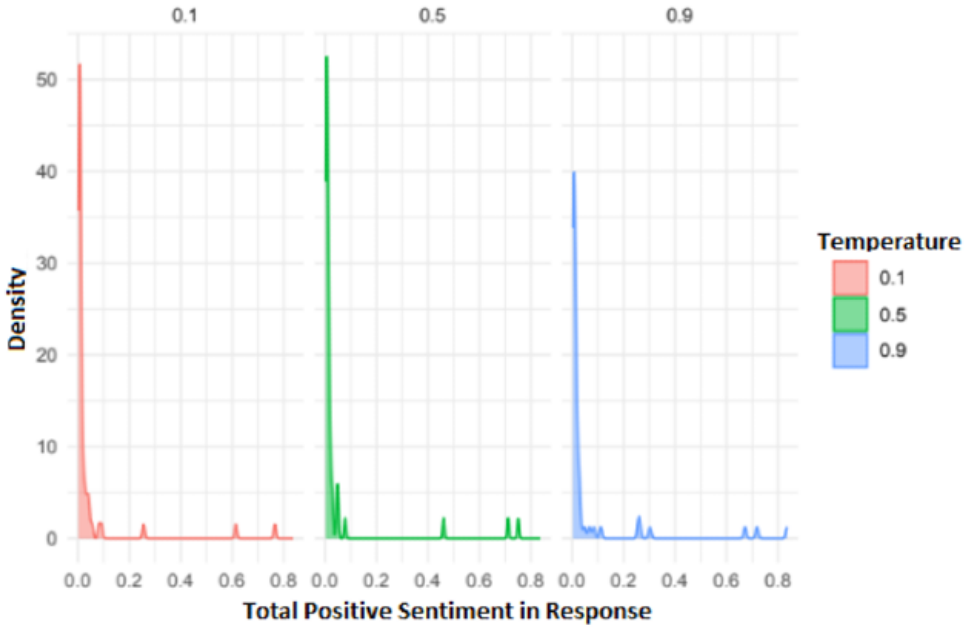


Figure 9. Density plot of total negative sentiment in generative artificial intelligence (GAI) responses, grouped by model temperature (0.1, 0.5, and 0.9).

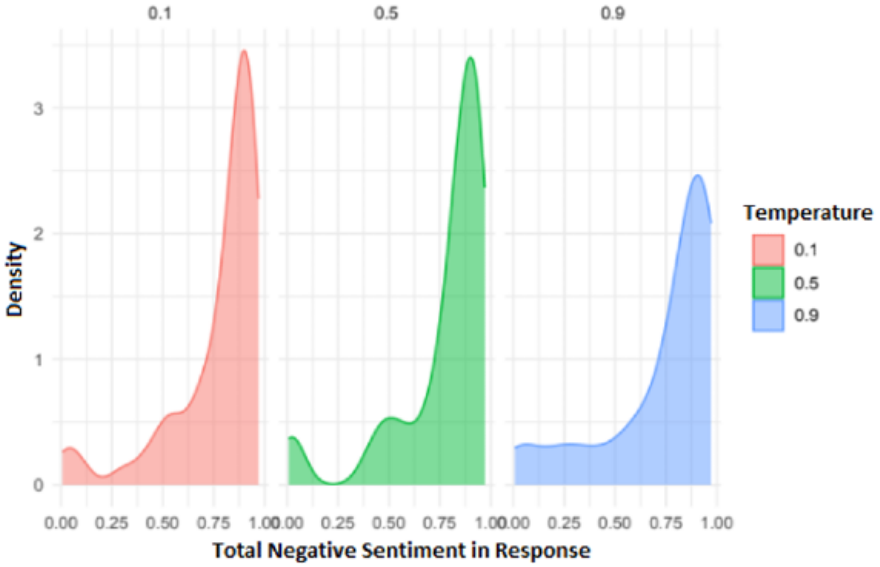

This sentiment configuration shown in Figures 8 and 9 could be partially attributed to the design of the VSPs themselves, as they were intentionally modeled to represent clinical profiles commonly seen in mental health settings. These profiles often contain emotionally charged content, which likely contributes to the predominance of negative sentiment over positive sentiment in the GAI responses. Consequently, higher temperature values may lead the model to deviate from the expected clinical behavior, producing more creative and expressive responses that go beyond the original configuration of the VSPs [28]. This creative drift may result in a more positive tone in the interaction, as the model becomes less constrained by the simulated symptoms or emotional distress typically expected from a psychological patient.

Additional results concerning sentiment analysis are available in Multimedia Appendix 6, together with other statistical results not included in the main document.

Content Analysis

A total of 1708 valid answers (excluding empty answers, nonalphabetic answers, or answers without meaning) were registered as positive comments (positive aspects found in the tool). The automated content analysis of those comments is detailed in Table 5.

Concerning negative comments (or improvement suggestions), a total of 1604 valid answers were registered (using the same exclusion criteria as for positive comments). Automated content analysis of negative comments is summarized in Table 6.

Table 5. Content analysis of positive comments.

Positive aspect	Repetitions, n	Details
Educational usefulness and practical application	~570	Most valued aspect. Users report that the tool helps apply clinical knowledge, practice interviews, and develop professional skills in a safe environment. Universally described as useful, effective, and enriching.
Quality and clarity of the VSP's[a] responses	~470	Responses are accurate, clear, and coherent. Relevant for diagnosis, allowing interview progress. Includes completeness, correctness, and clinical utility.
Clarity and fluency in the interaction	~320	Emphasis on conversational naturalness, ease of use, and absence of glitches. Enhances the interview experience and realism.
Engagement, motivation, and dynamic experience	~240	Tool is engaging, maintains interest, and motivates learners. Nonmonotonous interaction supports student engagement and active learning.
Accurate symptom description and diagnostic support	~250	VSP provides rich and detailed symptom descriptions. Aids clinical reasoning and realistic hypothesis formulation.
Perceived improvement and positive comparison	~140	Perceived positive evolution in tool functionality and response quality. Increases satisfaction and perceived quality.
Perceived realism and immersiveness	~120	Interaction closely resembles real interviews. Realism improves pedagogical value and clinical preparation.

[a]VSP: virtual simulated patient.

Table 6. Content analysis of negative comments

Suggestion	Repetitions, n	Details
Realism and content of the VSP's[a] responses	~110	Suggestions focus on enhancing coherence, depth, and appropriateness of the VSP's clinical language. Proposals include: avoiding repetition, tailoring responses to age (eg, young children), adding relevant details, and ensuring internal consistency.
Diagnostic clarity and symptom presentation	~82	Many comments highlight difficulties in interpreting symptoms due to the similarity between disorders. Some users report that the patient directly reveals the diagnosis, undermining the clinical exercise. There is a request for more subtle clinical clues and better-differentiated scenarios.
Technical functionality and system errors	~74	Recurrent technical issues are reported: connection failures, GAI[b] model not being available, automatic deletion of student answers, and the need to reload the activity. In some cases, users are forced to repeat the task.
User interface and navigation	~49	Recommendations include improving navigation, enhancing the visibility of return buttons, enabling users to go back without losing information, and simplifying transitions between patients or tasks.
Linguistic clarity and textual formulation	~37	There is a call to improve the phrasing of both questions and responses. Suggestions include using clearer, more precise language appropriate to students' comprehension level.

[a]VSP: virtual simulated patient.

[b]GAI: generative artificial intelligence.

Discussion

Principal Findings

Concerning temperature influence on results, although not all observed effects reached statistical significance, clear trends emerged, particularly when comparing the lowest temperature level tested (0.1) with the highest one (0.9). The results in terms of user satisfaction were significantly higher for the 0.9 setting. This suggests that the temperature parameter may play a meaningful role in shaping students' perceptions of the interaction.

Contrary to expectations, no significant relationship was found between the number of questions asked during the simulation or the participants' age and the rating they assigned. However, as one might anticipate, a negative correlation was observed between the number of connectivity failures and the students' evaluation of the experience.

This suggests that students' perception of usefulness or satisfaction may not depend on the quantity of interaction, but rather on qualitative aspects, such as the fluidity of the dialogue or the perceived realism of the conversation.

A notable finding of this study is the apparent paradox in academic performance: while GAI-powered VSP implementation (course 2024/2025) led to significantly lower average grades in practical sessions compared to the traditional paper-based method (course 2023/2024), grades obtained in the final practical examination were slightly higher, although not statistically significant. Far from suggesting lower efficacy, we interpret this as evidence that the VSP simulations provide a more demanding and clinically realistic learning challenge. Traditional static paper-based cases reward methodical information retrieval [8], whereas the dynamic VSP tool required students to actively engage in real-time clinical interviewing and hypothesis formulation [6], better mirroring real-world clinical ambiguity [4]. Further randomized experiments are required to draw more reliable conclusions.

Comparison to Prior Work

Our findings on the influence of the temperature parameter are consistent with those found in previous literature. For instance, the experiments carried out by Davis et al [29] in different clinical research scenarios emphasize the compromise between creativity and consistency of the GAI answers and suggest specific temperature levels depending on the task. Other recent studies warn about the impact of inconsistencies and errors in ChatGPT's responses on user satisfaction when higher temperature settings are used [30], but in our case, the highest temperature tested (0.9) offered the best results in terms of user satisfaction.

The general evaluation of the VSP platform was highly positive, indicating strong acceptance of this type of simulation in clinical training contexts. In general, this result aligns with previous studies that have highlighted the potential of VSPs to create immersive learning environments that foster the development of clinical reasoning from the early stages of professional training [8].

Compatible with our results, the work presented by Peralta et al [10], based on an experiment with 32 medicine students, found highly valued student perceptions for both realism and consistency of the VSP responses. In particular, the students answered "agree" or "strongly agree" in 91% of the cases for the question "the scenario was realistic and similar to an authentic clinical situation," and in 94% of the cases for the question "the virtual patient responded appropriately to my actions and questions."

Focusing on specific aspects, the previous work on VSPs presented by Kamath et al [31] (pharmacology students, n=19) showed strongly positive user satisfaction for most aspects, particularly for "authenticity of patient encounter and consultation" (92.11% of positive responses), but low values for "learning effect of consultation" (47.37% of positive responses). In comparison, our experiments with psychology students agree on high user satisfaction for authenticity (Table 5, row 3: "conversational naturalness," "realism") and also offer strongly positive values for learning improvement, with 94% of students answering "a great deal" or "quite a lot" to the question "Do you consider that interacting with virtual patients helped you improve your ability to identify relevant symptoms during the clinical interview?" (Table 4). The difference in this particular result may be related with the specificities of pharmacology and psychology studies.

Another previous study, with medicine students (n=9) is presented by Cross et al [32]. Contrarily to our results, their students found verisimilitude issues and lack of empathy in the VSPs' answers. Such result may be related to the use of standard values for the temperature parameter (since the experiments were carried out directly from the web interface of ChatGPT) or a too strict definition of the clinical cases.

Strengths and Limitations

According to the results shown in Table 6, students find the tool helpful, relevant, and motivating. In addition, they particularly valued the realism of the interactions. The most common suggestions, as shown in Table 5, refer to improvements in the clinical language used by the VSPs, increasing the difficulty of the cases, avoiding connection failures, and improving the user interface.

The findings of this study provide preliminary evidence for the feasibility of using LLMs such as GPT-4o to simulate virtual patients in educational settings. The tool was rated positively by most participants, suggesting it can serve as an effective strategy for training fundamental clinical skills—such as conducting psychological interviews or gathering relevant case information—in a safe and controlled environment [6,31].

Moreover, the ability to adjust the model's temperature setting allows educators to tailor the GAI's behavior to specific learning objectives, making it possible to design adaptable training experiences that align with the learner's level of competence and the complexity of the scenario.

Concerning content analysis results, one of the most repeated positive comments was "responses are accurate, clear, and coherent. Relevant for diagnosis, allowing interview progress. Includes completeness, correctness, and clinical utility" (Table 5). On the other hand, the most repeated improvement suggestion was focused on "enhancing coherence, depth, and appropriateness of the virtual patient's clinical language" (Table 6). Surprisingly, the coherence of the VSPs' responses was considered both as a strength of the platform and as a topic requiring improvement. That suggests that, according to the students, coherence is a key point in a VSP.

This study has several limitations.

First, this was a cross-sectional, observational study, which limits the ability to draw causal conclusions from the findings. In addition, a potential source of bias was identified in the rating scale: the value "5" appeared as the default option in the evaluation form, making it unclear whether selections of this score were made intentionally or by oversight.

Second, another limitation involves the uneven usage of different VSP profiles and GAI models, which may restrict the generalizability of the results. Future research would benefit from a more balanced distribution of exposure to each virtual character and system configuration.

Third, the study's design lacked randomization. The comparison of academic performance was quasi-experimental, contrasting

the 2024/2025 cohort (which used the VSP tool) against the previous 2023/2024 cohort (which used paper-based cases) rather than using a randomized controlled trial. This nonrandomized approach means we cannot definitively attribute observed differences, or the lack thereof, in academic performance solely to the VSP intervention, as other unmeasured confounding variables between the two academic years may have influenced the findings.

Fourth, sentiment analysis was only focused on 2 topics: first, checking the predominant sentiment in VSP responses (which should be negative to reflect the clinical case situations), and second, determining whether sentiment in student questions influenced sentiment on VSP answers or vice versa (details of results are available in Multimedia Appendix 6). However, deeper analysis is needed to measure how closely the VSP reflects the correct sentiment for each case, following, for example, the guidelines that can be extracted from the study of Cero et al [33].

Finally, special attention should be given to the gender imbalance in the sample, which was composed predominantly of female students. Although no significant differences were found between male and female participants across the main variables, this disparity raises questions about potential gender-related biases in perception or interaction with the system. Future studies should aim to recruit more gender-balanced samples to assess these effects more thoroughly.

Future Directions

One promising line of inquiry is the integration of multimodal features into virtual patient simulations, including speech recognition, nonverbal communication (ie, gesture recognition), or even animated avatars, to increase realism and bring the experience closer to real clinical encounters. These enhancements would allow researchers and educators to assess not only the verbal content of the interaction but also paraverbal and behavioral cues, which are crucial in clinical practice. Nevertheless, in our experience, the VSPs have mostly been used in classroom settings during in-person practical sessions, where keyboard interaction remains the most reliable and least susceptible to disruption from peer interactions.

Another important direction involves carrying out randomized experiments for direct comparisons between GAI-based training and traditional educational methods, such as working with standardized patients or in-person role-play sessions. This would provide clearer insights into the relative effectiveness of each approach in developing specific clinical competencies, as well as students' perceived realism, usefulness, and transferability to real-world contexts.

Other future studies may explore the implementation of automated feedback systems or peer-based assessments using the transcripts generated during the interactions. These additions could further enhance the educational potential of GAI-powered simulations in hybrid or fully virtual learning environments.

Finally, this study has shown that the VSP generation tool we have developed offers enough flexibility to be adapted across various specialties within psychology, as well as in medicine and nursing. Currently, the tool is also being used in nursing and pediatrics, and we have received requests to implement it in other fields. Given this positive reception, our future goal is to create a complete hospital metaverse—a shared virtual environment that enables practical training across multiple specialties.

Acknowledgments

This study was supported by several research projects that contributed both to the development of the virtual patient platform and to the analyses presented in this study. We gratefully acknowledge the following funded initiatives: "Investigación sobre sesgos de género en la generación de imágenes por Inteligencia Artificial" (Reference: 19-3-ID24), funded by the Instituto de las Mujeres under the 2024 Call for Feminist, Gender, and Women's Studies Research (14/05/2024); "Pacientes virtuales basados en Inteligencia Artificial y con características específicas de género para la formación en medicina y enfermería sobre entornos gamificados" (Reference: PID2024-157772OB-I00), funded within the Spanish National R+D+i Program in the area of Information and Communication Technologies; "Nuevas metodologías basadas en Inteligencia Artificial para la educación en medicina y enfermería: pacientes virtuales en entornos gamificados con especificidades de género" (Expediente: CIAICO/2024/283), funded under the 2025 Call in the area of Information and Communication Technologies; and the internal research grant from Miguel Hernández University of Elche (UMH), awarded through the Resolución Rectoral 00686/2025 as part of the 2025 UMH Research Grants Program for Science, Technology, and Innovation Dissemination Projects (Code: 04-541-4-2025-0033-N). The authors extend their sincere gratitude to all the students who participated in the psychopathology course activities.

The authors declare the use of generative artificial intelligence (AI) in the research and writing process. According to the Generative AI in Data and Text (GAIDeT) taxonomy (2025), the following tasks were delegated to generative AI tools under full human supervision: code generation, code optimization, data analysis, summarizing text, translation, and reformatting. The generative AI tool used for writing and editing was ChatGPT-4o. Responsibility for the final manuscript lies entirely with the authors. Generative AI tools are not listed as authors and do not bear responsibility for the final outcomes. Additionally, OpenAI GPT-4o models and Mistral large-latest models were used in this study for the creation and operation of conversational virtual patients. AI tools were not used for drafting the article's scientific interpretations.

This declaration was submitted by DG-T, CF, JJM, AM, and MAV.

Data Availability

The datasets generated or analyzed during this study are available in the Open Science Framework (OSF) [34]. Documents in this repository are password protected; please contact the corresponding author for more information on how to access the data.

Authors' Contributions

CF and MAV conceived the study design, supervised the development of the virtual patient platform, and coordinated data collection. DGT, CF, and JJM contributed to data processing, statistical analysis, and methodological review. AM and MAV supported the implementation of training sessions, student coordination, and qualitative data extraction. AM and JJM also contributed to designing the behavioral profiles and conversational characteristics of the virtual patients used in the study. All authors reviewed and approved the final manuscript and contributed to the interpretation of results.

Abstract

Background: The necessity for self-regulated, lifelong learners in the rapidly evolving field of medicine underscores the importance of effective study skills. Efforts to support students with these skills have had positive outcomes but are often limited in scope and accessibility, with a tendency to target groups facing immediate challenges.

Objective: This study aimed to explore the student perspective on study skills support at University College London Medical School through a student-staff partnership, with the goal of guiding future improvements.

Methods: A mixed methods approach was adopted using an anonymous questionnaire and focus groups. After analyzing questionnaire responses using descriptive statistics to refine focus group questions, focus groups were conducted to delve deeper into identified issues. Transcripts were analyzed thematically using inductive coding.

Results: In total, 116 students completed the questionnaire in full and 6 students participated in 2 focus groups. The questionnaire revealed that 68% (68/100) of respondents felt that they never received study skills support at University College London Medical School. Preferred methods of support included small group sessions (56/100, 56%) and topics like examination preparation (83/100, 83%) and study skills specific to medicine (72/100, 72%). Focus group themes were the lack of current study skills support, delivery of study skills support, specific study skills for medical school, personalized approach to support needed, and accessing support. Findings informed the co-creation of study skills resources.

Conclusions: Overall, the findings highlight the need for strategically incorporating study skills support at medical school, emphasizing early and consistent promotion and tailored delivery methods.

Introduction

In the dynamic realm of modern medicine, the need for practitioners to be self-regulated, lifelong learners is imperative if they are to keep up with ever-evolving medical knowledge [1]. In White et al's evidence-based model [2], self-regulated learning (SRL) is composed of a set of learnable skills: "planning, learning, assessment, and adjustment," acquisition of which can be facilitated by educators. Study skills, or "learning strategies," have been identified as an important component of the learning phase of SRL, and they can be defined as an "integrated repertoire of tactics and strategies, which facilitate acquisition, organization, retention, and application of such knowledge" [3].

SRL and study skills are relevant across higher education, and their importance is especially pronounced in medical education which incorporates theoretical and practical knowledge to develop graduates with the ability to learn independently and adaptively throughout their future careers [4,5]. In the clinical environment, SRL has been positively associated with students' academic achievement, clinical skills performance, and mental health outcomes [6]. SRL strategies have also shown a particularly strong association with affective outcomes such as attitude, motivation, and confidence [7], suggesting that SRL may support not only learning performance but also how students feel about their learning. The association between SRL strategies and learning outcomes is more pronounced in clinical clerkship than in preclerkship phases [7], and literature suggests that support for SRL should be more explicit and structured earlier in training [8,9]. This highlights the importance of

preparing students to self-regulate before they enter the clinical environment. This may be best supported by approaching SRL as a shared endeavor from the outset, with medical schools playing an active role in its early development [8,10].

The broader literature highlights the value of educational interventions to support SRL in medical students, such as tailored workshops [11] and mentor guidance [10]. Classroom-based SRL interventions and one-on-one academic coaching have also been positively received by first-year students and linked to greater anticipated use of SRL strategies [12]. In clinical settings, factors such as access to full-time clinical teachers, peer collaboration, and mentor support have been identified as significant predictors of SRL and are associated with improved clinical performance [13]. However, study skills interventions in medical education often follow a reactive-deficit model that targets students who have already encountered difficulties, such as those at risk of academic failure [14] or academically low-achieving [15], or a proactive-deficit model that focuses on students deemed "at risk," such as new entrants to medical school [16]. While identifying and supporting students in need is essential, this approach may inadvertently exclude students across the wider academic spectrum. Evidence indicates that study strategies influence academic achievement across the performance spectrum [17-19], supporting the case for more universal and inclusive approaches to study skill development.

At University College London Medical School (UCLMS), the MBBS program is a 6-year integrated degree, including an intercalated BSc in the third year [20]. The curriculum comprises themed modules, with clinical and professional practice running vertically throughout the program. Year 1 and 2 modules focus on the fundamentals of clinical science, and Years 4 to 6 modules emphasize clinical practice across specialties [21]. At the time of the study, UCLMS offered an array of study skills resources which supported SRL, such as "study skills clinics" (one-to-one or small group sessions with clinical staff members), support from personal tutors, and online learning resources. University College London (UCL) also provided study skill support accessible to all students such as online academic resources [22], alongside broader institutional support for students with specific learning differences or long-term health conditions, including tailored accommodations for assessments and teaching settings [23].

Despite the range of available support, a 2020 internal survey at UCLMS revealed that many students felt undersupported in developing effective study skills. This perceived gap between resource availability and student experience signaled a need to evaluate and improve current provision. In response to this, a student-staff partnership (the authors) was formed to explore and address the perceived gap in study skills support. Although student input into medical curriculum design is often limited or restricted to a needs analysis [24], literature suggests that engaging learners in the design process through student-staff partnership can enhance learning engagement, teaching effectiveness, and assessment outcomes [25]. This project adopted a student–staff partnership model to facilitate collaborative educational research that would not only develop the research skills of the team but also support a more authentic, peer-informed exploration of the student voice. By positioning students as coresearchers, supported by faculty mentorship and institutional resources, the partnership aimed to generate deeper insights into the student experience [26].

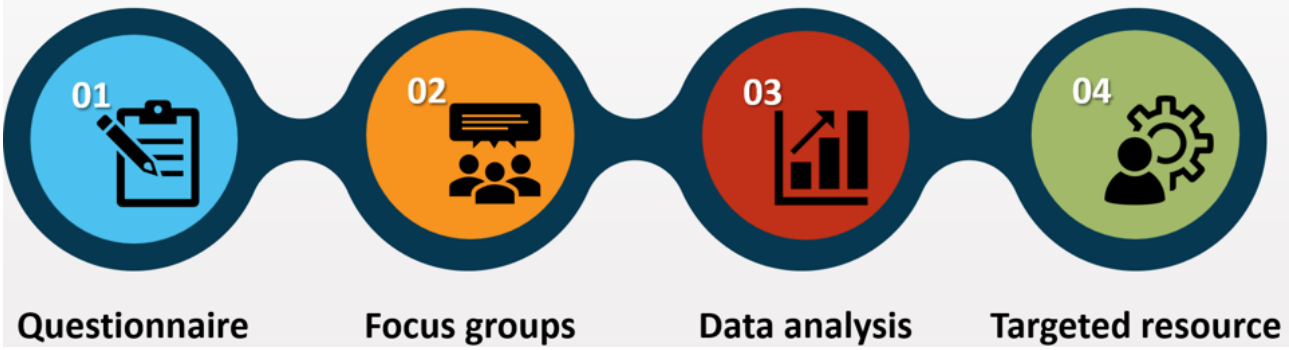
As interest in active student involvement in medical education grows [27], establishing models for successful collaboration is increasingly important. As a result, this research project aimed to use the student-staff partnership to explore the student perspective on study skills support at medical school, using findings to cocreate relevant resources and guide future improvements.

Methods

Overview

This is a mixed methods study consisting of a questionnaire and focus group, as depicted in Figure 1. A mixed methods design enabled collection of both qualitative and quantitative data, which allowed for greater confidence in the validity of any findings by means of triangulation [28], which was felt to be important given the relative lack of research in this specific area. This factor is also what led to the decision of conducting focus groups, due to their usefulness in exploratory research [29].

Figure 1. Summary of the methods.



An interpretivist paradigm was adopted for this study, recognizing that reality is subjective and socially constructed [30]. Aligned with social constructivism, this approach emphasizes the importance of understanding participants' experiences within their educational environment. It informed the use of focus groups and inductive thematic analysis to explore how students construct meaning based on their individual experiences. The collaborative student–staff research

model further reflects the interpretivist emphasis on coconstructed knowledge, positioning students as active contributors to the research process [26].

Questionnaire

Sampling Procedure and Recruiting Study Participants

The methodology of the web-based questionnaire is described in line with the CHERRIES checklist [31]. A web-based questionnaire was designed and distributed electronically, by purposive sampling of UCLMS medical students. Due to the diversity of intercalated BSc courses completed by students in their third year and the varying study skill requirements they entail, only students in Years 1, 2, 4, 5, and 6 of the MBBS program were recruited for this study.

Quality Assurance

A preliminary version of the questionnaire was developed by 2 students in the partnership and subsequently reviewed by the rest of the team. It was then further evaluated by the UCL Changemakers team, revised accordingly, and piloted by the other 2 students and 2 staff members within the partnership.

Recruitment Process

Students were initially sent a link to the questionnaire by email from the medical school, with a reminder email sent 1 month later. To further promote participation and increase response rates, online platforms such as WhatsApp [32] were also used. These channels were chosen due to their popularity among students and the observation by the medical student authors that their peers were particularly responsive through these platforms [33].

Survey Administration

The questionnaire was held on Opinio, accessible via link in the invitation email. As the study was voluntary, financial incentives were used to try and increase engagement [34]; students could enter a draw to win vouchers, which were funded by UCL Changemakers. The survey was anonymized with a separate link provided to enter the prize draw upon completion of the questionnaire. Data collection took place from March to May 2022.

Study Design

The questionnaire was structured to allow students to reflect on their current study skills, gather information on which existing UCL resources they accessed and their perceived effectiveness, and explore students' preferences for the delivery of future study skills support. It consisted of a total of 12 questions with various styles (multiple choice, multiselect multiple choice, Likert scale, and free text). The majority of questions used a 5-point Likert scale to enable participants' opinions to be quantitatively analyzed.

To facilitate targeted questioning on specific study strategies, seven study skill domains related to self-regulated learning were identified. This framework was developed through a scoping review of relevant literature in study skills and medical education and further refined through collaborative discussions within the research team, as shown in Textbox 1:

Textbox 1. Summary of the 7 study skill domains related to self-regulated learning.

- Time management
- Organization
- Exam preparation and technique
- Obtaining reliable sources of information
- Retaining information
- Study skills specific to a medical degree (eg, practical exams and navigating clinical years)
- Study skills and mental health (work or life balance and feeling overwhelmed)

A free space text box was provided near the end of the questionnaire for additional comments or suggestions. The full questionnaire can be found in "Multimedia Appendix 1: Questionnaire".

It was not mandatory for participants to complete all questions, and they could review and amend their answers before submission. We did not count view rates or participation rates, nor implement techniques which would prevent multiple entries. Partially completed questionnaires were analyzed.

Focus Groups

Before conducting the focus groups, the research team undertook a collaborative reflexive exercise to acknowledge potential biases during the research process and explore the diverse perspectives within the team [35]. This involved a semistructured discussion led by one of the staff researchers exploring individual assumptions and expectations, recognizing how the medical student researchers' unique position meant they had their own perceptions of study skills support and desirable outcomes of the project. Also discussed was how this position allowed them to better understand the student body and contextualize their opinions. The staff members also engaged in a separate reflexive discussion to consider their own positionality as educators and contributors to the support systems being evaluated.

Participants were recruited for the focus groups through the questionnaire, with interested individuals emailing the research team directly to maintain questionnaire anonymity. To encourage participation, each focus group attendee received a voucher funded by UCL Changemakers as a financial incentive.

The questionnaire results guided the development of the focus group questions. The focus groups were semistructured to allow students to freely elaborate on their views of study skills support

while maintaining enough structure to explore key questionnaire findings in greater depth. To ensure consistency, the interviewers followed an interview schedule with predetermined questions.

Two online focus group interviews were conducted in May 2022 using Zoom [36], a platform widely used for synchronous lectures and small-group teaching at UCLMS, to help participants feel comfortable engaging and turning on their cameras. Both focus groups were facilitated by 2 medical students from the research team to foster open, honest discussion and encourage participants to freely critique this study skills support without staff members present [37].

The focus groups began by inviting students to share their understanding of the term "study skills," with clarification provided as needed to ensure a clear understanding of the discussion topic. Respondents were asked a series of open-ended questions to establish their experience of study skills support at UCLMS, share their views on preferred methods of study skills support delivery, and explore further results of the questionnaire. Although questionnaire results were not shared with participants beforehand, they were introduced and explored during the discussions. The semi-structured focus group questions can be found in "Multimedia Appendix 2: Focus Group Questions".

Focus groups were video recorded and subsequently deleted after verbatim transcription by 2 of the authors, with all identifying information removed in accordance with the consent form the participants had signed before.

Analysis

Quantitative data from the survey were analyzed using descriptive statistics to compute percentages, means, and frequencies. Qualitative data from the focus groups were analyzed using inductive coding guided by Braun and Clark's phases of thematic analysis [38]. This process was informed by social constructivist principles, acknowledging that themes and insights emerge through the interactive process of data collection and analysis. Following familiarization with the transcripts through repeated readings, the questions were evenly distributed among the medical student researchers and coded independently. Initial codes were then reviewed collaboratively in meetings to standardize their interpretation across all questions. Each student researcher also reviewed and analyzed the coding completed by the other researchers to further ensure consistency. Through subsequent discussions, the codes were grouped into broad themes based on similarity, with subthemes developed where further categorization was needed. The codes and themes were then reviewed by the entire research team to refine them into more clearly defined categories. This process was supported by the program NVivo.

Ethical Considerations

Ethics approval for the study was granted by the Changemakers team—an initiative that provides funding and support for collaborative projects between students and staff aimed at enhancing the student learning experience at UCL (ethics approval number 12385/001). Informed consent was obtained from all questionnaire participants. No personally identifiable information was collected, aside from participants' year of study. All data were securely stored on a password-protected platform, accessible only to the research team. All data collected was anonymized in both the questionnaire and the focus group interviews. Students participating in the online questionnaire were given an option to partake in a USD $26.80 prize draw after completion; which was awarded to 1 student. Students participating in the focus group interviews all received compensation of USD $13.40.

Results

Questionnaire Results

In total, 1682 students across 5 years of medical school at UCL were sent the questionnaire. In total, 116 students out of 1682 (6.9% response rate) completed the online questionnaire in full; there was a 13.8% (16/116) drop-out rate from the start to the end of the survey. There was a UCL Central Study Skills Page available to all students for support, and 80% (80/100) of respondents indicated they had not accessed it. Among the 20% (20/100) of respondents who had accessed the page, its effectiveness was rated with a median score of 3/5.

A total of 68% (68/100) of students reported they never received study skills support during their time at UCLMS. Among the 32% (32/100) who reported they had received study skills support, the majority (81%, 26/32) indicated they received support 1 to 2 times a year.

When participants were asked to evaluate the effectiveness of various study skills delivery methods, all approaches—including lectures, self-directed learning, one-to-one support from staff or peers, personal tutors, and transition mentors (who provide weekly teaching sessions to support students' adjustment to university education in Years 1 and 2)—received a median effectiveness rating of 3 out of 5 across all year groups. In contrast, the study skills clinic received a lower median rating of 2.

The majority (56%, 56/100) of respondents indicated a preference for small group study skill sessions when asked about their preferred methods of delivery. Lectures (43%, 43/100), one-to-one support from staff (41%, 41/100), one-to-one support from peers (18%, 18/100), peer-to-peer support (34%, 34/100) and the study skills clinics (33%, 33/100) were also popular options. The 4 most popular topics preferred by students to be included within study skills support were: exam preparation (83%, 83/100), study skills specific to a medical degree (72%, 72/100), retaining information (69%, 69/100), and taking in new information (58%, 58/100). The demographics and summary of the questionnaire results can be found in the "Multimedia Appendix 3: Questionnaire results".

Focus Group Results

A total of 6 students participated in 2 focus groups: separated by those in Years 1 to 2 of study and those in Years 4 to 6 of study. This reflects that changes in SRL occur in a clinical learning environment [6], so the approach to study skills may differ in these groups as the modules in Years 4 to 6 are more focused on clinical practice.

Three individuals participated from Years 1 and 2, and three individuals participated from Years 4 to 6. Each focus group interview lasted around 40 minutes. Analysis identified 5 themes that explored the student perspective on study skills support: lack of current study skills support, delivery of study skills support, specific study skills for medical school, personalized approach to support needed, and accessing support.

Theme 1: Lack of Current Study Skills Support

Subtheme 1.1: - Lack of Support

In general, students felt there was a lack of study skills support provided by the University. This was more prominent in the Year 4 to 6 group, where students struggled to give any examples of formal teaching and acknowledged that the majority of their study support came from fellow students.

> *... I don't recall any, at least things I remember, any effective study skills teaching…* [(Participant 2, Year 4 to 6 group)]
>
> *... I feel like we haven't really had that much guidance, it's mainly from other students.* [(Participant 3, Year 4 to 6 group)]

In the Year 1 to 2 group, the problem identified was less to do with the availability of study skills support from the University, as students could provide several examples. Instead, their concern related to the effectiveness of that support.

> *... I don't think it [lecture on learning at medical school] was necessarily something that was particularly well supported or particularly well taught…* [(Participant 1, Year 1 to 2 group)]
>
> *... I signed up for it [study skills clinic], but I didn't end up going because it seemed like it was too generic, like it didn't seem medicine specific…* [(Participant 2, Year 1 to 2 group)]

Theme 2: Delivery of Study Skills Support

The way in which study skills support should be delivered was discussed. Although no unanimous consensus on the best method of delivery emerged, the advantages and disadvantages of various methods were acknowledged.

Subtheme 2.1 - One-to-One Staff Support

One-to-one staff support was a popular method of delivery among the students due to its focus on students' individual needs. Access to official guidance from medical school personnel, particularly those familiar with the curriculum and examination format, was considered especially beneficial. However, students emphasized the importance of staff fostering an open environment for students to voice their concerns without fear of judgment.

> *I think, as long as [the] staff member was kind of open [and] non judgmental and they make it a comfortable atmosphere for you to kind of open up and talk about your issues, I think that's what we need.* [(Participant 3, Year 1 to 2 group)]

Subtheme 2.2 - Peer Support

The concept of seeking study skills guidance from peers was positively received, with a preference for support from senior students who had completed the same style of assessments, allowing them to provide tailored, experience-based advice. In addition, while some students acknowledged the existence of established peer support systems in student societies, concerns were raised about the unfairness of the disparity in access to this support for students without such contacts.

> *...I feel like that's kind of unfair and some students also have like seniors who helped them out and stuff and not everyone has that, especially because of covid you know it's hard to make those contacts.* [(Participant 1, Year 1 to 2 group)]

Subtheme 2.3 - Small Group Teaching

Small group teaching was generally supported, as students valued the opportunity for interactive discussions and peer exchange of study habits and learning strategies. However, some expressed concern about feeling intimidated by the perceived workload and study strategies of their peers.

> *... sometimes I feel like other people are doing so much more than me or studying in so many like more efficient ways and I'm just like really behind and so yeah, I guess, in some ways it helps but in other ways, it can be quite intimidating as well.* [(Participant 3, Year 1 to 2 group)]

Subtheme 2.4 - Asynchronous vs Synchronous

Students preferred synchronous study skills lectures over asynchronous ones, as the live format was seen to promote better attendance.

> *... if it's asynchronous I don't think many people would go out of their way to do it because the workload is so much it wouldn't be anyone's priority* [(Participant 3, Year 4 to 6 group)]

Theme 3: Specific Study Skills for Medical School

Subtheme 3.1 - Medical School Is Unique

Students felt that studying medicine required a different learning approach than both school and other university degrees, particularly due to the unique nature of its assessment methods.

> *UCL medicine and medicine in general is really, really different to the way we're being assessed.* [(Participant 1, clinical group)]
>
> *... you can't just do it [learn] like A-levels or GCSE* [(Participant 2, Year 1 to 2 group)]

Subtheme 3.2 - Medical School Has a Lot of Content

Students often raised the fact that they felt overwhelmed with the volume of content they were expected to memorize in the course. They also found it challenging to discern the scope and depth of knowledge required, especially as expectations increased with each academic year.

> *... we still need to memorize the whole bunch of stuff to apply it and I struggle with that quite a bit just the sheer amount.* [(Participant 2, Year 4 to 6 group)]
>
> *I think it's really difficult to kind of ascertain what exactly we're expected to know and the level we're expected to know.* [(Participant 1, Year 4 to 6 group)]

Theme 4: Personalized Approach to Support Needed

Subtheme 4.1 - Study Skills Are Personal

Students recognized that not every approach to studying works for everyone as learning styles are very individual.

> *... everyone has like different circumstances and different areas that they struggle with; I struggle with time management.* [(Participant 3, Year 1 to 2 group)]

Subtheme 4.2 - Blind to Own Study Skill Weakness

Students expressed the challenge of identifying weaknesses in their study methods, noting that this awareness is an essential first step toward improvement.

> *"I don't know where I'm going wrong in order to fix it."* [(Participant 1, Year 4 to 6 group)]

Theme 5: Accessing Support

Subtheme 5.1 - Advertising Support

Students felt that study skills services available were not advertised well enough, suggesting promotion through The Royal Free, University College and Middlesex Medical Students' Association (RUMS), WhatsApp or Instagram (Meta) [20,28]. They also recommended the use of student testimonies so that students could gain a clearer insight into the benefits of the support.

> *If you made it a RUMS thing, because if you send it from the med school … I feel like people were kind of hesitant just because you know…I'm gonna be gone after or something. But if you make it like a RUMS thing it's like a community vibe…* [(Participant 3, Year 1 to 2 group)]

Subtheme 5.2 - Establishing Support Early On

Students believed that information about study skills support should be offered early in the year as opposed to just prior to exam season, allowing those struggling more time to access and benefit from the assistance.

> *... because they can connect earlier on in the year and kind of work on that, for the rest of the year rather than it being something that you do like a month before the exam and just panicking…* [(Participant 3, Year 1 to 2 group)]

Discussion

Principal Findings

Overall, the results from both the questionnaire and focus groups highlighted a perceived lack of study skills support. There was no unanimous consensus about students' preferences on how study skills support should be delivered. Despite the availability of established study skills services outlined in the introduction, 68% of questionnaire respondents (68/100) reported never receiving such support. This sentiment was echoed in the focus groups, where students indicated they primarily relied on peer advice for study skills guidance. This reinforces the importance of more personalized study support and the need for review of the promotion and accessibility of existing services.

Lectures, one-to-one support, peer group teaching, and study skills clinics all demonstrated comparable popularity as delivery methods; however, small group study skills sessions were the only format preferred by a majority of students (56%; 56/100) in the questionnaire. Focus group subthemes—"one-to-one staff support" and "small group teaching"—further illuminated mixed perceptions of small group sessions. While small groups facilitated peer sharing of study skills, some students found them intimidating due to comparisons with others. Conversely, whilst one-to-one support from staff was perceived as personalized to students' individual needs, especially if by a staff member familiar with the curricula and assessment process, its use was contingent on occurring in a nonjudgmental environment. These findings reflect the literature where both classroom-based learning and one-to-one academic coaching are shown to encourage the use of SRL techniques [12].

The focus group themes and subthemes highlighted that each method of study skills support delivery offers distinct advantages and disadvantages, catering to different student priorities. For example, some students valued direct support from staff for its perceived credibility, while others expressed concern about potential judgment when admitting difficulties. This stigma has been previously identified as a barrier towards medical students seeking help, particularly in the context of non-compulsory activities which offer additional support [39]. Moreover, regardless of delivery preferences, students acknowledged that study skills are highly individual, with no "one size fits all" solution—an insight consistent with existing literature [40]. This also aligns with the literature demonstrating the need for individualized support in the clinical environment to accommodate students' unique SRL strategies [10]. From a faculty perspective, these diverse needs and preferences must therefore be carefully considered when designing study skills support to maximize their effectiveness.

It is clear that social influences shape how students seek study skills support, with many highlighting that most of their support came from fellow peers. Help-seeking from classmates and senior students has been linked to higher levels of self-regulated learning [13], while friendships may also influence exam performance, likely through informal sharing of study strategies [41]. However, this dynamic can also result in unequal access to valuable resources, as demonstrated in the subtheme of "peer support," where senior students were reported to provide study skills guidance exclusively within their own societies. Similar patterns have been documented regarding the selective sharing of assessment materials, indicating that this issue extends beyond study skills alone [42]. Evidence from clinical skills education highlights that peer learning fosters a safe learning environment and aids SRL [43], whilst guidance from senior students has been identified as a positive predictor of SRL [13] . Given that future doctors must collaborate effectively, cultivating a culture

of inclusivity and cooperation around study practices is crucial, and medical schools are well positioned to facilitate this.

The four most popular topics identified in the questionnaire, for which students sought study skills support, were those most specific to medicine, primarily focusing on exam preparation and content management. This finding aligns with the theme "specific study skills for medical school" and underscores the distinctive nature of medical education compared to other disciplines, highlighting that students prefer support tailored to the unique demands of their degree rather than generic university-wide resources. This preference may partly reflect the distinctive assessment methods in medicine, which extend beyond cognitive knowledge to include behavioral competencies, necessitating learning methods that may not have been part of students' earlier educational experiences [44]. Furthermore, the vast volume of content in medical training—highlighted by the theme "medical school has a lot of content"—can be overwhelming and necessitates specific strategies for effective organization and retention.

Findings from both the questionnaire and focus group themes revealed that students highly value having access to a variety of study methods, including many which were already available at UCLMS or wider UCL. At the outset of the project, students in the research team recommended the creation of a centralized study skills page for the medical school on Moodle [22], the online platform used across UCL to deliver course material, and the data corroborated this suggestion from the wider student body. The research team, therefore, developed the page to provide UCLMS medical students with early and easy-to-access study skills support, directly addressing the need for improved accessibility highlighted in the theme "accessing support." The page signposts and advertises existing resources, including links to book onto one-to-one or group "study skills clinics" with staff. In addition, informed by study findings, new resources were made by the students in the partnership such as anonymous group forums for peer-to-peer interaction, evidence-based articles on effective study techniques, and videos with study skills tips from other students. Overall, the platform provides diverse support, allowing students to access guidance that meets their individual learning needs.

Strengths

This project offers several strengths. It adds to the existing literature on study skills support in medical education, with the advantage of a distinct emphasis on student perspectives. This was facilitated through multiple strategies, including the involvement of UCLMS students as members of the research team and as facilitators of the focus groups, which may have encouraged participants to speak more openly and candidly about the current provision of study skills support. Furthermore, while including the student authors' names in recruitment emails may have introduced some response bias, it likely also enhanced engagement by motivating students with personal connections to the authors to participate.

Staff involvement in the project enabled a well-rounded, collaborative approach to understanding and addressing the study skills needs of UCLMS students, increasing the likelihood of successful implementation of proposed changes. For students, this collaboration with staff was particularly beneficial as it fostered a sense of being heard and valued. It allowed them to communicate their needs more effectively and see their suggestions translated into action, which, in turn, enhanced their engagement and motivation. Ultimately, this student–staff partnership established a mutually inclusive and supportive environment that strengthened communication and promoted a more meaningful dialogue around study skills support.

The development of the online resource itself also has several key strengths. It provides a centralized, easily accessible platform that supports a diverse student cohort by consolidating a wide range of study skills resources in one place. While primarily designed for students, the resource also offers UCLMS staff valuable insights into student needs and perspectives, meaning that in the future, changes can be made on a wider scale if necessary. Its interactive design and capacity for continuous updates also ensure the resource remains responsive and relevant to evolving student requirements, preventing it from becoming outdated over time.

Weaknesses

The questionnaire had a low response rate, with just 6.9% (116/1682) of the medical student population participating, and 13.8% (16/116) of those respondents not completing all questions. This limits the generalizability of the findings and suggests results may disproportionately reflect students with a particular interest in study skills or those personally connected to the student researchers, whose names were included in the initial recruitment email. In addition, focus group recruitment relied on participants completing the questionnaire and then registering their interest via email at its conclusion, meaning the questionnaire dropout rate likely also contributed to the low focus group turnout. Finally, due to the small focus group sample, data saturation was not achieved, as novel themes emerged that could not be fully explored.

Future Directions

Future study proposals would like to evaluate student and staff opinion on the study skills resources created and implemented. Overall, this study provides insight into the medical student perspective on study skills at UCLMS, identifying key areas of improvement and methods to target this. Similar initiatives could be effectively undertaken at other medical schools.

Acknowledgments

We would like to extend our gratitude to Philip Marshall-Lockyer for assisting in data collection in this research. We also thank participants for completing the questionnaire and taking part in the focus groups and are grateful to the reviewers for their

constructive comments. We presented the findings at the ASME conference 2023, and we are thankful to the audience for their questions.

This study was funded by UCL Changemakers.

Abstract

Background: Basic life support improves survival prognosis after out-of-hospital cardiac arrest, but is too rarely provided before the arrival of professional rescue services. First responder networks have been developed in many regions of the world to decrease the delay between collapse and initiation of resuscitation maneuvers. Their efficiency depends on the number of first responders available and many networks lack potential rescuers. Medical, dental, and biomedical students represent an almost untapped source of potential first responders, and a first study, carried out during the COVID-19 pandemic, led to the recruitment of many of these future professionals even though many restrictions were still in effect.

Objective: The objective of this study was to determine the impact of an enhanced strategy on the recruitment of medical, dental, and biomedical students as first responders in the immediate aftermath of the COVID-19 pandemic.

Methods: This was a prospective follow-up study, conducted between November 2021 and March 2022 at the University of Geneva Faculty of Medicine, Geneva, Switzerland. A web-based study platform was used to manage consent, registrations, and certificates. A first motivational intervention was held early in the academic year and targeted all first-year medical, dental, and biomedical students. Participants first answered a questionnaire designed to assess their initial basic life support knowledge before following an e-learning module. Those who completed the module were able to register for a face-to-face training session held by senior medical students. A course certificate was awarded to those who completed these sessions, enabling them to register as first responders on the Save a Life first responder network. Since the number of students who had enlisted as first responders 2 months after the motivational intervention was markedly lower than expected, a second, unplanned motivational intervention was held in an attempt to recruit more students.

Results: Out of a total of 674 first-year students, 19 (2.5%) students had registered as first responders after the first motivational intervention. This was significantly less than the proportion achieved through the initial study (48/529, 9.1%; $P<.001$). The second motivational intervention led to the enrollment of 7 more students (26/674, 3.9%), a figure still significantly lower than that of the original study ($P<.001$). At the end of the study, 76 (11.3%) students had been awarded a certificate of competence.

Conclusions: Contrary to expectations, an earlier presentation during the academic year outside the COVID restriction period did not increase the recruitment of medical, dental, and biomedical students as first responders in the immediate aftermath of the COVID-19 pandemic. The reasons underlying this drop in motivation should be explored to enable the design of focused motivational interventions.

Introduction

Background

Basic life support (BLS) improves survival prognosis after out-of-hospital cardiac arrest (OHCA) but is too rarely provided before the arrival of professional rescue services [1-6]. Without BLS, the probability of survival decreases by 10% for each minute that passes [7]. Thus, professional rescue is of limited worth if BLS has not been provided either by bystanders or by first responders [8-10]. Indeed, several studies have demonstrated that initiation of BLS maneuvers by nonprofessionals improves survival and neurological outcomes [1,11,12].

Increasing global awareness regarding the importance of quickly initiating BLS maneuvers after OHCA will take time, and barriers to action often prevent bystanders from initiating cardiopulmonary resuscitation [1,13-15]. To overcome this limitation, first responder systems have been developed in many regions of the world. These systems rely on BLS-certified professional or nonprofessional rescuers who accept a call to respond to OHCA alarms if they happen to be nearby.

In Geneva, Switzerland, the Save a Life project was initiated in October 2019 by the Swiss Emergency Responder Association, with the objective of developing a regional network of first responders [7]. When an OHCA is identified by the emergency medical call center, an alert is displayed on the Save a Life first responder app. If a first responder is near enough and agrees to intervene, the position of the nearest automatic external defibrillator (AED) is displayed along with the exact location of the intervention. The main limitations of this system are the limited number of first responders, their availability, and their geographical distribution.

To improve the number of first responders, Taramarcaz et al [16] designed a process to recruit first-year medical students. Their study took place while the COVID-19 pandemic was still ongoing, and many restrictions were still in effect. In addition, the motivational intervention designed to catch the students' interest was held online rather than in an auditorium and took place rather late after the beginning of the academic year and close to a critical exam session. Thus, the authors hypothesized that an intervention taking place earlier in the academic year, and without the constraints imposed by the COVID-19 pandemic, could lead to higher participation rates and the recruitment of a higher proportion of medical students as first responders [16].

Objective

The objective of this study was to determine the impact of the modifications proposed by Taramarcaz et al [16] on first responder recruitment.

Methods

Study Design

This prospective follow-up study was conducted between November 2021 and March 2022 and followed a structure and sequence similar to that described by Taramarcaz et al [16].

The study platform used for the initial study was reset and reused for this follow-up study. Given the use of a web-based platform, methods and results are reported according to the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) guidelines when appropriate [17]. Data were managed in accordance with the European General Data Protection Regulation [18]. A more detailed description of the tools used can be found in Multimedia Appendix 1.

The learning path was identical to that described in Taramarcaz et al's [16] study and followed a flipped classroom design: after ensuring that no exclusion criteria were present, the first-year medical, dental, and biomedical students of the University of Geneva Faculty of Medicine (UGFM) answered a questionnaire designed to assess their initial BLS knowledge before following an e-learning module. After completing this module, they were able to register for a face-to-face training session held by senior medical students. The estimated time required to complete the e-learning and practice session was about an hour and a half. This duration was chosen as being long enough for learning and skill retention while avoiding an overt demand on their busy schedule. The participants who completed the entire learning path were awarded a BLS-AED course certificate enabling them to register as first responders on the Save a Life first responder network. The whole process, including the certification, was entirely free of charge, and there was no obligation for students to participate. The only incentive was to obtain a BLS-AED certificate.

Ethical Considerations

Since the regional ethics committee (Commission cantonale d'éthique de la recherche, Geneva, Switzerland) had already acknowledged that this design did not fall within the scope of the Swiss federal law on research involving human beings (Req-2020 - 01143), no further ethical assessment was required or requested.

Recruitment

A motivational intervention was performed live on November 29, 2021. This intervention was animated by 2 senior medical students and took place at the end of a basic medical science course. The presentation contained a short, humorous introductory video, a description of the project, and an overview of the Save a Life network. The last slide included a QR code and a URL link to the study platform as indicated in the research protocol [19]. On the same day, all potential participants received the same information by email through the class's

mailing list. To promote participation, a second motivational email was sent to the entire class on December 10.

Since participation was markedly lower than expected by the end of December, a second intervention was planned, this time at the start of a course on atherosclerosis given by the head of the cardiology department at Geneva University Hospital. This intervention took place on January 10, 2022, and a final reminder email was sent on January 13, 2022. For the second intervention, different support material was used, and various real-life scenarios were included, showcasing how BLS knowledge could enable them to act in the case of OHCA.

Enrollment

The QR code and URL provided during the motivational interventions and through the invitation emails redirected the students to an introductory page detailing the study's objectives and procedures. Those willing to participate were asked to answer 2 questions designed to detect the presence of either of 2 exclusion criteria: being registered as first responder and not being a UGFM student. If neither exclusion criterion was met, the students were redirected to a consent form (Table 1) including a disclaimer about data handling and security. Those who agreed were asked to create an account and to provide minimal personal information (first name, last name, and email address) for contact purposes and to allow for the creation of nominative BLS-AED certificates. The students who refused to participate and those who met either exclusion criteria were also given the possibility to follow the learning path and to receive a certificate allowing them to join a first responder system.

After completing the registration process, participants were asked to fill out a precourse questionnaire designed to gather demographic data and determine their precourse BLS knowledge (Table 2).

[c]BLS: basic life support.
[d]ACLS: advanced cardiovascular life support.
[e]AED: automatic external defibrillator.
[f]Items used to calculate the 10-point score (initial BLS knowledge).
[g]MAQ: multiple answer question (more than one answer accepted).
[h]OHCA: out-of-hospital cardiac arrest.
[i]CPR: cardiopulmonary resuscitation.

E-Learning and Practice Sessions

The interactive e-learning module used in Taramarcaz et al's [16] study was reused without any changes since it still matched the objectives, respected the Swiss Resuscitation Council's guidelines, and had not received any negative feedback from the students. This module was designed to last about 30 minutes, but no time limit was set and students were able to resume at will. A screen enabling participants to register for near-peer animated practice sessions was displayed upon completion of this e-learning module.

Practice sessions lasted 1 hour and were limited to 4 participants. A total of 32 sessions (128 slots) were planned between December 6, 2021 and March 11, 2022. The instructor-to-participant ratio (1:4) was kept unchanged to maintain high-quality training even though the COVID-19 restrictions had been lifted. The senior medical students who

animated these near-peer-led practice sessions were all certified as BLS-AED instructors according to the Swiss Resuscitation Council's guidelines. Most of the students who had already participated as instructors in Taramarcaz et al's [16] study (15/17, 88%) agreed to resume their involvement and 5 new instructors were trained. While all instructors were to ensure that the objectives had been met by using a standardized checklist, they were free to adapt the structure of their training sessions according to the participants' profiles.

Final Questionnaire and Certification

An email embedding a link to a postcourse questionnaire was sent to the students who successfully completed the practice sessions (Table 3). Participation in this questionnaire was mandatory to obtain a nominative BLS-AED certificate. These certificates, which had a 1-year validity, enabled participants to enroll as first responders on the Save a Life platform.

[a]MAQ: multiple answer question.

[b]OHCA: out-of-hospital cardiac arrest.

Adaptations From the Implementation Study

In line with this study's objectives, the main changes from the implementation study were that the initial presentation to first-year students and the training sessions were held earlier in the academic year [16], with the hypothesis that this would increase the number of registrations as first-year students would be further away from their final exams. Thus, the project was presented on November 29, 2 months earlier than the original study.

Despite this adaptation, and contrarily to our hypothesis, the number of participants was markedly lower than that in the original study. A second, initially unplanned intervention was therefore carried out in early January 2022, and constitutes the second major adaptation from the original implementation study.

Another difference was that biomedical students were also invited to participate in this study. Finally, the practice sessions were held between December 2021 and March 2022 in this study while they had taken place between January and April 2021 in the implementation study. The number of slots remained unchanged.

Outcomes

The primary outcome was the proportion of students who had registered as first responders before the second intervention took place, that is, by January 9, 2022. Secondary outcomes were the proportion of students who had registered following the second intervention, the overall proportion of students who had registered as first responders by May 1, 2022, and attrition at each step of the study [20]. The difference in self-reported confidence in performing BLS maneuvers was also assessed.

Statistical Analysis

Data curation and analysis were carried out using STATA/BE (version 17.0; StataCorp LLC). Descriptive statistics were used to describe the evolution of the number of students at each step of the learning path. Given the sample size, parametric tests were used when appropriate. A *P* value of less than .05 was considered statistically significant.

The chi-square test was used to assess the difference in student recruitment distribution between this study and Taramarcaz et al's [16]. This was carried out by reusing the original data file, which is freely available online as a Multimedia Appendix 1 of the original study. Since biomedical students had not been invited to participate in the original study, a sensitivity analysis was carried out by excluding them.

Potential differences between students who registered after following the first motivational intervention and those who registered after following the second one were looked for by applying a *t* test on the 10-point BLS score and by comparing attrition at each step. No weighting was used to compute the 10-point BLS knowledge score. A *t* test was performed to look for a difference between this score and interest in following BLS training.

A *t* test was also used to investigate whether there was a statistically significant difference between postcourse confidence and enrollment in the first responder network.

Given the presence of cells with very limited numbers (<5), Fischer tests were applied to analyze the factors influencing self-confidence and the desire to join the Save a Life first responder network.

Results

The 2021 - 2022 academic year included a total of 674 first-year students at UGFM in human and dental medicine and in biomedical sciences. The proportion of students who had registered as first responders after the first motivational intervention was 2.5% (19/674), significantly less than after Taramarcaz et al's [16] implementation study (48/529, 9.1%; *P*<.001). The second motivational intervention led to the enrollment of 7 more students (26/674, 3.9%). This figure is still significantly lower than that observed in Taramarcaz et al's study (*P*<.001) [16]. Even after excluding biomedical students from the analysis, the figure remained significantly lower (25/600, 4.2%) than in Taramarcaz et al's [16] study (*P*=.001).

A total of 502 (74.5%) students followed the link directing them to the study platform, of whom 447 (66.3%) students completed the screening questionnaire. Only 133 (19.7%) students registered on the platform and 76 (11.3%) students received a BLS-AED certificate at the end of the learning program. In the postcourse questionnaire, 68.4% (52/76) of students who obtained the certificate indicated a desire to join the network of first responders, but only 34.2% (26/76) of students followed through. Figure 1 shows participation at each step of the study.

There was a statistically significant relationship between prior BLS knowledge and e-learning completion (*P*=.007), practical session attendance (*P*<.001), and obtention of a BLS certificate (*P*=.003). Conversely, there was no statistically significant relationship between prior BLS-AED knowledge and enrollment in the Save a Life network (*P*=.05) or interest in the program (*P*=.94).

Students' confidence in their ability to initiate BLS maneuvers was significantly increased after following the learning path (*P*<.001, Multimedia Appendix 2). There was no statistical link between postcourse confidence and registration on the Save a Life platform (*P*=.09).

Postcourse satisfaction was 100% (76/76), as was the probability that students who had completed the learning path would recommend it to other students.

Figure 2 shows that a better understanding of health issues, a feeling of mastery of the subject, and an improvement in knowledge regarding resuscitation all contributed to promoting participant confidence.

Stress and fear of doing wrong were the 2 main factors reported as limiting one's confidence in performing BLS maneuvers (Figure 3).

Four factors promoting student willingness to register on the Save a Life platform were identified: feeling able to perform cardiopulmonary resuscitation, the possibility of making a difference, the stakes, and the desire to help (Figure 4).

Stress was the main factor preventing participants from registering as first responders (Figure 5).

Discussion

Main Considerations

Despite the modifications carried out according to the hypotheses outlined in the original study [16], and even after a second motivational intervention, recruitment was markedly lower than expected: indeed, in the original implementation study [16], the proportion of people who had registered on the platform at the end of the project was more than 2 times higher. The target set in the initial protocol was to recruit 10% of first-year students, a goal that has not yet been achieved.

These results deserve to be analyzed from a motivational point of view. The original study took place during the COVID-19 pandemic period, when student dynamics were probably

different, and students may have been more inclined to participate in a presential activity, due to the fact that they had no choice but to spend their first year remotely. The COVID period was a major awareness and health involvement on the part of medical students. Their involvement in medical tasks having a perceptible impact on the future of patients affected by the pandemic undoubtedly positively influenced their motivational reinforcement. This paradox probably partially explains the low recruitment observed in this study, carried out outside the pandemic context. Other factors may also have influenced student motivation during the COVID pandemic: during this period, the health care system was highly regarded by the population, and the project may have given the students a sense of belonging [21]. The feeling of being useless in the face of what was happening and the desire to help may also have been stronger at this time [21]. Conversely, the end of the restrictions may have decreased their motivation to take part in such a project, and students may have been keen to resume many of the activities they had been deprived of [22].

The profile of the teacher endorsing the motivational intervention may also have played a role since teachers can have a significant influence on their students [23]. Since most medical students are interested in the clinical field, any advice, opinion, or encouragement given by a clinician could have a particularly important influence on students [24]. Clinicians can also share their interest and experience in a subject [25], and their support can foster student interest in a particular field [24]. Indeed, human beings strive to feel connected to those they admire, and the sense of belonging that a prestigious clinician radiates can influence student motivation [24]. In addition, first-year students are more motivated by success, prestige, and money, compared with the upper years, who are more focused on the personal gratification of their activity [24,26]. Moreover, student motivation fluctuates over the years, both qualitatively and quantitatively. Understanding its evolution can help encourage students to enjoy their learning and possibly improve their performance [27].

According to the theory of self-determination, there are several types of motivation, depending on what influences it and what goals it aims to achieve: intrinsic motivation, extrinsic motivation, and amotivation [26]. Intrinsic motivation is linked to personal interest in or pleasure inherent to the activity. Extrinsic motivation aims at a goal, a consequence separable from the subject, such as a reward or the absence of inconvenience [26]. Extrinsic motivation can be described as a continuum through which a process of internalization takes place, finally resulting in integrating action towards self-determination [26]. In the educational environment, motivation can be seen as having 3 determinants: the perception of the value of an activity, its skill, and its controllability [28].

A clinician's valorization of the abilities and importance that each student can have in the health care system at their own level can influence the perception of their abilities, and their involvement and motivation [23]. A clinician's speech on public health issues can have a greater impact and radiate a positive perception of the values involved [24,28].

Despite these different aspects motivating first-year students to participate in an optional learning program can still be difficult since it does not bring them any short-term benefits, in this case passing their exams. According to Dweck, students pursue learning goals as well as performance goals [29]. In the short term, when the risk of success is low, students would restrict themselves to the performance goal and neglect activities they consider ineffective for success [28,30].

A considerable proportion of students did not continue with the learning path after completing the questionnaire assessing their BLS knowledge. These students' scores were lower than average, and their lack of knowledge may have had an impact on their perception of their skills for future activities, decreasing their self-confidence and motivation to continue their learning program [28]. This could be addressed by introducing BLS courses at school since, in Geneva, most schoolchildren receive only little, if any, first aid training before attending courses mandatory to obtain a driving license. Furthermore, training schoolchildren has been shown to improve OHCA outcomes [31]. Another option could be to remove this questionnaire from future studies to avoid any attrition linked to its administration.

Once enrolled in the learning program, students follow a certifying course, but registration on the Save a Life platform remains optional, and students therefore need further motivation to enlist as first responders. Participants agreed that perfecting their knowledge, mastering the subject, and understanding the health issues linked to early resuscitation all improved their self-confidence. This is in line with Viau and Louis's [28] opinion, that is, that the perception of the value of an activity and of one's own skills influence motivation.

Understanding the social impact of a first responder network could enable potential participants to internalize the values involved, and, according to the self-determination theory, increase motivation [26]. Thus, the societal impact of the Save a Life project could be further highlighted in future motivational interventions. This could improve recruitment since respondents unanimously agreed that the desire to help influenced their probability of registering as first responders.

Students reported that the main factors limiting their willingness to register as first responders were stress and the fear of making a mistake. Stress goes against the feeling of controllability of a situation, which is essential to self-confidence [28]. Addressing this issue will require further exploration, but a first step could be to point out the low risk of harm to the patient when practicing BLS maneuvers [14,15] and the clear benefits of early resuscitation early in the presentation [8-10].

Aspects modulating self-confidence need to be highlighted in future presentations to students, but also during the training program, to encourage these students as much as possible to join the Save a Life network. Their abilities and knowledge should be encouraged, and the efforts and gains they can make in the management of OHCA should be recognized. Any fears or doubts they may have must also be addressed during the learning path, and the effect of these motivational enhancements will need to be assessed in the next few years.

Limitations

Since the very low participation rate could not be anticipated, the design of this study had to be adapted. Even though the second motivational intervention was endorsed by a clinician while the first was endorsed by a specialist in basic medical science, the effect of each specific intervention could not be assessed given the design of this study. A randomized controlled trial could be considered to explore the effects of endorsement by either type of specialist. In addition, the motivational interventions themselves were also different, and the effect of specifically designed and theory-based motivational interventions would also deserve to be determined. Finally, the impact of specific factors on motivation was only assessed among the students who had followed the learning path, thereby leading to a selection bias. Therefore, participatory research should be considered to help identify better recruitment strategies, and focus groups held to gather a more thorough and less biased understanding of students' motivation and barriers to participation.

Conclusions

Contrary to expectations, an earlier presentation during the academic year outside the COVID restriction period did not increase the recruitment of medical students as first responders, which was more than 2 times lower than in the implementation study even after further motivational interventions. A thorough quantitative and qualitative exploration of motivational factors should be carried out to determine potential ways of improving the recruitment of first-year medical students as first responders.

Abstract

Background: Forensic medicine requires background medical knowledge and the ability to apply it to legal cases. Medical students have different levels of medical knowledge and are therefore likely to perform differently when learning forensic medicine. However, different medical curricula in Thailand deliver forensic medicine courses at different stages of medical study; most curricula deliver these courses in the clinical years, while others offer them in the preclinical years. This raises questions about the differences in learning effectiveness.

Objective: We aimed to compare the learning outcomes of medical students in curricula that either teach forensic medicine at the clinical level or teach it at the preclinical level.

Methods: This was a 5-year retrospective study that compared multiple-choice question (MCQ) scores in a forensic medicine course for fifth- and third-year medical students. The fifth-year students' program was different from that of the third-year students, but both programs were offered by Mahidol University. The students were taught forensic medicine by the same instructors, used similar content, and were evaluated via examinations of similar difficulty. Of the 1063 medical students included in this study, 782 were fifth-year clinical students, and 281 were third-year preclinical students.

Results: The average scores of the fifth- and third-year medical students were 76.09% (SD 6.75%) and 62.94% (SD 8.33%), respectively. The difference was statistically significant (Kruskal-Wallis test: $P<.001$). Additionally, the average score of fifth-year medical students was significantly higher than that of third-year students in every academic year (all P values were <.001).

Conclusions: Teaching forensic medicine during the preclinical years may be too early, and preclinical students may not understand the clinical content sufficiently. Attention should be paid to ensuring that students have the adequate clinical background before teaching subjects that require clinical applications, especially in forensic medicine.

KEYWORDS

multiple-choice question; MCQ; forensic medicine; preclinic; clinic; medical student

Introduction

Forensic medicine is a crucial field that intersects with the legal system. It involves the collection, analysis, interpretation, and presentation of evidence in legal cases [1]. Forensic medicine plays an essential role in assisting courts with making correct decisions by providing reliable and timely information. It also plays a critical role in protecting peoples' rights by ensuring that their legal, civil, and human rights are upheld throughout the legal process [2]. Furthermore, studying forensic medicine is important for medical students in different countries, as they are equipped with the necessary knowledge and skills to accurately assess and document injuries and provide expert opinions on causes of death and other relevant medical information that may have legal implications [3-6].

This subject is included among the professional subjects that every Thai medical student must study to comply with the Criminal Procedure Code of Thailand, which requires physicians working in public hospitals to be able to perform postmortem inquests with police in cases where no forensic physician is available [7]. The Medical Council of Thailand has included forensic medicine as a mandatory subject in every doctor of medicine program.

The doctor of medicine programs in Thailand are 6-year programs conducted after graduating from high school. They are generally divided into 3 years at the preclinical level (first through third year) and another 3 years at the clinical level (fourth through sixth year). The teaching of each university's curriculum differs in detail depending on various factors, such as the number of students, number of teachers, location, and

service characteristics. Forensic medicine is subject to these differences.

Studying forensic medicine involves dealing with dead bodies, crime scenes, and traumatic injuries that can be emotionally and mentally stressful for some students [8]. A study from Saudi Arabia revealed that medical students have poor attitudes toward and awareness of the importance of forensic medicine [9]. Additionally, forensic medicine courses cover a wide range of topics, such as anatomy, physiology, pathology, toxicology, psychology, and jurisprudence, which can be difficult to master and integrate [10,11].

Students with different levels of medical knowledge may experience different forensic medicine course outcomes. In Thailand, most medical curricula are currently designed to teach forensic medicine to medical students at the clinical level (fifth year) [12-14]. However, some curricula have been designed to teach forensic medicine to medical students at the preclinical or early clinical level (third or fourth year) [15]. There are no clear guidelines regarding the level of students who should be taught forensic medicine.

This study aims to compare the learning outcomes of medical students in a curriculum that teaches forensic medicine at the clinical level and those of medical students in a curriculum that teaches forensic medicine at the preclinical level.

Methods

Study Design

This retrospective study was conducted to compare multiple-choice question (MCQ) scores of fifth- and third-year medical students from two medical curricula that teach forensic medicine. Both groups of students studied forensic medicine with the same instructors, used similar content, and were assessed via MCQ examinations with similar difficulty levels. The scores indicated the participants' learning outcomes.

Setting and Participants

Samples

Our samples included (1) medical students in a curriculum that teaches forensic medicine at the clinical level (fifth year) through the Doctor of Medicine Program at Ramathibodi Hospital, Mahidol University (782 students), and (2) medical students in a curriculum that teaches forensic medicine as the last subject at the preclinical level (third year) through the Joint Program for Producing More Doctors for Rural Areas, Mahidol University (281 students).

Sample Size Calculation

The sample size was designed to compare 2-sided differences in the MCQ percentage scores between third- and fifth-year medical students studying forensic medicine. The null hypothesis (H_0) was that the MCQ percentage scores between third- and fifth-year medical students would not be significantly different. The alternative hypothesis (H_1) was that the MCQ percentage scores between third- and fifth-year medical students would be significantly different.

We calculated the sample size according to a 5% type 1 error (α) and an 80% study power ($1 - \beta$). The significant difference ($\mu 1 - \mu 2$) and SD (σ) were set at 10 and 11, respectively, based on MCQ score data for medical students who studied forensic medicine from 2010 to 2014. The required sample size was 38 (19 participants in each group; Multimedia Appendix 1) [16]. However, this study included more participants than the calculated sample size.

Intervention

Teaching Method

Both groups of medical students received on-site theoretical lectures before completing the MCQs. The content included basic knowledge of forensic pathology (including postmortem inquest, identification, time of death estimation, crime scene investigation, unnatural death, and sudden unexpected death), clinical forensic medicine (including patients who are wounded, child abuse, sexual assault, and forensic psychiatry), forensic evidence, forensic genetics, forensic toxicology, and medical law and ethics. Third-year medical students studied for 30 hours. Fifth-year medical students studied for 15 hours, using similar content that was more concise, and had the opportunity to visit a court for 3 hours. Neither group had the opportunity to attend crime scene investigations or autopsies (which they would attend later). This teaching method was performed regularly, and the authors did not intervene with any of the participants.

MCQ Examinations

For examinations, all teaching staff (4 staff members) created 5-option MCQs with a single best answer according to the topics they taught, including basic knowledge of forensic pathology (40% of questions), clinical forensic medicine (30% of questions), forensic evidence (5% of questions), forensic genetics (5% of questions), forensic toxicology (5% of questions), and medical law and ethics (15% of questions). The tests were designed to ensure that medical students are able to perform basic postmortem inquests, examine various types of forensic patients, produce accurate medicolegal reports, have basic knowledge of law and ethics, and understand the process of testifying in court. The MCQ examinations were structured via a balanced approach for cognitive function, allocating approximately 25% of the examination to knowledge, 30% to comprehension, 25% to application, and 20% to analysis level, according to the Bloom taxonomy. This distribution is maintained consistently from year to year. The examination was intended to have a moderate level of difficulty. Third-year medical students completed a 100-question examination in 2 hours, and fifth-year medical students completed an 80-question examination in 1.5 hours. Based on an analysis of the examination, most of the items had a difficulty level (p) in the range of 0.4 to 0.7 and a discriminatory power (r) in the range of 0.1 to 0.5. Internal consistency reliability (Kuder-Richardson Formula 20) was in the range of 0.6 to 0.7.

Data Collection

In this study, the data were collected retrospectively for 5 years, from academic years 2010 through 2014.

Statistical Analysis

For the comparison between the two groups, we used the means and SDs of the MCQ scores to test this study's hypothesis that the learning outcome is different between third- and fifth-year students. Kruskal-Wallis and Mann-Whitney *U* tests were used for continuous variables with normal and nonnormal distributions, respectively [17]. The significance level was set at 5% ($P<.05$). The program used for data analysis was SPSS software (version 26; IBM Corp).

Ethical Considerations

This study was approved by the Ethical Clearance Committee on Human Rights Related to Research Involving Human Subjects, Faculty of Medicine Ramathibodi Hospital, Mahidol University (MURA 2015/213). The need for informed consent was waived by the Ethical Clearance Committee on Human Rights Related to Research Involving Human Subjects, Faculty of Medicine Ramathibodi Hospital, Mahidol University. Data were collected by using an anonymous method—assigning numbers to all participants instead of names. No compensation was provided to participants.

Results

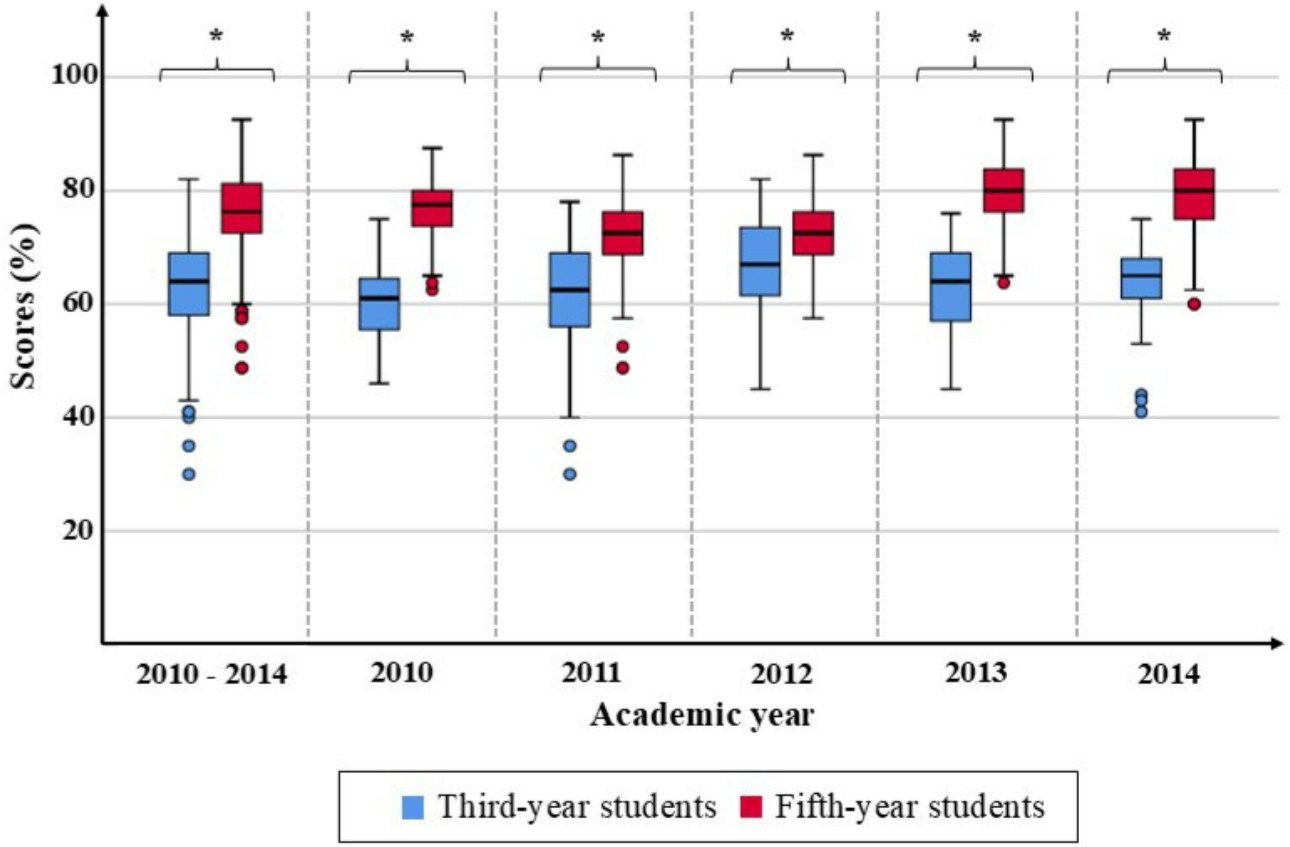
From the collection of MCQ scores of medical students from academic years 2010 to 2014 who were taught forensic medicine, the scores of 1063 students were used in this study. The scores were divided into scores of third-year medical students (n=281) and scores of fifth-year medical students (n=728), as shown in Table 1.

Table . Number of students in each academic year (N=1063).

Students	Academic year					Total
	2010	2011	2012	2013	2014	
Third-year students, n (%)						
Male	30 (2.8)	35 (3.3)	34 (3.2)	33 (3.1)	33 (3.1)	165 (15.5)
Female	21 (2)	23 (2.2)	21 (2)	23 (2.2)	28 (2.6)	116 (10.9)
Fifth-year students, n (%)						
Male	81 (7.6)	94 (8.8)	87 (8.2)	94 (8.8)	101 (9.5)	457 (43)
Female	53 (5)	64 (6)	71 (6.7)	64 (6)	73 (6.9)	325 (30.6)
Total, n (%)	185 (17.4)	216 (20.3)	213 (20)	214 (20.1)	235 (22.1)	1063 (100)

When comparing students' scores, it was found that fifth-year medical students had an average score of 76.09% (SD 6.75%), which was higher than that of third-year medical students (mean 62.94%, SD 8.33%). The difference was statistically significant (Kruskal-Wallis test: $P<.001$). In addition, when comparing the average scores in each academic year, it was found that the average score of fifth-year medical students was significantly higher than that of third-year students in every academic year (Mann-Whitney *U* test: all *P* values were <.001), as shown in Figure 1.

Figure 1. Comparing scores of third-year and fifth-year students. *Statistically significant (Mann-Whitney *U* test: *P*<.001).



Discussion

Principal Findings

According to this study's findings, fifth-year medical students achieved significantly higher marks on MCQs than those achieved by third-year medical students, despite the latter having more opportunities to prepare and take examinations due to their longer duration of study. The fact that the two groups of medical students had different scores may be due to their different levels of basic knowledge of medicine. Fifth-year medical students study basic clinical subjects. Therefore, they may have more comprehensive and complete basic medical knowledge and may be able to apply it to prove facts about legal cases better than third-year medical students who have not completed their basic clinical subjects. These results are consistent with a study in Italy, which showed that students' awareness of forensic medicine improved in the fifth or sixth year of a forensic medicine course [18].

When analyzing the data by academic year, fifth-year medical students still had higher MCQ scores than those of third-year medical students, with statistical significance for each academic year. These data show that the difference in MCQ scores was unlikely due to different medical students from year to year.

In forensic medicine, students should have the opportunity to learn about real cases, including examinations of legal patients, autopsies, and crime scene examinations. This would improve students' understanding of applying and ability to apply medical knowledge to legal applications. A study in India revealed that a court visit in a real scenario was the method that generated the most interest, and student-led objective tutorials comprised the method that best facilitated enhanced learning; the "model answer" method was also found to be an effective method for teaching forensic medicine [19]. Furthermore, a study in Mexico showed that crime scene investigation laboratory visits are an innovative method of learning that may help broaden medical students' perspectives on forensic sciences and help them understand the multidisciplinary processes of crime investigation [20].

By integrating forensic medicine into the medical curriculum, students also gain a deeper awareness of the complexities surrounding child abuse. Training on this topic not only enhances students' diagnostic skills but also instills a sense of responsibility to act in the best interests of the child, ensuring that they are better prepared to contribute to the early detection, intervention, and prevention of child abuse in their future careers [21].

This study used only MCQ scores from theoretical teaching, which may not measure all of the knowledge and skills of students. Although MCQs can test higher-order thinking, they are typically limited to the "application" and "analysis" levels of the Bloom taxonomy [22]. The use of MCQs is often driven by practical concerns, such as large class sizes, rather than pedagogical reasons. Although MCQs have their place, they may restrict the scope of teaching and require careful consideration to align with higher-order learning objectives [23]. Thus, a combination of test methods can be used. A study from Nepal found that objective structured practical examination is an acceptable and well-received method for medical students [24].

Integrating some content of clinical subjects via vertical integration for preclinical medical students may help to enhance their knowledge and understanding of forensic medicine. A previous study on learning environments found that undergraduate medical students from Egypt who received integrated curriculum teaching experienced a more positive learning environment [6]. Further, a similar study from Malaysia showed that integrated teaching positively affects medical students' learning environment [25]. These studies are also consistent with guidelines from the Medical Council of Thailand for developing medical curricula in Thailand, which support horizontal and vertical integration teaching [26]; that is, clinical teachers should teach about clinical experiences from the beginning and integrate basic medical science knowledge into the clinical years.

Limitations

A limitation of this study was its retrospective design; that is, past MCQ scores were analyzed to evaluate the medical curricula at the time of writing. No systematic interventions were conducted to test the hypothesis. In addition, this study used only MCQ scores; therefore, it may not include every learning outcome of the forensic medicine course.

Recommendations

Students' basic medical knowledge should be considered when teaching and learning subjects that require clinical application, especially in forensic medicine, which applies medical knowledge to law. Teaching such subjects to preclinical-level students, whose medical knowledge remains incomplete, may be too ambitious. It may be appropriate to integrate introductory content from clinical subjects to increase knowledge and understanding. In comparison, clinical-level students with complete basic knowledge may be more suitable for such clinical subjects.

Conclusion

Forensic medicine requires basic medical knowledge and the ability to apply this knowledge in legal cases. Students' basic medical knowledge should be considered when planning the teaching and learning of this subject. Teaching forensic medicine in the preclinical years may be too early, and doing so may result in students being unable to sufficiently understand the clinical content.

Abstract

Background: Japan faces a health care delivery challenge due to physician maldistribution, with insufficient physicians practicing in rural areas. This issue impacts health care access in remote areas and affects patient outcomes. Educational interventions targeting students' career decision-making can potentially address this problem by promoting interest in rural medicine. We hypothesized that community-based problem-based learning (PBL) using real-patient videos could foster students' understanding of community health care and encourage positive attitudes toward rural health care.

Objective: This study investigated the impact of community-based PBL on medical students' understanding and engagement with rural health care, focusing on their knowledge, skills, and career orientation.

Methods: Participants were 113 fourth-year medical students from Chiba University, engaged in a transition course between preclinical and clinical clerkships from October 24 to November 2, 2023. The students were randomly divided into 16 groups (7-8 participants per group). Each group participated in two 3-hour PBL sessions per week over 2 consecutive weeks. Quantitative data were collected using pre- and postintervention questionnaires, comprehension tests, and tutor-assessed rubrics. Self-assessment questionnaires evaluated the students' interest in community health care and their ability to envision community health care settings before and after the intervention. Qualitative data from the students' semistructured interviews after the PBL sessions assessed the influence of PBL experience on clinical clerkship in community hospitals. Statistical analysis included median (IQR), effect sizes, and P values for quantitative outcomes. Thematic analysis was used for qualitative data.

Results: Of the 113 participants, 71 (62.8%) were male and 42 (37.2%) female. The total comprehension test scores improved significantly (pretest: median 4.0, IQR 2.5-5.0; posttest: median 5, IQR 4-5; P<.001; effect size r=0.528). Rubric-based assessments showed increased knowledge application (pretest: median 8, IQR 7-9; posttest: median 8, IQR 8-8; P<.001; r=0.494) and self-directed learning (pretest: median 8, IQR 7-9; posttest: median 8, IQR 8-8; P<.001; r=0.553). Self-assessment questionnaires revealed significant improvements in the students' interest in community health care (median 3, IQR 3-4 to median 4, IQR 3-4; P<.001) and their ability to envision community health care settings (median 3, IQR 3-4 to median 4, IQR 3-4; P<.001). Thematic analysis revealed key themes, such as "empathy in patient care," "challenges in home health care," and "professional identity formation."

Conclusions: Community-based PBL with real-patient videos effectively enhances medical students' understanding of rural health care settings, clinician roles, and the social needs of rural patients. This approach holds potential as an educational strategy

to address physician maldistribution. Although this study suggests potential for fostering positive attitudes toward rural health care, further research is needed to assess its long-term impact on students' career trajectories.

KEYWORDS

community health care; community-oriented medical education; mixed method; problem-based learning; real-patient video

Introduction

Japan faces a significant health care delivery challenge owing to uneven physician distribution, notably affecting rural areas and community hospitals [1,2]. This maldistribution exacerbates community hospitals' challenges [3-5]. This issue is not confined to Japan; it impacts countries worldwide [6-11]. In 2019, the Ministry of Health, Labour and Welfare introduced the physician uneven distribution index as part of an intervention policy addressing prefectural geographical disparities in physician distribution [1,12-14]; it assesses the extent of physician maldistribution by evaluating prefectural medical supply and demand.

To combat the physician maldistribution, community hospital training has been integrated into second-year resident physicians' compulsory curriculum [15-17], highlighting the necessity of preparing future physicians with the competencies required to effectively meet rural communities' health care needs. Moreover, introducing community medicine principles early in medical education is an acknowledged need [18].

Japanese medical schools have begun to proactively adopt problem-based learning (PBL) as a foundational step before clinical rotations [19]. PBL emphasizes real-life medical scenarios, cultivating students' clinical reasoning and decision-making skills [20]. PBL prepares students for clinical rotations with an enriched understanding of community health care's challenges and prospects [21]. This approach bolsters medical students' clinical training and supports the alleviation of physician maldistribution by promoting community or rural medicine careers.

However, although PBL has been implemented in medical education settings, its integration with community-oriented medicine in addressing physician maldistribution remains underexplored. Furthermore, despite the global relevance of physician maldistribution, studies focusing on innovative educational interventions targeting this issue are limited [22-24].

We hypothesized that incorporating real-patient videos into community-focused PBL would significantly improve students' capacity to make well-informed career choices and identify with positive role models. This study addressed the aforementioned research gap by examining this approach's effectiveness within Japanese medical education.

Methods

Study Design

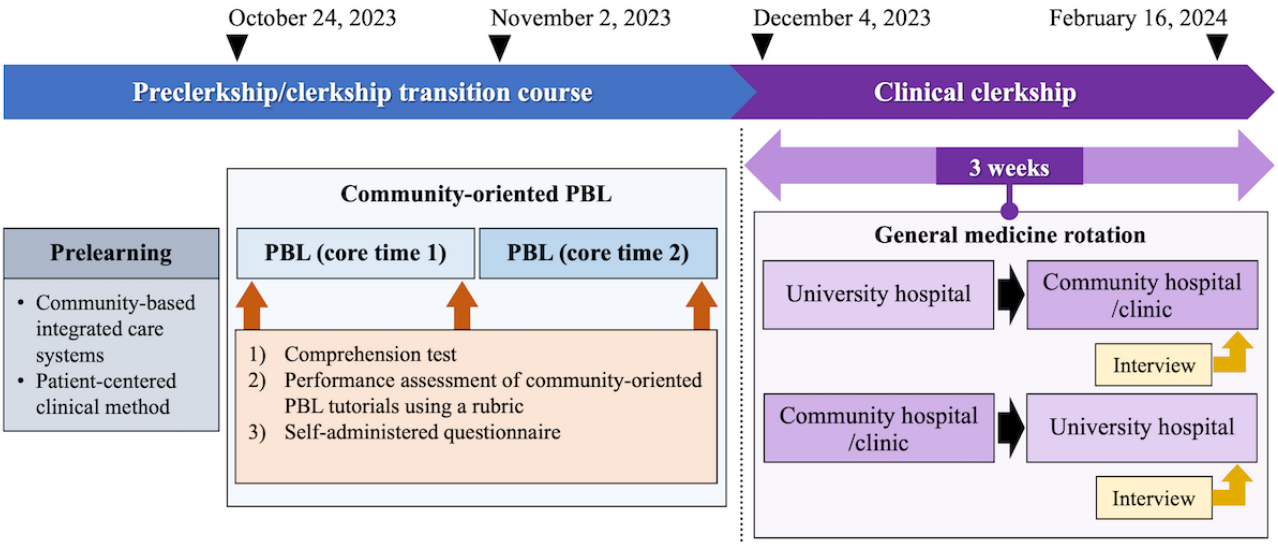
This study used an explanatory sequential mixed methods design following a pragmatic approach [25-27], capitalizing on quantitative and qualitative designs' strengths while minimizing their shortcomings. Furthermore, it allowed researchers to better understand experimental results while incorporating participants' perspectives. The National Institutes of Health advises a mixed methods approach "to improve the quality and scientific power of data" and to better address the complex issues facing health sciences today, including health professional education [28,29]. In the qualitative analysis, medical students' reflection papers were text-mined to analyze the word frequency in community-oriented PBL. Next, we conducted individual interviews with medical students during their clinical clerkship.

Participants and Trial Design

This study was conducted as part of the undergraduate medical curriculum at Chiba University, Japan. Community-oriented PBL was conducted from October 24 to November 2, 2023, as part of a preclerkship/clerkship transition course [30], a 5-week preparatory education period before clinical clerkship. Additionally, PBL is integrated into the Chiba University medical school's curriculum in years 1-4, and all students experience it. Participants were 113 fourth-year medical students who had attended lectures and received simulation training in basic and clinical medicine. To minimize potential biases and ensure an even distribution of student characteristics, participants were randomly divided into 16 groups of 7-8 each using the random number generation function in Microsoft Excel. The 16 groups received community-oriented PBL of a patient case using a community-based integrated care system with real-patient videos.

Quantitative data were gathered using the comprehension test, a tutor assessment with rubrics during the core time, and pre- and postintervention questionnaires to assess community health care perceptions (Figure 1). Additionally, a qualitative evaluation assessed community health care perceptions using a free-text reflection paper after PBL and follow-up interviews during clinical clerkships in community hospitals or clinics. The study used a mixed methods, sequential explanatory design to integrate the results [25,27,31].

Figure 1. Timeline from PBL in preclerkship/clerkship transition course to general medicine rotation in clinical clerkship. PBL: problem-based learning.



Community-Oriented PBL Educational Intervention

Real-patient videos were meticulously prepared to enhance the learning experience authenticity, simulating real-life scenarios in community health care settings (Multimedia Appendix 1). Prepared in collaboration with medical education experts, community health care professionals, and audiovisual production specialists, these videos aimed to accurately depict home health care characteristics, including medical interviews, physical examinations, and in-home patient interactions. Real patients participated in the production process under strict ethical guidelines to ensure authenticity and respect for patient privacy, emphasizing community health care's unique challenges and dynamics.

Each real-patient video was carefully scripted and filmed to represent common community health care situations, encompassing multiple scenes depicting different patient care stages and interactions, ranging from initial patient assessments in a community hospital setting to follow-up in-home visits. The video durations ranged from 3 to 5 minutes. Along with the videos, patient information sheets and tasks were presented to the students (Multimedia Appendix 2). One of the patient's primary conditions was underlying diabetes, and they presented with severe lower leg edema. The case involved transitioning from acute care to a chronic care hospital, followed by the introduction of home visit medical services. Patient consent was obtained for video use, and students were instructed to adhere to confidentiality guidelines.

During the community-oriented PBL sessions, students collectively viewed the real-patient videos in designated classrooms equipped with audiovisual facilities, allowing for simultaneous viewing on shared screens. Before watching the videos, students were divided into small groups and assigned a tutor to facilitate discussions and learning activities. The tutors observed whether the students could achieve the learning objectives and facilitated discussions. The tutors, randomly selected faculty members in medical education and community-oriented medical education, were given standardized instructions and materials before the sessions to ensure consistency and effectiveness [32].

Community-oriented PBL sessions were divided into 2 sessions per case, each lasting approximately 3 hours. In the first session (core time 1), students were presented with the patient's history and physical examination findings. In the second session (core time 2), the investigation findings and treatment plans were discussed. The same case scenario was used for all students.

Quantitative Measures

Comprehension Test

The comprehension test assessed the minimum essential knowledge required for problem solving in PBL, focusing on holistic medicine, patient-centered care, and the International Classification of Functioning, Disability, and Health (ICF). It comprised 5 multiple-choice questions (Q1-Q5, Multimedia Appendix 3). The test was administered as a pretest at the beginning of core time 1 and a posttest after core time 2, allowing for a comparison of test scores.

The comprehension test items were developed specifically for this study and have not been used in other contexts. They were based on the core learning objectives of the PBL sessions, which included understanding the structure of community health care systems, application of the ICF, and principles of patient-centered care. To ensure clarity and alignment with learning objectives, the questions underwent cognitive debriefing by faculty members in medical education. This process involved reviewing each question for relevance, accuracy, and comprehensibility, with feedback incorporated into the final version to enhance content validity.

Rubric-Based Performance Assessment

In addition to the comprehension test, each student's performance during the PBL sessions was assessed using a rubric. The rubric was determined based on previous studies after the authors discussed the validity of the criteria [33,34].

It evaluated 5 key dimensions: knowledge application, comprehensive care process, self-regulated learning, learning motivation, and communication skills with peers. Self-regulated learning refers to the ability of students to plan, monitor, and reflect on their learning process, fostering autonomy and adaptability in problem-solving contexts [35]. Each of the 5 dimensions was quantitatively evaluated on a 10-point scale (Multimedia Appendix 4). Performance assessments were conducted before and after the educational intervention to measure changes in the competencies.

Self-Administered Questionnaire

Students completed questionnaires before and after community-oriented PBL (Multimedia Appendix 5). They were assigned identification numbers to preserve their anonymity. Data were collected using a self-administered 5-point Likert-scale questionnaire ranging from 1 (strongly disagree) to 5 (strongly agree). The criteria were informed by previous studies and refined by the authors through discussions in focus groups [36,37]. After community-oriented PBL, 2 items ("I am interested in community health care" and "I can envision a community health care setting") were surveyed. The items assessed the students' interest in community health care and their ability to visualize a community health care setting.

Sample Size

This study also served as an educational program for fourth-year medical students in a basic clinical clerkship course. Altogether, 113 medical students from 12 groups were recruited. For quantitative data, the sample size required a 2-tailed *t* test of the difference between the pre- and post-PBL means, assuming a significance level of .05, a power of 0.8, and an effect size of 0.5. When the Mann-Whitney *U* test was conducted with those values, the required sample size was 54 in each group, totaling 108.

Data Analysis

All statistical analyses of quantitative data were conducted using SPSS Statistics for Microsoft Windows version 29.0 (IBM Corp), with a significance level under 5% for each analysis. The comprehension test results, including total scores and individual question responses (Q1-Q5), were analyzed using the Wilcoxon signed rank test for paired total scores. Additionally, the McNemar test was used to compare pre- and post-PBL correct response rates for individual questions. For rubric-based performance assessment, the Wilcoxon signed rank test was used to compare scores from core time 1 and core time 2 for total scores and individual rubric items. Effect sizes were calculated for all analyses: r values were derived from z scores for the Wilcoxon signed rank test, and the Cohen w value was calculated for the McNemar test.

Qualitative Measures

Follow-Up Interviews During Clinical Clerkships

Semistructured interviews (average duration: 20 minutes) with individual medical students were conducted by authors KS, KY, and NA. All sessions were recorded and transcribed verbatim, and interviews were conducted iteratively. An interview guide containing open-ended questions was constructed deductively based on the research question and thematic analysis findings. This guide was modified after the first 9 interviews to address emerging and previously unexplored themes in subsequent interviews. The interview participants received no gifts for participating.

Interview transcripts were analyzed using a template analysis approach [38,39]. An inductive code template was defined based on the research questions, thematic analysis findings, and interview guide. The initial template was developed through independent coding (performed by authors KS and IS) of the first 9 interviews. The template was further developed by coding the subsequent interviews. Regarding version 2 of the template, after coding 3 interviews, KS, NA, and IS agreed that the template adequately covered all texts. KS and IS individually coded the remaining transcripts using the template. At this stage, authors KY and SI discussed all further changes or additions to the template until they reached a consensus. After coding all 12 interviews, no additional changes were made to the templates. The final code template was further confirmed by analyzing the remaining 12 transcripts, which can be interpreted as a sign that code saturation was reached [40].

A qualitative evaluation was conducted to assess the acquisition of higher-order intellectual skills in which an interview was conducted after PBL and clinical clerkship. In the clinical clerkship interview, community-oriented PBL's effectiveness in improving clinical performance in home visit care was investigated. The interviewers (KS, KY, and NA) discussed the content and developed an interview guide. Students were asked the following open-ended question: "What is the effectiveness of community-oriented PBL for clinical clerkship?" The interviews were administered by 3 faculty members to 13 students from community-oriented PBL groups during their clinical clerkship. All target students had experienced home visits in their clinical clerkship 1-3 months after community-oriented PBL. The interviewers were trained facilitators from the faculty overseeing community-oriented PBL and conducted thematic analysis. Two researchers (KS and NA) independently read and coded the transcripts. Researcher triangulation was conducted in which the same 2 researchers conducted the analysis and consensus building.

KS and IS, who have extensive experience in qualitative research, defined and regularly discussed the themes and subthemes from the data to ensure the results' reliability. The cognitive process dimensions to which they corresponded were also evaluated.

Ethical Considerations

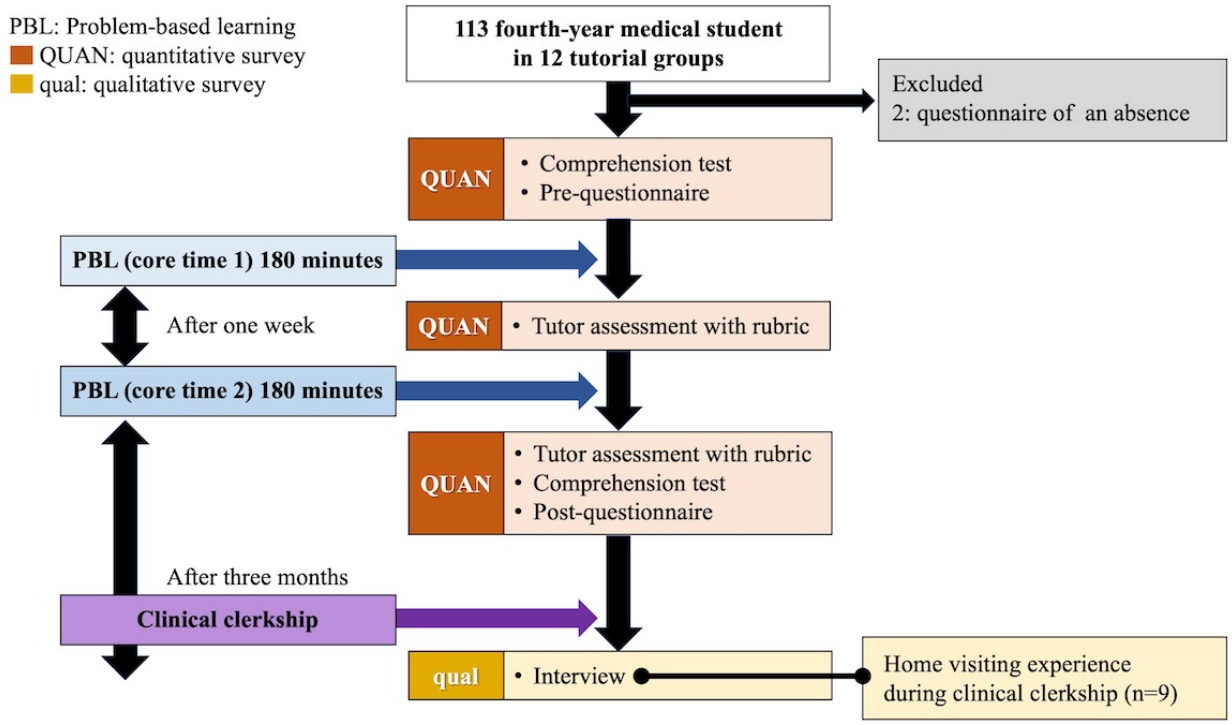
This study was approved by the Ethics Review Committee of the Graduate School of Medicine, Chiba University (approval number 3425). The procedures for obtaining informed consent were explained to the medical students, who were also informed that this study would not affect their grades. All data collected in this study were anonymized to ensure privacy and confidentiality. Participants did not receive any compensation for their participation in this study.

Results

Participant Characteristics

In total, 113 medical students participated in PBL. Of the 113 participants, 71 (62.8%) were male and 42 (37.2%) female. In addition, 2 (1.8%) students were excluded from the survey because they were absent for a core time session; 111 (98.2%) students participated in the quantitative evaluation. The study flowchart is shown in Figure 2.

Figure 2. Study flow diagram.



Quantitative Measures

Comprehension Test

The total comprehension test scores of the students significantly improved after the community-oriented PBL intervention (P<.001, effect size r=0.528). The total pretest scores had a median of 4.0 (IQR 2.5-5.0), whereas the posttest scores improved to a median of 5 (IQR 4-5). Table 1 provides the pre- and posttest analysis results of each question (Q1-Q5). All questions except Q4 showed significant improvements in the percentage of correct answers.

Table 1. Correct answer rates for individual questions in the comprehension test (N=113).

Question number	Pretest correct answers, n (%)	Posttest correct answers, n (%)	*P* value	Effect size (*r*)
1	104 (92.0)	112 (99.1)	.02	2.333
2	69 (61.1)	107 (94.7)	<.001	5.600
3	81 (71.7)	106 (93.8)	<.001	4.640
4	84 (74.3)	93 (82.3)	.19	2.180
5	77 (68.1)	99 (87.6)	<.001	4.310

Rubric-Based Performance Assessment of Community-Oriented PBL Tutorials

Table 2 presents the results of the rubric-based assessment of the students' performance in core time 1 and core time 2. The students' total scores significantly improved from core time 1 (median 38, IQR 33-43) to core time 2 (median 40, IQR 35-44), with P<.001 and an effect size (r) of 0.516. Regarding individual rubric items, significant improvements were observed in domains such as acquiring knowledge applicable to community health care, developing comprehensive care processes, and fostering self-directed learning. In contrast, no significant improvement was observed in the motivation to learn, whereas interpersonal skills showed a small but statistically significant enhancement.

Table 2. Performance assessment of community-oriented PBL[a] tutorials using a rubric.

Performance items	Core time 1, median (IQR)	Core time 2, median (IQR)	*P* value	Effect size (*r*)
Total score (0-50)	38 (33-43)	40 (35-44)	<.001	0.516
Domains				
1. Acquire knowledge that can be easily recalled and applied in community health care settings (0-10).	8 (7-9)	8 (8-8)	<.001	0.494
2. Develop an effective, comprehensive community care process (0-10).	8 (6-8)	8 (8-8)	<.001	0.532
3. Develop self-directed learning methods (0-10).	8 (7-9)	8 (8-8)	<.001	0.553
4. Motivate myself to learn (0-10).	8 (6-8)	8 (6-8)	.11	0.151
5. Acquire good interpersonal skills (0-10).	8 (7-9)	8 (7-9)	.03	0.201

[a]PBL: problem-based learning.

Self-Administered Questionnaire

Results indicated significant changes in students' perceptions of community health care after participating in community-oriented PBL. For the statement "I am interested in community health care," the preintervention median score was 3 (IQR 3-4), which increased to 4 (IQR 3-4) post intervention, with a statistical significance of $P<.001$ ($U=4446.5$). Similarly, the median score for the statement "I can envision a community health care setting" improved from 3 (IQR 3-4) preintervention to 4 (IQR 3-4) postintervention, also showing a significant difference, with $P<.001$ ($U=2589.5$).

Qualitative Measures

Follow-Up Interviews During Clinical Clerkships

We explored community-oriented PBL's impact on medical students' experiences during home visit consultations. In total, 12 (10.6%) medical students who had not experienced home visits before PBL consented to participate in the interview immediately after acquiring home visit experience during a community clinical clerkship. Through qualitative thematic analysis of the interviews, 7 main themes emerged: "building readiness for home care visit participation," "understanding and navigating the home care environment," "professional and personal growth," "interprofessional collaboration and team dynamics," "challenges and opportunities in home care," "community engagement and regional health care systems," and "ethical considerations and end-of-life care" (Table 3).

Table 3. Follow-up interviews and thematic analysis.

Theme	Subthemes
Building readiness for home care visit participation	• Broadened understanding of patient care beyond medical intervention • Enhanced preparedness for real-world clinical situations • Shift in perspective from theoretical knowledge to practical application
Understanding and navigating the home care environment	• Insights into the holistic approach required in home visits • Observations on the complexities of home care, including resource limitations and patient lifestyles • Recognition of the importance of patient and family communication
Professional and personal growth	• Aspiration to contribute meaningfully to patient care • Development of empathy and emotional intelligence • Recognition of the multifaceted role of health care providers in patient support
Interprofessional collaboration and team dynamics	• Importance of teamwork and a multidisciplinary approach in patient care • Learning from and contributing to the health care team • Navigating professional roles and patient relationships
Challenges and opportunities in home care	• Adapting PBL[a] knowledge to address specific patient needs • Confronting and managing unique patient care challenges • Opportunities for innovative care practices in constrained environments
Community engagement and regional health care system	• Enhancing community-oriented medical practice through targeted PBL • Gaining insights into community health care needs and resources • Understanding the impact of regional characteristics on health care delivery
Ethical considerations and end-of-life care	• Deepened understanding of end-of-life care preferences and practices • Navigating ethical dilemmas in patient care decisions • Valuing patient autonomy and quality of life in care planning

[a]PBL: problem-based learning.

Discussion

Principal Findings

This study demonstrated that integrating real-patient videos into community-oriented PBL improves medical students' knowledge, skills, and attitudes toward community health care. Comprehension test results showed significant improvements in students' understanding of core concepts, including community-based integrated care systems (Q1), the ICF framework (Q2 and Q3), and holistic, patient-centered care (Q5). These findings highlight students' enhanced theoretical knowledge essential for community health care practice.

Rubric-based performance assessments revealed notable improvements in 3 key domains:

- Knowledge application (item 1): Students showed improved abilities to recall and apply knowledge in community health care scenarios.
- Developing comprehensive care processes (item 2): Scores reflected stronger skills in designing patient-centered care plans tailored to community settings.
- Self-directed learning (item 3): Students demonstrated enhanced autonomy in planning, monitoring, and reflecting on their learning tasks.

Although interpersonal skills (item 5) improved slightly, no significant changes were observed in the motivation to learn (item 4), indicating areas for potential curriculum enhancement. Self-assessment questionnaires revealed increased interest in community health care and an improved ability to envision a community health care setting. These results suggest that the intervention can positively influence students' attitudes and readiness for community health care practice, potentially guiding their career interests toward rural areas.

Qualitative analysis of students' reflections underscored themes such as readiness for home care visits, professional and personal growth, and community engagement. Students reported a deeper understanding of the complexities of community health care, fostering empathy and patient-centered approaches essential for effective practice in underserved areas.

Implications of Findings

This study provided valuable insights into how community-oriented PBL, enhanced by real-patient videos, fosters medical students' ability to conceptualize their future professional roles. The qualitative data indicated that students develop a deeper understanding of the principles and complexities of rural care, including holistic approaches, patient-centered decision-making, and the importance of interprofessional collaboration. These findings suggest that the intervention successfully prepares students to engage with the challenges and rewards of rural and community-based practice.

Importantly, the qualitative analysis revealed that many students began to envision themselves as contributors to rural health care systems. Themes such as "professional and personal growth" and "community engagement" highlighted students' recognition of their potential roles in underserved areas. This shift was

supported by their increased interest in community health care, as measured by the "questionnaire for perceptions of community health care self-assessment." Postintervention, students reported greater interest and confidence in envisioning community health care settings.

However, although the data indicated a significant attitudinal shift, we lack sufficient evidence to confirm a direct impact on medical students' long-term career intentions to pursue rural care roles after graduation. Future studies should include longitudinal tracking to assess whether the observed changes in perceptions and interests translate into tangible career decisions. Additionally, research is needed to validate the predictive validity of the self-assessment questionnaire in forecasting students' career trajectories.

This intervention lays a strong foundation for addressing the global challenge of physician maldistribution by bridging theoretical knowledge with practical applications. However, further investigation is required to understand its long-term influence on medical workforce trends and rural health care outcomes.

Comparison With the Literature

Our findings will contribute to a growing body of evidence supporting the efficacy of PBL in medical education. Previous studies have demonstrated PBL's ability to enhance clinical reasoning and decision-making skills [19,21,41]. However, our research added a unique dimension by integrating real-patient videos, which provide authentic learning experiences and contextualize medical knowledge within the framework of community-oriented care. Similar studies have reported that experiential learning approaches, such as case-based learning with audiovisual materials, improve students' engagement and retention of knowledge [41].

The significant gains in self-directed learning observed in this study echo findings from Matsuyama et al [35], who emphasized the role of contextual attributes in promoting self-regulated learning. Additionally, the qualitative themes identified in our analysis, such as the importance of interprofessional collaboration and navigating the home care environment, align with the existing literature on the competencies required for effective community health care practice [42-48].

Limitations

Our study has some limitations. First, it was conducted as part of the curriculum of a single medical school, potentially limiting the findings' applicability to other institutions and geographical settings. Future research should involve multiple institutions to enhance the results' generalizability. Additionally, the demographic and cultural context of the participants may not fully represent broader populations, especially in countries with different health care challenges and educational frameworks. Second, the absence of a control group makes it difficult to attribute observed improvements solely to the intervention of incorporating real-patient videos into PBL. Our study evaluated a "bundle" of educational strategies, including real-patient videos, the PBL framework, faculty interventions, and testing conditions. We could not measure these components' differential effects or potential synergistic interactions. Although a randomized controlled trial (RCT) could offer stronger evidence, implementing RCTs in educational settings poses ethical and logistical challenges, such as withholding valuable learning resources from a control group or ensuring equivalent baseline characteristics. To address these limitations, we recommend that future research consider alternative designs to balance rigor and feasibility. Third, the scalability of real-patient videos poses a significant challenge. Producing high-quality real-patient videos requires substantial time, resources, and collaboration among medical educators, health care professionals, and audiovisual specialists. These demands may limit the feasibility of widespread adoption. We suggest collaborative efforts, such as interschool partnerships and the development of shared digital repositories, to distribute production costs and enhance scalability. Fourth, the mixed methods design relied on self-reported measures and reflections, which could introduce a response bias. Future studies could benefit from incorporating objective measures of clinical performance and patient care outcomes. Fifth, the effectiveness of clinical reasoning education via hybrid PBL may vary depending on instructors' teaching skills. Despite standardized training for tutors, differences in tutor effectiveness may have influenced the consistency of outcomes. We propose further methods to ensure uniformity in future implementations, such as advanced tutor workshops and peer evaluations. Sixth, because the study participants were fourth-year medical students at a single Japanese institution, the results may not be directly generalizable to other populations, such as residents or general physicians, or contexts outside Japan, underscoring the need for further validation. Seventh, the comprehension test used in this study, although developed specifically for the program's educational objectives, was not formally piloted with a separate cohort. Instead, the test underwent cognitive debriefing with faculty members to ensure clarity, relevance, and alignment with the intended learning objectives. Although this process enhanced content validity, the absence of a formal pilot test may limit the ability to fully validate the test's reliability and generalizability. Similarly, the 2 items in the self-assessment questionnaire—designed to evaluate medical students' interest in and ability to envision community health care—were developed based on previous studies and focus group discussions but have not been validated using established scales. This lack of formal validation for the comprehension test and self-assessment questionnaire limits the generalizability and robustness of the findings. Finally, although the qualitative data provided valuable insights into students' conceptualization of professional roles and their preparedness for community health care settings, the lack of longitudinal data limits our ability to assess the long-term impact of these interventions on career trajectories or practice in rural or underserved areas. Future research should include follow-up assessments to evaluate the sustained influence of such educational interventions on students' career decisions and professional development.

Conclusion

Integrating real-patient videos into a community-oriented PBL curriculum shows significant promise in fostering medical students' interest and competencies in community and rural medicine. Our study demonstrated improvements in knowledge

acquisition and application, as indicated by enhanced rubric and comprehension test scores. Moreover, qualitative analysis revealed PBL's effectiveness in developing essential skills and shaping medical students' perceptions toward community health care. Although these changes may not directly translate to career decisions, they represent an essential step toward fostering awareness of rural health care needs and aligning medical students' competencies with the demands of underserved areas. This approach highlights the potential of combining real-patient videos with PBL as an innovative educational strategy to address physician maldistribution and support rural health care systems.

Data Availability

The datasets generated and analyzed during the study are not publicly available, because they include participants' personal data, but they are available from the corresponding author upon reasonable request.

Authors' Contributions

KS, KY, and SI planned, designed, and conceived the study. KS drafted the manuscript. KS, KY, NA, and IS recruited participants. KS, KY, and NA conducted the interviews. KS and NA analyzed the initial coding. KS, KY, IS, and SI analyzed the final coding and interpreted the data. KS and KY performed statistical analyses. HK conceived the figures. KS, KY, NA, IS, TT, HT, LY, and SI participated as tutors. All authors have read and approved the final version of the manuscript.

Abstract

Background: Digital technologies (DTs) have profoundly impacted health care delivery globally and are increasingly used in clinical practice. Despite this, there is a scarcity of guidelines for implementing training in digital health competencies (DHC) in medical schools, especially for clinical practice. A lack of sustained integration of DHC risks creating knowledge gaps due to a limited understanding of how DT should be used in health care. Furthermore, few studies have explored reasons for this lag, both within and beyond the medical school curriculum. Current frameworks to address these barriers are often specific to individual countries or schools and focus primarily on curriculum design and delivery. A comprehensive framework is therefore required to ensure consistent implementation of DHC across various contexts and times.

Objective: This study aims to use Singapore as a case study and examine the perspectives of doctors in organizational leadership positions to identify and analyze the barriers to DHC implementation in the undergraduate curriculum of Singapore's medical schools. It also seeks to apply the Normalization Process Theory (NPT) to address these barriers and bridge the gap between health care systems and digital health education (DHE) training.

Methods: Individual semistructured interviews were conducted with doctors in executive and organizational leadership roles. Participants were recruited through purposive sampling, and the data were interpreted using qualitative thematic analysis.

Results: A total of 33 doctors participated, 26 of whom are currently in organizational leadership roles and 7 of whom have previously held such positions. A total of 6 barriers were identified: bureaucratic inertia, lack of opportunities to pursue nontraditional career pathways, limited protective mechanisms for experiential learning and experimentation, lack of clear policy guidelines for clinical practice, insufficient integration between medical school education and clinical experience, and poor IT integration within the health care industry.

Conclusions: These barriers are also present in other high-income countries experiencing health care digitalization, highlighting the need for a theoretical framework that broadens the generalizability of existing recommendations. Applying the NPT underscores the importance of addressing these barriers to effectively integrate DHC into the curriculum. The active involvement of multiple stakeholders and the incorporation of continuous feedback mechanisms are essential. Our proposed framework provides concrete, evidence-based, and step-by-step recommendations for implementation practice, supporting the introduction of DHC in undergraduate medical education.

Introduction

Background

The integration of digital technologies (DTs) into clinical care is transforming health care worldwide [1], underscoring the need to prepare future health care professionals with digital health competencies (DHC) through digital health education (DHE). Despite widespread recognition of the importance of DHC, medical schools worldwide—including those in Singapore—have been lagging in their efforts to implement such training in a meaningful and systematic manner [2-8]. Countries like the United States, the United Kingdom, Canada, and Germany face similar challenges, such as fragmented integration efforts, limited faculty expertise, and curriculum overload, which hinder the consistent incorporation of DHE into undergraduate medical curricula [9-14]. Singapore, a high-income nation in Southeast Asia with advanced education systems and extensive digitalization, provides a compelling case study to explore these barriers. While Singapore's unique sociopolitical and cultural context informs this study, the challenges it faces mirror those encountered by other high-income nations, highlighting the broader international relevance of this research.

Existing efforts to integrate DHE in medical schools, especially for clinical practice, are often disconnected, lacking systematic frameworks and sustained engagement with key stakeholders [2-8]. For example, in Europe and the United States, DHE initiatives are often siloed, leading to significant variability in the quality and scope of training [2,4,6]. Similarly, Australia has faced barriers such as a lack of standardized frameworks for digital health training and challenges in aligning medical education with rapidly evolving health care technologies [3].

These gaps result in inconsistencies in training, with DHC frequently treated as elective content rather than as a core component of medical education. This study applies Normalization Process Theory (NPT)—a framework designed to examine how new practices become embedded within institutions—to provide insights into systematically normalizing DHE and ensuring its sustainable integration [15].

This study addresses the following research questions: (1) What are the institutional and structural barriers to integrating DHE into undergraduate medical curricula? (2) How can the medical school experience be aligned with technological advances? (3) How can NPT be systematically applied to facilitate the effective and sustainable incorporation of DHE? By focusing on Singapore, this study not only provides a deeper understanding of these challenges but also offers insights that can inform global efforts to strengthen DHE integration in medical education.

Exploring the Perspectives of Doctors in Organizational Leadership Roles

Despite their influence on governance and standards, the perspectives of doctors in organizational leadership roles are often overlooked. Existing research that evaluates the opinions of this group of stakeholders primarily addresses challenges in implementing DT in health care, characteristics of effective health systems, and key attributes for health care leaders [16-18].

This study recognizes that doctors in organizational leadership roles possess a strategic understanding of both clinical practice and medical education. Their insights are crucial as they can influence curriculum design, resource allocation, and policy formulation. By leveraging their dual perspectives, the study identifies unique barriers that may not be visible to frontline educators or students.

Furthermore, leaders in health care organizations have the authority to implement change and drive initiatives. Understanding their perspectives ensures that any proposed solutions are both feasible and likely to gain support at the highest levels of the institution. Their endorsement can facilitate smoother implementation and wider acceptance of DHE initiatives.

In addition, these leaders are often involved in broader system-wide decision-making. They are also likely familiar with challenges related to integrating new technologies and practices into established systems. Hence, their experience can provide valuable insights into overcoming any institutional inertia, aligning new initiatives with existing policies, and addressing systemic barriers.

Medical Education in Singapore

Medical education in Singapore is provided by 3 schools, which are Yong Loo Lin School of Medicine (YLL) at the National University of Singapore (NUS), Lee Kong Chian School of Medicine (LKCMedicine) at the Nanyang Technological University (NTU), and Duke-NUS Medical School (Duke-NUS). YLL, established in 1905, and LKCMedicine, founded in 2013, both provide a 5-year undergraduate program. In this program, students spend 2 years studying the basics of medical sciences before undergoing clinical clerkships from the third to the fifth year. YLL was formed to address the critical health care needs of the local population during the colonial period, whereas LKCMedicine was established to meet the increasing health care demands due to an aging population [19]. To boost Singapore's capabilities in translational medicine, Duke-NUS was founded in 2005 through a partnership between NUS and Duke University in the United States. Duke-NUS is a graduate medical school that offers a 4-year MD program, where the first year focuses on basic sciences and the second year on clinical postings. In their third year, students focus on developing research skills, and in their final year, they engage in clinical clerkships [20]. All medical schools in Singapore receive public

funding, and students' tuition fees are subsidized by the government.

Despite their cutting-edge facilities and innovation-driven educational technology, disparities persist between medical school training and clinical application [8,21]. Efforts to integrate DHE courses, such as virtual reality and point-of-care ultrasound, also vary in content and duration across these institutions [8]. Hence, standardizing the curriculum and ensuring consistent training across all medical schools is crucial to bridging the gap between theoretical knowledge and practical skills. This approach would enhance the overall competency of future health care professionals and improve the quality of patient care. In addition, ongoing assessment and adaptation of these programs to incorporate emerging technologies and methodologies are essential for keeping pace with the rapidly evolving medical field.

Methods

Data Collection

A qualitative study was conducted using individual semistructured interviews with doctors who are currently or have previously held organizational leadership positions. Participants were identified by our principal investigator (PI), FKY, based on their leadership roles within public health care organizations, ensuring they possessed the requisite knowledge and experience aligned with the research objectives. Selection criteria focused on senior leaders with expertise in research, clinical education, and development.

This cohort represented a niche group of chief physicians leading public tertiary hospitals that serve as teaching hospitals for undergraduate and postgraduate medical training. Specifically, participants included group chief executive officers from all 3 public health care clusters in Singapore, chairmen of medical boards at public health care institutions, senior administrators from the Ministry of Health, and Directors of Training and Education. To ensure a consistent depth of expertise, participants were required to have a minimum of 5 years of leadership experience within public health care organizations. Those with less than 5 years of such experience were excluded from the study.

Purposive sampling was used to ensure a diverse representation of organizational leaders based on factors such as organizational type, that is, public health care clusters and institutions and functional domains, ie, clinical services and administration. This approach enabled the collection of rich, varied perspectives, enhancing the study's credibility.

Data collection took place from January to April 2021. Participants were invited by the PI by email, which provided a detailed outline of the study's purpose, procedures, potential risks, and benefits. The email also included a consent statement for participants to review and acknowledge before proceeding. In reviewing issues of reflexivity, the threat of potential researcher biases due to the established professional relationship between the PI and the research participants was overcome by having the research fellow, who had no previous relationship with any of the participants, as the interviewer. During the Zoom (Zoom Video Communications) interview, participants were given the opportunity to ask questions, and their verbal consent was recorded at the beginning of each session to ensure informed and voluntary participation. They were reminded of their right to withdraw from the study at any point. It was clarified that data collected prior to withdrawal would still be retained and analyzed to enable a comprehensive evaluation of findings.

To protect participants' anonymity, we assigned code identifiers beginning with "OL" (organizational leader) to each of them. Any identifying information and audio recordings were stored separately from the main dataset in a secure, password-protected file, accessible only to authorized research team members. In reporting results, care was taken to remove or generalize any details that could potentially identify individuals. The data collected and analyzed was used exclusively to inform curriculum development, with no intention to disclose identifiable information.

The interview guide was developed based on the NPT constructs of coherence, cognitive participation, collective action, and reflexive monitoring (Textbox 1). We then adapted the interview guide iteratively to allow participants to share their views on matters that were not initially included in the guide. Generally, the questions sought participants' views on the clinical skills that are still relevant in the digital age (coherence), additional skills that medical students and doctors need for clinical practice amid increasing health care digitalization (coherence), and the clinical skills that are currently being covered in local medical schools (coherence). We also asked participants for their opinions on the clinical skills that should be emphasized more in the medical school curricula (coherence), the challenges of integrating DHE into the compulsory curricula, and suggestions for curriculum improvement to better prepare students for future clinical practice (cognitive participation). To explore how "Collective Action" could be operationalized, we asked how medical schools could improve their collaboration with other stakeholders, particularly professional bodies, health care institutions, and the health care system, to better prepare medical students for clinical practice in the digital era (collective action). We also raised the question of how participants would evaluate the impacts, benefits, and areas for improvement of DHE initiatives within the medical school curriculum (reflective monitoring).

Textbox 1. Interview questions.

- In general, what are the clinical skills that a medical doctor should have?
- Which of these skills are still relevant in the digital age?
- Are there any skills that have been replaced by digital technology, be it partially or completely?
- Against the backdrop of increasing digitalization of health care, what new skills, clinical or otherwise, should a doctor have in order to practice medicine?
- What clinical skills are currently being covered in the local medical schools?
- Which of these skills should be emphasized more in the medical school curriculum?
- In your opinion, how well do the current medical school curricula prepare medical students for the digital aspects of health care? What do you think are some of the challenges in implementing digital health education in medical schools?
- What other improvements can be made to our local medical school curriculum to better prepare the students for clinical practice in light of rapid advances in technology (for example, the advent of artificial intelligence, big data, imaging, smartphone applications, and digital equipment such as handheld ultrasound)?
- How can local medical schools improve their collaborations with professional bodies and health care institutions to prepare medical students for clinical practice in this era of new technology?
- What can the health care system do to support medical students and young doctors in this era of new technology?
- Do you have any other comments on the digital transformations of medicine or health care before we end this interview?

Challenges of contextual differences and stakeholder variation are crucial factors that need to be carefully considered when applying NPT in diverse settings. The study was conducted in Singapore, where the adoption of DT within health care settings has been gradual [7]. This presents challenges for students who may not have adequate exposure to digital systems during their clinical placements. In response to this, the application of NPT should be focused on building digital literacy and ensuring that any intervention is compatible with ongoing efforts to integrate digital solutions into clinical practice. Furthermore, there is also a limited innovation culture in Singapore's health care system [7]. To overcome this, interventions that adopt NPT should incorporate elements designed to stimulate collaboration and mentorship programs with industry professionals. This would help bridge the gap between academic training and the innovation needs of the health care sector.

The study included 33 participants, with the sample size determined based on theoretical and practical considerations. Data collection continued until saturation was reached, ensuring that no new themes or insights emerged from the interviews. This indicates that the sample size was sufficient to capture the relevant perspectives for the study. While practical constraints, such as time and resources, influenced the final number of participants, the primary focus was on ensuring data richness and diversity. This approach allowed for a comprehensive exploration of the research questions.

A total of 30 interviews were conducted and recorded over Zoom due to the physical restrictions brought about by the COVID-19 pandemic, while 3 in-person interviews were held with participants who were located in areas with fewer restrictions at the time or who specifically preferred in-person interaction. All in-person interviews were carried out in accordance with local health guidelines to ensure participant safety. Each interview lasted approximately 40 minutes and was audio-recorded. The transcriptions were derived from the audio recordings of the interviews, which were processed using Otter.ai software (Otter.ai, Inc) before being reviewed for accuracy by the PI and research fellow.

Data Analysis

Thematic analysis using Braun and Clarke's [22] 6-step framework was used to explore barriers that emerged from the data, while a deductive approach based on the constructs of NPT was used to map suggestions for curricula improvement to relevant NPT constructs. To overcome potential interpretive bias and selective perception, coding was conducted by 2 researchers independently. After the initial coding, discrepancies were discussed, and a consensus was reached to refine the codebook and ensure consistency in the application of codes. To enhance credibility and trustworthiness, data were triangulated by comparing the findings across participants from various public health care clusters to identify any consistencies and divergences in opinions. This helped to ensure that the themes captured diverse perspectives and were not unduly influenced by any single group.

In addition, we contextualized the findings by examining studies from other high-income countries undergoing similar digital transformations in health care. Furthermore, we analyzed recently published data reflecting the perspectives of other stakeholders in the health care industry, such as clinical educators and leaders of medical schools, regarding the digital competencies required for future clinical practice [8,21]. In the reporting of findings, we followed the Standards for Reporting Qualitative Research of O'Brien et al [23].

Ethical Considerations

This study was classified as a quality improvement (QI) project focusing on medical education curricula by the Research Integrity, Compliance, and Ethics (RICE) committee of SingHealth. In line with institutional guidelines, QI projects aimed at enhancing existing practices, processes, or programs, such as curriculum development in medical education, do not meet the criteria for human subjects research. As such, the study

was granted an ethical waiver by the SingHealth Centralized Institutional Review Board (2020/2880). This decision was based on the determination that the activities involved posed no more than minimal risk to participants. Despite this waiver, the research adhered strictly to the ethical principles outlined in the World Medical Association's Declaration of Helsinki and institutional guidelines.

Results

A total of 33 participants took part in the study. They included 19 chief medical officers from local public health care institutions, 3 chief executive officers from public health care clusters, 4 senior administrators, and 7 former organizational leaders. Each had at least 5 years of organizational leadership experience and represented various specialties (Table 1).

Participants shared that local medical schools have not yet revamped the curricula to incorporate relevant competencies for the digital age. They identified 6 reasons for the lag in DHC training, some of which extended beyond the medical schools. The analysis of codes, along with the generation of subthemes and themes, is summarized in Table 2. Illustrative quotes from the interviews are provided below.

Table 1. Demographics of participants (N=33).

Characteristics	Participants
Age (years)	
Mean	62
Median	60
Minimum age	44
Maximum age	82
Gender, n (%)	
Male	31 (94)
Female	2 (6)
Years in organizational leadership	
Mean	18.7
Median	18
Discipline, n (%)	
Gastroenterology and hepatology	5 (15.2)
Pediatrics (including pediatrics genetics, pediatric emergency medicine, and pediatric gastroenterology)	4 (12)
General surgery	3 (9.1)
Psychiatry	3 (9.1)
Renal medicine	3 (9.1)
Anesthesiology	2 (6.1)
Geriatric medicine	2 (6.1)
Respiratory medicine	2 (6.1)
Cardiology	2 (6.1)
Orthopedic surgery	2 (6.1)
General medicine	1 (3)
Medical oncology	1 (3)
Ophthalmology	1 (3)
Surgery and urology	1 (3)
Hand and reconstructive microsurgery	1 (3)

Table 2. Codes, subthemes, and themes identified from the coding process.

Codes	Subthemes	Themes
• Lack of time. • Hard to change. • Resistance. • Not open to new technologies. • Not willing to try new technologies. • Academics have to be open.	• Packed curriculum. • Preference for status quo. • Traditional mindset of senior clinicians and faculty.	• Bureaucratic inertia.
• Lack of alternative career pathways. • Lack of role models. • Mindset changes needed.	• Expectations for graduates to become doctors with patient-fronting roles.	• Limited opportunities to pursue traditional career pathways.
• Safe. • Safe sandbox. • Safety nets. • Patient safety. • Safe and creative space. • Nurture and protect. • Talk about the pitfalls and dangers of using technology.	• Lack of safety mechanisms to use DT[a] for educational purposes. • Limited opportunities to experiment with new technologies due to lack of creative space.	• Lack of protective mechanisms for experiential learning and experimentation.
• Clear guidelines. • Clear policies. • Clear intent. • Clear boundaries. • Help students navigate data, fake news, and misinformation. • Data abuse. • Medical ethics. • Respect privacy. • Ethical competency. • Schools presume these (ethical competencies) are common sense.	• Gaps in outlining guidelines and boundaries for technology use. • Gaps in teaching students the pitfalls of using technologies for clinical practice. • Gaps in equipping students with skills in handling data, medical information, and patients' privacy.	• Lack of clear policies and guidelines for clinical practice.
• Interface. • Incorporate teaching facilities within health care institutions. • Correlate. • String information.	• Limited integration of educational and research facilities for medical students within clinical settings. • Lack of feedback on students' performance outcomes. • Lack of compatible data encountered in medical school and residency.	• Lack of integration between medical school education and experience in the health care system.
• Gap between IT and health care. • Nonintegration. • Disorganized. • Slave to the system. • Need to redesign the system. • Put up robust systems. • Involve IT experts. • Facilitating platforms. • Support end users. • Internet separation.	• Health care industry should drive the IT industry.	• Lack of IT integration within the health care industry.

[a]DT: digital technology.

Bureaucratic Inertia

Participants suggested that bureaucratic inertia within both the health care system and medical schools contributed to sporadic and limited training in DT. They attributed this inertia to faculty members' lack of awareness regarding the evolution of clinical practice, their limited expertise in DT, and their resistance to incorporating new competencies, which would require sacrificing some traditional areas of expertise. As shared by OL8 and OL26:

There are senior clinicians who may not be so open to using DT. They are not willing to use different methodologies to solve the same problem. [OL8, Internal medicine, and Respiratory and Critical Care Medicine]

I tried to teach ultrasound in a medical school but with limited success… Unfortunately, it was met with great resistance from people who are traditional. [OL26, Cardiology]

Furthermore, participants perceived that policy makers and senior clinicians were hesitant to invest in DT due to concerns over higher health care costs, further hindering efforts to optimize DT in clinical settings. This perspective is illustrated by the following comment:

> *Some new technologies are almost invariably more expensive and will increase the cost of care.* [OL4, General Surgery]

The above excerpts highlighted systemic barriers to the integration of DT in clinical practice and medical education, emphasizing how institutional inertia and hesitation to invest in new technologies are contributing to the stagnation in clinical training and practice. The reluctance of policy makers and leaders to embrace change and allocate resources for DT exacerbates these challenges, ultimately hindering the evolution of medical education.

Lack of Opportunities to Pursue Nontraditional Career Pathways

Participants also identified limited opportunities to pursue alternative career paths and nonclinical roles, as well as the absence of role models in new technology fields, as significant barriers to implementation. As opined by OL26:

> *I've seen promising students and residents fall through the cracks and give up along the way because we don't have enough career pathways and role models for those in the medical innovation track.* [OL26, Cardiology]

In addition, OL8 highlighted the stigma within the medical community, where students who left medical school to explore nontraditional pathways were often perceived as failures.

> *We lack the definition of what kind of medical graduates we want to train. Other than basic clinical knowledge, I don't think we have defined anything further than that, like a clinician with knowledge of innovation. If a student decides to be an entrepreneur, for example, create a new start-up and drop out of medical school, we should still take that as a success and not a failure.* [OL8, Internal Medicine and Respiratory and Critical Care Medicine]

Without embracing alternative career paths and addressing the stigma associated with leaving traditional medical roles, the health care system risks alienating promising talent and limiting progress in medical innovation. Establishing clear pathways and celebrating diverse career outcomes is essential to cultivating a dynamic and adaptable health care profession.

Lack of Protective Mechanisms for Experiential Learning and Experimentation

In addition, participants noted limited protective mechanisms for experiential learning and experimentation in the health care system. The lack of a "safe and creative space" hindered trainees from engaging in innovative and secure experimentation with DT. Some participants proposed establishing sandboxes where trainees could test ideas with safeguards in place. This would enable them to contribute to clinical practice improvements while receiving proper guidance when mistakes occur. As articulated by OL8 and OL9:

> *The senior clinicians may not be so open to new things. As health care leaders ourselves, we need to embrace the idea of creating a safe sandbox where students [are] allowed to use their imagination to innovate, with all the safety nets in check for patient safety.* [OL8, Internal Medicine, and Respiratory and Critical Care Medicine]

> *What's lacking is a safe space for students and residents. A safe space is a space that offers professional, psychological, and personal safety for them. Measures need to be taken to train, nurture, and protect them rather than condemn them when they do something wrong. The health care system should give them that safe and creative space that ensures they are not bullied, harassed, and ridiculed.* [OL9, Anesthesiology]

Without the establishment of structured and supportive environments for experiential learning, the health care system risks stifling innovation and deterring the next generation of clinicians from engaging with DT. Proactively establishing protected and guided learning environments is essential for fostering a culture of experimentation and ensuring meaningful contributions to clinical advancements.

Lack of Clear Policies to Guide DT Integration in Clinical Practice

Another significant barrier articulated by participants was the lack of clear policies to guide the effective integration of DT in clinical practice. They emphasized the need for well-defined guidelines at both institutional and ministerial levels to support the ethical and professional use of DT. As noted by OL11:

> *The policies that govern digital technologies like telemedicine must be reasonable. Currently, the intent is unclear. At the institutional and ministerial level, there must be clear guidelines and policies that outline the learning and growth in the use of these technologies.* [OL11, Geriatric Medicine]

The lack of comprehensive policies limits awareness of the risks, pitfalls, and ethical considerations associated with DT, deterring its use, particularly among students. OL25 elaborated on the importance of training students in ethics and professionalism to prevent potential misuse of data.

> *In the world of AI and digital medicine, the role of ethics and professionalism are going to be even more important because it opens up easy channels to data abuse, and doctors will have so much data in their hands. So, you need to teach the students medical ethics and values related to patient information and treatment prescription. It's going to be so critical you need to enforce that.* [OL25, Medical Oncology]

The absence of clear, comprehensive policies to govern the use of DT in health care creates ethical and professional ambiguities, deterring adoption and proper training. Establishing well-defined guidelines is critical to mitigating risks, ensuring ethical use,

and preparing future clinicians to navigate the complexities of digital medicine responsibly.

Lack of Integration Between Medical School Education and Clinical Experience

Participants shared that the perceived lack of integration between medical school education and students' clinical experience in the health care system is another barrier to DHE. They attributed this gap to the lack of systems interoperability, which prevents students from accessing and using health care data used in clinical settings and receiving feedback from these systems. As one participant explained, a more integrated system would allow student performance data to correlate with hospital data, enabling continuous feedback and supporting learners' improvement:

> *The biggest gap is that we don't know how students are performing. The data that students are trained for should be similar to the place of practice. If the system is built such that medical school data correlates with say, hospital data, I can string all the information about your learning journey and see how that impacts your performance outcome. From that perspective, we can support the learners better because we give them an environment where they are constantly receiving feedback from the system and seeking new ways to improve themselves. I think that will probably be the most meaningful thing for our learners.* [OL15, Psychiatry]

More broadly, participants noted that the lack of integration between educational and research facilities within health care institutions limits students' clinical immersion. According to OL16, closer collaboration between medical schools and health care institutions is essential for strengthening this connection and enhancing experience, not just physically but through more active interaction between the institutions and health care professionals.

> *I think medical schools should be in the health care institutions. They should interface very closely. One way is to incorporate teaching and research facilities within health care institutions so that the immersion is useful. Currently, our medical schools are within the proximity of the hospital campus. It makes sense, but that's just the physical infrastructure. The people need to be interfaced quite a fair bit.* [OL16, Psychiatry]

The fragmented nature of medical education and clinical training suggests that a more integrated approach, leveraging data-driven feedback mechanisms and collaborative partnerships between academic and health care institutions, is necessary to foster a culture of continuous learning and improvement in health care.

Lack of IT Integration Within the Health Care Industry

Participants also suggested that an integrated IT infrastructure in health care institutions would increase DHE effectiveness and enhance clinical care. However, they highlighted the current lack of interoperability between systems, which hinders the optimization of technical needs. A recurring concern was the IT sector's lack of ability to understand and address the specific needs of health care, with participants noting disorganization and a disconnect between IT and health care practices. As one participant expressed:

> *The gap between the IT and health care industry has not been bridged yet. We have a lot of IT in the health care industry, but a lot of it is record-keeping. It does not integrate [and] information is coming from every direction that is totally disorganized. How, then, can we teach our medical students to be responsible for the patient as a whole? Somebody who has the ability to do IT programming has to follow the doctors on their rounds. I've ever asked my IT colleagues, "Look, is this an IT industry or a health care industry? When they said it's a health care industry, I said, okay, then you have to listen to me and make things work for me, not enslave me to your products."* [OL9, Anesthesiology]

Furthermore, participants emphasized the challenge of internet separation and the need for platforms that allow seamless cross-sharing of information, which they identified as crucial for effective learning environments. As shared by OL12:

> *One of the biggest challenges is Internet separation…The availability and cross-sharing of information are all important facilitating platforms that we have to provide for medical students.* [OL12, Pediatrics]

The lack of integrated IT infrastructure and disjointed systems within health care settings creates significant barriers to enhancing DHE and clinical care, often leaving medical practitioners frustrated with ineffective solutions. To bridge the gap between IT and health care, a more tailored approach is needed, where technological systems are designed to directly support clinical workflows, ensuring both efficiency and improved educational outcomes.

Discussion

Principal Findings

By interviewing doctors in organizational leadership, we gained insider perspectives on gaps in both the medical curricula and the health care system. A total of 6 barriers were identified: bureaucratic inertia, lack of opportunities to pursue nontraditional career paths, limited protective mechanisms for experiential learning, unclear policy guidelines, limited integration between education and clinical experience, and IT integration issues. The findings contributed to the existing literature by showing that DHE barriers were not limited to medical school curricula but involved broader systemic issues. Comprehensive strategies were needed to address these challenges.

By using qualitative interviews, our study uncovered nuances in leadership decision-making that are often missed in quantitative surveys, providing a richer understanding of the factors influencing leadership perspectives. While most studies suggest that organizational leaders prioritize efficiency and sustainability [16-18], our findings reveal that leaders in this

context place a higher emphasis on experimentation and innovation, a factor not traditionally associated with corporate leadership. Furthermore, our research also highlights the growing influence of digital transformation on leadership styles, an area that received limited attention in previous studies focused on traditional management structures. It underscores the importance of adaptive leadership in an era of constant change, suggesting the need for leadership training programs that focus on flexibility.

Many of the barriers identified in this study align with findings from other high-income countries. These include the lack of the necessary information and communication technology (ICT) skills and limited awareness of the potential benefits of DT among some clinicians. For example, in Germany, an empirical study by Ernstmann et al [24] revealed that some primary care doctors perceived eHealth cards as less useful due to their limited ICT expertise and lack of involvement in technological development. These eHealth cards, which store medical data, treatment plans, medications, and electronic patient files, rely on a telematics infrastructure for communication [24]. The study recognized that without robust IT support, comprehensive training for medical professionals, and a standardized national implementation procedure, the acceptance, adoption, and sustained use of eHealth technology by doctors are likely to be hindered [25].

In addition, other studies have shown an increasing proportion of medical school graduates pursuing careers outside full-time clinical practice in some countries [26]. However, findings from countries such as the United States and South Korea indicate that medical school curricula often fail to adequately address the need for programs providing information on nontraditional careers or nonclinical career pathways [27,28]. Despite expressed interest in these career options, medical students often lack awareness of available training opportunities. To attract students to such careers, early outreach programs, combined with appropriate indemnity and support for innovative projects, are essential. These initiatives could be implemented through elective classes, incentives from professional societies, or partnerships with experts [27].

Furthermore, research from countries such as Canada and Taiwan highlights how technological tools can be leveraged to foster experiential learning among medical students. At the University of Ottawa, social accountability experiential logs were developed for third-year medical students to address the social determinants of health, which are often overlooked in clinical learning objectives [29]. These logs guided students in reflecting on clinical encounters and targeting psychosocial skill development, improving clinical confidence, and demonstrating adaptability for other medical schools (Fung et al [29]). Similarly, a Taiwanese study by Liao et al [30] showcased how the mPath (KU Leuven) e-learning tool supported communication skills training by providing a flexible, technology-enhanced learning environment [30]. Features such as remote accessibility, session recordings, peer feedback mechanisms, and visualized analytical reports enabled learners to engage in self-reflection, adapt communication strategies, and enhance subverbal communication skills [30]. Together, these initiatives exemplify how experiential learning tools can address both biomedical and psychosocial challenges in medical education.

The lack of clear laws and policies to guide DT integration in clinical practice is also a barrier in other high-income countries. For instance, health care leaders in Sweden have acknowledged the need for updated policies [16]. They noted that existing laws and regulations have not kept pace with rapid technological advancements and the evolving organization of health care. These policies require revision to ensure clarity regarding liability and accountability, particularly in addressing how errors are managed when artificial intelligence (AI) systems play a role in clinical decision-making [16].

Furthermore, the limited integration between medical education and clinical experience has been highlighted in various studies and reviews. For instance, Pereira et al [31] describe the implementation of a single competency-based Epic onboarding process for medical students in certain US medical schools with rotations across multisystem training sites. This initiative has enabled learners to spend more time in clinical settings with optimized access to electronic health records (EHRs) [31]. While this approach reduces the training burden, curricula could be further enhanced by emphasizing the practical application of EHRs in clinical settings. This includes training students to maintain professionalism and establish rapport with patients while using EHR systems [31]. In addition, Chan and Zary [32] emphasize that providing immediate and formative feedback on students' performance can support the effective use of AI in medical education. However, delivering high-quality feedback in clinical contexts remains a challenge, as it depends on the underlying knowledge base and model of the AI system, which still requires refinement [32].

Previous systematic reviews have consistently identified infrastructure and technical barriers as the most frequently cited barriers to technology integration in health care [33]. These challenges include limitations in health care capacity for technology adoption, inadequate interconnectedness, insufficient network resources, and incompatibility with existing daily workflows [33]. Addressing these barriers requires the active involvement of health care professionals in the development and implementation of health technology tools, which can also enhance their capacity to effectively manage such applications. Furthermore, the reviews emphasize the critical importance of user engagement and collaboration with system developers throughout all phases of design, development, deployment, and continued use [33]. This collaborative approach ensures that the applications are fit for purpose, as they are designed to align with and address health care providers' needs and expectations.

Our findings highlighted structural and bureaucratic barriers beyond medical schools that hindered DHE implementation. Although they are common in high-income countries, no comprehensive framework has been proposed to address them to date. This study applies May and Finch's [15] NPT to suggest ways to bridge these gaps. A summary of how the 4 constructs of NPT can be applied to each of these barriers is found in Table 3.

Table 3. Addressing each identified barrier with the Normalization Process Theory (NPT).

Barriers	NPT contributions
Bureaucratic inertia	• Coherence: enhance understanding and sense-making among stakeholders about the importance and benefits of DHC[a]. This could be achieved by hiring prospective faculty with the skill sets that are relevant to the needs of up-and-coming developments in medicine. • Cognitive participation: engage key stakeholders to foster buy-in and commitment. For example, leaders of medical schools can engage individuals with influence to encourage the integration of digitalization in the core curriculum. These include engaging clinical educators, teachers, and innovators trained in DT[b] in knowledge exchange and talking with the faculty to facilitate the training of DHC and keep them abreast of the latest technological developments in clinical settings. • Collective action: develop strategies to streamline decision-making processes and reduce red tape. • Reflexive monitoring: continuously evaluate and adjust strategies to address bureaucratic resistance and demonstrate early successes to build momentum.
Lack of opportunities to pursue nontraditional career pathways	• Coherence: clarify the relevance of DHC to future career opportunities and the evolving landscape of health care. • Cognitive participation: involve influential faculty and practitioners, such as medical innovators, in promoting the value of alternative career pathways. Medical schools should also provide sufficient training and mentoring opportunities for students who wish to pursue alternative career pathways. • Sufficient resources should be invested in implementing a curriculum that provides students with opportunities to diversify their skill sets, such as skills in clinical informatics relevant to clinical practice. It should include collaborative mentorship where students can explore new fields in DT by forming partnerships with experts from both the clinical and nonclinical fields. • Collective action: integrate DHC into career development programs and highlight role models who have successfully incorporated digital skills. • Reflexive monitoring: gather feedback from students and professionals to continually refine the approach and address concerns about career impact. Relevant recognition should also be given to medical graduates who embark on alternative pathways to encourage the growth of the fields and normalize these pathways for them.
Lack of protective mechanisms for experiential learning and experimentation	• Coherence: emphasize the importance of experiential learning for mastering DHC. • Cognitive participation: foster a culture of experimentation and learning by involving faculty in the design and delivery of experiential learning opportunities. • Collective action: develop and implement policies and resources that support protected time and space for experiential learning and innovation. These include creating more sandboxes and expanding reasonable access to EHRs in clinical settings. • Reflexive monitoring: continuously assess and improve experiential learning programs based on feedback and outcomes.
Lack of clear policy guidelines for clinical practice	• Coherence: clearly articulate the need for and benefits of standardized DHC policies. • Cognitive participation: engage policy makers, clinical leaders, and educators in developing and endorsing clear guidelines. To ensure that the threat of litigation does not hinder technological adoption, professional bodies should establish clear policies that regulate the effective implementation of DT in clinical settings. A technology assessment committee could also be set up to develop guidelines that enable young trainees to use DT effectively and ethically, both for their safety as well as for their patients. • Collective action: implement training and support systems to ensure consistent application of policies across clinical settings. Professional bodies should also work with schools to equip students with knowledge of cybersecurity as well as the limitations and pitfalls of using DT in various circumstances. • Reflexive monitoring: regularly review and update policies based on clinical practice feedback and emerging best practices. Dedicating time to reflect on what can be improved along the way would be a crucial step for schools.
Insufficient integration between medical school education and clinical experience	• Coherence: highlight the importance of integrating DHC across the continuum of medical education. • Cognitive participation: involve both academic and clinical faculty in designing integrated curricula that seamlessly blend theory and practice. • Collective action: develop joint academic-clinical initiatives and placements that reinforce DHC training in real-world settings. • Reflexive monitoring: evaluate the effectiveness of integrated programs and make adjustments to enhance alignment between education and practice.
Limited IT integration within the health care industry	• Coherence: communicate the critical role of IT in supporting DHC and improving health care outcomes. • Cognitive participation: collaborate with IT professionals and health care administrators to prioritize IT integration. To ensure that digital health care technologies can be used safely and effectively by clinicians, new technology or equipment introduced for clinical practice needs to be installed by IT personnel with knowledge of the health care system and with input from health care professionals so that the latter's needs are met. • Collective action: advocate for investments in IT infrastructure and training to support DHC initiatives. At the national level, a move towards interoperability of systems that allow users to share data would also facilitate students' adaptation to new systems in different health care settings. • Reflexive monitoring: continuously assess the state of IT integration and address gaps through ongoing improvement efforts.

[a]DHC: digital health competencies.

[b]DT: digital technology.

Limitations of the Study

This study has several limitations that should be acknowledged. First, the focus on the perspectives of organizational leaders may not fully represent the experiences of frontline educators or students, limiting the generalizability of the findings. Furthermore, interviewing organizational leaders may introduce a bias toward presenting their organizations in a favorable light. They may be reluctant to express views that could be perceived as critical of their organizations. This concern may stem from the constraints they feel due to their roles or the public image of their organizations. As a result, their responses might reflect a more measured or politically cautious perspective. To address this, we incorporated triangulation by cross-referencing their responses with published articles on similar topics. This approach provided a more balanced perspective, though we recognize the inherent limitations in capturing the full organizational dynamics.

Second, the relatively small sample size, while sufficient to achieve thematic saturation, may constrain the breadth of insights. We also recognize that the unique sociopolitical, cultural, and economic context of Singapore may limit the generalizability of our findings to other settings. Singapore's centralized governance and relatively small population create conditions that may differ from other countries. Consequently, while the insights from our study provide valuable lessons, they should be interpreted with caution when applying them to contexts with different governance structures or cultural dynamics.

The third limitation was the gender imbalance among the organizational leaders interviewed, with 94% (31/33) male and only 6% (2/33) female participants. While this reflects the current leadership demographics within public health care institutions, the barriers and challenges identified in our research are rooted in institutional and structural factors rather than individual-level or gender-specific experiences. As such, we do not expect that the gender distribution significantly influenced the findings. However, future research could benefit from a more gender-diverse sample to explore whether different leadership perspectives might offer additional insights or nuances.

Another limitation of our study is the use of Zoom for interviews, which was necessitated by the COVID-19 pandemic and which might have influenced the depth and dynamics of the discussions compared to in-person interviews. In face-to-face settings, nonverbal cues such as body language, eye contact, and physical proximity play a significant role in building rapport and fostering a more comfortable environment for in-depth conversations. These subtle cues can often provide valuable insights into a participant's emotional state, engagement level, and willingness to share more personal or sensitive information. Nonetheless, the insights obtained through Zoom still offer valuable contributions to understanding the barriers to DHE integration.

In addition, we acknowledge that the NPT's focus on individual experiences may not fully capture the diversity of perspectives of multiple stakeholders. To address this, we triangulated our data by comparing the findings across participants from various public health care clusters to identify any consistencies and divergences in opinions. This helped to ensure that the normalization process was not unduly influenced by any single group. By addressing these challenges, we believe our study provides a more nuanced understanding of NPT, particularly in contexts where contextual variations and diverse stakeholder groups are at play. These adaptations strengthen the applicability of NPT and offer valuable insights for its broader use in similar settings.

While we have made considerable efforts to adapt NPT to our specific context, we recognize that there may still be limitations in generalizing our findings across very different settings. Thus, future research should explore how NPT applies in more varied environments with larger sample sizes to further validate our findings. Furthermore, given that normalization is a gradual process, further studies should also conduct longitudinal follow-up assessments to monitor changes over time.

Strengths of the Study

This qualitative study informs us about the institutional and structural barriers present in Singapore's medical school curricula. The diverse sample of this study, spanning various health care institutions and specialties, yielded rich data. Participants possessed extensive organizational leadership experience and were attuned to the needs of contemporary clinical practice. Unlike previous research focusing mainly on institutional inertia and pedagogical strategies [5,34-37], this study uncovered structural barriers as well.

While findings may seem limited to Singapore's context, applying relevant NPT constructs could render results applicable globally since many other high-income countries faced similar challenges in technological development and curriculum digitalization [3,12,38]. Furthermore, the identified barriers necessitated universal solutions extending beyond Singapore.

A potential line of future research would be to gather the views of medical innovators and entrepreneurs to explore other barriers to the effective adoption of DT in health care institutions. Another area would be to evaluate the ways in which DHC training among medical trainees and graduates influences the efficiency and cost-effectiveness of health care delivery. This research could provide valuable insights into how DHC in medical education affects not only the preparedness of new health care professionals but also the overall performance of health care organizations.

Conclusions

Focusing on the perspectives of doctors in organizational leadership roles provides a comprehensive understanding of the barriers to incorporating DHE into Singapore's medical curricula. Their strategic insight, policy influence, experience with system-wide challenges, understanding of the

education-practice gap, resource management capabilities, and expertise in innovation and change management are invaluable for developing practical, effective, and sustainable strategies to address these barriers.

Unlike previous studies focusing solely on gaps within schools, our findings underscored the importance of collaborations with professional bodies and health care institutions to overcome various barriers. By applying NPT, this study provides a structured approach to understanding and overcoming the barriers. It offers a roadmap for other countries facing similar challenges in DHE. However, NPT should be seen as adaptable, requiring regular reevaluation to accommodate dynamic changes in the field.

Acknowledgments

This study was funded by SingHealth Duke-NUS Medicine Academic Clinical Programme under Seah Cheng Siang Distinguished Professorship in Medicine. The authors would like to thank the participants of this study for their invaluable insights and the reviewers of this journal for their helpful comments. They are also grateful to Associate Professor Warren Fong Weng Sen for his helpful feedback on the draft of this manuscript.

Abstract

Background: Global health care education that cultivates international orientation is important for providing medical care in consideration of diverse backgrounds and collaboration with foreign medical professionals. Virtual international exchange programs could be a new type of global education in the present postpandemic era.

Objective: This study aimed to examine the effectiveness of a virtual international exchange program in fostering quality academic and professional learning and international orientation from student perspectives across 5 countries. This research is expected to contribute to education for the development of global human resources in the health professions.

Methods: This quasi-experimental study used a before-and-after design using a convergent parallel mixed methods approach. In this study, a 5-day interactive virtual program was offered to occupational therapy students from Bangladesh, Indonesia, Japan, the Philippines, and Thailand. The students were asked about their expectations and international orientation before the program, and about their evaluation of the program and international orientation afterward. Numerical data from a questionnaire on program expectations and evaluations were analyzed using descriptive statistics. Data on international orientation were subjected to qualitative analysis using steps for coding and theorization.

Results: In total, 29 students participated in the program, out of which 12 students (response ratio 41.4%) answered the research questionnaires both before and after the program. Overall, the students' expectations of the program were met in terms of expertise, scientific learning skills, and group interactions. Comparing before and after the program, mean scores of how the program met expectations increased, and the mean scores after the program in all 12 items asking about program evaluation were from 3.8 (SD 1.19) to 4.9 (SD 0.67; range: score 1 [lowest]-5 [highest]). Even though their motivation for participating in the program was not specific before the program, after the program, they reported having a more concrete image and specific form of what they learned from an international perspective. The participants enjoyed communication with others from diverse backgrounds while recognizing the difficulty of understanding different values. They also expressed satisfaction with their understanding of occupational therapy professionals and diverse societies, including medical systems from other countries.

Conclusions: Even though the analyzed sample data were small, these findings suggest that the program in this study may provide the participants with valuable opportunities. The virtual exchange program could foster students to cultivate qualities such as problem-finding or problem-solving and having interactions with groups from diverse backgrounds.

KEYWORDS

virtual exchange program; occupational therapy education; global education; international orientation; intercultural competence; health professions education

Introduction

Background

As globalization has expanded, education for global human resources in medical education is increasingly being promoted. The significance of international exchange activities in professional fields beyond cultural exchange is also expected. In addition, there is a growing need in the rehabilitation profession to provide medical care to people with diverse backgrounds and collaborate with foreign medical professionals for the further development of the professional field. However, due to travel restrictions, international programs faced serious challenges during the COVID-2019 pandemic, and virtual learning was pursued as an alternative approach [1-3]. The objectives of international exchange programs include not only exchanging academic ideas but also gaining experience with interactive communication in different cultural contexts. Even when restrictions are placed on traveling abroad, educational institutions are expected to manage international academic and cultural programs by synchronizing online programs. During the COVID-19 pandemic, programs were conducted in which students joined from 2 or more universities and participated in activities together for several weeks [4], as well as a successful interactive program to learn professional knowledge and cultivate an international perspective [5,6]. As global health requires significant societal and pedagogical transformations regardless of physical mobility, virtual collaborative international learning has the potential to transform students in the health professions into global human resources. This approach can offer feasible, meaningful, and cost-effective solutions to students in the health professions, thereby enriching cultural competence and global understanding of health through virtual knowledge exchange [6,7].

However, in the present postpandemic era, the restarting of in-person educational programs that involve traveling abroad has created a new situation for virtual international exchange programs. The rapid development of IT during the COVID-19 pandemic has promoted learning knowledge that supports international collaboration toward addressing increasingly complex societal issues, and as such, higher education needs to leverage virtual education while addressing issues such as access, equity, cost, and ecology. In addition, virtual international education promotes internationalization at home (IaH) and provides more opportunities for students on campus to experience internationalization and develop an international orientation. IaH through virtual environments may provide benefits such as fostering a collaborative and diverse online community as a source of social and professional support and networking [8]. In globalization, virtual education may be a part of the essential skills and experiences necessary for generations familiar with and required to acquire IT skills and literacy. Students can feel more open to people from diverse backgrounds and international careers while becoming more familiar with different online technologies [8]. In the health professional education area, pharmacy students have learned about similarities and differences in socioeconomic determinants of health as well as the structure, functioning, and financing of different health care systems. Technology enables more students in diverse geographic locations to be exposed to various perspectives and health care experiences [9]. Student experiences of diversifying and further integrating using virtual platforms can help promote adaptation to global society, develop novel skills and knowledge, and contribute to future development in the medical field.

Global Human Resource Development in Virtual Education

Effective virtual international education should not be considered a replacement for traditional exchange programs that include travel abroad, but rather, a different educational method for increasing international orientation and acquiring the global qualities needed for IaH. Beelen et al [10] describe IaH as the purposeful integration of international and intercultural aspects into students in their home countries. With improvements in IT, virtual collaborative international learning can be effectively managed for interactive communication. For instance, in 2006, the State University of New York developed a collaborative online international learning (COIL) program to engage in an international experience as a virtual type of exchange education based on a collaborative and social constructivist learning approach [11]. As interest in COIL increased, it was regarded as not only an alternative method, but also a method that considered the carbon footprint and environmental impact of physical mobility in regard to air travel [12]. The COIL program offers students an authentic learning experience at their home institution and helps them develop intercultural competencies while serving as a relatively environmentally friendly, sustainable method to internationalize the curriculum. COIL has several characteristics that facilitate learning effectiveness [12]: collaboration between two or more educators from different institutions of higher education in different countries, the co-design and cofacilitation of a joint collaborative course by educators, an emphasis on learning intercultural content and developing collaboration skills through collaborative learning assignments, and several synchronized online meeting times during the course. In the medical professional education field, some studies have been conducted through the COIL program [13,14]. For instance, through the COIL program, nursing students had meaningful, valued engagement with peers in another country to prepare students for diverse, multicultural work settings for their professional futures. The COIL program also helped faculty members conceptualize lessons that promoted intercultural respect and appreciation using online learning methods [13]. Even though English was a second language, the program allowed nursing students to increase their intercultural sensitivity, improve their English proficiency, and obtain more confidence in their interactions and communication with individuals with different cultural backgrounds [15]. Moreover, COIL experiences opened

their eyes to a new way of thinking about preconceived ideas developed without actual knowledge of the situations outside their country, indicating that these cultural encounters led to better cultural awareness, humility, knowledge, skills, and desires [16].

Within virtual education, effectiveness should be judged in terms of not only understanding diverse cultures and increasing cultural awareness, but also developing global human resources. The concept of global human resources includes not only language and communication skills, but also initiative, positivity, a spirit of challenge, cooperativeness, and a sense of responsibility, as well as cross-cultural understanding, a broad range of education, deep expertise, problem-finding and -solving skills, teamwork and leadership, and a sense of ethics. These are not merely limited to an understanding of other cultures and language skills, but also correspond to the professionalism and qualities required of medical professionals. Therefore, cultivating global qualities contributes to not only internationalization but also professionalism in the development of students and institutions. In the medical area [17], the acquisition of necessary skill sets to foster globally competent dental students was enhanced through international virtual team-working, problem-solving, and person-centered multidisciplinary care planning activities. An online program fostering these qualities was beneficial for students from a broader global perspective and demonstrated an appreciation of the importance of delivering culturally sensitive person-centered dental care [17]. Furthermore, by combining virtual exchange and clinical simulation-based experiences for nursing students, the program was associated with statistically significant gains in the cultural intelligence of nursing students to function effectively in situations where cultural diversity was present, which was considered to have a positive impact on their future competence as global health care workers [18]. Another study found that nursing students reported gaining a profound comprehension of, and broadened perspective on, global health and cultural awareness, thereby enhancing their cultural competence [19]. Furthermore, such investments in international virtual education programs have the substantial benefit of offering all students on campus the opportunity to acquire global qualities. As a matter of equity, resources devoted to virtual exchange programs pay substantial dividends for students in historically marginalized and underresourced groups that have been underrepresented in international curricular experiences [20]. Therefore, well-organized virtual programs can be effective for various students to cultivate professional qualities as demonstrated by improvements in global cultural intelligence and academic performance. However, to our knowledge, no studies on rehabilitation professionals, including those in occupational therapy (OT), have been reported. Furthermore, no studies have been conducted on virtual international exchange programs between multiple non–English-speaking countries.

Aim of This Study

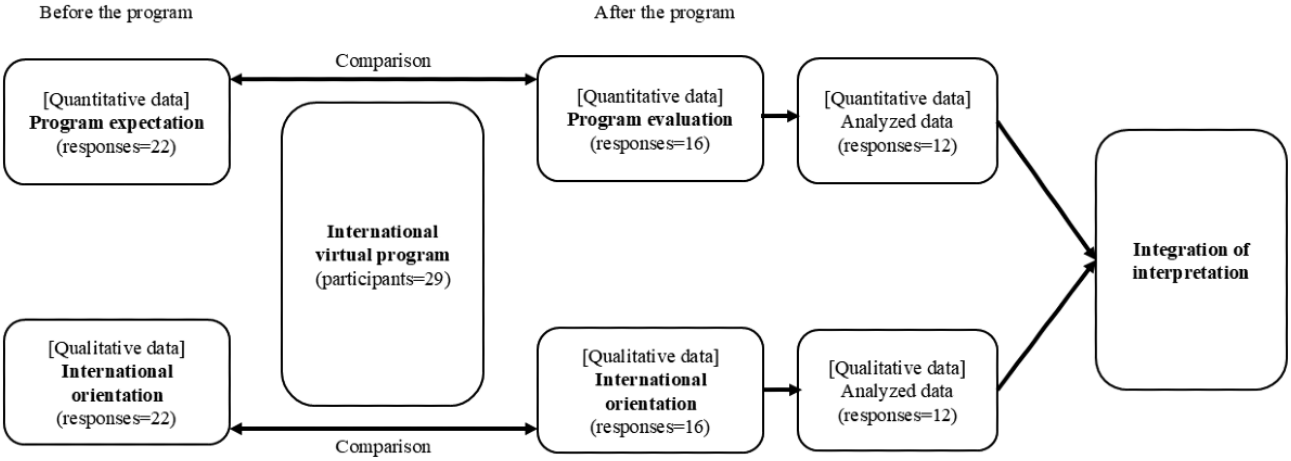
The development of virtual international exchange programs during the COVID-19 pandemic as a new method of fostering global human resources should have led to new adaptations, innovations, and equity considerations. Therefore, such programs need to be examined in terms of their feasibility and sustainability, not just as alternative options for in-person programs. Given this background, this study aimed to examine the effectiveness of virtual international exchange programs for improving academic learning skills, professional knowledge, and global communication abilities in group interactions from student perspectives and suggest meaningful ways to promote global education (global health knowledge and cultural intelligence). This report also aims to contribute to the educational effectiveness of virtual international programs in the rehabilitation professional education area in the postpandemic era, as well as to the development of global education, including OT education, via virtual learning among rehabilitation professionals. In addition, this research can be expected to contribute to the development of global human resources in various health professions through the exchange of information from multiple countries and various international backgrounds.

Methods

Study Design

This quasi-experimental study was conducted as intervention research using a before-and-after design and used a convergent parallel mixed methods approach (Figure 1) in which the researcher converges or merges quantitative and qualitative data to provide a comprehensive analysis [21]. In this study, both quantitative and qualitative data were collected before and after the intervention program and compared to evaluate students' international attitudes and perspectives. After the analysis, the quantitative and qualitative data were integrated into the interpretation of the overall results.

Figure 1. Study process.



Ethical Considerations

The questionnaire and methodology for this study were approved by the Research Ethics Committee of Arakawa Campus Tokyo Metropolitan University (ethics approval number 23060) and registered in the UMIN-Clinical Trials registry system (UMIN trial number UMIN000050884, Reception number R000056060). This study was performed in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki. Participation in this study was voluntary, and informed consent was obtained in writing from all participants before the study began. All participants' data were collected as anonymized data, and participants joined the research with no rewards.

Program Contents

The program was mainly organized by the host university (Tokyo Metropolitan University, Japan), with collaboration from 6 institutions from 4 countries (Angeles Foundation University, the Philippines; Bangladesh Health Profession Institute, Bangladesh; Chaing Mai University, Thailand; Mahidol University, Thailand; the Surakarta Ministry of Health Polytechnic, Indonesia; and the University of Indonesia, Indonesia). Tokyo Metropolitan University concluded a Memorandum of Understanding with all institutions to build relationships before the program was planned and primarily managed the program preparation through good collaboration. The goals of the program were to cultivate an international perspective, to understand OT in Asian countries through lectures and group work, and to learn basic research and presentation skills. During the development of the program, the Attention, Relevance, Confidence, and Satisfaction (ARCS) motivation model developed by Keller [22,23] was applied. The ARCS model proposes significant concepts regarding student attention in class, relevance to participants, student confidence in class, and student satisfaction. The ARCS model has been widely accepted and used to promote student motivation and active participation in class [24,25], and the online program was conducted effectively based on the ARCS model [5]. Hence, in the program, lecturers selected appropriate topics to achieve the program goals. In addition to the lecture contents, assignments and activities were organized to improve student understanding and maintain motivation in considering their academic progress and interests. All lecturers among the collaborative institutions involved in the management of the program agreed on the program contents.

As shown in Table 1, synchronized lectures from 4 countries were provided, and students were invited to join multimix group work on the last day. The group work topics included the role of OTs in the following areas: employment support in mental health, school, care for older adults, remote or isolated area care, assistive devices, stroke, addiction, and stigma. Students made 3 requests on the first day and were assigned to group work on the second. Lectures were provided by 4 countries, and students engaged in interactive group work within a small cultural program. A videoconferencing application (Zoom Communications, Inc) was used for the interactive live lectures, and a free cloud service (Google LLC) was used to share information and materials through an original website. The lecturers and students had access to the program contents and could provide or get handouts and recorded lecture materials for preparing and reviewing. During the program, students were encouraged to work together on their assignments and communicate with each other outside of the lectures through various tools and applications.

In all 7 institutions, the program participants were invited to participate in the virtual exchange program. In total, 30 - 35 students (n=5 from each institution) were targeted to join the program. The students were able to choose to participate in the program regardless of their involvement with the research data collection.

Table . Program contents from February 27 to March 7, 2024.

Session[a]	Date	Contents
1	February 27, 2024	Orientation: medical and welfare system in Japan, long-term care insurance (by Tokyo Metropolitan University lecturer)
2	February 28, 2024	Health and welfare system in Thailand (by Chiang Mai University lecturer)
3	February 29, 2024	Community care in Indonesia (by Surakarta Ministry of Health Polytechnic lecturer)
4	March 4, 2024	Community care in Indonesia (by Bangladesh Health Professions Institute lecturer)
5	March 7, 2024	Students' project presentations

[a]Each session was held at the following times: 10 AM–11:30 AM (Bangladesh), 11 AM-12:30 PM (Indonesia), 12 PM-1:30 PM (Philippines), 1 PM-2:30 PM (Japan).

Participants

The research participants were recruited from an exchange program. The students received no credits because the program was optional. Regarding recruitment, after obtaining ethical approval, Tokyo Metropolitan University lecturers requested research collaboration with joint researchers from each institution or the head of the department via a request letter. After obtaining approval from each institution, a coresearcher (KI) asked participating students by email to complete a questionnaire survey.

Data Collection

Questionnaires were prepared to examine the influence of virtual international learning and the students' international orientation. In addition to age, sex, and school year, before joining the program (within 5 d) and after joining the program (within 5 d), the research participants were asked to complete an online questionnaire survey that consisted of 2 sections: program expectations evaluations and international attitude. The online survey was conducted in accordance with the CHERRIES (Checklist for Reporting Results of Internet E-Surveys).

Program Expectations or Evaluations

The questionnaire asked about the students' expectations and evaluations based on the factors of academic experience, scientific learning skills, group interactions, learning value, program organization, assignments, and workload (refer to Multimedia Appendix 1). Responses were given on a 5-point Likert-type scale. These questionnaires on program expectations (before the program) and evaluations (after the program) were developed based on the student evaluation of educational quality questionnaire and other materials [26-28]. The student evaluation of educational quality questionnaire was originally developed by Marsh [26] as a student course evaluation in higher education and is now widely used around the world in multiple languages. The original questionnaire serves to evaluate the term course. In this study, we developed questionnaires that included items appropriate to the content of the program that could confirm the expected level of achievement. We selected questions that could compare the students' expectations and satisfaction before and after the program. In addition, some expressions were adjusted to fit the program. In total, 15 questions were used before the program to ask about program expectations, and 30 after the program to ask about program evaluations and satisfaction.

International Orientation

This questionnaire (free comments) asked about student motivation to join the international exchange program, the influence of the experience of joining the program, and international attitudes (refer to Multimedia Appendix 1). The questions on international attitudes were developed based on the revised version of IP [29,30], which was developed by Yashima [29,30], who devised an evaluation method for international orientation, from the work of Gardner [31] and Dörnyei [32] on the relationship between foreign language acquisition and international orientation. In this study, we used the IP factors that were appropriate for this study, including intercultural approach (avoidance) tendency, interest in international vocation, ethnocentrism (reaction to different customs or values or behaviors), interest in foreign affairs, and having things to communicate (willingness to communicate to the world).

Statistical Analysis

After the coresearcher (KI) removed all personally identifiable information, numerical data (questionnaire on program expectations or evaluations) were analyzed using descriptive statistics. Qualitative data (questionnaire on international orientation) were subjected to analysis using generative coding by means of steps for coding and theorization (SCAT), which is a qualitative analysis method developed based on the concept of grand theory [33,34]. This method is particularly effective for analyzing relatively small amounts of qualitative data, such as those from a single case or free comment sections of a questionnaire. SCAT consists of 4-step coding using a matrix accompanied by a procedure that describes the storyline and theory by spinning the constructs. The steps followed in SCAT are (1) a word or phrase in the data to focus on, (2) a phrase outside the data to paraphrase, (3) words and phrases to explain these, and (4) emerging themes and concepts. This 4-step coding process creates a storyline or theory that weaves together the themes or constitutive concepts in step 4. In particular, SCAT, as revised by Fukushi and Nago [34,35], is an effective method when there are many cases in which the linguistic data are very

short (eg, 1 or 2 lines), such as descriptions in the free comments column of the collected questionnaires. In the revised procedure, the intercepted data are grouped, paraphrased, and conceptualized. In this study, we used the revised version of SCAT for the data analysis. The first author (NS) analyzed the data, the validity of which was then confirmed by one of the coauthors (KI), who had experience with qualitative research and over 20 years of experience in verifying medical education data, followed by the other 3 coauthors (SSS, MHS, and SM). All data were analyzed and interpreted based on the participants' evaluations of the international program experience.

Results

Participant Characteristics

In total, 29 students (10 from Indonesia, 6 from the Philippines, 5 each from Japan and Bangladesh, and 3 from Thailand) joined the virtual exchange program from February 27 to March 7, 2024, among whom 22 completed a questionnaire before and 16 after the program. Data (from both before and after the program) were available from 12 participants (4 male and 8 female; mean 22.5, SD 2.6 years, age range 19‐28 years; response ratio: 41.4%) for analysis. Regarding the year of schooling, 3 participants were in their second year, 4 in their third, and 5 in their fourth (Figure 1)

Quantitative Data: Program Expectations or Evaluations

Table 2 shows the results of the questionnaires conducted before and after the program. The level of achievement before and after the program was compared for 15 items. The results indicated that the students were satisfied after the program. The students had high expectations before the program, and overall, these expectations were met in terms of academic experience, scientific learning skills, and group interactions. The students responded that they gained valuable knowledge and ideas from the program. The program contents were evaluated as being well prepared, and almost all the participants wanted to join a similar program if given the opportunity. However, some students expressed the need for more support from lecturers to engage in the program and the need to establish a good transmission of internet. In addition, the program schedule was a bit tight because regular classes were being managed at the same time. Overall, the program contents and workload seemed to be reasonable for the students. As a result, they gained new experience in deep expertise, scientific learning through problem-finding and problem-solving, and group interactions in an international context. Although significant differences were not found between before and after the program, the results indicated that the program met the students' high expectations.

Table . Results regarding student expectations and evaluations before and after the program (N=12).

Program expectation questionnaire (before program)	Student evaluation questionnaire (after program)	5-point Likert scale	Before program, mean (SD)	After program, mean (SD)
Academic experience		Strongly agree (5)-strongly disagree (1)		
I feel I will be able to increase my knowledge about OT[a] field.	I increased my knowledge about OT field.		4.5 (0.90)	4.5 (0.67)
I feel I will be more interested in academic learning.	I developed my interests in academic learning further.		4.1 (1.00)	4.3 (0.89)
I expect my knowledge of academia will change.	My knowledge of academia has changed.		4.4 (0.67)	4.0 (0.95)
Scientific learning skills		Strongly agree (5)-strongly disagree (1)		
I expect to learn about collecting and searching information skills.	I learned collecting and searching information skills.		4.8 (0.45)	4.9 (0.67)
I expect to learn about presentation and discussion skills.	I learned presentation and discussion skills.		4.8 (0.45)	4.6 (0.79)
I feel preparing for the presentation assignment will be good training for me.	Preparation for the presentation assignment was good training for me.		4.7 (0.49)	4.6 (0.79)
Group interaction		Strongly agree (5)-strongly disagree (1)		
I feel I will be able to understand my friends' thoughts in other countries.	I understood my friends' thoughts in other countries.		4.5 (0.52)	4.6 (0.67)
I feel I can communicate with OT students and OT lecturers from other countries.	I communicated with OT students and OT lecturers from other countries.		4.5 (0.52)	4.6 (0.67)
I feel I can learn from each other.	I learned from each other.		4.6 (0.51)	4.7 (0.65)
I expect to cultivate an international perspective through a student exchange program.	I cultivated an international perspective through a student exchange program.		4.5 (0.67)	4.6 (0.79)
—[b]	The atmosphere was good for sharing my ideas and thoughts in group discussion.		—	4.3 (0.78)
Learning value		Strongly agree (5)-strongly disagree (1)		
I expect to find the program intellectually challenging and stimulating.	I have found the program intellectually challenging and stimulating.		4.4 (0.67)	4.3 (0.75)
—	I have learned something that I consider valuable.		—	4.6 (0.67)
I feel my interest in the subject will increase as a consequence of this program.	My interest in the subject has increased as a consequence of this program.		4.5 (0.67)	4.2 (0.83)
—	I have learned and understood the subject materials of this program.		—	4.7 (0.65)

Program expectation questionnaire (before program)	Student evaluation questionnaire (after program)	5-point Likert scale	Before program, mean (SD)	After program, mean (SD)
Organization		Strongly agree (5)-strongly disagree (1)		
—	The lectures given by lecturers were very clear.		—	4.4 (0.79)
—	Program materials were well prepared and carefully explained.		—	4.5 (1.00)
I expect to deepen my knowledge about the areas of interest, and I will learn at my own pace through the program.	I learned interesting areas deeply at my own pace through the program.		4.4 (0.67)	4.2 (0.83)
—	The amount of support provided by lecturers was sufficient during the program.		—	3.9 (1.00)
—	Internet environment and technical support for the use of device and application were sufficient during the program.		—	3.9 (0.90)
Workload or difficulty		Too easy (5)-too difficult (1)		
—	How is the program difficulty?		—	3.3 (0.75)
—	How was the assignment workload?		—	3.1 (0.79)
—	How was the program pace?		—	2.6 (0.67)
I think the level of program content is suitable for me.	Overall, from Q23-25, the level of program content was suitable for me.	Strongly agree (5)-strongly disagree (1)	4.1 (0.67)	4.2 (0.72)
Assignment		Strongly agree (5)-strongly disagree (1)		
—	The required reading materials were valuable.		—	4.4 (1.00)
—	Required assignments contributed to appreciation and understanding of OT in the domestic and international fields.		—	4.6 (0.67)
Others		Strongly agree (5)-strongly disagree (1)		
—	Do you want to join a similar program if you have another opportunity?		—	4.7 (0.65)
—	The date and time schedule were reasonably good.		—	3.8 (1.19)
—	I actively participated.		—	4.3 (0.75)
How much do you expect out of this program overall?	The program met my expectation.	Very much (5)-not at all (1)	4.1 (0.90)	4.3 (0.75)

[a]OT: occupational therapy.

[b]Not applicable.

Qualitative Data: International Orientation

As a result of the SCAT coding of data before the program, 20 group concepts and 6 overall concepts emerged regarding international orientation (Table 3). In the text, [ ] indicate overall concepts and < > indicate group concepts.

Students decided to join the program because they were interested in [Learning new knowledge in the professional area] to <expect to know and learn about OT in other countries> and, they were interested in the [opportunity to have international experiences] and <seeking that opportunity>, but sometimes they had <no opportunity to exchange with people from other countries> or <they did not use that actively and usually>, even though they had the opportunity to communicate with people from other countries before joining the program. In addition, they were <interested in studying or working abroad>, but it might be <difficult for some of them due to financial and family concerns>. The virtual program was not concerned about these issues; therefore, it was easy to join to have international experiences. Furthermore, the students expected to [Have new international experiences with different cultures and values] from <making friends and having interactive communication with students in other countries> and <learning and experiencing something new>. In the international context, they <expected the program to lead to being more open-minded internationally>, as well as <learning about the cultures and values of other countries would make me change something> and being <interesting and fun to learn about diverse cultures and values>. On the other hand, some students were worried about <difficulties in understanding other cultures and values>. Similarly, in [international interactive communication], some students had <expectations of and interests in exchanging ideas and opinions>, <expectations of multicountry exchange experiences>, and <using English as a second language>; however, others experienced the <challenge of exchanging ideas and opinions>. Moreover, regarding [general global attitude sensitivity], depending on the individual, some <cared about international issues as usual interest>, but others did not or had <no opportunity to learn about that information>. They were interested in other values or study areas in other countries, but their general international awareness did not always explain their motivation to join the program.

Table . Results regarding concepts, group concepts, and participant descriptions of international orientation before the program (N=12).

Group concepts	Examples of participant descriptions
Concept: [Learning new knowledge in the professional area]	
Expectation to know and learn about OT[a] in other countries	• Good opportunity to know more about different dimensions of OT in different countries. • I want to know about the OT field in other countries.
Expectation to experience an international perspective in the medical health professional field	• From lectures given by other countries, I can compare their system with ours. • In the discussion session, my understanding about health care will be deepened from a student perspective. • I think this is a great opportunity to get a glimpse of the wider global professional perspective regarding OT.
Concept: [Having new international experiences with different cultures and values]	
Hope to make friends and have interactive communication with students in other countries	• I would like to participate in discussions with other students from other countries. • Participating in the virtual exchange program will improve my communication skills.
Expectation of learning and experiencing something new	• Sounds interesting, I will learn a lot from the program. • It can increase my vision about how I can become successful in the future.
Expectation of the program leading to a more open-minded international perspective	• It drives me to behave as politely as I can to accept diversity. • I will learn more about other perspectives, and it will also affect my international perspective.
Interesting and fun to learn about diverse cultures and values	• It is very fun to discover the diverse values and ideas of others. • I really enjoy and am open-minded about interacting with and discussing things with people who have different values and ideas. • I am very interested in learning about culture and other things from abroad.
Perceiving difficulties in understanding other cultures and values	• Sometimes it is hard to be on the other side of a position. • I feel like it takes effort to understand fully people from other cultures with different opinions.
Learning about other cultures and values changes me	• It encourages me to dive into other perspectives affected by my culture. • Exchange programs can open my mind and teach me lessons.
Concept: [Opportunity to have international experiences]	
Interested in or aspiration of studying or working abroad	• I have a big dream to study overseas. I am very motivated to participate in any cross-cultural opportunity. • I am really interested in studying abroad and later working abroad to increase my knowledge and experience. • I really want to continue my OT study abroad.
Difficulties of studying and working abroad	• I know that I will face many challenges abroad. • I have financial concerns.
Seeking more opportunities to communicate with people from other countries	• If I have an opportunity to contact people with other nationalities, I will be grateful. • I would like to have multicultural exchanges.
No previous exchange opportunities with people from other countries	• I am a little hesitant. • I have not had the opportunity to explore cultures in other countries.
Concept: [General global attitude sensitivity]	
Not interested in international issues or situations	• I rarely consume news from other countries. • I am not concerned about world affairs.

Group concepts	Examples of participant descriptions
Interested in international issues and situations	• We should know what is going on in other countries, this is our responsibility as human beings. • I always follow international news because I think everything that happens always affects everyone. • I am always curious about social conditions in other countries. • I can learn from updated information related to policy, health, and so on in other countries.
Not enough opportunities to know about international issues or situations	• I am not very informed about issues in other countries. • I don't have enough knowledge about international issues.
Concept: [International interactive communication]	
Expectations of and interest in exchanging ideas and opinions	• I would like to express my opinions on diverse positions. • I would like to share and discuss my perspectives with others. • I would like to exchange and receive opinions from different perspectives as it would help me to reflect and modify my knowledge or viewpoints.
Challenge of exchanging ideas and opinions	• I think it is challenging for me to exchange my ideas with others. • I feel like it will take effort to organize and tell people with other nationalities to understand ideas fully because of language barriers.
Expectation of a multicountry exchange experience	• I have the chance to work on projects and communicate with people from many countries. • We will share our perspectives in groups with students from different countries.
Using English as a second language	• It is a good opportunity to practice English skills. • The language barrier creates some difficulties while communicating with people from other countries.
Concept: [Motivation to engage in international experience through external encouragement]	
Recommendations from others	• Participating with some international OT students and teachers motivates me to learn more.

[a]OT: occupational therapy.

As a result of the SCAT coding of data after the program, 19 group concepts under 7 overall concepts regarding the participants' international orientation were extracted (Table 4). In the text, [ ] indicate overall concepts and <>indicate group concepts.

Through the program, students reported [knowing and learning new knowledge about OT and other topics in other countries in an international context]. They <learned about OT, including clinical and working situations in other countries> and <gained a wide knowledge of other countries>. With this [opportunity to have international experiences], they <enjoyed it by having international exchange experiences> and <multicultural exchange opportunities>. Some were <seeking the next opportunity for an international exchange experience> and were <interested in or aspiring to study or work abroad>, but they had <difficulties studying or working abroad> and did not have <much opportunity for international exchange after the program>. In the program, the students had the opportunity to [understand the cultures and values of others], which was good in terms of <learning from others and enjoying diverse values and ideas>, but it was <not easy to understand others> in some situations. The program involving multiple countries helped promote [mutual understanding in an international context] in terms of <understanding the viewpoints of others in an international context>, <knowing international perspectives>, and <gaining new ideas from others>. The students reported <enjoying sharing opinions, ideas, and interests with others> in [interactive communication with others], even though one student perceived a <language barrier>. After the program, some students reported the need <to know more about international issues and situations> and expressed <interest in and care about international issues and situations>, but others did <not care about international issues or situations> as part of [general global attitude sensitivity]. They had the experience of learning about the knowledge and values of other countries and enjoyed having interactive communication with people from other cultures and backgrounds.

The qualitative questionnaire was conducted from the perspective of intercultural approach tendencies; interest in international vocations; reactions to different customs, values, or behaviors; interest in foreign affairs; and having things to communicate; these corresponded with the group concepts. Regarding the comparison of data between before and after the program, before joining the program, participants were motivated by interests and curiosity about knowing about OT from overseas, not the concrete contents. However, after the

program, they had more concrete images about specific forms (eg, employment support and clinical skills) from what they learned from an international perspective. A lot of the participants sought opportunities for international exchange, but could not easily find them. Therefore, the chance to join the program was valuable for students, who reported that they wanted to participate the next time they had the opportunity. However, no participants indicated that they wanted to expand opportunities by themselves in the future. Some participants said that they would like to study or work abroad, but felt that it was difficult because of financial and family issues. As for attitudes toward different cultures and behaviors, the participants attempted to understand and enjoyed communicating with others from diverse backgrounds, even though they recognized that understanding different values was not always easy. On the other hand, interest in general international affairs was not necessarily a motivation for participation, and no changes were seen as a result of participating in the program.

Table . Results regarding concepts, group concepts, and participant descriptions of international orientation after the program (N=12).

Group concepts	Examples of participant descriptions
Concept: [Knowing and learning new knowledge about OT[a] and other topics in other countries in an international context]	
Learning about OT, including clinical and working situations in other countries	• We talked about the details of how OTs work and the OT process in every country. • I did not know anything about the system before. Now I know about OT situations in different countries. • I have learned so much about OT situations in other countries.
Gaining wide knowledge about other countries	• My knowledge horizons were widened with OT students from other countries. • I got to know things I did not know before.
Concept: [Understanding other cultures and values]	
Not easy to understand others	• I feel that it takes effort to understand and adapt to other people from different countries.
Learning from others and enjoying diverse values and ideas	• I really enjoyed hearing about and discussing differences in values and cultures. • I enjoy interacting with people who have different ideas. • I find it interesting that I can have discussions with students from other countries and see their perspectives.
Concept: [Mutual understanding in an international context]	
Understanding the viewpoints of others in an international context	• I gained a deep understanding about the different perspectives of other countries compared with us. • It allowed me to respect the other participants. • I know for a fact that no country has a perfect program, each has its own flaws and we can continue to grow by learning and appreciating them.
Knowing international perspectives	• It gave me a lot of new information about other countries so I can learn and know more about international situations. • I do not have that much knowledge about the OT field in other countries, so the program affected my international perspective. • My international perspective did not change.
Gaining new ideas from others	• I was able to improve my knowledge and see other perspectives. • I love to learn about how people think differently.
Concept: [Opportunity to have international experiences]	
Having and enjoying opportunities to have international exchange experiences	• I enjoy having the ability to communicate and participate in an international program. • This was the first time I had an experience like this.
Seeking new international exchange experience opportunities	• I would like to if there is another opportunity. • It was wonderful and I hope to participate in more programs like this if I get the chance in the future.
Multicultural exchange opportunities	• I would love to have the opportunity to communicate with students from other nationalities and cultures. • I really like multicultural exchanges. • I was usually a little hesitant to contact strangers, but now I am happy because I can contact students with other nationalities.
No opportunity for international exchange after the program	• I very rarely have this opportunity. • We didn't have any international program to facilitate us.
Interested in or aspiring to study or work abroad	• I always dream about working outside the country. • I had a dream to pursue higher education abroad. • My goal is to continue my studies abroad. I hope I have the chance someday.

Group concepts	Examples of participant descriptions
Difficulties studying or working abroad	• I have financial concerns. • I have some family concerns. • Working abroad is equally exciting and challenging.
Concept: [General global attitude sensitivity]	
Not interested in international issues or situations	• No time to see. • Normally I do not care about what is going on.
Need to know more about international issues and situations	• I think I need to have a look at situations happening around the world. • I am interested in other countries because I can compare and learn things from them. • I should be interested in it because it is called globalization.
Interested in and care about international issues and situations	• I am really interested as it gives me the opportunity to gain information about the world, which is very important in this era of digitalization. • Now, I am interested. • It is a very helpful example for us to develop.
Concept: [Interactive communication with others]	
Enjoying sharing opinions, ideas, and interests with others	• I really enjoy sharing my thoughts and interacting with people from other countries. • I really like to express my opinions on diverse positions. • I felt like they were close to me.
Language barriers	• It was a bit difficult to communicate with others while we were using our second language.
Concept: [Difficulty arranging the schedule of the international program as an optional program]	
Time management	• I did not have time to participate in our class.

[a]OT: occupational therapy.

Discussion

Principal Findings

This study examined the educational effectiveness of a virtual international exchange program focusing on fostering global qualities involving academic and professional learning and international orientation from students' perspectives. The research participants expressed satisfaction with the program in regard to cultivating an international perspective, understanding OT professionals from other countries, learning academic skills through international communication, and learning about diverse cultures and societies, including medical systems. Even though the results of the quantitative survey did not indicate significant differences, the program participants had high expectations and indicated that they were satisfied with the contents. In addition, the program gave participants a valuable opportunity to cultivate global qualities such as problem-finding and problem-solving, and to have group interactions with people from diverse backgrounds.

The results could indicate that the virtual program was capable of meeting student expectations for international experience through the learning of professional knowledge and communication skills, in line with previous studies [6,7]. This program consisted of lectures, understanding medical situations in other countries through OT professional knowledge, and interactive group work followed by presentations. This program was developed to maintain student motivation and cultivate global qualities based on the ARCS model. The participating students expected to gain new knowledge and ideas about professional areas in international contexts and communicate with others with diverse opinions and backgrounds; from this perspective, their expectations were met. Even though the results of the quantitative survey did not show significant differences between before and after the program because of the participants' high expectations (ceiling effect), the results indicated a mutual understanding of diverse opinions and a recognition that the participants' differences and similarities were valuable. In addition, the vague image of international exchange before the program became more concrete and practical after the program. Thus, the participants had the opportunity to foster their international orientation. On the other hand, the program period may have affected workload or difficulty; for example, the program pace was a bit fast, so the student might not have had time to absorb and review knowledge or brainstorm with international friends in their groups before presenting an assignment. However, the schedule for the long-term program is difficult to structure because of the busy curriculum, including practical placement in health education in multiple institutions. Therefore, even in the short term, the program should make more improvements from the students' perspective.

Implications of the Findings

The virtual program in this study provided students with meaningful experiences, in terms of cultural awareness, competence, and intelligence, for growing as global human resources, in line with previous studies [13,16,19]. Participants showed interest in international communication with professional knowledge both before and after the program, including having friends with different values and learning new things about other countries, even though some of them felt difficulties in communicating with those with different backgrounds. After the program, students reported having more concrete knowledge about OT in other countries and communicating with people with various values through professional knowledge. This may indicate the need to cultivate the ability to build a global community with a common understanding of global health and raise awareness of safety and cultural competency for people from diverse backgrounds in health care. Global institutional collaboration fosters international collaboration between not only students but also educators and researchers [19]. In addition, the virtual interactive program could enhance the development of student competency by contextualizing knowledge, fostering collaboration and innovation among universities, creating an international professional network for students and instructors, and promoting professional skills [36].

Therefore, it is essential to manage communication in virtual programs and foster solid relationships among educational institutions. Student experiences could lead to a global campus environment, which includes faculty and administrators. The establishment of virtual programs relies on existing relationships, clear communication, and a commitment to collaborate [37]. In addition, communication within each institution and with participating students is key to a successful program. Some participants reported that they might have needed more support from faculty members. Interuniversity communication and collaboration among administrators, faculty, prospective students, and partner universities are also important [36,37]. Furthermore, a previous study demonstrated that in practice, these strategies need significant modifications, at least in part, to suit local contexts. Regarding logistical support to achieve effective internationalization “at home,” the present program, which included participants from 5 different countries, should have given more consideration to mutual understanding [38]. Other concerns in regard to the management of virtual programs include the online environment and program schedules [1,5]. In this study, the satisfaction score was not bad, but the satisfaction level was lower than the other items. Therefore, communication among institutions to manage and arrange schedules is important, and a solid, reliable relationship is essential to improve virtual educational programs.

Due to its short duration and contents, the program did not lead to significant changes in global attitudes; however, participants seeking an opportunity were able to learn and think about different values and conditions in other countries. As some students expressed concerns about financial and family issues in terms of studying or working abroad, virtual education was an easy option that allowed them to cultivate global qualities at home [8,20]. Furthermore, IaH programs based on virtual exchange and simulation have been shown to improve general student self-efficacy in the short term [39]. Virtual programs such as the one described in this study could therefore help foster an awareness of international orientation in global human resources. In OT education, OT knowledge and skills are mainly required; however, the experience of learning about and understanding different cultures and values is very helpful to support the lives of others and contribute to development in this field through collaborative communication with other countries [40]. Regarding virtual environments, even though students have adequate communication tools, interactive communication can be difficult, and thus, facilitating interactive activities such as group work is needed [6]. In this study, the participants expressed satisfaction with interactive communication, even in English as a second language. Therefore, the COIL program helps students cultivate meaningful interactive communication skills as a global quality to develop and coordinate team management skills among individuals with various values.

In this postpandemic era, some students may regard virtual education as an alternative option to in-person learning by traveling abroad. However, educators need to demonstrate the value and benefits of virtual education as IaH and clarify how virtual learning abroad programs should be promoted to students [41]. It was clear from the literature that international virtual education can not only maintain and create sustainable ties with international partners, which adds depth and richness, but also provides opportunities to create meaningful, lasting collaborative spaces for the ongoing expansion of global activities [42]. In addition, this type of program can be a positive influence as it gives all students on campus the opportunity to participate in global human resource development, even though the result of this study might indicate only the possibility due to the small sample size.

Limitations and Future Research

This study has some limitations. First, the sample size was small, and the program was only conducted over a short period (1 wk). Therefore, the results may not fully reflect the students’ perspectives. On the other hand, conducting a virtual program with a much larger number of participants would make its quality difficult to maintain. Furthermore, at the moment, international programs are not mandatory in medical education in general, so it remains difficult to recruit many participants for practical reasons. Second, there is no comparison group in this study; therefore, the degree to which this program influenced student perspectives remains unclear. In the future, the effectiveness of the virtual program in each country should be assessed, and the program structure and preparation should be tailored to each country’s situation. This should lead to richer research data.

Conclusions

As globalization has been increasing, it is important to provide medical care to people with diverse backgrounds and collaborate with foreign medical professionals for the development of the professional field. Effective virtual international education should not replace traditional exchange programs, but rather, offer a different educational method to increase international orientation and acquire global qualities as IaH. Within virtual

education, effectiveness should be judged based not only on understanding diverse cultures and increasing cultural awareness, but also on developing global human resources. This study aimed to develop a meaningful virtual international exchange program to promote global education and examine academic learning skills, professional knowledge, and global communication ability from student perspectives. The results would be expected to contribute to education for the development of global human resources in the health professions through the exchange of information by people from various countries and international backgrounds. The present virtual international program was conducted using a quasi-experimental before-and-after design that used a convergent parallel mixed methods approach among 5 countries (Bangladesh, Indonesia, Japan, the Philippines, and Thailand). The program could provide students with meaningful experiences as global human resources in terms of cultural awareness, competence, and intelligence. In this postpandemic era, some students may regard virtual education as an alternative to in-person learning combined with traveling abroad. However, educators need to show the benefits and value of virtual education as IaH and clarify how these benefits should be promoted to students. Assigning projects that necessitate teamwork across different countries can compel students to engage more deeply with their peers, thereby fostering stronger communication skills and a better understanding of diverse perspectives. These collaborative tasks can simulate real-world scenarios where multidisciplinary and multicultural teams work together to solve complex problems. This approach can not only enhance learning experiences but also prepare students for professional environments where international collaboration is often essential. By requiring students to navigate language barriers, cultural differences, and varied working styles, such tasks can significantly enhance their global competence and teamwork abilities. These deeper interactions could bridge the gap between mere exposure to international elements and the development of a truly global perspective.

Acknowledgments

We wish to thank all the faculty members at Tokyo Metropolitan University, Angeles Foundation University, Bangladesh Health Profession Institute, Chiang Mai University, Thailand; Mahidol University, Thailand; The Surakarta Ministry of Health Polytechnic, Indonesia; and the University of Indonesia, as well as all participating students. In particular, Ms. Mohuya Akter and Ms. Cahya Ramadani Renhoran were very supportive of the progress of this program. The authors also thank FORTE Science Communications [43] for English language editing. This work was partially supported by the General Research Fund of Tokyo Metropolitan University for manuscript writing and publication.

Data Availability

The data used to support the findings of this study are included within the article. However, for more information, the datasets generated and analyzed in this study are available from the corresponding author upon reasonable request.

Authors' Contributions

All authors contributed to the study conception and design. Material preparation, data collection, and analysis were performed by NS, KI, SSS, MHS, and SM. The first draft of the manuscript was written by NS, and all authors reviewed and commented on the previous version of the manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: To further optimize the clinical and scientific training of high-level doctoral graduates, the Office of the National Postdoctoral Administration launched a clinical postdoctoral program in 2015. This program provides postdoctoral clinical medicine trainees with 3 years of individualized, intensive training through a full mentorship system, interdisciplinary collaboration, and a multiteam teaching platform.

Objective: This study aimed to compare the effectiveness of this novel clinical postdoctoral training program against conventional doctoral training, using specific, quantifiable metrics. Our primary research questions were as follows: (1) Does the program lead to superior clinical performance, as measured by theoretical examination scores and Case Mix Index (CMI)? (2) Does it enhance scientific research productivity, measured by publication output and success rates in procuring provincial and national NSFC (National Natural Science Foundation of China) funds? (3) Are there differences in teaching capacity and overall career advancement?

Methods: This was a retrospective, nonrandomized controlled study. Doctoral graduates who entered the hospital for standardized residency training between 2015 and 2019 were enrolled and divided into a postdoctoral training group (n=23) and a doctoral training group (n=106).

Results: The postdoctoral group demonstrated significantly higher clinical performance, as indicated by higher theoretical examination scores (445.70, SD 14.67 vs 435.12, SD 15.29; *P*=.003) and a higher median CMI (1.14 vs 0.92, *P*=.03), reflecting greater ability to manage complex clinical cases. In terms of research productivity, the postdoctoral group outperformed the doctoral group in the number of published papers (2.35, SD 2.39 vs 1.11, SD 1.47; *P*=.002) and the proportion of approved provincial-level NSFC projects (47.83% vs 17.00%, *P*=.001). However, no significant differences were observed in the acquisition of national-level NSFC funding (60.87% vs 44.34%, *P*=.15), teaching capacity (0.22, SD 0.518 vs 0.10, SD 0.306; *P*=.16), or overall competency indicators such as the rate of professional title promotion (100% vs 94.34%, *P*=.53) and the attainment of a master's-degree supervisor qualification (13.04% vs 5.67%, *P*=.42).

Conclusions: The clinical postdoctoral training program demonstrates promising effectiveness in enhancing both clinical performance and scientific innovation among medical trainees. These findings support the value of integrating clinical practice, research, and mentorship in advanced postgraduate medical education and suggest that this model is worth promoting in more medical institutions.

KEYWORDS

clinical medicine postdoctoral program; standardized residents training; clinical competence; scientific research ability; teaching skills; comprehensive ability

Introduction

Background

China’s medical education system has undergone significant reform in recent years, evolving into a 3-stage model: medical school education, standardized residency training (SRT), and continuing professional development. SRT serves as the cornerstone of clinical training, aiming to produce physicians who are competent in managing common diseases with strong ethical standards and clinical skills [1-3]. However, while SRT focuses on standardized clinical practice, it often falls short in cultivating research literacy, academic leadership, and

innovation capabilities—key competencies required for high-level clinical scholars.

To address this gap, the Office of the National Postdoctoral Management Committee launched a clinical postdoctoral training program in 2015 [4]. As the first pilot institution, Zhejiang University introduced a novel training model that builds upon SRT but goes beyond it by integrating advanced clinical training with rigorous scientific research and teaching development [5].

This program is specifically designed for highly qualified medical doctors who have completed their doctoral studies and seek to become leaders in both clinical practice and biomedical research. Unlike traditional SRT, which emphasizes competency in routine diagnosis and treatment, the clinical postdoctoral program enhances trainees' abilities in clinical reasoning and management of complex cases, original research and evidence-based medicine, medical education and mentorship, and innovation and translational application of clinical findings [6].

The curriculum combines structured clinical rotations with independent research projects under the supervision of multidisciplinary mentors. It also includes formal teaching experiences, international exchanges, and interdisciplinary collaboration, all aimed at fostering a new generation of clinicians who can lead in academia, contribute to global health, and drive clinical innovation.

Ultimately, the program seeks to cultivate clinician scientists and clinician educators who possess not only excellent clinical expertise but also the capacity to conduct high-impact research, mentor future generations of physicians, and translate scientific discoveries into clinical practice. This represents a significant departure from conventional postgraduate medical training models seen worldwide and aligns more closely with integrated clinical-academic pathways found in some elite programs in North America and Europe [7-9].

This study focuses on the pioneering program at Zhejiang University to evaluate its effectiveness in bridging the gap between clinical training and academic development, thereby providing evidence for its potential role in advancing China's medical education system.

Objectives

While Zhejiang University School of Medicine and its Second Affiliated Hospital have a long-standing tradition of excellence in medical education, traditional postresidency training often fails to provide integrated development in advanced clinical practice, research, and teaching. To address this, we launched the Clinical Medical Postdoctoral Training Program in 2015. This study aims to evaluate the effectiveness of this program's first 8 years of implementation (2015 - 2023) through a retrospective, nonrandomized, controlled design.

Specifically, we sought to compare the postdoctoral trainees with conventionally trained counterparts using a set of predefined, quantifiable metrics as proxies for key competencies: (1) clinical performance measured based on standardized theoretical examination scores and the Case Mix Index (CMI) of treated patients, (2) research productivity measured by publication output and success rates in obtaining provincial and national-level NSFC (National Natural Science Foundation of China) funds, (3) teaching engagement measured by the number of formal teaching sessions conducted, and (4) career advancement measured by the rate of professional title promotion and qualification as a master's-degree supervisor.

We hypothesized that this program would significantly improve participants' clinical reasoning, research productivity, and teaching capabilities compared to conventional postresidency pathways. The findings are expected to be of particular interest to medical educators, hospital administrators, and policymakers involved in designing advanced clinical training programs, especially in countries seeking to strengthen their clinical academic workforce.

Methods

Ethical Considerations

This study was approved by the Ethics Committee of The Second Affiliated Hospital, Zhejiang University School of Medicine (approval number 2023-0974). Informed consent was waived by our Institutional Review Board because of the retrospective nature of our study.

Study Design and Participants

We conducted a retrospective, nonrandomized, controlled study. The study population consisted of medical doctoral graduates who entered the hospital between 2015 and 2019 and were required to undergo SRT. Individuals without a numeric score on the SRT completion test were excluded to ensure the quantitative evaluation of training outcomes.

Participants were divided into 2 groups based on their training pathway:

- Doctoral group (control): graduates who completed only SRT.
- Postdoctoral group (intervention): graduates who successfully applied for and completed the additional 3-year Clinical Medicine Postdoctoral Training Program.

Admission to the postdoctoral program was competitive, based on academic merit, clinical performance, and personal motivation. The program provided enhanced, structured training in clinical practice, scientific research, and teaching under a dedicated mentorship team [10,11].

Outcome Measures

To evaluate the program's effectiveness, we selected a comprehensive set of quantitative metrics designed to proxy competencies in clinical practice, scientific research, teaching, and career advancement (Table 1). Data for all metrics were collected over the 3-year training period. All metrics were analyzed with stratification by age, gender, clinical discipline, and prior training duration.

Table . Primary outcome measures and their operational definitions.

Metric category	Operational definition and data source	Construct measured
Clinical performance		
Theoretical examination score	Final examination score; source: Education Department	Mastery of clinical knowledge
SRT[a] completion pass rate	Binary outcome (pass/fail) for the standardized national residency completion examination; source: Education Department	Attainment of the minimum competency standard required for independent clinical practice
Annual assessment score	Composite annual review score; source: Education Department	Overall clinical performance and professionalism
Case Mix Index	The average diagnosis-related group (DRG) weight of patients treated; source: Medical Record Room	Complexity of clinical experience
Scientific research ability		
Number of papers published	Total count of peer-reviewed research articles published; source: Scientific Research Department	Scientific output and research ability
The number of achievement awards won as a participant	The number of scientific research achievement awards (at the provincial/ministerial level or above) won by the trainee as a contributor; source: Scientific Research Department	Peer recognition and impact of research output
National/provincial NSFC[b] projects	Total number of grants obtained as a principal investigator; source: Scientific Research Department	Competitiveness in securing research funding
Teaching ability		
Teaching engagement	Total number of teaching articles/teaching reform projects/teaching competitions; source: Education Department	Contribution to medical education
Comprehensive ability		
Professional title promotion	Binary outcome (yes/no) for promotion from a junior to an intermediate title; source: Human Resources	Institutional recognition of competence
Master's degree supervisor qualification	Binary outcome (yes/no) for being approved as a supervisor; source: Education Department	Recognition of academic standing

[a]SRT: standardized residency training.

[b]NSFC: National Natural Science Foundation of China.

Data Collection and Processing

Data were collected from the hospital's departmental databases (Education Department, Human Resources, Scientific Research Department, and Medical Record Room). The collection process involved extracting structured data from electronic source files, including examination records, personnel files, grant management systems, and publication databases. To ensure data quality, we handled missing data through listwise deletion and checking for implausible values or outliers. This process was conducted by 2 independent researchers to minimize error.

Statistical Analysis

SPSS (version 27.0; IBM Corp) was used for statistical evaluation of the data. Numerical/count data were expressed as the n (%) values, and the *t* test or chi-square test was used for comparison between groups. Normally distributed data are expressed as mean (SD) values, and the *t* test was used for comparison between groups. Nonnormally distributed data are expressed as median (IQR) values, and between-group comparisons were made using the Mann-Whitney *U* test. *P* values of <.05 were considered statistically significant.

Results

Study Participants

A total of 251 trainees (admitted from 2015 - 2019) met the inclusion criteria of this study. After excluding 17 trainees with less than 1 year of training, 6 trainees with more than 3 years of training, and 99 trainees without a specific score on the SRT completion test, 129 trainees were finally enrolled, including 23 postdoctoral trainees and 106 control trainees (Figure 1). Table 2 shows that there was no statistically significant difference between the two groups of trainees in terms of gender, age, distribution of disciplines, and other aspects. The difference in training years was statistically significant (*P*<.001).

Figure 1. Flowchart for the study. A total of 251 trainees (admitted from 2015 to 2019) met the inclusion criteria of this study. Exclusion criteria: 1 year of training, more than 3 years of training, and not having a specific score on the SRT completion test. In total, 129 trainees were finally enrolled, including 23 postdoctoral trainees and 106 control trainees. SRT: standardized residency training.

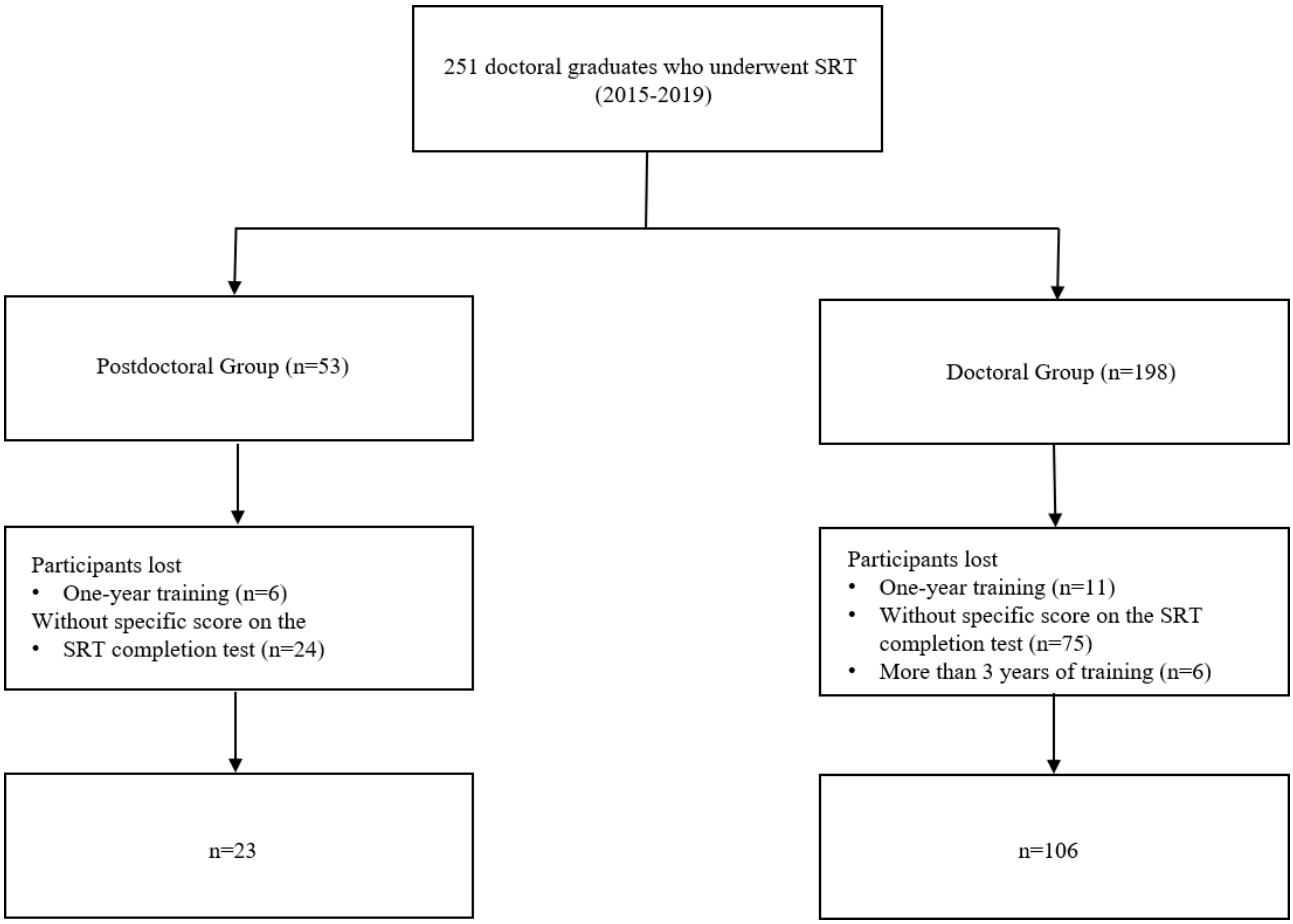

Table . General information of all the trainees enrolled in the study (N=129).

Parameter	Doctoral (n=106)	Postdoctoral (n=23)	Statistic (*df*)	*P* value
Gender, n (%)			0.706 (1)[a]	.40
Male	59 (55.66)	15 (65.22)		
Female	47 (44.34)	8 (34.78)		
Age (years), mean (SD)	28.05±1.73	27.85±1.91	0.485 (127)[b]	.63
Discipline, n (%)			1.346 (2)[a]	.51
Internal medicine	31 (29.25)	4 (17.39)		
Surgery	36 (33.96)	9 (39.13)		
Others	39 (36.79)	10 (43.48)		
Training years, n (%)			18.612 (1)[a]	<.001
2 years	16 (15.09)	13 (56.52)		
3 years	90 (84.91)	10 (43.48)

[b]*t* values.

Clinical Performance

The postdoctoral group demonstrated significantly higher clinical performance, as measured based on the standardized theoretical examination scores (445.70, SD 14.67 vs 435.12, SD 15.29; *P*=.003). The CMI was also significantly higher in the postdoctoral group (1.14 vs 0.92, *P*=.03), indicating exposure to and management of more complex clinical cases. However, analysis revealed no statistically significant differences between the 2 groups regarding the three key metrics: graduation

examination pass rate, annual theoretical assessment scores, and annual skill assessment scores (as shown in Table 3).

Table . Comparison between the doctoral and postdoctoral groups.

Parameter	Doctoral (n=106)	Postdoctoral (n=23)	Statistic (*df*)	*P* value
Clinical performance				
Theoretical scores of SRT[a] completion test, mean (SD)	435.12 (15.29)	445.70 (14.76)	–3.024 (127)[b]	.003
Pass rate of graduation examination, n (%)	99 (93.40)	20 (86.96)	0.380 (1)[c]	.54
Annual assessment of theoretical scores, mean (SD)	81.84 (10.44)	80.70 (12.67)	0.455 (127)[b]	.65
Annual assessment of skill scores, mean (SD)	86.24 (4.81)	87.85 (4.72)	–1.455 (127)[b]	.15
CMI[d], median (IQR)	0.92 (0.39)	1.14 (0.46)	–2.130[e]	.03
Scientific research ability				
Number of papers published, mean (SD)	1.11 (1.47)	2.35 (2.39)	–3.225 (127)[b]	.002
Number of achievement awards won as a participant, mean (SD)	0.06 (0.303)	0.09 (0.288)	–0.439 (127)[b]	.66
Proportion of national NSFC[f] approvals, n (%)	47 (44.34)	14 (60.87)	2.072 (1)[c]	.15
Number of provincial NSFC applications approved, n (%)	18 (17.00)	11 (47.83)	10.318 (1)[c]	.001
Teaching ability				
Teaching articles/teaching reform projects/teaching competitions, mean (SD)	0.10 (0.306)	0.22 (0.518)	–1.402 (127)[b]	.16
Comprehensive ability, n (%)				
Promotion of professional title	100 (94.34)	23 (100)	0.387 (1)[c]	.53
Master's degree supervisor	6 (5.67)	3 (13.04)	0.654 (1)[c]	.42

Scientific Research Ability

According to the statistics provided by the Scientific Research Department of the hospital, the number of published papers per capita was significantly higher in the postdoctoral group than in the doctoral group (2.35, SD 2.39 vs 1.11, SD 1.47; P=.002). In the doctoral group, 18 of 106 (17.00%) participants received a provincial NSFC fund, while in the postdoctoral group, 11 of 23 (47.83%) participants received a provincial NSFC fund, and the difference was significant between the 2 groups (*P*=.001). In terms of the number of provincial NSFC funds and the number of published papers per capita, the postdoctoral group had significantly better metrics than the doctoral group. As for NSFC applications, 14 of 23 (60.87%) postdoctoral participants and 47 of 106 (44.34%) doctoral trainees received approval. Although there was no significant difference between the 2 groups, the postdoctoral group may have been granted more funding if the sample size was large enough.

Teaching Skills

In this study, the trainees' teaching ability was described by the number of approved teaching improvement projects, number of published teaching papers, and whether they had participated in teaching competitions and awards. These indicators allow for the assessment of the trainees' participation and creativity in clinical teaching. As most trainees did not fully participate in clinical teaching and few papers were published or approved, there was no significant difference between the 2 groups.

Comprehensive Ability

In this study, there was no significant difference between the 2 groups on comparing whether or not an intermediate title was obtained within 3 years. On the other hand, trainees are eligible to become graduate supervisors, which requires a strong scientific research background. Applicants must meet the following criteria: they must chair at least 1 ongoing national or provincial research project, publish academic papers in high-level journals as first author or corresponding author, or receive a research award at the provincial or ministerial level or higher. A certified supervisor's evaluation is additionally necessary. Due to the very limited number of supervisors authorized to supervise graduate trainees, there was no significant difference between the postdoctoral and doctoral groups.

Discussion

Principal Findings

In this study, we compared the competencies of medical graduates who completed SRT (the doctoral group) with those who undertook the advanced clinical postdoctoral program (the postdoctoral group). The principal findings reveal distinct advantages for the postdoctoral group in key areas. Specifically, these trainees demonstrated a superior capacity to manage complex clinical cases, as evidenced by a significantly higher median CMI (1.14 vs 0.92, *P*=.03). Their research productivity was also markedly greater, reflected in a higher number of published papers (2.35, SD 2.39 vs 1.11, SD 1.47; *P*=.002) and a significantly greater success rate in securing provincial-level NSFC-funded projects (47.83% vs 17.00%, *P*=.001). Furthermore, the postdoctoral group achieved significantly higher scores on standardized theoretical examinations over the final 3 years of the study period (445.70, SD 14.67 vs 435.12, SD 15.29; *P*=.003), indicating a deeper mastery of medical knowledge. Collectively, these quantitative findings support the hypothesis that the integrated, postdoctoral training model more effectively enhances clinical readiness, scientific innovation, and theoretical understanding among medical graduates.

Implications of Findings

The findings from this study have significant implications for advancing medical education and workforce development. The superior clinical performance of the postdoctoral group, as quantified by higher theoretical examination scores and a greater ability to manage complex cases (reflected in the significantly higher CMI), suggests that such integrated training can produce clinicians with enhanced diagnostic acumen and decision-making confidence, which may directly translate to improved patient care and clinical outcomes. Furthermore, the program's effectiveness in cultivating physician scientists is clearly demonstrated by the marked increase in research output and success in securing provincial-level grants, bridging a critical gap between clinical practice and scientific innovation. While teaching competence showed limited quantitative difference, the structured mentorship and teaching experiences are posited to foster essential communication skills and educational confidence, building a foundation for future academic leaders. Collectively, these results provide a strong evidence-based rationale for other institutions and policymakers to adopt similar integrated clinical academic training models, underscoring the value of a unified framework that concurrently develops clinical, research, and teaching competencies to prepare physicians for multifaceted roles in modern health care.

Comparison to the Literature

Our findings align with those of previous studies highlighting the importance of structured postdoctoral training in fostering clinical and academic excellence [6,10-12]. For instance, integrated clinical academic training models in Western countries—such as clinical fellowships and combined MD/PhD programs—have been shown to enhance research output and leadership roles among physicians [13,14].

However, unlike traditional postresidency research fellowships, the clinical postdoctoral program described here places equal emphasis on clinical service, academic inquiry, and teaching, reflecting a unique model tailored to China's evolving health care and educational systems. Our results contribute to the growing body of evidence supporting innovative postdoctoral medical training models that extend beyond conventional residency programs.

Strengths and Limitations

This study represents one of the first efforts to evaluate the effectiveness of a clinical postdoctoral training program in mainland China, offering a comprehensive assessment of trainees' clinical, research, and teaching competencies. A key strength lies in the use of objective performance indicators, such as the CMI and research output metrics, which provide quantifiable evidence of clinical complexity management and academic productivity. Additionally, the inclusion of multiple competency domains allows for a more holistic understanding of the program's impact on professional development. However, several limitations should be acknowledged. As a single-center study with a relatively small sample size (23 postdoctoral participants), the findings may lack generalizability and statistical power, increasing the risk of type II error. It should be noted that this analysis only included participants who completed the entire program and possessed complete assessment data. Exclusions from the final analysis were primarily for 2 reasons: voluntary withdrawal due to personal circumstances and the absence of a quantitative theoretical score in the completion examination, which precluded a fair comparative assessment. These exclusions may introduce elements of attrition and selection bias. The 3-year observation period may also be insufficient to capture the long-term developmental trajectory of medical professionals. Furthermore, selection bias cannot be ruled out, as participation in the postdoctoral program was self-selected, potentially reflecting preexisting differences in motivation or academic background. Some outcome measures, particularly those related to teaching and comprehensive abilities, relied on qualitative or semiquantitative assessments, limiting their objectivity and reproducibility. To address these limitations, future studies should adopt multicenter designs with larger cohorts and extended follow-up periods to better assess the longitudinal impact of the program. In addition, more standardized and

validated tools should be developed to objectively measure teaching and comprehensive competencies. Comparative analyses with international postgraduate training models could further inform best practices and opportunities for cross-learning in clinician scientist development.

Conclusion

As a new medical education mode in China, the clinical medical postdoctoral training program enhances the trainees' clinical performance and scientific research innovation ability, which is helpful to cultivate the top innovative talents in clinical medicine. This training mode is effective and can be promoted in various medical teaching institutions as an important supplement to the current medical degree system in China.

Acknowledgments

We appreciate the hospital's Human Resources, Scientific Research Department, and Medical Record Room for providing data for this study.

Funding

This study was supported in part by a grant from Ministry of Education industry-university-research cooperation project (220604942134732) and a grant from the Teaching Reform Project of the School of Medicine, Zhejiang University (jgyb2025025).

Abstract

Background: Clinical reasoning is increasingly recognized as an important skill in the diagnosis of common and serious conditions. eCREST (electronic Clinical Reasoning Educational Simulation Tool), a clinical reasoning learning resource, was developed to support medical students to learn clinical reasoning. However, primary care teams now encompass a wider range of professional groups, such as physician assistants (PAs), who also need to develop clinical reasoning during their training. Understanding PAs' clinical reasoning processes is key to judging the transferability of learning resources initially targeted to medical students.

Objective: This exploratory study aimed to measure the processes of clinical reasoning undertaken on eCREST by PA students and compare PAs' reasoning processes with previous data collected on medical students.

Methods: Between 2017 and 2021, PA students and medical students used eCREST to learn clinical reasoning skills in an experimental or learning context. Students undertook 2 simulated cases of patients presenting with lung symptoms. They could ask questions, order bedside tests, and select physical exams during the case to help them form, reflect on, and reconsider diagnostic ideas and management strategies while completing a case. Exploratory analysis was undertaken by comparing students' data gathering, flexibility in diagnosis, and diagnostic ideas between medical and PA students.

Results: In total, 159 medical students and 54 PA students completed the cases. PAs were older (mean 27, SD 7 y vs mean 24, SD 4 y; $P<.001$) and more likely to be female (43/54, 80% vs 84/159, 53%; $P<.001$). Medical and PA students were similar in the proportion of essential questions asked (Case 1: mean 70.1 vs mean 73.2; $P=.33$; Case 2: mean 74.6 vs mean 70.9; $P=.27$), physical examinations requested (Case 1: mean 54.7 vs mean 54.0; $P=.59$; Case 2: mean 69.3 vs mean 67.5; $P=.59$), bedside tests selected (Case 1: mean 74.4 vs mean 83.3; $P=.05$; Case 2: mean 47.9 vs mean 50.0; $P=.69$), and number of times they changed their diagnoses (Case 1: mean 2.8 vs mean 2.8; $P=.99$; Case 2: mean 2.8 vs mean 2.5; $P=.81$). Both student groups improved in their diagnostic accuracy during the cases.

Conclusions: These results provide suggestive evidence that medical and PA students had similar clinical reasoning styles when using an online training tool to support their diagnostic decision-making.

Introduction

Diagnostic error has been identified as the most common cause of avoidable harm in primary care [1]. Efforts to improve the clinical reasoning processes of health care staff who investigate and refer patients are critical for limiting the burden of disease by reducing diagnostic errors [2]. Clinical reasoning broadly encompasses the thought processes and strategies that underlie

clinical judgments. Clinical reasoning is a core skill with relevance to many facets of clinical practice [3] and with a particular influence on clinicians' judgments when attending to patients with symptoms that might be serious disease [4-6]. As a result, a need for formal education around clinical reasoning at all stages of the journey—from student to advanced professional—has been articulated [7,8].

eCREST (electronic Clinical Reasoning Educational Simulation Tool), an online patient simulation training tool, was developed for medical students to address this need [9]. It was tested with final-year medical students in UK medical schools, demonstrating good efficacy and receiving positive feedback from student testers about its value as an educational resource in improving clinical reasoning skills [10]. Interviews with medical student learners using eCREST, combined with analysis of their actions whilst using eCREST, demonstrated they displayed a range of data gathering strategies, with those more experienced on eCREST displaying more thorough data gathering strategies and identifying more essential diagnostic information [11].

Since eCREST was first developed, the landscape for primary care provision changed. In England, for example, primary care now encompasses a wider range of professionals beyond physicians and nurses to include pharmacists and social prescribers [12]. In addition, many primary care organizations now use physician assistants (PAs), with numbers working in primary care set to expand further [13]. PAs are a relatively new role in the United Kingdom, comparable to that of the PA in the United States, which have existed for over 50 years [14]. PA roles typically include taking patients' medical histories, conducting physical exams, formulating differential diagnoses, and proposing management plans, including potential referrals [15]. Qualified PAs are master's-level graduates who have completed a 2-year postgraduate course following a medical curriculum.

The expanded primary care team and the expansion of clinical roles have resulted in a need for clinical reasoning training suitable for a range of future clinical professionals, not just medical students. In a recent review of clinical reasoning across health professions, no resources were identified targeted toward PAs, as students or qualified professionals [7]. We adapted eCREST for PA students, in consultation with PA faculty, which involved ensuring the case description referred to PAs not just general practitioners (GPs). Adaptations were minimal but included changing the introduction at the start of cases to frame the cases for PAs and selecting from existing eCREST cases those that best fit the PA curriculum. The usefulness of eCREST as a meaningful and useful tool for PAs rests on the assumption that PAs approach clinical reasoning in a similar way to medical students. However, there is very limited understanding of how PA students in the United Kingdom acquire clinical reasoning skills, and whether they would exhibit similar reasoning processes to medical students. Insight into their reasoning processes while learning could be useful in designing multiprofessional education, for both current and future clinical professionals.

This exploratory study aimed to measure the processes of clinical reasoning undertaken on eCREST by PA students and compare PAs' reasoning processes with previous data collected on medical students. It tests the a priori hypothesis that PA learners exhibit similar reasoning processes to those of medical students when using eCREST.

Methods

Theoretical Framework

In common with Young et al [16], we recognize that clinical reasoning is not a homogenous construct, nor is it understood in the same way by different individuals or professional groups. How clinical reasoning is defined has implications both for the focus of learning resources and how the effectiveness of such resources is evaluated.

Young et al [17] have mapped how different reasoning constructs and theories influence approaches to teaching and assessment, distinguishing between theories focused on acquisition of knowledge, knowledge organization, cognitive processes, or meta-cognitive processes. Informed by Plackett et al's [18] review of the effectiveness of online simulated patient tools, eCREST was designed to focus on dimensions of clinical reasoning amenable to improvement and that are associated with common diagnosis-related biases in reasoning [9]. In this paper, therefore, we focus on clinical reasoning theories related to cognitive and meta-cognitive processes and display how these relate to eCREST in Table 1. Aligned with Young et al [16,17], we consider the process of clinical reasoning focusing on cognitive skills, with the outcome being reduction in cognitive biases supporting a goal of improving diagnostic reasoning.

Table . Application of clinical reasoning theory taken from Young et al [17] to the design and content of eCREST[a].

Theoretical focus: good clinical reasoning requires...	Approaches to support students to develop clinical reasoning	Application to design of eCREST to develop reasoning skills	Reasoning measures derived from students' completion of eCREST
...an ability to recognize relevant features in a clinical presentation and test hypotheses	Case-based learning using real or simulated cases	eCREST comprises a series of simulated patients through which students work.	• Data gathering • Diagnostic accuracy
...an ability to monitor one's own processes for possible errors or biases and reflect on one's own reasoning	Prompted reflection, clinical justification (eg, in patient notes)	eCREST seeks to influence learning through prompting reflection.	• Diagnostic flexibility • Reflections after the case
...sufficient knowledge base	Lectures and readings	eCREST was not designed to impart knowledge, but it starts with a knowledge quiz as a self-diagnostic, so students can revise key content before the case starts if needed.	Multiple-choice questions

[a]eCREST: electronic Clinical Reasoning Educational Simulation Tool.

Design

We conducted a retrospective comparison of clinical reasoning processes and outcomes between medical and PA students using the eCREST online educational platform to teach clinical reasoning.

Platform

eCREST is an online patient simulation training tool that has been tested with final-year medical students in medical schools in the United Kingdom [10,11]. eCREST [19] is proprietary software but the platform is available for use free to educational settings that are willing to contribute anonymized data and provide feedback to support its evaluation.

A workflow through eCREST is shown in Figure 1, with illustrative screengrabs from eCREST's website during a simulated case. Briefly, students log on to the eCREST website and enter a virtual "waiting room." They select a "patient" by clicking on a still of a patient actor and name, which opens a video of a patient actor who gives a brief account of the problem from the patient's perspective for which they are seeking medical advice (Figure 1, panel 1). The student is then prompted to provide their ideas about likely diagnosis, through selecting 5 differentials from a long list of potential diagnoses; indicating on a scale of 1 - 5 how worried they are about the patient, their ideas about likely diagnosis and typing as free text their reasoning behind their choices (Figure 1, panel 2). The student can then click on options to obtain further information—as videos or in text form—about the patient's disclosed symptom, the presence or absence of other symptoms, and wider health (Figure 1, panel 3). At regular points during the "consultation," the student is prompted to revisit their initial differential diagnosis choices. Finally, once students decide they have sought all the information they need, they are required to finalize their differential diagnosis and propose a management plan by selecting from further investigation and referral options and entering their rationale as free text (Figure 1, panel 4). Students can then access feedback, in the form of videos of GPs discussing why they prioritized certain differentials over other options. Once the case is completed, they are asked for their reflections and have the option to download a summary of their reasoning processes and GP feedback for each case (Figure 1, panel 5).

Figure 1. A student's typical workflow through eCREST. Author JS is pictured in this figure. eCREST: electronic Clinical Reasoning Educational Simulation Tool; GP: general practitioner.

The content for the simulated cases included in this study was developed with clinicians, researchers, and patients informed by literature on diagnosis of common symptoms that could indicate lung cancer. A panel of GPs with a range of experience was convened to discuss and agree on the form of feedback. For each case, a GP in training developed the initial iteration of the case and proposed which information (ie, which questions, tests, and examinations) would be "essential" and what

diagnoses would be most clinically important to consider. Each case was then reviewed by experts in primary care, diagnostics, and the disease systems as relevant to the case, to agree on the case content, including the options for differentials and the relevance of information sought.

Recruitment

We worked with higher educational institutions (HEIs) in the United Kingdom to recruit participants. HEIs were sought with a diversity of teaching approaches and identified through personal contacts of the research team. Between 2017 and 2021, 4 universities providing PA programs and 3 medical schools used eCREST with their students. In the United Kingdom, undergraduate medicine courses typically have a duration of at least 5 years. In some cases, courses last 6 years, where students take an intercalated BSc between years 2 and 3. In the first years of training, students are typically mainly classroom-based. In later years of training, students have longer and more concentrated clinical placements, which include general practice, where they are required to be present in a general practice environment, primarily for educational purposes. During clinical placements in undergraduate medicine, students are mainly observing clinical interactions with opportunities for case-based discussion before and afterwards, though they may have some small direct care tasks under supervision, which increase in their volume and complexity, to prepare undergraduates for the foundation stage in their medical career, in clinical environments [20]. PAs typically undertake a 2-year master's program, which covers similar content to medicine (eg, anatomy, physiology, and pharmacology) and provides exposure to clinical environments, including primary care, through clinical placements. Master's graduates who pass the national Faculty of PA exams are then permitted to work as PAs throughout the United Kingdom's National Health Service.

Medical students in this study in all 3 HEIs were in their final year of undergraduate training, PAs were in their final year of their master's program. Students at each HEI were mainly recruited through advertisement in faculty newsletters, lecture "shout-outs," social media, and tutor promotion between 2017 and 2018 and subsequently through the medical school promotion of eCREST via the teaching tutors. For medical students, participation was part of a feasibility trial. It was outside of timetabled lectures and entirely voluntary. However, for PA students, eCREST was introduced in relevant modules (eg, respiratory) by the study team in collaboration with teaching faculty during a scheduled session with the option for discussion of cases during later teaching sessions. Educators in each setting were consulted as to the best way to introduce eCREST to maximize possible educational value to students and educators and minimize burden to both.

As eCREST is an educational resource implemented within educational settings, the sample size was determined by uptake among students from the schools that had agreed to use eCREST. We did not perform a priori sample size calculations as part of this exploratory project. The content on eCREST was presented in English and accessed online by students.

Procedure

On the advice of educators, UK medical students had access to 4 cases on eCREST, while PA students only had access to 2 cases. Analysis was undertaken on the 2 simulated cases that were common to all students. The cohorts completing each case were slightly different, but the results from both cases did not differ substantively, so we present data for the first case in the main text and the second case in Multimedia Appendix 1.

Simulated Case

Students were presented with a 58-year-old female of Asian ethnicity presenting with chest pain (Case 1) and a 91-year-old male of White British ethnicity presenting with a cough (Case 2). Other information on the cases, including other symptoms experienced by the patient but not volunteered, was available to the student through selecting questions to ask the "patient" (to which they received a video reply) and by clicking on medical history or examination results. A full description of eCREST is available in Kassianos et al [9].

Measures

When registering for eCREST, all students self-reported their program [medical student or physician assistant student], gender identity [male or female], and age [in y].

We selected quantitative outcome measures to align with three domains of clinical reasoning identified in the literature: data gathering, flexibility in thinking about diagnoses, and diagnostic accuracy [18]. We also included measures coded from student reflections obtained from free text data. These dimensions are:

1. Data gathering: students' ability to elicit the necessary information to make an informed judgment.
2. Flexibility in thinking about diagnoses: students' capacity to remain open-minded and to consider alternative views.
3. Diagnostic accuracy: students' ability to identify the most relevant potential diagnoses for the patient.

Our previous work identified a gap in validated measures of clinical reasoning processes that are sensitive to change from short-term courses or training [10,11]. We have therefore developed our own measures of each of these dimensions, specific to eCREST.

In addition, we compare students' free-text reflections about their own performance and transferable learning from the case to clinical settings.

Data Gathering

Three measures were selected to reflect students' case-specific clinical reasoning processes:

1. Essential questions asked: an expert panel of GPs determined that 20 of the 32 available questions were essential for coming to an informed diagnosis. For data analyses, this measure was calculated as (number of essential questions asked/20) × 100. For case 2, the expert panel identified 14 essential questions.
2. Essential bedside tests requested: an expert panel of GPs determined that for case 1, three of the 9 available questions were essential for coming to an informed diagnosis and for data analyses it was calculated as (number of essential

bedside tests requested/3) × 100. For case 2, the expert panel identified 2 essential bedside tests.

3. Essential physical exams selected: an expert panel of GPs determined that for both cases, 6 of the 11 available physical exams were essential for coming to an informed diagnosis. For data analyses, this measure was calculated as (number of essential physical exams selected/6) × 100.

Flexibility in Thinking About Diagnoses

Students were asked to select 6 specific diagnoses at the very beginning of the cases. They could then review their diagnoses at any point (with the option to change any of the diagnoses or leave it the same). They were also prompted to review their list of diagnoses every time they asked 6 questions, after they had asked 8 tests or exams, and then after they had asked for 2 more types of information (eg, question answer or a test or exam). We measured flexibility in thinking about diagnoses in 2 ways as the average number of times students changed diagnosis and the proportion of students who changed diagnoses at least once. We defined changing diagnosis as any one of the following: (1) introducing a new diagnosis they had not previously considered, (2) removing a diagnosis that they had previously considered, and (3) revising the order in which they prioritized the diagnoses they were considering.

Relevant Diagnostic Accuracy

This was measured as the proportion of relevant diagnoses considered. An expert panel of GPs determined that, for both cases, 6 of the 13 available diagnoses were relevant to the patient case. This measure was calculated as (number of relevant diagnoses selected/6) × 100.

Student Reflections

At the end of the case, students responded to four reflective questions on the case they had just completed, comprising: (1) What do you think you did well? (2) What do you think you need to improve? (3) What changed during the case? (4) What will you take forward from doing these simulated cases to your clinical work?

Data Analysis

All analyses were conducted in R Studio (version 1.4.1106; Posit PBC) [21]. We compared whether the proportion of essential questions asked, bedside tests requested, physical exams selected, number of times changed diagnoses, and relevant diagnoses considered differed according to student type (medical student vs PA students). Qualitative responses to the four reflection questions were reviewed and coded to indicate whether the student's reflection related to any of 6 themes, selected in part deductively based on eCREST's goals of challenging cognitive biases, and in part inductively informed by ideas expressed in many of the student reflections: Knowledge, open-mindedness, awareness of cognitive biases, confidence or uncertainty, content of the case, no meaningful response.

These are retrospective analyses from a larger study of the eCREST tool. They were not preregistered, and a sample size calculation was not conducted. Significance was set at 2-sided α=.05 and we did not perform any adjustment for multiple comparisons in this exploratory study and instead report unadjusted effect sizes, 95% CIs, and raw *P* values [22].

Ethical Considerations

This study was approved by University College London and the participating medical schools (15453/002). Invited student participants consented to take part and for their data to be analyzed as part of research on eCREST.

The undergraduate medical students in the United Kingdom were final-year students in a 6-year course, whereas the PAs were final-year students on a 2-year postgraduate training course, with an undergraduate degree in biomedical sciences. Information sheets and consent forms were shared through each student's course lead and were also available for download on eCREST. Medical students participated as part of a trial and were offered compensation for completing cases (a maximum of £30 [US $40.54 at the time of the study; US $39.47 in 2025] in vouchers). PAs participated as part of their course. The information sheets confirmed that data would be stored in secure servers at University College London and used for research purposes and confirmed that their performance would not be shared with their course organizers.

Results

Participant Characteristics

A total of 654 students accessed and registered on eCREST during the study period. Of these, 213 students completed the patient case and were included in the analyses. Most were medical students (159/213, 75%), evenly distributed between 3 medical schools (School A: 51/159, 32.1%; School B: 60/159, 37.7%; School C: 48/159, 30.2%). Of the 54 physician assistant students, the majority came from one medical school (School D: 40/54, 74.1%; School E: 7/54, 13%; School F: 4/54, 7.4%; School G: 3/54, 5.6%; Table 2).

Table . Student institutions according to student type.

		Student participants	Completion[b]	
	Recruitment years[a]	Values, n (%)	Rate	Percent
Medical students				
School A	2017 and 2020	51 (32.1)	51/162	31.5
School B	2017 - 18 and 2020 - 21	60 (37.7)	60/168	35.7
School C	2017 - 18 and 2020 - 21	48 (30.2)	48/159	30.2
Physician assistant students				
School D	2021	40 (74.1)	40/126	31.7
School E	2020 - 21	7 (13)	7/15	46.7
School F	2020	4 (7.4)	4/18	22.2
School G	2020	3 (5.6)	3/5	60

[a]All 2017 cohorts were part of a larger feasibility trial evaluation. Any other cohorts were recruited openly.

[b]Completion was calculated with all students who registered for eCREST from each school as the denominator.

The mean age of students in our sample was 25 (SD 5; range 19-48) years and most were female (n=127, 60%). The PA student group was older on average than the medical student group (*P*=.001) and contained a greater proportion of females (*P*=.001; Table 3).

Table . Student demographics overall and according to student type.

	Overall (n=213)	Medical students (n=159)	Physician assistant students (n=54)	Medical students versus physician assistant students	
				Values	*P* value

Data Gathering

Essential Questions

Overall, students asked around 70% (14/20) of essential questions on average. We found no evidence of differences between PA students (mean 73.2, SD 18.9) and medical students (mean 70.1, SD 22.2) in the proportion of essential questions asked by each group (*P*=.33). Across all 20 essential questions, we found no evidence of differences between PA students and medical students in the proportion who asked each question (see Multimedia Appendix 1). For case 2, it was PAs (mean 74.6, SD 22.0) and medical students (mean 70.9, SD 22.9; *P*=.27; Multimedia Appendix 1).

Physical Exams

Overall, both medical and PA students selected around 55% (3.3/6) of essential physical exams on average. We found no evidence of differences between PA students (mean 54.0, SD 21.1) and medical students (mean 54.7, SD 18.6) in the proportion of essential physical exams selected by each group (*P*=.59). For case 2, it was PAs (mean 67.5, SD 17.9) and medical students (mean 69.3, SD 17.9; *P*=.59; Multimedia Appendix 1).

Bedside Tests

Overall, students selected around 77% (2.3/3) of essential bedside tests on average. On average, PA students (mean 83.3, SD 28.8) appeared to have selected a greater proportion of essential bedside tests than medical students (mean 74.4, SD 29.1), though the *P* value (*P*=.053) suggests there is only weak evidence for this difference. For case 2, it was PAs (mean 50, SD 50.0) and medical students (mean 47.9, SD 34.6; *P*=.69; Multimedia Appendix 1).

Flexibility in Thinking About Diagnoses

Number of Times Students Changed Diagnoses

Overall, we found students changed diagnoses 2.8 times on average. We found no evidence of differences between physician assistant students and medical students in the number of times they changed diagnoses (*P*=.99). For case 2, the average number of times the diagnosis was changed was 2.5, and there was no difference between PAs (mean 2.8, SD 1.1) and medical students (mean 2.5, SD 1.1; *P*=.08).

Changed Diagnosis at Least Once

Overall, 203 of 213 (95%) students changed their diagnosis at least once. We found no evidence of differences in the proportion of PA students (151/159, 96%) and medical students (52/54, 95%) who changed their diagnosis at least once (*P*=.98). For case 2, all students changed diagnosis at least once.

Diagnostic Accuracy

Overall, in their initial diagnosis, students included around 45% (2.7/6) of the relevant diagnoses on average. Compared with medical students (mean 43.4, SD 14.4), PA students (mean 51.5, SD 14.2) included a greater proportion of relevant diagnoses in their initial diagnosis (*P*<.001). For case 2, it was 43% (2.6/6) overall and did not differ between student groups (PAs: mean 41.5, SD 14.1 vs medical students: mean 44.4, SD 15.0; *P*=.19).

Both PA students and medical students had more relevant diagnoses in their final diagnosis than they did initially in case 1, with the overall proportion of relevant diagnoses included rising to 64% (3.8/6) on average overall. Notably, the average improvement was steeper among medical students (mean 19.5, SD 16.6) than PA students (mean 14.2, SD 16.7; *P*=.05). In their final diagnoses, both PA students (mean 65.7, SD 14.6) and medical students (mean 62.9, SD 15.5) were similar in the proportion of relevant diagnoses included (*P*=.23). For case 2 overall, it rose to 48% (SD 14.2; 2.9/6). Both PAs (mean 47.7, SD 13.9, +6.1 from initial) and medical students (mean 48.1, SD 14.3, +3.73 from initial; *P*=.84) were similar.

Student Reflections

The reflections of both PA students and medical students were similar overall, with the following themes emerging from the data:

1. Knowledge-based: Reflections that focus on acquiring, applying, or deepening clinical or biomedical knowledge relevant to the case content.
2. Open-mindedness: Comments indicating a willingness to consider alternative diagnoses, questions, tests, exams, or approaches, and to revise initial assumptions.
3. Awareness of cognitive biases: Reflections that explicitly mention or imply recognition of cognitive biases (eg, anchoring, confirmation bias) and their potential impact on clinical reasoning.
4. Confidence: Statements related to the student's self-assessed confidence in their clinical decision-making, diagnostic reasoning, or use of the eCREST tool.
5. Content: Reflections that comment on the structure, usability, or educational value of the eCREST tool itself, rather than the clinical case or reasoning process.
6. No meaningful response: Responses that lacked substantive reflection or were too brief or vague to be categorized under other themes.

Student responses are shown in Table 5.

Table . Reflection measures overall and according to student type.

	Overall (n=236), n (%)	Medical students (n=282), n (%)	Physician assistant students (n=46), n (%)	Medical students versus physician assistant students

No meaningful response	14 (5)	12 (5)	2 (4)	0.00 (5)	.99

Both groups of students focused most of their reflections on the content of the case (ie, describing their strategy or perceptions of how "accurate" they were) when asked what they did well, could improve, and would take into their clinical work. Recognizing the importance of being open-minded and flexible was also a common reflection by both groups of students.

However, there was moderate evidence of a difference in the learning students reported they would apply to their clinical work, in two respects. A greater proportion of medical student reflections related to open-mindedness and flexibility (48% vs 26%; *P*=.01). For example, one medical student reflected that, from now on, they would "always keep an open mind, not to be fixed on one diagnosis. Ask questions to rule out all possible differential diagnosis."

A greater proportion of PA student reflections related to improving knowledge related to the clinical content of the case

(87% vs 70%; *P*=.03). For instance, one PA student noted that they would take into their clinical work that they "have learnt which factors to consider" for the patient case, while another mentioned that "I will need to develop my knowledge of gastrointestinal differentials that cause respiratory-related symptoms."

Discussion

Principal Results

This study yielded three key findings. First, we found no differences in data gathering through eCREST between medical students and PA students. Overall, both groups of students performed well on the proportion of essential questions asked (14/20, 70.9%), with scope for improvement on the essential physical exams selected (3.3/6, 55%). Second, we also found no differences between medical and PA students on our measures reflecting their flexibility in thinking about diagnoses. Third, we found that over the course of the cases, both PAs and medical students improved in the number of relevant diagnoses that they considered for the patients. These findings provided suggestive evidence that PAs and medical students used eCREST in similar ways to apply and develop diagnostic reasoning skills.

Limitations

There are several methodological limitations to consider when interpreting the present findings. The use of just 2 simulated cases where differential diagnoses largely concerned respiratory and cardiovascular causes significantly limits the extent to which it is possible to generalize from these findings to cases seeking to develop diagnostic reasoning relevant to other bodily systems. The low sample size limited our ability to make strong statistical inferences or to adjust for possible confounders. Additionally, the medical students in our study self-selected to participate, and completion rates among those who registered were generally low. As we did not collect overall class cohort numbers, we were also unable to calculate response rates for all eligible students. Thus, there is a clear need for additional studies that can achieve greater recruitment and retention of student participants, particularly for the PA students, to yield larger and more representative samples. Notably, there was disproportionate representation of participants from School D, which may have introduced institutional bias and limited the generalizability of the findings across other PA programs.

The education context in which our two student groups also differed. As the medical students in our study had access to more cases (n=4) than their physician assistant counterparts (n=2), it is possible that they may have benefitted from being more familiar with the eCREST platform or from having practice with other cases. The context differed also in that medical students were completing cases before the COVID-19 lockdowns where online teaching was relatively unusual. In contrast, PAs were completing the cases in 2021, when online educational delivery was much more normalized. The difference in context, however, does not appear to have affected students' responses to eCREST.

Comparison With Prior Work

The findings of our study are broadly aligned with a review of performance of qualified PAs compared with physicians, which found performance on specific diagnostic tasks related to cancer was similar across both professional groups [23]. This review, however, is limited in its applicability to this study for two reasons. First, it was restricted to practicing clinicians, rather than those in training. Second, most of the literature included came from outside of the United Kingdom, in countries where primary care systems are not the same as the United Kingdom. As Barnhill et al found with respect to PAs in the United States, the role of PAs in primary care is different from the role of PAs in other health care settings [24].

We reflect also on the qualitative reflections of medical students and PAs in this study. We note this was a small exploratory study, so we are cautious about drawing firm conclusions regarding the underlying reasons for these differences but instead have reflected on key reflections from the groups. It is perhaps not surprising that a high proportion of PAs recognized in themselves a knowledge deficit (87% of PAs vs 70% of medical students; *P*=.03). At the point at which they commenced eCREST, they had experienced approximately 1.5 years of clinical training. In contrast, medical students would have had approximately 5 years of exposure to medical curricula. However, we interpret it as encouraging that a high proportion of both groups expressed a motivation to address knowledge gaps given the consistent evidence that knowledge deficits are a cause of diagnostic error [25].

It was interesting that nearly half of the medical students reported a need to develop open-mindedness and flexibility versus a quarter of PA students (48% vs 26%; *P*=.01). In light of evidence suggesting that confidence is a poor predictor of diagnostic accuracy [26], and that high levels of confidence lead to less information gathering, fewer changes in diagnosis, and biased evaluations [27], these reflections suggesting lower confidence and an increased awareness of the need to develop their reasoning could lead them to be better diagnosticians. The students' reflections accord with the educational experiences of tutors using eCREST with a range of student groups who have observed that eCREST exposed students to clinical uncertainty and welcomed the stimulus provided by eCREST to discuss diagnostic complexity and uncertainty (unpublished data). We therefore consider it as encouraging for students' future diagnostic reasoning that they identified the need for more open-mindedness as one of their key reflections.

Conclusions

Developing students' clinical reasoning skills is critical for improving patient care and reducing diagnostic error. These exploratory results provide suggestive and positive evidence that medical and PA students had similar clinical reasoning styles when using an online patient simulation training tool to support their diagnostic decision-making, and both groups reported some changes in their reasoning styles through using eCREST. As primary care teams widen to include a range of clinical professionals, further evidence is now needed to understand and compare how different clinical groups at all

stages of training develop and apply essential clinical reasoning skills.

Abstract

Background: Shared decision-making (SDM) is a crucial aspect of patient-centered care. While several SDM training programs for health care professionals have been developed, evaluation of their effectiveness is scarce, especially in mental health disorders such as generalized anxiety disorder.

Objective: This study aims to assess the feasibility and impact of a brief training program on the attitudes toward SDM among primary care professionals who attend to patients with generalized anxiety disorder.

Methods: A feasibility randomized controlled trial was conducted. Health care professionals recruited in primary care centers were randomized to an intervention group (training program) or a control group (waiting list). The intervention consisted of 2 web-based sessions applied by 2 psychologists (VR and YA), based on the integrated elements of the patient-centered care model and including group dynamics and video viewing. The outcome variable was the Leeds Attitudes Towards Concordance scale, second version (LATCon II), assessed at baseline and after the second session (3 months). After the randomized controlled trial phase, the control group also received the intervention and was assessed again.

Results: Among 28 randomized participants, 5 withdrew before the baseline assessment. The intervention significantly increased their scores compared with the control group in the total scale (b=0.57; P=.018) and 2 subscales: communication or empathy (b=0.74; P=.036) and shared control (ie, patient participation in decisions: b=0.68; P=.040). The control group also showed significant pre-post changes after receiving the intervention.

Conclusions: For a future effectiveness trial, it is necessary to improve the recruitment and retention strategies. The program produced a significant improvement in participants' attitude toward the SDM model, but due to this study's limitations, mainly the small sample size, more research is warranted.

KEYWORDS

person-centered care; primary care; shared decision-making; anxiety disorder; training program; SDM

Introduction

About 264 million people in the world are affected by anxiety disorders, according to the latest estimates of the World Health Organization [1]. In Spain, around 2 million people (4.1% of the population) suffer from anxiety disorders [1]. In primary care (PC) settings, the generalized anxiety disorder (GAD) is one of the most prevalent anxiety disorders [2]. GAD is characterized by a continuous state of worry and alertness most

of the time [3] and sometimes, its high comorbidity with other psychiatric and somatic disorders makes diagnosis difficult [4]. GAD has a tendency to chronicity, due to its specific characteristics, leading to the person being worried and alert most of the time [3]. Information on the causes of the disorder and the available treatments is an unmet need in this population, given that some patients with GAD are willing to have an active or collaborative role in their health care [5].

Person-centered care (PCC) is considered the gold standard for medical care in health care settings because it humanizes the person and places him or her at the center of clinical decision-making [6]. The PCC model consists of several components, one of which is shared decision-making (SDM), whose goal is to create a collaborative dialogue between patients and health care professionals, in which patients' values, preferences, and concerns about the different available treatment options are taken into account and incorporated into the decision-making process [7-9].

Patient decision aids are tools designed to facilitate SDM. Its use can help patients participate in the clinical decisions, improving the decision-making process and promoting informed decisions that are concordant with patients' values and preferences [10]. On the part of professionals, it is important to develop communication skills and empathy to help patients participate in the decisions [11-13]. Research has shown that interventions and training programs aimed to promote the PCC model may improve professionals' knowledge and the ability to communicate with patients [12,14] as well as patients' satisfaction [15]. However, there are some barriers to apply the PCC model related to time constraints, clinical uncertainty, poor expectations, patients' characteristics (eg, age, comorbidity, and attitude), lack of continuity of care, or knowledge about SDM [16-19]. Despite some SDM training programs have been developed for health care professionals, very few of them have been evaluated [20-22]. Therefore, despite the growing acceptance of interventions to implement SDM in health care settings, several gaps remain in the demand, perception, and clinical application of the PCC model [23,24]. In mental health care, and specifically in GAD, interventions to promote the SDM process are still very limited [25,26]. A recent qualitative study with patients with GAD concluded that there is scarce orientation to elicit patients' preferences and values throughout the process of care [27], emphasizing the need of interventional studies aimed at promoting SDM in the clinical encounter.

The aim of this study is to evaluate the feasibility and effect of a brief training program on the attitudes toward SDM for professionals in PC who attend patients with GAD.

Methods

Design

A feasibility randomized controlled trial (RCT) was conducted, in which participants were allocated to a PCC training program or a control group (waiting list). It was carried out in 13 PC centers in Tenerife (Canary Islands, Spain), from January 2021 to February 2022.

Ethical Considerations

The study was approved by the ethics committee of the Hospital Universitario Nuestra Señora de La Candelaria (reference: CHUNSC_2019_58). The study was not registered because participants were health professionals and not patients, the intervention was educational, and the only outcome measured was attitudinal. Participants who agreed to participate signed a web-based informed consent form.

Participants

Participants were health care professionals working in PC centers (ie, physicians and nurses) or community mental health units (ie, psychiatrists, psychologists, and nurses) for at least 1 year before the start of the study, who attend patients with GAD in the Canary Islands, Spain. There were no exclusion criteria.

Procedure, Randomization, and Allocation Concealment

The directors of the health centers were contacted and informed about the study. They were asked to invite the professionals from their centers to participate. The invitation included an infographic, graphically describing the study and a link to a web platform, where health professionals could register their willingness to participate and contact information. Then, they were contacted by telephone to provide a full explanation of the study. Those who agreed to participate signed a web-based informed consent form (reference: CHUNSC_2019_58). Participants were randomly assigned to either the intervention or control group (waiting list), using a computer-generated random number table. The randomization process was conducted by an independent researcher who was not involved in the recruitment or assignment of participants. In addition, the researcher who recruited the professionals was blinded to the group assignments in order to maintain allocation concealment. Due to the nature of the intervention, the study participants could not be blinded.

Intervention

Intervention group participants received 2 training sessions via Zoom (version 5.15.7. [21404]) based on the integrated elements of the PCC model [28]. The training was originally intended to be applied in person, in a group format, but this was not possible due to the COVID-19 pandemic, so it was finally applied on the web. Sessions were conducted by 2 researchers (VR and YA [psychologists]). The first session lasted approximately 2 hours and was focused on presenting the principal elements of intervention: (1) introduction, which included a description of common clinical relationship models (first 20 minutes); (2) basic characteristics of the basic PCC model, through group dynamics and video viewing of a role-play in the clinical practice with a patient with GAD; this included a description of the Feelings, Ideas, Function, and Expectations model [29] (60 minutes), which was developed at the University of Western Ontario and explores the patient's emotions, his or her ideas on what caused the problem, the effects of the illness on his or her functioning and relationships, and his or her expectations for the future and from medical care [29,30]; and (3) presentation of the Three-Talk Model for SDM, a multistage consultation process developed by Elwyn et al [31] (30 minutes). The

Three-Talk Model for SMD is a theoretical approach that describes collaborative deliberation. It outlines 3 broad steps that form the core elements of SDM [31]. The last 10 minutes of the session were aimed at the resolution of doubts. The detailed contents of this first SDM training session are shown in Table 1.

Table . Content of first shared decision-making (SDM) training session.

Module and content	Form of communication	Learning objectives
Introduction		
Clinical relationship models	• Lecture • Video examples • Interactive live • Feedback with group dynamic	• Be able to know the characteristics of the paternalistic, informative or contractual, interpretive or personalized, and deliberative or friendly models
Characteristics of a basic PCC[a] model		
Explore the disease	• Lecture	• Acquire skills in active listening and directed anamnesis in the use of SDM
Know the patient's perspective (beliefs, fears, expectations, repercussions, etc)	• Lecture • Video examples • Interactive live • Feedback with group dynamic	• Acquire skills in how to prepare the ground and how to explore the personal experience of the disease in terms of SDM • Be able to use the FIFE[b] model to improve the quality of communication in terms of SDM
Know the person ("moving from patient to person")	• Lecture • Video examples	• Acquire skill about how exploring the personal and social context of the disease in terms of SDM
Involve the patients in their disease	• Lecture • Video examples • Interactive live • Feedback with group dynamic	• Acquire information skills to reach agreements on problem solving, to seek shared solutions, and to involve the patient in the use of SDM
Three-Talk Model for SDM		
Team dialogue	• Lecture	• Acquire skills to establish a team dialogue based on the needs for change on beliefs and preferences
Dialogue on options	• Lecture	• Acquire skills to discuss the treatment options that exist for the disease
Dialogue on the decision	• Lecture	• Acquire skills to help the patient decide on which option to choose

[a]PCC: person-centered care.

[b]FIFE: Feelings, Ideas, Function and Expectations.

The second session was carried out 3 months later (review session), with an approximate duration of 1 hour. The structure of the session included (1) the review of the main contents of the first training module, together with comments on participants' potential and sharing their experiences applying the SDM model since then (30 minutes), and (2) the discussion on the main barriers and facilitators for patients and professionals in applying the SDM process in the clinical practice (30 minutes). Detailed content of this session is present in Table 2.

Control group participants did not receive any intervention. They were informed that they could access the training program after the feasibility RCT was completed. Participants completed the baseline and 3-month (postintervention) assessments. Subsequently, participants in the control group received the intervention and were reevaluated 3 months later (second postintervention measure).

Table . Content of second shared decision-making (SDM) training session.

Unit and content	Form of communication	Learning objectives
(1) Introduction and (2) characteristics of a basic PCC[a] model		• Review the characteristics of the paternalistic model,: informative or contractual, interpretive or personalized, and the deliberative or friendly models • Review tasks in active listening and directed anamnesis in the use of SDM: how to prepare the ground and how to explore the personal experience of the disease; how to explore the personal and social context of the disease; and how to reach agreements on problem solving, to seek shared solutions, to involve the patient-shared solutions, and to involve the patient in the use of SDM
Clinical relationship models Explore the disease; know the patient's perspective (beliefs, fears, expectations, repercussions, etc); know the person ("moving from patient to person"); and involve the patients in their disease	Lecture	
(3) Characteristics of the Three-Talk Model for SDM		• Be able to apply the principal components of the Three-Talk Model for SDM • Have knowledge about how to apply this model in clinical practice to support SDM
Fifteen characteristics total of a Three-Talk Model for SDM are described: *First step*: Take a step back, present the possibility of choice, justify the choice, personalizing preference, uncertainty, check the reaction, and postpone closure *Second step*: Check knowledge, list of options, provide decision support to the patient, and summaries *Third step*: Focus on preferences, elicit a preference, lead toward a decision, and offer review	Lecture	
(4) Barriers and enablers to apply Three-Talk Model for SDM		• Invite to participate by presenting the experience from a professional point of view in clinical practice • Openly share and discuss observations of the professional communication • Offer, explicitly and without judging, feedback on implementation
Identification of barriers from a professional point of view that can condition the application of the 3-step model for SDM	Identification of professionals' own barriers to communication with their patients	
Identification of barriers from a patient's point of view that can condition the application of the 3-step model for SDM	Identification of patients' own barriers to communication with their care team	
Identification of facilitators who may exist to carry out the 3-step model for SDM	Identify the individual facilitators in communication to implement a SDM model	

[a]PCC: person-centered care.

Measures

The outcome measure was the professionals' attitude toward PCC. It was assessed with the Leeds Attitudes Towards Concordance scale, second version (LATCon II) [32]. This self-report instrument includes 20 items with a 4-point Likert format from strongly disagree (0) to strongly agree (3). Although the original instrument includes 5 subscales, we used the 3 components identified by means of principal component analysis in the Spanish validation [33], carried out with psychiatrists and psychiatry residents. These subscales were labeled "communication/empathy" (CE, 12 items about the importance of a good communication and the consideration of patient's feelings and beliefs), "shared control" (SC, 4 items reflecting a positive attitude toward equality and SDM), and "eventual paternalistic style" (EPS, 4 items stating that sometimes a paternalistic style is necessary; these items are reverse-coded, and therefore higher scores indicate lower agreement with EPS) [33]. Scores on the total scale and the subscales are divided by the corresponding number of items, thus ranging 0 - 3. The LATCon II has shown good internal consistency in previous studies [33-35].

The following sociodemographic and professional variables were measured at baseline: age, gender, specialty (medicine or nursing), years of professional experience and work in the health care center, level of perceived workload (low, medium, and high), and previous training on PCC or SDM.

Statistical Analysis

We calculated that a mixed model with 2 repeated measures per participant (cluster) requires 38 subjects (19 in each group) in order to detect a significant moderate-to-strong between-group effect (standardized mean difference of 0.80), assuming type I and II errors of 0.05 and 0.20, respectively, and an intraclass correlation of 0.50 [35].

Descriptive statistics were calculated for continuous and categorical variables (means, SDs, and percentages). Cronbach α was calculated for the LATConII scale and its 3 subscales, as well as the correlations between the subscales (Spearman ρ). The effect of the intervention was analyzed with mixed lineal models, including fixed effects for time (pre, post), group (intervention, control) and its interaction, and the participant as a random effect (assuming an unstructured covariance matrix). Successive models were carried out adjusting for 1 covariate at a time (ie, sociodemographic and professional variables). Unstandardized β values and effect sizes (Hedges *g*) are reported.

Changes from baseline to postintervention were evaluated analyzing the effect of time in a mixed model separately for each group. The same test was used to analyze the change in the control group after receiving the intervention upon completion of the RCT. Analyses were performed with SPSS (version 25; IBM Corp) and STATA (version 17; StataCorp LLC).

Results

Thirty-four health professionals were interested in participating and were contacted by phone. After being informed in detail, 6 declined participation and 28 accepted, signing informed consent and being randomly allocated to the intervention or control group (14 each). However, 5 of them (4 in the intervention group) withdrew from the study before completing the baseline assessment (Figure 1). Table 3 shows the characteristics of the 23 participants. There were 18 women (18/23, 78.3%) and the mean age was 48.3 (range: 26 - 64) years. They had an average of 22.3 years of professional experience, and 52% (12/23) considered having a high caseload. Only 5 (21.7%) had had previous training in PCC.

Figure 1. CONSORT flow diagram. *The analysis includes 3 control participants lost at postintervention.

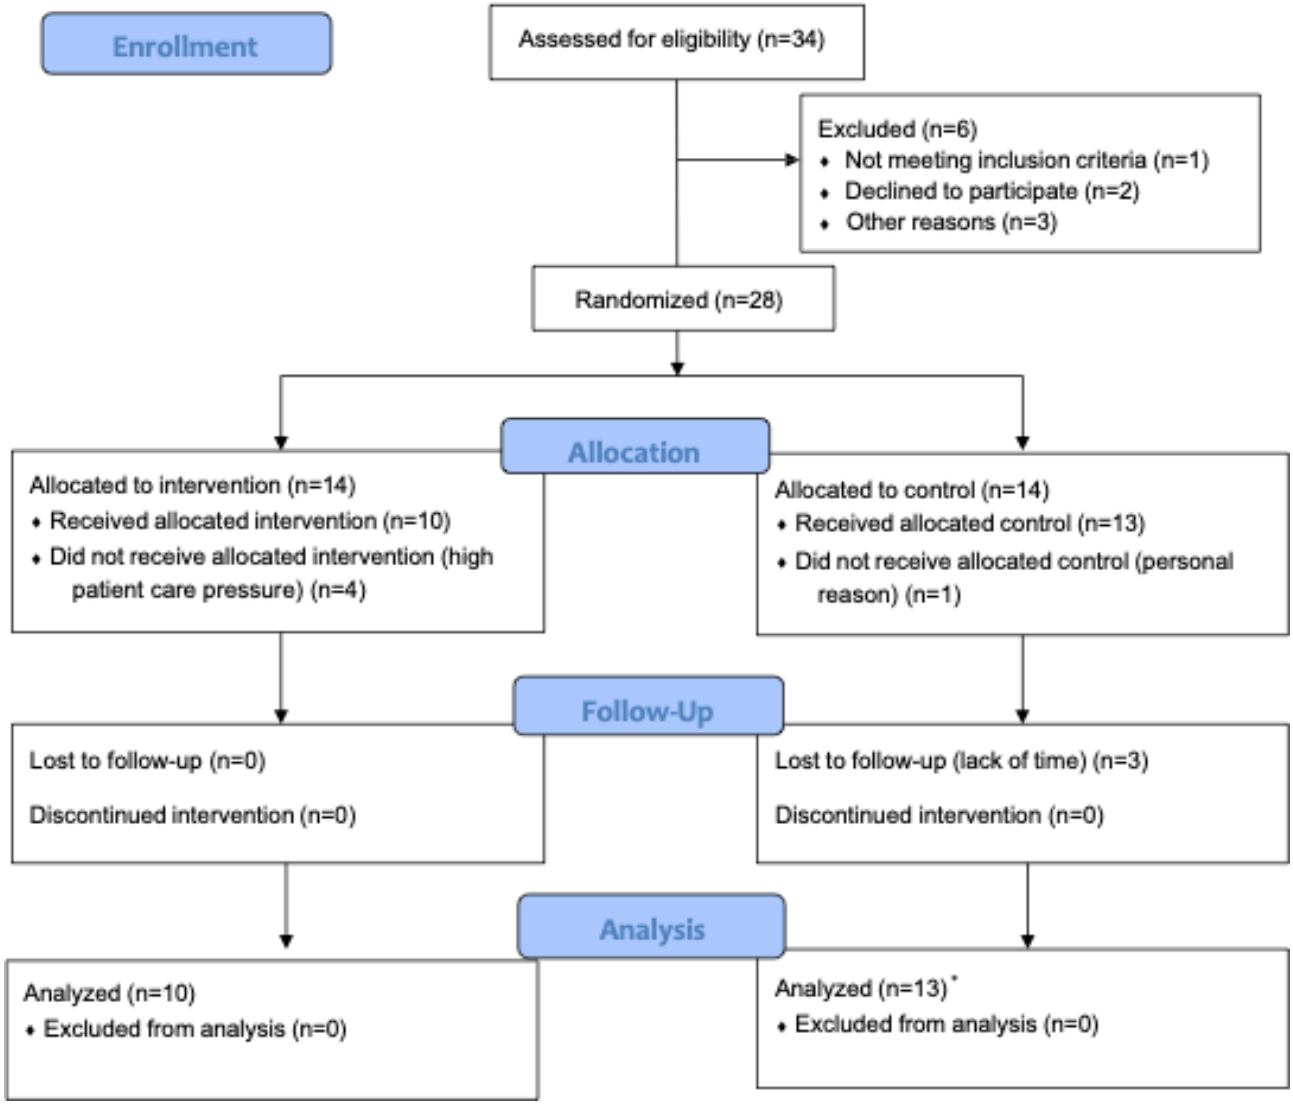

Table . Characteristics of participants.

	Intervention (n=10)	Control (n=13)	Total (N=23)
Female, n (%)	10 (100)	8 (61.54)	18 (78.26)
Age, mean (SD)	45.60 (10.82)	50.38 (9.77)	48.30 (10.24)
Specialty, n (%)			
Nursing	3 (30)	2 (15.38)	5 (21.74)
Medicine	7 (70)	11 (84.62)	18 (78.26)
Years of professional experience, mean (SD)	19.70 (9.44)	24.33 (9.42)	22.32 (9.51)
Years working in the center, mean (SD)	7.05 (7.15)	6.40 (7.02)	6.68 (6.92)
Previous training in PCC[a], n (%)	1 (10)	4 (30.77)	5 (21.74)
Self-perceived care load, n (%)			
Low-medium	6 (60)	5 (38.46)	11 (47.83)
High	4 (40)	8 (61.54)	12 (52.17)

[a]PCC: person-centered care.

At baseline, internal consistency (Cronbach α) was 0.94 for the total LATConII scale, and 0.97 (CE), 0.88 (SC), and 0.25 (EPS) for the subscales. The total mean score was 2.08 (SD 0.60), and the mean scores were 2.29 (SD 0.78), 1.77 (SD 0.85), and 1.78 (SD 0.41) for the subscales CE, SC, and EPS, respectively (Table 3). CE and SC were significantly correlated (ρ=0.49; *P*=.01), whereas EPS was not significantly associated with CE (ρ=0.11; *P*=.62) or SC (ρ=0.29; *P*=.180) (Table 4).

Table . Effect of the intervention.

Time[a]	Intervention (n=10), mean (SD)	Control (n=10), mean (SD)	Time × group interaction, *b* (*P*)[b]	Between-group effect size, Hedges *g* (95% CI)
LATCon II[c] total (range: 0 - 3)			0.57 (.018)	0.92 (0.13 to 1.71)
Pre	1.87 (0.76)	2.25 (0.40)[d]		
Post	2.27 (0.51)[e]	2.08 (0.61)		
Post2	—[f]	2.60 (0.24)[g]		
Communication/empathy (range: 0 - 3)			0.74 (.036)	0.86 (0.06 to 1.65)
Pre	1.98 (1.02)	2.52 (0.46)[d]		
Post	2.57 (0.70)[e]	2.34 (0.86)		
Post2	—	2.84 (0.20)[e]		
Shared control (range: 0 - 3)			0.68 (.040)	0.76 (0.01 to 1.52)

[a]Pre-post: randomized controlled trial (intervention vs waiting list); post2: intervention period for the control group, after the randomized controlled trial.

[b]Unstandardized β coefficients (*P* value) from mixed lineal models analyzing the randomized controlled trial (pre-post), including the participant as a random effect (the analysis includes 3 control participants lost at postintervention).

[c]LATCon II: Leeds Attitudes Towards Concordance scale, second version.

[d]n=13.

[e]*P*<.05.

[f]Not applicable.

[g]*P*<.001, compared with the previous assessment (effect of time in mixed models separately by group).

[h]*P*<.01.

Three control participants were lost at postintervention (3 months), but their baseline scores were included in the mixed models on an intention-to-treat basis (postintervention scores were not imputed). The time × group interaction was statistically significant for the total scale, showing a differential increment in scores favoring the intervention (*b*=0.57; *P*=.01) (Table 4). The same occurred with the subscales CE (*b*=0.74; *P*=.036) and SC (*b*=0.68; *P*=.04). The inclusion of potential confounders in the model did not change the results (see Table S1 in Multimedia Appendix 1 for the total scale). The intervention group significantly increased their scores compared with baseline in the total scale (*b*=0.4; *P*=.033) and CE (*b*=0.58; *P*=.030), whereas the control group significantly decreased in SC (*b*=−0.43; *P*=.037) (Table 4).

After the trial was completed, the control group received the intervention and showed significant increments in the total score (*b*=0.52; *P*<.001) and the 3 subscales: CE (*b*=0.50; *P*=.020), SC (*b*=0.75; *P*=.002), and EPS (*b*=0.35; *P*=.02) (Table 4).

Discussion

Principal Findings

This study aimed to evaluate the feasibility and effect of a brief web-based training program on the attitudes toward SDM and PCC of PC professionals who treat patients with GAD. The program was initially intended to be conducted in person at the professionals' centers, but due to the pandemic context, it was shifted to a web-based format. The 2 sessions went smoothly and the professionals actively participated, asking questions

and describing their experiences related to SDM. Previous studies evaluating learning programs for health professionals or university students have not shown relevant differences between web-based and in-person formats [36-39], although in some cases better results have been observed with the face-to-face intervention [40]. Given the brevity of our program, we do not expect that there will be relevant differences between both formats.

The recruitment and retention rate were low, only 33 eligible professionals showed interest in the study (2.5 per center) during the 5-month recruitment period, and 5 declined participation when they were fully informed about the study. It is possible that direct contact with professionals, instead of the general call that was made through center directors, would have improved the recruitment rate to some extent. Among the 28 randomized participants, 5 more did not start the trial and 3 did not complete the study. The high workload, a common situation in the Spanish public health system even in a nonpandemic context, was the main reported cause of these withdrawals. On the other hand, the group format enriches the training process by enabling the interaction of professionals, but it also represents a difficulty when coordinating their schedules and availability. In summary, the participation and retention rates were not satisfactory, and for future trials it is necessary to develop more structured and intensive strategies. Theoretical frameworks as proposed by Solberg [41] that identified 7 factors that influence the recruitment of health care professionals (ie, relationships, reputation, requirements, rewards, reciprocity, resolution, and respect) could help to this aim.

Regarding effectiveness, the results showed significant moderate-to-strong effects (although with very wide confidence intervals) on the total scale and the CE and SC subscales. The pre-post change in the intervention group was greater on the former, and the similar between-group effect size was due in part to a significant decrease in SC in the control group. The EPS dimension was not affected by the intervention, but this result is unclear given the low internal consistency of this subscale (future studies should confirm the factorial structure of the instrument). After the RCT was completed, the control group received the intervention and showed significant before-after improvements of similar magnitude in the 3 dimensions. Due to the wide confidence intervals, the results should be interpreted with caution and verified in studies with greater statistical power.

Baseline scores indicated a positive attitude (values above the midpoint of the scale) for the total scale and the 3 subscales, although scores on CE and SC suggest that, comparatively, participants seemed more favorable to empathetically communicate with their patients than sharing decisions with them. This result has also been observed in several studies that applied the Patient - Practitioner Orientation Scale [42], the most frequently used instrument to assess health professionals' attitudes toward PCC, showing higher scores on the *caring* subscale of the questionnaire (ie, empathy, warmth, and treating patients as whole persons) than on the *sharing* one (ie, sharing information, decisions, and power) [43-47].

Other studies also have shown significant benefits of different training programs on professionals' and medical students' attitudes toward SDM and PCC and their intention to apply it in the future, showing high levels of satisfaction with the program [48-52]. A positive attitude toward the PCC model is an obvious requisite for the professionals' learning and demonstration of behaviors aimed at promoting SDM in consultation. Validation studies with the Patient - Practitioner Orientation Scale showed that more favorable attitudes were significantly associated with more patient - centered behaviors in consultations [53], and that concordance of patients and physicians' attitudes was associated with greater patient's satisfaction [53-55], trust, and endorsement of physicians [53], as well as fewer referrals to specialized care [56]. Nonetheless, for the implementation of SDM it is necessary to have not only a positive attitude toward PCC but also the appropriate knowledge and communication skills required by this model, for which training programs have been developed. However, the effect of interventions targeting health professionals on the actual promotion of SDM in consultation remains uncertain. The last update of a Cochrane systematic review reported a significant effect of these interventions (eg, educational meetings and materials, outreach visits, and reminders), compared with usual care when SDM in consultation was assessed by external observers, but not by patients, even when the intervention is directed to both patients and professionals [11]. Observational studies have also shown a lack of association between patients' and external observers' perception of SDM [57-59], but the causes of this discrepancy have not been investigated. Furthermore, the evidence about the effects of SDM interventions targeting health professionals on patients' cognitive, affective, behavioral, and health outcomes is also scarce [10].

Although the PCC and SDM models are a paradigm to be applied to every patient regardless of his or health problems, patients with GAD could present specific psychological characteristics that might affect the decision-making process. In experimental settings involving stimulus reinforcement, these patients have shown greater intolerance to uncertainty and impaired decision-making [55,57-59]. Nonetheless, this does not translate into a preference for a passive role in decision-making, since a recent study showed that more than 80% research participants desired to play an active or collaborative role when making decisions about treatment, although one-third of them perceived more involvement than they preferred [60]. Therefore, professionals should adapt the SDM process to the patients' preference for involvement and manage the unavoidable uncertainty about the potential adverse effects of treatment and the likelihood and intensity of symptoms' improvement.

Limitations

The study has important limitations. First, feasibility of in-person group sessions could not be evaluated due to the emergence of the COVID-19 pandemic, but that allowed us to check the web-based application of the program, which was delivered without problems. However, the recruitment and retention rates were low. The recruited sample was small and there were some relevant differences in baseline variables,

including the scores on the LATCon, and therefore a high risk of selection bias is present. The intervention group was 5 years younger and less experienced, included more nurses and less participants with prior experience on SDM training, and showed a less favorable attitude toward SDM. These characteristics suggest a greater margin for potential benefit in this group. Although the inclusion of these covariates in the model did not change the results, this analysis is strongly underpowered. Nonetheless, given the strong effects sizes obtained and the similar ones showed by the control group after receiving the training, it is reasonable to think that the intervention could produce a real improvement in attitudes, although effects sizes are probably inflated due to the mentioned confounders. The small sample size and the fact that participants were voluntary also challenges the external validity of the results, since it is probable that they were more motivated or favorable to the SDM model.

On the other side, this was a pilot study and we did not assess other professionals' outcomes (eg, knowledge of SDM, satisfaction with the program, and intention to apply SDM in the future), whether the observed effect is maintained over time or its influence on professionals' behavior in consultation as well as on patients' outcomes, which is the ultimate aim of these interventions. An RCT with an adequate sample size is warranted to confirm the results on professionals' attitude and to investigate the mentioned issues.

Acknowledgments

The authors would like to thank all those who contributed to the realization of this study: health managers, health care professionals, and all the researchers who made this study possible.

Conflicts of Interest

None declared.

Abstract

Background: Mentoring, advising, and coaching are essential components of resident education and professional development. Despite their importance, there is limited literature exploring how anesthesiology faculty perceive these practices and their role in supporting residents.

Objective: This study aims to investigate anesthesiology faculty perspectives on the significance, implantation strategies, and challenges associated with mentorship, advising, and coaching in resident education.

Methods: A comprehensive survey was administrated to 93 anesthesiology faculty members at Washington University School of Medicine. The survey incorporated quantitative Likert-scale questions and qualitative short-answer responses to assess faculty perceptions of the value, preferred formats, essential skills, and capacity for fulfilling multiple roles in these support practices. Additional areas of focus included the impact of staffing shortages, training requirements, and the potential of these practices to enhance faculty recruitment and retention.

Results: The response rate was 44% (n=41). Mentoring was identified as the most important aspect, with 88% (n=36) of faculty respondents indicating its significance, followed by coaching, which was highlighted by 78% (n=32) of respondents. The majority felt 1 faculty member can effectively hold multiple roles for a given trainee. The respondents desired additional training for roles and found roles to be rewarding. All roles were seen as facilitating recruitment and retention. Barriers included faculty burnout; confusion between roles; time constraints; and desire for specialized training, especially in coaching skills.

Conclusions: Implementing structured mentoring, advising, and coaching can profoundly impact resident education but requires role clarity, protected time, culture change, leadership buy-in, and faculty development. Targeted training and operational investments could enable programs to actualize immense benefits from high-quality resident support modalities. Respondents emphasized that resident needs evolve over time, necessitating flexibility in appropriate faculty guidance. While coaching demands unique skills, advising hinges on expertise and mentoring depends on relationship-building. Systematic frameworks of coaching, mentoring, and advising programs could unlock immense potential. However, realizing this vision demands surmounting barriers such as burnout, productivity pressures, confusion about logistics, and culture change. Ultimately, prioritizing resident support through high-quality personalized guidance can recenter graduate medical education.

Introduction

The current landscape of medical education is influenced by both medical culture and shifting demographics among learners. Factors such as medical provider burnout [1], a nationwide shortage of medical staff [2], and the evolving characteristics of different generations of learners are reshaping medical education [3]. It is imperative that the well-being and guidance of learners, both personally and professionally, are recentralized as the core of medical education. Emphasizing principles such as advising, mentoring, and coaching is crucial to support learners in their journey toward academic and personal fulfillment. These principles should be thoroughly examined

and reevaluated to empower learners to pursue paths of academic and personal success, foster self-assessment, ensure a nurturing learning environment, and encourage a commitment to lifelong learning [1,2]. The objective of this paper is to examine the attitudes and experiences of clinical-academic anesthesiology faculty with respect to their understanding and practice of mentoring, advising, and coaching. Our aim is to identify key themes that more clearly define these roles within medical education, as well as to elucidate potential barriers to their implementation and sustainability. Furthermore, we seek to understand faculty perspectives on the need for formalized educational support in these areas. We anticipate that the insights gained from this study could be broadly applicable across the graduate medical education spectrum, particularly as the focus in education increasingly shifts toward professionalism and well-being.

The education and welfare of medical residents hinge upon a multifaceted network of connections. Residents at different stages of their training will necessitate varying forms of engagement: mentoring, advising, or coaching. While these 3 avenues are distinct, they all share the common aim of nurturing education, wellness, and career progression [2,3]. Each approach serves its unique purpose and uses diverse methodologies [2]. Identifying the most suitable modality for the learner is paramount. Facilitators must adeptly involve themselves and customize sessions to ensure that expectations and objectives resonate with the learner [2].

Traditionally, mentoring has been the primary means of providing guidance [4]. It entails a sustained personal relationship between mentor and mentee, with the learner's overarching aspirations guiding the interaction. Conversations, career mapping, and counsel are derived from the mentor's experiences and expertise [2,3]. Typically, mentors possess knowledge in the pertinent field and share their insights with the learner. The mentor guides sessions, posing direct questions with long-term goals as the focal point. In residency education, mentoring often follows a structured format, though informal mentorships may naturally evolve. Institutions may request mentors to provide feedback or document these sessions for accreditation purposes [2,3].

Advising typically comprises a single, informal session focused on a specific issue or inquiry. The advisor leads the session and provides solutions or strategies based on their own experiences. The learner has the autonomy to decide whether to heed the advice. Unlike mentoring, a sustained relationship is not necessarily a prerequisite for advising, and subsequent follow-up is usually with independence and self-driven by the needs of the advisee [5]. Advisors may possess limited insight into the learner's personal or academic strengths and weaknesses, resulting in advice limited to specific scenarios [6].

Academic coaching differs from advising and mentoring in that it prioritizes the learner's agency. Coaches refrain from offering advice or engaging in decision-making. Instead, their role is to facilitate self-discovery and create a supportive atmosphere for self-assessment and future planning [2]. Coaches assist learners in identifying actions that may lead to success or failure. Unlike mentors and advisors, coaches may not necessarily possess expertise in the medical field. Coach engagement is supported by actively listening to the learner and offering questions to encourage self-awareness. Coaching fosters a consistent, enduring relationship characterized by an educational partnership between coach and learner [2].

No single form of guidance is adequate to meet the needs of today's students, and students' needs evolve as they move through residency [7]. Faculty must be facile in their ability to intuit what type of guidance is appropriate for a specific student or situation, and be able to provide that guidance or refer the student to someone who can [8]. For this reason, faculty development programs play a crucial role in supporting faculty as they rise to meet the challenges of guiding trainees, and faculty training in these support modalities may be lacking [9]. Training educators on how to target student needs by using the most effective guidance strategy will help decrease role confusion [8]. Training and developing faculty in advising, mentoring, and coaching help cultivate an ongoing culture of scholarship [10] and can help faculty navigate the competing challenges of their clinical and nonclinical roles [11]. Faculty report that lack of support from leadership and lack of proper training are barriers to their role as advisors, coaches, and mentors [11], and training and assessment tools for faculty members are crucial [7,9].

Methods

Study Design

A survey (Multimedia Appendix 1) was sent to 93 Washington University School of Medicine Anesthesiology clinical educator faculties. This target population was used as a convenience sample, representing a cohesive cohort with consistent interactions with trainees. This survey was developed based on core competencies and conceptual differentiations outlined for the roles of advisors, coaches, and mentors in medical education [5,6,8,9]. Drawing from Wolff et al [9], support modality definitions and key characteristics were designed to reflect critical distinctions regarding focus, relationship context, longevity, skill sets, and objective alignment [9]. Survey questions were formulated to assess physician perspectives across these theoretical domains for each resident support role.

A group of coaching experts within the Department of Anesthesiology was selected to create a novel survey tool. To facilitate the design and construction of the survey instrument, the research team used a modified Delphi technique, a widely recognized method for achieving consensus among experts. A subset of academic faculty was invited to participate in a pilot study aimed at testing multiple dimensions of the survey's implementation. This pilot study served several purposes: (1) to ensure the clarity and comprehensibility of the survey questions, (2) to evaluate the technical functionality of the survey platform, and (3) to assess the feasibility of applying inductive thematic analysis to the pilot data. Through iterative revisions and rounds of expert feedback, the survey underwent several modifications to enhance both face validity and content validity. The final version of the survey, which reflects the culmination of this rigorous development process, is presented in Multimedia Appendix 1. The survey is composed of 2 Likert

5-point scale quantitative items and 11 qualitative open-ended questions.

Quantitative items examined perceptions of importance and optimal configurations applying the principles of Wolff et al [9] regarding situational demands and need for role clarity [9]. Quantitative data were collected using the REDCap (Research Electronic Data Capture) Consortium platform (Vanderbilt University), a secure web-based application designed to support data capture for research studies. Faculty received the voluntary survey through department email, no incentives offered, and faculty log-in prevented duplicate entries. Data were analyzed using descriptive statistics. Qualitative questions elicited feedback on specialized skills, training interests, and implementation barriers grounded in advising, coaching, and mentoring competency frameworks [5-9]. The sequence of survey topics reflects established theory comparing and contrasting these support avenues [6-8]. An inductive qualitative analysis was conducted, using the Braun and Clarke [12] 6-phase approach to thematic analysis. This methodological framework, widely used in qualitative research, ensures both the flexibility and rigor required for the interpretative analysis of complex datasets. The 6 stages—familiarization with data, generating initial codes, searching for themes, reviewing themes, defining and naming themes, and writing up—provide a structured yet adaptable framework for data interpretation [12]. Qualitative data were collected through open-response questions included in the REDCap survey. The text from these open-response questions was analyzed using the Dedoose coding themes platform.

The process begins with open coding to identify initial patterns within the data. Codes were then further examined to uncover relationships, allowing for the grouping of related codes into broader thematic categories. Subsequently, these groups were analyzed to identify overarching themes that reflect deeper insights into the data. This iterative process was designed to ensure a comprehensive exploration of the qualitative data and enhance the interpretive depth of the analysis.

To ensure the reliability of the findings, at least two independent researchers reviewed and coded all data. The initial coding and preliminary analysis of the qualitative data was conducted by 1 author (SN-B), using Dedoose—a cloud-based software platform designed to facilitate mixed methods analysis. After the initial coding phase, 2 members of the research team engaged in collaborative discussions to reconcile coding discrepancies and synthesize their interpretations. This process of researcher triangulation not only strengthens the credibility of the findings but also helps to ensure that the emerging themes are robust and reflect the nuances present in the data [13].

The survey contained a brief textual description of the difference between the roles of mentor, advisor, and coach, respondents. Respondents were asked how important they thought each role is in graduate medical training, whether 1 individual can fulfill all 3 roles, what kind of training is needed for faculty to perform these roles, and whether resident needs for different forms of faculty relationship change over time. In addition, faculty were asked if they had ever performed any of the 3 roles. Questions were both quantitative (responses on a 5-point Likert scale) and qualitative (open-ended short responses). A total of 41 surveys were completed (44% response rate).

Ethical Considerations

This study used both quantitative and qualitative data collection and analysis. This study was approved by the Institutional Review Board at Washington University (202310164). Faculty were informed about this study via an initial email announcement, followed by 2 reminder emails. Informed consent was obtained with faculty selecting “accept” on the survey; the ability to opt out was provided. Electronic data were password protected, encrypted, and transmitted using recognized security for electronic submission. No compensation was provided.

Results

Roles

Respondents had varying opinions about the importance of mentoring, advising, and coaching in graduate medical education. Mentoring was seen as most important, with 88% of respondents indicating that they agreed or strongly agreed that it was important, and coaching was seen as less important, with only 78% of respondents indicating agreement or strong agreement that it was important (Table 1).

Table . Importance of mentoring, advising, and coaching.

	Agree or strongly agree, n (%)
Coaching	32 (78)
Advising	34 (83)
Mentoring	36 (88)

In total, 90% of respondents agreed that 1 faculty member could fulfill two or more roles for a single resident. For example, respondent 2 explained, “Faculty can possess more than one skill set and/or the relationship between a faculty and resident may benefit from a multi-faceted focus once trust has been developed.” However, others noted that there may be conflicts between roles and that the unique skills required for each role are not always possessed by the same person. Respondent 3 noted, “This works sometimes, I think, but can’t dependably work all the time. Some faculty are better at one role or another. Obviously, some coaching and advising can only be done by faculty with certain skills or areas of expertise.”

Additionally, respondents noted the role faculty mentoring and coaching play in recruitment and retention efforts for faculty and trainees. For example, respondent 3 noted, “if it were made clear that we offered thoughtful assignment of each of these roles, with examples for coaching and advising, I think that would likely be seen as a significant benefit.” Others agreed

that providing these roles to residents in a systematic way would be beneficial for recruitment, but noted barriers to implementation, as respondent 33 explained, "I think that these three roles are important to recruit residents for fellowships and faculty. Fostering a supportive environment through these roles is very important for recruitment; however, other factors such as the job market and hours worked often overshadow these aspects in recruiting."

Training

Most respondents agreed that specialized training in all 3 roles was important, especially for coaching, which was seen as requiring a unique skill set. Formal training for all 3 roles was endorsed, especially for coaching. Respondents noted that the skills required for the roles came naturally to some faculty. For the advising role, having career experience and expertise in the graduate education process was seen as especially useful. For example, respondent 10 noted, "Knowing the residency experience well and knowing what challenges residents face. Additionally, it's important to know career options after." Mentoring was regarded as being based on relationship building and interpersonal skills, as well as necessitating emotional intelligence. Respondents reflected that mentorship involves skill sets not necessarily embedded in clinical training. Respondent 21 explained, "Teach the teacher/instructor courses are helpful. Being a good clinician and/or researcher do not provide us the skills of being a good teacher. A bit of more understanding, empathy, and psychological support are necessary for knowing ourselves better and using these abilities for others. Patience, more listening, time, sharing experiences, sometimes coming up with a challenging scenario to discuss, widen the horizon, show other possibilities never thought of before as options."

Respondents indicated that they would be interested in targeted training. Coaching (63%) was the highest, however, respondents were less interested in specialized training in advising and mentoring skills (Table 2).

Table . Interest in specialized training in coaching, advising, and mentoring.

	Interest in specialized training, n (%)
Coaching	29 (63)
Advising	17 (41)
Mentoring	16 (39)

Experience

Nearly 88% of respondents had fulfilled one or more of these roles in their career, and they noted that holding all 3 roles was personally and professionally rewarding. Of the 36 faculty members who reported fulfilling these roles in the past, 15 (42%) mentioned the satisfaction of watching students progress through their training and career. Coaching was noted as being the most challenging, but also the most rewarding. For example, respondent 22 said, "Honestly, I think that serving in this role for strong residents is one of the most rewarding parts of my job. I love to see people be successful in their careers."

Barriers

Respondents identified barriers to faculty engaging in quality mentoring, coaching, and advising, which included faculty burnout, time limitations, and confusion about roles, responsibilities, and expectations. Respondent 10 said, "The residents have so many rotations. It's rare to have consistent clinic time to coach and mentor/advise. Coaching off hours is very time consuming." Lack of time was mentioned by 68% of respondents, for example as respondent 29 explained "I was a terrible mentor. Never could find time to meet with my mentee."

Respondents had mixed responses about whether the national anesthesia provider shortage had impacted their engagement with or performance of any of these roles. Respondents noted lack of time in general, and lack of protected time more specifically, as factors influencing their ability to engage in these roles, and some attributed the challenge with time to provider shortage. For example, respondent 17 said, "The shortage has decreased faculty time to provide these aspects, may be important for departments to assign a subgroup of faculty to serve these roles so time is protected."

Table 3 presents the results of the thematic analysis, offering a detailed synthesis of the emergent themes and subthemes derived from the qualitative data. The richness of respondent narratives facilitated a comprehensive exploration, allowing for nuanced insights into the key thematic categories. These findings provide a robust framework for understanding the underlying patterns and relationships within the data, supporting the depth and validity of the analysis.

Table . Main themes and representative quotes.

Theme and subtheme		Representative quotes
Roles		
	Faculty can perform multiple roles	• "Faculty can possess more than one skill set and/or the relationship between a faculty and resident may benefit from a multi-faceted focus once trust has been developed." [Respondent 2] • "Different skill sets are needed and faculty may possess one or many of the skill sets needed." [Respondent 9] • "I believe the necessary skills can be learned and employed by a single person. It also depends upon the mentee's needs and the qualities of their relationship with the mentor/advisor/coach." [Respondent 5] • "A faculty member can take different roles throughout the 4 years that a trainee is counseled. I find that interns need mentoring and advising, as the resident progresses coaching and mentoring is important." [Respondent 16]
	Faculty cannot perform multiple roles	• "This works sometimes, I think, but can't dependably work all the time. Some faculty are better at one role or another. Obviously, some coaching and advising can only be done by faculty with certain skills or areas of expertise." [Respondent 3] • "Sometimes the line between just providing feedback for a specific case as an advisor can be hard if you are also a mentor to that person." [Respondent 37] • "Different goals and different time frames over which those goals are realized. The trainee asking advising may be frustrated by a "mentoring" approach. Some great career mentors may not have the specific subspecialty background for focused advising." [Respondent 7]
Training		

Theme and subtheme		Representative quotes
	Request for formal education or faculty development	• "I think at least some sort of education on how to be an advisor would be helpful." [Respondent 1] • "Teach the teacher/instructor courses are helpful. Being a good clinician and/or researcher do not provide us the skills of being a good teacher. A bit of more understanding, empathy, and psychological support are necessary for knowing ourselves better and using these abilities for others. Patience, more listening, time, sharing experiences, sometimes coming up with a challenging scenario to • discuss, widen the horizon, show other possibilities never thought of before as options." [Respondent 21] • "Coaching should require some training/knowledge of professional coaching, which is more structured that mentorship or career advising which can be more informal." [Respondent 4] • "Didactics/workshops/peer mentoring needed." [Respondent 31] • "Training focused to the knowledge and skillset as well as teaching techniques and current best practices." [Respondent 2] • "Structured professional coaching training." [Respondent 6]
Experiences		

Theme and subtheme		Representative quotes
	Mentor role	• "I was a terrible mentor. Never could find time to meet with my mentee." [Respondent 29] • "Mentoring has been the most rewarding, coaching second. Advising feels limited and one-directional." [Respondent 5]
	Coach role	• "All three - coaching seems to be the most challenging." [Respondent 7] • "I have played all 3 roles during my time as an educator. The coaching roles are always the most rewarding. The ability to guide residents through self-discovery is extremely rewarding. I find that coaching residents later in their training prepares them for being faculty and having a successful trajectory." [Respondent 17] • "I have been a coach and an advisor. Coaching is extremely rewarding." [Respondent 39] • "Primarily coaching, which I found rewarding when a trainee felt our interaction was beneficial through skill-based or confidence improvements." [Respondent 41]
	Advisor role	• "Advising in clear goal-directed tasks, such as a conference, abstract, paper." [Respondent 8] • "I have served as a mentor and advisor, both of which were very rewarding. I felt that it made it easier to discuss topics at work that we may otherwise would not have brought up. I also felt satisfaction getting to know the trainees better and become more a part of their lives." [Respondent 27] • "Clinical teaching while supervising trainees fulfills the "advisor" role. I was also a designated faculty mentor for a clinical fellow." [Respondent 34] • "Clinical teaching while supervising trainees fulfills the advisor role." [Respondent 33]
	Combination of roles	• "Have provided all three of these roles in different capacities. I enjoy fostering learning with the goal of being the attending I wish I had as a trainee." [Respondent 33] • "Yes, I feel that I serve as an advisor to residents and mentor to fellows." [Respondent 20] • "I would say informally on day-to-day basis interactions with residents and fellows, yes for all 3. Advisor more than mentor more than coach. It is rewarding when it seems welcomed and appreciated by the residents and fellows and I can see them grow and improve. It is frustrating when I am putting in the effort/trying to do these things and the trainees are not receptive, not appreciative, or feel as though I am being too particular or micromanaging." [Respondent 35] • "I have provided all 3. The coaching roles are always the most rewarding. The ability to guide residents through discovery is extremely rewarding." [Respondent 20]
	Recruitment role	

Theme and subtheme	Representative quotes
	• "The biggest drivers right now for recruitment are time and money. The biggest long-term satisfaction will come from deeper meaning. Using the relationships in these roles may help highlight some of these deeper meanings and may help recruit fellows and faculty if they have the sense that this is best for themselves and their families. At the same time, there has to be felt and sustained room for the individual to act on these deeper meaningful insights. Solving for individual growth requires commitment from the system as well as the individual." [Respondent 9] • "Yes. When residents can see faculty care about their education and also enjoy working here it's easier to recruit. " [Respondent 20] • "Mentorship and coaching require a relationship, that may be beneficial for recruitment." [Respondent 17] • "A structured mentor/coaching program would be very appealing to most applicants." [Respondent 31]
Barriers	

Theme and subtheme		Representative quotes
	Discrete roles	• "If role/project is not clearly defined, could cause some confusion. Time." [Respondent 1] • "Mentorship is often a friendly and personal relationship, which could make it harder to, for example, challenge the mentee in a coaching scenario. Very specific example - perhaps a mentee would feel uncomfortable doing mock oral boards with their mentor, if they're relatively advanced in training, but early in the oral boards prep process." [Respondent 3] • "Different goals and different time frames over which those goals are realized. The trainee asking for advising may be frustrated by a "mentoring" approach. Some great career mentors may not have the specific subspecialty background for focused advising." [Respondent 7]
	Time	• "Time and lack in continuous interactions with the resident." • [Respondent 18] • "Time to meet with the trainee and to establish a relationship." • [Respondent 14] • "Time and managing the balance btw one's professional responsibilities and taking on additional responsibilities that the above would entail." [Respondent 6] • "The residents have so many rotations. It's rare to have consistent clinic time to coach and mentor/advise. Coaching off hours is very time-consuming." [Respondent 10]
	Burnout	• "It would be a good recruitment tool but difficult to deliver in near future with current staffing shortages and burn-out among faculty members. In practice, it would require significant training, time, and effort to optimize and ensure an equal experience among trainees. Remuneration could increase participation but doesn't get around the issue of lack of time." [Respondent 12] • "Yes, particularly for faculty. Relatively little resources currently to develop faculty. More investment needed to reduce the chance of burnout/disengagement/attrition to other practices." [Respondent 31] • "We are all strapped for time and burnt out." [Respondent 40]
	Anesthesia shortage	• "These 3 are probably even more important for our trainees and may be beneficial to expand these past trainees and onto faculty as well. The shortage has decreased faculty time to provide these aspects, may be important for departments to assign a subgroup of faculty to serve these roles so time is protected." [Respondent 17] • "I think that with the shortages, faculty have taken on more solo assignments and have overall less contact with the residents and don't get to know them as well." [Respondent 36]

Discussion

Overview

This study explored perceptions of anesthesia faculty regarding the roles of mentoring, advising, and coaching in graduate medical education. The results highlight the perceived benefits of these practices as well as barriers to implementation. Anesthesia residency is unique in its internship, and a vast majority of education and interactions with faculty occurs at bedside in the operating room. Medical training and trainee progression differ across disciplines. This study focuses specifically on anesthesia faculty and a single institution, which overall limits generalizability.

Principal Findings

The survey results indicate that faculty view mentoring, advising, and coaching as important for resident education and development. These practices have been shown to improve resident well-being, promote career planning, facilitate reflection and self-assessment, and identify knowledge gaps [5,6]. Furthermore, implementing structured programs in these areas can aid recruitment and retention of both residents and faculty.

Of the 3 roles faculty partake in, there is a consensus on the importance of mentoring throughout training and prioritizing this role over advising and coaching. However, the data suggests a significant interest in specialized training for coaching versus roles in advising and mentoring. Investigating the differences in practice versus desire, recurrent themes of time and experience were identified. Although the roles as a mentor, advisor, and coach can overlap, a majority of the cohort indicated they prioritize mentoring given the noted constraints of time and experience.

Implications of Findings

To actualize these practices, each department must clearly define the roles of mentor, advisor, and coach. Expectations, training requirements, and time commitments should be delineated. Assignments of roles can be made between faculty and residents based on alignment of career goals, personalities, and logistics. Protected nonclinical time should be designated for these meetings separate from clinical work. Success stories and positive impacts on residents should be tracked and celebrated.

Comparison to the Literature

Recurrent themes were identified when comparing to other literature, such as the establishment of a clear definition and terms of each role. This would help faculty facilitate their approach to the learner needs [5,8]. Additional repeated themes of the overlap in roles, limitations in time, and experiences were highlighted in other studies in reference to mentorship, advising, and coaching [5,10]. Anesthesiology training presents challenges specific to the discipline, which can be generalized to medical training programs at other institutions. There has been an increased productivity within the academic institutions leading to less bedside education opportunities and difficulty establishing dedicated time for routine meetings with trainees.

Limitations

This study has several limitations. First, this study was based on a single survey with a 44% response rate, which may limit the generalizability of the findings. Nonresponders may have had different perspectives on the importance and implementation of mentoring, advising, and coaching. Second, this study was conducted at a single academic medical center, so the results may not be representative of other institutions. Additionally, this study was solely conducted with anesthesia faculty. Other specialties may not portray the same obstacles and constraints in fulfilling the roles of mentorship, advising, and coaching. The learning environment and progression through training also differ between anesthesiology and other specialties, which limits the generalizability across disciplines. The limited time and consistency with faculty may lead to less specific demands from trainees and unfulfillment from educators. Third, the survey relied on self-reported perceptions and experiences, which are subject to recall bias and social desirability bias. Fourth, this study did not explore the perspectives of residents themselves on these support modalities. Future research should examine resident experiences with and preferences for mentoring, advising, and coaching. Finally, while this study identified perceived barriers to implementing these practices, it did not evaluate specific strategies for overcoming these obstacles. Further work is needed to develop and test interventions to enhance faculty engagement in resident support roles.

Conclusion

Addressing barriers such as faculty burnout, role ambiguity, time constraints, and the need for specialized training is critical for the success of mentoring, advising, and coaching initiatives. Implementing comprehensive faculty development programs aimed at enhancing skills in these domains is essential, particularly for coaching, which requires distinct pedagogical approaches. The recruitment and retention of faculty, as well as their career longevity, may be positively influenced by the intrinsically rewarding nature of relationships with trainees.

To facilitate meaningful faculty engagement, institutional leadership must ensure protected time for participation in these activities without detriment to clinical productivity. Moreover, a cultural shift may be necessary in programs that place disproportionate emphasis on service obligations, potentially at the expense of educational and developmental support for residents. Prioritizing resident education and well-being can contribute to improved morale and overall program satisfaction.

By investing in faculty development, enhancing institutional infrastructure, and fostering a culture that values educational alliance, graduate medical education programs can realize significant benefits from high-quality mentoring, advising, and coaching relationships. Such investments are pivotal for advancing the professional development of both faculty and trainees, ultimately enhancing the overall quality of medical education.

Abstract

Background: The GPT-4 is a large language model (LLM) trained and fine-tuned on an extensive dataset. After the public release of its predecessor in November 2022, the use of LLMs has seen a significant spike in interest, and a multitude of potential use cases have been proposed. In parallel, however, important limitations have been outlined. Particularly, current LLMs encounter limitations, especially in symbolic representation and accessing contemporary data. The recent version of GPT-4, alongside newly released plugin features, has been introduced to mitigate some of these limitations.

Objective: Before this background, this work aims to investigate the performance of GPT-3.5, GPT-4, GPT-4 with plugins, and GPT-4 with plugins using pretranslated English text on the German medical board examination. Recognizing the critical importance of quantifying uncertainty for LLM applications in medicine, we furthermore assess this ability and develop a new metric termed “confidence accuracy” to evaluate it.

Methods: We used GPT-3.5, GPT-4, GPT-4 with plugins, and GPT-4 with plugins and translation to answer questions from the German medical board examination. Additionally, we conducted an analysis to assess how the models justify their answers, the accuracy of their responses, and the error structure of their answers. Bootstrapping and CIs were used to evaluate the statistical significance of our findings.

Results: This study demonstrated that available GPT models, as LLM examples, exceeded the minimum competency threshold established by the German medical board for medical students to obtain board certification to practice medicine. Moreover, the models could assess the uncertainty in their responses, albeit exhibiting overconfidence. Additionally, this work unraveled certain justification and reasoning structures that emerge when GPT generates answers.

Conclusions: The high performance of GPTs in answering medical questions positions it well for applications in academia and, potentially, clinical practice. Its capability to quantify uncertainty in answers suggests it could be a valuable artificial intelligence agent within the clinical decision-making loop. Nevertheless, significant challenges must be addressed before artificial intelligence agents can be robustly and safely implemented in the medical domain.

Introduction

The GPT—recently updated to its fourth iteration (GPT-4)—is a generative and autoregressive large language model (LLM). It is pretrained on a vast corpus of internet text and fine-tuned on a labeled dataset using a transformer architecture [1-3]. GPT generates coherent and contextually appropriate text. It likely discovered a semantic grammar of language (ie, semantic regularities), enabling it to construct semantically and syntactically correct sentences [4,5]. However, GPT does not perform meaningful computations on symbolic representations [4-8]. The Wolfram language, a Turing-complete computational language, in contrast, allows such symbolic representation. GPT and the Wolfram language combined hence cover 2 different aspects of human cognition [4,9,10]. Combining these features, particularly when computation and symbolic representations are needed, represents a significant step toward general artificial intelligence (AI). This combination has already been successfully used to examine contradictions in Einstein Special Theory of Relativity equations [11].

In the light of these technological advances, LLMs show increasing promise in supporting medical training and practice. However, the models must acquire an in-depth and accurate representation of medical knowledge to be used in these sensitive domains. A medical board examination exemplifies these domains well, as it determines the qualification of medical students to obtain their license to practice medicine.

Our primary outcome is the model's ability to achieve the minimum required score for passing the 2 written parts of the German medical licensing examination. This task poses a different challenge to an LLM than medical board examinations in the English language [12,13], as the performance of such models in other languages and in combination with more recent GPT versions and available plugins has not been explored. In the medical field, where mistakes can have severe consequences, assessing the amount of uncertainty is of paramount importance [14]. It is therefore crucial to gain insights into the depth and structure the LLMs have of the medical knowledge representation and where its limitations lie [15]. Hence, our secondary outcomes were the total correct answer rates, the presence of logical justification of the answer, the presence of information internal to the question, the presence of information external to the question, the confidence GPT displays in its answers, the difficulty of the question, information errors, logical errors, reasoning errors, and the correctness of a second try answer when the first answer was wrong. Insights into these 2 dimensions of outcomes can contribute to facilitating a meaningful use of novel LLM technologies in the medical domain.

Methods

Medical Board Examination Dataset

The German medical board examination consists of 3 steps. The first board examination, taken after 2 years of study, primarily covers basic natural sciences. It comprises 320 questions, which students answer over 2 consecutive days. The second board examination takes place after 6 years of study. It likewise consists of 320 medical questions, which students answer over 3 consecutive days. The third board examination, also after 6 years of study, is an oral examination and was, hence, excluded from this study. The German medical board examination takes place biannually, once in spring and once in fall. As a representative sample, we used the medical board examination from spring 2023. We excluded questions the medical board examination committee deemed inconsistent with the medical literature in the regular post examination review of the content. Additionally, we did not include questions displaying images, as GPT models could not analyze them at the time of our analysis. Furthermore, LLMs are not able to analyze images, GPT4vision which became broadly accessible in the second half of 2023 combines computer vision algorithms—which generate a text description of images—and LLMs to analyze this text. All questions and answers were exported from AMBOSS SE, a German medical education content creator and service provider.

GPT Models and Prompt Engineering

We evaluated several GPT models with varying characteristics using OpenAI's web interface. The models tested included GPT-3.5, GPT-4, GPT-4 integrated with the Wolfram, ScholarAI, and Web Request (WeGPT.ai) plugins, and GPT-4 integrated with the Wolfram, ScholarAI, Web Request plugins, and an additional feature for translating German inputs into English. We did not investigate earlier versions of GPT as they demonstrated lower performance in a similar study on the American medical board examination [12].

Creating a precise and adequate context is crucial for generating expected results [16,17]. Thus, we aimed to be as specific as possible, simulating the context of a medical student taking the medical board examination. The prompts hence included the request to answer each respective question with 5 possible answers, where only 1 answer was correct. We asked the models to justify their choices based on the provided patient case information, and to estimate their confidence in the answer's accuracy as a percentage of maximal confidence (ie, 100%). If the selected answer was incorrect, the GPT models were asked to explain their mistake in a second attempt. For the GPT-4 model with plugin integration, we asked the model to use the available plugins (Wolfram, ScholarAI, and Web Request). For the GPT-4 model with plugin integration and English translation, we first asked the model to translate the input into the English language, and then to use the translated text to perform the abovementioned tasks. All used prompts are available in Multimedia Appendix 1.

Model Testing and Outcome Parameters

For each GPT model, we used the appropriate prompt followed by the question and the possible answers. The investigators then analyzed the GPT's answer to assess the defined primary and secondary outcomes, which were either binary or in proportions. In cases of uncertainty, the investigators (JM, TS, and LB) convened to resolve the issue.

First, the correctness of the answer was recorded (binary variable), followed by the presence of logical justification, the presence of information internal to the question, and the

presence of information external to the question (binary variables).

Next, we recorded the model's confidence in its answer (proportion), and the difficulty of the question, derived from the number of students who answered correctly on the AMBOSS platform (proportion).

To enhance our understanding of where GPT models falter, we sought to classify potential errors. As literature on error types is limited, we conducted a formal analysis to determine distinctive error types and established a formal definition. We propose a classification into 3 categories: information error, logical error, and reasoning error.

The GPT response can be formalized as "answer A" is given "link" because of "information B." There are only three possibilities for errors: (1) "answer A" is incorrect because "information B" is incorrect—termed an information error; (2) "answer A" is incorrect while "information B" is correct, but the link between them is incorrect—termed a logical error; (3) "answer A" is incorrect, "information B" is correct, and the link between "answer A" and "information B" is correct—termed a reasoning error (Figure 1). If the answer provided was incorrect, the investigator informed the GPT of its faulty answer, recorded whether it understood its mistake, and provided the correct answer in a second attempt. In the models with integrated plugin use, the active use of plugins was documented for Wolfram, ScholarAI, and Web Requests (binary variables).

Figure 1. Formal definition of error types; we propose a classification into 3 categories: information error, logical error, and reasoning error. The GPT response can be formalized as “answer A” is given “link” because of “information B.” There are only three possibilities for errors: (1) “answer A” is incorrect because “information B” is incorrect—termed an information error; (2) “answer A” is incorrect while “information B” is correct, but the link between them is incorrect—termed a logical error; and (3) “answer A” is incorrect, “information B” is correct, and the link between “answer A” and “information B” is correct—termed a reasoning error.

Data Analysis

Summary statistics were calculated for the outcome variables (Table 1 and Multimedia Appendices 2 and 3). Dichotomous variables were represented by frequency and proportions with 95% CIs, while continuous variables were expressed as mean values with 95% CIs. Uncertainty calculations displayed as 95% CIs were computed via bootstrapping [18].

Table . Characteristics of GPT model answers (N=541).

	GPT-3.5	GPT-4	GPT-4 + plugin	GPT-4 + plugin + translation
Correct answer (proportion±95% CI)	373 (0.69±0.65 to 0.73)	493 (0.91±0.89 to 0.93)	493 (0.91±0.89 to 0.94)	486 (0.9±0.87 to 0.92)
Logical justification (proportion±95% CI)	479 (0.89±0.86 to 0.91)	526 (0.97±0.96 to 0.98)	529 (0.98±0.96 to 0.99)	527 (0.97±0.96 to 0.99)
Question's difficulty mean (±95% CI)	0.288 (0.272 to 0.303)	0.288 (0.272 to 0.303)	0.288 (0.272 to 0.303)	0.288 (0.272 to 0.303)
Error overall (proportion±95% CI)	168 (0.31±0.27 to 0.35)	48 (0.09±0.07 to 0.11)	48 (0.09±0.06 to 0.11)	55 (0.1±0.08 to 0.13)
Presence of internal information (proportion±95% CI)	521 (0.96±0.95 to 0.98)	537 (0.99±0.98 to 1)	537 (0.99±0.98 to 1)	537 (0.99±0.98 to 1)
Presence of external information (proportion±95% CI)	538 (0.99±0.99 to 1)	540 (1±0.99 to 1)	541 (1±1 to 1)	541 (1±1 to 1)
Information error (proportion±95% CI)	37 (0.22±0.16 to 0.29)	5 (0.1±0.02 to 0.19)	5 (0.1±0.02 to 0.2)	7 (0.13±0.05 to 0.22)
Logical error (proportion±95% CI)	61 (0.36±0.29 to 0.43)	18 (0.38±0.25 to 0.52)	12 (0.25±0.125 to 0.375)	19 (0.35±0.22 to 0.47)
Confidence mean (±95% CI)	0.912 (0.904 to 0.918)	0.938 (0.934 to 0.942)	0.919 (0.915 to 0.924)	0.919 (0.915 to 0.923)

[a]N/A: not applicable.

The primary outcome was determined by comparing the performance of the GPT-4 model, integrated with the plugins and the English translation, to the required passing score for the medical board examination, which is 60%. The difference of proportions was calculated with 95% CI using bootstrapping (Multimedia Appendix 4).

Subsequently, secondary outcomes were calculated: the final examination rate for each GPT model was compared to both chance and the required passing score for the medical board examination. The difference of proportions was calculated with 95% CI using bootstrapping (Multimedia Appendix 4).

The proportions of logical justification within the answer, information internal to the answer, and information external to the answer were compared between correct and incorrect responses. The difference of proportions was calculated with 95% CI using bootstrapping (Table 2 and Multimedia Appendix 5).

Table . Analysis of plugin-integrated GPT-4 model answers.

		All correct answers (n=493)	All incorrect answers (n=48)	Difference in proportions or Cohen *d* or Pearson *r* (±95% CI)	Confidence accuracy (±95% CI)
Comparison of GPT models justifications between correct and incorrect answers

[a]Difference in proportions.

[b]Not available.

[c]Cohen *d*.

[d]Pearson *r*.

The model's confidence in its answers was compared between correct and incorrect responses. Additionally, the relationship between the model's confidence in its answers and the difficulty of the question was assessed. Cohen *d* values and 95% CI were computed using a linear regression model and bootstrapping (Table 2 and Multimedia Appendices 6 and 7).

To evaluate the accuracy of the model's confidence in its answers, we developed a parameter termed confidence accuracy (CA). It is defined as follows:

CA = (confidence of correct answers in percentage – confidence of incorrect answers in percentage)/100

Consequently, this parameter can take values from −1 to 1, where 1 accurately reflects the model's uncertainty, 0 indicates no ability to quantify uncertainty, and −1 suggests incorrect quantification.

The difficulty of the question was assessed using real correct response proportions from students available on the AMBOSS platform. The difficulty was assessed as follows:

Difficulty=1 – correct answer proportion

Then, the difficulty of the question was compared between correct and incorrect answers, with Cohen *d* calculated using a linear regression model (Table 2 and Multimedia Appendix 7).

Furthermore, we compared the proportion of correct answers between models (Table 2 and Multimedia Appendix 8).

We compared the proportion of correct answers in the GPT-4 models with the proportion of correct answers in the answers where a plugin has been used. We compared the proportion of plugin usage in GPT models with German and English input. We compared the confidence of the model when using plugins to the confidence of the model overall. We compared the proportion of correct answers when averaging the 4 different models to each model in particular (Multimedia Appendix 9).

In instances where questions were accompanied by images, GPT models sometimes responded by describing the image, although the models could not access the respective images. This phenomenon is known as a type of hallucination [19]. Therefore, we compared the proportion of hallucinations present in each model when answering questions, including image questions. We calculated the proportion of correct answers for each model when keeping the questions with pictures (Multimedia Appendix 9).

We compared the different error proportions between different models. We compared the proportion of logical errors when using the Wolfram plugin to the proportion of errors when using the entire model. We compared correct second-try answers between different models (Multimedia Appendix 9).

The 95% CIs were calculated using bootstrapping. Where necessary, parametric assumptions were tested using quantile-quantile plots for normality and Levene tests for the homogeneity of variances. The independence of question answers was assumed. All statistical analyses were performed in RStudio (version 2023.06.0+421). The significance level for all tests was set a priori at 95% CI.

Results

All tests were performed on the 541 questions of the German medical board examination from spring 2023. Sub analyses were performed on other subgroups, the respective sample sizes are indicated in the appropriate tables. All results for GPT-3.5, GPT-4, GPT-4 + plugin (GPT4P), and GPT-4 + plugin + translation (GPT4PT) are listed in full detail in the tables and the supplementary materials. To ensure legibility, only relevant results are addressed in the results section.

Descriptive statistics with CIs for the first board examination, second board examination, and the overall examination are displayed in Table 1 and Multimedia Appendices 2 and 3.

All models performed significantly better than chance. Furthermore, all GPT models were significantly better than the required proportion to pass the final medical board examination.

All GPT models had a significantly higher proportion of providing a logical justification for correct answers compared to incorrect answers (Table 2 and Multimedia Appendix 5). Yet, there was no statistical significance for the proportion of used internal information for correct and incorrect answers (Table 2 and Multimedia Appendix 5). Similarly, there was no statistical significance for the proportion of used external information for correct and incorrect answers (Table 2 and Multimedia Appendix 5).

Although generally high for both incorrect and correct answers, models had a confidence mean which was significantly higher for correct answers than incorrect answers (Table 2 and Multimedia Appendix 6). This is reflected in CA values significantly different from zero: GPT-3.5 (0.028, 95% CI 0.011 to 0.048), GPT-4 (0.041, 95% CI 0.023 to 0.062), GPT4P (0.037, 95% CI 0.021 to 0.053), and GPT4PT (0.043, 95% CI 0.028 to 0.059).

From all models, only GPT4P made significantly more reasoning errors than logical errors (0.37, 95% CI 0.125 to 0.60). All models made significantly more reasoning errors than information errors: GPT-3.5 (0.21, 95% CI 0.11 to 0.30), GPT-4 (0.44, 95% CI 0.27 to 0.60), GPT4P (0.52, 95% CI 0.31 to 0.71), and GPT4PT (0.40, 95% CI 0.20 to 0.58). All models but GPT4P made significantly more logical errors than information errors: GPT-3.5 (0.14, 95% CI 0.029 to 0.26), GPT-4 (0.27, 95% CI 0.10 to 0.44), and GPT4PT (0.22, 95% CI 0.05 to 0.38). GPT-4 (0.12, 95% CI 0.05 to 0.22) and GPT4P (0.12, 95% CI 0.02 to 0.22) made significantly less information errors than GPT3.5.

The GPT4-based models all performed better than the GPT 3.5 model in providing correct answers as reflected in the difference of correct answer proportions (Table 2 and Multimedia Appendix 8). However, no GPT4-based model was better than another GPT4-based model, as reflected in the difference of correct answer proportions (Table 2 and Multimedia Appendix 8).

Discussion

Primary Outcome

All GPT models assessed performed above the minimum required score of 60%. The GPT-4 models performed particularly well, outperforming most students in the given examinations. Specifically, for the first board examination, all GPT-4 models performed better than 98.6% of students. For

the second board examination, they surpassed 95.8% of students, as detailed in the records of the examining body [20].

In general, there was a significant gap between GPT-3.5 and the GPT-4 models. The more recent models, with substantially more parameters and the capacity to remember longer prompts, appear to increase the accuracy of responses. However, we observed no additional benefit when GPT-4 models were paired with plugins.

The use of plugins did not yield a higher proportion of correct answers than the standard model. It is possible that GPT-4 already achieves a very high rate of accuracy, resulting in a ceiling effect. Hence, the addition of plugins may not offer a significant advantage for the questions prompted.

During our study, we noted that the Wolfram plugin was frequently used for more complex calculations. Yet, in the context of clinically applicable questions, complex mathematical procedures are typically not required and the use of symbolic language is usually not required. Thus, using the Wolfram Alpha plugin is likely more beneficial for questions that involve extensive computations or advanced mathematical problems requiring symbolic representations. The ScholarAI plugin was activated for complex informational queries, but the resulting papers were not consistently useful. Surprisingly, the Internet Access plugin (WeGPT.ai) was the least used. This may be because answering medical questions typically demands expert-level knowledge, and general internet searches do not provide sufficiently specific information. Moreover, since the model has been trained on a vast amount of internet data, it likely already encompasses the knowledge available from the world wide web within its parameters.

We speculated that posing questions in German might hinder the model's access to the broader body of knowledge available in English. However, this was not the case; the GPT model equipped with translation capabilities did not outperform the GPT-4 models without translation features. The GPT model likely abstracts high-level concepts and is not impeded by the language of the queries. This aligns with the LLMs' transformer architecture, which accesses higher-level concepts prior to translating text into another language [21].

Interestingly, the GPT-4 model with translation invoked plugins less frequently than the model without translation. We hypothesize that plugin calls occur at a lower level in the neural network, making them less necessary in English due to the larger available language corpus. In German, the model might need to delve deeper into the latent representation of concepts not tied to a specific language. However, this remains speculative and warrants further research.

Secondary Outcomes

While all models provided a very high proportion of logical justification for correct answers, it was significantly less extensive for incorrect answers. However, upon further analysis, we did not detect a significant difference in the proportion of internal information from the question in the answer or in the use of external information not contained in the question between correct and incorrect answers. One study already assessed the presence of logical justification in answers to United States Medical Licensing Examination questions, where all answers exhibited logical justification regardless of their accuracy [12]. Hence, this metric could not be used as a discriminator for correctness.

We were unable to demonstrate a significant correlation between the model's confidence in an answer and the difficulty level of the question for humans. This suggests that the model's interpretation of question difficulty differs from that of humans. However, as with humans, the model showed improved performance on easier questions compared to more challenging ones. Thus, it appears that the representation of question difficulty is distinct between LLMs and humans.

Conceptual Implications

Use for Medical Education

This performance suggests that LLMs such as GPT could assume a greater role in medical education, as their integration could significantly change the conventional approach to medical education, which has traditionally emphasized the acquisition and maintenance of medical knowledge. The emergence of AI agents with superior information retention abilities, however, prompts a reevaluation of our educational focus. In this light, teaching methodologies could shift toward navigating and structuring available information with respective AI agents. The approach could hence shift from retaining information to learning how to efficiently access information and deeply understand these systems, along with their benefits and drawbacks.

Use in Clinical Practice

The utility of LLMs is not limited to educational settings but also extends to clinical practice. Although LLMs may not be as effective in highly specialized tasks where dedicated machine learning algorithms excel—for instance, XGBoost in identifying pulmonary embolisms [22-24] — LLMs are highly proficient in text processing and information integration from diverse algorithms [25]. This positions them as intelligent medical assistants, capable of transforming complex data into narratives that are comprehensible in a human context. Currently, clinicians have a limited understanding of AI agents and their functions. Clinicians must, therefore, gain a thorough understanding of how various AI agents function, including their strengths and weaknesses.

With insufficient knowledge on the principles of LLM-based assistants, clinicians are at risk of blindly following such assistant's guidance without fully understanding its operations [26,27]. Due to the inherent complexity of LLMs, which often function as a black box, we can only partially monitor their operations at varying levels of complexity and behavior [26]. Given the marginal uncertainty intrinsic to such complex models, the AI agent should not supplant clinicians in decision-making, but rather provide additional informed perspectives.

To serve as a useful assistant, however, the assessment of uncertainty for any output provided by such is crucial. The key attribute enabling this evaluation is the ability to quantify uncertainty, a trait humans are presumed to possess [14]. For

LLM-based assistants to provide a comparable estimate, a standardized measure is needed to gauge the confidence in an AI agent's output. For binary outcomes such as healthy or diseased, metrics such as specificity, sensitivity, and area under the curve are effective. For more complex queries with multiple potential answers—as managed by LLMs—traditional measures such as sensitivity and specificity are inadequate. We therefore developed a new metric called "confidence accuracy" (CA) which correlates the confidence assigned to an answer with its empirical accuracy. This allows for the quantification of uncertainty, crucial for clinical decision-making. Although our work showed that all GPT models have the ability to quantify uncertainty, the expression in percentage does not seem to reflect the confidence for any specific decision (ie, the models were overall largely overconfident). Although statistically different from zero, CA values were consistently close to zero. New LLM methodologies aim to enhance this by incorporating uncertainty estimation [28]. Future AI agents should be fine-tuned using the CA metric in order to improve uncertainty quantification, a critical objective for implementing AI as a supportive tool for physicians in clinical environments.

Identified Errors

We observed that GPT models commit different types of errors, particularly reasoning errors. Reasoning errors typically occur in situations where multiple options are correct, but one is more critical than the other. GPT models over proportionately make reasoning errors likely because this skill is acquired through human experience and is challenging to learn from text-based web sources. The second most common error type in GPT models was logical errors. Since LLMs use a statistical approach to reconstruct human-written text, we anticipated difficulties with logic and mathematics, which require formal symbolic representation [4-8]. We hypothesized that the Wolfram plugin, using the Wolfram language, would mitigate these challenges. Yet, using the Wolfram plugin did not reduce the number of logical errors. Finally, fewer information errors were observed compared to other error types across all GPT models. This likely reflects the strength of these LLMs, which have assimilated a vast corpus of knowledge. In addition to the 3 error types derived from the informational and logical structure of GPT's answers, there are 2 sources of bias that arise prior to answer generation. First, due to the stochastic nature of token generation, there is likely a stochastic bias inherent in all GPT responses. Second, due to in-context generation conditioned by the prompting strategy, a systematic bias probably occurs as well. We attempted to mitigate the stochastic bias by averaging the results from all models and selecting the most common outcome. However, the performance of such averaged models did not surpass that of the GPT-4 models.

To assess whether the GPT models could recognize and correct their own mistakes, we prompted them to attempt another answer after providing incorrect responses. In most instances, the model would acknowledge the mistake and provide the correct answer along with a new explanation. This phenomenon could likely be attributed to the differing mechanics of forward and backward reasoning in LLMs. With forward reasoning, the LLM calculates the probability of the next token without a specific reasoning goal [29]. In contrast, backward reasoning enables the LLM to better contextualize the information. It is crucial to note, however, that we did not request the model to immediately reassess the answer; instead, we informed it of the answer's incorrectness before asking for a reevaluation [29]. Future studies could further investigate the model's ability to self-correct without prior notification of its errors.

In instances where questions were accompanied by images (ie, the model did not have access to the images), GPT models, particularly GPT-3.5, often responded by describing the image that the model had not actually seen. This unexpected information error, known as a hallucination [19], persisted in the GPT-4 models, albeit at a significantly reduced frequency compared to GPT-3.5. Nevertheless, the propensity for overconfidence in entirely fabricated information remains a challenge for the latest generation of LLMs and is a phenomenon not fully understood [30].

Limitations

Technological Limitations of LLMs

Although the results were impressive with GPT outperforming most students in the German medical board examination, it is crucial to remember that these models still possess significant limitations. At the time of our data collection, GPT-4 was incapable of interpreting medical images, such as chest x-rays or histological samples. This is a considerable drawback, given that medical information is inherently multimodal, and the ability to integrate multimodal data will be essential for the adoption of such models in academic and clinical settings. It is anticipated that future GPT iterations and other LLMs will be fully multimodal, which necessitates additional research to evaluate their performance across a more diverse array of questions.

A second concern relates to the stochastic nature of token generation, meaning that answers may vary slightly when questions are posed multiple times [31].

A third concern pertains to the prompt sensitivity of LLMs. This trait can be advantageous as it allows the incorporation of context into the generation of meaningful output and may contribute to the models' Bayesian characteristics [32]. However, prompt sensitivity also increases the risk of systematic errors with repetitive use of the same prompt. Prompt engineering is a discipline that emerged in trying to minimize systematic errors [33,34].

Within the extensive volume of data available online, there are significant risks of bias. Given that LLMs are trained on vast datasets, there is an inherent risk of adopting biases from the underlying data structures. However, fine-tuning through supervised learning on labeled data can help mitigate these risks [35,36].

Limitations of the Use of LLMs in a Medical Context

Despite the seemingly immediate promise of using LLMs in both educational and clinical contexts, the current ethical and regulatory environment needs to be considered to advance the use of these novel technologies safely.

As the representation of medical information of an LLM must not be confused with medical knowledge from a medical professional, it remains crucial to enable students and medical professionals alike to identify LLM-generated outputs as such in order to interpret them very carefully. Different to, for example, a senior medical colleague providing guidance for a clinical decision, an LLM-generated output is neither based on clinical knowledge, nor experience. The risk of such confusion has been described as anthropomorphic projection and efforts for advancing these novel technologies in the medical field need to simultaneously foster the awareness of such phenomena. This differentiation resonates with the provisions of the European Union (EU) on a risk-based assessment approach [37] and, more recently, with the Bletchley Declaration [38]. The latter emphasizes the risks at the "frontier" of AI, at which we operate with the presented project.

While the concerns discussed in the context of medical education—and, more widely, training—are mainly within the realm of AI ethics, more specific limitations apply to the clinical use of these technologies. At the time of our analysis, no commercially available LLM in the EU—including the GPT versions assessed in this work—have an assigned intended medical use, a basic regulatory prerequisite for their use in a clinical context. Without such intended medical use, the Medical Device Regulation (MDR), the regulatory framework for medical devices in the EU, is not applicable. Hence, such a device would not be a medical device in the regulatory sense and could, therefore, not be used in a clinical context without irresponsible safety and liability risks. While it is not the user (eg, researchers or clinicians), but the manufacturer (eg, OpenAI for the ChatGPT models) who assigns an intended medical use—which itself comes with further regulatory requirements—the clinical use of the currently available and mostly all-purpose LLMs remains challenging.

Yet, even developing an LLM with an intended medical use and fulfilling all adjacent regulatory requirements would—as of now—not necessarily resolve the challenge centering around the clinical use of such program, as a key requisite for software as a medical device outlined in the MDR ("devices that incorporate electronic programmable systems, including software, or software that are devices in themselves, shall be designed to ensure repeatability, reliability and performance in line with their intended use." MDR Annex I, Rule 17.1 [39]) is currently considered to be violated, although this question remains subject to debate.

However, the rapid development of technological advances and the concurrent establishment of respective regulations should not be perceived as a "race to get to grips with AI" [40], but should be viewed as a co-evolution to eventually yield the best population-wide benefit from these technological advances. In this light, the emphasis of a "pro-innovation and proportionate governance," as proposed in the Bletchley Declaration, is equally as crucial as the implementation of regulatory frameworks.

Limitations of This Study

Our study has several limitations. We used a specific German medical board examination as a sample to represent the general distribution of medical questions. While it is acknowledged that questions evolve over time and may introduce bias, the objective of the medical board examination is to maintain a consistent level of difficulty, reflecting the minimum required knowledge to attain board approval for medical practice. The distribution of student grades has remained relatively stable over time, leading us to believe that this potential bias is minimal. In the model with translation, we used GPT to translate the questions before applying them to the model. Although we did not observe any, it is possible that translation errors occurred, potentially acting as a confounder in this study. In the context of the medical board examination, multiple-choice questions are posed to elicit clear answers that can be quantitatively assessed. By contrast, in a clinical setting, questions tend to be open-ended, which introduces a different dynamic. Nevertheless, we asked the model to justify its answers to glean insight into its computational process, thus rendering the questions more comparable to open-ended inquiries.

Conclusion

The performance of GPT models in the German medical board examination have surpassed both the passing threshold and the performance of most students. While GPT appears to possess a latent representation of uncertainty, it currently exhibits a significant degree of overconfidence. The introduced metric of CA could facilitate the appropriate measurement and fine-tuning of models to improve this aspect. However, there are numerous limitations that clinicians should be aware of. Challenges such as hallucinations, the stochastic nature of token generation, and prompt sensitivity are highlighted, indicating areas for further research and development. Further, we see the remaining open questions regarding the ethical and regulatory use of LLMs in the educational and clinical context, which need to be addressed on a policy level.

Authors' Contributions

JM participated in the conceptualization, data acquisition, data curation, formal analysis, investigation, methodology, project administration, software, validation, visualization, writing of the original draft, and review and editing of the writing, and should be considered the first author. PD, MS, BR, FPH, and HJB participated in the methodology and review editing and should be considered as second authors. LB and TS participated in the conceptualization, data acquisition, formal analysis, investigation, methodology, validation, review and editing of the writing, and should be considered last authors. Correspondence should be addressed to JM and LB.

Abstract

Background: Although electrocardiogram (ECG) interpretation training begins early in medical school, achieving accuracy in interpretation of 12-lead ECG remains a persistent challenge. We conducted a pilot educational program to compare the effectiveness of a conventional didactic lecture, self-drawing, and self-drawing following a flipped classroom (SDFC) approach.

Objectives:: This study aimed to evaluate the effectiveness of three instructional strategies—traditional didactic lecture, self-drawing, and SDFC approach—in improving ECG interpretation skills among first-year postgraduate (PGY-I) medical residents.

Methods: This study was conducted among postgraduate-year PGY-I residents at MacKay Memorial Hospital over 3 years. The study enrolled 76 PGY-I residents, who were randomized into three groups: conventional control (group 1), self-drawing (group 2), and SDFC (group 3). All participants were provided with the same learning material and didactic lectures. Knowledge evaluation was performed using pre- and posttests, which were administered using questionnaires.

Results: The groups involving self-drawing, both combined with and without a flipped classroom approach, demonstrated better performance on the written summative examination. These findings highlight the benefits of self-drawing in integrating theoretical knowledge with practical approaches to ECG interpretation.

Conclusion: Our study demonstrated promising effects of self-drawing on the recognition of ECG patterns, which could address the inadequacies of traditional classroom teaching. It can be incorporated into routine teaching after validation in a larger cohort.

flipped classroom; electrocardiogram learning; lecture; postgraduate education; junior residents

Introduction

Electrocardiogram (ECG) interpretation remains one of the most important diagnostic tools in health care for screening, early diagnosis, and treatment of cardiovascular diseases such as arrythmias and acute coronary syndrome [1]. ECG interpretation is a cognitive skill that requires considerable time and effort to master [2].

Inaccurate ECG interpretation can lead to missed critical diagnoses, resulting to failure in providing life-saving treatments (eg, complete atrioventricular block, ventricular arrhythmias, and acute coronary syndrome) or unnecessary medical interventions [3,4]. Bogun et al [3] reported that misdiagnosing atrial fibrillation in 4% of patients led to inappropriate treatments such as the unwarranted use of anticoagulant or antiarrhythmic therapies.

Teaching ECG interpretation poses significant challenges due to its complexity, often leading to reluctance among students while engaging with the subject. Although a variety of pedagogical materials (eg, textbooks, research articles, quizzes, videos) are available, and teaching methods vary across medical schools and countries (eg, self-directed learning, workshop-based training, lecture-based instruction), the most effective approach remains unclear [4-7]. It is important to note that self-directed learning refers to student-led engagement with content, while self-drawing is a structured activity aimed at enhancing visual-spatial learning through active reconstruction of ECG patterns. Flipped classroom, another active learning strategy, involves learners reviewing instructional content (eg, videos or readings) before class, allowing in-class time for discussion, problem-solving, and interactive application.

Research indicates that self-directed learning correlates with lower interpretation competence, whereas summative assessment

is associated with improved interpretation competence compared to formative assessment [4]. Studies have suggested that self-drawing enhances memory retention, particularly by reinforcing the characteristic waveform patterns of specific cardiac conditions [5]. Additionally, flipped classroom models have been reported to increase student engagement and facilitate active learning in ECG education [6-8].

This study aimed to evaluate the effectiveness of different ECG teaching strategies, including lecture-based learning (LBL) alone, LBL combined with self-drawing, and LBL combined with self-drawing and a flipped classroom model. By assessing the impact of these approaches, this study aimed to identify effective pedagogical strategies for improving ECG interpretation skills among medical trainees.

Methods

Study Design and Participants

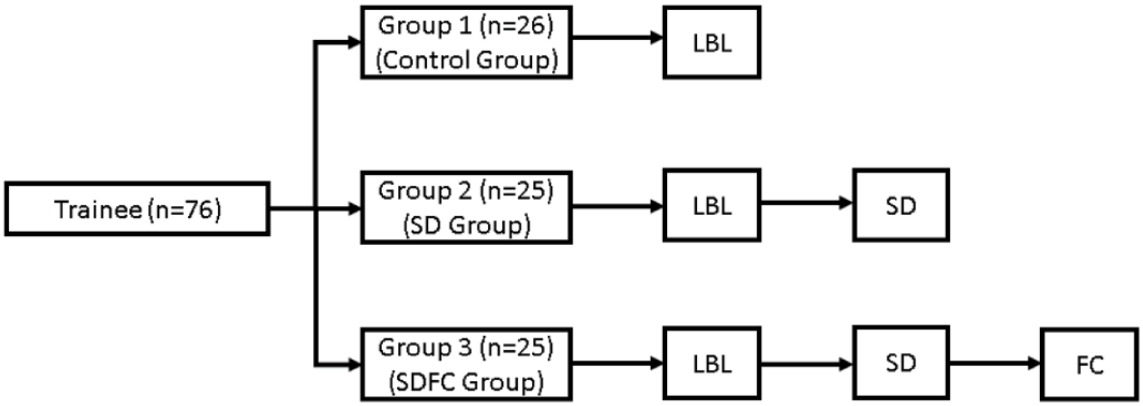
This retrospective study was conducted between September 2020 and June 2023 and included three consecutive cohorts of first-year postgraduate residents at MacKay Memorial Hospital. Participants were divided into three instructional groups based on their training year, with each group drawn from a distinct cohort:

- Group 1 (LBL only) included residents from the 2020 - 2021 academic year (September 2020 to June 2021)
- Group 2 (lecture + self-drawing) from the 2021 - 2022 academic year (July 2021 to June 2022), and
- Group 3 (lecture + self-drawing + flipped classroom) from the 2022 - 2023 academic year (July 2022 to June 2023)

Participants were categorized into three groups: group 1 (control group) underwent conventional LBL; group 2 (self- drawing; SD group) received the same LBL but incorporated self-drawing exercises; and group 3 (self- drawing after flipped classroom; SDFC group) engaged in LBL and the same self-drawing exercises as group 2, followed by a flipped classroom approach (Figure 1).

All participants completed a pretest at the beginning of their cardiovascular ward rotation and a posttest on the final day. The interval between the pre- and posttest was approximately 2 weeks, corresponding to the duration of each participant's cardiovascular ward rotation.

Figure 1. Schematic demonstration of the process of teaching activities. Group 1: Control group: traditional lecture-based learning (LBL) method; Group 2: traditional LBL and self-drawing (SD) method; Group 3: traditional LBL+SD+flipped classroom (SDFC) method.



Conventional LBL Approach

The control group (ie, group 1) was provided preclass learning materials 3 weeks before the teaching session. These materials included textbook chapters, supplementary electrocardiogram resources, online materials, and ECG exercises. During the teaching session, instruction was delivered in a traditional LBL format, consisting of a 120-minute lecture followed by a 15-minute question-and-answer session. After the session, students were given access to the lecture slides for self-directed learning.

Self-Drawing Method

In group 2, students engaged in self-drawing exercises to enhance cognitive processing of ECG patterns. The instructor first illustrated a characteristic ECG pattern for a specific disease, highlighting key features. After the explanation, students were instructed to replicate the ECG from memory without assistance after a 10-minute interval. Upon completion, students' drawings were compared against the standard reference ECG, and differences were discussed to reinforce understanding.

The ECG drawings were required to include the following key elements: (1) rate and rhythm of the ECG; (2) identification of P waves, QRS complexes, T waves, PR interval, QT interval, and QRS duration; (3) characteristic ECG findings for the specific disease being studied.

In group 3, the self-drawing component was introduced following the flipped classroom session.

Flipped Classroom Method

The flipped classroom approach in group 3 consisted of two phases:

- Preclass preparation: (1) Instructor preparation: Teachers underwent microteaching training and developed microvideo lessons, each featuring a real clinical case with guided learning instructions; (2) Student preparation: Three weeks before the teaching session (ie, immediately after the pretest), students were informed of the course structure and FC requirements. They were provided with microlessons and assigned reading materials, including textbook sections, lecture slides, and supplementary ECG resources. One day before their cardiovascular ward rotation, students submitted questions, which were compiled and reviewed by instructors.
- Classroom phase: Each 70-minute session was divided into three stages: (1) Stage 1 (20 minutes): Instructors addressed students' presubmitted questions, clarifying challenging concepts; (2) Stage 2 (20 minutes): An interactive discussion between students and instructors facilitated deeper engagement with ECG interpretation; (3) Stage 3 (30 minutes): A concise lecture was delivered emphasizing on the core and complex concepts.

ECG Competency Assessment

To evaluate students' comprehension and ability to apply acquired knowledge, all three groups completed the same standardized examination. To ensure consistency in difficulty levels, the questions in the pre- and posttests were reviewed and validated by two independent instructors.

The ECG cases used in the pre- and posttests featured the same diagnoses but were derived from different patients, ensuring similar ECG morphology while varying the sequence of questions. Each test consisted of 10 ECG interpretation questions, with each correct response awarded 1 point, yielding a maximum possible score of 10 points. The time limit for the test was 25 minutes.

Statistical Analysis

Baseline characteristics of the three groups were analyzed using appropriate statistical tests. Continuous variables such as age and pretest scores, were expressed as mean (SD) and compared using one-way ANOVA. Gender distribution was presented as a proportion and analyzed using the χ^2 test.

Ethical Considerations

This study was reviewed and approved by the institutional review board of MacKay Memorial Hospital, Taiwan (IRB number: 24MMHIS128e) in accordance with the ethical standards of the Declaration of Helsinki. We prioritized the rights and welfare of our participants. For secondary analyses using existing data, the original consent or institutional review board approval encompasses secondary analysis without the need for additional consent. To ensure participant privacy, all data collected were either anonymized or deidentified. If data could not be fully anonymized or deidentified, we implemented robust protective measures, including data encryption, restricted access, and data use agreements, to safeguard participant information and maintain confidentiality. Participants in this research study are resident physicians, therefore, they did not receive monetary compensation for their involvement. Instead, we provided nonmonetary incentives such as access to professional development resources, educational materials, or opportunities for mentorship. This approach ensured transparency and fairness in the compensation process while acknowledging the valuable time and contributions of the participants.

Within-Group Comparisons

To evaluate whether there was a significant improvement in scores from pretest to posttest within each group, paired, two-tailed *t* tests were conducted. The Shapiro-Wilk test was first applied to assess the normality of the data distribution. Since all groups met the normality assumption ($P>.05$), a parametric paired *t* test was deemed appropriate. The test was conducted separately for each group, with a significance level set at $\alpha=.05$.

Between-Group Comparisons

To determine whether the posttest scores differed significantly among the three groups, a nonparametric approach was chosen due to violations of normality assumptions. Specifically, Mann-Whitney *U* tests were performed for pairwise comparisons of posttest scores between groups. Effect sizes for each between-group comparison were calculated using the formula, $r=z/\sqrt{N}$, where z is the standardized test statistic from the Mann-Whitney *U* test and N is the total number of observations across the two groups. The resulting values were interpreted according to Cohen criteria (small: $r=0.1$; medium: $r=0.3$; large: $r=0.5$). To account for multiple comparisons across the three groups, a Bonferroni correction was applied, setting the significance threshold at $P<.0167$ (.05/3). The following comparisons were analyzed.

Pairwise comparisons were performed with one-tailed Mann-Whitney *U* tests**,** as the hypothesis was directional, aiming to determine whether higher posttest scores were observed in the latter group of each comparison.

While within-group differences (pretest vs posttest) were normally distributed and permitted the use of parametric paired *t* tests, the distribution of posttest scores across the three independent groups violated normality, warranting a nonparametric approach (Mann-Whitney *U* test) for between-group comparisons.

Visualization and Interpretation

Results were visualized using bar plots, where the mean values for pre- and posttest were displayed for each group. Pretest values were represented in blue, while posttest values were depicted in red. Statistical significance was indicated directly on the plots, with *P* values reported as follows: $P<.05$ was considered statistically significant; conversely, $P\geq.05$ was reported as nonsignificant (n.s.), with exact *P* values provided where relevant.

The visualization approach aimed to facilitate the interpretation of both within-group improvements and between-group differences, ensuring clarity in the presentation of statistical findings.

All statistical analyses were performed using SPSS (version 25.0; IBM Corp). Continuous variables such as age and pretest scores were presented as mean (SD) and analyzed using one-way ANOVA. Categorical variables such as gender distribution were expressed as percentages and analyzed using the χ^2 test. The dataset consisted of three independent groups, each undergoing pre- and posttest assessments. Descriptive statistics including mean and SD were calculated for each group to summarize the central tendency and variability of the scores.

Results

Baseline Participants

A total of 76 trainees were enrolled in this study, with 26 students in group 1 (control group), 25 trainees in group 2 (SD group), and 25 students in group 3 (SDFC group). There were no significant differences in age, gender, or baseline ECG test scores among the three groups prior to training (Table 1). Specifically, the findings showed that there were no significant differences in age (F=0.134, P=.88) or pretest scores (F=0.024, P=.98) among the three groups, indicating a similar baseline distribution. The gender distribution (% of men) was also not significantly different among the groups (χ^2=0.126, P=.94). These findings suggest that all three groups were well-balanced in terms of demographic characteristics before the intervention. (Table 1)

Table . Baseline characteristics of enrolled trainees.

Characteristics	Group 1 (n=26)	Group 2 (n=25)	Group 3 (n=25)	F test (df)/χ^2 (df)	P value
Age (years), mean (SD)	26.5 (1.1)	26.4 (0.6)	26.4 (0.6)	0.134 (2,73)[a]	.88
Pretest score, mean (SD)	2.96 (1.31)	2.92 (1.44)	2.88 (1.20)	0.024 (2)[b]	.98
Gender (men), n (%)	80.8	84.0	84.0	0.126 (2)[b]	.94

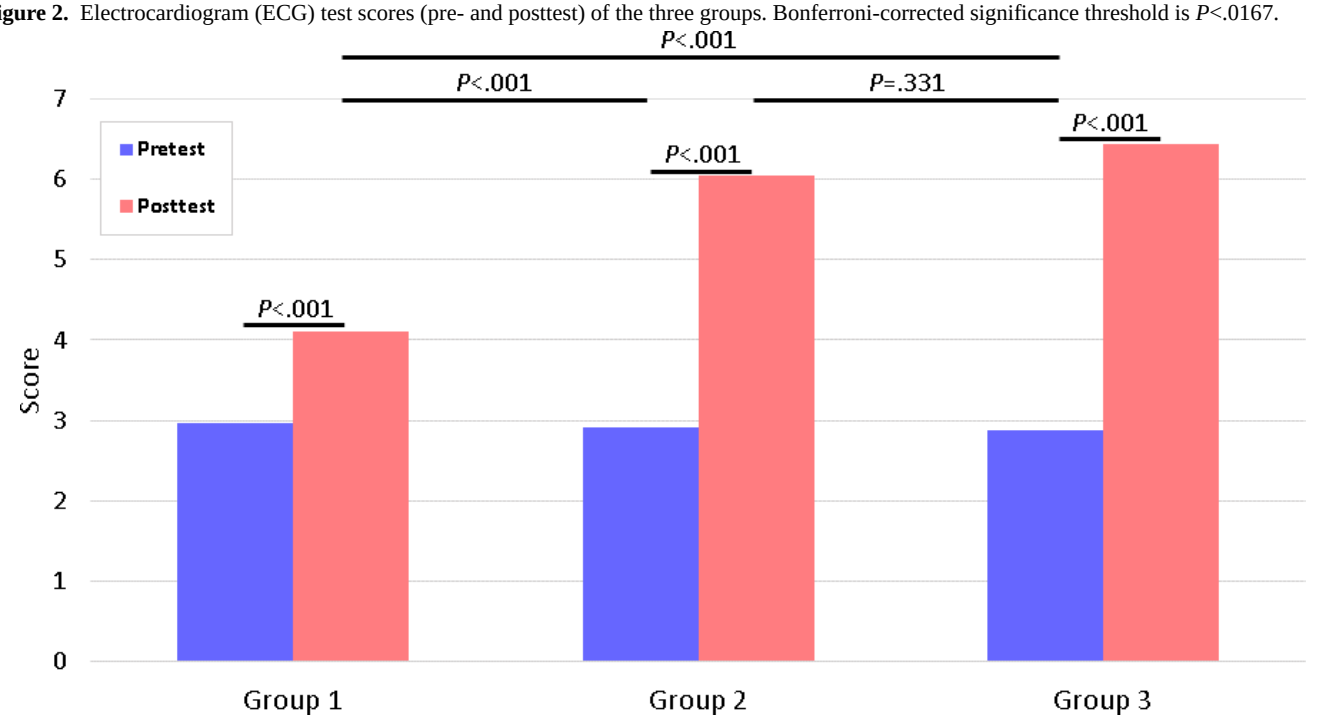
[a]ANOVA.

[b]Chi-square (χ^2) test.

Within-Group Comparisons (Pretest vs Posttest)

The findings demonstrated a statistically significant improvement in posttest scores across all three groups. Group 1 exhibited a significant increase from pretest to posttest. Group 2 also showed a significant improvement, with posttest scores being higher than pretest scores. Group 3 followed a similar trend, with a significant increase from pretest to posttest. These findings suggest that all three groups benefited from the training, with group 1 exhibiting the most substantial improvement (Figure 2).

Figure 2. Electrocardiogram (ECG) test scores (pre- and posttest) of the three groups. Bonferroni-corrected significance threshold is P<.0167.



Between-Group Comparisons (Posttest Scores)

Group 2 outperformed group 1 significantly (U=120.0, z=−3.86, P<.001, r=0.541), which remained statistically significant after applying Bonferroni correction (adjusted α=.0167). Group 3 also significantly outperformed group 1 (U=75.5, z=−4.70, P<.001 , r=0.658), meeting the corrected significance level. However, the difference between group 2 and group 3 was not statistically significant (U=263.0, z=−0.96, P=.33 , r=0.136), even before correction. These results indicate that while group 2 demonstrated a statistically significant advantage over group 1, the difference between group 2 and group 3 was not significant. (Figure 2).

Discussion

Principal Findings

The results of this study demonstrate that all three groups exhibited significant improvements in their ECG interpretation skills following training, suggesting that the instructional methods employed were effective in enhancing students' understanding and application of ECG principles. Among these methods, self-drawing emerged as a particularly impactful learning strategy, as evidenced by the superior posttest performance of students in group 2 (SD group) and group 3 (SDFC group) compared to group 1 (control group). These statistically significant differences were further substantiated by effect size metrics, which demonstrated medium-to-large magnitude improvements in ECG interpretation performance in the intervention groups compared to the control. Statistical differences between groups remained robust after applying Bonferroni correction for multiple comparisons (adjusted α=.0167), confirming that the observed advantages of the self-drawing and flipped classroom interventions were not attributable to chance or multiple testing artifacts.

A key reason why self-drawing may have contributed to improved learning outcomes is its ability to engage sensorimotor processes, spatial reasoning, and active recall. Blended learning yields significantly better ECG competence and confidence among medical students compared to conventional teaching. A stepwise approach to ECG analysis combined with deliberate practice and feedback may serve as an effective complement to lectures for electrocardiography education [9]. Unlike passive learning methods such as reading textbooks, watching videos, or participating in discussions, self-drawing requires students to actively reconstruct ECG waveforms, compelling them to process the anatomical and electrophysiological principles in a highly interactive manner. Prior research suggests that hand-drawn illustrations enhance memory encoding and retrieval by reinforcing visual-spatial associations [10,11]. This effect is particularly relevant for ECG interpretation, where recognizing waveform morphology and associating it with clinical conditions is crucial. The act of manually reproducing ECG patterns may thus create stronger mental representations, leading to enhanced retention and diagnostic accuracy.

Interestingly, the findings indicate that adding a flipped classroom component to self-drawing (group 3) did not lead to statistically significant gains over self-drawing alone (group 2; P=.18). While flipped learning has been widely recognized for enhancing engagement and promoting deeper conceptual understanding, its benefits appear to be diminished when self-drawing is already incorporated as a core learning strategy [12-17]. A previous study revealed that students using a flipped classroom format outperformed their classmates in the ability to interpret ECGs; however, this advantage was not evident when compared to lecture-delivered content. The students were able to prioritize their time when making decisions about attendance, based on teaching modality [18]. One possible explanation is that self-drawing is already an inherently active learning process, requiring students to deconstruct, analyze, and synthesize ECG patterns in a way that other instructional formats—such as passive content review or peer discussion—may not fully replicate. A previous prospective randomized trial indicated summative assessments significantly affect midterm retention of ECG interpretation skills. More intensive teaching showed no advantage over self-directed learning in retention test performance, and the substantial performance decline over eight weeks occurred independently of overall performance levels. These findings have implications for the design of ECG teaching and assessment intervention [19]. As a result, while flipped classroom elements may provide additional instructional support, their relative impact on learning may be reduced when students have already engaged in self-directed drawing exercises.

Moreover, the self-drawing process itself may offer an engaging and enjoyable learning experience, further reinforcing knowledge retention. The act of physically sketching ECG waveforms may create a sense of personal involvement that fosters intrinsic motivation, a factor that has been shown to positively influence long-term knowledge retention [5]. Student feedback on the teaching model indicated that they found self-directed activities beneficial, reinforcing the notion that active participation enhances learning engagement.

Despite these promising findings, certain challenges and limitations should be acknowledged. First, while self-drawing appears to be a highly effective tool for ECG interpretation training, its applicability to other domains of medical education remains to be explored. Second, although efforts were made to standardize the pre- and posttest difficulty levels, individual variations in artistic ability or drawing confidence could have influenced the results. Future studies should investigate whether guidance in sketching techniques or structured drawing templates may further optimize learning outcomes. Additionally, although self-drawing with flipped classroom instruction did not show a statistically significant advantage over self-drawing alone, further research is needed to explore whether longer-term retention benefits emerge when flipped learning is combined with self-drawing over extended periods.

Limitations

Several limitations should be acknowledged in this study. First, the improvement in ECG interpretation skills was assessed by comparing pre- and posttest scores using the same exam questions, albeit with a six-week interval between assessments. It is possible that some participants may have memorized the exam questions, potentially influencing the evaluation of their true ECG interpretation ability. Second, the posttest was

conducted immediately after the teaching program, which may not fully reflect long-term retention and competency in ECG interpretation. Future studies should incorporate delayed posttests to assess whether the observed improvements persist over time.

Third, although self-drawing was found to be an effective tool for ECG training, its applicability to other areas of medical education remains to be explored. Although efforts were made to standardize learning quality by using a checklist for discussions following ECG drawing, the drawing process itself is inherently subjective. Variations in artistic ability or drawing confidence among participants may have influenced the subsequent discussions and, consequently, the learning outcomes. Future research could examine whether structured guidance in sketching techniques or the use of standardized drawing templates might further optimize learning effectiveness.

Last, although self-drawing with flipped classroom did not demonstrate a statistically significant advantage over self-drawing alone, further research is required to explore whether longer-term retention benefits emerge when flipped learning is combined with self-drawing over an extended period. Additionally, investigating the interactive dynamics between different active learning modalities may provide insights into how to better integrate self-drawing within broader medical education frameworks.

Conclusion and Future Directions

This study highlights the effectiveness of self-drawing as a learning tool in ECG education, particularly in enhancing students' ability to recognize and interpret waveform characteristics. The findings suggest that self-drawing offers cognitive and experiential advantages that may not be easily replicated through passive learning modalities such as textbooks, videos, or discussions. While the flipped classroom remains a valuable pedagogical approach, its benefits appear to be moderated when self-drawing is already implemented as a central learning strategy. Given these insights, future research should explore the role of self-drawing across different medical education contexts and investigate how best to integrate flipped learning techniques to maximize knowledge retention and engagement.

Abstract

Background: Augmentative and alternative communication (AAC) is a therapeutic approach and modality of expression for patients with limited or no expressive language. Speech-language pathologists and phoniatricians need to be competent in AAC to treat patients with complex communication needs. For knowledge acquisition and enhancement in AAC, a significant number of e-learning tools are available. To improve e-learning in AAC, it is essential to understand the attributes of these tools, such as formats, content areas, learning styles, or learning goals. However, these structures have yet to be investigated.

Objective: With this study, we aimed to (1) explore free access AAC e-learning tools that are appropriate for students and professionals of phoniatrics and speech-language pathology; (2) gain insight into formats, content areas, learning styles, and learning goals; and (3) investigate structural differences within and between basic and advanced learner level.

Methods: In 2023, we conducted a systematic web-based search with defined search terms in PubMed, peDOCS, Google Scholar, Google, the Apple App Store, and the Google Play Store in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 guidelines and piloting a protocol for data abstraction and validation. Inclusion criteria were free access, a mandatory minimum AAC content, and the use of the English or the German language. Social networks, video-sharing platforms, blogs, and forums were excluded. We analyzed formats (websites, online courses, apps, and podcasts), content areas (types of AAC, diagnostics, therapy, and other content areas), learning styles (visual, auditory, and audio-visual), and learning goals (receptive and performative) within and between basic and advanced level tools.

Results: We identified 131 tools, of which 57 (43.5%) were basic level and 74 (56.5%) were advanced level. Of these 131 tools, 105 (80.2%) were websites, 21 (16%) were online courses, 3 (2.3%) were apps and 2 (1.5%) were podcasts. Only 12 out of 74 (16.2%) tools for advanced learners offered performative tasks. For basic learners no such tasks could be identified. For learning style, all basic tools and most of the advanced level tools were “visual (text)” (57/57, 100% basic vs 66/74, 89.2% advanced). In terms of content, advanced level tools pertained more often to “diagnostics” (28/57, 49.1% basic vs 65/74, 87.8% advanced) and “therapy” (17/57, 29.8% basic vs 64/74, 86.5% advanced). Advanced level courses were more likely online courses (2/57, 3.5% basic vs 19/74, 25.7% advanced) and more often showed audio-visual learning styles compared with basic level tools (5/57, 8.8% basic vs 27/74, 36.5% advanced).

Conclusions: Our study showed that free-access AAC tools for phoniatrics and speech-language pathology varied in formats, content areas, learning styles, and learning goals. Furthermore, we found differences within and between learner levels. Thus, we established a basis for future research in e-learning in AAC.

KEYWORDS

E-learning; digital learning; augmentative and alternative communication; speech-language pathology; phoniatrics; communication disorders; complex communication needs; communication aid

Introduction

Background

Augmentative and alternative communication (AAC) describes ways to support or replace spoken words for people who are unable to speak or communicate effectively using natural speech. Types of AAC include facial expressions, gestures, signs, cards with symbols, letterboards, or the use of electronic communication aids such as voice output devices [1-3]. Some published works concur that sign languages belong to AAC

[4,5] while others state that they are not considered AAC [6]. The types of AAC are categorized into "unaided" and "aided," depending on whether the patient uses solely their body to communicate or a communication aid [7]. Therefore, patients with limited expressive language may use various types of AAC to communicate.

A significant number of patients may benefit from AAC. Numerous medical conditions are known to be the cause of severe speech and language impairments that require AAC. These medical conditions are genetic disorders (eg, Down syndrome [8,9], Rett syndrome [10], and Angelman syndrome [11]), neurological impairments (eg, cerebral palsy [7,12-14], aphasia [7,15,16], dysarthria [7], apraxia of speech [7], Parkinson's disease [14]), motor neuron diseases (eg, amyotrophic lateral sclerosis and progressive muscular atrophy) [14,17,18], intellectual and developmental disabilities [19], severe hearing loss or deafness [20,21], different states of consciousness [22-24], postsurgical states affecting speech (eg, laryngectomy and tracheostomy) [7,25], and other medical conditions such as dementia [14], multiple sclerosis [14], autism spectrum disorder [7,14,26,27], visual impairment [28-30], locked-in-syndrome [31], and treatment in intensive care [32,33]. Creer et al [14] estimate that approximately 0.5% of the population of the United Kingdom are potential AAC users. Thus, AAC is a common therapeutic approach for various kinds of patients.

Patients with special communication needs, who may benefit from AAC, seek treatment in hospitals and established practices for phoniatrics and speech-language therapy [4,34]. Zinkevich et al [35] demonstrated the importance of the implementation of AAC in medical service delivery. Accordingly, phoniatricians and speech-language pathologists need to be competent in AAC. In preparation of this study, we formulated 3 main competences that phoniatricians and speech-language therapists may need in order to provide service to potential AAC users. First, phoniatricians and speech-language therapists should be able to identify patients that benefit from AAC. Second, they should be able to differentiate the types of AAC. Third, they should be able to decide which patients may benefit from what types of AAC. Thus, clinical professionals in phoniatrics and speech-language pathology (SLP) require specific knowledge in AAC to treat patients who may benefit from AAC.

What are sources of knowledge when it comes to AAC? Medical students are not obligatorily taught AAC at university. In Germany, even university students of SLP may have limited knowledge of AAC. In view of this fact, students as well as clinical professionals may search the web for information on AAC. Phoniatricians and speech-language pathologists use e-learning tools to acquire and enhance their expertise in their respective field [36,37], among other learning methods. Consequently, AAC e-learning tools are relevant in phoniatrics and SLP.

e-Learning tools can be described by their structures including formats, content areas, presentation modes, sensory modes, learning goals, target groups, and other describing structures [38]. In terms of formats, a tool can be a website, an online course, an app, a podcast, or another digital format. The learning styles of e-learning tools can be visual, auditory, or audio-visual [39,40]. Furthermore, e-learning tools have either a receptive or a performative learning goal [40]. In addition, e-learning tools may vary in content. Consequently, there are various possibilities to classify e-learning tools. This study focusses on the following e-learning structures: formats, content areas, learning styles, and learning goals.

Why is it essential to gain insight into the nature of AAC e-learning tools? Certain attributes such as "online course," "audio-visual," or "performative" characterize e-learning tools. This characterization may attract a specific group of learners (eg, learners who prefer a visual learning style may use websites with diagrams). A quantitative analysis could identify predominant or lacking structures. A "baseline" or status quo of the e-learning structures of AAC tools would be a starting point for further investigations, understanding and improving e-learning in AAC in the long term. However, the nature of AAC e-learning tools has yet to be investigated.

Goals of This Study

With this study, we aim to (1) explore free access AAC tools that are appropriate for e-learning in phoniatrics and SLP, (2) gain insight into the e-learning features of these tools (formats, content areas, learning styles, and learning goals), and (3) investigate structural differences within and between basic and advanced level tools. Furthermore, our goal is to establish a basis for future research in which we plan to test and evaluate a newly developed AAC e-learning tool for students of medicine and SLP.

Previous Work and Contribution

The study of Lin and Neuschaefer-Rube [38] in 2021 was about the onset of e-learning studies that discussed the improvement of e-learning in SLP, phoniatrics, and otolaryngology. They investigated the e-learning structures of tools in SLP, phoniatrics, and otolaryngology. Differences within and between academic-level learners and clinical-professional learners were found in terms of formats, content areas, and learning goals. Thus, their study presented an initial overview of existing e-learning tools in the interdisciplinary field of SLP and phoniatrics.

Our study contributes to the improvement of e-learning in AAC as being one of the many fields of interest in phoniatrics and SLP. By systematically searching the web for AAC e-learning tools, we gain an understanding of the overall quantity of AAC tools and their availability. An analysis of the e-learning tools in AAC provides further insight into the formats, content areas, learning styles, and learning goals that were state of the art during the time of search. Accordingly, this study should add new findings to the ongoing e-learning research in phoniatrics and SLP.

Methods

Protocol, Checklist, and Registration

Our study is an original, new, and exploratory investigation within the interdisciplinary field of medicine and SLP that targeted interactive learning tools on a niche topic. Therefore,

our study does not conform to the conventional framework of a systematic review. To find the tools, a novel approach was necessary. To adhere the tenets of good scientific practice, we developed structured protocols for the following processes: systematic web-based search, tool selection, and data abstraction and validation. For transparent, complete, and accurate reporting, we proceeded in accordance with PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 [41]. The checklist is provided in Multimedia Appendix 1. This study was registered at our institution Rheinisch-Westfälische Technische Hochschule (RWTH) Aachen University (no CTC-A 24 - 036) and has not been registered elsewhere.

Systematic Web-Based Search

In the summer of 2023, we conducted a systematic web-based search in "Google" (Google Search), Google Scholar, PubMed, peDOCS, the Apple App Store, and the Google Play Store using company owned devices. The use of nontraditional information sources such as "Google" and Google Scholar was necessary in the search for interactive tools. We combined general, academic, medical, and educational search engines to obtain optimal results. The combination of medical and educational databases was chosen since AAC is an interdisciplinary field. By searching App store, we targeted apps that teach about AAC. Gray literature search was not conducted. We used various search terms in English (American and British) and German ranging from specific to broad in the fields of education and medicine. Our IT center ensured that the IP address would not affect the search results. The same computer was used for all web-based searches. However, random checks with a different computer were done to ensure the results were the same. Multimedia Appendix 2 shows a protocol of our search including dates of search, search engines, search terms, number of records screened, and the final tools that met the inclusion and exclusion criteria.

Tool Selection Process

Records Identified, Removed, and Screened for Eligibility

Thousands of search results had been obtained, thus necessitating the implementation of limits for the screening process. We set a limit of the first 25 search results for each broad search term and a limit of the first 10 search results for specific terms. If the number of search results was less than 25 or 10, respectively, the records were limited to that number. In total, this strategy led to 1616 search results that were screened for eligibility. The screening was done by author [JB]. Automation tools were not used. We estimate that half of the records were discarded because they had no relation to AAC. The rationale behind this can be attributed to the polysemy of the acronym "AAC." For that matter, the originally planned search terms with the German abbreviation "UK" were dismissed. In addition, all tools pertaining to how AAC users can learn digitally, rather than how one can learn about AAC digitally, were removed, as well as duplicates.

Screening for Inclusion and Exclusion Criteria

After the initial filtering, approximately 700 - 800 tools remained to be screened for inclusion and exclusion criteria. Those results underwent a selection process based on access, content, and language. According to access, only tools that had a free, immediate, and full access were chosen for this study. Registration and email confirmation were tolerated. In terms of content, we defined a mandatory minimum. To be selected for this study, a tool had to contain a definition of AAC. In addition, a tool had to at least cover one of the following content areas: types of AAC, diagnostics, or therapy to ensure the tools were appropriate for the fields of phoniatrics and SLP. Tools, in this case apps, that only taught sign languages or functioned solely as a talker were excluded. Regarding language, only tools in English and German were included. However, social networks, video-sharing platforms, blogs, and forums were excluded. The search results obtained from the academic search engines yielded research papers. Since we targeted interactive tools rather than books and papers, we screened the results for links to free tools (eg, online courses). Reference lists were not reviewed. Using this technique, we found 3 websites that we added to our tool list. Nevertheless, these 3 tools had also previously been identified in the Google search. The tool list was supplemented by 2 websites added by the authors. Again, duplicates were removed. Finally, 131 tools were left for data abstraction.

Data Abstraction and Validation Process

To ensure a clear and concise method for data abstraction, we piloted a protocol (Multimedia Appendix 3). The data abstraction was done by author JB. Automation tools were not used. Author CNR checked for validity. Both authors followed the protocol and reported no bias. Uncertainties were solved in an interdisciplinary discussion between JB as a speech-language pathologist and CNR as a medical professor.

Tool Analysis

The tools were analyzed by basic and advanced level in terms of the following e-learning structures: formats (websites, online courses, apps, and podcasts), content areas (types of AAC, diagnostics, therapy, and other content areas), learning styles (visual, auditory, and audio-visual), and learning goals (receptive and performative).

Learner Level

We defined the criteria for basic-level and advanced-level tools based on our clinical and teaching experience. Basic level tools provided only general information. This level is appropriate for learners with no previous knowledge of AAC such as students of medicine and SLP. Advanced level tools exceeded general information and required either previous knowledge of AAC or clinical experience. Advanced-level tools are appropriate for students of medicine and SLP with previous knowledge as well as for professionals with clinical experience in AAC.

Formats

The tools of this study were either websites, online courses, apps, or podcasts. We analyzed websites of speech-language pathologists, clinics, consultation offices, self-help groups, institutions for special needs, and specific websites such as the website of the American Speech and Hearing Association and the German Society of AAC. We participated in online courses from universities and other teaching institutions. The online courses were recorded lectures, presentations, or modules on learning platforms. With regards to apps, we targeted those that

taught AAC. However, almost all apps functioned as a talker or trained the user in sign language while lacking a definition of AAC. Consequently, these apps were excluded from this study, leaving only 3 apps to our analysis. Finally, 2 podcasts were analyzed, although we had not explicitly searched for podcasts. In conclusion, the 4 formats in this study were websites, online courses, apps, and podcasts.

Content Areas

We analyzed the tools' content according to our previously defined 3 main competences that professionals in SLP and phoniatrics need: (1) knowledge about the types of AAC, (2) identification of potential AAC users, and (3) assignment of a type of AAC to a patient. Accordingly, the following 4 content areas were defined. The first content area was "types of AAC" for tools that provided a detailed explanation of at least 1 type of AAC or an overview of the types of AAC. The second content area was "diagnostics" for tools that identified at least 1 medical condition of AAC users. The third content area was "therapy" for tools that provided at least 1 example of a patient and their type of AAC. The fourth content area was "other content areas" for tools that provided other valuable information. This information could be downloads (eg, communication boards, sign language cards, collections of symbols, and other material), glossaries or descriptions of specific approaches in AAC. Thus, the 4 content areas in this study were "types of AAC," "diagnostics" "therapy," and "other content areas" to ensure the tools meet the needs of learners in phoniatrics and SLP.

Learning Styles

A total of 4 learning styles were identified, depending on whether the tools contained texts, pictures, diagrams, audio-files, or videos. When information was received via vision (eg, reading a text, interpreting diagrams, and looking at pictures), the tools were "visual (text)" or "visual (picture or diagram)." Auditory tools were audio-files where information was received via hearing. The audio-visual learning style was assigned to videos.

Learning Goals

Inspired by Lin and Neuschaefer-Rube [38], we defined the following learning goals for this study: "receptive" and "performative." A tool was "receptive" when information was only transmitted via reading or listening (ie, passive consumption). When a tool required action, it was "performative." Performative tools were further differentiated into "directive" and "guided discovery" [42]. A tool was "performative (directive)" when the learner had to fulfill directive tasks (eg, "fill-in-the-blank tests," multiple- and single choice tests, and assignment tasks). A tool was "performative (guided discovery)" when reasoning, thinking, and the integration of knowledge was required (eg, exploration of different chapters and submodules and decision making during the learning process) [42]. Performative tools could be both, "directive" and "guided discovery," while "performative," and "receptive" were mutually exclusive.

Statistical Analysis

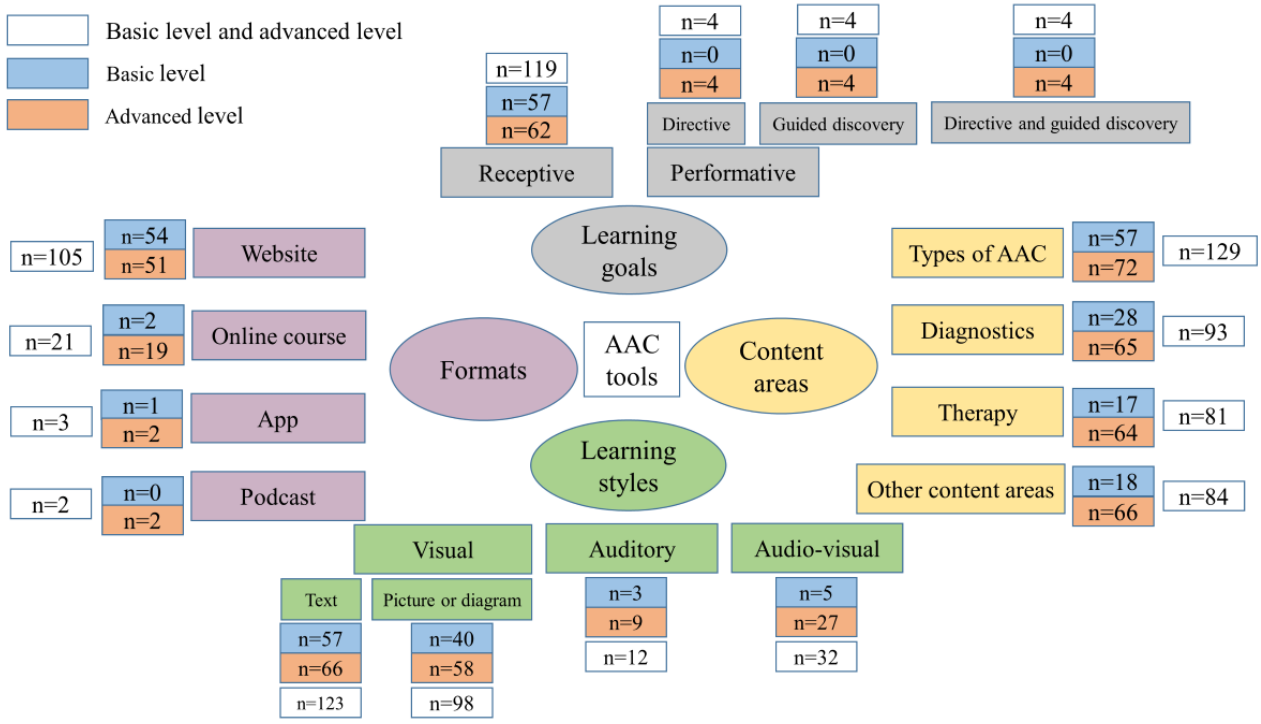
The results were analyzed using descriptive statistics. The attributes (formats, learning styles, content areas, and learning goals) of all tools were calculated, as well as inter- and intragroup differences regarding basic and advanced learner level. With respect to learning styles and content areas, overlaps were taken into consideration. The analysis was conducted using Microsoft Excel.

Results

Overview

We identified 131 tools that met the inclusion and exclusion criteria. Multimedia Appendix 4 shows a summary of the list of tools. Of all tools, 43.5% (57/131) were basic level and 56.5% (74/131) were advanced level. Figure 1 shows the number of basic-level tools and advanced-level tools according to formats, content areas, learning styles, and learning goals. The numbers of content areas and learning styles included overlaps (ie, a tool could cover multiple content areas).

Figure 1. Number of basic level tools and advanced level tools according to formats, content areas, learning styles, and learning goals; n=57 for basic level; n=74 for advanced level. AAC: augmentative and alternative communication.



e-Learning Structures Across All Tools

Of all 131 tools, 105 (80.2%) were websites, 21 (16%) were online courses, while only 3 (2.3%) were apps, and 2 (1.5%) were podcasts. In addition, it is worth mentioning that of the 21 online courses, only 2 (9.5%) were in German. Of the 387 content areas including overlaps, 129 (33.3%) pertained to “types of AAC,” 93 (24%) to “diagnostics,” 81 (20.9%) to “therapy,” and 84 (21.7%) to “other content areas.” Of the 265 learning styles including overlaps, “visual (text)” was predominant with 46.4% (123), followed by “visual (picture or diagram) with 37% (98). Only 12.1% (32) were “audio-visual” and only 4.5% (12) were “auditory.” For learning goals, 90.8% (119) of all 131 tools were “receptive,” while only 9.2% (12) were “performative.” Of these 12 performative tools, 4 (33.3%) pertained to “performative (directive),” 4 (33.3%) to “performative (guided discovery),” and 4 (33.3%) to “performative (directive and guided discovery).” Consequently, most of the tools were websites, taught about the types of AAC, showed the “visual (text)” learning style, and had a receptive learning goal. Multimedia Appendix 5 illustrates the distribution of formats, content areas, learning styles, and learning goals across all tools.

Within-Learner Level Analysis

Basic Level

Within all 57 basic level tools, 54 (94.7%) were websites, 2 (3.5%) were online courses, only 1 (1.8%) was an app and none was a podcast. The total number of content areas including overlaps was 120. Of these 120 counts, 57 (47.5%) pertained to “types of AAC,” 28 (23.3%) to “diagnostics,” 17 (14.2%) to “therapy,” and 18 (15%) to “other content areas.” The total number of learning styles including overlaps was 105. Of these 105 counts, 57 (54.3%) were “visual (text),” 40 (38.1%) were “visual (picture or diagram),” 5 (4.8%) were “audio-visual,” and 3 (2.9%) were “auditory.” As for learning goals, all basic-level tools were “receptive” and none were “performative. In conclusion, most of the basic level tools were websites, taught about the “types of AAC,” showed a “visual (text)” learning style, and all of them were "receptive" (Table 1).

Table . Distribution of augmentative and alternative communication e-learning tools in basic and advanced level according to formats, content areas, learning styles, and learning goals.

	Basic level	Advanced level
Formats		
Formats, n	57	74
Websites, n (%)	54 (94.7)	51 (68.9)
Online courses, n (%)	2 (3.5)	19 (25.7)
Apps, n (%)	1 (1.8)	2 (2.7)
Podcasts, n (%)	0 (0)	2 (2.7)
Content areas		
Content areas, n	120	267
Types of augmentative and alternative communication, n (%)	57 (47.5)	72 (27)
Diagnostics, n (%)	28 (23.3)	65 (24.3)
Therapy, n (%)	17 (14.2)	64 (24)
Other content areas, n (%)	18 (15)	66 (24.7)
Learning styles		
Learning styles, n	105	160
Visual (text), n (%)	57 (54.3)	66 (41.3)
Visual (picture or diagram), n (%)	40 (38.1)	58 (36.3)
Audio-visual, n (%)	5 (4.8)	27 (16.9)
Auditory, n (%)	3 (2.9)	9 (5.6)
Learning goals		
Learning goals, n	57	74
Receptive, n (%)	57 (100)	62 (83.8)
Performative (directive), n (%)	0 (0)	4 (5.4)
Performative (guided discovery), n (%)	0 (0)	4 (5.4)
Performative (directive and guided discovery), n (%)	0 (0)	4 (5.4)

Advanced Level

Of the 74 advanced-level tools, 51 (68.9%) were websites, 19 (25.7%) were online courses, 2 (2.7%) were apps, and 2 (2.7%) were podcasts. The total count of content areas including overlaps was 267. Of these 267 counts, 72 (27%) belonged to “types of AAC,” 65 (24.3%) to “diagnostics,” 64 (24%) to “therapy,” and 66 (24.7%) to “other content areas.” The total number of learning styles including overlaps was 160. Of these 160 counts, 66 (41.3%) were “visual (text),” 58 (36.3%) were “visual (picture or a diagram),” 27 (16.9%) were “audio-visual,” and only 9 (5.6%) were “auditory.” Within the 74 advanced-level tools, 62 (83.8%) were “receptive,” 4 (5.4%) required directive tasks, 4 (5.4%) offered a guided discovery, and 4 (5.4%) were directive and offered a guided discovery. To summarize, most of the advanced tools were websites, the content areas were evenly distributed, “visual (text)” was the predominant learning style, and most of the tools were “receptive” (Table 1)

Between-Learner Level Analysis

We investigated between-learner level differences in formats, content areas, learning styles, and learning goals. To compare basic and advanced level, the higher number of advanced level tools (respectively smaller number of basic level tools) had to be taken into account (57 basic and 74 advanced). Therefore, the absolute numbers cannot be compared. Instead, the percentages (of each component, eg, “website”) within learner levels were compared. In the following paragraphs, the results are presented as “basic level versus advanced level" when results for both learner levels appear in parentheses.

Formats

Websites were more common in basic tools (54/57, 94.7% vs 51/74, 68.9%), whereas online courses were more common in advanced tools (2/57, 3.5% vs 19/74, 25.7%). Apps were slightly more common in advanced tools (1/57, 1.8% vs 2/74, 2.7%). Podcasts only appeared in advanced tools (0/57, 0% vs 2/74, 2.7%). In conclusion, websites were more common in basic

level, whereas online courses, apps, and podcasts appeared more often in advanced level (Multimedia Appendix 6).

Content Areas

All basic level tools and almost all advanced level tools covered "types of AAC" (57/57, 100% vs 72/74, 97.3%). Diagnostic-related content was much more common in advanced level tools (28/57, 49.1% vs 65/74, 87.8%) as were "other content areas" (18/57, 31.6% vs 66/74, 89.2%) and therapeutic-related content (17/57, 29.8% vs 64/74, 86.5%). Advanced level tools were more likely to cover multiple content areas, while showing more diagnostic- and therapy-related content as well as more other content areas (Multimedia Appendix 7).

Learning Styles

All basic level tools and most of the advanced level tools had a learning style pertaining to "visual (text)" (57/57, 100% vs 66/74, 89.2%). "Visual (picture or diagram)" was more common in advanced level (40/57, 70.2% vs 58/74 78.4%), as were "audio-visual" (5/57, 8.8% vs 27/74, 36.5%) and "auditory" (3/57, 5.3% vs 9/74, 12.2%) learning styles. Consequently, "visual (picture or diagram)," "auditory," and "audio-visual" learning styles were more common in advanced level (Multimedia Appendix 8).

Learning Goals

All basic level tools and the majority of the advanced level tools were receptive (57/57, 100% vs 62/74, 83.8%). Respectively, basic level tools did not require performance whereas some of the advanced tools did (0/57, 0% vs 12/74, 16.2%) (Table 1).

Discussion

Principal Results

Our study set out to explore e-learning tools in AAC for phoniatrics and SLP, analyze their e-learning features and investigate differences in basic and advanced learner level. We identified 131 free access e-learning AAC tools and gained insight into their formats, content areas, learning styles, and learning goals. Most of the tools were websites, while apps and podcasts were rare. The predominant content area was "types of AAC" and "visual (text)" was the most common learning style. Most of the tools were "receptive." Within both learner levels, "website" was the predominant format. Within basic level, none of the tools were podcasts and the predominant content was "types of AAC." Within advanced level, the content areas were almost evenly distributed. "Visual (text)" was the predominant learning style in both learner levels. Most of the advanced tools and all basic level tools were "receptive." Websites were more common in basic level, whereas online courses, apps, and podcasts appeared more in advanced level. The content of advanced level tools was more diagnostic-related and therapy-related. "Visual (picture or diagram)," "auditory," and "audio-visual" learning styles were more common in advanced level. All basic-level tools and the majority of the advanced-level tools were receptive.

Interpretation

Number of Tools

The relatively large number of 131 tools is encouraging, given that AAC is not yet fully implemented in the curricula of phoniatrics and SLP (at least not in Germany). This number of tools was a good sample size for our analysis. In addition, the number of tools indicates that AAC appears to be a topic of interest in e-learning. This supports a recent study by Burgio [43], who claim that new AAC e-learning tools evolve constantly.

Formats

It is not surprising that websites were the predominant format for both learner levels due to the web-based nature of this study. However, we were surprised about the rare number of apps that met our inclusion and exclusion criteria. We found a fair amount of AAC-related apps. However, almost all apps functioned as a communication aid (eg, talker) while lacking a definition of AAC, therefore not being an e-learning tool. Other researchers dealt with these kinds of AAC apps [44]. Unanticipated was the relatively high number of online courses. This supports our claim that AAC is a topic of interest in e-learning. If we had not restricted the inclusion to "free access," we might have analyzed even more online courses. The fact that most of the online courses pertained to advanced level is in the nature of the thing. Since almost all online courses covered more than just general information, they were assigned to "advanced level." That made us question our learner level criteria. We could have set the boundary between basic level and advanced level differently (eg, only very detailed tools would be considered as advanced level) or formulated a third category (eg, "intermediate"). That only 2 of the 21 online courses were in German indicates that German-speaking countries lag behind English-speaking countries when it comes to e-learning in AAC. Nevertheless, it is obvious that English (as the predominant language worldwide) is used more often in teaching. The small number of podcasts can be explained by not having specifically searched for podcasts in the first place. Overall, AAC e-learning tools exist in various formats, which indicates that AAC is a topic of interest in e-learning, however, more so in English rather than in German.

Content Areas

It is not surprising that advanced level tools covered more content areas. The more detailed the content, the more likely was a tool assigned to advanced level. Again, this might question our learner-level criteria. However, it is interesting that the contents were almost evenly distributed in advanced level, whereas basic level tools covered more "types of AAC" content. Notwithstanding, it seems logical that general information is about the types of AAC. Therapeutic- and diagnostics-related content have a more "advanced" attribute. What do these results mean? We interpret that "types of AAC" seems to be a "basic" content or "general information" that is essential for learners with no previous knowledge of AAC. Information on the types of AAC seems to be an essential content of AAC e-learning tools and should therefore be considered in the development of future modules.

Learning Styles

As expected, the predominant learning style was "visual (text)," given that 80.2% of all tools were websites. The fact that online courses and podcasts were more likely in advanced level explains the prevalence of "auditory" and "audio-visual" learning styles in this category. These findings may be somewhat limited by the fact that we had not specifically searched for podcasts. However, it is still interesting to note that audio files and podcasts were more common in advanced level.

Learning Goals

In terms of learning goals, we found performative tools only in advanced level. In hindsight, this is obvious. Tools that exceed general information (respectively "advanced level"), more likely required active sensemaking and reasoning. However, we were surprised about the overall small number of performative tools. We therefore suggest that new AAC e-learning tools should offer performative tasks to fill this gap.

Comparison to Previous Work

This study appears to be the first to investigate the structures of AAC e-learning tools in English and German. In designing our study, we were inspired by Lin and Neuschaefer-Rube [38] who analyzed e-learning tools for SLP, phoniatrics, and otolaryngology by their e-learning structures. Although they set slightly different criteria, their overall idea of investigating e-learning tools can be compared with our study. In their study, for example, learner levels were classified into "academic level" and "clinical professional level." We chose a different classification for our study, since it cannot be assumed that all clinical professionals have previous knowledge in AAC. Most of our results reflect those of Lin and Neuschaefer-Rube [38] who also found that visual tools were predominant as well as most of the tools were receptive. The difference between the studies was, interestingly, that performative tools pertained more to academic level learners.

The comparison of our findings to yet another study turned out to be challenging. e-Learning studies increased since the COVID-19 pandemic resulting in numerous available research papers. However, other works in the fields of otolaryngology and SLP focused on surveys [45,46], the effectiveness of e-learning [47] or specific online programs [48,49], rather than exploring and analyzing the attributes of e-learning tools. Therefore, our study is a specific examination in the overall bewildering and evolving field of e-learning research.

Limitations

The findings of this study must be seen in light of 5 limitations. These are (1) incompleteness and difficult replication, (2) limited search terms and search engines, (3) strict inclusion criteria, (4) binary learner level categorization, and (5) quantitative assessment rather than quality rating.

First, e-learning tools are not static since the World Wide Web is an ongoing field of updates and changes [50]. Therefore, this study is only a snapshot of the available tools at the time of data collection undergoing certain inclusion and exclusion criteria. In addition, different IP addresses may lead to different search results. Accordingly, this study is not an investigation of all existing e-learning tools in AAC nor is it replicable. Nevertheless, with a total number of 131 tools, we managed to investigate a high amount, which appears to be a fair representation of the present AAC e-learning scope.

Second, in terms of our web-based search, we could have used more search engines to possibly find more tools [51]. Likewise, we could have added more search terms. Nonetheless, our chosen search engines and search terms led to many results that would not have been manageable without strict inclusion criteria.

Third, the inclusion criterium of a mandatory definition of AAC may have eliminated some advanced tools. In fact, the authors cannot recollect that this was the case during the process of finding the tools. Nevertheless, if we had included tools that did not provide a definition of AAC, probably almost every website within the search results would have entered our study.

Fourth, the binary categorization into either "basic level" or "advanced level" did not leave room for learners with knowledge in between those levels (eg, intermediate level). However, we think that this categorization allows students and clinical professionals to choose a tool according to their knowledge level rather than to their professional status.

Finally, this quantitative study cannot give quality evaluations of the 131 tools, nor do we have proof that the authors of the tools were professionals or well versed in AAC. However, since we investigated the content of the tools, we can conclude that all tools seemed to provide correct information. Despite of its limitations, our study certainly adds to the understanding of e-learning in AAC.

Future Directions

Our study lays the groundwork for future research in e-learning in AAC. More work needs to be done to gain further insight into e-learning in AAC, such as (1) expanding the analysis to other formats, (2) assessing the quality of the tools, (3) conducting a survey study on e-learning in AAC, and (4) developing new AAC e-learning tools.

First, the analysis of AAC e-learning tools on video sharing platforms, social networks, blogs, and forums would be interesting, since we excluded them in our study. Furthermore, an explicit search for a particular format (eg, podcasts) could lead to more results that might be worth investigating. In addition, an assessment of misinformation on AAC in social media would be informative.

Second, a qualitative analysis of AAC e-learning tools would be beneficial for the users of these tools. The best rated tools could be added to a possible future toolbox app [37], or to a German "AAC online learning platform" suggested by Burgio [43]. Furthermore, it would be interesting to investigate correlations between the e-learning structures and the quality of the tools.

Third, a survey study in phoniatrics and SLP could help identify the preferred structures of possible AAC e-learning tools. It would be worth investigating whether phoniatricians and speech-language pathologists have the same demands and would therefore benefit from the same tool.

Finally, we suggest practical applications for the development of new e-learning tools in AAC for students and professionals in phoniatrics and SLP. One example of a possible AAC e-learning tool could be a German, advanced level, audio-visual online course with a knowledge quiz that covers all content areas relevant to phoniatricians and speech-language pathologists. On the basis of this study, we developed such an online course which is currently being tested with students of medicine and SLP at RWTH Aachen University. Another example would be the development of apps that teach AAC (in both languages).

Conclusion

To the best of our knowledge, our exploratory study marks the beginning of the investigation of e-learning tools in AAC for phoniatrics and SLP. We found a fair number of tools and gained insight into their formats, content areas, learning styles, and learning goals. Our data indicate that e-learning in AAC is a topic of interest and needs to be further investigated. Overall, we established a basis for future research and suggested practical applications for e-learning in AAC.

Acknowledgments

This study had no funding or sponsors. JB conducted this study in her role as a scientific speech-language pathologist at the Clinic for Phoniatrics, Pedaudiology and Communication Disorders, University Hospital Rheinisch-Westfälische Technische Hochschule (RWTH) Aachen.

Authors' Contributions

JB conceived the study design, carried out the investigation, performed the analytical calculations, interpreted the data, created the figure, the table, and the multimedia appendices, wrote and revised the manuscript with input from CNR. CNR conceived the original idea, encouraged JB in the study design, suggested the investigation of learner level differences, supervised the conduction of the study, and revised the manuscript.

Abstract

Background: Studies confirm a relationship between learning style and medical career choice in the learning style patterns observed in distinct types of residency programs. Such patterns can also be applied to general surgery, from medical school to the latest stages of training. Aligning teaching strategies with the predominant learning styles in surgical residency programs has the potential to make training more effective.

Objective: This study aimed to determine the learning styles of general surgery residents and professors in a Brazilian teaching hospital and compare the results with the existing literature.

Methods: This was a cross-sectional study conducted in a teaching hospital of a public university in Brazil. Thirty-four general surgery residents of any year of training and 30 professors participated in the study. Participants completed a sociodemographic survey and David Kolb's Learning Style Inventory. This was used to classify participants into one of four distinct types of learners: accommodating, diverging, assimilating, and converging. The relationship between sociodemographic data and learning styles was analyzed using the Fisher test, adjusted using the Bonferroni method, and the effect size was measured using the Cramer V test.

Results: The learning style distribution was similar in both groups, with 43,75% diverging, 42,18% accommodating, 10.93% assimilating, and 3.12% converging styles. A significant relationship was found between sex and learning style (P=.049) and between age and learning style for professors (P=.029). The effect sizes were strong (0.46) and very strong (0.506).

Conclusions: The prevalence of learning styles among general surgery residents and professors at this Brazilian hospital differs from that observed in previous studies, with more diverging and accommodating learners and fewer converging learners, suggesting a shift in learning styles. Understanding learning styles is important for effective surgical training programs. Further research with larger and more diverse populations is needed to confirm these results and explore the factors contributing to the observed differences in learning styles.

Introduction

Background

The concept of learning styles was first developed at the beginning of 1960 as a result of the interest in individual differences while learning [1]. According to Dunn [2], everyone has a unique learning style, like a signature. In this prospect, adjusting the teaching to the different learning styles may help learners and improve educational outcomes. In the current literature, there are various models to determine the learning styles. There is a long and active discussion about whether learning styles are fixed or flexible, and to what extent the context can determine it [3]. Adapting learning styles can enhance student engagement, motivation, and academic performance [4]. Furthermore, the integration of technology and personalized learning approaches has shown promise in enhancing medical education [5].

To provide a more comprehensive understanding, learning styles can be defined as the cognitive, affective, and physiological traits that serve as relatively stable indicators of how learners

perceive, interact with, and respond to the learning environment [6]. Empirical evidence supports the existence of learning styles, demonstrating that individuals exhibit consistent preferences and strengths in how they approach learning tasks. For example, some learners may excel in visual tasks, while others thrive in auditory or kinesthetic activities [7].

The Kolb Experiential Learning Theory (ELT) is a prominent framework for understanding learning styles. The ELT posits that learning is a cyclical process involving four modes: concrete experience (CE), reflective observation (RO), abstract conceptualization (AC), and active experimentation (AE) [8]. Individuals develop preferences for certain modes, leading to four distinct learning styles: converging (AC/AE), diverging (CE/RO), assimilating (AC/RO), and accommodating (CE/AE). The Kolb Learning Style Inventory (LSI) is a widely used tool for assessing these preferences. The validity of Kolb's work in the context of medical education has been demonstrated in numerous studies [9-13], which have found that medical students and professionals exhibit distinct learning style preferences that can influence their academic and professional performance.

Knowledge is the main domain of medical education, but outcomes strongly depend on other domains such as attitude, lifelong learning, and empathy; in surgery, some domains are central including resilience, craftsmanship, and decision-making, among other domains [14].

Research Gap and Problem Statement

Despite the established importance of learning styles in education, limited research has specifically examined their prevalence and impact within general surgery residency programs, particularly in diverse cultural and geographical settings. The clinical and surgical environments present unique challenges for both trainees and educators, requiring the development of complex skills and behaviors [14]. Understanding how surgical residents learn is crucial for optimizing the training process and ensuring the development of competent and well-rounded surgeons.

Moreover, current surgical trainees come from diverse educational, cultural, ethnic, and gender backgrounds, and personal factors also influence their learning characteristics [15]. Little is known about the teaching and learning preferences among surgeons and how they influence the effectiveness of training [16]. Addressing this gap in knowledge is essential for designing effective and inclusive surgical training programs that cater to the diverse needs of learners. To this end, simulation-based surgical training has emerged as a valuable tool for enhancing technical skills and improving patient outcomes [17].

Research Aims and Objectives

Little is known about the teaching and learning preferences among surgeons and how they influence the effectiveness of training [16]. Despite its relevance, studies investigating learning styles in the context of general surgery residency are scarce, especially in countries outside North America and Europe.

Therefore, to address the gaps in understanding learning styles in general surgery, particularly in diverse cultural and geographical settings, this study aims to (1) determine the learning styles of general surgery residents and professors in a Brazilian teaching hospital; (2) compare these findings with existing literature on learning styles in surgery; and (3) discuss the implications of these findings for surgical training programs.

By providing data from a Brazilian teaching hospital, we aim to contribute to a more comprehensive understanding of learning styles in surgical training and inform the development of more effective and inclusive surgical education strategies. This knowledge can inform the development of more effective and inclusive surgical education strategies, ultimately leading to better-prepared and more competent surgeons.

Methods

Study Design and Setting

This cross-sectional study was conducted in 2022 at the Hospital de Base de São José do Rio Preto, a teaching hospital affiliated with Faculdade de Medicina de São José do Rio Preto (a public university in São Paulo, Brazil).

Participants and Recruitment

The study population consisted of general surgery residents in any year of training and hospital professors. All participants were over 18 years old and signed the free and informed consent form.

Data Collection

Data collection involved two instruments: a sociodemographic survey and David Kolb's LSI. The sociodemographic survey collected information on participants' age and sex, and years of residency (for residents) or teaching experience (for professors). The LSI is a validated tool that consists of 12 questions, each with four statements that the participants ranked from 1 to 4 according to their learning preferences. The LSI tool classifies the participants into one of four types of learners based on Kolb's learning cycle: (1) accommodating (learn primarily by experience), (2) diverging (learn by RO), (3) assimilating (learn by exploring associations and interrelationships), and (4) converging (learn by doing or trying things with practical results) [18].

The LSI test was administered in a controlled environment, with a researcher present to provide instructions and clarify any doubts. Participants had 30 minutes to complete it. The sociodemographic survey was completed immediately after completing the LSI test.

Statistical Analysis

Software

Data analysis was performed using the Statistical Package for the Social Sciences (SPSS), version 26.0 (IBM Corp.).

Normality Check

Due to the relatively small sample size and the nature of the data, the Shapiro-Wilk test was used to assess the normality of continuous variables (age and years of experience).

Statistical Tests

A *P* value <.05 was considered statistically significant. The relationship between data was calculated using the Fisher test, adjusted by the Bonferroni method [19]. The Fisher exact test was chosen due to the small sample size and the presence of categories with expected frequencies lower than 5 [20]. The size effect was measured using Cramer V test, which indicates the grade of association between variables: the result is stronger as it approaches the value of 1 [21].

Power

The sample size was calculated using the formula for finite populations, considering a confidence level of 95%, a margin of error of 5%, and an expected prevalence of 50% for each learning style. The minimum sample size was 67 participants, and the total number of residents and professors was 80 [22].

Data Exclusion

Questionnaires that were responded to incorrectly according to Kolb's rules were discarded.

Ethical Considerations

The study was approved by the Research Ethics Committee of Faculdade de Medicina de São José do Rio Preto (approval number: 12345/2022). All participants signed the free informed consent form. Data were anonymized.

Recruitment

This study is grounded in Kolb's ELT, which posits that learning is a cyclical process involving four modes: CE, RO, AC, and AE [23]. Individuals develop preferences for certain modes, leading to four distinct learning styles:

- Converging: Individuals with this learning style excel in AC and AE. They are practical, enjoy problem-solving, and are skilled at applying theories to real-world situations.
- Diverging: Individuals with this learning style excel in concrete CE and RO. They are imaginative, enjoy brainstorming, and are skilled at generating ideas.
- Assimilating: Individuals with this learning style excel in AC and RO. They are logical, enjoy analyzing data, and are skilled at creating models and theories.
- Accommodating: Individuals with this learning style excel in concrete CE and AE. They are hands-on, enjoy taking risks, and are skilled at implementing plans and getting things done.

Our logic model is based on the premise that aligning teaching strategies with the predominant learning styles of surgical residents and professors can enhance the effectiveness of surgical training. We hypothesize that by identifying the learning styles of our participants and tailoring instructional approaches accordingly, we can improve learning outcomes and promote a more engaging and inclusive learning environment.

Table 1 provides a more detailed overview of the four learning styles, including concrete examples of learning activities and instructional approaches that are best suited for each style.

Table . Learning styles, characteristics, and instructional approaches. Source: [8].

Learning style	Characteristics	Example learning activities	Example instructional approaches
Converging	Practical, problem-solver, applies theories	Simulation-based training, case studies	Problem-based learning, hands-on workshops
Diverging	Imaginative, brainstormer, generates ideas	Group discussions, reflective writing	Mentoring, collaborative projects
Assimilating	Logical, analytical, creates models	Literature reviews, data analysis	Lectures, seminars
Accommodating	Hands-on, risk-taker, implements plans	Surgical procedures, clinical rotations	Apprenticeship, on-the-job training

All general surgery residents were invited to answer printed free and informed consent form and the LSI's test, in person. The same was done with the faculty members. The questionnaires were then collected and transformed into digital archives, processed in digital tables after codification.

Statistical Analysis

Power

The sample size was calculated using the formula for finite populations, considering a confidence level of 95%, a margin of error of 5%, and an expected prevalence of 50% for each learning style. The minimum sample size was 67 participants, and the total number of residents and professors was 80 [22].

Results

A total of 64 participants (34 residents and 30 professors) were included in this study. The sociodemographic characteristics of the participants are presented in Table 2. Among the 34 residents, 18 (52.9%) were male and 16 (47.1%) were female. Most residents (91.2%, 31/34) were under 30 years of age. Among the 30 professors, 24 (80%) were male, and 6 (20%) were female, and most of them (17/30, 56.7%) were between 40 and 70 years of age. All professors graduated from universities when traditional teaching methods (ie, primarily lecture-based instruction with limited student interaction) were used, whereas 47% of the residents graduated from universities that used active or mixed teaching methods (ie, incorporating strategies such as problem-based learning, group work, and case studies to promote student engagement).

Table . Sociodemographic characteristics of participants.

Characteristics	Residents (n=34) N (%)	Professors (n=30) N (%)
Age (years)		
<30	31 (91.2)	2 (6.7)
30 - 39	3 (8.8)	11 (36.7)
40 - 70	0 (0)	17 (56.7)
Sex		
Male	18 (52.9)	24 (80)
Female	16 (47.1)	6 (20)
Teaching method used at the University of origin		
Traditional	18 (52.9)	30 (100)
Active or mixed	16 (47.1)	0 (0)

The distribution of Kolb's learning styles is presented in Table 3 and Multimedia Appendix 1. The most prevalent learning styles were diverging (18/34) in the residents' group and accommodating (17/30) in the professors' group.

Table . Learning styles among surgery groups.

Learning styles	Residents N (%)	Professors N (%)	Total N (%)
Converging	1/34 (2.94)	1/30 (3.33)	2/64 (3.12)
Assimilating	5/34 (14.7)	2/30 (6.7)	7/64 (10.93)
Accommodating	10/34 (29.4)	17/30 (56.7)	27/64 (42.18)
Diverging	18/34 (52.9)	10/30 (33.3)	28/64 (43.75)

The relationship between sociodemographic data and learning styles was analyzed using the Fisher exact test (Table 4). A significant association was found between sex and learning style (*P*=.049; Cramer V=0.46), indicating a strong effect size. However, determining which specific categories were significantly different using the Bonferroni post-hoc test was not possible. Among professors, a significant relationship was observed between age and learning style (*P*=.029; Cramer V=0.506), suggesting a very strong effect size. However, specific age groups that differed significantly could not be identified with the Bonferroni post-hoc test, possibly due to the small sample size.

Table . Relationship between sociodemographic data and learning styles.

Variables	*P* value (Fisher exact test)	Effect sizes (Cramer V)
Sex	0.049[a]	0.46 (strong)
Age (residents)	0.999	0.12 (weak)
Age (professors)	0.029[a]	0.506 (very strong)
Teaching method used at the university of origin (residents)	0.999	0.08 (weak)

[a]Statistically significant at P<.05

Discussion

Principal Findings

Our study, utilizing Kolb's LSI, identified the distribution of four learning styles among general surgery residents and professors at a Brazilian teaching hospital. These learning styles are:

- Diverging: Learners who excel in CE and RO, are imaginative, and generate ideas effectively.
- Accommodating: Learners who excel in CE and AE, are hands-on, and enjoy implementing plans.
- Assimilating: Learners who excel in AC and RO, are logical, and create models and theories.
- Converging: Learners who excel in AC and AE, are practical, and apply theories to real-world situations.

The most prevalent learning styles were diverging (52.9%) in the residents' group and accommodating (56.7%) in the professors' group (Table 2 and Multimedia Appendix 1). A significant association was found between sex and learning style

(*P*=.049; Cramer V=0.46), indicating a strong effect size. Among professors, a significant relationship was observed between age and learning style (*P*=0.029; Cramer V=0.506), suggesting a very strong effect size.

Table 2 and Multimedia Appendix 1 show that while diverging was the most common style among residents and accommodating was most common among professors, the overall learning style distribution was relatively similar between the two groups. This convergence, where both residents and professors exhibit a blend of diverging and accommodating tendencies, can potentially facilitate both teaching and learning [16]. The shared presence of these styles suggests that both groups may value CEs and RO (diverging) as well as hands-on activities and practical application (accommodating).

This alignment can be leveraged to support instruction in different ways. For diverging learners (both residents and some professors), emphasize group discussions, brainstorming sessions, and reflective writing assignments. Encourage the sharing of diverse perspectives and the exploration of different approaches to surgical problems. In contrast, for accommodating learners (both professors and some residents), Provide opportunities for hands-on practice, simulation-based training, and real-world clinical rotations. Encourage AE and problem-solving in practical settings. By incorporating these strategies, educators can create a learning environment that caters to the predominant learning styles of both residents and professors, fostering more effective communication, engagement, and knowledge acquisition.

However, it is important to acknowledge that the similarity in distribution does not guarantee a perfect match for all individuals. The relatively lower prevalence of converging and assimilating styles in both groups suggests that those learners might require more tailored support and learning opportunities to ensure their needs are met. This underscores the importance of mapping learning styles when designing a comprehensive residency program, as it provides a basis for guiding the learning needs of all residents and professors, not just the majority.

Implications of Findings

The findings of our study have important implications for surgical education. Understanding the predominant learning styles of residents and professors can help adapt teaching strategies and curriculum design to better meet their needs. For example, incorporating more RO and practical experiences can benefit diverging and accommodating learners while also providing opportunities for AC and AE to support assimilating and converging learners.

Furthermore, with the occurrence of the pandemic, the increased distances imposed by contact restrictions have further deepened these changes. The COVID-19 pandemic has also presented unique challenges to surgical training, with restrictions on in-person learning and clinical experiences. A pan-Romanian survey by Moldovan et al [24] highlighted the impact of the pandemic on orthopedic residents, including reduced surgical volume, limited access to educational resources, and increased stress and anxiety. These challenges may have further influenced the learning styles and preferences of surgical residents and professors during this period.

Comparison With Prior Work

Few studies on learning styles in surgery were found in the literature, but we can state that our results are different from previous results.

In the 1980s, Baker III et al [25] reported a prevalence of converging (46%), followed by accommodating (26%) and assimilating (20%) styles among surgeons. In the 2000s, this pattern was confirmed by Contessa et al [26]. They argued that surgical practice requires quick decision-making and problem-resolution, justifying the converging style and its more pragmatic view. In 2007, Mammen et al [27] published similar results obtained in the US population.

After Quillin [28] reduced his working hours in general surgery residency, he showed the results collected from 1999 to 2012. At that time, the proportion of accommodating learners was higher, especially after 2003, when the workload was reduced [28].

In 2017, for the first time, diverging learners became the majority in a study with 47 surgeons in the United Kingdom [29]. In 2018, also in the United Kingdom, a study with residents in various surgical areas found that converging, followed by accommodating styles were predominant [30]. In 2020, similar results were published in Scotland by Hopkins et al [15]. The most recent publication on the topic reported a predominance of assimilating followed by converging styles in Spain [31]. Table 5 and Multimedia Appendix 2 show the existing literature.

Table . Data of learning styles in surgery through time around the world.

Author	Publication year	Country	Population (n)	Diverging	Accomodator	Assimilating	Converging
Baker III	1985	USA	Surgeons (39)	8%	26%	20%	46%
Drew	1999	UK	Basic surgical trainees (52)	3.9%	27%	9.6%	59.5%
Mammen	2007	USA	General surgery residents (91)	10.6%	14.6%	17.2%	57.8%
Brown	2018	UK	Medical students (60)	20.8%	30.2%	17%	32%
Parra	2021	Spain	Surgical residents and staff (64)	14.1%	21.9%	39.1%	25%

The results of the present study were diverging (43,8%), accommodating (42,2%), assimilating (11,0%), and converging (3,12%) styles. These results amplify the existing literature, showing an increase in diverging and a decrease in converging styles over the years. These findings indicate a shift in the learning preferences of surgical residents and professors, which may have been influenced by various factors, such as changes in surgical education, technological advancements, and sociocultural aspects.

The geographical location may be a possible explanation for our results, as previous studies were conducted in North America and Europe (Multimedia Appendix 1). Cultural differences and variations in surgical training programs across countries may have contributed to the observed differences in learning styles. Another hypothesis may be the course of time: the last two decades have seen huge technological changes, when social media, smartphones, and laptops became widely available, greatly impacting the teaching-learning process [32]. Recent studies have further explored the impact of digital technologies on medical education, highlighting both the opportunities and challenges associated with their integration [5]. Furthermore, with the occurrence of the pandemic, the increased distances imposed by contact restrictions have further deepened these changes [33].

The differing proportions of female residents (47.1%) and professors (16.0%) highlight the ongoing evolution of gender representation in surgery. The historical underrepresentation of women in surgical fields may contribute to differences in observed learning styles between residents and professors [34]. Despite this, the increasing participation of women in surgery over recent decades is a positive trend [22].

Strengths and Limitations

The population included is a small sample of a larger Brazilian surgical group. More data can be further collected to compare the country with other nations, in America, Europe or even Asia. The medical reality in Brazil is diverse and worth a broader approach.

In addition to the small sample size, our study has several other limitations that should be acknowledged. The study had a sampling bias. Our sample was drawn from a single teaching hospital in Brazil, which may not be representative of all general surgery residents and professors in Brazil or other countries. This limits the generalizability of our findings. Additionally, the voluntary nature of participation may have introduced selection bias, as those who chose to participate may differ systematically from those who did not. In addition, there was measurement bias; the Kolb LSI is a self-report instrument, which is subject to social desirability bias and response bias. Participants may have answered the questions in a way that they perceived as more favorable or aligned with societal expectations, rather than reflecting their true learning preferences. Moreover, our study did not fully explore the potential influence of various sociodemographic factors, such as cultural background, socioeconomic status, and prior educational experiences, on learning styles. However, we did not collect data on other potentially relevant sociodemographic factors such as ethnicity, social class, migration background, or detailed information about prior educational experiences. These factors may interact with learning styles in complex ways and could have influenced our results.Finally, the cross-sectional design of our study limits our ability to draw causal inferences about the relationship between learning styles and other variables. A longitudinal study would be needed to examine how learning styles evolve over time and how they impact training outcomes. These limitations should be considered when interpreting our findings.

Further research is needed to explore the underlying factors that influence these learning styles, such as personality traits, prior educational experiences, and cultural background. Understanding these factors could allow for more tailored interventions to optimize learning. Moreover, future studies should investigate the potential impact of different learning styles on surgical performance metrics, such as technical skill acquisition, error rates, and patient outcomes. This would provide valuable insights into how learning style preferences translate into real-world surgical practice.

Conclusions

This study found that diverging and accommodating learning styles were more prevalent among general surgery residents and professors in a Brazilian university hospital, differing from previous North American and European studies. The decreased prevalence of the converging style is notable and may be due to changes in surgical education, technology, and cultural differences. Understanding these learning styles can guide more effective and inclusive teaching strategies in surgical residency programs. Further research with larger, diverse populations is needed to explore the relationships between learning styles, demographics, and training outcomes.

Abstract

Background: Medical students face high levels of burnout and mental health issues during training. Understanding associated factors can inform supportive interventions.

Objective: This study aimed to examine burnout, psychological well-being, and related demographics among Iranian medical students.

Methods: A cross-sectional survey was conducted among 131 medical students at an Iranian University. The instruments used included the Maslach Burnout Inventory-Student Survey and the Symptom Checklist-90-Revised. Descriptive statistics, multivariate regression, and tests for group differences were used to analyze the data.

Results: The MBI-SS subscale scores indicated moderate emotional exhaustion, mean 15.00 (SD 7.08) and academic efficacy, mean 14.98 (SD 6.29), with lower cynicism, mean 10.85 (SD 5.89). The most commonly reported mental health issues were depression and obsessive-compulsive disorder. Poor psychological well-being was associated with higher overall burnout, but no significant gender differences were found. Burnout levels varied by academic year across all Maslach Burnout Inventory-Student Survey domains.

Conclusions: Despite their health education, medical students in this study reported significant burnout and mental health distress, with strong associations between the two. These issues may impact student retention and post-graduation practice plans. Supporting well-being during training is critical for positive student and physician outcomes.

Introduction

Kary and Pines [1] initially posited the concept of academic tedium and its impact on students. They suggested that this phenomenon is not confined to a specific educational level but can manifest at various stages of schooling, including both school and university environments [1]. Based on the author's viewpoint, students might be struggling with a condition marked by a fading enthusiasm for learning, noticeable lack of motivation, and an overwhelming sense of emotional exhaustion. Later, Maslach and Jackson [2,3] specified burnout as the experience of physical and emotional drain caused by chronic stress. Burnout is the state of physical and mental fatigue caused by work, study, or any caregiving activities. It can also be known as an adverse emotional, cognitive, and physical reaction to the study, work, and life pressures. Burnout was officially classified by the World Health Organization as an occupational phenomenon in 2019 and included in the International Classification of Diseases (*ICD-11*).

Educational burnout is a type of burnout experienced during studying. To better view educational burnout, it was expanded to three factors: emotional exhaustion, cynicism, and feelings of inefficacy [4,5]. Emotional exhaustion reflects feelings of exceeding emotional resources due to academic demands. Cynicism is a negative, unresponsive, or overly snapped response to a phenomenon. Feelings of inefficacy refer to a

reduction in academic effort, leading to a sense of incompetence and reduced academic achievement. Based on findings from a systematic review published in 2021, it was determined that educational burnout affected more than 40% of students [6]. This outcome implies a heightened susceptibility to burnout among medical students on a global scale. However, few studies have examined this problem, specifically among medical students in Iran. While 16% of Iranian medical students reported burnout in one study [7], assessing prevalence rates at individual universities could further inform supportive programs. Educational burnout has an essential role in medical students' overall health and could easily impact the quality of their learning [8].

A study on 14,000 students from different countries showed that approximately 35% of the students had been diagnosed with at least one mental health disorder, such as depression or anxiety [9]. Among students, university students showed a higher likelihood of mental health disorders, and among them, medical students' issues were significant. Medical schools pose multiple demands on students. First, enrollment in medical training coincides with adolescence and early adulthood, periods already associated with vulnerability to mental health disorders [10-12]. Second, the intense nature of medical education requires students to assimilate vast amounts of health information while coping with exposure to myriad diseases [11,12]. Consequently, studies report substantial rates of depression (11% - 37%), anxiety (7.4% - 30%), and other issues in this population internationally [13-15]. Evidence suggests that positive mental health aids coping [16], yet remains understudied in Iranian cultures.

Extensive evidence demonstrates intricate connections between burnout and mental health issues among medical students. Additional studies reveal substantially higher risks of depression, anxiety, suicidal ideation, concentration deficits, and physical symptoms compared to their peers [12,17-20]. Up to half of graduating students experience burnout, linking this syndrome to exacerbated mental health decline [18]. Ultimately, these concerning rates significantly exceed general population trends, underscoring the crisis of psychological well-being in medical education. Implementing supportive interventions requires further investigating specific student populations.

The aims of this study are twofold. Primarily, we assess the prevalence of mental health issues and burnout among native Iranian medical students at Zanjan University of Medical Sciences. Additionally, we delineate connections between mental health status and burnout risk by evaluating associated academic and personal factors. By understanding these relationships, targeted interventions can eventually be developed to promote the psychological well-being of Iran's future physicians during their demanding training period.

Methods

Study Design and Participants

This cross-sectional study was conducted at Zanjan University of Medical Sciences, Zanjan, Iran, focusing on the experiences of 1500 medical students. These trainees constituted the target of our research, with their perspectives and characteristics as students comprising the central subject of investigation. Participants were recruited using a convenience sampling method. Our research team directly contacted the students, explained the study's aims, invited their voluntary participation, and emphasized the confidentiality of their responses. We then sent an electronic survey link to consenting participants. Strict data quality control measures were implemented, with incomplete questionnaire submissions excluded from the analysis to uphold the integrity of the results. Based on a previous study [21], the minimum required sample size was 120 students; however, 140 surveys were distributed, and 131 fully completed questionnaires were returned. Those with missing data or students who indicated having a diagnosed mental health issue were excluded.

Measures

Demographics

The basic sociodemographic information included age, sex, residence, history of a positive COVID-19 test, underlying diseases, diagnosis of mental health issues, and level of education. The levels of education were categorized into three sections: the initial seven semesters, referred to as preclinical, followed by a two-semester externship, and finally, a three-semester internship. At the preclinical level, students learned about basic sciences and pathophysiology; in the externship phase, they would pass a short course in each hospital unit. The residential status comprises a parental home, independent home, or a dormitory. Students were asked directly about underlying diseases, including diabetes, hypertension, and chronic disease. Additionally, they were asked whether they had been diagnosed with any mental health condition and whether they had received any treatment.

Burnout Measurement

Burnout symptoms were measured by the Persian version of the MBI-SS [3,22,23]. It comprises 15 items, which are divided into three dimensions: emotional exhaustion, cynicism, and academic efficacy . Each item has been rated on a 7-pointed Likert scale. Academic efficacy scores were reverse-coded; therefore, it was scored oppositely. A high score in three dimensions indicated greater burnout. The maximum possible scores for emotional exhaustion, cynicism, and academic efficacy were 30, 24, and 36, respectively.

Mental Health Measurement

The Symptom Checklist 90 (SCL-90), developed by Derogatis was used to assess mental health. This scale consists of 90 items, each rated on a 5-point Likert scale, effectively measuring ten primary psychological symptoms [24]. The ten psychological symptoms measured by the Symptom Checklist-90-Revised (SCL-90-R) are somatization, obsessive-compulsive, interpersonal sensitivity, depression, anxiety, hostility, phobic anxiety, paranoid ideation, psychoticism, and sleep problems. If a person's average score for the questions related to these symptoms was greater than 2, it indicated potential psychological issues. The Global Severity Index (GSI) was calculated for our analysis, which measures the extent or depth of psychiatric disturbances. Specifically, the GSI is the average

score across all responded items and serves as an overall measure of psychiatric distress. Therefore, this study analyzed the positive rate of each subscale and the GSI. Notably, the validated Persian version of the SCL-90-R was used for this student population [25].

Statistical Analysis

We performed all statistical analyses using SPSS (version 20.0; IBM Corp) and Stata (version 12; StataCorp), and figures were drawn using R software (version 4.4.1; R Foundation for Statistical Computing) was used for visualization, including the ggplot2 package (version 3.5.1). Multivariable regression was used to assess factors associated with the three burnout subscales to examine the correlation between the response variables. The model included sociodemographic variables such as history of COVID-19, place of residence, and mental health status. The variables that were found to have a significant impact on the outcome were retained in the model.

Ethical Considerations

Ethics approval for this study was provided by the Ethics Committee of Zanjan University of Medical Sciences (IR.ZUMS.REC.1400.418). This committee approved all experimental protocols. The authors confirmed that relevant guidelines and regulations were used in all experiments. No participants were younger than 16 years. All students provided written informed consent.

Results

The study initially involved 140 students; after excluding those who dropped out due to missing answers or diagnosed mental illness, the remaining sample consisted of 131 participants. The average age of these remaining participants was approximately 24 years, with a mean of 23.95 (SD 3.69) years. Table 1 summarizes other sociodemographic characteristics of the student group. Approximately 66% were female students, while only 10% of the participants were married. An almost equal percentage of students across different academic levels completed the questionnaires. Additionally, 62% of the students had a history of a positive COVID-19 test, while 3.8% reported underlying diseases.

Table . Socio-demographic characteristics.

Sociodemographic variables	Participants (N=131), n (%)
Sex	
Male	44 (33.6)
Female	87 (66.4)
Marital status	
Single	118 (90.1)
Married	13 (9.9)
Residence	
Parental home	53 (40.5)
Own home	43 (32.8)
Dormitory	35 (26.7)
Positive COVID-19 test history	
No	50 (38.2)
Yes	81 (61.8)
Underlying diseases	
No	126 (96.2)
Yes	5 (3.8)
Academic level	
Preclinical	42 (32.1)
Externship	47 (35.9)
Internship	42 (32.1)

Table 2 shows the positive rates of SCL-90-R subscales by sex. Obsessive-compulsive disorder and depression showed the highest prevalence among symptoms. A χ^2 test examined the percentage differences between male and female students. The only symptom found to be statistically significant between the two sex was phobic anxiety. Among female students, paranoid ideation had the highest prevalence, whereas obsessive-compulsive disorder was more prevalent among male students.

Table . Comparison of SCL-90-R[a] subscales based on sex.

	SCL-90-R positive rates in male students n (%)	SCL-90-R positive rates in female students, n (%)	Total SCL-90-R positive rate, n (%)
Hostility	10 (22.7)	13 (14.9)	23 (17.6)
Anxiety	11 (25.0)	14 (16.1)	25 (19.1)
Obsessive-compulsive disorder	14 (31.8)	18 (20.7)	32 (24.4)
Interpersonal sensitivity	10 (22.7)	19 (21.8)	29 (22.1)
Somatization	6 (13.6)	12 (13.8)	18 (13.7)
Psychoticism	5 (11.4)	7 (8.0)	12 (9.2)
Paranoid ideation	8 (18.2)	21 (24.1)	29 (22.1)
Depression	12 (27.3)	20 (23.0)	32 (24.4)
Phobic anxiety[b]	9 (20.5)	7 (8.0)	16 (12.2)
Others	8 (18.2)	11 (12.6)	19 (14.5)

[a]SCL-90-R: Symptom Checklist-90-Revised.

[b]*P* value (χ^2 test)=.04 male versus female.

The boxplots in Figures 1 and 2 display the MBI-SS subscale scores across genders and academic levels. According to this figure, academic efficacy had the widest range of scores for male students. Additionally, female students exhibited lower mean scores compared to male students across all subscales. These boxplots indicate that interns had higher burnout scores overall. More detailed descriptive statistics can be found in Multimedia Appendix 1. Figure 3 shows a comparison of the total scores on the SCL-90-R between different levels, revealing that externs had the highest scores.

Figure 1. Comparison of Maslach Burnout Inventory-Student Survey subscale scores by sex.

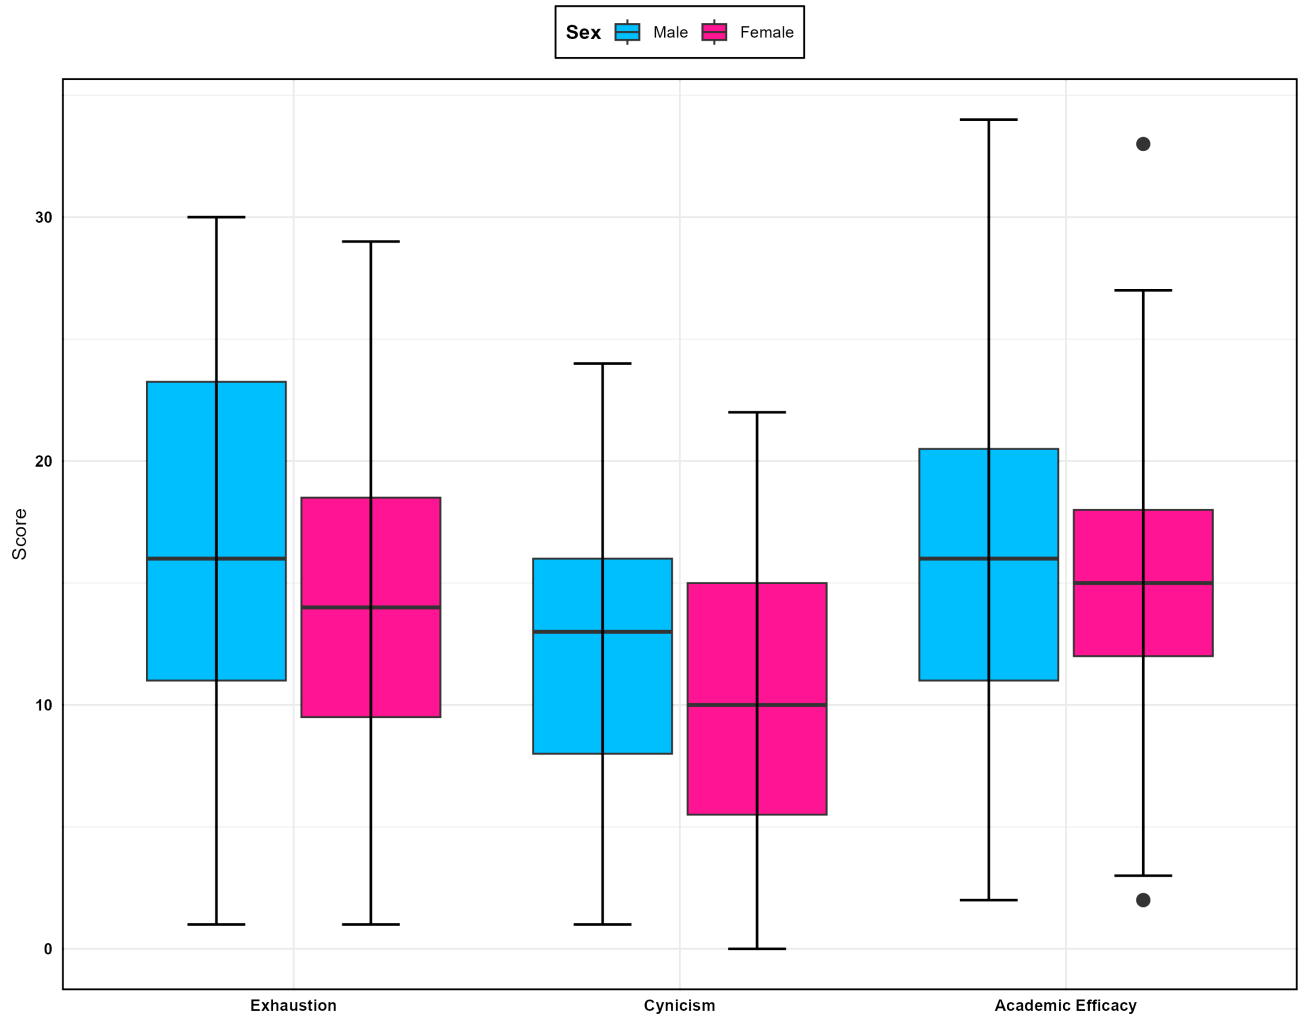

Figure 2. Comparison of Maslach Burnout Inventory-Student Survey subscale scores across academic levels.

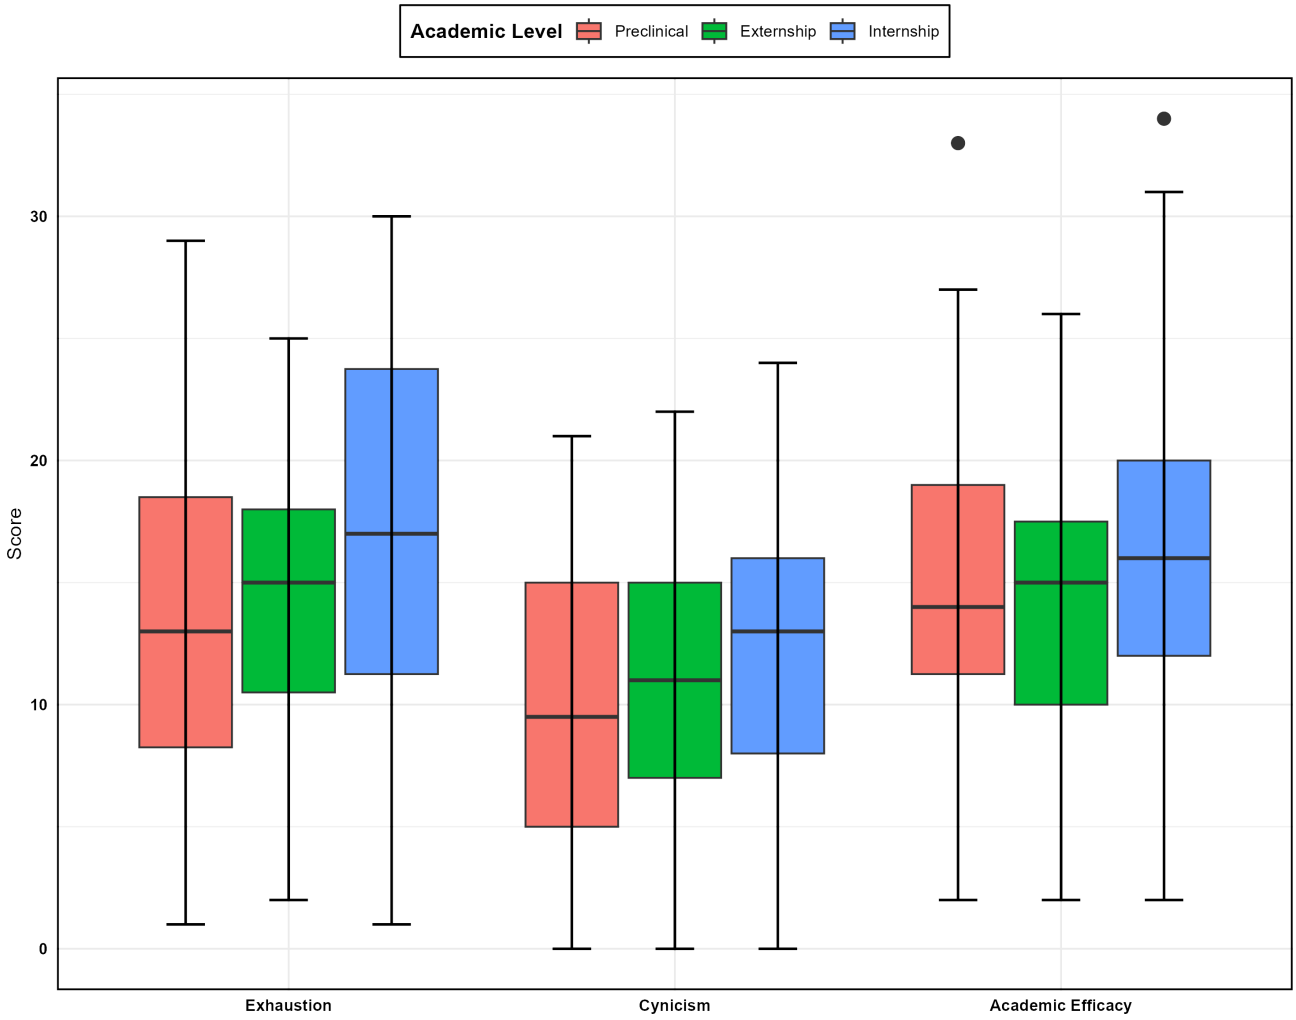

Figure 3. Comparison of Global Severity Index scores across academic levels.

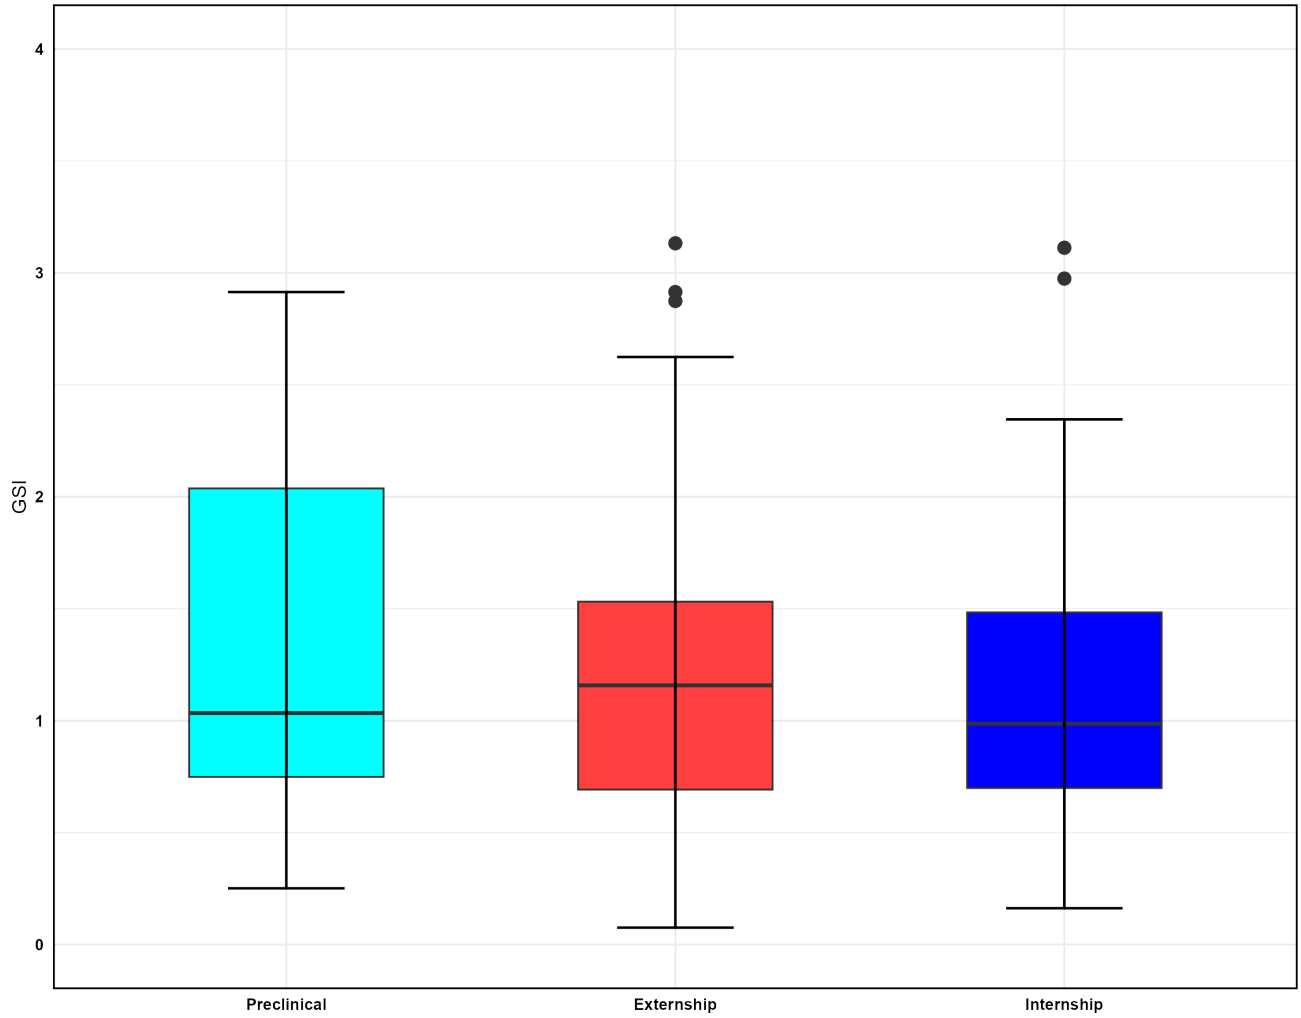

Initially, the correlation between the three dimensions of burnout (academic efficacy, cynicism, and emotional exhaustion) was examined in the modeling data. The findings revealed that academic efficacy had a significant correlation with both cynicism (r=0.41, P<0.05) and emotional exhaustion (r=0.37, P<0.05). Additionally, emotional exhaustion positively correlated with cynicism (r=0.78, P<0.05). Given these significant correlations among the burnout dimensions, a multivariable regression analysis was deemed appropriate for further modeling. Table 3 presents the results of the multivariable regression analysis. An increase of one score in GSI corresponded to an increase of 5.67, 1.71, and 4.69 scores in emotional exhaustion, cynicism, and academic efficacy, respectively. Overall, the students in the internship phase has 4.19 and 3.02 scores higher than preclinical students in emotional exhaustion and academic efficacy, respectively, whereas they had only a 0.24-difference in cynicism. Furthermore, males scored 1.53 and 0.10 points lower than female students, respectively. A comparison of β coefficients shows that GSI and internship status had significantly different effects on the three dimensions of the MBI-SS.

Table . The association of educational burnout with mental well-being, academic level, and sex.

	Emotional exhaustion				Cynicism				Academic Efficacy				Equality of β coefficients	
	β coefficient	95% CI	*F* value	*P* value	β coefficient	95% CI	*F* value	*P* value	β coefficient	95% CI	*F* value	*P* value	*F* value	*P* value
GSI[a]	5.67	4.02-7.32	6.55	<.001	1.71	1.41-2.00	5.56	<.001	4.69	3.31-6.07	4.79	<.001	18.72	<.001

[a]GSI: Global Severity Index.

Discussion

Principal Findings

Zanjan University, a prominent institution in Iran, attracts students from various cities. Therefore, studying its students' mental and physical well-being can provide valuable insights into the overall condition of Iranian students.

Our study examined crucial mental health issues such as hostility, obsessive-compulsive disorder, and interpersonal sensitivity among medical students. In brief, our study did not detect any statistically significant differences in overall mental health scores between students across different academic level or sex. However, phobic anxiety was the only mental health issue that was significantly different between genders. Students at the externship level had higher GSI scores. This increase in mental health problems among the students is understandable, as it occurred during their clinical rotations in hospitals, where they were exposed to diverse patient cases and experienced various illnesses for the first time in their academic careers. Facing such novel and potentially challenging situations can reasonably be expected to take an emotional toll.

In previous studies, depression, stress, and anxiety are the three most prevalent mental health issues among medical students [7,11-13,15,26,27]. Cuttilan et al [13], who reviewed studies from Asia in their meta-analysis, showed that 30% of Middle Eastern students experienced depression. While our study found a slightly lower prevalence, the difference could be caused by the university environment, sample size, and social or climatic differences. Nonetheless, the rate of depression remains considerable. Aghajani Liasi et al [7], who studied the prevalence of burnout and mental health at one of Tehran's universities, reported a 37% of depression among medical students. They used the Depression, Anxiety, and Stress Scale questionnaire to survey mental health. Therefore, despite being of the same nationality, the main reason for the variation between the findings of our study compared to those reported by Aghajani Liasi et al may be due to differences in the questionnaires.

Anxiety is one of the significant issues experienced by medical students. A systematic review revealed the wide range of anxiety prevalence across different countries (15.5%-70.0%) [27]. Our study found an anxiety disorder prevalence of 19% among students at Zanjan University of Medical Sciences; this places our sampled student population in the lower quartile of anxiety rates compared to the broader range reported by medical trainees across the world.

Unlike the questionnaire used in our study (ie, SCL-90-R), many previous studies on student stress have used the DASS scale and reported high rates of stress among students. For example, a meta-analysis found that 52.7% of medical students reported significant stress during training [13]. Additionally, studies by Aghajani Liasi et al [7] and Moutinho et al [28] reported stress rates of approximately 30% and 47%, respectively within their student samples, despite the differences in study populations. While these percentages vary, these studies collectively highlight that clinically significant stress is a widespread and impactful issue for many students across educational contexts [7,28]. However, our study did not directly measure student stress, which is a limitation compared to previous existing research.

Our study showed that although there was no statistically significant difference in burnout scores between male and female students, female students reported lower burnout levels in the three burnout subscales compared to male students. Additionally, students in later years of medical education reported higher burnout levels than students in the initial phases. This indicates

that the interns about to graduate showed higher burnout levels, especially feeling emotionally drained.

The relationship between years of medical education and burnout levels is interesting. While some studies have suggested that burnout levels may increase with advancing years of medical education due to prolonged exposure to stressors, the evidence remains inconclusive [29,30]. This suggests that the intense pressures of medical school take an cumulative toll.

Prior studies have found that medical students experience some of the highest rates of burnout compared to other populations [4,6,11,20]. However, findings regarding the relationship between gender and burnout have been mixed [29,31-33]. There was more evidence suggesting that male students are more likely to face burnout than female students [6]. Therefore, it can be concluded that the relationship between gender and burnout in medical students may be influenced by various factors such as the specific population, sample sizes, and the definition of burnout used in the research.

Our study explored several potential influencing factors on the three burnout dimensions in medical students, including mental health status, gender, and academic level. These variables significantly impacted emotional exhaustion, cynicism, and academic efficacy scores. To date, no study had directly examined the linkage between mental health disorders and burnout in this population, representing a gap in understanding. However, related research by Dyrbye et al [16] showed associations between positive well-being and professionalism, which burnout may undermine. Additionally, psychologists have suggested that students with psychiatric conditions demonstrate greater emotional exhaustion [17,18,34]. Notably, in our analysis, mental health had a much more significant effect on emotional exhaustion compared to the other burnout facets. Other studies found students with higher burnout reported more suicidal thoughts and behaviors [6,17,18,26,27,34,35]. Integrating those findings with our results suggests that mental health could play an intermediary role between burnout and suicidal risks. These interrelationships between wellness, distress, and functioning highlight the need for more holistic support to promote student resilience.

Limitations

This study has some limitations. The cross-sectional design cannot determine causal relationships between variables. Additionally, the convenience sampling and voluntary participation could indicate that students with psychological issues may have been less inclined to take part or answer honestly. While different variables were recorded, others such as physical activity, social support, and economic status, should be investigated in future studies. Longitudinal follow-up studies warrant a better understanding of mental health's impact on burnout trajectories.

Another limitation was the rate of female participation compared to male participants for two reasons. According to the university's annual statistics, about 55% of students are women, increasing the female sample rate in the convenience sampling method. However, among the Iranian population, women are more interested in psychological issues and experience exhaustion about improving mental health, resulting in more women participation in our study.

An additional limitation is the potential link between financial issues, mental health, and burnout. Our survey did not include detailed questions about participants' financial situations, which could have influenced their responses to other questions. To partially address this, we included a question about place of residence, which could indirectly reflect financial circumstances and their possible effects on other survey responses.

Conclusion

The demanding nature of academic work and personal lives faced by medical students can take a severe mental toll, leading to burnout. Despite being educated on physical and psychological health, students often neglect their own well-being. This research confirms that mental health issues directly contribute to students' emotional exhaustion, cynicism, and reduced feelings of academic self-efficacy. Both burnout and psychological problems increase the risk of students dropping out or deciding against careers as general practitioners after graduation, resulting in wasted resources invested in their training. Most alarmingly, if the society cannot ensure the mental well-being of its future doctors, the overall population's health will suffer consequences. There is an undeniable connection between medical trainees' health and the communities they will serve. Fostering resilience and coping abilities in students must be a key priority, as their personal health and capacity to provide quality patient care in the future hinges on it. The findings of this study highlight the prevalence of burnout and mental health issues among medical students, underscoring the profound importance of addressing this problem for the well-being of the general population, who will rely on these future physicians for care.

Acknowledgments

The authors express their gratitude to Prof. Xiaolin Xu for his contributions as a senior author in guiding the research and to Dr. Omid Saed for his suggestion for the questionnaires, Department of Clinical Psychology, Zanjan University of Medical Sciences.

Abstract

Introduction: Extracorporeal membrane oxygenation (ECMO) is a critical tool in the care of severe cardiorespiratory dysfunction. Simulation training for ECMO has become standard practice. Therefore, Keck Medicine of the University of California (USC) holds simulation-training sessions to reinforce and improve providers knowledge.

Objective: This study aimed to understand the impact of simulation training approaches on interprofessional collaboration. We believed simulation-based ECMO training would improve interprofessional collaboration through increased communication and enhance teamwork.

Methods: This was a single-center, mixed methods study of the Cardiac and Vascular Institute Intensive Care Unit at Keck Medicine of USC conducted from September 2021 to April 2023. Simulation training was offered for 1 hour monthly to the clinical team focused on the collaboration and decision-making needed to evaluate the initiation of ECMO therapy. Electronic surveys were distributed before, after, and 3 months post training. The survey evaluated teamwork and the effectiveness of training, and focus groups were held to understand social environment factors. Additionally, trainee and peer evaluation focus groups were held to understand socioenvironmental factors.

Results: In total, 37 trainees attended the training simulation from August 2021 to August 2022. Using 27 records for exploratory factor analysis, the standardized Cronbach α was 0.717. The survey results descriptively demonstrated a positive shift in teamwork ability. Qualitative themes identified improved confidence and decision-making.

Conclusions: The study design was flawed, indicating improvement opportunities for future research on simulation training in the clinical setting. The paper outlines what to avoid when designing and implementing studies that assess an educational intervention in a complex clinical setting. The hypothesis deserves further exploration and is supported by the results of this study.

Introduction

Simulation training for extracorporeal membrane oxygenation (ECMO) has become standard practice for reinforcing technical skills, facilitating troubleshooting, and building teamwork [1]. ECMO is a critical tool in the care of severe cardiorespiratory dysfunction among patients of all ages [1]. Within the intensive care unit (ICU), ECMO is one of the most complicated therapies, requiring not only extensive knowledge of cardiopulmonary physiology and expertise with intricate circuit components but also skills to rapidly respond to emergent situations [2]. Therefore, high-fidelity simulation trainings are critical to practice skills and work through different emergency scenarios, such as the blood pump falling from the drive unit [3]. A randomized control study concluded that exposure to high-fidelity simulated ECMO emergencies leads to significant improvements in technical and behavioral skills among clinicians. This study demonstrated that simulation training creates a learning environment that replicates the clinical setting and fosters acquisition of cognitive, technical, and behavioral skills [4].

The Extracorporeal Life Support Organization, an international nonprofit association of health care institutions focused on ECMO research and education, recommends simulation training didactic sessions, water drills, animal sessions, and bedside training [5]. However, a randomized controlled trial published in *Critical Care Medicine* compared traditional water drill with simulation and found that simulation-based training is more effective than traditional training [6]. Water-based drills do not offer the same hands-on experience of real-time troubleshooting, and the use of animals is expensive and complex [6]. Nevertheless, traditional and simulation-based training are both beneficial to ECMO education. The benefits of simulation training on reinforcing skills have been noted in the literature [3,7-9]. Therefore, Keck Medicine of the University of California (USC) has held ECMO simulation-training sessions since 2013 for nursing education and 2021 for interprofessional simulation to reinforce and improve providers knowledge and hands-on skills in high-risk, low-frequency scenarios at no risk to patients [6].

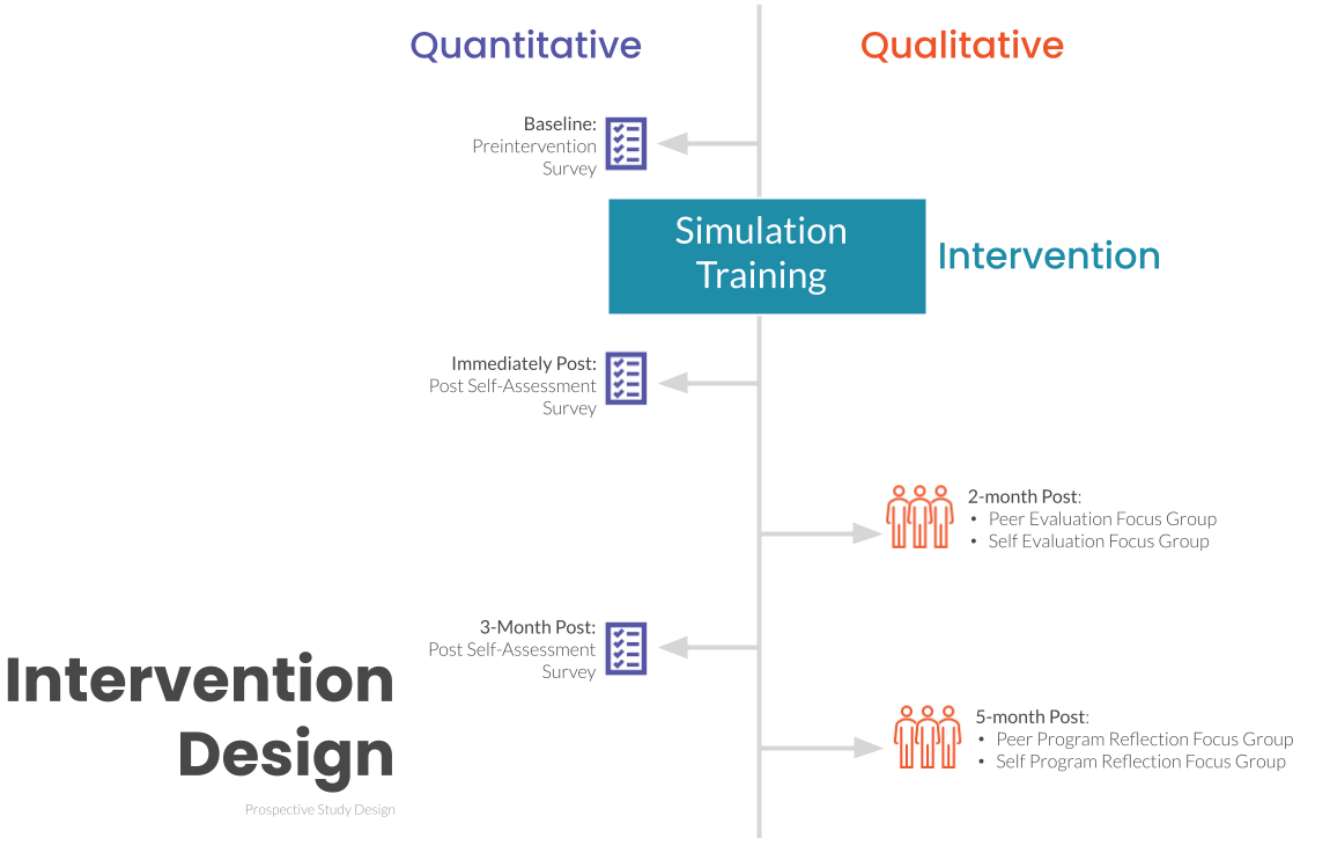
We implemented simulation-based ECMO training to improve interprofessional collaboration through increased communication and enhanced teamwork. Moreover, the intention of the simulation training was to strengthen collaboration skills and increase confidence in providers to work through emergency scenarios. The specific aim of the study was to understand the impact of our simulation training approach on interprofessional collaboration. However, ICU staffing models impacted the ability to execute the study design as intended. This paper outlines the original study design, the challenges the research team faced during the study, and the lessons learned to ensure future studies mitigate the challenges posed by real-world ICU operations. Our primary outcome shifted to the development and validation of measurement tools and offers recommendations for the evaluation of simulation approaches in future studies.

Methods

Overview

This was a single-center, mixed methods study of the Cardiac and Vascular Institute (CVI) ICU at Keck Medicine of USC conducted from September 2021 to April 2023. The study was designed to elicit quantitative feedback through an electronic survey before and post a voluntary training simulation exercise, and qualitative feedback from a participants via a series of focus groups that incorporated self- and peer evaluations (Figure 1).

Figure 1. Study design.



Participants

A census sampling strategy was used to recruit participants; in other words, all trainees that participated in the training were offered participation in the study. Participants included: (1) trainee physician fellows and residents in the CVI ICU who were offered attendance to the simulation training by their program director, and (2) peer evaluators, including the CVI ICU's Medical Director, nurse manager, nurse clinical educator, and lead respiratory therapist. Participant trainees attended a single 1-hour simulation training with roles played by clinical staff members from the CVI ICU, including an intensivist, clinical nurse educator, and respiratory therapist. To be eligible for the study, participants needed to be in a fellowship on rotation at Keck Medicine of USC. Fellows were recruited by intensivist leaders of the CVI from departments that rotated through or interacted with the CVI ICU (Pulmonary Critical Care Medicine, Cardiology, Anesthesia, Surgical Critical Care, and Cardiac Surgery). All study recruitment took place via email by the CVI Medical Director and Program Director to physicians in fellowship based on department and rotation schedule from pulmonary critical care medicine, surgical critical care medicine, cardiac surgery, and cardiology.

Simulation Training

Simulation training was designed as part of the continuing clinical education offered to the clinical team for 1-hour monthly, where participants attended a single session. Simulations were designed to focus on the interprofessional collaboration and decision-making needed to evaluate a patient for the initiation of ECMO therapy (Table S1 in Multimedia Appendix 1). Initially, low-fidelity simulations were held in a conference room using (1) a resuscitation training mannequin, (2) simulated vital signs via a hospital patient monitor connected to a rhythm simulator, (3) simulated intravenous access, (4) simulated medications, and (5) emergency equipment. In January 2022, collaboration with the Keck School of Medicine Simulation department allowed for training to be held in a simulation lab with a high-fidelity simulation mannequin and integrated simulation software LLEAP, version 8.5 from Laerdal. The availability of a higher fidelity training environment was meant to improve the training experience of the learners.

Each training session began with an orientation to the simulation environment and assigned roles. The scenario (Table S1 in Multimedia Appendix 1) was created to include relative contraindications to ECMO therapy and a potentially reversible condition that led to a cardiac arrest requiring resuscitation. Participants were assigned into roles of primary physician, code blue response provider, and cardiac surgeon prior to entering the simulation and entered the scenario when prompted by the facilitator or requested during the simulation by another participant. The patient was introduced to the learners as a 65-year-old female in-patient on a hospital cardiac telemetry unit with a past medical history of coronary artery disease, congestive heart failure, and peripheral vascular disease. The simulation began when a facilitator in the role of the patient's nurse requested help from a participant. The simulated patient was initially responsive with complaints of palpitations and shortness of breath with intermittent ventricular tachycardia displayed on the cardiac monitor. The simulated patient then became unresponsive in persistent ventricular tachycardia, and the imbedded facilitator activated the resuscitation team. When

the simulated patient's cardiac rhythm changes, the participants performed the roles of a code blue response, including coordinating the resuscitation, performing a simulated echocardiograph, and performing simulated invasive procedures including endotracheal intubation, arterial line insertion, and central line insertion. The participants collaborated to identify the candidacy of the simulated patient for ECMO therapy and proceeded to participate in a moderate-fidelity mock cannulation with ECMO training equipment. The participant in the surgeon role chose a method and site of cannulation for the simulated patient, and a practice ECMO circuit was connected to the simulator. Participants proceeded to respond and troubleshoot as the patient was set to be initially unstable during the transition to ECMO support. The simulated patient remained in ventricular tachycardia, and the participants were required to decide whether to continue attempting interventions, including, for example, chest compressions, medication, and defibrillation once the patient was placed on ECMO. The simulation ended when the patient was stabilized on ECMO and the participants decided to transfer the patient to the ICU. Areas of safety concern (Figure S1 in Multimedia Appendix 2) were emphasized in the training as points for communication to consider the decision to initiate ECMO with an unstable patient. A postsimulation debriefing session was facilitated by the simulation faculty.

Qualitative Approach

To understand the social environment factors the simulation training impacted, a total of 12 qualitative focus groups were planned (Figure 1). The 12 interviews were divided into 6 focus groups with the trainee attendees of the simulation training as a self-evaluation and 6 focus groups with colleague participants as a peer evaluation (Figure S2 in Multimedia Appendix 3). Each focus group was designed to have 2 - 4 participants. The study was designed to use the same peer evaluators for each peer evaluation focus group for the study duration. Each peer evaluation focus group was meant to target the evaluation of the individuals in the 6 simulation cohorts with a total of 4 peer participants. The focus groups were designed to be a duration of 30 minutes. Questions were developed to assess how the simulation training impacted the trainees' practice related to collaboration and teamwork (Table S3 in Multimedia Appendix 4). Questions were reviewed by the study expert in mixed methods study application.

Interviews were conducted by the simulation facilitators experienced in ECMO therapy and simulation education. Sessions were recorded using the Voice Memo application (Apple, Inc.). Once the focus groups were completed, the simulation facilitators sent the audio file to the data management author for transcription. The transcribed focus group sessions were de-identified, then uploaded and stored to a HIPAA (Health Insurance Portability and Accountability Act)-compliant Microsoft OneDrive. All audio and video files containing identifiers were deleted following transcription. Transcription documents were reviewed and coded for key themes using grounded theory methodology, an iterative process that will identify conceptual categories emerging from the comparative analyses of the data.

Quantitative Approach

An electronic survey was distributed with a QR code in person and electronically via email using Qualtrics XM software version December 2019. A total of 49 questions were posed to trainees across the pretraining, posttraining, and 3-month posttraining questionnaires (Table S2 in Multimedia Appendix 5). Teamwork-focused questions were obtained from the validated Mayo High Performance Teamwork scale (16 questions) [10]. The remaining questions regarding the effectiveness of training were devised using the Kirkpatrick Training Evaluation Framework as a basis for query design [11]. The study biostatistician performed a psychometric review to assess the validity and reliability of the survey questions. The use of existing validated tools ensured high reliability and validity of the teamwork elements of the survey tool [10]. Additionally, field tests (1 MD, 2 RNs, and 1 RT) of the survey tool showed an average survey duration of 7 minutes or less and promoted consistent comprehension of the study questions across individuals.

Exploratory factor analysis was conducted to assess questions reflecting underlying factors. The number of factors included in the final model was determined by eigenvalue and Scree plot. In the final factor pattern table, questions with a value>0.4 were considered well loaded for the factor. The Validated Mayo High Performance Teamwork scale (16 questions) was used as a sum score as recommended by the study [10]. Secondary outcomes analysis included department-level patient mortality, average device days on ECMO, decannulation percentage, and percentage of staff that had simulation training.

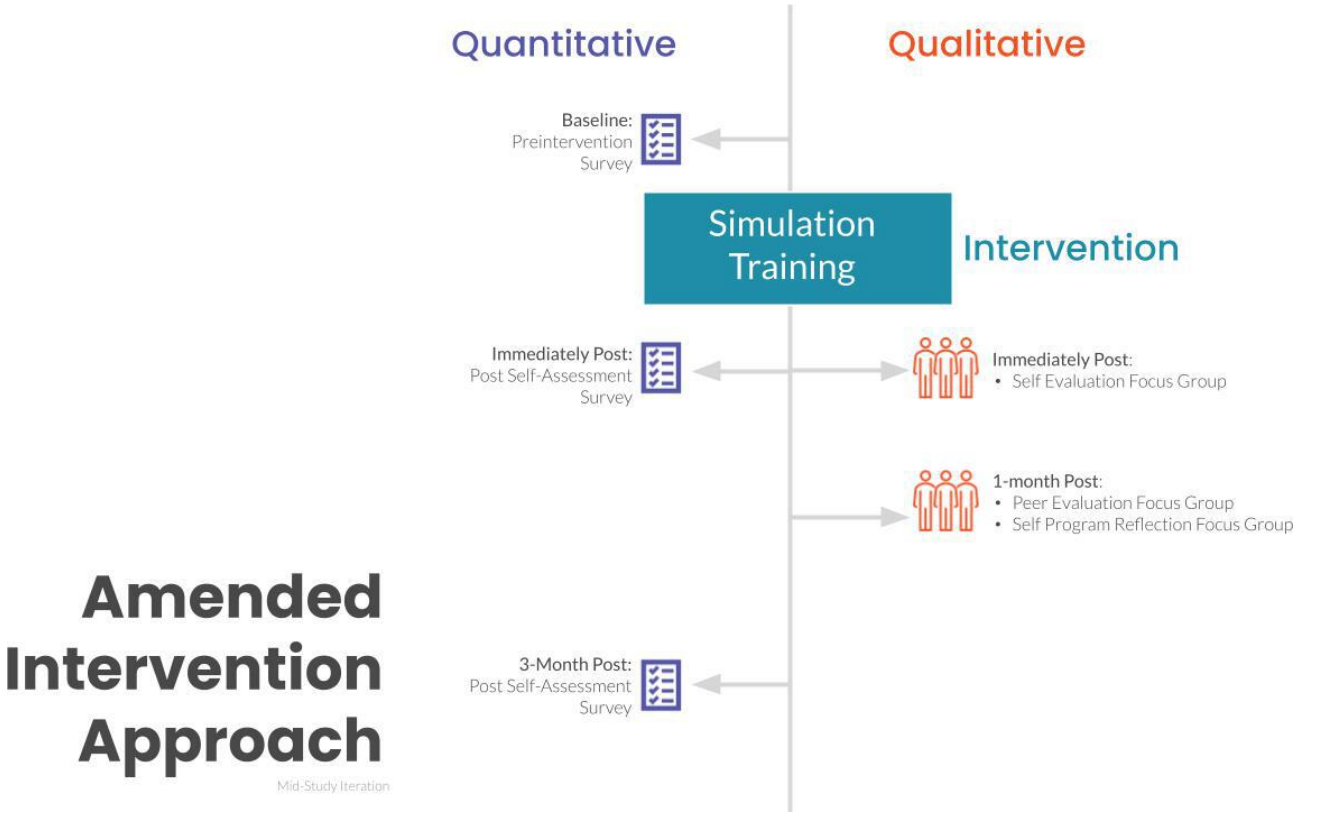
Ethical Considerations

The study was approved by the University of Southern California institutional review board (UP-21-01021). Prior to participation, all study participants were required to sign an informed consent form, thereby confirming their voluntary engagement in the survey process. The study data were anonymous.

Results

A total of 37 trainees attended the training simulation from August 2021 to August 2022. However, only 7 trainees opted to participate in the qualitative portion of the study. Due to lack of participant engagement, mid-study the study design was amended to increase study participation (Figure 2). The quantitative approach remained as originally designed; however, the analysis approach was done descriptively due to the inability to compare pre- and postsurvey results on an individual basis. In other words, survey analysis aggregated all preresponses and then postresponses to compare the pregroup and postgroup responses. The qualitative approach shifted to trainee participants attending a total of 2 focus groups, an initial self-evaluation immediately following simulation and a 1-month post-program reflection if they were available (Figure S3 in Multimedia Appendix 6).

Figure 2. Amended study design.



Qualitative Approach

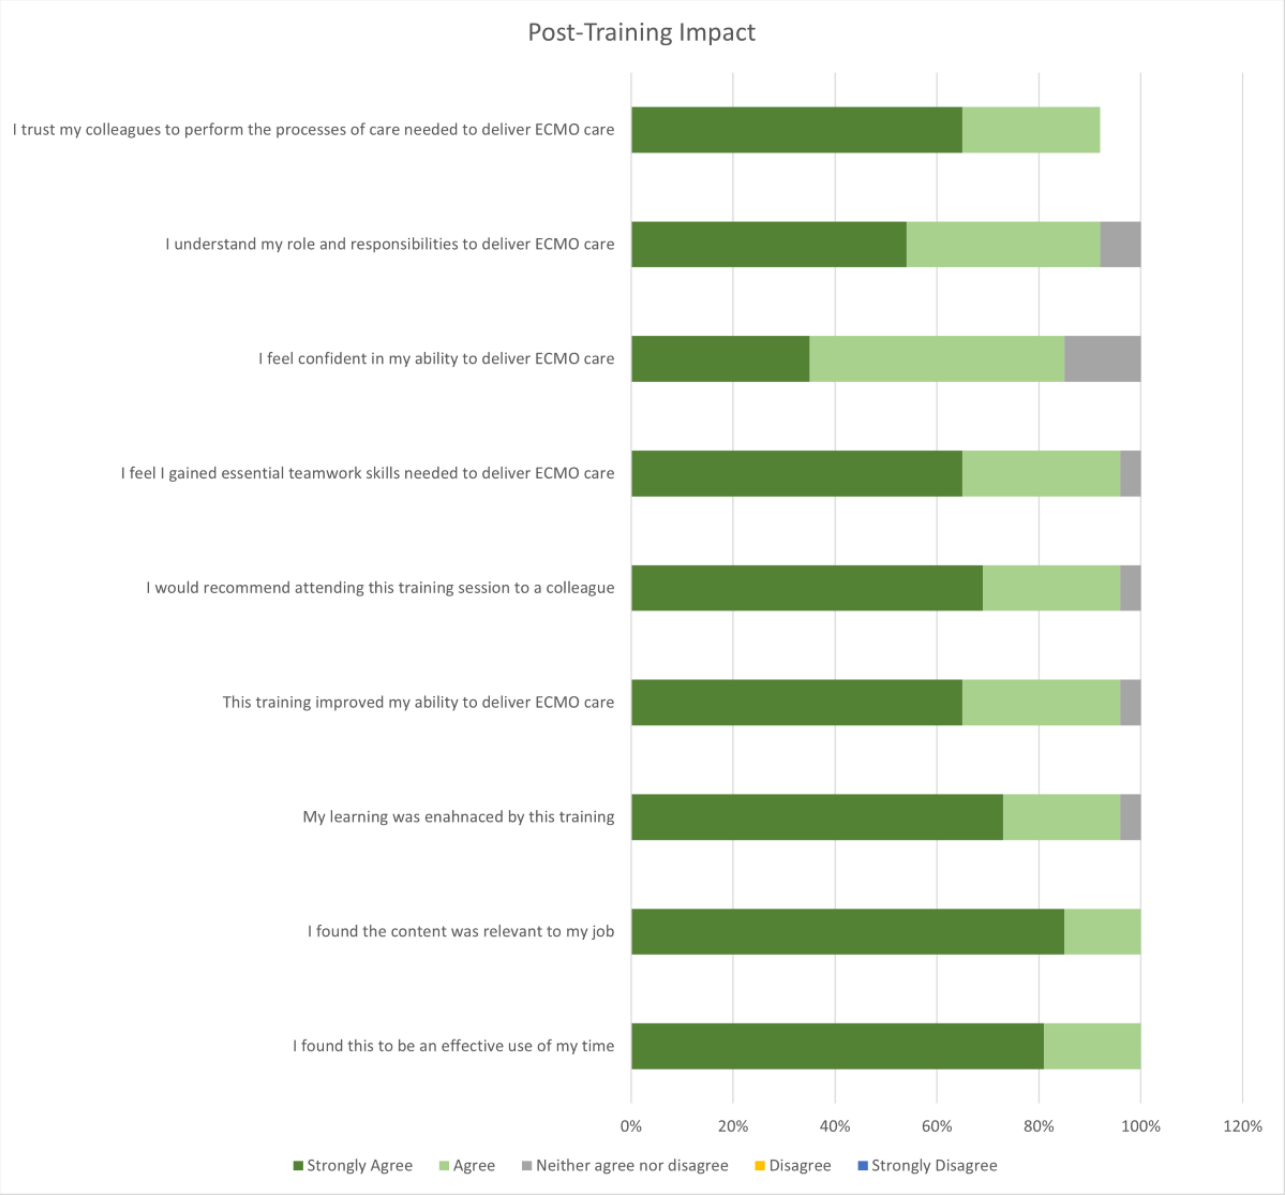
A total of 4 focus groups were conducted between January 2022 and August 2022 including 2 trainee self-evaluations (n=7) immediately post the training simulation and 2 peer evaluations 2-months post-training evaluation with the group of 4 peers. Focus groups for participants between August 2021 and December 2021 were not coordinated due to lack of trainee engagement in study participation. The 2 peer focus groups held highlighted an issue in trainee exposure with the peer team. Peer participants noted that they had limited clinical working exposure to the trainees being evaluated due to the nature of the fellow's rotation in the ICU. Meaning, peers did not have any recollection of working with the trainees prior to and following the simulation training to provide an appropriate evaluation of their skills in teamwork during ECMO therapy decision-making. In other words, peers remembered a trainee prior to or following the simulation, but not both. The 2 trainee self-evaluations that occurred highlighted themes that showed the simulation training benefited the trainees, including that the simulation training resulted in (1) working together as a stronger and more confident team because of simulation and (2) the creation of a space to improve communications, decision-making, and express concerns (Table S5 in Multimedia Appendix 7).

Quantitative Approach

All trainees were asked to complete the pre-, immediately post-, and 3-month surveys as part of the simulation training experience. There were a total of 37 entries recorded for the pre-survey, yielding a 100% response rate. Of those entries, 9 records were excluded due to lack of record ID or mismatching question numbers, leaving 28 entries for analysis. There was a total of 35 entries recorded for the postsurvey, yielding a 95% response rate. Following data cleaning, 9 records were excluded, leaving 26 postsurvey entries for analysis. There were a total of 2 entries for the 3-month posttraining survey, yielding a 5.4% response rate. The 3-month postsurvey results were excluded from analysis due to the low response rate. Table S4 in Multimedia Appendix 8 details the survey results of each question.

Questions posed in the post-survey focused on assessing levels 1 (reaction) and 2 (learning) of the Kirkpatrick Training Evaluation Framework demonstrated a high level of agreement for positive postsimulation training impact (Figure 3). Additionally, an increase in knowledge and understanding were noted descriptively when comparing the pre- and postresponses of the survey (Table S4 in Multimedia Appendix 8). For example, question "I understand the mechanism for activating ECMO at Keck Hospital" in the presurvey 46% of respondents agreed or strongly agreed to the statement compared to the postsimulation training survey where 100% of participants responded with a level of agreement. Levels 3 (impact) and 4 (results) of Kirkpatrick's framework were unable to be assessed due to the low response rate for the 3-month postsimulation survey.

Figure 3. Posttraining impact. ECMO: extracorporeal membrane oxygenation.



The Mayo Teamwork Scale was used to understand changes in the trainee's perspective on teamwork before and after the simulation training. The 16 focused teamwork questions demonstrated a positive shift in teamwork ability; that is, in the presurvey participants had a 71% average response on performing each question consistently, postsurvey showed an increase of the average to 95% consistently.

Exploratory Factor Analysis

An exploratory factor analysis was conducted to validate the use of the survey in evaluating the effectiveness of team training in ECMO simulation (Table 1). Entries with missing questions were excluded from the factor analysis; that is, only records with all questions answered were used. A total of 28 data points were available in the presurvey and 26 for the postsurvey. For the factor analysis, 0.4 was used as the cutoff. For the Mayo High-Performance Teamwork scale, 23 records were collected with a mean sum score of 26.87 (SD 6.41) at the presurvey and 21 records at the postsurvey with a mean sum score of 31.1 (SD 1.88). For the presurvey, we asked six 5-likelihood questions. Using 27 records for exploratory factor analysis, only 1 question, "Q5," did not reflect the underlying factor. Standardized Cronbach α was 0.686 when using all 6 questions. After excluding Q5, the standardized Cronbach α is 0.717. For the postsurvey, 26 records were used for analysis with 3 factors. Standardized Cronbach α was 0.919 when using all 15 questions. For questions from the Mayo High-Performance Teamwork scale, 21 records were used for analysis with a mean sum score of 31.1 and a SD of 1.88.

Table . Exploratory factor analysis.

[b]Not applicable.

Triangulation of Quantitative and Qualitative Results

Applying procedures of convergent mixed methods design, we converged the quantitative and qualitative results that were obtained separately to obtain a nuanced understanding of the core research aims. The themes identified of teamwork and improved communication in the qualitative analysis were supported by the quantitative survey results (Tables 2 and 3). Qualitative subthemes were supported by the positive shift observed descriptively from the pre- compared to the post-simulation training survey results.

Table . Triangulation of quantitative and qualitative results between frequently endorsed survey items and themes emerging from postsimulation focus groups (part).

Question	Agree level (Strongly Agree + Agree), %	Neither agree nor disagree, %	Disagree level (Strongly Disagree + Disagree),	Qualitative theme
I understand the mechanism for activating ECMO [a] at Keck Hospital				Working together as a stronger and more confident team because of simulation
Prestimulation	46	18	36	
Poststimulation	100	0	0	
I understand my role in a bedside cannulation				Working together as a stronger and more confident team because of simulation
Prestimulation	23	48	30	
Poststimulation	100	0	0	
I feel comfortable using the 2- challenge rule				Working together as a stronger and more confident team because of simulation
Prestimulation	4	29	68	
Poststimulation	69	15	15	
I feel confident to voice concerns to leadership during a critical situation				Working together as a stronger and more confident team because of simulation
Prestimulation	78	11	11	
Poststimulation	96	4	0	
I found this to be an effective use of my time (poststimulation)	100	0	0	Creating a space to improve communications, decision-making, and express concerns via simulation

Poststimulation	0	4	96	
Poststimulation	0	0	100	

Discussion

Principal Findings

This study was designed to evaluate the impact of ECMO therapy simulation training, specifically focused on enhancing teamwork and communication. The study was successful in validating the survey for future use in assessing the effectiveness of ECMO simulation training in improving teamwork and communication. However, while rigorous and well thought out in design, clear flaws were identified that need to be addressed in future attempts to study this type of simulation exercise. We outline the limitations of the study with recommendations for research with the intention to share what to avoid when

designing and implementing studies that assess a clinical education approach in a complex clinical setting. We provide a unique validated tool to assess teamwork and collaboration across clinical disciplines during ECMO therapy, where existing evidence assesses the impact of simulation approaches on knowledge.

Strengths and Limitations

First, the original focus of the study targeted physician fellows and residents from various clinical teams that practice in the CVI unit. An assumption was made in the study design that peer evaluators would have enough interaction with trainees before and after the simulation training to evaluate changes in their behavior. Due to the nature of the rotation of this participant population, the peers were unable to assess any impact. Additionally, the rotation of the trainees contributed to difficulty in follow-up for study participation in both the quantitative and qualitative aspects of the study. Only 2 responses were received for the 3-month postsimulation training survey, and the qualitative study was altered midstudy to garner more participation in study focus groups. The team was unable to obtain commitment from trainees for the 2-month and 5-month planned focus groups and amended the study for a trainee self-evaluation focus group immediately following the simulation training and 1 month post. The study team was unable to coordinate the 1-month post–focus group due to a lack of availability of the fellow and resident trainees. The lack of participation led to the inability to assess levels 3 and 4 of the Kirkpatrick Training Evaluation Framework [11]. Additionally, the lack of participation reduced the validity of the qualitative data obtained in the focus groups. To generalize the qualitative results of the study, the original target of 6 simulation cohorts with a total of 4 peer participants each would be necessary. We suggest future studies alter the study design to broaden study participants to the entire interprofessional team to ensure the target participant enrollment and focus groups are reached. Second, the trainee rotation also did not guarantee exposure of the trainees to ECMO cannulation postsimulation training to practice the technical skills gained from the simulation training. Third, quantitative results demonstrated there is merit to this training simulation approach. Where there were positive shifts from pre- compared to postsimulation training survey results. However, we were unable to calculate statistical significance in pre- and postresponses due to survey collection methods. Survey participation was anonymous and a routine part of the simulation training program. We were unable to align individual pre- and postsurvey responses to apply this statistical strategy or follow up with specific trainees that missed questions. Fourth, although the trainees had a qualitatively and quantitatively favorable response in ECMO initiation following the simulation exercise per survey results, the study did not conclusively demonstrate their ability to actively use that attained knowledge beyond the original simulation date given the lack of actual cannulations and, again, being observed by staff who could claim that teamwork was significantly improved in future interactions. Lastly, the study team anticipated a larger sample of participants, but the recruitment challenges, focus on physician fellows and residents, and staff shortages due to the impact of the COVID-19 pandemic were severe limitations of the study.

Despite these limitations, the quantitative survey results descriptively highlighted the positive impact on the trainees. Level 1 questions of the Kirkpatrick Training evaluation [11] were met with a strong level of agreement, with no level of disagreement responses (Figure 1). Additionally, each of the level 2 questions shifted to a higher level of agreement post the simulation training. The same was true for the responses to the Mayo Teamwork Scale, where each response shifted to more consistent teamwork behavior pre- and postsimulation training (Table S4 in Multimedia Appendix 8).

We know team-based interprofessional care has historically demonstrated gains in positive patient outcomes in the ICU and is seen as the solution to reduce medical errors and poor quality [12-15]. Moreover, a key component of ECMO care is interprofessional collaboration, as it requires a large and multifaceted team of providers collaborating to carry out complementary tasks to one another [16]. Simulation-based team training can cultivate and preserve interprofessional teamwork and communication [16]. However, collaboration across the care team is not a standard topic covered in clinical curriculum [13,15]. We believe our survey results support the merit of our teamwork-focused simulation training approach and its ability to foster a higher level of collaboration when the clinical team is faced with deciding to initiate ECMO therapy in the cardiac and vascular patient population. These findings highlight the importance of simulation training from other innovative ways of ECMO skills training, such as game-based mobile apps, which might not cultivate a teamwork approach to the same extent [17]. This approach could be applied to supplement the lack of practical teamwork focus in today's clinical curriculum.

Despite the identified limitations, the study underscored several positive aspects of ECMO simulation training. The quantitative survey results notably revealed a significant positive impact on the trainees. Level 1 questions of the Kirkpatrick Training evaluation demonstrated a strong level of agreement without any disagreement responses, indicating a high degree of satisfaction with the training (Figure 1). Furthermore, each of the level 2 questions exhibited a shift towards higher levels of agreement postsimulation training. Similarly, responses to the Mayo Teamwork Scale demonstrated a consistent improvement in teamwork behavior before and after simulation training (Table S4 in Multimedia Appendix 8). This reaffirms the notion that team-based interprofessional care, a cornerstone in ICU settings, can lead to enhanced patient outcomes and reduced medical errors. The study's focus on cultivating interprofessional collaboration through simulation-based training aligns with the demands of ECMO care, which relies heavily on coordinated efforts among various health care professionals. These findings highlight the effectiveness of the teamwork-focused simulation training approach in preparing clinical teams to make critical decisions regarding ECMO therapy in the cardiac and vascular patient population. Moreover, they emphasize the importance of incorporating such training into clinical curricula to ensure a holistic approach to health care education. The study's insights pave the way for future research endeavors to further explore

and refine the application of simulation training in improving teamwork and patient outcomes in complex clinical settings. By addressing the outlined recommendations and leveraging innovative approaches, such as virtual reality simulation, the medical community can continue to advance ECMO care delivery and interprofessional collaboration, ultimately enhancing patient care outcomes.

Future research may build upon the learning of this study to strengthen the understanding of a teamwork-focused simulation approach. We would encourage implementation of the following and plan for our future studies to include (1) continuing the study with the entire interprofessional team, using the survey to build on exploratory factor analysis that validated the survey questions and provide a confirmatory factor analysis to validate results; (2) emphasize established continuity with the learners and the peer evaluators in the study design to mitigate the limited interactions with the study participants outside of the actual simulation and during their clinical rotation; (3) training operational staff participating in gathering data on best practices of data collection for operations and research; (4) the team would encourage incorporating and evaluating the impact of the results on patient outcomes. Answering if patient outcomes improved with increased teamwork and collaboration of the interprofessional team. This would require a larger sample size of trainees involved in simulation training.

Conclusions

We were challenged with the reality of executing a research protocol in a highly complex health care environment, for example, clinician availability, time, response, ability for follow-up, change in protocol, data collection from clinical staff, etc. While these difficulties altered our study approach, the study team believes the design attempted in this study had merit in understanding the impact of a teamwork-focused ECMO simulation approach. We would encourage the medical community to build on the strengths of the design, fortify the weaknesses, and continue to emphasize the need for simulation training to improve ECMO care delivery and teamwork in the clinical setting. Especially as the field of simulation training continues to expand into new mediums like virtual reality [18].

Abstract

Background: Assessment of nontechnical attributes is important in selecting candidates for surgical training. Currently, these assessments are typically made based on ineffective methods, which have been shown to be poorly correlated with later performance.

Objective: The study aimed to examine preliminary evidence regarding the use of game-based assessment (GBA) for assessing cognitive abilities and personality characteristics in candidates for surgical residencies.

Methods: The study had 2 phases. In the first phase, a gamified test was developed to assess competencies relevant for surgical residents. Three games were chosen, assessing 14 competencies: planning, problem-solving, ingenuity, goal orientation, self-reflection, endurance, analytical thinking, learning ability, flexibility, concentration, conformity, multitasking, working memory, and precision. In the second phase, we collected data from 152 medical interns and 30 expert surgeons to evaluate the test's feasibility, acceptability, and validity for candidate selection.

Results: Feedback from the interns and surgeons supported the relevance of the test for selection of surgical residents. In addition, analyses of the interns' performance data supported the appropriateness of the score calculation process and the internal structure of the test. Based on this data, the test showed good psychometric properties, including reliability (α=0.76) and discrimination (mean discrimination 0.39, SD 0.18). Correlations between test scores and background variables indicated significant correlations with gender, video game experience, and technical aptitude test scores (all P<.001).

Conclusions: This study presents an innovative GBA testing cognitive abilities and personality characteristics. Preliminary evidence supports the validity, feasibility, and acceptability of the test for the selection of surgical residents. However, evidence for test-criterion relationships, particularly the GBA's ability to predict future surgical performance, remains to be established. Future longitudinal studies are necessary to confirm its utility as a selection tool.

KEYWORDS

resident selection; assessment; surgical training; cognitive abilities; personality characteristics; gamification; game-based assessment

Introduction

Selection of surgical training residents is an essential process aimed at ensuring that only the most capable candidates are chosen to undergo the rigorous training required to become qualified surgeons. Alongside technical skills, there is broad consensus that it is also crucial to assess nontechnical attributes, including cognitive abilities (eg, deductive reasoning, learning ability, and concentration) and personality characteristics (eg, decision-making, stress tolerance, and communication skills), in potential surgical residents [1-7]. Indeed, some even consider nontechnical attributes to be more relevant for selecting surgical trainees than technical aptitude [7-9]. In a recent study [7], 19 nontechnical competencies were identified as relevant to surgeons in the 21st century (6 cognitive abilities and 13 personality characteristics).

Traditionally, surgical training programs have assessed nontechnical attributes almost exclusively through proxies such as academic achievement, curricula vitae, letters of recommendation, and unstructured interviews [10,11]. However, studies suggest that these methods are poorly correlated with

later performance during residency [11-16]. In light of such findings, some studies have examined the use of self-report measures as a potential alternative. For example, studies have explored the potential of self-report questionnaires for assessing personality, emotional intelligence, and grit. But there is as yet no consistent evidence that these methods improve the selection of surgical residents [5,17]; and these tools are subject to all the potential problems and biases of self-reports, from poor introspective ability to outright dishonesty [18,19]. Hence, better ways of assessing surgical residency candidates are needed.

One promising new approach is to analyze behavior itself using simulated tasks, where examinees are exposed to controlled situations designed to elicit behaviors relevant to the assessment of specific competencies. This method is expected to have higher predictive value than either traditional methods or self-reports.

A simulation test can be conducted in the real world by evaluators or actors, or on a computer using emerging technologies such as virtual reality and gamification. Gamification refers to the incorporation of game elements into nongaming activities, and its application to personnel selection has led to the development of game-based assessments (GBAs). GBAs use gameplay behaviors to assess job-related skills, abilities, and characteristics, and they have many advantages over traditional assessments and noncomputerized simulation tests for predicting job performance [20-23]. First, GBAs promote a more positive assessment experience that reduces examinees' stress levels and increases their engagement and motivation. Second, GBAs are based on an automated scoring system, which eliminates the bias often associated with human assessments. Finally, GBAs can collect rich high-resolution spatiotemporal data capturing examinees' behavior throughout the test, allowing the entire solving process to be examined rather than just the final result or answer. These advantages may lead to a more reliable and valid assessment of examinees' skills and abilities.

As GBAs are still relatively new, only a limited number of studies have examined their use in hiring and recruitment [24-26], and to the best of our knowledge, no study has evaluated GBAs as a tool for selecting medical residents. The current study examines the use of GBA for assessing cognitive abilities and personality characteristics identified as relevant for surgical residents in an initial phase of job analysis [7]. This study is the first in a planned series of studies aimed at establishing the validity of the GBA. Here, we present preliminary evidence of its feasibility, acceptability, and validity in the context of surgical resident selection, based on feedback and behavioral data from potential candidates and expert surgeons. Further research linking the GBA scores to future surgical performance will be necessary to complete the validation process.

Methods

We developed a gamified assessment test relevant for appraising the cognitive abilities and personality characteristics of potential surgical residents and examined preliminary evidence for its validity, feasibility, and acceptability. In accordance with the contemporary understanding of validity as a unified concept, we collected and evaluated evidence related to 4 sources of validity: content, internal structure, response process, and relationships with other variables [27,28], although the evidence for relationships with other variables was limited and did not include test-criterion relationships. The evidence collected is based on both the procedures used in the development and revision of the test and the empirical data collected during the study.

Ethical Considerations

The study was approved by the ethics committee of the Hebrew University of Jerusalem (approval no. 13032023), and all participants provided informed consent. Participant data were stored using a unique fake identifier; the key linking these identifiers to real identities was kept in a password-protected file stored offline, ensuring that no identifying information was accessible online. Interns received US $75 for participating in the study, as well as feedback regarding their performance in both tests relative to the rest of the sample (the percentile rankings of their total scores).

Test Development

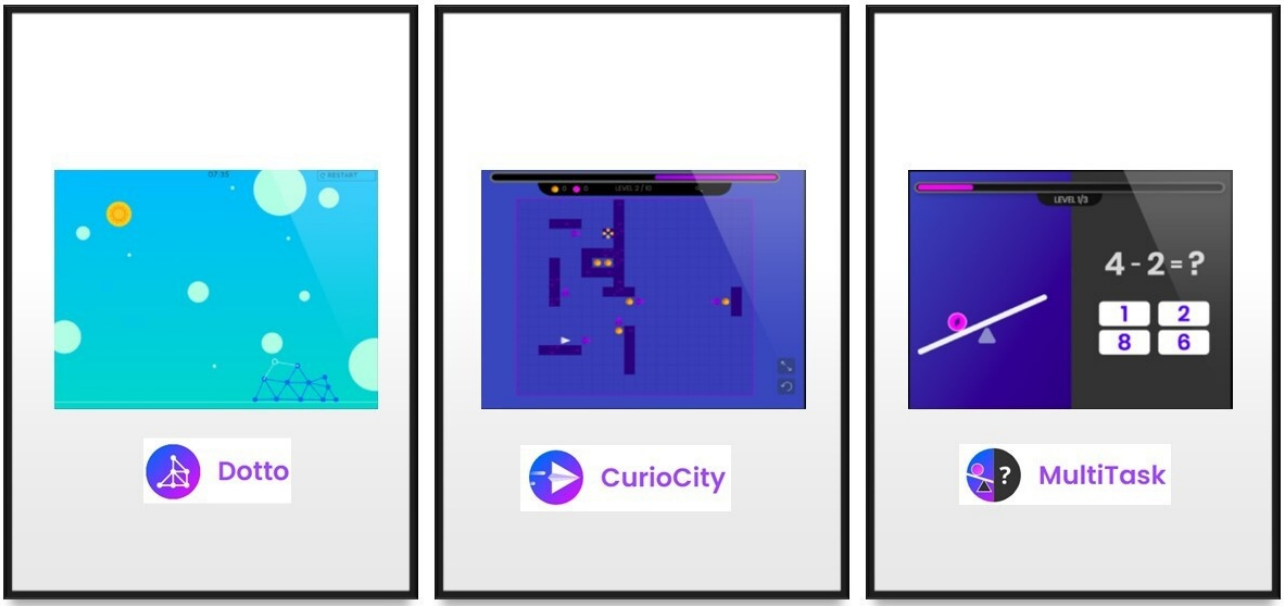
The GBA

The GBA used in this study was developed in cooperation with Benchmark.games LTD (Hungary), a company that produces GBAs for use in organizational hiring and recruitment. Tests are tailored to the organization's needs, based on video games developed specifically for the assessment of various competencies (eg, analytical thinking, planning, or multitasking). Each test is administered on a standard computer and requires only a stable internet connection and a mouse.

The test developed for this study is based on three video games adapted to capture competencies needed by surgical residents: (1) Dotto, (2) CurioCity, and (3) MultiTask (refer to Figure 1). In the Dotto game, the goal is to build a structure by inserting and manipulating points and lines to reach a target while overcoming physics-based challenges. The game confronts examinees with a problem-solving situation that is not clearly defined, requiring them to discover the rules for solving the problem on their own. In CurioCity, examinees are tasked with finding their way through a maze to reach the target area. The game consists of 16 levels with varying requirements and levels of difficulty. Once again, some of the rules must be discovered by examinees, and some rules change as the game proceeds, to test the adaptability and flexibility of the examinees. Finally, in the MultiTask game, examinees are asked to perform 2 nonverbal tasks simultaneously (eg, a swing balancing task and a simple arithmetic task). The game has three levels, each using a different combination of 2 tasks. The initial versions of the games were developed by psychometricians and psychologists employed by Benchmark.games, and the games were validated using data from hundreds of employees by Benchmark.games for general personnel selection. For this study, all 3 games were modified based on feedback from the research team in 3 ways: levels that were insufficiently challenging for candidates with high abilities were excluded; tasks that assessed irrelevant competencies (eg, typing speed and accuracy) were replaced with tasks assessing competencies relevant for surgical trainees

(eg, concentration and working memory); and, to ensure that the assessment would be objective and standardized, the instructions and demonstrations for each game were revised and improved. Instructions were provided in English and included both written instructions and video demonstrations. Furthermore, to ensure that the instructions were understood correctly, each game was preceded by a few minutes of practice. The initial version of the test was then pilot-tested with 8 medical students. Based on their feedback, changes were made in the instructions and in the test interface. The entire test takes about 45 - 60 minutes to complete, with each game taking 15 - 20 minutes.

Figure 1. Illustrations of the video game assessments selected for the test. The games are shown in the order in which they appeared in the test.



The video games were selected to assess 14 relevant competencies: planning, problem-solving, ingenuity, goal orientation, self-reflection, endurance, analytical thinking, learning ability, flexibility, concentration, conformity, multitasking, working memory, and precision. Definitions of the competencies are provided in Table 1.

The competencies were drawn from a set of cognitive abilities and personality characteristics identified as relevant for selection of surgical residents in a previous phase of job analysis conducted by the research team [7]. However, the GBA does not assess some of the competencies which were identified as relevant to selection for surgical training (in particular, “soft skills” such as interpersonal skills, teamwork, leadership, and integrity). These competencies were not assessed in the present research because they are not susceptible to measurement using computerized and automated systems. The GBA was designed such that each game would elicit specific behaviors relevant to 2 or more of the 14 competencies, with each competency assessed using information obtained from one game (except for precision, which was assessed in all 3 games).

Table . Competencies assessed in the game-based assessment (GBA) test.

Competency	Description	Video game used to assess the competency
Planning	Ability to plan the steps required to solve the task, and to implement the plan in order to achieve the goal.	Dotto
Problem-solving	Ability to work through unexpected obstacles and challenges that arise during the task.	Dotto
Ingenuity	Ability to test the boundaries of a problem and to seek unique and creative solutions.	Dotto
Goal orientation	Ability to translate an intention into action (ie, to stay focused on achieving the goal).	Dotto
Self-reflection	Ability to learn from failure and to adopt a new approach.	Dotto
Endurance	Ability to invest effort for an extended period of time.	Dotto
Analytical thinking	Ability to collect, organize, and implement the information needed to solve the problem.	CurioCity
Learning ability	Ability to recognize "rules" quickly and effectively and apply them in the relevant situation.	CurioCity
Flexibility	Ability to adapt to changes in the situation.	CurioCity
Concentration	Ability to stay focused and to maintain high performance even in monotonous repetitive tasks.	CurioCity
Conformity	Ability and willingness to follow rules and instructions.	CurioCity
Multitasking	Ability to split attention between two tasks without harming performance.	MultiTask
Working memory	Ability to store and retrieve information in short-term memory.	MultiTask
Precision	Ability to perform the task in an accurate manner, with few errors.	All games

Scoring

The gamified tasks provide the stimuli by which the program measures candidates' behavior. In each game, all actions of examinees (eg, mouse movements and key presses) are recorded and logged. Approximately 2000 data points are recorded for each 15-minute gameplay session. These raw data are then transformed into higher-level variables that describe a set of meaningful measurements (eg, time to first response, time between actions, accuracy, number of steps, and learning curve). Then, competency scores are calculated using an aggregation (ie, linear combination) of the relevant variables, with higher weight given to variables characterized by larger variance between candidates.

The initial mapping between different variables and competencies was determined by a team of psychologists and psychometricians employed by the company following a theory-driven approach [20]. This mapping was tested and improved based on empirical data from hundreds of employees, and variables that did not converge with the expected pattern were excluded from consideration. The mapping was then further validated based on correlations with other measures of cognitive abilities and personality (eg, Raven's Progressive Matrices, the Stroop test, scales of the International Personality Item Pool, and the Bar-On Emotional Quotient Inventory; refer to Table S1 in Multimedia Appendix 1).

Competency scores are computed and standardized based on a norm created using a database of over 5000 observations. Scores are presented on a scale of 1 - 10. For this study, we also calculated a total test score for each examinee by averaging the individual competency scores (with equal weight for each competency). To facilitate interpretation of the results, the total scores were then scaled to have a mean of 100 and a SD of 20.

Validation

Sample and Procedure

To evaluate the test's validity, feasibility, and acceptability, we recruited 30 experienced surgeons from 3 hospitals and 152 medical interns from 10 hospitals in Israel. The surgeons were asked to review the test and then complete a feedback questionnaire (see below). The interns were asked to complete the test, and their test data was collected and analyzed to evaluate the internal structure and psychometric characteristics of the test (discrimination, reliability, and correlations between competency scores). The interns also completed a feedback questionnaire similar to that filled in by the surgeons.

The expert surgeons were recruited using an email invitation. Email addresses of potential participants were obtained from hospital websites or from the Israeli medical association database. Recruitment continued until we had 30 participants. Surgeons who were willing to participate in the study were invited to review the gamified test and to complete the feedback questionnaire.

The interns were recruited using an invitation posted in relevant Facebook and WhatsApp groups. Recruitment continued until at least 150 participants were enrolled. Participants were invited to attend a session in which we administered the gamified assessment test and a separate technical aptitude test developed by Gazit et al [29]. The technical aptitude test included 10 basic tasks performed on the Lap-X VR laparoscopic simulator [30] and was designed to assess technical skills relevant for surgery such as dexterity, visuospatial perception, coordination, and arm-hand steadiness. The order of the tests varied, such that some participants started with the GBA and others with the technical aptitude test, with a short break between the two. The interns were told that each game in the GBA should take around 15 - 20 minutes to complete.

Questionnaire

The questionnaires filled in by the surgeons and interns were nearly identical. Participants in both samples were asked to provide four main ratings for each game: (1) its relevance for selecting candidates for surgical training (on a 5-point Likert scale, 1=not relevant, 5=extremely relevant); (2) its difficulty (also on a 5-point Likert scale, 1=very easy, 5=extremely difficult); (3) whether the time limit was sufficient (yes or no); and (4) whether the instructions were clear (yes or no). In addition, participants provided 2 ratings for the test as a whole: the relevance of the entire test and the comfort of the test platform (both on 5-point Likert scales, 1=not relevant or not comfortable, 5=extremely relevant or comfortable). Participants were also invited to share general comments and suggestions for improving each game and the whole test using free text. Finally, each participant provided demographic information (for interns: age, gender, dominant hand, desired training field [surgical or nonsurgical], and previous experience with video games; for the surgeons: age, gender, surgical specialty, and number of years working in the field). Previous experience with video games was reported on a 5-point scale (1=no experience, 5=very extensive experience).

Analyses

Some validity evidence is encompassed in the procedures used in the development of the test described above (selection of games and tasks based on job analysis; development of the games and scoring method by psychometricians and psychologists; and calculation of scores based on a norm sample). Further evidence of validity is derived from the empirical data collected in this study. In particular, internal structure evidence, response process evidence, and relationships with other variables were obtained from analysis of the interns' test performance data. Content evidence, feasibility, and acceptability were obtained from the feedback questionnaires completed by both the interns and surgeons.

To analyze the performance data of the interns, we first examined the distribution of the competency scores and calculated Pearson correlations between them to support computation of a composite score for each participant, representing that participant's total performance in the test (response process evidence of validity). We then conducted an item analysis to assess the discrimination of each competency and the reliability of the whole test, and a factor analysis to assess whether the structure of the test variables accords with what is theoretically expected (together these provide internal structure evidence for validity). Finally, we calculated correlations between participants' scores in the gamified test and other variables: their demographic characteristics (age, gender, dominant hand, desired training field, and previous experience with video games) and their technical aptitude test scores (evidence of relationship to other variables).

To analyze the data from the feedback questionnaires of the interns and surgeons, we first calculated, for each sample, mean relevance and difficulty ratings for each game. We then analyzed the data on the time limits and clarity of instructions for each game, as described above, and calculated the mean relevance and comfort ratings for the whole test. Finally, we analyzed the general comments obtained from participants in the open-ended question to identify common remarks and suggestions. All statistical analyses were performed using R, version 4.2.2 (R Foundation for Statistical Computing, Vienna, Austria).

Results

Overview

In total, 152 interns (71 females, 46%) from 10 academic hospitals in Israel and 30 expert surgeons (4 females, 13%) from three academic hospitals in Israel participated in the study. Demographic characteristics of the participants are presented in Table 2.

Table . Demographic characteristics of study participants.

Group and characteristic	Values
Interns (n=152)	
Age in years, mean (SD)	28.3 (3.8)
Gender (female), n (%)	71 (46)
Dominant hand (left), n (%)	13 (9)
Desired training field, n (%)	
Surgical training	100 (65)
Nonsurgical training	36 (24)
Not decided	17 (11)
Experience with video games, n (%)	
No experience	22 (14)
Little experience	45 (29)
Moderate experience	46 (30)
Considerable experience	20 (13)
Very extensive experience	20 (13)
Expert surgeons (n=30)	
Age in years, mean (SD)	53.8 (8.4)
Gender (female), n (%)	4 (13)
Years of experience, mean (SD)	13.5 (7.9)
Surgical specialty, n (%)	
General surgery	8 (27)
Gynecology	5 (17)
Orthopedics	10 (33)
Otorhinolaryngology–head and neck surgery	4 (13)
Urology	3 (10)

Performance Data of Interns

First, competency scores and total test scores were calculated for each of the interns. The means and SDs of the competency scores and total scores are presented in Table 3. The total test scores ranged from 44 to 142 (a range of 98). Figure 2 displays the distribution of the total scores for the 152 interns (The distributions of the individual competency scores can be found in Figure S1 in Multimedia Appendix 1).

Table . Descriptive statistics and item analysis of the game-based assessment (GBA) test.

Competency	Mean	SD	Skew	Competency discrimination	Cronbach α if deleted
Planning	6.30	2.24	−0.29	0.64	0.72
Problem-solving	5.75	2.51	−0.08	0.47	0.73
Ingenuity	4.22	2.19	0.13	0.34	0.74
Goal orientation	4.79	2.38	−0.29	0.21	0.76
Self-reflection	4.87	3.09	0.14	0.23	0.76
Endurance	3.77	2.50	0.31	0.06	0.77
Analytical thinking	7.79	1.87	−1.13	0.46	0.74
Learning ability	7.23	1.97	−0.70	0.40	0.74
Flexibility	6.15	2.71	−0.25	0.36	0.74

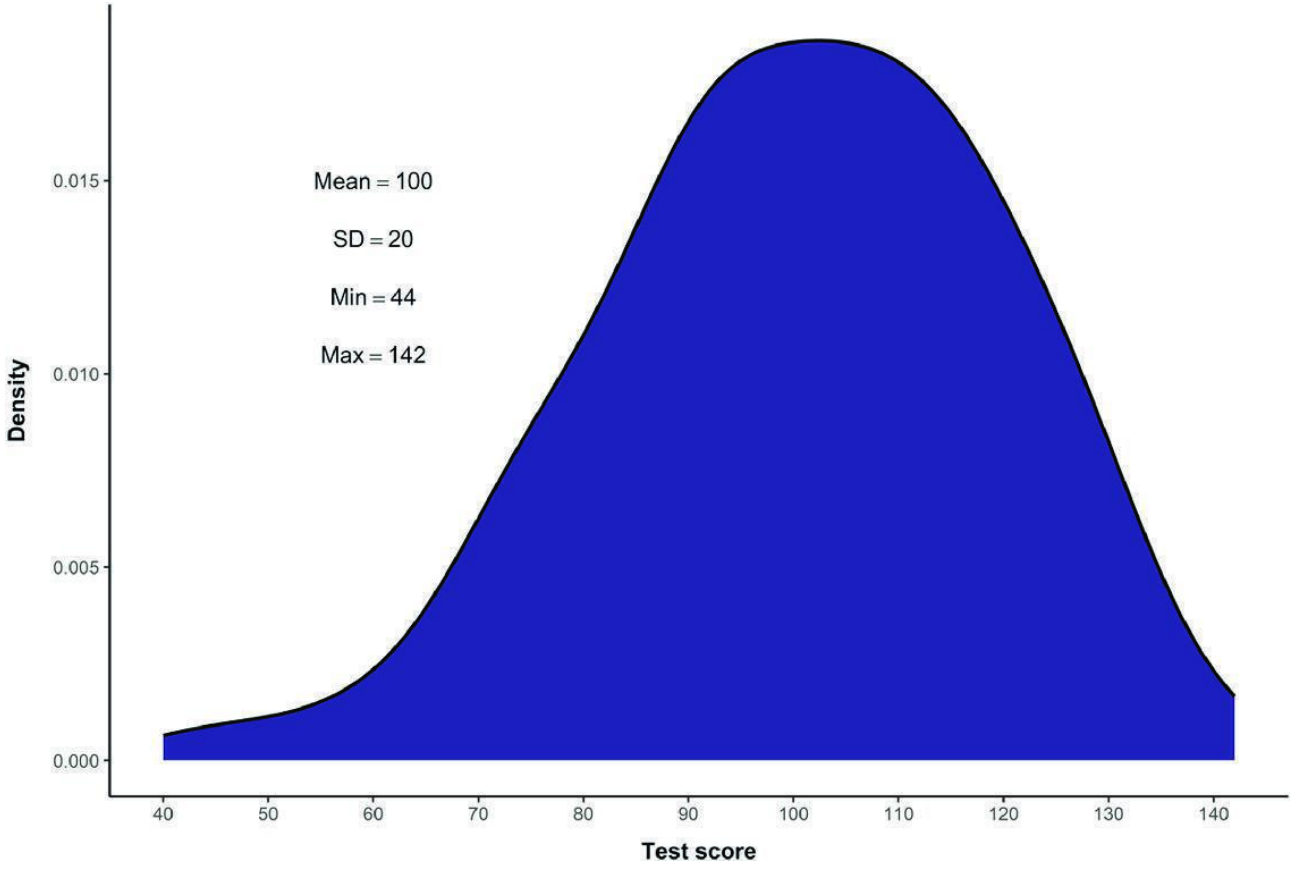
[a]Cronbach α=0.76.

[b]Not applicable.

Figure 2. Distribution of total GBA test scores in the intern sample (n=152). GBA: game-based assessment.



To support the calculation of a total test score based on the competency scores, we examined the Pearson correlations between the competency scores. Most of the correlations were high (refer to Table S2 in Multimedia Appendix 1). To support the internal structure of the test, an item analysis was then

conducted to assess the discrimination of each competency and the reliability of the whole test (see Table 3).

The results showed good psychometric properties: the discrimination was satisfactory for all competencies (mean 0.39, SD 0.18), and the test's internal reliability was high (α=0.76). In addition, we conducted exploratory factor analysis with Promax rotation on the 14 competencies. The Kaiser–Meyer–Olkin measure of sampling adequacy suggested that the data was factorable (Kaiser–Meyer–Olkin=0.69). The factor analysis yielded a 2-factor solution, such that seven competencies (analytical thinking, learning, flexibility, concentration, working memory, multitasking, and precision) loaded on one factor, and 6 competencies (planning, problem-solving, ingenuity, goal orientation, self-reflection, and endurance) loaded on the second factor. The only exception was conformity, which did not load on either of the factors. Based on our previous job analysis [7], we defined the first group as cognitive abilities and the second group as personality characteristics. The correlation between the two factors was 0.5. Detailed results for the factor loadings can be found in Table S3 in Multimedia Appendix 1.

We next calculated correlations between the total test scores in the GBA and external variables, including participants' demographic characteristics and their scores in the separate technical aptitude test described earlier. No significant correlations were found between age, dominant hand, or desired training field and the total GBA scores. However, a significant difference emerged with respect to gender, such that males (mean 104.6, SD 16.8) scored significantly higher than females (mean 94.3, SD 21.9) on the gamified test (mean difference 10.9, 95% CI 3.1-17.6, t_{150}=2.8, P=.002, Cohen d=0.52). This represents a small-to-medium effect size. In addition, we found a significant low positive correlation between the total GBA scores and reported amount of previous experience with video games (r_{150}=0.26, P<.001). Interestingly, when we controlled for video game experience, the difference between the genders was no longer significant, suggesting that this difference is mainly due to different levels of video game experience.

Finally, we also calculated the correlation between the total GBA scores and scores in the technical aptitude test. We found a significant correlation between the 2 sets of scores (r_{150}=0.46, P<.001). When controlling for video game experience, the correlation remained significant, though slightly reduced (semipartial r_{152}=0.38, P<.001), suggesting that while gaming experience contributes to the association, the majority of the shared variance likely reflects underlying competencies relevant to both assessments. Supporting this interpretation, we found significant correlations between technical aptitude test scores and several nontechnical competencies measured by the GBA: planning, r_{150}=0.28; problem-solving, r_{150}=0.28; analytical thinking, r_{150}=0.27; learning ability, r_{150}=0.30; flexibility, r_{150}=0.50; and precision, r_{150}=0.30; all P<.001. In the absence of these 6 competencies, the total GBA scores showed no significant correlation with the technical aptitude test (r_{150}=0.11, P=.17). These findings suggest that shared cognitive and behavioral attributes may play an important role in performance on both tests.

Questionnaire Data

Table 4 presents the main results for the questionnaire data, including mean relevance and difficulty ratings for each game, and the rates at which participants judged the time limits as sufficient and the instructions as clear.

Table . Feedback of interns and expert surgeons on the relevance,[a] difficulty,[b] time limit,[c] and clarity of instructions[d] for each game in the game-based assessment (GBA) test.

Game and group		Relevance rating, mean (SD)	Difficulty rating, mean (SD)	Time limit, n (%)	Clarity of instructions, n (%)
Dotto					
	Interns	3.5 (0.8)	4.5 (0.4)	95 (62)	94 (61)
	Surgeons	3.8 (0.6)	4.2 (0.7)	22 (73)	21 (70)
CurioCity					
	Interns	3.8 (0.6)	2.9 (0.8)	151 (99)	144 (94)
	Surgeons	3.7 (0.7)	3.7 (0.6)	27 (90)	24 (80)
MultiTask					
	Interns	3.7 (0.6)	2.9 (0.7)	142 (93)	147 (96)
	Surgeons	3.6 (0.7)	2.5 (0.5)	29 (97)	27 (90)

[a]The relevance rating scale ranged from 1 to 5, with higher scores indicating greater relevance for selection of surgical residents (1="not relevant", 2="slightly relevant", 3="moderately relevant", 4="very relevant", 5="extremely relevant").

[b]The difficulty rating scale ranged from 1 to 5, with higher scores indicating greater difficulty (1="very easy", 2="easy", 3="moderately difficult", 4="very difficult", 5="extremely difficult").

[c]Participants were asked whether the time limit was sufficient for the task. The number in the table represents the number of interns and surgeons who responded "yes."

[d]Participants were asked whether the instructions for the task were clear. The number in the table represents the number of interns and surgeons who responded "yes." The instructions were modified slightly based on the surgeons' feedback before the test was administered to the interns.

Addressing the latter first, overall, both the interns and expert surgeons regarded the time limits as sufficient (the lowest time limit approval rating was 62% of the interns for the Dotto game; for CurioCity and MultiTask, all ratings were 90% or above). Both samples also considered the instructions to be generally clear (again, the lowest approval rating was by the interns for the Dotto game, at 61%; see Table 4). Before the test was administered to the interns, some of the instructions were modified slightly and improved based on feedback provided by the expert surgeons either verbally or in writing.

The difficulty ratings varied between games, with the CurioCity and MultiTask games perceived overall as being moderately difficult, and the Dotto game largely perceived as very difficult to extremely difficult. The mean difficulty rating across the games and samples was 3.5 (SD 0.7), meaning that the test as a whole was perceived as moderately to very difficult. All games were considered by both the expert surgeons and the interns as relevant for assessing cognitive abilities and personality characteristics in the selection of candidates for surgical training (manifested in average ratings of 3.5 or above; see Table 4). The mean relevance rating across the games and samples was 3.6 (SD 0.1). Looking at the whole-test ratings, the mean relevance ratings were relatively high (interns: mean 3.6, SD 0.7; expert surgeons: mean 3.7, SD 0.6). In addition, the test platform was perceived as comfortable to use (interns: mean 4.2, SD 0.2; expert surgeons: mean 4.0, SD 0.3).

As noted, we also analyzed participants' written feedback (in the free-text portion of the questionnaire), as well as feedback provided orally by the expert surgeons. Some of the surgeons indicated that their relevance ratings would have been higher if the tasks in the GBA were more directly related to surgical tasks and scenarios. Some participants also suggested that the test would be more relevant if it assessed other important competencies not covered in the current version, such as interpersonal skills, teamwork, leadership, and integrity. Finally, participants also expressed concern that prior experience with video games could affect performance on the test.

Discussion

Study Overview and Significance

This paper presents an innovative gamified test designed to assess cognitive abilities and personality characteristics relevant to the selection of surgical residents. While several studies have evaluated the use of GBAs in assessing applicants for employment, this is, to our knowledge, the first to evaluate their use in selecting surgical residents. As part of a broader program of validation research, this initial study provides preliminary evidence supporting the tool's feasibility, acceptability, and validity.

Evidence for Validity

Overview

On the basis of feedback from surgeons and interns regarding the test's relevance, difficulty, and administration, the results of this study support the feasibility and acceptability of the test. We also present preliminary evidence concerning 4 of the 5 main components of construct validity: content, response process, internal structure, and relationships with other variables (the fifth component, consequences, could not be examined in this study) [27,28]. In some cases, the evidence is based on procedures used in the development and adaptation of the test; in others, it is based on empirical data collected during the study.

Content

In terms of content, the games used in the GBA were selected to assess relevant cognitive abilities and personality characteristics based on competencies identified in a previous job analysis [7]. The games were developed and validated by psychometricians and psychologists to evaluate these specific competencies, and both the interns and surgeons participating in the study rated the games as relevant for selecting candidates for surgical training. Some of the expert surgeons indicated that their relevance ratings would have been higher if the content of the games were more directly related to surgery or medicine. This weakens somewhat the content evidence for validity. However, the literature on gamification suggests that GBAs can effectively assess relevant competencies even when the game scenario seems unrelated to the profession [26]. Future studies should examine whether GBAs that more directly mimic job-related situations are more valid for selecting qualified candidates.

Response Process Evidence

Response process evidence of validity has 2 components. The first is the elimination of sources of error associated with test administration [28]. Toward this end, we provided detailed and thorough instructions for each game. The instructions were revised based on feedback provided by the expert surgeons before the test was administered to the interns. The ratings of both the expert surgeons and interns indicate that on the whole, the instructions were perceived as clear.

The second component of response process evidence is the appropriateness of the methods used to combine different performance parameters to produce a composite score. To support the calculation of a total test score based on the competency scores, we examined the correlations between the competency scores. Strong correlations were obtained, supporting the calculation of a composite performance score.

Internal Structure Evidence

Internal structure, as a source of validity, relates to the statistical or psychometric characteristics of the test. The item analysis conducted on the test data of the interns showed good psychometric properties, supporting the internal structure of the test. In addition, the factor analysis yielded two groups of competencies, one reflecting cognitive abilities and the other personality characteristics. This result is consistent with previous classifications of these competencies [4,7,31], and therefore also in keeping with the test's expected internal structure.

Relationships With Other Variables

This source of evidence relates to the "degree to which these relationships are consistent with the construct underlying the proposed test score interpretation" [32]. Most commonly, this evidence is assessed based on correlations of assessment scores

with a criterion measure of future workplace performance. While this type of evidence is indeed crucial for the validation of the current test, it was not available in this initial study.

Instead, the present analysis relies on a different methodology, namely, examining whether the relationships found in this study between test scores and external variables are consistent with what is known from the literature regarding the relationship between nontechnical competencies and those variables. Based on the data of interns, we calculated the correlations between participants' performance on the gamified test and other variables.

As expected, no correlations were found with age, dominant hand, or the intern's desired training field. We found relatively small but statistically significant correlations with both gender and self-reported video game experience, with males and frequent gamers obtaining higher GBA scores. Notably, the gender difference was largely accounted for by differences in video game experience, suggesting that the observed gender effect is explained by greater familiarity with video games among males. These findings are in line with other studies showing that gamers and males may potentially have advantages over nongamers and females in the context of GBAs [33,34], and they raise questions regarding the fairness of these tests. Since there is evidence that playing video games improves cognitive and mental abilities [35,36], it is unclear whether the correlation between video game experience and the gamified test scores found in this study reflects a genuine positive influence of video games on gamers' abilities, or whether it is simply an artifact of the test format that may bias the selection process. Future research should examine whether changes in instructions, allowing more practice time before the test, or changes in GBA features and measures may eliminate these advantages [33]. In addition, further studies should examine whether increasing women's exposure to video games in general would help to minimize this gender gap. However, it is important to note that the observed gender effect was small to medium in size, and the effect of video game experience was small. Thus, while caution is warranted, these differences should not be overstated. Until further evidence is available, the use of adjusted cutoffs or gender-specific norms may help avoid exacerbating the underrepresentation of women in surgical fields.

In addition, it is important to acknowledge that the GBA examined in this study does not encompass the full range of cognitive abilities and personality characteristics relevant for selecting surgical residents. Notably, key nontechnical competencies such as interpersonal skills, teamwork, leadership, and integrity were not addressed in the current assessment. Furthermore, the tasks included were primarily procedural and did not involve verbal abilities. As previous research has shown that males and females may excel in different domains—with females often demonstrating strengths in tasks that require verbal abilities [37] and interpersonal skills [38,39]—it is plausible that a more comprehensive assessment approach could mitigate the small gender differences observed in this study. For example, incorporating tools that evaluate verbal and interpersonal competencies might balance the overall selection outcomes. Future research should investigate whether expanding the assessment battery to include gamified situational judgment tests [21,40] or other instruments targeting these nontechnical domains could enhance fairness and reduce gender disparities in selection.

Moreover, we found a medium correlation between the gamified test scores and scores on a technical aptitude test performed using a virtual reality laparoscopic simulator. Since video game experience has been shown to correlate with initial performance on laparoscopic simulators [41], we considered the possibility that this shared factor may contribute to the observed association, that is, that previous video game experience might positively influence performance on both assessments. However, the correlation remained significant even after controlling for video game experience, suggesting that gaming experience only partially explains the relationship between the 2 tests.

In addition to this shared factor, our findings suggest that common underlying competencies may also play a role. Specifically, scores on the technical aptitude test were significantly associated with nontechnical competencies measured by the GBA, such as planning, problem-solving, analytical thinking, learning ability, flexibility, and precision. These results indicate that both assessments may tap into similar cognitive processes or behavioral tendencies. This interpretation is supported by prior research demonstrating meaningful correlations between nontechnical skills and performance on laparoscopic simulators [42-44].

To further disentangle the effects of gaming experience from shared competencies, future research should examine whether the correlation between GBA and laparoscopic simulator performance persists among individuals with previous laparoscopic experience. Alternatively, exploring the relationship between GBA scores and performance on open surgery tasks—which are not influenced by video game experience—could help clarify whether the observed correlation is driven by familiarity with gaming or by genuine overlap in nontechnical competencies.

Finally, as only 21% of the variance in GBA scores is explained by the technical aptitude test, it is clear that the GBA primarily measures competencies beyond those assessed by the laparoscopic simulator. This finding supports both the convergent and divergent validity of the GBA and aligns with its intended construct interpretation [32].

Implications

Nontechnical skills are important for surgeons no less, and perhaps even more, than technical skills [7]. Indeed, many underlying causes of error within and outside the operating room originate from nontechnical aspects of performance [8]. Hence, training programs recognize the importance of assessing candidates' cognitive abilities and personality characteristics when selecting each year's cohort of surgical residents. Yet traditional assessment methods (academic achievement, curricula vitae, letters of recommendation, and interviews) are poorly correlated with later performance; and self-report measures, a potential alternative, are subject to bias and dishonesty.

The present study introduces an innovative solution for assessing relevant competencies: game-based assessment [21,22,25]. Building on existing GBAs developed for hiring and recruitment contexts, we implemented a systematic process to develop a gamified test tailored for surgical resident selection and conducted an initial investigation into its validity. Gamified assessment tests offer numerous advantages over other assessment approaches. First, they examine the entire solving process, as opposed to traditional tests which only examine the final product, allowing for a deeper understanding of the candidate's competencies and work style. Compared to self-report measures, GBAs measure candidates' actual behavior, which is harder to fake. Finally, gamified tests are based on automated scoring, thus minimizing the influence of bias in the selection process.

The present findings provide preliminary support for the feasibility, acceptability, and validity of the gamified test, suggesting that it may contribute to improving the selection of surgical residents by offering a potentially more reliable assessment of candidates' abilities and attributes. It follows that implementing this test—or a similar tool—may assist program directors in identifying candidates with strong potential for success in surgical training. This improved selection process should, in turn, result in more capable surgical residents and surgeons, ultimately leading to better surgical outcomes and increased patient safety. Our findings may be relevant to nonsurgical training programs as well, since some of the competencies assessed in the gamified test developed in this study apply to residents in all medical fields.

The gamified test presented in this study does not assess all cognitive abilities and personality characteristics relevant for selecting surgical residents. As mentioned by the participants in this study, competencies missing in the present work include interpersonal skills, teamwork, leadership, and integrity. Future studies should examine whether other types of GBAs, such as gamified situational judgment tests [21], or other assessment methods may be useful in improving this area.

Strengths and Limitations

This is the first study to examine the use of GBAs in selecting surgical residents, or indeed medical residents in any field. As such, one of its key strengths is use of a systematic process to develop a novel test for assessing candidates' cognitive abilities and personality characteristics and to evaluate its validity, feasibility, and acceptability. Another strength is the large sample of expert surgeons (30) and interns (152) from various hospitals who provided data for statistical analysis (the interns) and feedback (both samples).

The study has some limitations. First, our participants came from a single country, thereby restricting the generalizability of our findings. However, it seems unlikely that the competencies we assessed are distributed differently among candidates from other nations. In addition, since the interns in our study were volunteers, it is possible that our sample does not represent the population of candidates for surgical training. Future studies should aim to recruit a more randomized and representative sample to ensure the findings are generalizable to the broader population of surgical trainees. However, the large variance in competency and test scores observed in our sample suggests that our sample was likely sufficiently representative of candidates with different qualifications. Finally, an important limitation of this study is the absence of evidence for test-criterion relationships. While we present data supporting various sources of validity, we have not yet assessed whether the GBA scores predict future performance in surgical residency. Given the high-stakes nature of surgical selection, establishing evidence for test-criterion relationships is critical before the tool can be adopted for widespread use. Longitudinal studies that track residents' real-world performance over time are planned to address this essential aspect.

Conclusions

The use of GBAs holds potential for contributing to improvements in resident selection. The present study presents an innovative gamified test designed to assess cognitive abilities and personality characteristics relevant to the selection of surgical residents. Preliminary evidence supports the feasibility, acceptability, and validity of the gamified test. However, further research is needed, particularly to assess evidence for test-criterion relationships, before the tool can be fully recommended for surgical resident selection.

Abstract

Background: The Japanese National Medical Licensing Examination (NMLE) is mandatory for all medical graduates seeking to become licensed physicians in Japan. Given the cultural emphasis on summative assessment, the NMLE has had a significant impact on Japanese medical education. Although the NMLE Content Guidelines have been revised approximately every five years over the last 2 decades, objective literature analyzing how the examination itself has evolved is absent.

Objective: To provide a holistic view of the trends of the actual examination over time, this study used a combined rule-based and data-driven approach. We primarily focused on classifying the items according to the perspectives outlined in the NMLE Content Guidelines, complementing this approach with a natural language processing technique called topic modeling to identify latent topics.

Methods: We collected publicly available NMLE data for 2001-2024. Six examination iterations (2880 items) were manually classified from 3 perspectives (level, content, and taxonomy) based on pre-established rules derived from the guidelines. Temporal trends within each classification were evaluated using the Cochran-Armitage test. Additionally, we conducted topic modeling for all 24 examination iterations (11,540 items) using the bidirectional encoder representations from transformers–based topic modeling framework. Temporal trends were traced using linear regression models of topic frequencies to identify topics growing in prominence.

Results: In the level classification, the proportion of items addressing common or emergent diseases increased from 60% (115/193) to 76% (111/147; $P<.001$). In the content classification, the proportion of items assessing knowledge of pathophysiology decreased from 52% (237/459) to 33% (98/293; $P<.001$), whereas the proportion assessing practical knowledge of primary emergency care increased from 21% (95/459) to 29% (84/293; $P<.001$). In the taxonomy classification, the proportion of items that could be answered solely through simple recall of knowledge decreased from 51% (279/550) to 30% (118/400; $P<.001$), while the proportion assessing advanced analytical skills, such as interpreting and evaluating the meaning of each answer choice according to the given context, increased from 4% (21/550) to 19% (75/400; $P<.001$). Topic modeling identified 25 distinct topics, of which 10 exhibited an increasing trend. Non–organ-specific topics with notable increases included “comprehensive clinical items,” “accountability in medical practice and patients’ rights,” “care, daily living support, and community health care,” and “infection control and safety management in basic clinical procedures.”

Conclusions: This study identified significant shifts in the Japanese NMLE over the past 2 decades, suggesting that Japanese undergraduate medical education is evolving to place greater importance on practical problem-solving abilities than on rote

memorization. This study also identified latent topics that showed increased prominence, possibly reflecting underlying social conditions.

Introduction

Background

The National Medical Licensing Examination (NMLE) is a mandatory, high-pressure test that all medical school graduates in Japan must pass before becoming licensed physicians. Japan has 82 medical schools with an annual enrollment capacity of more than 9000 students [1]. Upon completing the 6-year medical curriculum, students are eligible to participate in the NMLE program [1]. Unlike licensing examinations in countries such as the United Kingdom, Australia, and Singapore, which primarily assess foreign medical graduates [2], passing the Japanese NMLE is compulsory for all domestic and international graduates who wish to practice medicine in Japan. In 2024, approximately 10,000 candidates took the examination [3]. The NMLE comprises multiple-choice items similar in format to examinations in South Korea, China, Thailand, and Germany [4]. Although there have been discussions regarding transitioning to a computer-based format [1], the examination remains paper-based, with all the candidates in a given year responding to identical items [5]. It is held annually, and all examinees take the examination on the same day. The items and answers are disclosed after the examination, and the item set is completely altered each year. Unlike the United States Medical Licensing Examination (USMLE), repeated attempts are not permitted in the same year, making it a one-shot opportunity. A partially norm-referenced grading system is applied to the pass-or-fail decision, ensuring that approximately 10% of candidates fail each year, thereby maintaining the examination's competitive nature [1]. Consequently, the pressure on examinees is considerable because failing the examination delays medical licensure by a full year.

Cultural factors contribute to the heightened significance of the NMLE in Japan. The belief that academic achievement determines future stability is deeply rooted in Japanese society, a mindset often associated with Confucian-influenced cultures [1]. This perspective is reinforced by the highly competitive nature of Japanese university entrance examinations, with medical school admissions being particularly competitive and reportedly having an acceptance rate of approximately 8.3% (12 applicants per spot). This fosters a learning culture that prioritizes summative assessments over formative feedback. In this context, students are accustomed to receiving model answers from instructors rather than engaging in critical discussions [6]. These educational values shape how medical students approach learning and preparation for high-stakes examinations such as the NMLE.

The scope and content of the NMLE are defined by the "NMLE Content Guidelines," published by the Ministry of Health, Labour and Welfare (Japan) [7] (an English summary of which is provided in Multimedia Appendix 1, as no official English version exists). The original Japanese document is titled "*Ishi Kokka Shiken Shutsudai Naiyō Shishin (Reiwa 6 Edition)*." They specify the fundamental knowledge and skills physicians are expected to possess when taking their first steps into clinical practice. The NMLE Content Guidelines categorize these competencies by topic and outline the performance expectations for each one. To streamline the examination's administration, the NMLE was reduced from a 3-day, 500-question format to a 2-day, 400-question format [1,7,8]. In addition, the question content was regulated to avoid excessive specialization, and competency levels were clearly defined to ensure clarity regarding the knowledge expected of medical graduates [1]. These guidelines are revised approximately every five years to reflect the evolving requirements for medical professionals.

Another key framework shaping Japanese medical education is the "Medical Education Model Core Curriculum (MCC)," issued by the Ministry of Education, Culture, Sports, Science, and Technology (Japan) [9]. The official Japanese title is "*Igaku Kyouiku Moderu Koa Kyarikyuramu (Reiwa 4 Edition)*." The MCC guidelines oversee approximately two-thirds of the medical education curriculum and are revised approximately every five years. Since its introduction in 2001, the MCC has evolved significantly; the 2016 revision adopted a competency-based medical education approach and shifted from traditional discipline-based learning to an integrated curriculum [10], aligned with international standards followed in the United States, Singapore, Canada, the Netherlands, and the United Kingdom [11]. The most recent 2022 MCC further elaborates on good practice and offers recommendations for medical education strategy and assessment [12].

Despite these comprehensive educational guidelines, the NMLE continues to exert considerable influence on medical education in Japan. Some universities underemphasize the MCC, and students often prioritize knowledge acquisition for NMLE preparation over more holistic learning experiences [13,14]. To enhance medical education in Japan, it is essential to consider the influence of the NMLE on learning behaviors and curriculum design, particularly given the strong preference for summative assessments in Japanese educational culture. As both the NMLE Content Guidelines and the MCC have evolved, it is increasingly important to examine how the actual content of the NMLE reflects these changes. However, there is a lack of objective longitudinal analysis of the examination itself, highlighting the need for systematic research in this area.

Study Goal

The objective of this study was to analyze trends in the content of the NMLE across the 21st century. A priori dimensions of interest were defined by the recent NMLE Content Guidelines and included 3 perspectives: level, content, and taxonomy classifications of examination items. Accordingly, the specific research questions were as follows: (1) How has the distribution of examination items changed across these predefined dimensions since 2001? (2) What latent themes, which cannot be fully captured by these dimensions, can be identified through topic modeling, and how have they evolved over time?

Based on prior revisions of the MCC and national examination policy reports, the following a priori hypotheses were formulated: (1) the proportion of items requiring highly specialized knowledge beyond the scope of generalist training has decreased; (2) the overall proportion of practical questions has increased; (3) among the items with higher-order cognitive demands, the proportion of more complex, context-dependent problem-solving items has increased; and (4) in addition to the above dimensions, topic modeling can identify latent themes whose prominence has increased over time, reflecting evolving social priorities and educational expectations. To address these questions, we used a hybrid methodology that integrates rule-based manual classification with exploratory natural language processing (NLP) techniques, particularly topic modeling [15]. Manual classification allowed us to directly reflect the emphases outlined in official medical education guidelines, whereas topic modeling enabled the discovery of previously unknown patterns beyond predefined frameworks.

By integrating these complementary approaches, this study aims to not only provide an evidence-based understanding of how the NMLE has evolved in terms of content emphasis and cognitive skill requirements but also offer practical insights for key stakeholders. For policymakers, our longitudinal data offers insights into the current medical training system's adaptive flexibility and helps identify remaining areas for further adjustment. For curriculum designers and educators, the trend data serve as an empirical basis for the timely update of educational content to align with contemporary medical education needs. Finally, for medical education researchers, this study's approach to quantitatively capturing the evolution of examination content offers a new analytical model for education evaluation research, both domestically and internationally.

Methods

Study Design

This cross-sectional study comprehensively analyzed NMLE examination items from 2001 to 2024, using a hybrid methodology that integrates rule-based and data-driven approaches in a complementary manner. To elucidate trends in the NMLE, we combined systematic analysis through manual classification with exploratory analysis using artificial intelligence (AI).

In the rule-based component, we focused on 6 specific examination sessions—2001, 2005, 2009, 2013, 2018, and 2024—that each represented the first examination administered after a major revision of the NMLE Content Guidelines. These datasets, comprising a total of 2880 items, were manually classified using 3 classification systems developed based on the guidelines: level, content, and taxonomy.

In the data-driven component, we performed topic modeling across all 24 NMLE sessions conducted between 2001 and 2024, encompassing a total of 11,540 items. This AI-based analysis provided an objective perspective independent of the guidelines, offering valuable complementary insights. Specifically, we used bidirectional encoder representations from transformers–based topic modeling framework (BERTopic) [16,17], a state-of-the-art NLP framework.

Setting

The NMLE Content Guidelines accompanying the 2024 edition outlined the revisions to be made to the NMLE. The 2024 NMLE was the first to be administered following the revisions [7]. The examination comprises 3 sections: essential, general clinical, and specialized clinical [7]. Each section includes items covering a wide range of medical specialties and public health domains (Figure S1 in Multimedia Appendix 2).

Classification Procedures

Level Classification

The revision process of the NMLE Content Guidelines emphasized the careful selection of diseases to be tested, clarification of the required depth of knowledge for each disease, and the exclusion of topics requiring only basic factual recall that should be mastered before clinical training [5]. To define the breadth and depth of knowledge appropriate for new graduates entering clinical residency, a level classification system was introduced [5]. The 2024 edition of the NMLE Content Guidelines explicitly assigns a level classification to each subcategory within a specialized clinical section [7].

In this study, the level of each question was determined by identifying the disease or condition being tested, either as the main topic or as the correct answer. These were matched to corresponding items in the 2024 NMLE Content Guidelines, and the preassigned level classification was used to categorize each question (Table 1). For items involving multiple key diseases or answer choices, the highest assigned level among the relevant classifications was used to represent the level of the question, with the ranking order as follows: "A > B > C > not classifiable." Detailed classification criteria are provided in Multimedia Appendix 3.

Table 1. Disease categorization. English translations of terms are based on official sources where available. For terms without official translations, translations were made by the authors and validated against published English-language literature.

Level	Disease types	Competencies required for initial treatment	Competencies required for subsequent treatment	Knowledge to be tested
A	Common diseases in primary care settings and acute diseases requiring emergency treatment	Possess enough knowledge to diagnose and manage patients under supervision, while appropriately consulting attending physicians as necessary	Possess enough knowledge to solve problems arising in subsequent treatment	• Knowledge of pathophysiology • Clinical reasoning skills • Knowledge of primary emergency care • Knowledge of continued care
B	Diseases that should be learned during postgraduate clinical training	Possess enough fundamental knowledge to manage patients under supervision	Possess enough knowledge to recognize when and how to present concerns to supervisors	• Knowledge of pathophysiology • Clinical reasoning skills • Knowledge of primary care
C	Diseases requiring a high level of clinical experience (beyond the postgraduate clinical training level)	Ability to integrate understanding of the outline of illnesses and clinical reasoning to reach a differential diagnosis	N/A[a]	• Ability to recall the names of diseases

[a]N/A: not applicable.

Content Classification

The NMLE Content Guidelines impose certain restrictions on test content based on the level classification of each question. As seen in Table 1, the guidelines classify required knowledge such as pathophysiology, clinical reasoning, primary emergency care, and continued care, to help define the focus of examination items [7]. Although explicit definitions of these terms are not provided, they generally align with the cognitive processes expected of a practicing clinician.

This study categorized the items based on the cognitive processes required for clinical practice. The following 4 content categories were defined: pathophysiology, clinical reasoning, primary emergency care, and continued care. Pathophysiology items require reasoning based on a given diagnosis, typically presenting a disease or pathological condition and assessing knowledge of its mechanisms, associated symptoms, and potential complications. Items requiring an approach to making a diagnosis were classified as clinical reasoning. While clinical reasoning is broadly defined and encompasses multiple components—including data gathering, hypothesis generation, problem representation, differential diagnosis, provisional diagnosis, diagnostic justification, management, and treatment [18]—this study applies the term in a narrower sense. Specifically, it is limited to the diagnostic process, as described in the **Accreditation Council for Graduate Medical Education** Internal Medicine Milestones [19], excluding elements related to management and treatment to avoid overlap with other categories. Primary emergency care items focus on urgent decision-making, which is commonly applied in emergency settings and requires immediate problem-solving. Continued care items address long-term management and preventive strategies, often in the context of scheduled outpatient visits or inpatient care. Detailed classification criteria are provided in Multimedia Appendix 4.

Notably, in the official Ministry of Health, Labour and Welfare guidelines, both “primary emergency care” and “continued care” are conventionally categorized under “examination & treatment.” In this study, these were purposefully separated into distinct categories to enable a more process-oriented analysis and to track the evolving focus of the NMLE more accurately.

Taxonomy Classification

Internationally, examination items in medical education are often evaluated using Bloom’s taxonomy, which categorizes cognitive complexity levels [20,21]. In Japan, a traditional classification system derived from Bloom’s taxonomy is used to categorize items based on the cognitive skills required to answer them. This system classifies items into 3 levels, as outlined in Figures 1 and 2 [5].

Figure 1. Schematic representation of the cognitive processes required to solve examination questions. Traditional 3-tier taxonomy commonly used in Japan. A potential gap exists between Type II and Type III in terms of cognitive progression.

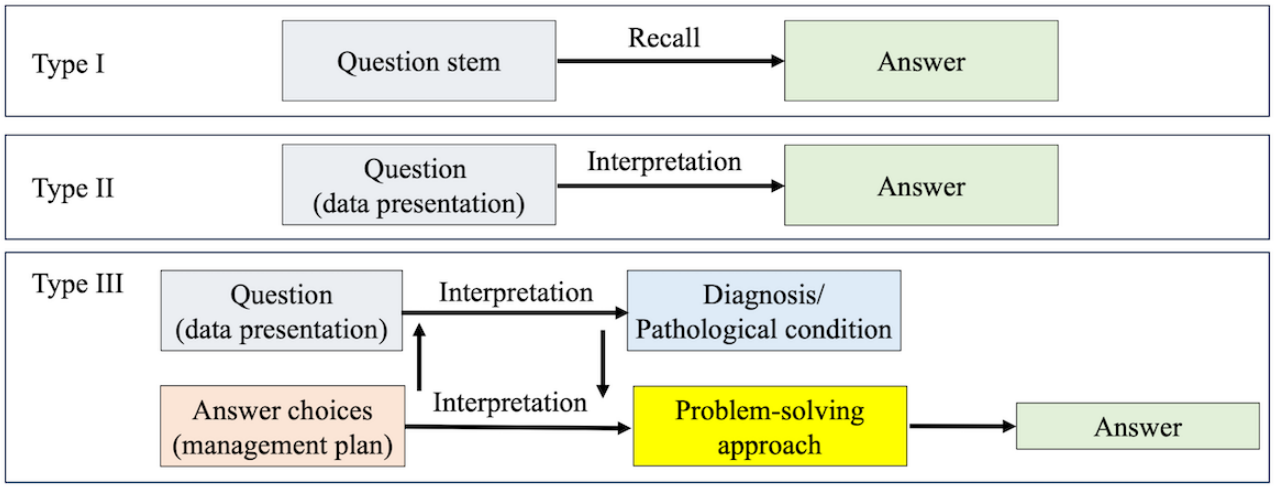

Figure 2. Schematic representation of the cognitive processes required to solve examination questions. Modified 4-tier taxonomy that introduces Type IIIa and Type IIIb to improve continuity between cognitive categories. Type III is defined as a combination of Type IIIa and Type IIIb in this system.

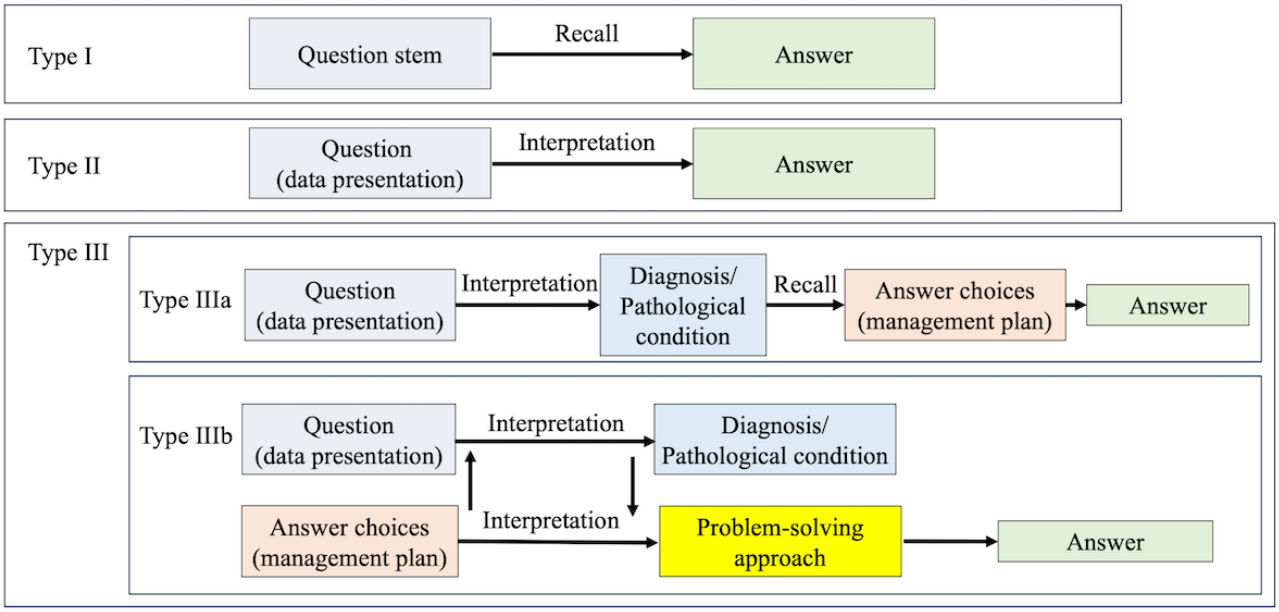

- Type I (recall-based items) can be answered purely by recalling factual knowledge.
- Type II (interpretation-based items) require understanding and interpreting the given information to derive an answer.
- Type III (problem-solving items) involve comprehending the scenario, analyzing the meaning of each answer choice, and solving a clinical problem.

Past revisions of the NMLE Content Guidelines have strongly emphasized Type II and Type III items, which test higher-order cognitive skills rather than simple recall.

Although the traditional classification system offers a straightforward framework, it does not guarantee an exhaustive or mutually exclusive categorization of NMLE items. An undefined region between Type II and Type III items may exist. We noted a substantial number of items wherein once the stem was correctly interpreted to reach a diagnostic conclusion, the subsequent answering process required little more than rote recall. Such items often arise when medical students memorize a direct correspondence between diagnoses and their associated treatments. Although prevalent, these items are not adequately defined within conventional classification frameworks.

Therefore, we introduced a novel classification system to address this limitation and enhance exclusivity and comprehensiveness. While retaining the traditional definitions for Types I and II, we refined the definition of Type III and subdivided it into 2 distinct categories: Types IIIa and IIIb. The revised classification system is as follows (Figures 1 and 2):

- Type I (recall-based): Same as the conventional Type I.
- Type II (interpretation-based): Same as the conventional Type II.
- Type III (problem-solving–based): A collective term encompassing Types IIIa and IIIb.
- Type IIIa (interpretation + recall-based): Items in which once the stem is correctly interpreted, the answer can be derived through a simple recall process. This type

corresponds to the previously undefined region between Types II and III.

- Type IIIb (interpretation + interpretation-based): Items requiring interpretation of both the stem and the meaning of the answer choices before responding. Unlike Type IIIa, the mere recognition of a diagnosis is insufficient; the examinee must also consider the context and apply higher-order reasoning. This includes scenarios where appropriate decision making is contingent upon factors such as disease severity, stage, comorbidities, allergies, or other patient-specific conditions that influence the selection of an optimal intervention.

The introduction of Type IIIa is particularly relevant, as it addresses a previously unclassified domain wherein interpretation and recall are intertwined. However, the cognitive demand is less rigorous than that in Type IIIb. The distinction between Types IIIa and IIIb is intended to capture the complexity of clinical problem-solving more accurately, particularly in cases where decision making requires contextual understanding beyond simple diagnosis. Detailed classification criteria are provided in Multimedia Appendix 5. To enhance the validity of the revised taxonomy, we aligned the definitions of Types IIIa and IIIb with established educational frameworks, including Revised Bloom's Taxonomy and the Accreditation Council for Graduate Medical Education Internal Medicine Milestones, thereby ensuring content validity. Furthermore, the distinction between Types IIIa and IIIb reflects whether the clinical reasoning process involves context-sensitive decision making, which supports its construct validity. Reliability was ensured through the use of a detailed classification manual, structured assessor training, calibration exercises, and interrater reliability testing, with discrepancies adjudicated by a senior physician.

Topic Modeling

Various topic-modeling techniques exist, such as Non-Negative Matrix Factorization (NMF) and Latent Dirichlet Allocation (LDA). However, with rapid advancements in NLP following the emergence of transformer models, more sophisticated analytical methods have been developed [22]. One such method is BERTopic, an advanced topic-modeling approach that leverages BERT (bidirectional encoder representations from transformers) embeddings, which are context-aware representations of text. Unlike traditional models that assign a fixed meaning to each word, BERT learns word meanings by considering the words that come before and after it. This bidirectional contextual understanding enables the model to capture nuanced relationships between terms—particularly important for medical texts wherein similar concepts can be expressed in diverse ways. By transforming each examination item into a BERT embedding—a numerical vector reflecting its contextual meaning—BERTopic can more accurately cluster semantically related items and identify coherent topics [16]. For Japanese texts, additional preprocessing was required because, unlike English, words are not separated by spaces. We therefore applied morphological analysis using MeCab—the most widely used tool for Japanese language processing—to segment sentences into words. To ensure accurate recognition of medical terminology, a specialized dictionary (MANBYO) was incorporated into MeCab. We then used a Japanese Sentence-BERT model ("sonoisa/sentence-bert-base-ja-mean-tokens-v2") to generate embeddings, which provided context-aware numerical representations of each examination item (stem + answer choices). These embeddings were subsequently processed through dimensionality reduction and clustering—core steps of the BERTopic topic modeling pipeline. Owing to its high customizability, BERTopic is well suited for applications beyond English-language texts and particularly effective for time-series analyses [23]. It has gained attention for its ability to uncover novel patterns and provide insights into textual data [17,23].

In this study, we applied BERTopic by inputting textual data that combined the item stems and answer choices for each examination item. The topic-modeling process was conducted in six steps using the BERTopic Python package:

- Preprocessing: For the tokenization of the Japanese text, we used the morphological analyzer "MeCab" [24,25]. To ensure appropriate analysis of texts containing symptoms and disease names, we applied a specialized dictionary for medical terms, "MANBYO" [26].
- Embedding: As a Japanese Sentence Transformer model, we used "sonoisa/sentence-bert-base-ja-mean-tokens-v2," available on Hugging Face [27].
- Dimensionality Reduction: Uniform Manifold Approximation and Projection (UMAP) was used.
- Clustering: Hierarchical Density-Based Spatial Clustering of Applications with Noise (HDBSCAN) was used.
- Tokenization: CountVectorizer was used.
- Weighting Scheme: Class-based term frequency–inverse document frequency (c-TF-IDF) scoring was used.

After analyzing the extracted keywords and various representative items, the authors determined the topic labels through mutual agreement.

To enhance transparency, we also describe the process of parameter selection in BERTopic. While default settings were maintained whenever possible, 3 key parameters were adjusted through systematic trial-and-error to optimize interpretability and stability. For UMAP, n_neighbors was set to 3 to emphasize local structures and uncover fine-grained latent topics, and n_components was set to 10 to preserve information while ensuring clustering stability. For HDBSCAN, min_cluster_size was set to 20, which balanced interpretability and granularity and resulted in 25 coherent topics. We also confirmed that the main conclusions of this study, such as the increase in items under "comprehensive clinical items" and "accountability in healthcare and patient rights," remained stable across reasonable parameter variations.

Each examination item was assigned to a single topic only, reflecting the multiclass nature of the clustering process. While some items (eg, questions combining "renal disease" and "research") could plausibly relate to more than one topic, the dimensionality reduction and clustering steps ultimately placed each item in one cluster. This design choice facilitates clearer identification of longitudinal shifts in topic prevalence, whereas

a multilabel approach would have assigned multiple simultaneous labels and obscured such temporal trends.

In addition, the process of topic interpretation and labeling was refined. For each topic, the top 20 representative keywords with the highest c-TF-IDF values and the list of examination items assigned to that topic were extracted. The research team carefully reviewed these materials, designating clearly irrelevant words (eg, laboratory units, particles, auxiliary verbs) as stop words to improve the quality of the keyword lists without altering the BERTopic analysis. Final topic labels were established through repeated focus group discussions, with reference to representative items and prior literature, until consensus was reached. For transparency, the representative keyword lists for each topic are provided in Table S2 in Multimedia Appendix 6.

Following the automatic clustering, several closely related topics were manually integrated through consensus discussions (eg, merging "male" and "female" patient clusters into "comprehensive clinical items") to enhance thematic coherence and prevent over-splitting.

Selection Criteria for Analysis

For each rule-based analysis, we examined question datasets from the NMLEs for 2001, 2005, 2009, 2013, 2018, and 2024. The 2001 NMLE was included because of its coincidence with the initial publication of the MCC. For the level classification analysis, only items from the specialized clinical section were considered, as the 2024 NMLE Content Guidelines have defined level classifications for this section. Items without an explicitly assigned level were excluded from the statistical analysis. For the content classification analysis, items related to public health knowledge (eg, health policies, legal frameworks, and statistical concepts) were excluded because of their distinct nature. The analysis focused on items from other medical specialties, whereas items that could not be assigned to a predefined content category were excluded from statistical analysis. For the Taxonomy classification analysis, all items were included without exception.

For the data-driven analysis, we used complete question datasets from the 2001-2024 NMLEs. All items were included in the topic-modeling analysis without exception.

Between 2001 and 2006, each examination included 30 or 50 pilot items that were not subject to scoring. However, as the specific pilot items were not disclosed, the dataset was analyzed with all items included.

Study Variables

The primary outcome variable was the distribution of items across the 3 classification systems in each examination year. The primary predictor variable was the examination year, which was treated as representing time progression, allowing for the assessment of trends in the item distribution. Secondary outcome variables included topic distribution, measured as the proportion of items assigned to each topic, and the slope coefficient from the linear regression, which represented the annual rate of change in the proportion of each topic over time.

Data Sources and Measurement

Each classification system was evaluated by 10-12 assessors, including clerkship students and licensed physicians. All assessors were provided with a detailed classification manual developed iteratively through expert discussion (Multimedia Appendices 3-5). Prior to the formal classification, assessors participated in structured training sessions, which included video-based instructions and multiple practice rounds with sample items. These sessions were followed by calibration exercises wherein assessors independently classified a pilot set of items, then discussed discrepancies with senior physicians to ensure consistent interpretation of the manual. Clerkship students were included only if they had completed at least one year of clinical clerkship. In addition, when required, their classifications were cross-checked against those of licensed physicians to confirm reliability. The initial draft of the manual was created by a general internist (YM) with reference to the 2024 (Reiwa 6) NMLE Content Guidelines and the official report of the Ministry of Health, Labour and Welfare's Working Group on Improvements to the NMLE. The draft was reviewed by the study team and refined through expert focus group discussions involving KS, an experienced physician and medical educator. During these discussions, operational rules were established for each system. For the level classification, each item was mapped to the most relevant blueprint subitem, and when multiple disease themes or answer keys were plausible, assessors selected the theme most central to the item's core; if options were equally plausible, priority was given to the condition with higher frequency or urgency (A > B > C). For the content classification, we adopted 4 mutually exclusive categories—pathophysiology, clinical reasoning, primary emergency care, and continued care—derived from the official guidelines, and refined definitions to avoid overlap. For the Taxonomy classification, we clarified the boundaries among Types II, IIIa, and IIIb through iterative examination of numerous examination items and consensus-based discussions among the research team. In particular, the cognitive distinction between "recall" and "interpretation" was deliberated extensively to define the boundary between Types IIIa and IIIb. Disagreements encountered during manual development were resolved through consensus, supported by additional sample questions when necessary. When discrepancies occurred, a third-party adjudicator (a general internist) made the final decision. We believe that this structured process ensured that all assessors, including students, were adequately trained and able to apply the classification framework reliably.

In this study, clerkship students are defined as medical students who have passed common achievement tests (computer-based tests and objective structured clinical examinations), and been certified to possess the necessary knowledge, skills, and professionalism to participate in clinical clerkships. Given the importance of clinical experience in accurate classification, content and taxonomy classifications were conducted exclusively by licensed physicians or clerkship students with at least two years of clinical clerkship experience.

This ensured that classifications requiring higher clinical expertise were performed only by adequately trained and experienced assessors. All translations of Japanese terms were

based on official bilingual documents whenever available. When no official translation was available, translations were performed by the study team and cross-checked against existing English-language literature to ensure consistency and accuracy.

Statistical Analysis

Interrater reliability of the classification system was assessed using Fleiss' κ coefficient [28] (0.8-1.0=almost perfect; 0.6-0.8=substantial; 0.4-0.6=moderate; 0.2-0.4=fair). Chi-square tests were conducted to evaluate the relationship between item distribution and examination year. Cochran-Armitage trend tests were conducted to assess time-series trends in question distribution. Statistical analyses were performed using R (version 4.3.3; The R Project for Statistical Computing). The trends of each topic over time were traced using linear regression models based on topic frequencies using NumPy (version 1.26.4; NumPy Developers) in Python (version 3.12.4; Python Software Foundation).

Ethical Statement

This study did not collect any human or patient information and was thus exempt from ethical approval, informed consent requirements, and institutional review board approval. Additionally, as no identifying information was included, the data did not need to be anonymized or deidentified. No compensation was offered because there were no human participants in this study.

Results

Overview

Fleiss' κ coefficients were calculated to assess the reliability of all 3 classification systems (level, content, and taxonomy). Most coefficients indicated substantial agreement (κ>0.6), although the content classification in the 2013 examination showed a moderate κ coefficient (κ=0.54). Detailed values for each classification across 6 representative examination years are provided in Table S3 in Multimedia Appendix 7, which also describes the procedures for calculating κ coefficients. For the level, content, and taxonomy classifications, a chi-square test revealed a significant association between examination year and the distribution of question categories (P=.02, P<.001, and P<.001, respectively). Based on these results, Cochran-Armitage trend tests were conducted for all 3 classifications to evaluate temporal trends.

Level Classification

Among the 1100 items in the specialized clinical section, a total of 1073 (97.5%) were successfully classified into one of 3 predefined levels (Table 2). The remaining 27 (2.5%) items were classified as "not classifiable" and excluded from further statistical analysis. Level A items accounted for 743 (69.2%) of classified specialized clinical items, making them the most common. Items at levels B and C accounted for 244 (22.7%) and 86 (8%), respectively. Over 23 years, the proportion of level A items increased significantly from 59.6% (115/193) in 2001 to 75.5% (111/147) in 2024 (P<.001). By contrast, the proportion of level B and C items declined significantly, from 29.5% (57/193) to 19.7% (29/147; P=.008) and 10.9% (21/193) to 4.8% (7/147; P=.009), respectively (Figure 3A). These trends suggest a shift toward assessing higher-priority knowledge over time.

Figure 3. Temporal trends in question distribution across classification systems. (A) Level classification, (B) content classification, and (C) taxonomy classification (Types I, II, and III), and (D) taxonomy classification (Types IIIa and IIIb). Points represent observed data. Solid lines indicate fitted trends estimated using linear regression, with shaded areas representing the 95% CIs. Cochran-Armitage trend tests were performed for each category, and the associated *P* values are displayed. The significant increase in Type IIIb questions observed in subpart D primarily accounts for the overall increase in Type III questions shown in subpart C, whereas no significant trend was found for Type IIIa.

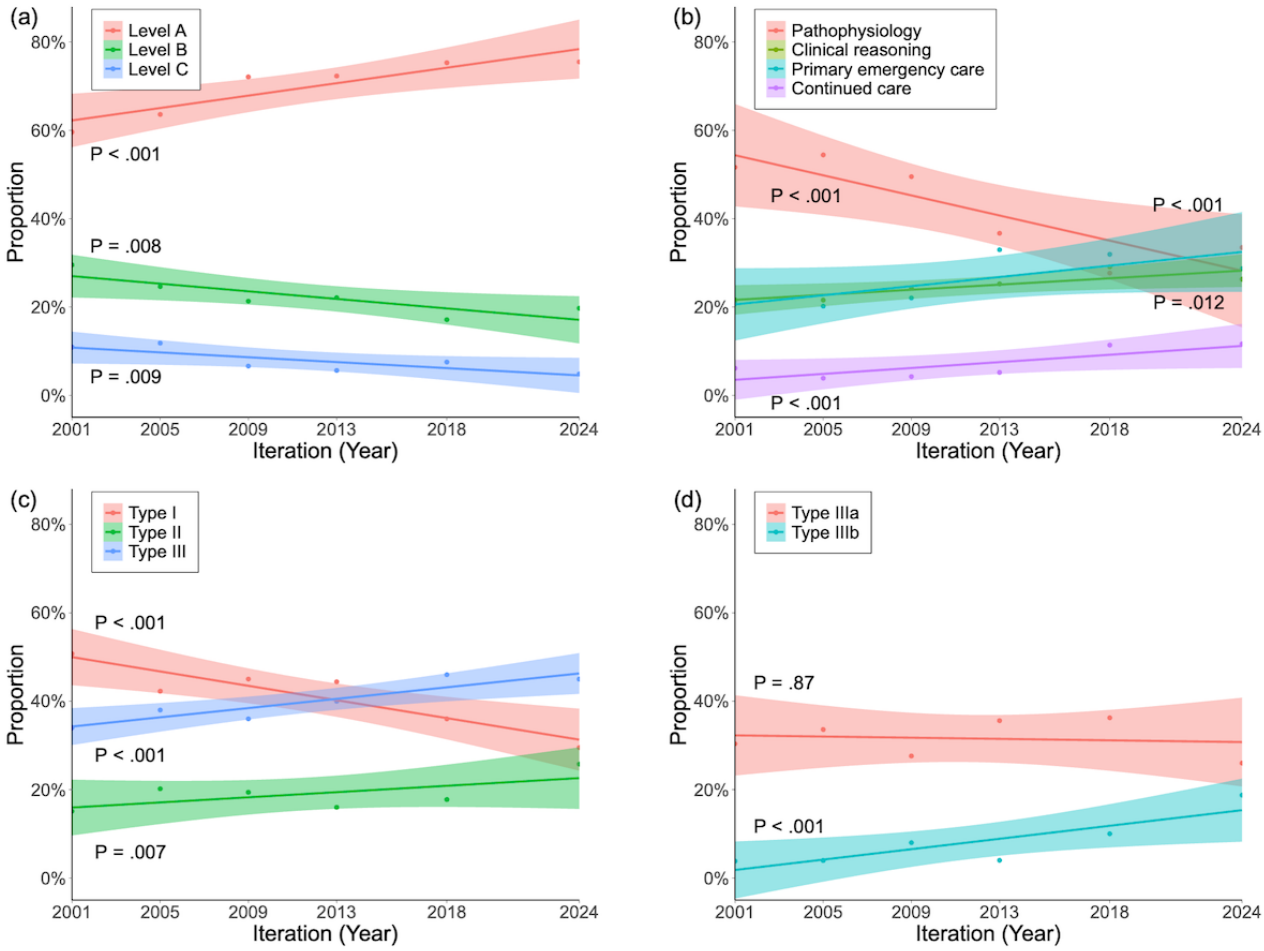

Table 2. Level classification.

Year	2001 (n=200), n (%)	2005 (n=200), n (%)	2009 (n=200), n (%)	2013 (n=200), n (%)	2018 (n=150), n (%)	2024 (n=150), n (%)	Total (n=1100), n (%)
Level A	115 (57.5)	124 (62)	142 (71)	141 (70.5)	110 (73.3)	111 (74)	743 (67.6)
Level B	57 (28.5)	48 (24)	42 (21)	43 (21.5)	25 (16.7)	29 (19.3)	244 (22.2)
Level C	21 (10.5)	23 (11.5)	13 (6.5)	11 (5.5)	11 (7.3)	7 (4.7)	86 (7.8)
Not classifiable	7 (3.5)	5 (2.5)	3 (1.5)	5 (2.5)	4 (2.7)	3 (2)	27 (2.5)

Content Classification

Of the 2518 items (excluding public health–related items), a total of 2228 (88.5%) were assigned to one of 4 content categories (Table 3). The remaining 290 (11.5%) items were classified as "not classifiable" and excluded from further statistical analysis. Pathophysiology was the most frequently tested category, appearing in 981 (44%) of all classified items, followed by primary emergency care (562, 25.2%), clinical reasoning (539, 24.2%), and continued care was the least common (146, 6.6%). However, the proportion of pathophysiology items exhibited substantial fluctuations, ranging from 54.4% (240/441) in 2005 to 27.7% (78/282) in 2018. Over 23 years, the overall proportion of pathophysiology items declined significantly, from 51.6% (237/459) to 33.4% (98/293; *P*<.001). Conversely, the proportions of clinical reasoning, primary emergency care, and continued care items showed significant upward trends. From 2001 to 2024, the proportions increased from 21.6% (99/459) to 26.3% (77/293) for clinical reasoning (*P*=.01), 20.7% (95/459) to 28.7% (84/293) for primary emergency care (*P*<.001), and 6.1% (28/459) to 11.6% (34/293) for continued care (*P*<.001; Figure 3B). These trends indicate a progressive shift toward assessing clinical decision-making and patient management skills.

Table 3. Content classification.

Year	2001 (n=488), n (%)	2005 (n=473), n (5)	2009 (n=442), n (%)	2013 (n=436), n (%)	2018 (n=343), n (%)	2024 (n=336), n (%)	Total (n=2518), n (%)
Pathophysiology	237 (48.6)	240 (50.7)	200 (45.2)	128 (29.4)	78 (22.7)	98 (29.2)	981 (39)
Clinical reasoning	99 (20.3)	95 (20.1)	98 (22.2)	88 (20.2)	82 (23.9)	77 (22.9)	539 (21.4)
Primary emergency care	95 (19.5)	89 (18.8)	89 (20.1)	115 (26.4)	90 (26.2)	84 (25)	562 (22.3)
Continued care	28 (5.7)	17 (3.6)	17 (3.8)	18 (4.1)	32 (9.3)	34 (10.1)	146 (5.8)
Not classifiable	29 (5.9)	32 (6.8)	38 (8.6)	87 (20)	61 (17.8)	43 (12.8)	290 (11.5)

Taxonomy Classification

All 2880 items were successfully classified into one of the 4 taxonomy types (Table 4). Type I items were the most common, accounting for 1212 (42.1%) of all items, followed by Type IIIa (n=910, 31.6%), Type II (n=541, 18.8%), and Type IIIb (n=217, 7.5%). Over 23 years, the proportion of Type I items declined significantly, from 50.7% (279/550) in 2001 to 29.5% (118/400) in 2024 (P<.001). Conversely, the proportions of Types II and IIIb increased significantly, from 15.1% (83/550) to 25.8% (103/400; P=.007) and from 3.8% (21/550) to 18.8% (75/400; P<.001), respectively (Figures 3C and D). Notably, the combined proportion of Types IIIa and IIIb surpassed Type I in 2018 and 2024, reflecting a progressive shift toward assessing higher-order problem-solving skills.

Table 4. Taxonomy classification.

Year	2001 (n=550), n (%)	2005 (n=530), n (%)	2009 (n=500), n (%)	2013 (n=500), n (%)	2018 (n=400), n (%)	2024 (n=400), n (%)	Total (n=2880), n (%)
Type I	279 (50.7)	224 (42.3)	225 (45.0)	222 (44.4)	144 (36)	118 (29.5)	1212 (42.1)
Type II	83 (15.1)	107 (20.2)	97 (19.4)	80 (16)	71 (17.8)	103 (25.8)	541 (18.8)
Type III	188 (34.2)	199 (37.6)	178 (35.6)	198 (39.6)	185 (46.3)	179 (44.8)	1127 (39.1)
Type IIIa	167 (30.4)	178 (33.6)	138 (27.6)	178 (35.6)	145 (36.3)	104 (26)	910 (31.6)
Type IIIb	21 (3.8)	21 (4)	40 (8)	20 (4)	40 (10)	75 (18.8)	217 (7.5)

Topic Modeling

Topic modeling effectively classified 10,129 of the 11,540 (88%) items into 25 topics. The remaining 1411 (12%) items were treated as outliers and could not be assigned to any topic. A summary of these topics is presented in Table 5. Further details on these topics are presented in Multimedia Appendix 6. The most frequently appearing topics included “comprehensive clinical items,” “pediatrics,” “accountability in medical practice and patients’ rights,” “cardiology,” and “metabolic and endocrinology.” A visualization of the popular topics is shown in Figure 4. Ten topics exhibited an increasing trend, among which topics not limited to specific organs were identified, including “comprehensive clinical items,” “accountability in medical practice and patients’ rights,” “care, daily living support, and community health care,” “intensive care,” and “infection control and safety management in basic clinical procedures.”

Figure 4. Hot and cold topics. Bar chart showing topic trends from 2001 to 2024, based on the slope of linear regression lines fitted to topic proportions over time. Topics are sorted in descending order of slope, with “hot” (increasing) topics at the top and “cold” (decreasing) topics at the bottom.

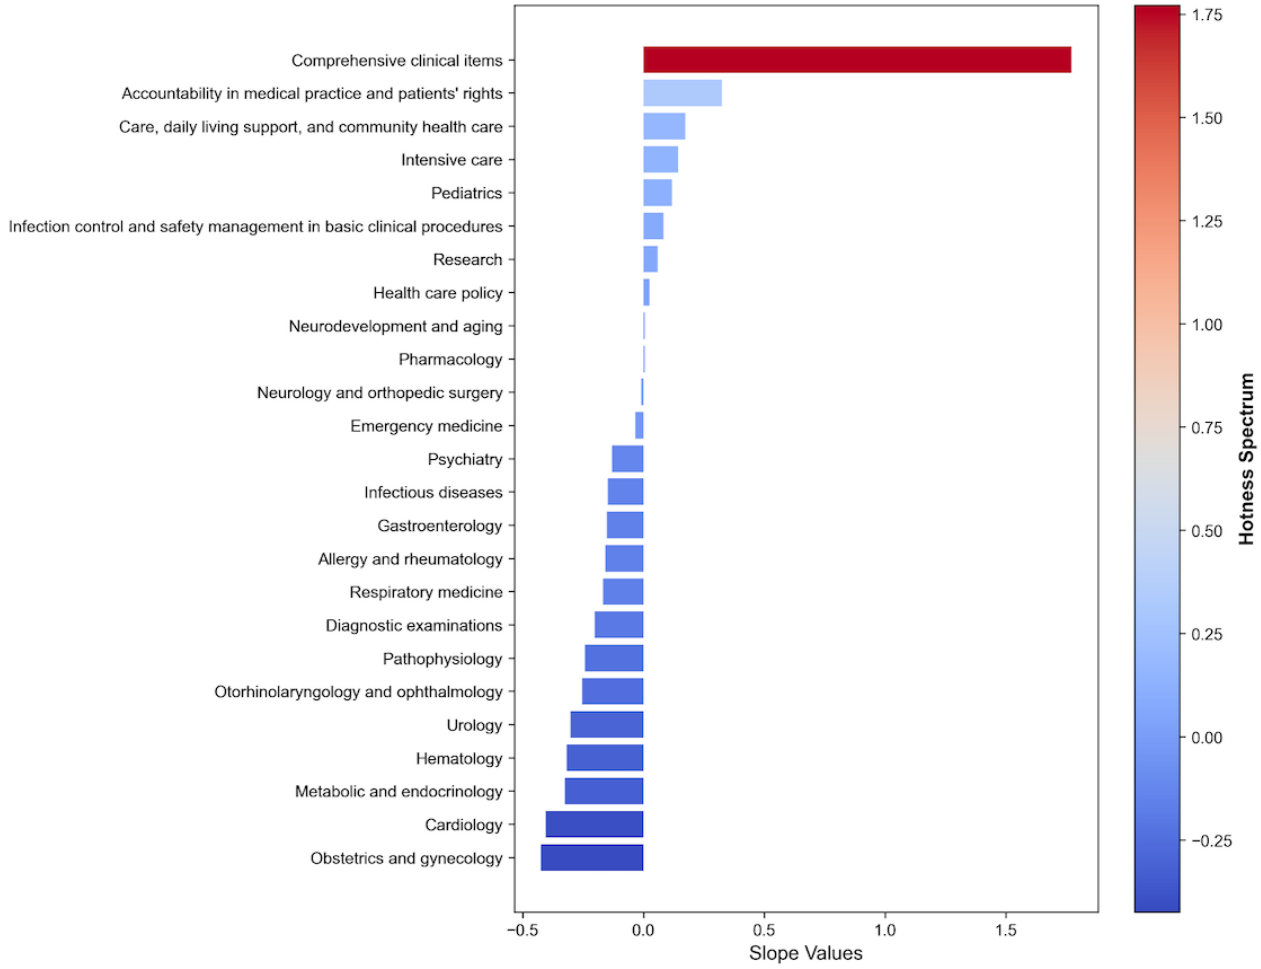

Table 5. Summary of the topics.

No	Topic name	Number of items, n (%)
1	Comprehensive clinical items	4515 (39.12)
2	Pediatrics	752 (6.52)
3	Accountability in medical practice and patients' rights	412 (3.57)
4	Cardiology	381 (3.30)
5	Metabolic and endocrinology	324 (2.81)
6	Obstetrics and gynecology	305 (2.64)
7	Diagnostic examinations	303 (2.63)
8	Otorhinolaryngology and ophthalmology	288 (2.50)
9	Emergency medicine	271 (2.35)
10	Hematology	239 (2.07)
11	Pathophysiology	237 (2.05)
12	Neurology and orthopedic surgery	208 (1.80)
13	Respiratory medicine	208 (1.80)
14	Urology	190 (1.65)
15	Care, daily living support, and community health care	183 (1.59)
16	Infectious diseases	171 (1.48)
17	Research	171 (1.48)
18	Neurodevelopment and aging	169 (1.46)
19	Psychiatry	154 (1.33)
20	Gastroenterology	147 (1.27)
21	Allergy and rheumatology	139 (1.20)
22	Pharmacology	128 (1.11)
23	Intensive care	122 (1.06)
24	Health care policy	60 (0.52)
25	Infection control and safety management in basic clinical procedures	52 (0.45)

Discussion

Principal Results

This study revealed significant changes in the Japanese NMLE over the past 2 decades, highlighting a shift in content and cognitive complexity. The increasing emphasis on common diseases (level A), with a corresponding reduction in highly specialized or rare conditions, aligns with the NMLE Content Guidelines' focus on core medical knowledge relevant to general clinical practice [9]. Additionally, the dominance of pathophysiology-related items decreased. Concurrently, clinical reasoning, primary emergency care, and continued care have become more prominent, reflecting a transition from knowledge-based assessment to practical clinical skills and decision-making. Furthermore, the decline in factual recall items (Type I) and rise in higher-order cognitive skill items (Type IIIb), which require data interpretation and problem-solving, indicate a broader educational shift toward competency-based medical education, consistent with the MCC's emphasis on clinical reasoning and problem-solving abilities. These findings suggest that the NMLE is evolving into a more practice-oriented examination, better aligned with the skills required for real-world clinical settings, including clinical clerkship.

The level classification analysis indicates that common diseases (level A) have been increasingly emphasized in the NMLE, with their proportion rising significantly in recent years. This suggests a greater focus on common diseases, while highly specialized or less frequently encountered conditions have been increasingly restricted in the examination content. This shift aligns with the policies outlined in the NMLE Content Guidelines, which emphasize core medical knowledge applicable to general clinical practice. Although the level classification was first formally introduced in the 2024 edition of the NMLE Content Guidelines, efforts to minimize discrepancies between the MCC and NMLE Content Guidelines by aligning lists of examinable diseases have already been reported [13]. To fully integrate this shift in medical education, students must be sufficiently exposed to common diseases during clinical clerkships [29,30]. Since university hospitals often manage complex or rare cases [31], structured rotations in regional or community hospitals, where students can encounter a broader range of common conditions, may enhance their preparedness

for the NMLE and future clinical practice. In this context, future analyses of the NMLE based on level classification will be essential for monitoring the alignment between national medical education policies, clinical clerkship experiences, and licensing examinations.

The results of the content classification analysis indicated a decreasing dominance of pathophysiology-related items, with a concurrent increase in items assessing clinical reasoning, primary emergency care, and continued care. This suggests a transition from a knowledge-based focus to a more practice-oriented approach in the NMLE, emphasizing clinical decision-making and patient management skills. Compared with pathophysiology, primary emergency care and continued care require more practical competence, as they involve real-time decision making, prioritization, and the ability to manage ongoing patient care [32,33]. Such changes align with the directive of the NMLE Content Guidelines to assess the practical knowledge and skills acquired through clinical clerkship. Moreover, this shift is consistent with the ongoing transition in Japanese medical education, from a discipline-based to a competency-based framework, as promoted by the MCC. Notably, the NMLE blueprint also specifies organ system-based distributions (eg, nephrology, urology, and reproductive medicine: approximately 12%), and these proportions have remained relatively stable across the years. Because such distributions are explicitly monitored and reported in the blueprint, further analysis of organ system–based proportions would provide limited additional value. Conversely, the categorization into pathophysiology, clinical reasoning, primary emergency care, and continued care was newly introduced in the 2024 (Reiwa 6) NMLE Content Guidelines, without any specified proportions. Therefore, retrospectively applying this framework to past examinations enabled us to conduct the first longitudinal analysis of how the examination's process-oriented emphases have evolved. This approach provides educators and policymakers with unique insights that complement the existing organ system-based blueprint.

Taxonomy classification analysis highlights a declining emphasis on simple factual recall items (Type I), with a corresponding increase in items requiring data interpretation and a critical analysis of answer choices (Types II and III). Notably, the proportion of Type IIIb items requiring interpretation of both the stem and answer choices increased. This suggests that the NMLE's emphasis on higher-order cognitive skills extends beyond surface-level modifications in question format, reflecting a genuine shift toward assessing problem-solving and clinical reasoning abilities. This trend can be understood from the perspective of Revised Bloom's Taxonomy, which categorizes cognitive processes into 6 levels: remembering, understanding, applying, analyzing, evaluating, and creating [20,21,34]. While traditional medical assessments have focused primarily on recall (remembering) and comprehension (understanding), the increasing prevalence of Type IIIb items suggests a shift toward the "analyzing" level, where examinees must break down complex clinical information, assess relationships between data points, and apply their knowledge in a more integrative manner. These changes align with the MCC's competency framework, particularly in the problem-solving domain, which aims to develop medical graduates capable of integrating evidence-based medicine, experiential learning, and clinical reasoning to address complex patient issues. Consequently, the NMLE increasingly demands the ability to apply knowledge and critically evaluate and interpret clinical scenarios, requiring a higher degree of practical competence.

Educational and Assessment Implications of the Distinction Between Types IIIa and IIIb

Our introduction of Type IIIa (interpretation + recall-based) and Type IIIb (interpretation + patient-specific contextualization) further clarifies the trend toward practical competence. The increasing proportion of Type IIIb items highlights the NMLE's emphasis on context-sensitive clinical decision-making, where even after reaching a diagnosis, learners must make management choices based on severity, comorbidities, contraindications, or patient-specific factors. From an educational perspective, this has several implications. First, students can be guided away from "one disease–one answer" memorization and toward comparative reasoning among multiple plausible options. The level classification can help prioritize high-yield diseases for such practice. Second, curricula should incorporate structured case-based or simulation-based exercises that vary clinical modifiers (eg, renal function, allergies, and social context), requiring explicit justification of choices. Third, the use of visual or video-based materials may further reinforce the reasoning processes captured by Type IIIb, as they allow learners to engage with patient cues and procedural nuances beyond what text alone can convey [35]. For examination development, the IIIa-IIIb framework offers guidance for constructing items that embed contextual modifiers, use distractors requiring applied reasoning, or leverage multimedia formats. Collectively, these strategies can foster more authentic assessment and deeper learner preparation.

The following section discusses selected topics that show an increasing trend in the topic-modeling analysis.

- Comprehensive clinical items: Approximately 40% of the items are categorized under this topic, which includes questions that ask examinees to select appropriate diagnoses, tests, or treatments based on a patient's history, physical findings, and test results, excluding discipline- or organ-specific cases. As many items from various departments share a common format, they appear to have been grouped into this overarching category. For examinees, these items require a cross-disciplinary perspective because the relevant organ system is not immediately apparent at first glance. The increasing prevalence of such items likely reflects the shift in medical education toward a competency-based approach, moving away from traditional discipline-based outcome assessments [36].
- Accountability and patients' rights: This topic pertains to the knowledge essential for the prevention and management of medical accidents, as well as physicians' accountability to patients and society, and how they confront such responsibilities. This overlaps with 2 of the 4 pillars of professionalism described by Arnold and Stern's model: accountability and altruism [37]. These elements are

considered fundamental components of medical professionalism. According to the MCC, professionalism is to "acknowledge the professional responsibility of physicians to be deeply involved in people's lives and to protect health, respect diversity and humanity, and take an altruistic approach to medical practice throughout one's career" [9]. Each revision of the MCC has increasingly emphasized the importance of professionalism. The current version lists it as the foremost quality and competency required by physicians. This heightened emphasis likely contributed to the observed increase in this topic.

- Care, daily living support, and community health care: This topic encompasses items related to long-term care insurance policies, the roles of long-term care hospitals and welfare facilities, and housing with daily living support. In Japan, where the population is rapidly aging alongside a declining birthrate, the comprehensive and seamless provision of health care, long-term care, and social support services within the community has become increasingly important [38]. This growing need is reflected in the increased attention given to this topic following the government's introduction of a community-based integrated care system in 2006.
- Infection control and safety management in basic clinical procedures: This topic encompasses items that assess knowledge related to safety management and infection control during basic clinical procedures, such as the safe implementation of blood collection and intravenous access, appropriate handling of collected specimens, hand hygiene, and precautions against needlestick injuries. While such clinical skills are also evaluated in the objective structured clinical examination (OSCE), concerns have been raised regarding the lack of sufficiently validated OSCE stations for assessing patient safety competencies [39]. Medical incidents began to attract public attention in the 2000s, culminating in the establishment of a Medical Accident Investigation System in 2014. Reflecting the growing emphasis on patient safety, the 2018 revision of the examination guidelines incorporated terminology such as "medical accident investigation system," "medical accident prevention manual," and "medical safety management departments and risk managers." The increase in items from this topic area on the NMLE has likely been in response to this heightened awareness.

The observed trends in the NMLE reflect the broader expectations of undergraduate medical education in Japan. There is a growing emphasis on acquiring practical knowledge that cannot be gained solely through lectures, developing problem-solving skills for real-world clinical challenges, and fostering deeper analytical thinking beyond rote memorization [40,41]. Given these trends, clinical clerkships play a crucial role in medical education [42-45]. Japanese medical schools allocate an average of 67 weeks to clinical training [1]. While efforts have been made to extend clerkship duration, the focus must shift toward ensuring that these experiences are participatory rather than observational. The MCC and Japan Accreditation Council for Medical Education advocate participatory clinical clerkship models, emphasizing active involvement in patient care [46]. Furthermore, clinical clerkships at community hospitals could be strategically utilized if the goal is to enhance exposure to common diseases [47-49]. In addition, the topic-modeling results suggest that themes showing an increasing trend, such as "care, daily living support, and community health care," can be particularly well demonstrated and understood through community hospital clerkships, wherein students are more likely to encounter patients requiring long-term care, home-based support, and interprofessional collaboration. Recent studies have highlighted the educational value of such experiences for developing patient-centered and community-oriented care competencies [50,51]. A well-balanced integration of university-affiliated hospital rotations and regional hospital training will foster more practical hands-on learning experiences in undergraduate medical education.

In addition, the major topics highlighted in this study, such as "comprehensive clinical questions" and "accountability in medical practice and patients' rights," were robust to reasonable variations in parameter settings (eg, *n_neighbors*, *n_components*, and *min_cluster_size*). The same topics were consistently extracted across these sensitivity checks and continued to demonstrate increasing trends, suggesting that this study's main conclusions are stable and not merely artifacts of specific parameter configurations.

Practical and Policy Implications

The findings of this study provide practical insights for both policymakers and educators. For policymakers, longitudinal analysis of the NMLE offers an evidence-based foundation for examination reform, helping ensure a balance between theoretical knowledge and practical competencies, and between common and specialized conditions. Meanwhile, educators can apply the hybrid methodology demonstrated in this study to evaluate whether undergraduate curricula are aligned with national examination priorities and to analyze internal institutional examinations for continuous improvement of test content balance. From a curricular perspective, structuring clerkships to include rotations at community hospitals provides valuable opportunities for students to directly encounter common diseases, continuity of care, and outpatient management in real-world contexts. Such experiences complement the predominantly specialty-oriented training at university hospitals and strengthen the acquisition of the competencies emphasized by recent trends in the NMLE.

Limitations

This study has several limitations that should be considered when interpreting the findings. First, the classification framework used in this study was designed specifically for the Japanese NMLE, based on the perspectives outlined in the NMLE Content Guidelines. Therefore, applying this methodology to other medical licensing examinations would require modifications to reflect country-specific guidelines and educational frameworks. In particular, regional variations in disease prevalence, differences in the expected competencies of first-year physicians, and the complexity of taxonomy classifications based on examination formats must be considered when adapting this approach to other national examinations. Second, while interrater reliability was generally acceptable, the κ coefficient for the content classification in specific

examination sessions was lower than ideal. In particular, the 2013 examination (107th NMLE) showed a moderate κ coefficient (0.54), which was lower than that of other years. Closer examination revealed that many disagreements arose between the categories "pathophysiology" and "not classifiable." The 2013 examination also represented a transitional phase in test design, as the proportion of "pathophysiology" items decreased markedly compared to earlier years (eg, 2009), while the proportion of "not classifiable" items increased. These shifts suggest that evolving examination policy and the emergence of intermediate item styles between pathophysiology and other categories contributed to assessor disagreement and the lower κ coefficient. To improve the classification reliability in future studies, it may be beneficial to use experienced physicians instead of clerkship students as assessors, particularly for the content classification, which requires clinical judgment. Third, approximately 11.5% of items in the content classification were categorized as "not classifiable." This group was heterogeneous and included items such as specific cautions for diagnostic procedures, drugs, and surgical techniques; calculation problems (eg, A–aDO_2); and procedural tasks such as donning and doffing personal protective equipment. Although these are clinically relevant, they do not align neatly with disease- or patient-centered cognitive processes and, therefore, were grouped under "not classifiable" in this study. Representative examples are provided in Multimedia Appendix 4. However, because of their diversity, designing a more detailed classification system would be necessary to identify meaningful patterns, and future systematic analyses of this group may provide valuable insights for medical education and examination design. Fourth, public health–related items were excluded from the content classification analysis. While this decision was made to maintain consistency with the focus on clinical competencies, public health items can vary in their emphasis on factual knowledge versus practical applications. Future research should explore how public health–related items align with competency-based medical education frameworks, especially as global health and preventive medicine are increasingly emphasized in clinical training. Fifth, this study did not assess item difficulty levels; instead, it focused on the examination content and cognitive complexity. However, item difficulty plays a crucial role in examinations wherein the absolute grading criteria determine the pass–fail outcomes. If these findings are to be applied to other examinations, the potential confounding effect of difficulty adjustments must be considered, as difficulty regulation could influence the trends observed in this study. Sixth, this study did not consider the impact of examination preparation on the taxonomy classification. Because Japanese medical students frequently study past NMLE items, previously used or closely resembling past items may be answered at a lower cognitive level than initially intended. This effect is particularly relevant for examinations with a high proportion of reused or recycled items, wherein students may rely on pattern recognition rather than problem-solving skills. If this classification system is to be applied to such examinations, additional considerations in taxonomy categorization may be necessary. Finally, while BERTopic provided valuable insights by capturing contextual information more effectively than traditional topic-modeling methods such as LDA, it also introduced specific challenges when attempting a more rigorous validation. We adjusted several model parameters (Multimedia Appendix 8) to obtain a reasonable number of topics; however, the relative ranking of topics and the slopes of their temporal trends in the linear regression were sensitive to these settings. Therefore, it should be noted that the statistical robustness of these observations is not guaranteed, although our discussion focused on topics that consistently appeared at the top or showed increasing trends over time. Moreover, a key characteristic—both a potential strength and limitation—of this method is its flexibility: entirely different parameter configurations may yield novel and potentially insightful topics. Nevertheless, because the interpretation of topics ultimately relies on human judgment, there is an increased risk that certain outputs may lack clear interpretability or thematic coherence.

Conclusions

This study identified significant shifts in the content and cognitive complexity of the Japanese NMLE over the past 2 decades. The findings indicated a greater emphasis on common diseases (level A) and a decline in highly specialized topics, suggesting a prioritization of core medical knowledge applicable to general clinical practice. Additionally, the transition from content heavy on pathophysiology to a greater focus on clinical reasoning, primary emergency care, and continued care reflects a broader shift in assessment priorities, aligning with competency-based medical education reforms in Japan.

Moreover, the reduction in factual recall items (Type I) and increase in problem-solving items (Type III), particularly those requiring dual interpretation (Type IIIb), indicate a growing emphasis on higher-order cognitive skills. These trends correspond with the MCC's competency framework, particularly its problem-solving domain, which aims to develop physicians capable of integrating evidence-based medicine, clinical reasoning, and patient-centered care.

Topic modeling using NLP suggested an increasing emphasis on clinical items considered from a cross-organ perspective. In addition, topics not limited to specific organ systems that are increasingly represented in the NMLE, such as "accountability in medical practice and patients' rights," "care, daily living support, and community health care," and "infection control and safety management in basic clinical procedures," were identified. These trends are considered to reflect broader societal developments.

The observed changes in the NMLE suggest that Japanese undergraduate medical education is evolving to place greater importance on practical problem-solving abilities than on rote memorization. Given this trend, enhancing participatory clinical clerkship and leveraging regional hospital rotations will be crucial in further aligning medical education with evolving expectations. Future research should continue to monitor the alignment between national medical education policies and licensing examinations to ensure that assessments reflect the skills and knowledge necessary for competent medical practice.

Acknowledgments

We thank M Ueda for kindly facilitating the initial connections between the first and corresponding authors. We also thank S Sasaki for organizing and managing the dataset, including the examination items, answer sheets, and classification results. We thank T Watanabe for managing the task allocation among the physician staff and clerkship students. Finally, we thank the clerkship students for performing the classification according to the manual.

Funding

No external financial support or grants were received from any public, commercial, or not-for-profit entities for the research, authorship, or publication of this article.

Data Availability

The datasets generated and analyzed in this study are available from the corresponding author upon reasonable request. However, the original datasets are owned by Medic Media Corp, Tokyo, Japan, and any use of the data requires permission from the company.

Authors' Contributions

YM, KS, NY, and SI planned, designed, and conceived the study. YM drafted the manuscript. YM gathered data resources. YM, KS, NY, and SI analyzed the qualitative and quantitative data. YM, KS, NY, and SI have read and approved the final version of the manuscript.

Conflicts of Interest

Medic Media Corp, Tokyo, Japan, was involved in collecting public data related to the National Medical Licensure Examination. However, it did not participate in the design or conduct of the study, data analysis or interpretation, manuscript review or approval, or the decision to submit the manuscript for publication.

Abstract

Background: Appropriate antithrombotic drug use is crucial knowledge for pharmacy students.

Objective: We sought to compare the inverted classroom (IC) approach to a traditional question-and-answer educational approach with the aim of enhancing pharmacy students' engagement with a case-study course on antithrombotic drug use.

Methods: Third-year PharmD (Doctor of Pharmacy) students from Paris Cité University were randomly assigned to control (n=171) and IC (n=175) groups. The latter were instructed to read and prepare the preprovided course material 1 week before the in-class session to assume the instructor role on the target day, whereas students of the control group attended a traditional case-study course carried out by the same instructor. All students completed pre- and posttest multiple-choice questions surveys assessing their knowledge levels as well as stress, empathy, and satisfaction questionnaires.

Results: A significantly higher participation rate was observed in the control group (93/171, 54%) compared to the IC group (65/175, 37%; *P*=.002). Women (110/213, 52%) participated more than men (48/133, 36%; *P*=.002) whatever the group was. Students' knowledge scores from both groups had similar results with no difference neither in the prescore (1.17, SD 0.66 and 1.24, SD 0.72 of 5, respectively) nor in the short-term knowledge retention (2.45, SD 0.61 and 2.35, SD 0.73, respectively). The IC approach did not increase student stress or enhance their empathy for the instructor. It increased the preclass workload (*P*=.02) and was not well received among students.

Conclusions: This study showed that the traditional educational approach remains an efficient method for case-study courses in the early stages (ie, third-year) of the 6-year PharmD curriculum, yet dynamic methods improving the active role of students in the learning process are still needed.

KEYWORDS

antithrombotic drugs; case-study course; inverted classroom; pharmacy students; traditional educational approach; medical education

Introduction

The French Regional Centers of Pharmacovigilance recently revealed that 8.5% of hospital admissions of 141 short-stay specialist medical wards randomly selected in 69 public hospitals, were related to adverse drug reactions [1]. Antithrombotic drugs were involved in 11.6% of the cases, placing them in second place right behind antineoplastic drugs. Some of the adverse drug reactions (mainly bleeding) were considered to be preventable because the drugs had not been used per the summary of product characteristics or guidelines [2]. In the French health care system, antithrombotics are mainly available in pharmacies, and for some also on websites but under the responsibility of a pharmacist. Pharmacists, particularly community-based pharmacists, are easily accessible health care professionals [3]. They are experts in drug therapy use, assessing

each patient through observation, dialogue, and consideration of clinical indicators. They are involved in monitoring the patient's compliance with treatment as well as their response to drug therapy through regular follow-up. This allows for the early detection of adverse effects or drug misuse. Therefore, pharmacist intervention should have a positive impact on the management of patients on antithrombotic therapy. All the above reasons makes the optimal use of antithrombotic drugs of utmost importance to learn for pharmacy students to prevent iatrogenesis.

In France, the PharmD (Doctor of Pharmacy) curriculum consists of a 6-year course. Three teaching models are used mainly: the lecture-based classroom, the case-study class, and the practical session. Case-study class is a hands-on approach to learning that involves presenting realistic scenarios and helps students to apply theoretical knowledge in clinic-like settings and attain a high-order cognitive level per Bloom's taxonomy [4]. The instructor asks students to participate in the case study analysis and discussion. This method favors the development of a deep understanding of the subject and avoids passive note-taking in students. However, this objective is not necessarily always reached. Since its introduction in 2000, the inverted classroom (IC) approach, switching away from the traditional educational approach for the lecture-based classroom, literally inverts the focus per Bloom's taxonomy: the bottom parts of the taxonomy (ie, understand and memorize basic concepts) are reserved for student self-instruction through readings, short recorded video, audio lectures, etc, while the class time is focused on the upper parts of the taxonomy (ie, analyze, justify a stand, and create original work). The IC approach has been increasingly studied in health professions students' education including pharmacy school [5-17]. These studies reported a positive impact of this approach on students' knowledge and skills in most of the cases in comparison to lecture-based courses [8-11,13,14,18-24]. It has been introduced into various courses including pharmacotherapy, pharmacokinetics, pharmaceutical calculations, pharmacy practice, and others [7,12,25-32]. That said, the added value of the IC approach has rarely, if at all, been tested for case-study courses in pharmacy education. Hence, we sought to conduct a monocentric study investigating the added value of an IC approach in a case-study course during the PharmD curriculum at Paris Cité University. In this IC approach, students received the course material before the in-class session and were asked to prepare it and assume the role of the instructor on the target day. We aimed to assess knowledge acquisition, preclass workload and students' self-assessment of their stress, empathy, and global satisfaction. It was hypothesized that the IC approach would lead to improved outcomes compared to the traditional question-and-answer educational approach.

Methods

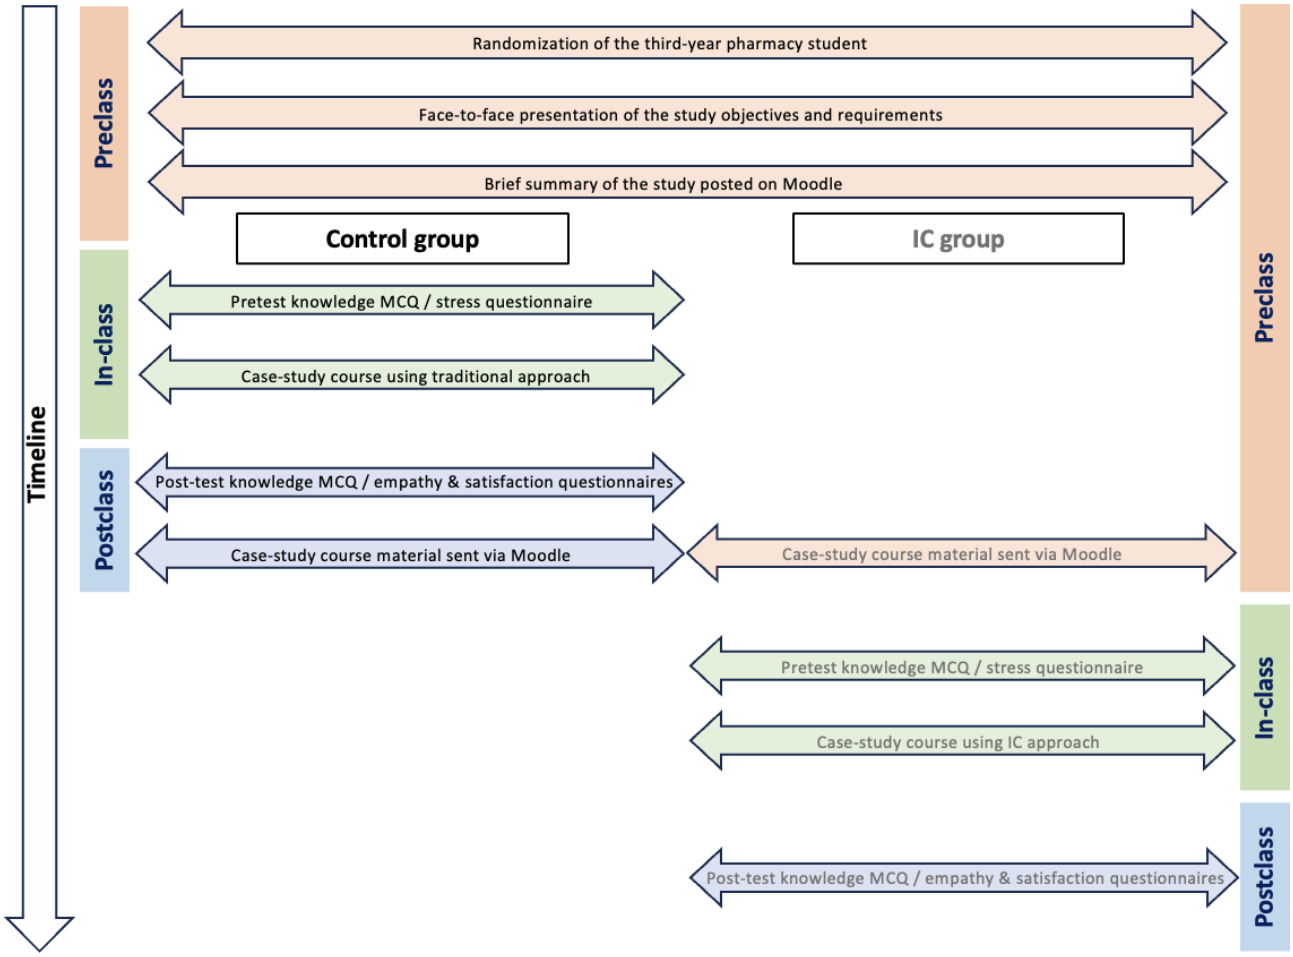
Ethical Considerations

This study was approved by the Institutional Review Board and Ethics Committee of Paris Cité University (00012023 - 20) and all procedures were performed per the Helsinki Declaration. Students were completely free to participate or not in this study. They were informed that neither participation nor nonparticipation in this study would influence their passing of this course or their grades. The participants were also informed about the option to withdraw from this study at any time. Informed consent was obtained from all the students who participated in this study. They were not paid for their participation. Collected data were anonymously analyzed.

Participants

We conducted this study at the faculty of Pharmacy of Paris Cité University in March 2023 (2022/2023 academic year). The participants were in the spring semester of the third year of the PharmD curriculum. At the beginning of the semester, students had basic courses on hemostasis (physiology and pathology) and thrombosis. During the month preceding the case-study course, they also had 3 lecture-based courses for a total of 4 hours on antithrombotic drugs. The recordings of the lectures were then available on a teaching platform ("Moodle"). The 90-minute case-study course on antithrombotic drug use entailed 16 groups consisting of about 20 to 22 students each, which were randomly assigned to the groups by the office of student affairs of the faculty of Pharmacy without any influence from the instructor. Therefore, a randomized assignment can be assumed. Students were highly required to respect their group assignment. Each time, 2 groups assisted simultaneously in one course, thus the course was repeated 8 times by the same instructor. Participants were assigned to 2 major groups: the control group and the IC group (Figure 1). Attendance was not mandatory.

Figure 1. Overview of this study's design. IC: inverted classroom; MCQ: multiple-choice question.



Study Design and Procedure

Three weeks before the case-study course, the instructor informed all the students about the concept of the IC approach and this study's process in addition to the importance of their engagement in the learning process. A summary of the process was also posted on Moodle. Students were informed that half of them would be assigned to the IC group where they would receive the course material for preparation 1 week before the in-class session to take the role of the instructor on the target day. The course material was delivered as a PDF document of a PowerPoint (Microsoft Corp) presentation (encompassing 63 slides) file via Moodle. The same course material was used in both approaches. The courses took place on Monday and Tuesday. One week separated the courses of the control from the IC groups.

Six cases concerning various clinically relevant scenarios were included in this course in addition to some incorporated slides to review and emphasize selected foundational concepts. They were centered on the most relevant aspects of antithrombotic drug use in different clinical settings: (1) treatment of pulmonary embolism associated with proximal deep vein thrombosis in a posttrauma patient aged 63 years; (2) prevention of thrombotic events postelective knee replacement surgery in patient aged 78 years; (3) treatment of pulmonary embolism that occurred under combined pill contraception in a woman aged 20 years; (4) prevention of thrombotic events in an acutely ill medical patient aged 80 years; (5) prevention of stroke and systemic embolism in a patient aged 82 years with atrial fibrillation and renal insufficiency; and (6) antithrombotic treatment of myocardial infarction in a patient aged 54 years. Each case was accompanied by a set of standardized questions about antithrombotic treatment decisions and adequate monitoring. Students in the control group attended a case-study course carried out by the instructor with a traditional question-and-answer approach, whereas students in the IC group took on the role of the instructor and were able to recall basic concepts or add details to the course material freely. Two to three students were randomly asked to present and discuss 1 of the 6 cases on the target day. By doing so, students were able to draw on each others' knowledge and understanding. The instructor added details, provided guidance, clarity and feedback whenever required during the progress of the students' presentation and summarized the main features at the end of each case. The classes in the control and IC groups were conducted by the same experienced instructor who is familiar with the content and organization of the case-study course to guarantee the consistency of the teaching content and objectives in the 2 educational approaches. This study's design and progress are illustrated in Figure 1.

Data Collection

On the target day, students in both control and IC groups were asked to complete a pretest (ie, at the beginning) and a posttest (at the end) survey (Multimedia Appendix 1): it consisted of

the same 5 multiple-choice questions (MCQs) to be completed within 5 minutes, then collected in an identified way (ie, including the student name, and the date and the hour of the questionnaire completion) to pair pre- and posttest scripts. Questionnaires were anonymized by a secretary and corrected afterward by an independent assistant instructor. Another 5-minute survey assessing the stress in the week preceding the in-class course (thus assessing how they were affected from the moment they knew which group they belonged to till the target day) was also completed by all the students at the beginning of the course. At the end of the course, students were asked to complete 2 additional surveys, 1 assessing their empathy for the instructor and the other their global satisfaction. The first consisted of rating 3 items by a 7-point Likert scale (1=strongly disagree, 2=disagree, 3=somewhat disagree, 4=neutral, 5=somewhat agree, 6=agree, and 7=strongly agree). The second included 3 questions regarding the preclass workload associated with the educational approach and the related students' perception, and 6 others linked to the students' satisfaction with the course objectives, course material, in-class progress, and educational approach. Surveys were built based on previously validated assessment tools [33-35]. Stress, empathy, and satisfaction surveys (Multimedia Appendices 2-4) were filled out anonymously. Students were not allowed to keep a copy of the different surveys nor to take a photo of these documents.

Statistical Analysis

The distribution of the data was evaluated using the Shapiro-Wilk test. The percentage of participation was compared between groups and sexes using a 2-way ANOVA followed by the 2-stage setup method of Benjamini, Krieger, and Yekutieli [36] for multiple comparisons. The results of the pre- and posttest MCQs were compared for statistically significant differences using the nonparametric Wilcoxon matched-pairs signed rank test. The preclass workload was compared between the 2 groups using the Mann Whitney test. The data relative to the empathy and stress self-assessment were compared between both groups using chi-square test whereas those relative to satisfaction were analyzed using the Fisher exact test. Error probability with a *P* value less than .05 was considered significant. Statistical analysis and graphical representation were performed using GraphPad Prism (version 10.0.2, GraphPad Software, Inc).

Results

Participants Characteristics

In this study, 346 third-year adult students (women: n=213, 62%; men: n=133, 38%) were randomized. As attendance is not mandatory, only 46% (n=158) attended the in-class session. All of them took part in this study. Ninety-three (women: n=70, 75%; men: n=23, 25%) were in the control group whereas 65 (women: n=40, 62% women; men: n=25, 38%) were in the IC group (Table 1). A significantly higher participation rate was observed in the control group (93/171, 54%) compared to the IC group (65/175, 37%; *P*=.002). Women (110/213, 52%) participated more than men (48/133, 36%; *P*=.002) in the case-study course no matter the allocation group. No other demographic information regarding the students was collected.

Table . Characteristics of the participants. Absolute numbers with the percentages concerning the corresponding randomized participants are reported. Women participated more than men in the case-study course whatever the group was (*P*=.002) and a significantly higher participation was observed in the control group compared to the IC[a] group (*P*=.002).

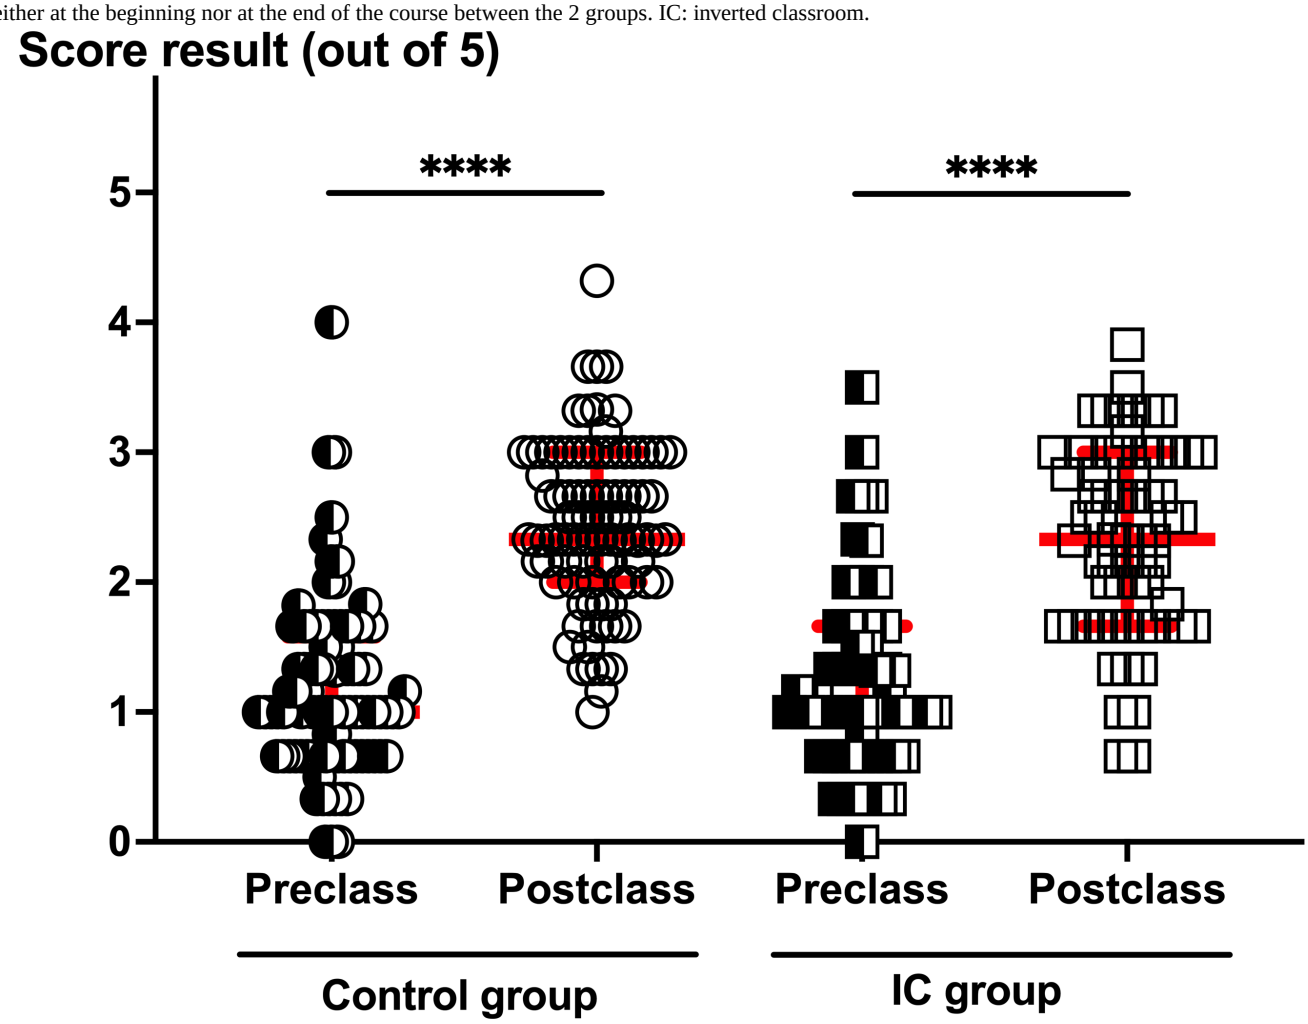
	Sex	Control group	IC group	Total
Randomized participants				
	Men	55	78	133
	Women	116	97	213
	Total	171	175	346
Effective participants, n (%)				
	Men	23 (42)	25 (32)	48 (36)
	Women	70 (60)	40 (41)	110 (52)
	Total	93 (54)	65 (37)	158 (46)

[a]IC: inverted classroom.

Pre- and Postclass Knowledge Survey

On the target day, the in-class session started for both groups with a 5 MCQ survey for 5 minutes to assess the students' readiness to discuss cases and stimulate the recall of knowledge learned before the case-study course. Questions were on the "take-home messages" related to antithrombotic drug use in real-life clinical settings. These MCQs also help students to identify their possible misconceptions at the beginning of the course. The mean and SD of the prescore (out of 5) did not differ between the control group (1.17, SD 0.66) and the IC group (1.24, SD 0.72; Figure 2). To evaluate the students' short-term knowledge retention, the same survey was completed immediately after the class. The mean score improved from the prescore (*P*<.001), in both the control group 2.45 (SD 0.61) and the IC group 2.35 (SD 0.73; Figure 2). Knowledge improvement was comparable in students from both groups.

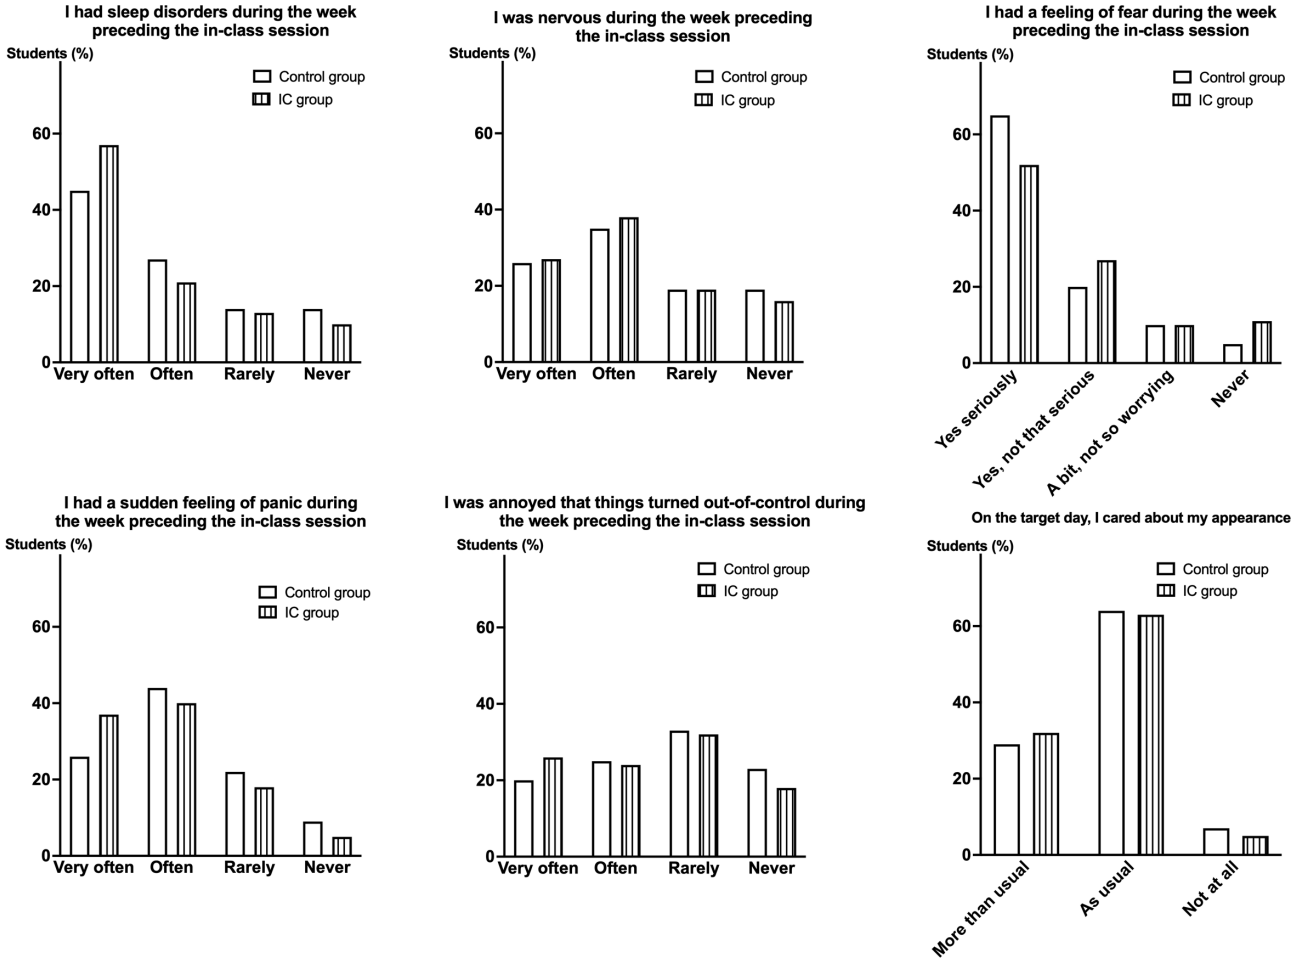
Figure 2. Pre- and postclass knowledge assessment survey per group. Five multiple-choice questions were completed by the control (circles, n=93) and IC (squares, n=65) groups before (semiclosed symbols) and after (open symbols) the completion of the case-study course. Red bars reflect median values with IQRs. Students' scores significantly increased (P<.001) at the end of the course in both groups. No difference in the scores was observed neither at the beginning nor at the end of the course between the 2 groups. IC: inverted classroom.



Stress Self-Assessment

Apart from the preclass knowledge assessment survey, students in both groups completed a stress survey at the beginning of the class during 5 minutes. Questions related to sleep disorders, nervousness, fear, panic, and annoyance during the week preceding the in-class course were completed (Figure 3). Although approximately 50% of the students reported sleep disorders and a feeling of fear during the week preceding the in-class session, no significant difference was observed between the 2 groups for any of the above-mentioned parameters. Likewise, students care for their appearance on the target day did not differ between the control and the IC groups.

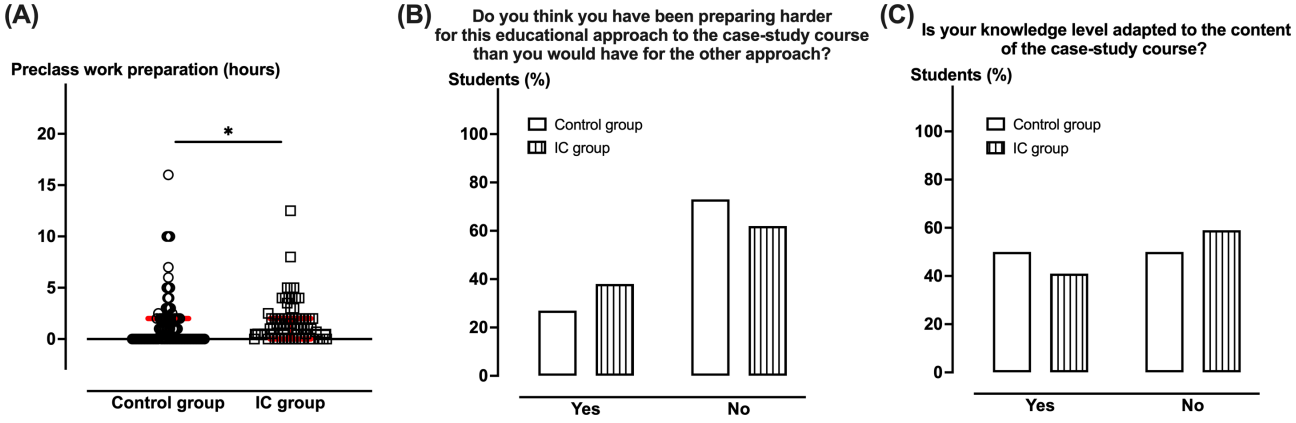
Figure 3. Stress self-assessment questionnaire. A 6-question stress self-assessment survey was completed by both the control (n=93) and IC (n=65) groups at the beginning of the case-study course. No significant difference for any of the 6 questions was observed between the 2 groups. IC: inverted classroom.



Preclass Workload

Students of both groups were asked to provide the number of hours spent preparing for the course, their perception of the preclass preparation difficulty in comparison to the other educational approach as well as the self-assessment of the required skill level. Preclass workload was estimated at 1 (IQR 0-2) hour in the IC group as a median, which was significantly higher (P=.02) than in the control group, 0 (IQR 0-2) hour (Figure 4A). While 38% of the students in the IC group considered that they had been preparing harder for the case-study course than it would have been if they were in the control group, 27% of the latter considered that as such it resulted in no significant difference between both groups (Figure 4B). Approximately half of the students in each group considered having a knowledge level adapted to the case-study course content. No difference was observed between both groups (Figure 4C).

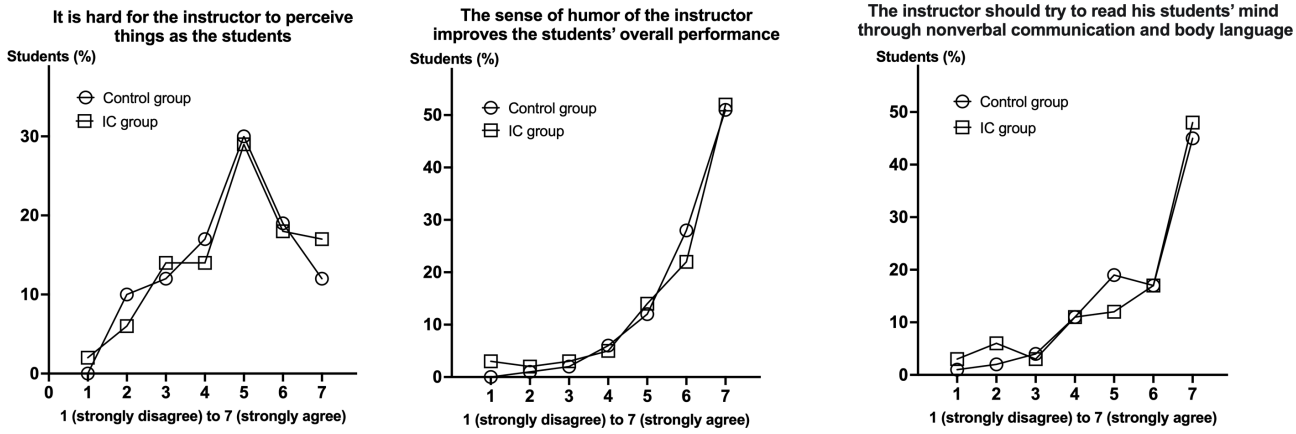
Figure 4. Self-assessment of the preclass work per group. (**A**) Preclass preparation requirements concerning working hours, (**B**) student perception, and (**C**) knowledge level self-assessment were compared between the control and IC groups. Red bars reflect median values with IQRs. While preclass work preparation necessitated more time for the IC compared to the control groups (P=.02), no difference was observed between the 2 groups in terms of work difficulty perception and the self-assessment of the knowledge level adapted to the course. IC: inverted classroom.



Empathy Self-Assessment

Student empathy for their instructor favors engagement and learning behavior in class, hence 3 related questions rated by a 7-point Likert scale were completed by students of both groups at the end of the course (Figure 5). Although only students in the IC group assumed the role of the instructor within the class, students' opinions were quite similar between both groups. Approximately 30% of the students considered that it is hard for the instructor to perceive things as the students while 50% confirmed the importance of the sense of humor of the instructor in enhancing students' performance and of reading the students' minds through nonverbal communication and body language. These results did not differ between both groups.

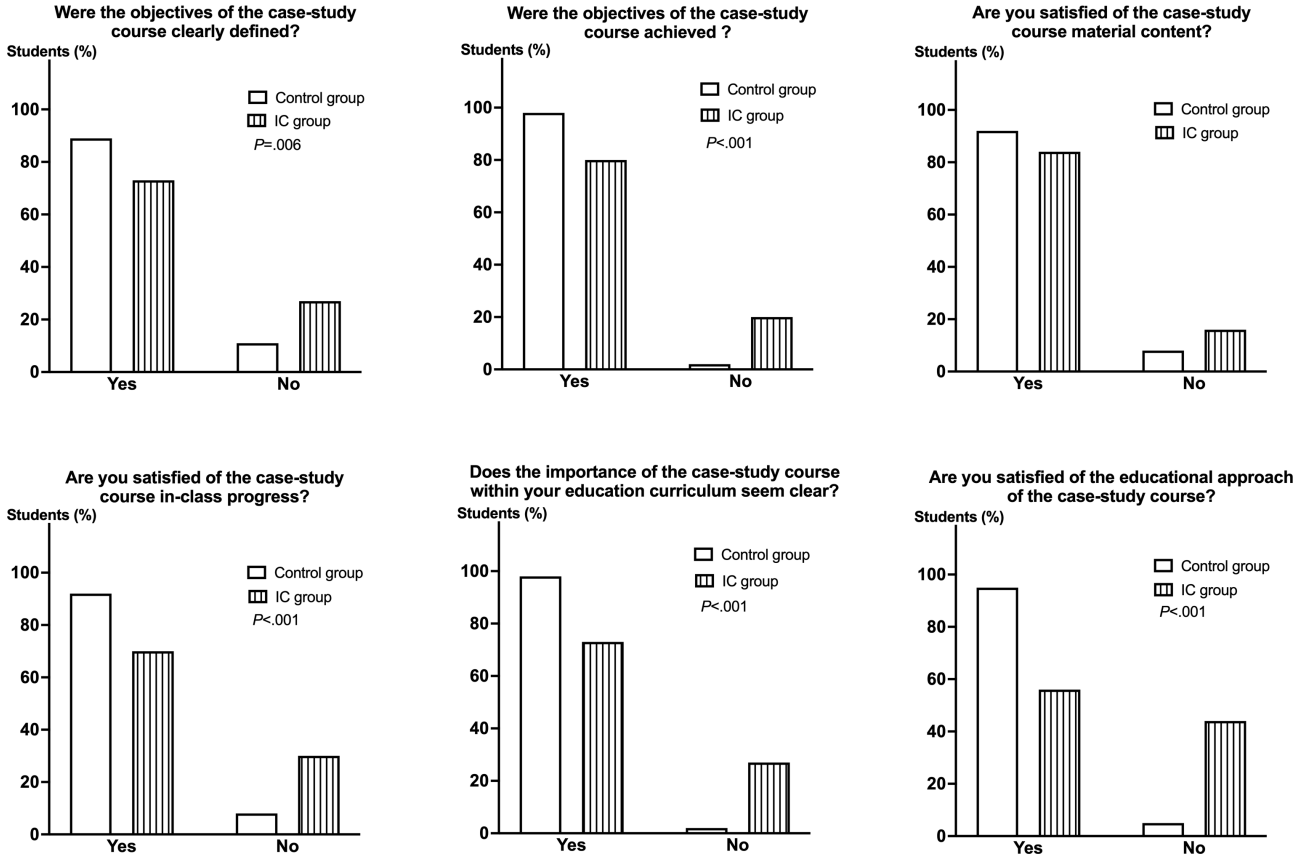
Figure 5. Empathy assessment questionnaire. The empathy of students for the instructor was assessed using 3 questions completed at the end of the case-study course. No difference was observed between the control and the IC groups for any of the 3 raised issues. IC: inverted classroom.



Global Satisfaction Assessment

The students' global satisfaction was evaluated at the end of the course using a 6-item questionnaire (Figure 6). While more than 80% of the students were satisfied with the content of the course material in both groups, the satisfaction survey revealed that the IC approach was not well received among the students. Indeed, 18/65 (28%) of the students found that the objectives of the case-study course not clearly defined and 13/65 (20%) considered that they were not achieved, in comparison to 10/93 (11%*; P*=.006) and 2/93 (2%*; P*<.001) in the control group, respectively. A total of 20/65 (30%) of the students in the IC group were not satisfied with the in-class progress of the course versus 7/93 (8%) in the control group (*P*<.001). While 91/93 (98%) of the students in the control group considered this case-study course on antithrombotic drug use important for pharmacy education, only 47/65 (72%) did so in the IC group (*P*<.001). When it came to the question of the overall satisfaction of the educational approach, 88/93 (95%) of the students in the control group were satisfied versus (36/65) 55% in the IC group (*P*<.001).

Figure 6. Satisfaction survey. A 6-item questionnaire relative to the students' satisfaction with the pedagogical strategy (ie, traditional [n=93] vs IC [n=65]) was completed at the end of the case-study course. Overall, students in the control group were significantly more satisfied than those in the IC group. IC: inverted classroom.



Discussion

Principal Findings

Education methodology is increasingly shifting from a teacher- to student-centered learning approach [37]. In this context, we sought to assess whether applying an IC approach for a case-study course has an added value for conveying optimal antithrombotic drug use skills to pharmacy students. Such an educational approach would increase the communication, critical-thinking, problem-solving, and self-learning skills of pharmacy students. Our study revealed that while the IC approach did not increase student stress, it did not enhance their short-term knowledge retention or their empathy for the instructor. It increased the preclass workload and was not well received among the students. Of note, the case-study course on antithrombotic use was the first on this topic in the PharmD curriculum.

For any educational method to be considered successful, there must be evidence that student learning is enhanced. Many small-scale studies showed enhanced student learning following flipping lecture-based pharmacy courses [5-11,24]. Here, the IC approach applied to the case-study course was not associated with an enhanced preclass knowledge level and did not improve the students' short-term knowledge retention. This was also the case in the Everly and Cochran study in which no significant differences in examination question performance between students in the lecture-based section and the flipped format section were observed [9]. That said, MCQ and examination scores are often used as a proxy measure for learning; however, the ultimate goal is for students to be able to apply classroom learning to real-life situations, which is more difficult to assess. Perhaps we need to examine other nonquantitative student characteristics outcomes following the IC approach in case-study courses (such as intellectual curiosity, personal responsibility, reasoning skills, etc) to identify pharmacy students most likely to succeed.

A recent systematic review including 45 studies with a total of 8426 students from various health professional pathways showed that implementing flipped classes may improve academic performance, and may support student satisfaction, yet the certainty of the evidence is low [37]. A second systematic review and meta-analysis including 11 randomized controlled Chinese studies enrolling 1200 participants suggested that flipped classroom pedagogy enhances students' learning enthusiasm, self-learning ability, thinking and communication skills as well as cooperative ability [38]. Although, another systematic review focusing on students in pharmacy education, incorporated 6 observational studies with 1395 participants. No overall significant difference in final academic performance between the 2 educational models was reported [39]. An important heterogeneity of student perspectives from flipped classrooms has emerged in the literature, ranging from positive [10,24,40-42] to negative [21,39,43,44] and mixed [45] perceptions. These differences are potentially due to the different contexts in which these studies were carried out as well as different student populations, backgrounds, sample sizes, and outcome measures. Apart from that, some instructors may be

more effective teachers than others regardless of the teaching modality. Research evaluating which elements contribute to the efficacy of an IC approach in pharmacy education is still needed. Moreover, it is still unclear if there is a particular area or topic that is better suited for the use of the IC approach in the PharmD curriculum. Besides, with the increased use of the IC method, it is important to consider the impact on students when this approach is incorporated into multiple concurrent courses. Determination of the ideal amount of preclass preparation time across the curriculum would provide helpful guidance to pharmacy faculties implementing such teaching methods.

One of the major limitations of the IC approach is its high dependence on the attendance to class time and on student engagement and discipline for reading and preparing the preclass material as previously emphasized [26]. As the class time attendance is not obligatory in our faculty, only 46% of the students were present in the antithrombotic drug use case-study course. The percentage of attendance was more important in the control group than in the IC group. A more elaborate strategy for students' motivation should thus be implemented to obtain a higher engagement and adherence to our case-study courses in general, and to such IC experience if it shall be repeated. Providing clear expectations to students, keeping the preparation tasks focused, and explicitly linking preparation activities to in-class active learning could be some key methods for instructors to increase the proportion of students who prepare for classes. Future research should also be devoted to assessing the potential effect of sex, gender, socioeconomic background, and age on the outcomes of such an approach in the PharmD curriculum.

Preclass preparation could be considered as a considerable "extra" work [10,29,30,46]. Indeed, students in the IC group of our study reported an increased preclass workload which might take up an amount of their spare time leading to negative feedback on this approach. It is to be mentioned that the course materials made available beforehand should not be too complex to be understood by the students on their own. We did our best to include 6 uncomplicated cases issued from real-life settings and incorporate few slides to recall knowledge learned in the three lecture-based courses during the month preceding the case-study course.

Case-study courses with an IC approach are probably important in pharmacy education as they would help students promote higher-level critical-thinking skills, foster analyzing, and improve their communication skills therefore improving their motivation and attitudes [47]. Assisting them in learning how to think and communicate like a graduated pharmacist will prepare them for their future beyond pharmacy school. Communication skills are required to ensure patient understanding and compliance [48,49]. If a patient does not understand the purpose of the antithrombotic treatment, adherence will likely be low. Communication training in pharmacy students is thus mandatory to improve their later effectiveness as future health professionals. Although third-year students were overall not satisfied with this experience, such an approach is worth being retested with "older students," from the fourth to the sixth year of the PharmD curriculum. Successful pharmacy students are expected to have the ability to manage their learning and adequately communicate their knowledge. Self-learning skills are particularly crucial to achieving effective lifelong learning in pharmacy, where scientific knowledge is continually evolving. Consequently, pharmacy students should be trained to be effective self-learners. Antithrombotic drug use assessed using a case-study course is an application-based activity, while the material taught previously is mostly a knowledge-based presentation. Therefore, third-year students may have significant difficulty in providing an application-based activity when their skill level may have been still on a much lower level of Bloom's taxonomy [4] which may explain the low postclass knowledge scores in both groups. They will complete 2 additional learning years where it is anticipated they will gain more knowledge, clinical experience, and communication skills through their traineeships in community-based and hospital pharmacies as well as clinical laboratories. That said, many students were very interested in participating in this pedagogical study and found the experience to be innovative and enjoyable.

From the instructor's perspective, the IC approach might be more challenging than a traditional session with a question-and-answer approach due to the risk that students' presentation and case discussion activities create an unsettled classroom, thus a chaotic environment in which students may feel lost, and the fear that students may be unable to deliver the course adequately. However, the IC approach makes student engagement in the course easier and empowers them as active participants in their learning in comparison to the traditional educational approach. It allows the instructor to guide students in deeper learning processes as previously shown [38,46]. A more interactive teaching strategy may be more attractive than the IC approach, such as the adventure game recently developed by Perrin et al [50]. It is a video game in which the player assumes the role of a protagonist in an interactive story driven by exploration and problem-solving tests. Briefly, the pharmacy student assumes the role of a hematology superhero named SUPER HEMO. SUPER HEMO can meet 5 unwell characters in 5 different steps. The player must answer their questions and find the best way to diagnose and cure them. At the final hematology evaluation, students who played SUPER HEMO had a slightly better (but not statistically significant) median knowledge score than those who did not [50]. The value of such an innovative strategy for case-study courses on antithrombotic drug use in the PharmD curriculum remains to be established. Team-based learning is another educational approach that provides structure, defined timeframes, and formative assessment opportunities. It was previously shown to develop students learning enthusiasm, self-study, and thinking abilities as well as communication skills [51]. Therefore, it might be considered as an alternative approach for improving case-study courses in the PharmD curriculum, and thus is worth being assessed.

One possible limitation of our study is that the long-term effect of our IC approach on knowledge retention and skill application was not assessed. The question relative to this course was deliberately not included in the final exam in order not to create any lack of equity among the students of both groups. We did not complete any postclass knowledge survey 3 to 6 months

later, nor did we assess the acquired skills through, for instance, an objective structured clinical examination. This remains to be specifically investigated. Second, we did not collect data on how many students effectively accessed the course material before the in-class session, although it might be feasible via the information technology service. As the preclass results of the students in the IC group were not better than those of the control group, we hypothesized that a lot of students had not read the course material before the target day. Noteworthily, it is hard to control whether students had effectively read and prepared the course material before the in-class session. Students might only click on the material folder without reading it or read parts of it. Also, several students might have accessed the material via 1 student user ID. We also did not ask students in the presurvey questionnaire whether they had read the assignment. However, they would, most probably, have not told the truth. Third, ideally, students in the IC group should have been asked to prepare the course material by themselves, yet this was not the case to avoid a high level of absenteeism as in-class attendance is not mandatory according to Paris Cité University policy. Despite this, a relatively small number of students effectively participated in this study. Fourth, in-class sessions with the traditional approach were completed 1 week before those with the IC approach to prevent students in the former group from having access to the material course from those of the latter group before the in-class session. Consequently, we cannot rule out the possibility that some students initially assigned to the IC group had changed their group assignment to get the case-study course at an early date. Finally, our findings cannot be generalized to other contexts, particularly to students in other year cohorts or to other specialties. This remains to be specifically investigated.

Conclusions

Our study showed that an IC approach does not appear to be suited to the case-study course on antithrombotic drug use in the third-year PharmD curriculum. While no additional gain in short-term knowledge was observed using this approach in comparison to the traditional educational approach, we perceived significantly lower student satisfaction. However, the increased instructor-student and student-student interactions are still convincing arguments to try this pedagogical approach. Hence, additional research in this field is still needed to implement innovative educational approaches aiming at improving the knowledge and skills of our future pharmacists.

Acknowledgments

The authors thank the members of the Institutional Review Board and Ethics Committee of Paris Cité University for the rapid review of the project, Farah Berrich, MSc, for her administrative support, and the 2022/2023 third-year pharmacy students of Paris Cité University for their participation in this study.

Abstract

Background: Since January 2022, Sharjah in the United Arab Emirates has implemented the 4-day work week model for the first time in the public and private sectors, including universities. While this framework may enhance productivity and work-life balance for many professionals, the current study specifically explores the perceptions of students in medicine, dentistry, and health sciences programs regarding the impact of transitioning from a 5-day to a 4-day work week on their academic performance.

Objective: The objective of this study was to explore and analyze the perceptions of students in medicine, dentistry, and health sciences regarding the implementation of a 4-day academic week in the Emirate of Sharjah, United Arab Emirates.

Methods: Twenty-four university students (mean age 20.95, SD 1.30 years; 12 men) studying in medicine, dentistry, physiotherapy, nursing, or medical diagnostic imaging programs, who experienced a transition from a 5-day week to a 4-day week, participated in semistructured interviews lasting approximately 20 - 30 minutes. All interviews were recorded and transcribed verbatim. The Braun and Clarke 6-phase framework of thematic analysis was used.

Results: We identified 5 themes: academic journey, academic work-life balance, support systems, classroom dynamics, and common stressors of the 4-day academic week. Overall, most students reported increased motivation, engagement, and academic achievement following the transition from a 5-day to a 4-day week. In addition, participants described a positive academic work-life balance, improved physical and mental well-being, optimal use of time for both academic and personal commitments, favorable support from faculty and family members, and maintained or even improved attendance levels. Nevertheless, some students expressed concerns about condensed schedules and longer days, increased stress, disrupted work-life balance, and inadequate support systems to cope with this new framework.

Conclusions: Overall, the 4-day academic week enhanced motivation, academic performance, work-life balance, and the physical and mental well-being of medicine, dental, and health science students. However, some students experienced challenges related to condensed schedules and increased stress. These mixed outcomes highlight that while the 4-day work week offers notable advantages, careful planning and support are essential to mitigate the potential drawbacks and ensure all students can succeed within this new academic framework. Future research could explore strategies to address these challenges and further improve the 4-day week experience for all students.

(JMIR Med Educ 2025;11:e67775) doi:10.2196/67775

four-day academic week; students; academic performance; work-life balance; support systems; United Arab Emirates

Introduction

The concept of a 4-day work week has gained significant attention, particularly in the aftermath of the global pandemic [1]. This shift has sparked a movement toward reducing the traditional 5-day work week to 4 days across various industries, including higher education. Typically, universities operate on a 5-day schedule, but with the adoption of a 4-day week, classes are now condensed into 4 days, which allows a long (3-day) weekend. Numerous studies have highlighted the advantages of this model, such as enhanced productivity, improved job satisfaction, better academic work-life balance, lower stress levels, and reduced personal expenses, such as commuting costs [2,3].

The 4-day school week was introduced in a South Dakota school in 1936. In 1973, many schools across the northeastern United States adopted this model to address economic challenges, particularly those related to energy and operational costs [4,5]. In more recent years, the number of school districts transitioning from the traditional 5-day week to a 4-day week with extended hours has increased [6]. Hewitt and Denny [4] reported minimal differences in the academic performance of students attending schools on the 5-day schedule compared to those following the 4-day system. Furthermore, this study recommended considering multiple factors beyond academic performance when evaluating the effects of the 4-day work week model [4].

According to Sagness et al [7], the 4-day school week offers potential advantages for both rural and suburban schools, particularly in terms of student achievement, behavior, attendance, as well as job satisfaction among teachers and staff. Thompson and Ward [6] revealed that students in nonrural 4-day schools had a reduction in on-time grade progression and absenteeism with the implementation of 4-day week. However, a few United States district schools reverted to a 5-day week due to reduced academic achievement [8].

A recent study found that school schedules during a 4-day school week have had detrimental impacts on student achievement, with a decline in math and reading scores [9]. On the contrary, another study conducted on students found that there is a positive correlation between implementing a 4-day school week and academic performance in reading and mathematics [10].

Since January 2022, Sharjah, one of the 7 Emirates in the United Arab Emirates, has adopted the 4-day (work) week model across both the public and private sectors. This happened after the United Arab Emirates moved its weekend from Friday-Saturday to Saturday-Sunday, mainly for governmental institutions, to better align its business economy with global markets. A government study, presented to the Sharjah Executive Council in 2023, revealed significant improvements in job performance, happiness, and mental well-being among the government employees [11]. A survey conducted in 2023 among 40,000 parents and employees of schools by the Sharjah Private Education Authority revealed that school children's absenteeism decreased, motivation increased, and behavioral problems reduced while teachers' work-life balance improved significantly [12]. A recent survey analyzing the impact of a 4-day academic week on dental students in the United Arab Emirates revealed high levels of satisfaction with both their academic and clinical training. Students expressed contentment with the extended weekend, which they found beneficial for reducing stress, improving exam preparation, and allowing them to spend more time with family and friends [13]. However, only dental students with or without the experience of both 4-day week and 5-day week were included in this survey. These findings cannot be generalized to all medicine and health sciences students, as their coursework, clinical practice, and laboratory skills requirements are relatively different. In addition, those students who have not experienced a transition from a 5-day week to a 4-day week may not be able to appreciate the benefits and challenges of this changeover. Although electronic surveys are easy to administer, cost-effective, and quick to deploy, they present challenges such as difficulty in identifying the characteristics of nonrespondents and maintaining confidentiality, among others. They do not provide the same in-depth understanding of participants' perceptions, actions, thoughts, and experiences as (semistructured) interviews do [14].

Although numerous studies have investigated the effects of a 4-day academic or work week in schools and various sectors, no research has specifically examined its impact on university students in medicine, dental, and health sciences programs who transitioned from a 5-day to a 4-day academic week. Therefore, it is crucial to assess how this shift affects the academic performance of students in these programs. To the best of our knowledge, this is the first qualitative study of the perceptions of medicine and health sciences students in Sharjah regarding the 4-day work week model using semistructured interviews. If the 4-day work week is found to improve academic outcomes, the results could have broader implications for educational institutions still operating on a 5-day work week, prompting them to consider adopting a 4-day work week schedule to support student performance in the other 6 Emirates. The themes and insights emerging from this study will provide valuable perspectives on how the 4-day work week impacts the academic performance of students in medicine, dental, and health sciences programs.

Methods

Study Design, Setting, and Participants

In this study, we adopted an exploratory qualitative research design using semistructured interviews. A qualitative approach enabled the understanding of the perceptions of students who had used both the 5-day week and were not exposed to the 4-day week. We adhered to the COREQ (Consolidated Criteria for Reporting Qualitative Studies) guidelines for reporting this qualitative research [15].

Study Population

All students enrolled in the medical and health sciences colleges at the University of Sharjah, United Arab Emirates, were invited to participate in the study through advertisements posted on university notice boards, emails, and word of mouth. The participants included students who had experienced the transition from a 5-day week to a 4-day week, with the study taking place during the Fall semester of 2023. These students had been exposed to 3 semesters since the introduction of the 4-day work week. Students were selected based on their willingness and availability to participate. Purposive sampling was used to ensure representation from the 4 different colleges on the medical campus, including medicine, dental medicine, pharmacy, and health sciences. Recruitment of participants continued until data saturation was reached. The interviews were conducted in one of the classrooms on the medical campus, free from noise and distractions.

Instrument

An electronic search of PubMed, Scopus, and Google Scholar was conducted to inform the development of interview questions. We used the following search terms: ("student" OR "learner" OR "pupil" OR "scholar") AND ("perception" OR "attitude" OR "view" OR "opinion") AND ("transition" OR "change" OR "shift" OR "move") AND ("four-day" OR "4-day" OR "four day") AND ("five-day" OR "5-day" OR "five day" OR "traditional") AND ("academic week" OR "school week" OR "educational week" OR "work week"). We could not find qualitative studies on university students' perceptions of transitioning from a 4-day to a 5-day academic week. Only one survey published in 2024 has reported the impact of a 4-day week on academic performance and study–life balance of university students studying dental medicine [13]. To inform the development of the interview guide, we reviewed existing literature on the transitions in education, school and university students, and alternative workweek models in other sectors [6,13,16-19]. Although some studies were based on survey designs rather than qualitative studies, they provided relevant prompts, clues, and contextual insights that shaped the structure and content of our questions tailored to answer our aims of the study.

Our interview questions and probes were explicitly designed to align with the study's specific research aims, allowing a focused exploration of participants' perspectives that are consistent with our objectives. Two independent external content experts with qualitative research experience—one a physiotherapy academic from India and the other a nursing academic from the United Arab Emirates, both not involved in the study—reviewed the interview guide and suggested minor amendments. The interview guide was piloted during mock interviews prior to data collection to ensure clarity. The final interview questions are presented in Textbox 1.

Textbox 1. Semistructured interview questions.

Questions

1. In your opinion, would you tell me about the impact of a 4-day workday week on your lectures and lab sessions?
   a. How would you describe your current attendance levels in lectures and labs compared to a 5-day week?
   b. In your opinion, are there any specific changes in the method of lectures and lab taught?
   c. Would you like to describe any specific consequences or concerns over the 4-day work week in your academic life?
2. In what ways has the 4-day work week impacted your assignments and coursework?
   a. In what ways has the 4-day week impacted individual and group assignments compared to a 5-day week?
   b. In your opinion, were there any specific changes in the type of assignments and course work compared to a 5-day week?
3. In what ways has the 4-day work week impacted on learning theoretical information and honing practical (lab or clinical) skills?
4. In what ways did the 4-day work week affect your performance in mid-term and final exams?
   a. How do you feel that the 4-day work week has affected your ability to prepare for exams or complete assignments in a timely manner?
5. How did the 4-day work week affect your clinical placements and gaining clinical skills?
6. Would you share with us some strategies which you adopted to maintain your academic performance during a 4-day week compared to a 5-day week?
7. Could you describe the support or help you would have received from your faculty, department, and college to support your academic performance following the transition to a 4-day weekday week?
   a. What external help or support have you received?
   b. How effective was the help or support? In what ways did you benefit from the support?
8. Can you tell me how you feel about the 4-day work week in terms of your academic performance? Has it improved or gone down?
9. In your opinion, what are the benefits and drawbacks of having a 4-day work week on your academic performance?
10. How would you describe any changes in your motivation or level of engagement with your coursework or lab sessions since the implementation of the 4-day work week?
11. How do you think the 4-day work week has affected your ability to balance your academic workload with other commitments and responsibilities?
12. Do you think there's anything else I can do to understand your academic performance during a 4-day week better, but I have not asked?

Collection of Data

This qualitative research relied on collecting data directly from students using an exploratory approach, which enabled an in-depth understanding of their perception of the 4-day work week and its impact on their academic performance [20]. Semistructured interviews are a well-established method in qualitative research. Each interview lasted between 20 and 30 minutes. The interviews were recorded after obtaining written informed consent from all participants. Two female team members (RMQ and RJS) who are graduate research assistants with master's degrees of science in physiotherapy received training in qualitative interview techniques from an expert researcher in the research team (JMD) who was experienced in conducting qualitative interviews. The first 4 interviews were conducted in the presence of JMD, after which RMQ and RJS conducted the remaining interviews independently. They wrote field notes to facilitate data analysis. They recorded all interviews and transcribed them verbatim in English. Throughout the interviews, participants were encouraged to ask questions or express doubts to ensure clarity and reduce ambiguity. The research team members were always available to answer any questions from students and provide clarifications where required. All transcripts were sent back to the students to ensure accuracy of the data captured and to ensure member checking. A range of viewpoints was captured, and data saturation was achieved.

Data Analysis

Thematic analysis was used to analyze the data. The interviews were transcribed verbatim by two members of our team (RMQ and RJS). The 6 phases of thematic analysis as defined by Braun and Clarke were followed [21] : (1) familiarizing oneself with the data, (2) generating codes, (3) constructing themes, (4) reviewing potential themes, (5) defining and naming themes, and (6) producing the report. Two investigators (AA and JMD) initially read the transcripts to generate codes and to document where and how patterns occurred. They performed data reduction, and they collapsed data into labels to create categories to facilitate efficient analysis. Six team members (AA, JMS, RMQ, RJS, SN, and SR) were involved in an iterative and analytical process to develop themes from the initial codes. We identified patterns (differences and similarities) in the data by repeatedly reading the transcripts and memos. The use of memos throughout the data analysis promoted reflexivity, precluded a priori biases, and ensured the credibility of our analysis and associated findings. Themes were revised through constant comparison across transcripts, and an audit log was maintained

to document data-driven decisions and ensure transparency. All team members reviewed the data to ensure consistency and coherence between the raw data, the generated codes, and the resulting themes. Representative quotations were used to support the themes, ensuring transparency, and justification of interpretations in the data.

Team Reflexivity

Our research team included members from diverse disciplinary backgrounds, including physiotherapy, nursing, medicine, dental medicine, pharmacy, public health, medical education, and qualitative research. Moreover, the team's experience levels ranged from research assistants and lecturers to senior academics and professors. Our multidisciplinary approach with variations in roles and expertise allowed for a rich interpretation of the data while promoting reflexivity throughout the study. All investigators acknowledged and discussed their own professional perspectives, assumptions, and potential biases prior to data collection and during the thematic analysis process.

To enhance reflexivity, memos were used throughout data analysis to document emerging thoughts, evolving decisions, and reflections. Regular team meetings were held to critically examine how our positionalities and prior experiences might influence coding and theme development. Two research assistants not involved in teaching responsibilities conducted the interviews to mitigate the influence of faculty on students and social desirability bias. We involved two external content experts in reviewing the interview guide, further improving the objectivity of our semistructured interview guide.

Ethical Considerations

The study was performed in line with the principles of the Declaration of Helsinki. Ethical approval was granted by the University of Sharjah Ethics Committee (reference number: REC - 23 - 06 - 13 - 01 - F). Informed consent was obtained from all the participants who were assured of the anonymity of their responses and that their participation in this research would not affect their course grades. Each participant was assigned a random, alphanumeric code to ensure confidentiality. Interview content was analyzed by the research team, and data were securely stored with the primary investigator (AA) on a password-protected computer. The data will be retained for 5 years, after which it will be destroyed.

Results

Overview

In total, there were 24 participants with equal male and female representation in the health professions. All 4 colleges at the medical campus of our university were represented, including medicine, dentistry, pharmacy, and health sciences. The demographics of the study participants are listed in Table 1.

The findings from this study offer a wealth of valuable data. Students' perspectives were grouped into 5 main themes. Each theme was further divided into one or more subthemes. Figure 1 and Multimedia Appendix 1 summarize the themes and subthemes derived from the students' responses.

Table . Demographic characteristics of participants.

Participant ID	Age (years)	Sex	College	Program of study
P1	20	F[a]	Health sciences	Medical Diagnostic Imaging
P2	21	F	Health sciences	Nursing
P3	22	M[b]	Health sciences	Nursing
P4	20	M	Health sciences	Physiotherapy
P5	20	M	Health sciences	Physiotherapy
P6	21	F	Health sciences	Physiotherapy
P7	20	M	Medicine	Medicine
P8	20	F	Medicine	Medicine
P9	19	F	Medicine	Medicine
P10	19	F	Medicine	Medicine

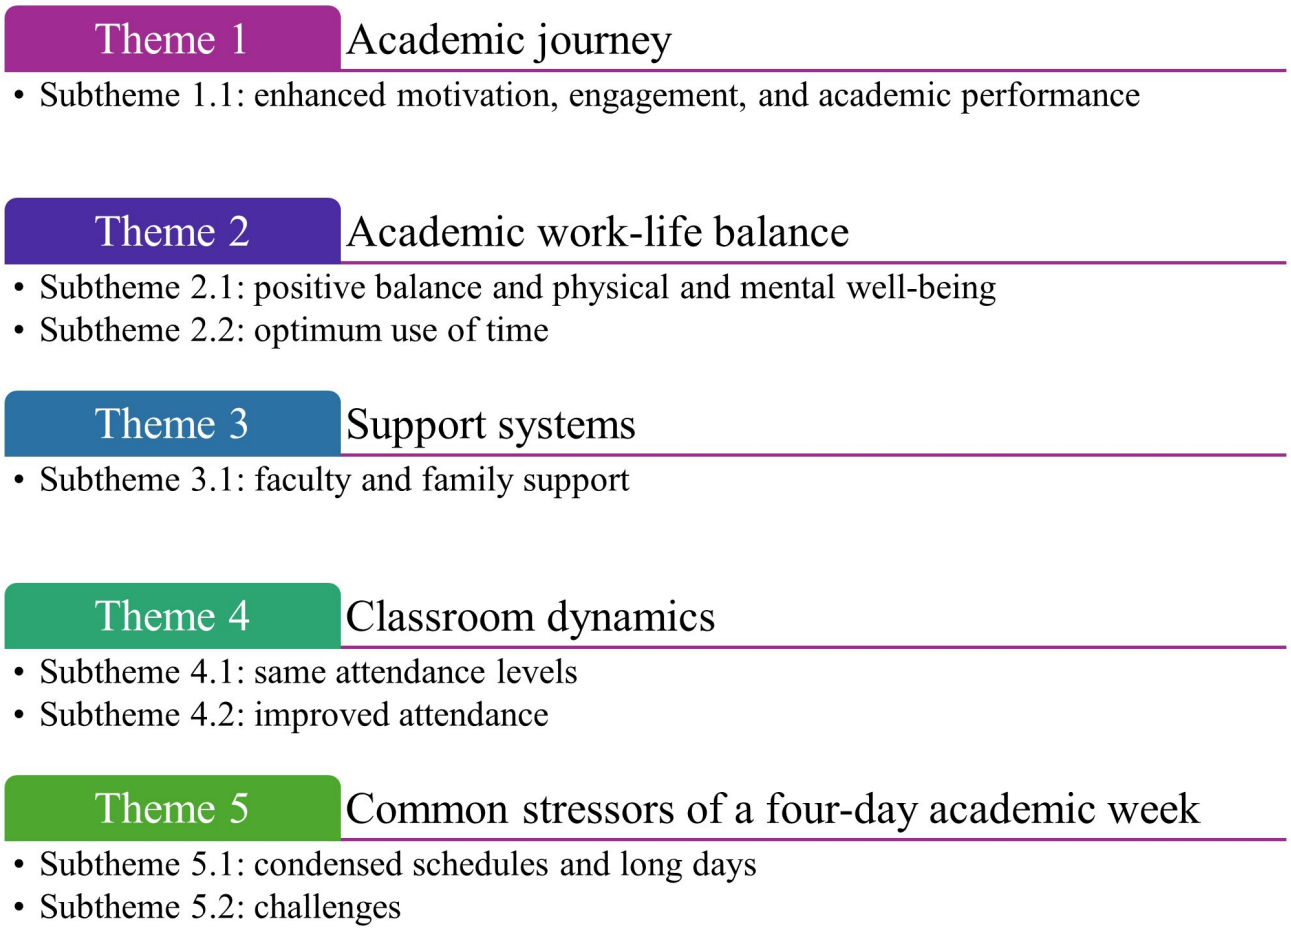
Figure 1. A summary of themes and subthemes reflecting medicine, dentistry, and health sciences students' perspectives on the impact of the transition from a 5-day to a 4-day week on their academic performance.



Theme 1: Academic Journey

Subtheme 1.1: Enhanced Motivation, Engagement, and Academic Performance

The implementation of a 4-day academic week has notably enhanced students' motivation, engagement, and academic performance, as expressed by many health sciences students. Many students reported a marked increase in motivation, attributing it to having more time to prepare for exams, complete assignments, and organize their studies.

> *Since the implementation of the four-day week, my motivation levels increased. Having an extra weekend day will help you have more time to prepare for upcoming exams and complete assignments on time.* [P6]

One student added that additional time during the weekend improved his grades.

> *My grades got better because I had more time to study.* [P13]

Some students observed that with more time to rest during the extended weekend, they returned to their studies feeling more focused and refreshed. The extra day off also encouraged greater self-reliance for one's own learning, with students feeling more motivated to study independently rather than relying solely on instructors. Furthermore, the 4-day work week not only helped them stay engaged but also made them more productive, providing a sense of balance and convenience that positively impacted their academic efforts.

Theme 2: Academic Work-Life Balance

Subtheme 2.1: Positive Balance and Physical and Mental Well-Being

A significant number of study participants reported that the transition to a 4-day academic week markedly improved their academic work-life balance. Many appreciated that the additional day off allowed them to allocate more time to their studies, extracurricular activities, and personal commitments. Students highlighted that the extra time enabled them to better manage academic workload and responsibilities, while also dedicating time for rest, exercise, family gatherings, and social interactions.

> *As I mentioned, because now I have one extra day, I can enjoy during the weekend, I can distribute the work better, so I have better actual balance between both my studies and extracurricular (activities).* [P5]

The resident students in the dormitory found the extended weekend particularly beneficial for traveling back to their families.

> *So, it's easier to travel to your family outside the country.* [P21]

Some students noted that having an additional day to themselves contributed to better mental health, allowing for reflection,

relaxation, and a reprieve from the daily academic pressures. While the 4-day schedule condensed the lab and lecture sessions, students acknowledged that the 3 days off helped them recharge and maintain a healthy balance between their academic and personal lives. Overall, the shift to the 4-day academic week was seen as highly beneficial in promoting both academic productivity and overall well-being.

Subtheme 2.2: Optimum Usage of Time

The shift to a 4-day academic week had a positive impact on the students' ability to manage and optimize their time. Many expressed that under the previous 5-day schedule, there was insufficient time to complete coursework, particularly clinical documentation, which often had to be completed at home. With the additional day off, students found they had more time to focus on assignments, manage their academic workload, and balance extracurricular activities. An extra weekend day allowed for better organization of tasks, leading to improved time management and more efficient studying.

> *Having the three-day weekend helped me organize my time better.* [P7]
>
> *Having an extra weekend day allowed me to balance both workload and commitments, helping me manage my time better.* [P11]

In addition, students noted that the 3-day weekend gave them more energy and focus during the week, as they had more time to rest and recharge. Some also emphasized that the extra day helped them achieve a better balance between academic responsibilities and personal commitments, including spending time with family, which had been challenging with the previous schedule. In summary, a considerable proportion of the university students noted a major improvement in terms of time management and productivity after shifting to the 4-day academic week.

Theme 3: Support Systems

Subtheme 3.1: Faculty and Family Support

Health care students expressed a strong sense of support from both faculty and family, which played a pivotal role in their academic success and well-being. Many students highlighted the encouragement they received from specific faculty members who were not only understanding but also flexible in accommodating their needs. Whether it was adjusting lab timings, rescheduling exams, or providing additional resources such as opening labs on weekends, faculty demonstrated a commitment to helping students balance their academic and personal responsibilities. One student mentioned how faculty members worked around their professional commitments, enabling them to complete a movie shoot while staying on track academically.

> *Yes, from Doctor xxxx (a faculty member's name) and Doctor xxxx (another faculty member's name) as well; basically, in one of the semesters, I had Netflix shoot, and I was going to be absent from university for two months in a row. I talked with Doctor xxxx (a faculty member's name) as she's my advisor and she helped me out, also Doctor xxxx (another faculty member's name) helped me and they made it possible for me to do my shooting, to do my work and to attend my makeup (exams) better.* [P3]

Moreover, the emotional and motivational support from family and friends further empowered students to stay focused and motivated, allowing them to better organize their priorities and excel in their studies. Based on the perceptions of the 4-day academic week, it can be inferred that the combined support from faculty, family, and peers significantly enhanced the students' academic experience, making the 4-day academic week more manageable and effective whilst attending to personal responsibility outside of academia.

Theme 4: Classroom Dynamics

Subtheme 4.1: Same Attendance Levels

Nearly 70% of the participants reported that their attendance levels did not alter in the shift from 5-day week to 4-day academic week.

Subtheme 4.2: Improved Attendance

Around 25% of the study respondents recorded that their attendance got better, and they have started attending all the classes with the 4-day academic week, while before they used to stay absent or attend the maximum number of required classes and clinical practicums.

Theme 5: Common Stressors of a 4-Day Academic Week

Subtheme 5.1: Condensed Schedules and Long Days

The extended working hours and condensed schedules brought about by the shift to a 4-day academic week were one of the major concerns raised by the health care students. Many found that the teaching content was compressed into fewer days, leaving minimal time for breaks or adequate reflection.

> *The negatives of having four days are that the materials are compressed into these four days, leaving minimal time.* [P1]
>
> *But on the other side, the drawbacks for having 4 days is (are) that we usually have a lot of materials that's compressed on us in these four days that we have minimal time.* [P5]

Some students noted that their weekdays became more stressful, with longer hours and more back-to-back lectures, making it difficult to manage their workload effectively. The compact schedule, though allowing for a longer weekend, resulted in longer days, leading to increased fatigue and diminished focus during lectures.

> *The days became longer and compact. It became more stressful because the days became longer.* [P4]

Despite these challenges, some students accepted the trade-off, stating that they valued the extra day off on weekends, even though the compressed weekdays required more intense time management.

> *The drawback is for example, nowadays the classes are many; let's say for example today is Monday, so I started at 8:00 (am) and I finished at 4.00 (pm), but*

> *before I used to start at 10 and then I would finish that too (at 4.00 pm). We have more time to divide the classes, but for me personally, and I think most people will agree with me, it's fine to have everything compacted on the weekdays as long as on the weekend we have an extra day off.* [P3]

Therefore, the main drawback of the 4-day academic week appeared to be the increased workload on each individual day, which students found challenging to manage, despite the perceived benefits of extended weekends for relaxation and study.

Subtheme 5.2: Challenges

While the 4-day academic week was beneficial to the health care students, many of them also voiced several challenges associated with this model. Some noted that the longer weekend led to a tendency to neglect studies during the break, resulting in lapses in focus or forgotten material.

> *…. but the drawbacks that we may forget things we may like that we will not study in these three days and sometimes it happened.* [P1]

The compacted schedule caused others to arrive late to lectures or struggle with back-to-back classes, which they found overwhelming.

> *I'm arriving late to the lectures by around 15 minutes because of the back-to-back classes.* [P2]

Several students reported a decline in their grades, attributing it to increased stress and the tutors' inability to cover all the material during class time, leaving more for self-study.

> *My grades got decreased due to stress.* [P9]
>
> *but for the negative impact, as I mentioned, the tutors are unable to finish materials. So, there are a lot (of) self-study material.* [P10]

Balancing personal responsibilities, family time, and academic workloads became harder for many, as they found it difficult to manage their time effectively within the condensed 4-day academic week. Though the extended weekend was considered a benefit, it often came at the cost of a worsened balance between academic and personal responsibilities.

Discussion

Principal Findings

This study revealed that the shift to a 4-day academic week from a 5-day week had a significant impact on various aspects of our students' academic and personal lives. We found that the 4-day academic week had a positive impact on most of our student participants, enhancing their motivation, engagement, academic work-life balance, and physical and mental well-being. Some students received positive support from faculty and family. However, a few students encountered increased stress and struggled to balance academic and personal commitments with this model.

Most participants reported increased motivation, focus, and engagement in both lectures and laboratory sessions, which positively impacted their academic performance. These findings align with the study by Gaballah et al [13] where most students acknowledged improvements in academic performance with the 4-day academic week, although one-third did not report such benefits.

The shift to a 4-day academic week improved students' academic work-life balance, allowing them to allocate more time to rest, personal commitments (with family and friends), and extracurricular activities. The extra day off provided an opportunity for reflection and relaxation, which contributed to better mental health and well-being. These findings agree with Gaballah et al [13], who reported that around 90% (257 out of 284) of their dental student participants reported stress relief and spending quality time with friends or families, in addition to having extra time for studies and exam preparation because of the long (3-day) weekend [13]. Dormitory students particularly appreciated the reduced need to travel frequently (considering an extra day off), which decreased physical exhaustion. Many participants emphasized that they could now distribute their academic workload more evenly, avoiding burnout, which is supported by the theory of self-regulated learning**,** which focuses on students' ability to manage their own learning processes [22]. The improved balance between academic and personal responsibilities not only boosts productivity but also helps students maintain a healthier lifestyle [23]. However, managing this balance required effective time management and self-care to avoid procrastination during the longer weekends, as some students feel that a 4-day academic week has led to academic overload [24-26]. Academic overload may be regarded as students' feelings of being overwhelmed by their academic requirements or responsibilities while pursuing a degree at university.

While the students enjoyed a 4-day academic week with the exemption of commuting time on an extra day, the long workday and compact schedule took its toll on some students. Entry-level students in higher education have been reported to experience difficulties in managing the academic workload at university [27]. Chambel et al [28] found that students' inability to manage academic workload had a negative impact on academic adjustment to university and academic performance. Some students were happy with the support received from faculty and family, which would have played a pivotal role in helping students adapt to the 4-day academic week. Indeed, some faculty members were flexible in accommodating students' needs, offering extra lab time or adjusting deadlines to help them balance their academic and personal responsibilities. The findings show that faculty members played a key role in providing cognitive flexibility by helping students adjust to the new schedule and commitments while maintaining the professorial standards [29]. However, one-third of the dental students, from the previous survey conducted at our institution, reported limited time to meet their professors and advisors, while the rest expressed satisfaction with the support provided by faculty [13].

Many students appreciated the flexibility offered, such as optional assignments and extended lab hours. These arrangements could be beneficial for students who had other professional obligations to improve their academic achievement [30,31]. Emotional support from family also encouraged students

to stay focused and motivated. With this support system in place, students felt more confident in managing the demands of their studies. The combined support from faculty, family, and friends might have alleviated much of the stress associated with the compressed schedule, helping students navigate challenges more effectively.

Despite some students receiving favorable support, a few participants reported a lack of adequate support from faculty to facilitate their transition to this new framework. Universities using a 4-day academic week model need to improve manual (eg, student advisors, counselors) and digital support systems (through a dedicated service desk), amongst others, to help mitigate or alleviate the stressors and enhance the academic performance of students adjusting to this transition from a 5-day week.

For most students, attendance levels remained unchanged after the shift to a 4-day academic week, indicating that the change did not negatively affect class participation. All faculty members use an online attendance tracking system at our institution, which issues automatic warnings when students reach 10%, 15%, and 20% absence thresholds. Those exceeding the 20% absence limit are prohibited from attending exams, ensuring consistent attendance and academic engagement. However, a minority of students reported improved attendance, attributing this to increased motivation and better preparation. The extra day off might allow students to rest and recharge, which would have made them more consistent in attending classes [32]. This improvement in attendance also reflects a stronger commitment to academic schedules and responsibilities [33]. However, for those whose attendance remained the same, the extra day was more of a personal benefit than an academic one.

While the 4-day academic week offered clear benefits, many students found the condensed schedule challenging, especially in the clinical rotations, which is in line with the findings of the earlier study [34]. The longer days, with back-to-back lectures and lab sessions, left little time for breaks or reflection. This intensified workload increased stress and fatigue, making it harder for students to stay focused during classes. The compressed schedule might pose challenges to faculty in covering all the materials included in their course syllabi, and some students pointed out their reliance on self-study in this regard.

A few participants felt a lack of extra support from faculty to adjust to this transition to the 4-day academic week. Despite these difficulties, many students accepted the trade-off, valuing the extended weekend for relaxation and personal commitments. The challenge lay in balancing the intensified academic schedule with the need for rest and fulfilling other (personal) commitments [35]. The mixed findings of our study provide a nuanced understanding of the 4-day academic week's benefits and drawbacks, particularly in the context of higher education in health care in Sharjah, United Arab Emirates.

Academic overload could lead to lower academic adjustment among university students. This means that those students who feel overwhelmed by their daily academic requirements and responsibilities will have lower academic adjustment. This result is in accordance with previous research by Bitzer et al [27]. Although we did not have access to the grades, this may be a plausible explanation. Students who feel confident about their skills, who are confident about their academic and learning capabilities, and who have a positive attitude or perception toward their abilities will perform better academically and adapt to the academic demands of the university. Moreover, a previous study indicated a positive relationship between self-efficacy and academic adjustment [36].

The more time students allocate toward studying, the higher their level of self-efficacy and the better their academic adjustment. In general, the 3-day extended weekend appeared to be conducive to learning.

Strengths and Limitations of the Study

A variety of students from the different colleges within the medical campus has resulted in rich data, and they provided interesting perspectives on the impact of the 4-day academic week on academic performance across the different colleges. In addition, the study followed a robust protocol to reduce bias and enhance credibility of the findings and adhered to the COREQ guidelines (Consolidated criteria for Reporting Qualitative research) checklist to improve transparency in reporting.

A limitation of the study is that we had included medicine, dentistry, and health science students only from the University of Sharjah, which may not be generalizable to students studying different programs (eg, engineering, law, arts, and science) and other universities and in the other emirates within the United Arab Emirates. However, at present, the Emirate of Sharjah is the only emirate that has implemented the 4-day academic week for universities.

Implications and Future Recommendations

The findings clearly illustrate the nature in which the transition to the 4-day week in the United Arab Emirates has occurred, along with the positives and negative side. The themes and trends identified in this work will inform and guide current and future research studies, thereby broadening the scope of our work. Future studies are needed to test whether the identified themes are common in the emirate of Sharjah and beyond.

Given the mixed results, a need for a study skills program to accompany the transition to the 4-day work week is required to mitigate the issues encountered by some students. This would include prioritizing and scheduling academic activities by creating a weekly schedule that allocates dedicated time to both academic and personal activities, along with prioritizing tasks and setting realistic goals for every identified task. Students need to manage time efficiently by breaking tasks into smaller, manageable segments and using tools like time-blocking and to-do lists. These strategies can help students stay organized and in control of both academic and personal lives. Students would need to clearly define boundaries between academic and personal life, which is an area of life skills for the future. Moreover, students can practice self-care for themselves, like meditation, exercise, and hobbies that rejuvenate them mentally and physically. Students should be able to seek help from the faculty and family whenever required to accommodate and balance their expectations and needs in the best way possible.

Students need to reflect and adjust as necessary, as their academic demands and priorities may change over time.

This study offers recommendations, including that the 4-day academic week, while working in the favor of most university students, needs to have a supportive mechanism. One such support system is an effective advisory system so that students (advisees) can seek help with study skills and time management from their faculty advisors or mentors to mitigate the drawbacks of the extended hours during the 4-day academic week. Our university already has such an advising system (with each student assigned to a faculty advisor), a disability resource center, and counselors in place to support all students, including but not limited to those at risk of academic probation because of their poor performance in studies, to thrive with the current framework. Moreover, our university has introduced peer tutoring activities and is planning peer advising initiatives to further facilitate this transition from a 5-day to a 4-day academic week in the emirate of Sharjah, United Arab Emirates. Further studies involving students from diverse academic disciplines (eg, engineering, arts, literature, science, and law) and from other universities in the United Arab Emirates that have adopted the 4-day academic week are required to generate wider insights and provide implications for policy.

Conclusion

Overall, students studying medicine, dentistry, and health sciences programs perceived that the 4-day academic week had a positive impact by enhancing their motivation, engagement, class attendance, and work-life balance, along with the support of faculty and family. However, a few students encountered increased stress and struggled to balance academic and personal commitments with this model. Universities using a 4-day week model need to improve manual (eg, student advisors and counselors) and digital support systems (through a dedicated service desk), amongst others, to help mitigate or alleviate the stressors and enhance the academic performance of students adjusting to this transition from a 5-day week to a 4-day week.

Abstract

Background: In the rapidly changing realm of medical education, Competency-Based Medical Education is emerging as a crucial framework to ensure residents acquire essential competencies efficiently. The advent of mobile-based platforms is seen as a pivotal shift from traditional educational methods, offering more dynamic and accessible learning options. This research aims to evaluate the effectiveness of mobile-based apps in emergency residency programs compared with the traditional paper- and web-based formats. Specifically, it focuses on analyzing their roles in facilitating immediate feedback, tracking educational progress, and personalizing the learning journey to meet the unique needs of each resident.

Objective: This study aimed to compare mobile-based emergency residency training programs with paper- and web-based (programs regarding competency-based medical education core elements.

Methods: A cross-sectional web-based survey (Nov 2022-Jan 2023) across 23 Taiwanese emergency residency sites used stratified random sampling, yielding 74 valid responses (49 educators, 16 residents, and 9 Residency Review Committee hosts). Data were analyzed using Mann-Whitney *U* test, chi-squared tests, and *t* tests.

Results: MB programs (n=14) had fewer missed assessments (P=.02) and greater ease in identifying performance trends (P<.001) and required clinical scenarios (P<.001) compared with paper- and web-based programs (n=60). In addition, mobile-based programs enabled real-time visualization of performance trends and completion rates, facilitating individualized training (P<.001).

Conclusions: In our nationwide pilot study, we observed that the mobile-based interface significantly enhances emergency residency training. It accomplishes this by providing rapid, customized updates, thereby increasing satisfaction and autonomous motivation among participants. This method is markedly different from traditional paper- or web-based approaches, which tend to be slower and less responsive. This difference is particularly evident in settings with limited resources. The mobile-based interface is a crucial tool in modernizing training, as it improves efficiency, boosts engagement, and facilitates collaboration. It plays an essential role in advancing Competency-Based Medical Education, especially concerning tailored learning experiences.

KEYWORDS

app; mobile; web-based; competency-based medical education; residency training program

Introduction

The competency-based medical education (CBME) model has been a global trend in residency training for over a decade [1-4], with timely, personalized, and meaningful coaching feedback as one of its core elements [4]. At the same time, advances in mobile technology are reshaping both medical education and clinical practice [5-11]. Mobile learning has emerged as a cost-effective, accessible approach that supports context-driven, real-time learning and continuous feedback—despite challenges

like technical limitations and potential distractions [5]. A national survey indicates that tablet use, predominantly iPads, is on the rise, with strong support for further integration to enhance clinical efficiency, particularly among younger clinicians [8]. In addition, guidelines for mobile technologies in workplace-based assessments show that these devices can streamline real-time data capture, reduce administrative burdens, and facilitate competency-based decision-making through intuitive interfaces, robust security, and comprehensive training [12].

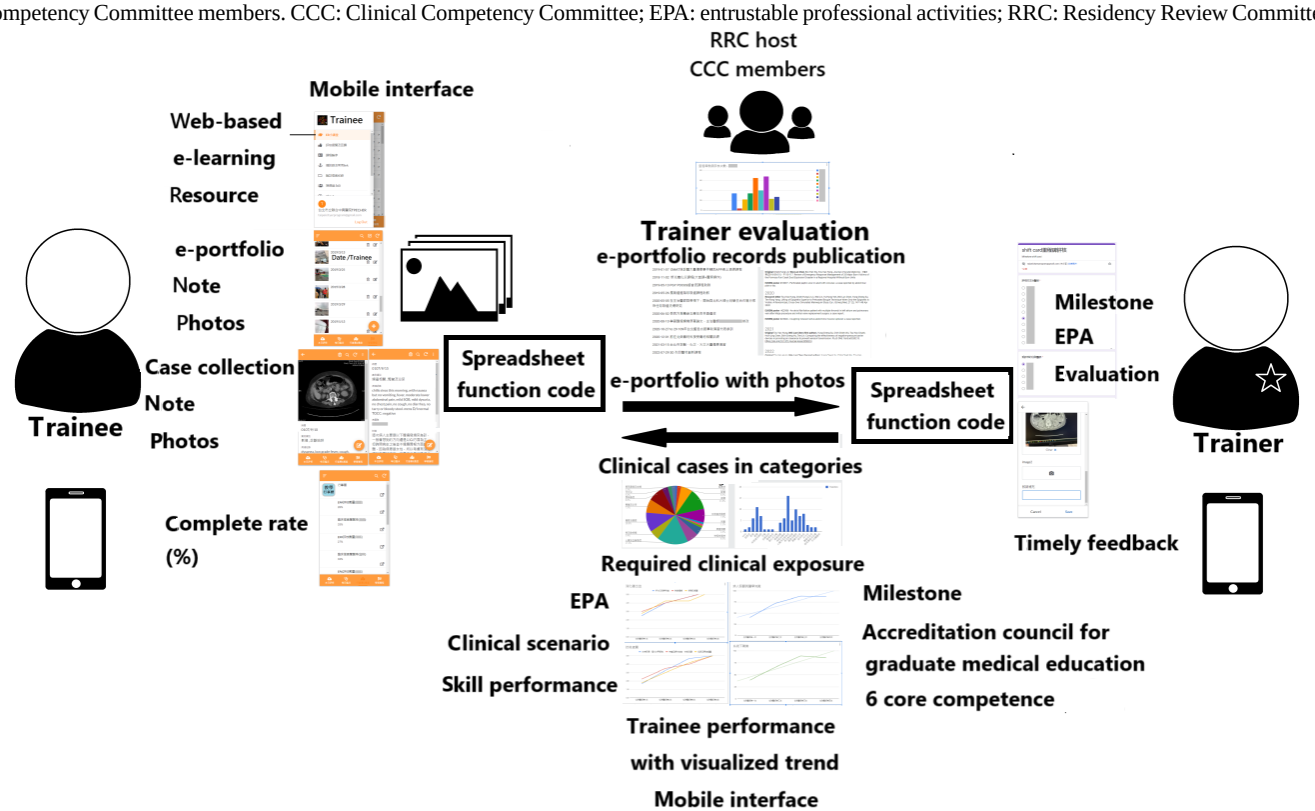
A residency training program is designed to help residents manage patients effectively across diverse scenarios while continuously improving their skills. The goal is to foster intrinsic motivation and enhance performance by creating an environment that supports autonomy, competence, and relatedness [13].

Repeated, multisource evaluations provide a more reliable trainee assessment than one-off reviews [14,15]. Oudkerk Pool et al [14] found that multiple evaluators help mitigate biases by iteratively acquiring, organizing, and integrating evidence. As CBME emphasizes longitudinal performance tracking, effective data management is crucial. Leveraging big data enables objective, evidence-based promotion decisions, reducing reliance on subjective faculty recall [16].

However, performance evaluation demands extensive documentation, data collection, and analysis, which can be time-consuming and resource-intensive, potentially affecting the quality of feedback. In addition, interpreting performance trends is complex and must generate meaningful insights for program committees to tailor and individualize training. For resource-limited programs, the infrastructure required to integrate evaluation interfaces and visualize performance trends across trainers, trainees, and program committees poses a significant challenge [5,12,16].

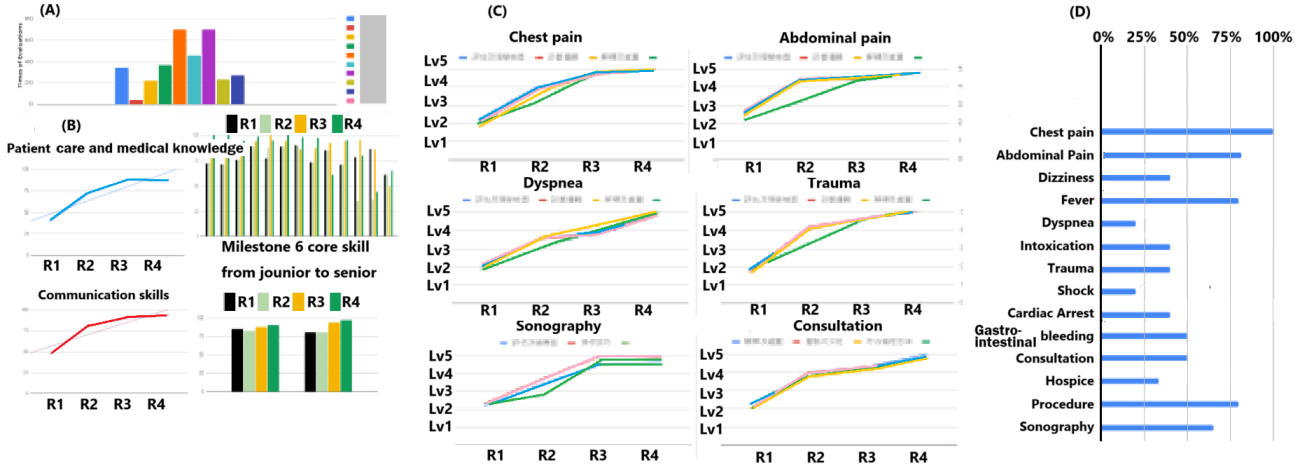
Although mobile apps for medical learning have advanced significantly [5-7,9,17,18], assessment in training programs has largely relied on paper- or web-based systems [19]. However, computers and laptops can be cumbersome and require stable internet access, which is not always available. In contrast, mobile interfaces on smartphones and tablets offer a more accessible and user-friendly alternative without compromising content quality (Figure 1) [5-9,12]. These platforms facilitate frequent performance monitoring and review, promoting continuous improvement in alignment with evolving educational and professional needs [12].

Figure 1. The illustration of the mobile-based interface is shared among trainers, trainees, the Residency Review Committee host, and Clinical Competency Committee members. CCC: Clinical Competency Committee; EPA: entrustable professional activities; RRC: Residency Review Committee.



Ideally, residents and faculty can exchange real-time feedback, allowing both groups to track performance trends and refine learning and coaching strategies. Rather than relying on one-time scores, the Residency Review Committee (RRC) and Clinical Competency Committee (CCC) can assess performance through visual trend analyses (Figure 2), enabling personalized program adjustments and targeted interventions for underperformance [12]. This framework consolidates evaluations from multiple sources, transforming data into motivational insights for trainees and actionable trends for program directors. In addition, visualizing progressive percentages helps trainees understand their clinical diversity requirements and ensures they receive adequate competency evaluations throughout emergency residency training.

Figure 2. (A) The assessment distribution by the trainer is based on one training site with a mobile-based assessment system. The trainee's milestones are assessed weekly, and these data can be accumulated and transformed into visualized trends quarterly and annually to track progress. (B) Entrustable professional activities, with scenarios characterized by varying levels of emergency, can be accumulated and transformed into visualized trends quarterly and annually to gauge progress. (C) The required assessments of entrustable professional activities can be converted into a completion rate to aid trainers in more comprehensive assessments of trainees. EPA: entrustable professional activity.



Workplace-based assessments are a cornerstone of CBME, particularly in emergency residency training, where timely feedback and performance tracking are essential [12]. While paper-based and some web-based platforms (eg, Google Forms and SurveyCake) facilitate structured evaluations, they often present challenges in real-time data integration, accessibility, and administrative burden for trainers and trainees.

Despite advancements in medical education technology, our preliminary data from Taiwan suggest that mobile interface assessments remain significantly underused compared with web-based alternatives, with an approximate ratio of 1:4-1:5. This disparity may reflect institutional technological barriers, faculty adoption challenges, or security and interoperability concerns, all of which hinder the seamless aggregation and visualization of multisource evaluation data. While web-based platforms are widely implemented, the potential of mobile-based platforms to enhance real-time feedback and streamline competency tracking in residency training remains underexplored [16,17].

This pilot study aims to determine whether mobile-based platforms can address these challenges by improving real-time performance monitoring and optimizing feedback mechanisms in emergency residency training. By evaluating user adoption, data integration efficiency, and feedback effectiveness, this study seeks to provide insights into the feasibility and impact of mobile technology in workplace-based medical assessments.

Methods

Overview

A cross-sectional, web-based survey was conducted from November 3, 2022, to January 3, 2023, to explore the perspectives of educators and resident physicians on assessment platforms in emergency residency training. As a preliminary investigation, this study aimed to assess the feasibility of mobile-based assessments, refine survey methodology, and identify key themes for future large-scale research.

We calculated the sample size using a *t* test for 2 independent proportions. Given that mobile-based programs constitute approximately one-fourth of RRC programs, we based our estimation on a 1:4 ratio. Assuming a 1-point difference in evaluations regarding training individualization, we determined that a minimum of 11 mobile-based participants and 44 paper- and web-based participants would be needed to achieve 80% power at α=.05 [20].

The survey targeted program hosts, trainers, and trainees across emergency residency training sites in Taiwan, inviting them to participate anonymously (Multimedia Appendix 1). A stratified random sampling method was applied, proportionally selecting participants from accredited emergency residency training hospitals as recognized by the National Emergency Medicine Association. From a total of 1068 qualified educators and 313 resident physicians, a 5% sampling rate was used, resulting in invitations sent to 55 educators and 20 resident physicians. In addition, to gather insights on the perspectives of RRC hosts, 10 were invited to participate in the survey [20].

This study evaluates assessment designs used across different emergency residency training sites. Participants from diverse programs were categorized into paper- and web-based or mobile-based evaluation methods for detailed analysis. Paper- and web-based programs were grouped together due to shared limitations, such as delayed feedback, lack of real-time performance tracking, and reliance on periodic evaluations rather than continuous competency monitoring. In contrast, mobile-based programs provided immediate feedback and seamless trainee progress tracking, distinguishing them as a separate category.

The questionnaire was developed using the Delphi method, ensuring expert consensus on its content and structure. It included a background survey capturing details, such as the name and level of the training site, the number of trainers and trainees, and the participant's role in the training program. The core survey items consisted of Likert-scale questions (5-point scale, ranging from "Strongly Disagree" to "Strongly Agree") designed to assess perceptions of CBME core elements. These

responses were analyzed and compared to evaluate differences in assessment approaches. To ensure the integrity and reliability of the collected data, only fully completed surveys were included in the final analysis. Incomplete responses were excluded to maintain data accuracy. In addition, responses underwent internal consistency checks to detect and exclude any contradictory or inconsistent answers.

The questionnaire was distributed on the web, with participants invited via email to complete it voluntarily and anonymously. No monetary incentives were provided; however, participants were informed that their input would contribute to improving workplace-based assessments in emergency residency training. While hosts offered additional insights, their responses were categorized under trainers for analysis, as their primary role aligned with faculty responsibilities.

Statistical Analysis

Analyses were conducted using IBM SPSS Statistics (version 23). Dependent variables included assessment satisfaction, assessment and feedback duration, frequency of missed assessments, ability to identify performance trends, ability to review and respond within 24 hours, ability to individualize training programs based on performance results, and ability to track the completion rate of required clinical scenarios and assessments.

Independent variables included the training site level (district, regional, or center hospitals), participants' age, participant role (trainee or trainer), and assessment platform (mobile-based or paper- and web-based).

The Mann-Whitney *U* test was used to compare differences in dependent variables across training sites and participant roles. A linear regression model with repeated measurements at the hospital level was applied to evaluate the ability to individualize training programs based on performance results, adjusting for potential confounders, including the number of trainers and trainees. The chi-squared test was used to analyze differences in assessment platform performance, with statistical significance set at $P<.05$. The chi-square test was used to analyze differences in assessment platform performance, with statistical significance set at $P<.05$.

Ethical Considerations

This pilot study received ethical approval from the Taipei City Hospital institutional review board (TCHIRB-11110007-E). The study was conducted after being approved by the Taipei City Hospital institutional review board on November 24, 2022. The survey was anonymous. The informed consent was waived by the Taipei City Hospital institutional review board.

Results

Demographics

In this study, 62.22% of emergency residency training sites nationwide participated, amounting to 28 out of 45 sites. A total of 74 valid responses were collected from 28 emergency residency training sites across Taiwan, including district, regional, and center hospitals. Among the respondents, 49 trainers participated, reflecting an 89.1% response rate, while 16 resident trainees responded, yielding an 80% response rate. To further explore the perspectives of RRC hosts, 10 were invited to participate, with 9 providing responses. Regarding assessment platform usage, 14 participants reported using mobile-based assessments, whereas the remaining 60 relied on either paper- or web-based platforms. Within this group, 3 participants used paper-based assessments, and 57 used web-based systems.

Survey Validity Results

The questionnaire demonstrated strong reliability for trainee responses, with a Cronbach α of 0.83, indicating high internal consistency. For trainers, the reliability was moderate, with a Cronbach α of 0.61, which is acceptable for exploratory research. In addition, the content validity index of 0.96 confirmed strong expert agreement on item relevance, supporting the overall validity of the questionnaire.

Survey Results

The analysis revealed no significant differences between trainers and trainees concerning the distribution of assessment platforms, satisfaction with the evaluation process, the time taken for evaluation and feedback, the likelihood of forgetting mutual assessments, or responses to core CBME-related questions (Table 1). However, when comparing mobile-based assessments with paper- and web-based platforms, mobile interfaces demonstrated several advantages. Respondents using mobile-based platforms reported higher satisfaction with the assessment process, a lower likelihood of missing assessments, and an improved ability to identify performance trends. In addition, they were more likely to review feedback within 24 hours, found it easier to tailor training programs based on performance results, and experienced greater ease in identifying required clinical scenarios and necessary assessments (Table 2).

Table . Characteristics of internet survey participants from emergency residency training sites. Data are presented as N (%), mean (SD), or median (IQR).

Discussion

Principal Findings

This pilot study found that mobile-based programs more frequently used visualized performance trends (85.71%) than paper- and web-based programs (73.33%), enhancing trainees' understanding (mean 4.71, SD 0.61 vs mean 2.72, SD 1.06; *P*<.001). Mobile-based platforms also enabled faster review of ad hoc responses within 24 hours (mean 4.5, SD 0.85 vs mean 2.22, SD 0.88; *P*<.001) and better supported individualized training in alignment with CBME principles (mean 4.36, SD 0.84 vs mean 2.27, SD 0.78; *P*<.001). Statistical analysis indicated a significant association between MB assessments and improved training individualization (2.08-point increase, 95% CI 1.73 - 2.43; *P*=.002), suggesting mobile-based platforms facilitate more timely and adaptive program adjustments than paper- and web-based (Table 3).

Comparison With Previous Work

Since 2009, CBME has become a global standard in medical training [1]. Oudkerk Pool et al [14] highlight that competency judgments are formed through an iterative process of acquiring and synthesizing evidence, underscoring the need for structured, multisource assessments. However, effective CBME implementation requires more than data collection; it demands meaningful integration and interpretation among instructors, residents, and program coordinators, including RRC hosts and CCC members [14,16].

Despite advancements in assessment methods, paper- and web-based evaluations remain prevalent in Taiwan's residency programs (Table 2). These static, retrospective tools limit

real-time performance tracking and individualized feedback. Chan et al [16] demonstrated that programmatic workplace-based assessments, such as the McMaster Modular Assessment Program (McMAP), improve competency evaluations by replacing single-assessor recall with multisource, continuous feedback. Likewise, our findings suggest that mobile-based platforms offer a promising alternative by enabling timely communication, visualizing performance trends, and tracking clinical exposures in real time, aligning with CBME's emphasis on progressive competency tracking.

However, while convenience is improved, adopting a mobile-based platform alone does not guarantee the effective integration of summative performance trends. As Oudkerk Pool et al [14] emphasize, competency judgments require active evidence synthesis rather than passive data aggregation. Therefore, mobile-based platforms must be supported by faculty training and institutional commitment to continuous assessment. Beyond technology, mobile-based platform development reflects institutional investment in assessment culture. Successful implementation requires standardized tools, integration, and a culture that embraces real-time feedback. Chan et al [16] highlight that workplace-based assessment systems like McMAP not only streamline logistics but also normalize structured, frequent evaluations, shaping residency training [12]. This may explain why, in our study, the mobile-based platform yielded higher satisfaction and a more tailored training experience compared with the paper- and web-based group.

Compared with mobile-based assessment evaluations, paper- and web-based assessments, though practical, are often less accessible, time-consuming, and associated with lower compliance [19]. Mobile-based platforms provide easy access and real-time feedback, allowing trainers and trainees to review performance trends anytime and anywhere. In addition, their integration with smartphone features—such as cameras, note apps, calendars, GPS, and barcode scanners—enhances efficiency and usability [18,19,21-23]. However, while mobile-based platforms improve accessibility, Walsh [5] noted that mobile learning in medical education may also introduce distractions, potentially affecting engagement and focus during training sessions.

Previous studies have demonstrated the feasibility and effectiveness of mobile-based assessment tools in medical training. Nethala et al [11] found that mobile apps enable real-time assessment and individualized skill training in urology residency programs, facilitating structured competency tracking. Similarly, Sung and Park [22] reported that a mobile-based training program improved nurses' competence through enhanced accessibility and interactive learning. Green highlighted the cost-effectiveness and usability of smartphone platforms for surgical resident evaluations, reinforcing the practical benefits of mobile-based assessments in medical education [23].

In our study, while assessment and feedback durations did not differ significantly between mobile-based and paper- and web-based platforms, mobile-based assessments yielded higher satisfaction and a lower frequency of missed evaluations (P<.001 and P=.02, respectively; Table 1). These findings suggest that the convenience and accessibility of mobile platforms may enhance trainer engagement and encourage more consistent assessment documentation.

Beyond technological advantages, integrating multisource evaluations into visualized trend tracking on mobile-based platforms may enhance participant engagement, foster active participation, and support continuous improvement. According to self-determination theory, providing trainees with tools for real-time performance monitoring fosters autonomy, competence, and relatedness, key psychological needs that enhance motivation and self-directed learning [13]. When trainees and trainers can instantly track progression and performance trends, they gain a clearer perception of their self-determination (Figure 2), which may drive greater accountability and active participation in their own professional growth. This aligns with Association for Medical Education in Europe Guide No. 59, which highlights the role of real-time feedback in enhancing intrinsic motivation and engagement in competency development [12,13].

Our survey found that although some web-based programs included visualized trends and completion rates, mobile-based programs had a significantly greater impact on both trainers and trainees (mean 2.3, SD 0.8 vs mean 4.4, SD 0.8; P<.001; Table 2). This advantage likely stems from the mobile-based platform's accessibility, enabling real-time review compared with paper- and web-based assessments, which are typically evaluated only during biannual or quarterly CCC meetings [24]. Delayed review in paper- and web-based evaluations may hinder timely performance adjustments, whereas immediate access to evaluation results in mobile-based programs enables trainees to modify their performance on the next shift, reinforcing self-directed learning [13].

The observed advantages of mobile-based platforms should not be attributed solely to their technology but rather to the broader institutional commitment to structured assessment and a culture of continuous feedback. While mobile-based platforms facilitate real-time performance tracking and self-directed learning, their effectiveness depends on institutional investment in faculty training, standardized assessment frameworks, and integration within CBME structures [4,16]. The shift from paper- and web-based biannual review model [24] to continuous monitoring reflects not just technological convenience but a deeper transformation in how competency is assessed and supported. As previous studies highlight, frequent, structured feedback is essential for meaningful competency development [12,15], and the adoption of MB platforms likely signifies an institutional prioritization of learner-centered training and assessment rigor rather than merely a technological upgrade. This shift, reinforced by evidence-based coaching and real-time decision-making, aligns with a growing recognition that assessment culture, not just digital tools, drives improved training experience [13,16].

The higher satisfaction with mobile-based platforms compared with paper- and web-based (P<.001, Table 2) may be attributed to their ability to provide real-time accessibility, structured assessments, and visualized performance trends, benefiting trainees, trainers, and RRC hosts. For trainees, mobile-based platforms enabled immediate feedback and continuous

performance tracking, allowing timely adjustments rather than relying on periodic CCC reviews. This aligns with CBME principles by supporting self-directed learning and competency progression. In addition, mobile-based platforms facilitated easier identification of required clinical scenarios and assessments (P<.001), which may contribute to a more structured training experience.

For trainers, mobile-based platforms allowed more flexible and timely assessments, reducing recall bias and documentation burden. The ability to complete evaluations outside clinical hours (P=.02; Table 2) suggests increased convenience and consistency in providing feedback. The integration of smartphone tools, such as cameras and note apps, may have contributed to streamlined documentation and more structured evaluations [21]. For RRC hosts, mobile-based platforms provided a longitudinal perspective on trainee progress, reducing reliance on episodic assessments and allowing competency decisions to be based on continuous performance data rather than retrospective impressions [14,16]. The findings suggest that mobile-based platforms improve accessibility and assessment efficiency, reflecting a shift toward more continuous, data-driven evaluation in residency training.

The preference for mobile-based platforms in tailored training (P<.001; Table 2) stems from their ability to provide real-time feedback, trend visualization, and individualized learning, aligning with CBME's emphasis on continuous assessment [2,4]. Unlike paper- and web-based periodic evaluations, mobile-based platforms empower trainees with self-directed learning and immediate performance adjustments while enabling trainers to deliver data-driven coaching with minimized bias [12,16]. For RRC hosts, mobile-based platforms enhance longitudinal competency tracking, overcoming the limitations of CCC's fixed evaluation intervals and allowing timely interventions [1,3,24]. However, their success depends on structured implementation, faculty engagement, and integration within CBME frameworks to ensure meaningful assessment without cognitive overload [5,6,17].

Overall, while mobile-based platforms show promise in improving feedback timeliness and training individualization in our pilot study, further research is needed to evaluate their long-term impact on competency development, clinical outcomes, and residency training culture.

Highlights

First, mobile-based platforms provide real-time feedback and continuous performance tracking, complementing scheduled CCC reviews and addressing paper- and web-based limitations in integrating multisource evaluation results. Second, structured mobile-based evaluations improve engagement and training individualization, offering more timely and adaptive learning opportunities that better align with CBME principles compared with paper- and web-based platforms. Finally, successful integration depends on faculty training and strategic implementation, enhancing assessment validity, competency tracking, and institutional commitment to resident development, ultimately leading to greater satisfaction.

Structured mobile-based evaluations improve engagement and training individualization, offering more timely and adaptive learning opportunities that better align with CBME principles compared with paper- and web-based platforms. Successful mobile-based integration depends on faculty training and strategic implementation, enhancing assessment validity, competency tracking, and institutional commitment to resident development, ultimately leading to greater satisfaction.

Limitations

First, the study results were based on a convenience sample from an internet survey. However, enrollment only covered 62.22% of the emergency residency training sites in the country. Second, the survey results indicated that only 14 out of 74 responses applied mobile-based assessment. Further investigation to evaluate mobile-based assessment will be needed as more training programs start being delivered through the mobile interface. Finally, in the survey, participants provided responses based on their experience with the interface's ability to facilitate tailored training adjustments, rather than on direct evidence of its actual implementation. Further research is needed to assess the long-term impact of mobile-based platform implementation on training outcomes.

The survey results indicated that only 14 out of 74 responses applied mobile-based assessment. Further investigation to evaluate mobile-based assessment will be needed as more training programs start being delivered through the mobile interface.

In the survey, participants provided responses based on their experience with the interface's ability to facilitate tailored training adjustments, rather than on direct evidence of its actual implementation. Further research is needed to assess the long-term impact of mobile-based platform implementation on training outcomes.

Conclusion

In conclusion, the mobile-based interface emerges as a dynamic and effective platform for emergency residency training programs. It facilitates rapid updates and individualized program modifications, thereby increasing the engagement and satisfaction of trainers, trainees, and other stakeholders. Contrarily, the conventional paper- and web-based methods face limitations due to prolonged review periods in committee meetings, which may lead to delays in crucial program modifications and impede the progression of the program. The adoption of mobile-based technology in this context demonstrates its capacity to greatly enhance the efficiency and efficacy of CBM, particularly in making tailored adjustments. This technology also promotes better-informed and more collaborative interactions among all involved parties.

Acknowledgments

During the preparation of this work, the authors used ChatGPT 4 in order to improve readability and language. After using this tool or service, the authors reviewed and edited the content as needed and take full responsibility for the content of the publication. The visualization trend and completion ratio were inspired by the design of a web-based e-portfolio by the Department of Emergency, Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Chiayi County, Taiwan. Abstract

Background: Artificial intelligence–powered chatbots (AI-PCs) are increasingly integrated into educational settings, including health care disciplines. Despite their potential to enhance learning, limited research has investigated physiotherapy (PT) students' acceptance of this technology.

Objective: This study aims to assess undergraduate PT students' acceptance of AI-PCs and to identify personal, academic, and technological factors influencing their acceptance.

Methods: Over a 4-month period, a cross-sectional survey was conducted across 7 PT programs in 5 countries. Eligible participants were national undergraduate PT students. The technology acceptance model (TAM)–based questionnaire was used for capturing perceived usefulness, perceived ease of use, attitude, behavioral intention, and actual behavioral use of AI-PCs. The influence of personal, academic, and technological factors was examined. Descriptive and inferential statistics were conducted.

Results: The mean total TAM score was 3.59 (SD 0.82), indicating moderate acceptance. Of the 1066 participants, 375 (35.2%) showed high acceptance, 650 (60.9%) moderate, and 41 (3.9%) low. Prior experience with artificial intelligence (AI) tools emerged as the strongest predictor of acceptance (β=.43; P<.001), followed by university affiliation (ANOVA P<.001). Cumulative grade point average percentage was positively correlated with TAM score (r=0.135; P<.001) but was not a significant predictor in regression (P=.23). Age (P=.54), sex (P=.56), academic level (P=.26), and current use of AI-PCs (P=.10) were not significant predictors.

Conclusions: PT students demonstrated moderate acceptance of AI-PCs. Prior technological experience was the strongest predictor, underscoring the importance of early exposure to AI tools. Educational institutions should consider integrating AI technologies to enhance students' familiarity and foster positive attitudes toward their use.

KEYWORDS

artificial intelligence; AI-powered chatbots; health care students; physiotherapy education; TAM; technology acceptance model; technology acceptance

Introduction

Background

Artificial intelligence (AI) enables computer systems to imitate human intelligence by processing external data and learning to perform specific tasks [1-4]. Large language models, a type of AI, are trained for human-like communication, with artificial intelligence–powered chatbots (AI-PCs) being one of their key applications [5-7]. AI has gained significant attention in health care and health professional education due to its potential to make learning more accessible, affordable, and effective [8,9]. Universities are increasingly adopting AI technologies, with AI-PC use expected to grow as technology advances [6,10-12].

In the 1970s, chatbots were known as pedagogical agents [13] and are now referred to as conversational agents, tutors, or simply bots [14]. Literature identifies AI-PCs as valuable educational tools that enhance learning experiences and outcomes [6,15,16], though they also face challenges such as accuracy, bias, and user attitudes [14,17]. The acceptance of AI-PCs in education remains underexplored, with a need for further research to clarify their adoption in universities [16,18]. To examine students' acceptance of AI-PCs, it is important to use a well-established technology acceptance model (TAM) [19].

TAM, originally developed by Davis in 1989 and updated in 1993 [20,21], is the most widely used framework for studying technology acceptance in education [22,23]. It is considered a reliable source for understanding the students' acceptance of learning technologies due to its educational focus and robust structure [24,25]. According to TAM, technology acceptance follows a 3-stage process, in which external factors trigger cognitive responses, perceived usefulness (PU) and perceived ease of use (PEU), that subsequently shape affective responses, namely attitude toward using technology and behavioral intention (BI), ultimately resulting in actual behavioral use (ABU) [20,21].

The PU refers to the individual's beliefs that a technology will enhance task performance, while PEU reflects how effortless it is to use [26,27]. While BI and attitude represent the potential consequences of the behavior [28], ABU is the outcome [23]. Investigating external factors such as students' age and prior knowledge could provide valuable insights [6].

AI is among the top 10 priorities for physiotherapy (PT) service improvement [29], and while its role in treatment is documented, research on its application in PT education remains scarce [5]. Further studies are required to explore the role of AI-PCs in educational settings and external factors influencing their adoption [6]. Moreover, understanding how students' characteristics interact with AI-PCs is crucial for educators and policy makers.

Objective

Building on this need, this study aims to assess undergraduate PT students' acceptance of AI-PCs and to identify personal, academic, and technological factors influencing their acceptance.

Methods

Ethical Considerations

Ethics approval was obtained from the respective institutional research boards in each participating institution: Fatima College of Health Sciences (FCHS) Institutional Research Board (approval: FECE-1-24-25ELSOBKEY), Beni-Suef University (BSU) Ethical Committee (approval: 12492024), Al-Zaytoonah University of Jordan (ZUJ) Institutional Research Board (approval: 10/10/2024 - 2025), Modern University for Technology and Information (MTI) Research Ethical Committee (approval: REC/2111/MTI.PT/2410292), Beirut Arab University (BAU) Institutional Research Board (approval: 2024-H-0206-HS-M-0643), October 6 University (O6U) Research Ethical Committee (approval: O6U.PT.REC/024/002009), and King Abdulaziz University (KAU) Research Ethics Committee (approval: 320 - 24). The students' confidentiality measures were explained in a participant information sheet. The questionnaire was anonymous, and the researchers are the only authorized body to have access to the collected data. Additionally, it was emphasized that participation was entirely voluntary, without academic consequences for nonparticipation. Participants signed a consent form, which was provided at the end of the participant's information sheet. For digital surveying, the following statement was included in the first section of the Google Forms: "Responding to this questionnaire will be considered as agreement to participate in the study."

Study Design

This study used an international cross-sectional survey design. The study was conducted across 7 PT programs in 5 countries (Table 1). Data were collected from September 29, 2024, to January 26, 2025. Undergraduate PT students in the participating universities were the target population and were recruited through bulletin boards, college emails, WhatsApp messages, and verbal invitations. A participant information sheet was distributed for paper-based surveying and was the first section on the digital questionnaire. It explained the study's purpose, procedure, and the average time to respond (7, SD 1.5 minutes). Convenience sampling was used. Eligible participants were national students enrolled in a bachelor-level PT program who voluntarily provided informed consent. Exclusion criteria included digital or hybrid learning enrollment, repeating multiple courses, being at the internship level (as not all programs included this level), or not completing the questionnaire. All eligible students were invited to participate.

Table . Countries, Universities, physiotherapy programs, and number of participating students (N=1066).

Country and university		College or department	Participating students, n (%)
1. Egypt			
	Beni-Suef University	Faculty of Physical Therapy	200 (18.8)
	October 6 University	Faculty of Physical Therapy	200 (18.8)
	Modern University for Technology and Information	Faculty of Physical Therapy	200 (18.8)
2. United Arab Emirates			
	Institute of Applied Technology	Physiotherapy Department, Fatima College of Health Sciences	107 (10.0)
3. Saudi Arabia			
	King Abdulaziz University	Department of Physical Therapy, Faculty of Medical Rehabilitation Sciences	67 (6.3)
4. Lebanon			
	Beirut Arab University	Physical Therapy Department, Faculty of Health Sciences	200 (18.8)
5. Jordan			
	Al - Zaytoonah University of Jordan	Department of Physical Therapy-Faculty of Applied Medical Sciences	92 (8.6)

Variables

Variables were aligned with TAM constructs and relevant external factors. Outcome variables included the TAM 5 constructs: PU, defined as students' perception of AI-PCs' benefits to their studies; PEU, referring to how easy students find AI-PCs to use; attitude, representing students' overall feelings toward AI-PCs; BI, assessed as the intention to use AI-PCs among nonusers and the intention to continue use among current users; and ABU, measuring AI-PC use. A total TAM score was calculated as the average of these 5 constructs. External factors included personal: age and sex; academic: university affiliation, academic level, cumulative grade point average percentage (CGPA%), and current use of AI-PCs; and technological: prior experience with technologies or AI tools other than AI-PCs.

Data Collection Process

Students first answered an initial screening question about their prior experience with AI-PCs to determine which version of the questionnaire to complete. Those with experience received questionnaire A, and those without experience received modified questionnaire B. For the digital version, researchers provided clear instructions and links, highlighting the importance of selecting the appropriate questionnaire according to prior AI-PCs' use. The digital questionnaire back button character was enabled to allow respondents to review and change their answers. To avoid multiple entries from the same student, the form setting of a limit to 1 response was activated.

Data Sources or Measurement

Two structured questionnaires were used. Questionnaire A (for students who are currently using or who had previously used AI-PCs) included assessed external factors (7 items) and the basic TAM section (24 items, covering 5 constructs, scored by a 5-point Likert scale) [20,21,27]. Instructions were adapted from Lewis [27]. Mean scores were calculated for each construct and overall acceptance, with scores ranging from 1 to 5. Students were categorized into high (≥4), moderate (2 - 3.9), and low (<2) acceptance. Questionnaire B (for students with no prior AI-PC experience) followed the same structure but excluded the ABU construct. Both questionnaires were anonymous and were available in digital (Google Forms) and paper-based formats. The digital questionnaire was an open survey for students who received the link from the corresponding investigators. In both questionnaire versions, students were instructed that the questionnaire is divided into 2 sections, and they need to respond to each question by choosing the most accurate answer that reflects their personal experience or opinion. The 5-point Likert scale was also explained, and if they have any questions or concerns, they can freely contact the research team at their institution.

Pilot Study

The questionnaire was piloted with at least 5 students per institution. Feedback led to 1 minor revision from King Abdulaziz University. Completion time ranged from 5 to 15 minutes (average 7, SD 1.5 minutes). The final version was used in both formats. Additionally, the digital questionnaire was tested for usability and technical functionality.

Efforts to Address Potential Sources of Bias

Student enrollment varied widely across institutions, ranging from approximately 100 to 1000s of PT students, posing a risk of statistical bias. To reduce overrepresentation, all eligible students from smaller institutions were included, while 200 students were sampled from larger ones. Additionally, to ensure curricular consistency, only bachelor's students were included,

excluding those in Doctor of Physiotherapy programs due to structural and competency differences. Internship-level students were also excluded, as not all institutions offered this academic level. These measures aimed to enhance sample homogeneity and minimize variability that could affect the study's outcomes.

Further, only national students were included to minimize cultural and linguistic variability across diverse settings, as such cross-cultural differences may influence students' acceptance of AI-PCs. Similarly, students who were repeating more than 1 course during the data collection semester were excluded, as repeated exposure to content may lead to an inflated perception of the chatbot's usefulness and a biased response in TAM-related items. These measures were taken to enhance sample homogeneity and reduce variability that could affect the study's outcomes.

Handling of Data

Digital responses were exported to a Microsoft Excel sheet, and paper-based data were entered manually. All entries were reviewed for accuracy before statistical analysis.

Statistical Methods

Descriptive statistics included means and SDs for continuous variables and frequency distributions for categorical variables. Inferential tests included the chi-square test and Pearson or Spearman correlations to assess associations and correlations between total TAM score, acceptance categories, and external factors. An independent 2-tailed *t* test compared TAM scores between users and nonusers. ANOVA with Tukey post hoc tests examined differences in TAM scores, construct scores, CGPA%, and prior experience across universities. The chi-square test also assessed differences in categorical variables like acceptance categories and academic level across universities. Finally, linear regression identified significant predictors of AI-PCs and measured effect sizes. The threshold for statistical significance was set at $P<.05$.

Handling Missing Data

All items of the digital questionnaire were mandatory to be answered to enable the questionnaire submission. Instead, a few number of students, fewer than 10 students, answered by placing a dot for age and cumulative grade point average (CGPA) items. Missing data for these 2 items were replaced with mean values calculated separately for each institution.

Reporting

This study was reported by the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) checklist for cross-sectional studies in addition to the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) [30].

Results

Participants

A total of 1066 PT students participated in the study (Table 1). Four institutions (BSU, O6U, MTI, and BAU) each contributed 200 students, meeting the target sample size. The remaining 3 institutions (FCHS, ZUJ, and KAU) had fewer participants but achieved a 100% response rate among eligible students. These institutions follow a 4-year study plan, unlike the 5-year structure on the other sites. At FCHS and ZUJ, many students were nonnationals and excluded based on eligibility criteria. At KAU, 67 students participated, as PT specialization begins in the second year; this number represented the entire eligible cohort.

Demographic and Academic Characteristics

Table 2 presents the demographic and academic characteristics of participating PT students. The mean age was 20.1 (SD 1.5) years, and 64.1% (n=683) were female. Students were enrolled across all academic years, with the highest proportion in the second year (n=367, 34.4%) and the lowest in the fifth year (n=103, 9.7%). The fifth year applies only to Egyptian universities (BSU, O6U, and MTI), while others follow a 4-year program. Due to differences in CGPA scales (4.0 vs 5.0) across universities, CGPA% was used for standardization, resulting in a mean of 79.7% (SD 14%). CGPA% was not applicable for first-year students in their first semester, as their CGPA was not yet available.

Table . Demographic, academic, and technological characteristics of the participating physiotherapy students (N=1066).

Characteristic		Values
Age (years)		
	Mean (SD)	20.1 (1.5)
	Range	17.0-28.0
Cumulative grade point average percentage (n=924)		
	Mean (SD)	79.7 (14.0)
	Range	26.8-100.0
Sex, n (%)		
	Female	683 (64.1)
	Male	383 (35.9)
Academic level, n (%)		
	First year	176 (16.5)
	Second year	367 (34.4)
	Third year	237 (22.2)
	Fourth year	183 (17.2)
	Fifth year	103 (9.7)
Use of artificial intelligence–powered chatbots, n (%)		
	Yes	586 (55.0)
	No	480 (45.0)

PT Students' Acceptance of AI-PCs

PT students' acceptance of AI-PCs, as measured by the TAM, had a mean total score of 3.59 of 5 (SD 0.81), reflecting overall moderate acceptance across all universities. The mean scores for the 5 TAM constructs were: PU=3.69 (SD 0.92), PEU=3.68 (SD 0.88), attitude=3.58 (SD 0.91), BI=3.57 (SD 0.91), and ABU=3.40 (SD 0.91). Based on TAM categories, 35.2% (n=375) of students demonstrated high acceptance, 60.9% (n=649) moderate, and 3.9% (n=42) low.

External Factors Influencing PT students' Acceptance of AI-PCs

Personal, academic, and technological factors were assessed as potential predictors of acceptance of AI-PCs. Among personal factors, age (Table 3) showed no significant correlation with the TAM mean score (P=.54), and sex showed no significant association with TAM acceptance categories (P=.56).

Table . Correlation between physiotherapy students' total mean score of technology acceptance of artificial intelligence–powered chatbots (AI-PCs) and external factors (N=1066).

External factors	*r*	*P* value
TAM[a] total score of AI-PCs*students' age	−0.019	.54
TAM total score of AI-PCs*students' CGPA%[b]	0.135	<.001
TAM total score of AI-PCs*students' previous experience of using other artificial intelligence–powered learning tools or applications beyond chatbots	0.445	<.001

[a]TAM: technology acceptance model.

[b]CGPA%: cumulative grade point average percentage.

In contrast, academic factors had a notable impact. University affiliation significantly influenced the TAM mean score (P<.001; Table 4), TAM acceptance categories (P<.001; Figure 1), and the 5 constructs mean scores (P<.001; Figure 2). CGPA% (Table 3) was positively correlated with the total TAM score (P<.001), while academic level was not significantly associated with TAM acceptance categories (P=.26).

Table . Mean total score of physiotherapy students' acceptance of artificial intelligence–powered chatbots across universities (N=1066).

University	Values, n	Mean score (SD)	Range	*P* value
Fatima College of Health Sciences	107	3.78 (0.70)	1.0 - 5.0	<.001
King Abdulaziz University	67	3.77 (0.97)	1.0 - 5.0	<.001
October 6 University	200	3.73 (0.79)	1.6 - 5.0	<.001
Beirut Arab University	200	3.66 (0.62)	1.4 - 5.0	<.001
Beni-Suef University	200	3.60 (0.76)	1.1 - 5.0	<.001
Modern University for Technology and Information	200	3.50 (0.85)	1.0 - 5.0	<.001
Al-Zaytoonah University of Jordan	92	3.03 (0.91)	1.0 - 5.0	<.001
Total	1066	3.59 (0.81)	1.0 - 5.0	<.001

Figure 1. Distribution of physiotherapy students' acceptance categories of AI-powered chatbots across universities (N=1066; *P*<.001). AI: artificial intelligence.

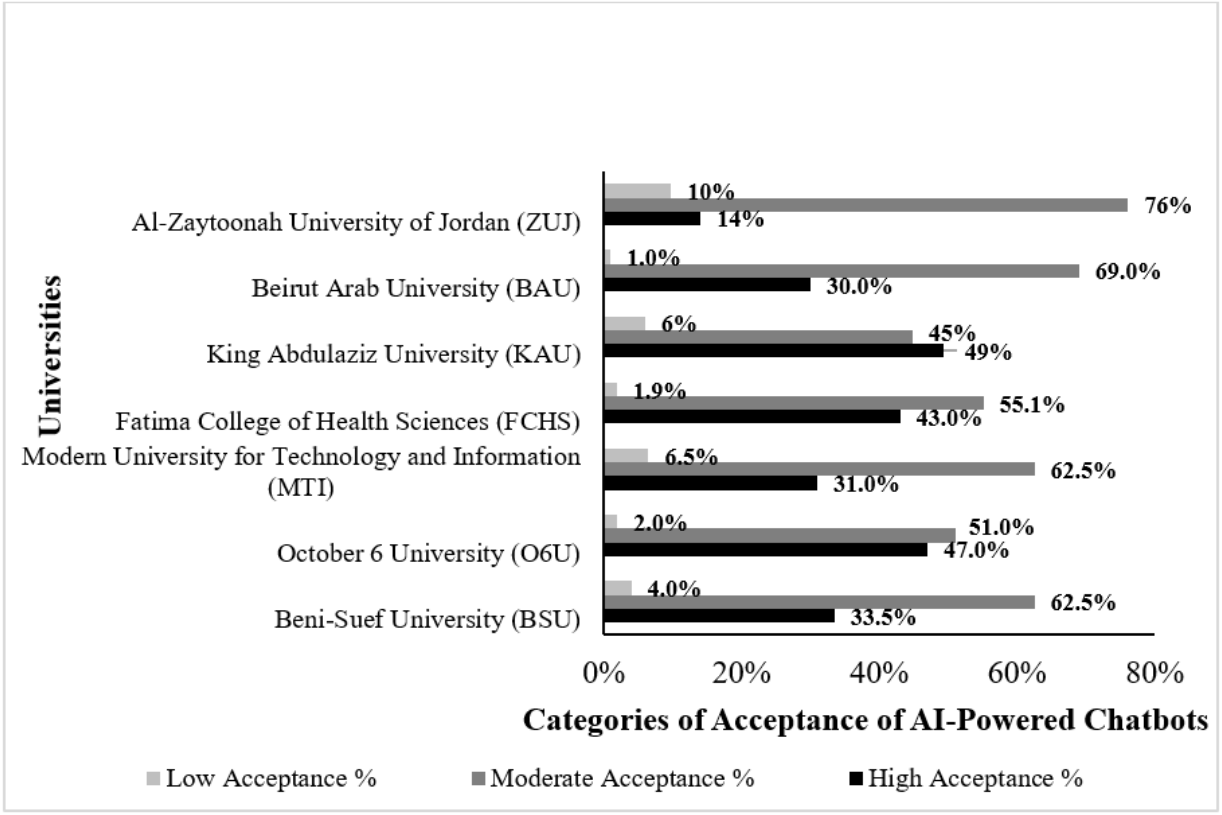

Figure 2. Physiotherapy students' perception of usefulness, ease of use, attitude, behavior, and actual behavior use of AI-powered chatbots mean scores across universities (N=1066 for all and n=586 for actual behavior use; *P*<.001). AI: artificial intelligence.

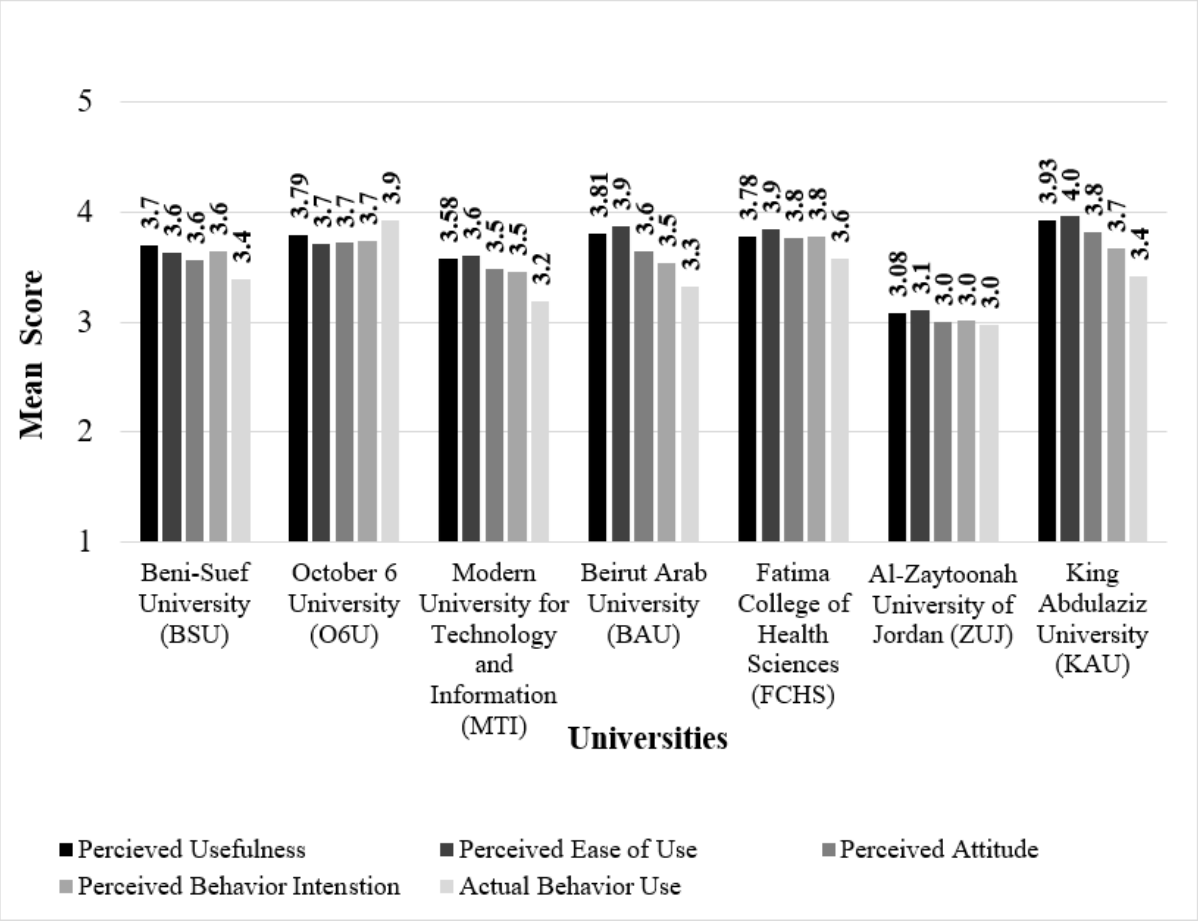

Technological factors also showed strong effects. A significant positive correlation was found between prior experience with AI-powered tools beyond chatbots and TAM scores (*P*<.001; Table 2). Additionally, current users of AI-PCs had significantly higher TAM scores (mean 3.89, SD 0.81) than nonusers (mean 3.48, SD 0.79; *P*<.001).

In summary, university affiliation, CGPA%, prior technological experience, and current use were the key factors influencing PT students' acceptance of AI-PCs. These variables were compared across institutions to further explore their impact.

University Affiliation and PT Students' Acceptance of AI-PCs

Significant differences in TAM total scores were observed across universities (*P*<.001; Table 4). ZUJ had the lowest score (mean 3.03), and FCHS the highest (mean 3.78). Post hoc Tukey analysis revealed that ZUJ's score was significantly lower than all other universities (*P*<.001), while FCHS did not significantly differ from other universities.

TAM acceptance category also varied significantly by universities (*P*<.001; Figure 1). KAU had the highest proportion of students in the high-acceptance category (n=33, 49.3%), whereas ZUJ had the lowest (n=13, 14.1%) and the highest proportion of students in the low-acceptance category (n=9, 9.8%).

Universities also differed significantly in TAM constructs' scores (*P*<.001; Figure 2 and Table 5). ZUJ had significantly lower PU, PEU, attitude, and BI scores than all other universities (*P*<.001; *P*=.001 for BI vs MTI). It also had the lowest, though nonsignificant, ABU score (2.98). KAU had the highest nonsignificant PU (3.93), PEU (3.96), and attitude (3.82) scores. FCHS had the highest nonsignificant BI score (3.78), while O6U had the highest ABU score (3.93), significantly exceeding all other universities except FCHS (*P*=.42).

Table . Summary of technology acceptance model (TAM) constructs mean scores of artificial intelligence (AI)–powered chatbot across universities (N=1066).

TAM constructs of AI-powered chatbots	Overall mean score out of 5	*P* value	Highest score university	Lowest score university	Significant Tukey post hoc test	*P* value
Perceived usefulness	3.69	<.001	KAU[a]	ZUJ[b]	ZUJ is lower than all other universities	<.001
Perceived ease of use	3.68	<.001	KAU	ZUJ	ZUJ is lower than all other universities	<.001
Perceived ease of use	3.68	<.001	KAU	ZUJ	MTI[c] is lower than BAU[d]	.03
Attitude	3.58	<.001	KAU	ZUJ	ZUJ is lower than all other universities	<.001
Behavior intention	3.57	<.001	FCHS[e]	ZUJ	ZUJ is lower than all other universities	<.001 and .001
Behavior intention	3.57	<.001	FCHS	ZUJ	MTI is lower than O6U[f]	.03
Actual behavioral use	3.40	<.001	O6U	ZUJ	O6U is higher than all other universities except FCHS	<.001

[f]O6U: October 6 University.

CGPA% Across Universities

CGPA% differed significantly among students in the academic levels 2-5 (*P*<.001; Table 6), as level 1 students lacked CGPA data. Post hoc test showed that ZUJ had the lowest CGPA% across all universities (*P*<.001), while BSU recorded the highest. BSU's CGPA% was significantly higher than ZUJ, BAU, FCHS (*P*<.001 for each), and MTI (*P*=.002) and higher, though nonsignificant, than KAU (*P*=.10) and O6U (*P*=.10). Additionally, BAU had significantly lower CGPA% than KAU (*P*<.001), MTI (*P*=.03), and O6U (*P*=.001). FCHS also had significantly lower CGPA% than BSU, KAU (*P*<.001 each), MTI (*P*=.04), and O6U (*P*=.003).

Table . Comparison of physiotherapy students' mean cumulative grade point average percentage (CGPA%) and previous technological experience across universities.

Universities	CGPA%			Previous technological experience (1 - 5 scale)		
	Students, n	Mean (SD)	*P* value	Students, n	Mean (SD)	*P* value
Al-Zaytoonah University of Jordan	92	67.2 (17.5)	<.001	92	2.4 (1.6)	<.001
Beirut Arab University	163	76.3 (14.0)	<.001	200	3.3 (1.4)	<.001
Beni-Suef University	171	86.0 (10.6)	<.001	200	3.1 (1.4)	<.001

Total	924	79.7 (14.0)	<.001	1066	3.1 (1.5)	<.001

Previous Technological Experience Across Universities

PT students' prior experience with AI tools beyond chatbots varied significantly across universities (*P*<.001; Table 6). ZUJ students had the lowest prior experience, significantly lower than all other universities (*P*<.001). Additionally, MTI students had significantly less prior experience than FCHS students (*P*=.04).

Current Use of AI-PCs Across Universities

PT students' use of AI-PCs differed significantly across universities (*P*<.001). KAU students reported the highest use rate (n=56, 83.6%), while FCHS had the lowest (n=34, 31.8%; Table 7).

Table . Physiotherapy students' use of artificial intelligence (AI) chatbots across universities (N=1066).

Use of AI chatbots	Beni-Suef University, n (%)	October 6 University, n (%)	Modern University for Technology and Information, n (%)	Fatima College of Health Sciences, n (%)	King Abdulaziz University, n (%)	Beirut Arab University, n (%)	Al - Zaytoonah University of Jordan, n (%)	Total, n (%)

Key Predictors of AI-PCs' Acceptance Among PT Students

A multiple linear regression was conducted to identify predictors of AI-PCs' acceptance among PT students. To meet regression analysis requirements, university affiliation was converted to dummy variables (ZUJ as the reference group), and current use was coded numerically. The model was statistically significant ($F_{9,914}$=32.33; *P*<.001), with an R^2 of 0.24, indicating that 24% of the variance in TAM score was explained. Significant predictors included prior experience with AI-PCs (B=0.23; *P*<.001) and university affiliation. Students from all universities scored significantly higher than those from ZUI, with the strongest effects seen at O6U (B=0.59; *P*<.001), FCHS (B=0.44; *P*<.001), and BAU (B=0.42; *P*<.001). CGPA% and current use were not significant predictors (*P*=.23 and *P*=.10, respectively; Table 8).

Table . Regression analysis results: predictor factors of physiotherapy students' acceptance of artificial intelligence–powered chatbots (N=1066).[a]

Predictor	B (unstandardized coefficient)	SE	β (standardized coefficient)	*t* test (*df*)	*P* value
Constant	2.33	0.15	0.00	15.90 (2)	<.001
Beni-Suef University (BSU_dummy)	0.36	0.10	0.17	3.63 (2)	<.001
October 6 University (O6U_dummy)	0.59	0.10	0.27	6.00 (2)	<.001
Modern University for Technology and Information (MTI_dummy)	0.27	0.10	0.13	2.82 (2)	<.001
Beirut Arab University (BAU_dummy)	0.40	0.10	0.19	4.16 (2)	<.001
Fatima College of Health Sciences (FCHS_dummy)	0.44	0.11	0.15	3.86 (2)	<.001
King Abdulaziz University (KAU_dummy)	0.45	0.12	0.14	3.65 (2)	<.001
Prior experience	0.23	0.02	0.43	13.93 (2)	<.001
CGPA%[b]	0.0	0.0	0.04	1.21 (2)	.23
Use	0.00	0.05	0.00	0.01 (2)	.99

[a]Al Zaytoonah University of Jordan is the reference group.

[b]CGPA%: cumulative grade point average percentage.

Regression Equations

Full Model (All Predictors)

TAM score=2.33+0.00 (use)+0.23 (prior experience)+0.36 (BSU)+0.27 (MTI)+0.42 (BAU)+0.44 (FCHS)+0.45 (KAU)+0.59 (O6U)+0.00 (CGPA%)

Simplified Model (Significant Predictors Only)

TAM score=2.33+0.23 (prior experience)+0.36 (BSU)+0.27 (MTI)+0.42 (BAU)+0.44 (FCHS)+0.45 (KAU)+0.59 (O6U)

(Note: To calculate a student's score, assign "1" to their university and "0" to all others.)

Previous experience emerged as the strongest predictor (standardized β=.43), followed by O6U (β=0.27), indicating that students' prior experience with AI tools had a larger impact on their acceptance score than university affiliation.

Discussion

Principal Findings

PT students demonstrated a moderate acceptance of AI-PCs. University affiliation, CGPA%, prior technological experience, and current use were identified as external factors influencing students' acceptance. However, the regression model confirmed that students' prior technological experience is the strongest predictor.

AI-PCs' use is steadily increasing in university education, with students' acceptance playing a key role in their adoption. For PT students, the clinical and practical demands of their curriculum present unique challenges to AI-PCs' acceptance. This study addressed the need to assess undergraduate PT students' acceptance of AI-PCs in their studies and identify personal, academic, and technological factors that influence it.

The multisite design enhances validity and generalizability, offering a broad view of AI-PCs' acceptance among PT students. Including all academic levels captures diverse perceptions, while a mean CGPA% of 79.7% reflects an average profile, minimizing academic performance–related bias.

Despite the rigorous nature of PT programs—with their intensive practical and clinical components—PT students still showed a moderate level of acceptance toward AI-PCs. This suggests a continued openness to AI-PCs, even within a rigorous academic environment. A study was conducted in South Korea among medical students and physicians, and it revealed that although physicians were cautious about the use of AI-PCs, particularly ChatGPT, in guiding patients' treatment, students had a positive perception of using ChatGPT for guiding treatment and medical education [31], which supports the concept that students might be more open to using advanced technology.

TAM constructs' scores provided deeper insight into the PT students' acceptance of AI-PCs. All scores fell within the moderate range, with PU and PEU scoring the highest means, indicating that PT students perceived AI-PCs as both useful and easy to use. However, slightly lower scores for attitude and BI suggest that while students acknowledge these benefits, their enthusiasm and intent to adopt AI-PCs are still developing. The lowest score for ABU highlights limited real-world use, reinforcing the study's overall finding of moderate acceptance.

In line with TAM's 3-stage process [21], external factors play a crucial role in shaping students' acceptance of AI-PCs. The

first stage includes PU and PEU, which reflect students' perceptions of usefulness and ease of use [26,27]. These influence attitude, which may substitute for BI [21,28], forming the second stage. Together, PU, PEU, attitude, and BI predict ABU [23]. Personal, academic, and technological factors influence students' perceptions, attitudes, and adoption behaviors toward AI technologies [6] such as AI-PCs. Among all the external factors, predictors, prior experience with AI-powered tools and applications beyond chatbots, and university affiliation had the strongest predictive influence on students' acceptance of AI-PCs.

Older students might be expected to show greater acceptance of AI-PCs due to increased exposure through academic progression and peer networks. Conversely, younger students, particularly Generation Z, could also be more accepting, having grown up immersed in digital technology. Similarly, male students are often presumed to show higher acceptance due to greater interest in technology and gaming. However, the findings did not support these assumptions, as age, sex, and academic level showed no significant correlation with AI-PCs' acceptance. Several hypotheses may explain this. First, institutional integration of AI tools may provide equal exposure to all students, minimizing demographic differences. Second, although Gen Z is highly technology competent, their adoption of AI-PCs may depend on perceived academic relevance. Third, sex-based assumptions about technology enthusiasm may not translate into actual academic tool use.

Students with greater exposure to AI tools demonstrated higher acceptance of AI-PCs, a logical outcome, as familiarity builds confidence. For these students, chatbots were a natural extension of technologies they already use, making adoption more intuitive. Supporting this, Horowitz et al [32] found that individuals with more familiarity and expertise in AI were more likely to support autonomous technologies than those with limited understanding, suggesting that experience enhances acceptance of new technologies.

University affiliation emerged as a key predictor of AI-PCs' acceptance. ZUJ recorded the significantly lowest total TAM score and the significantly lowest scores in 4 of the 5 constructs (except ABU). It also had the smallest proportion of students in the high-acceptance category and the highest proportion in the low-acceptance group, raising the question: What explains ZUJ's lower acceptance?

One possible factor is CGPA%, as ZUJ had the lowest CGPA%. However, CGPA% alone is unlikely to explain the outcome. For example, BSU, despite having the highest CGPA%, ranked the third lowest in TAM and the fourth lowest in the proportion of high-acceptance students. This suggests that academic performance is not a decisive factor in acceptance.

Prior technological experience, however, appears more influential. ZUJ students had the lowest prior technological experience across all universities, which aligns with their low acceptance rate. While prior experience was notably higher in the 3 universities with better acceptance (FCHS, KAU, and O6U), it was also relatively low in universities with low acceptance, such as BSU and MTI.

Although academic level was not significantly correlated with acceptance, most participating ZUJ students were in levels 1 to 3, as nearly all level 4 students were nonnationals and thus excluded. Additionally, ZUJ's PT department was established only 4 years ago. Together, these factors likely contributed to students' limited prior technological experience, and consequently, their lower acceptance of AI-PCs.

In contrast, examining the current use, ZUJ showed a moderate percentage of users, like O6U, the only university with a significantly higher score in one of the constructs. Meanwhile, FCHS demonstrated the lowest percentage of students currently using AI-PCs. If current use was a key factor in acceptance, both FCHS and O6U would be expected to have a high use rate, which was not the case. These patterns suggest that current use is not a reliable predictor of acceptance.

Hence, linear regression analysis was essential to clarify which external factors significantly predict PT students' acceptance of AI-PCs. Although the model explained 24% of the variance, it identified prior technological experience as the strongest predictor, confirming earlier assumptions about its importance. The analysis also confirmed that CGPA% and current use were not significant predictors and were excluded from the regression equation. In addition to prior experience, university affiliation emerged as an external predictor, though with a smaller effect size. These results confidently attribute ZUJ's low acceptance to its students' limited prior technological experience.

While the findings highlight university affiliation as a key predictor of acceptance, this study did not elaborate on the detailed cultural characteristics of studentship within each country or institution. Cultural norms, instructor-student dynamics, technological infrastructure, and pedagogical styles can certainly influence students' attitudes toward innovation. However, including a comprehensive cultural profile for each country or institution would have lengthened the paper unnecessarily. To reduce cultural bias and isolate academic and technological factors, only national students were recruited. This approach served to eliminate variability related to cross-national cultural differences, providing a more homogeneous sample to assess institutional influence on AI chatbot acceptance.

Interestingly, construct-level results revealed 2 cases where students' ABU did not align with their PU or PEU. These discrepancies suggest gaps between perceptions and actual use of AI-PCs or the influence of external factors on behavior. Supporting this, a study of 399 students in Hong Kong revealed that while attitudes toward AI technologies were generally positive, actual use remained limited, highlighting a gap between favorable perception and limited actual use of AI chatbots in education [33]. Another example is a study conducted in the United Arab Emirates among 265 recently graduated medical students, which reported an overall positive attitude and optimism toward the future of AI in medical education and health care but also revealed limited use of AI-PCs [34]. Similarly, a national survey of 693 medical students across 57 Chinese universities reported that only 28.7% used AI chatbots for studying, despite 91% acknowledging their usefulness for accessing medical information, reinforcing the disconnect

between intention and practice [35]. Specifically, O6U demonstrated the highest ABU across all universities, despite reporting only moderate PU and PEU scores. In other words, O6U students used AI-PCs in their studying, even though they perceived them as only moderately useful or easy to use. Several external factors may explain this pattern. One possibility is a university mandate, such as a course assignment, which may have driven use regardless of personal perception. Another is social influence, where encouragement from peers or faculty members promotes greater use. A third explanation could be habituation exposure; students may have become accustomed to using the AI-PCs through repeated encounters, resulting in higher ABU despite lower PU and PEU.

In contrast, KAU students showed the opposite pattern, high PU and PEU scores but lower ABU. This highlights the common gap between what students perceive and what they do, especially when technology is available but not fully integrated into the learning process. In this case, positive perceptions of AI-PCs were not sufficient to drive consistent use in academic practices. A large-scale study, which analyzed responses from over 34,000 college students, supports this pattern, showing that favorable views of educational technology did not always result in increased use, particularly when the tools were not embedded in instruction [36].

Findings from O6U and KAU highlight the complexity of technology acceptance and the influence of external factors beyond individual perceptions. They illustrate how such external factors can sometimes override personal perceptions in driving actual behavior, warranting further exploration.

Limitation

While this study examined selected personal, academic, and technological factors, many other factors may contribute to PT students' acceptance of AI-PCs. These include students' learning style, personality traits, academic load, technology anxiety, self-regulated learning skills, language proficiency, faculty support, and access to physical resources such as internet connectivity.

Further Work

While this study focused on personal, academic, and technological factors influencing PT students' AI-PCs, several broader contextual variables warrant exploration in future research. These include deeper investigations into the culture of studentship, both within and across countries in the region, such as how students interact with instructors and technology, their expectations, and the learning environments they are embedded in. Additionally, variations in the structure of PT programs, such as 4- versus 5-year tracks, patterns of matriculation, and progression rates, could provide further insight into students' readiness and attitudes toward adopting educational technologies. Future studies may also benefit from considering national regulations and licensing frameworks, which shape the continuum of PT education, including the integration of internship, postgraduate training, and continuing education. These elements, although beyond our study's scope, are crucial for developing a comprehensive understanding of technology acceptance within the broader context of PT education.

Conclusions

PT students demonstrated a moderate acceptance of AI-PCs. University affiliation, CGPA%, prior technological experience, and current use were identified as external factors influencing students' acceptance. However, the regression model confirmed that prior technological experience is the strongest predictor of AI-PCs' acceptance among PT students.

Abstract

Background: Artificial intelligence (AI) is increasingly embedded in medical education, providing benefits in instructional design, content creation, and administrative efficiency. Tools like ChatGPT are reshaping training and teaching practices in digital health. However, concerns about faculty overreliance highlight risks to pedagogical autonomy, cognitive engagement, and ethics. Despite global interest, there is limited empirical research on AI dependency among medical educators, particularly in underrepresented regions like the Global South.

Objective: This study focused on Palestine and aimed to (1) identify factors contributing to AI dependency among medical educators, (2) assess its impact on teaching autonomy, decision-making, and professional identity, and (3) propose strategies for sustainable and responsible AI integration in digital medical education.

Methods: A qualitative research design was used, using semistructured interviews (n=22) and focus group discussions (n=24) involving 46 medical educators from nursing, pharmacy, medicine, optometry, and dental sciences. Thematic analysis, supported by NVivo (QSR International), was conducted on 15.5 hours of transcribed data. Participants varied in their frequency of AI use: 45.7% (21/46) used AI daily, 30.4% (14/46) weekly, and 15.2% (7/46) monthly.

Results: In total, 5 major themes were identified as drivers of AI dependency: institutional workload (reported by >80% [37/46] of participants), low academic confidence (noted by 28/46, 60%), and perfectionism-related stress (23/46, 50%). The following 6 broad consequences of AI overreliance were identified: Skills Atrophy (reported by 89% [41/46]): educators reported reduced critical thinking, scientific writing, and decision-making abilities. Pedagogical erosion (35/46, 76%): decreased student interaction and reduced teaching innovation. Motivational decline (31/46, 67%): increased procrastination and reduced intrinsic motivation. Ethical risks (24/46, 52%): concerns about plagiarism and overuse of AI-generated content. Social fragmentation (22/46, 48%): diminished peer collaboration and mentorship. Creativity suppression (20/46, 43%): reliance on AI for content generation diluted instructional originality. Strategies reported by participants to address these issues included establishing boundaries for AI use (n=41), fostering hybrid intelligence (n=37), and integrating AI literacy into teaching practices (n=39).

Conclusions: While AI tools can enhance digital health instruction, unchecked reliance risks eroding essential clinician competencies. This study identifies cognitive, pedagogical, and ethical consequences of AI overuse in medical education and highlights the need for AI literacy, professional development, and ethical frameworks to ensure responsible and balanced integration.

KEYWORDS

AI dependency; generative AI; procrastination; AI reliance; hybrid intelligence

Introduction

Background

The rapid incorporation of artificial intelligence in education (AIED) has significantly changed the educational landscape, providing unique chances for tailored teaching and learning experiences, instant feedback, and enhanced efficiency [1]. Consequently, institutions across the globe are increasingly using AI-powered tools, including generative models like ChatGPT, to customize the educational process, streamline administrative duties, and reduce faculty workload [2]. Despite important benefits, stakeholders have concerns regarding overdependence on AI, which is simply defined as students' and instructors' uncritical acceptance of AI-generated material

[3]. In addition, overreliance on AIED hinders cognitive involvement, productive critical thinking and decision making, and long-term skill growth [4].

While literature on the topic of AIED is abundant, it primarily focuses on the gains of integrating AI in the educational setting [5]. Ethical, cognitive, and professional challenges related to AIED, on the other hand, are far less explored [6,7]. Furthermore, most of the available research on overreliance on AIED is investigated in relation to students, exploring how excessive dependence on AI can negatively impact their ability to think critically and independently and to perform self-directed learning [4,8]. Other student-related studies have linked AI reliance to psychological factors such as perfectionism, impulsivity, and the need for immediate cognitive relief, drawing comparisons to internet and social media dependence [9].

Empirical research investigating AI dependency among educators is still meager [7], and most of the existing studies explore how AI enhances educators' productivity and decision-making [10]. Risks and challenges pertaining to AIED, on the other hand, are less explored. In addition, most research on AIED has been conducted in Western or Chinese contexts, with limited cross-cultural perspectives [11]. This study has three aims: to examine the causes of educators' overreliance on AI, to assess its impact on teaching autonomy and pedagogical identity, and to identify challenges and strategies for responsible AI use. Focusing on Palestinian higher education, the research offers insights to guide policy, faculty development, and ensure that AI enhances—rather than replaces—educators' professional expertise.

This study conceptualizes the "AI Paradox" in higher education, where AI's benefits in streamlining academic work are offset by concerns over skill atrophy, ethics, and autonomy. It explores how faculty navigate these competing effects, highlighting the coexistence of innovation and emerging professional vulnerabilities.

Research Questions

The research questions are as follows (1) What key factors contribute to AI dependency among educators in higher education? (2) How does AI dependency impact educators' teaching autonomy, decision-making, and professional identity? (3) What strategies help educators maintain a balanced use of AI while maintaining pedagogical creativity and instructional effectiveness?

Theoretical Foundation of the Study

The Interaction of Person-Affect-Cognition-Execution (I-PACE Model; Figure 1), developed by [12], provides a comprehensive framework for understanding problematic technology use, including AI dependency. The I-PACE model explains how individual traits, emotional responses, cognitive processes, and behaviors interact to shape technology reliance. Its 4 components are: person-level predispositions (personality traits and cognitive styles), affect (emotional states like stress or anxiety), cognition (decision-making and impacts on autonomy), and execution (behavioral outcomes such as deskilling). This framework helps analyze how and why AI dependency develops among educators and its effects on autonomy and professional agency.

Figure 1. I-PACE Model. I-PACE: Interaction of Person-Affect-Cognition-Execution.

Previous Studies Using I-PACE

Research using I-PACE has demonstrated how individual predispositions, emotional states, and cognitive processes interact to influence excessive reliance on digital tools. For instance, studies on internet and social media addiction have found that individuals with high neuroticism**,** impulsivity, or perfectionism are more likely to develop problematic usage patterns, often as a coping mechanism for stress [12]. Similarly, research on AI reliance in education suggests that educators and students with low self-efficacy in digital literacy or high performance expectations tend to offload cognitive tasks to AI, reducing engagement in critical thinking and problem-solving [8,13]. Studies show that institutional pressures and workload demands can drive educators to rely on AI for efficiency, often at the expense of pedagogical autonomy. Applying the I-PACE model, these studies highlight how occasional AI use can evolve into habitual dependence, shaped by psychological, cognitive, and behavioral factors.

Reliance on AI in education may lead to unhealthy dependence on AI tools that can reduce student autonomy, hinder skill acquisition, and elevate the risk of academic stress [8,14]. Although tactical application of AI is likely to improve teaching effectiveness and student engagement, students could still delegate crucial cognitive activities to technology rather than participating in reflective or creative thought [9,15,16]. When consistently depending on AI for writing tasks, research projects, or making decisions, students jeopardize their chances of developing critical thinking, creativity, and self-directed learning techniques [4,16]. While AI can serve as a valuable complement to teaching strategies, instructors must ensure that embracing technology does not impede human-centered exploration [17].

The psychological implications of reliance on AI are complex, involving personality characteristics, emotional control, and cognitive distortions [8]. According to [7] and [8], neuroticism, self-critical perfectionism, and impulsivity elevate the chances of excessive dependence on AI-driven tools. Neuroticism, marked by increased responses to stress, frequently leads individuals to pursue immediate technological solutions for anxiety or performance apprehensions [18]. Similarly, self-critical perfectionists might be drawn to the flawless results that AI is thought to produce, seeking to prevent errors and the unease linked to learning through trial and error [19]. Instead of developing study habits, impulsive learners might resort to AI whenever they face challenges, perpetuating a pattern of dependence on external sources. This AI dependency diminishes creativity and independent thought [8].

Scholars use the I-PACE model to explore how personal traits—like perfectionism and impulsivity—interact with emotional states and cognitive functions and sometimes result in maladaptive technology use [8,12]. This model illustrates how some individuals deal with academic pressure by consistently looking for digital shortcuts. Depending on digital shortcuts compromises an individual's need for autonomy, competence, and relatedness, which, according to the Basic Psychological Needs theory, are crucial for one's well-being and motivation [20]. If AI reliably addresses unmet needs—like providing quick responses that protect learners from the unease of ambiguity—an excessive dependence might develop, reducing the intrinsic motivation essential for authentic learning and developmental progress [8,13]. Simultaneously, determining which aspects of AI design—such as user interface, adaptive feedback, or customization features—enhance or reduce dependency could assist developers in creating more ethically responsible platforms [21].

Adverse academic emotions—like anxiety and frustration—can greatly heighten reliance on AI, hindering students' motivation and their capacity to manage their own learning [22]. As unaddressed psychological needs build up, students might seek emotional support or affirmation from AI [8,23]. Performance expectations further amplify this dependence: when students think AI significantly enhances their grades or educational results, they might overrate the technology's necessity [24]. This corresponds with extensive research on performance expectancy, an element demonstrated to be essential in the adoption and ongoing usage of new technologies [25]. Eventually, this persistent trend of pursuing immediate solutions or emotional comforts causes learners to neglect crucial cognitive activities like integrating information or contemplating mistakes [8].

Methods

Overview

This study used a qualitative research approach to explore the factors influencing AI dependency and the consequences of AI dependency in medical education. A mixed approach of semistructured interviews and focus group sessions was used to gain insight into the experiences and perspectives of faculty members and to explore how using AI tools in their practice affects them as educators [26].

To ensure participant anonymity while distinguishing between data sources, a consistent coding system was used. "E" refers to individual educators who participated in semistructured interviews, followed by a number identifying the participant (eg, E5=Educator 5). **"**EFG" refers to participants in focus group discussions (eg, EFG14). This system enabled pattern recognition across data types while maintaining confidentiality.

Semistructured Interviews

Semistructured interviews were conducted with 22 faculty members to explore factors driving AI dependency and its consequences in medical education [27]. Participants were purposively sampled from multiple universities and represented diverse disciplines (eg, nursing, pharmacy, optometry, medicine, and dental sciences). Variation in roles, teaching experience, and frequency of AI use was considered to ensure maximum variation and minimize overlap in perspectives due to shared institutional or disciplinary contexts. The interview protocol (Multimedia Appendix 1) was informed by the study's theoretical framework. Each interview lasted 25 - 35 minutes and was audio-recorded with consent. The interview guide (Multimedia Appendix 1) was informed by the I-PACE framework and developed to explore individual, cognitive, and emotional dimensions of AI use. This guided the formulation of probes around motivation, attitudes, and usage patterns.

Focus Group Sessions

To complement the interviews, 4 focus group sessions (n=24) were held with educators not involved in the interviews. This method enabled reflection and interaction, encouraging participants to build on shared experiences [28-31]. Purposive sampling ensured diversity across institutions, disciplines, and levels of AI engagement. All participants held teaching, research, or administrative roles. Focus group prompts (Multimedia Appendix 2) were generated from preliminary interview analysis to deepen insight into shared institutional experiences. Sessions were audio-recorded and lasted approximately 1 hour. In total, the study involved 46 participants.

Data Collection

In total, 22 semistructured interviews (25-35 min each) were audio-recorded with consent. Questions explored participants' use of generative AI in teaching, research, and administration, including frequency, delegated tasks, and changing reliance. Follow-ups addressed motivations, benefits, and challenges in maintaining professional autonomy alongside AI integration.

Although the average duration of these interviews may appear relatively short for qualitative research, this was a deliberate methodological decision based on both logistical and conceptual considerations. Participants were full-time faculty members in medical and health sciences disciplines with heavy teaching, research, and clinical responsibilities. To respect their limited availability and ensure meaningful engagement, a focused and well-structured interview protocol was designed, aligned with the I-PACE model. This protocol was pilot-tested and refined to elicit conceptually rich responses within a concise time frame.

Despite the shorter duration, the interviews yielded dense, thematically robust narratives. To enrich data depth and validate emerging themes, 4 focus group discussions—each approximately 1 hour—were also conducted. These provided opportunities for reflection, triangulation, and deeper elaboration of core issues. Importantly, thematic saturation was achieved after 18 interviews, with subsequent interviews and focus groups confirming the stability of the thematic framework. Thus, while longer interviews might have allowed for further elaboration, the approach adopted ensured a balance between feasibility and qualitative rigor, without compromising the credibility or conceptual depth of the data.

To supplement these insights, four 1-hour focus groups (2 in person and 2 online) with 24 participants were held, facilitated by 2 researchers using prompts from interview analysis. Discussions explored AI usage patterns, reliance, and impacts on teaching and decision-making. All sessions were audio-recorded, providing broader perspectives that complemented the interview findings.

To ensure conceptual depth and data adequacy, recruitment and data collection continued until thematic saturation was achieved. Saturation was defined as the point at which no new themes or insights emerged during ongoing data analysis. This was observed after conducting 18 interviews, with subsequent interviews and focus group discussions confirming the stability and completeness of the thematic framework.

In this study, AI dependency is defined as overreliance on generative AI tools for academic tasks, leading to reduced cognitive engagement, professional autonomy, or pedagogical creativity. This contrasts with effective AI integration, which involves strategic, ethical use that maintains human oversight. Semistructured interviews probed these distinctions, exploring both the benefits and drawbacks of AI use and assessing impacts on teaching autonomy, motivation, and professional identity.

Data Analysis

An inductive thematic analysis was conducted following Braun and Clarke's 6-phase framework (2006) to analyze data. The dataset comprised 12.25 hours of interview recordings and 3.25 hours of focus group sessions. All recordings were transcribed verbatim and verified through participant member checking to ensure accuracy.

Coding was performed using NVivo, with initial codes iteratively refined into subthemes and themes aligned with study objectives and relevant literature. Data collection and analysis were concurrent, and thematic saturation was reached after the 18th interview, confirmed by later focus groups.

To strengthen credibility, the study used methodological triangulation with interviews, focus groups, and artifacts such as anonymized AI-generated lesson plans and teaching notes. Analyzing these artifacts alongside participant reports provided contextual depth and validated emerging themes. Preserving cultural and linguistic nuances, coding and theme development were conducted in Arabic by bilingual researchers, with themes collaboratively translated into English. Backward translation ensured accuracy and contextual depth, while team discussions resolved discrepancies, maintaining conceptual equivalence and data integrity.

Participant responses were categorized using standardized terms: "most" (35/46, >75%), "many" (50% [23/46,] - 75% [35/46]), and "some" (23/46, <50%). Where participants expressed multiple perspectives, responses were coded under all relevant categories to reflect the complexity of AI integration in practice. This structured and multisource approach ensured the robustness, transparency, and trustworthiness of the findings.

Trustworthiness

To ensure trustworthiness, the study systematically addressed the 4 key criteria of qualitative rigor: credibility, confirmability, dependability, and transferability. Credibility was strengthened through triangulation of data sources—semistructured interviews, focus groups, and AI-generated teaching artifacts—which provided multiple perspectives on the phenomenon. In addition, member checking was conducted by inviting participants to review selected transcripts and thematic summaries to validate interpretations.

The study used a hybrid coding approach, integrating both deductive and inductive strategies. A preliminary codebook based on the I-PACE model guided the initial round of coding, allowing the researchers to identify theoretically grounded patterns. Simultaneously, the analysis remained open to emergent inductive themes not captured by the model, thereby

ensuring that the coding process was both conceptually informed and data-driven.

Confirmability was supported through independent coding by 2 researchers on a subset of transcripts (20/60, 30%), followed by peer debriefing and consensus-building sessions to refine code definitions and resolve discrepancies. While no formal interrater reliability statistic (eg, Cohen Kappa) was calculated, a shared audit trail was maintained to document analytic decisions, code evolution, and theme development. Final coding was conducted collaboratively using NVivo software.

Dependability was reinforced by clearly outlining data collection and analysis procedures, adhering to Braun and Clarke's 6-phase thematic analysis protocol, and using NVivo for systematic coding and data management. Transferability was supported through purposive sampling for maximum variation across discipline, institutional context, and AI use frequency, along with thick descriptions of participants' backgrounds and contextual settings. Linguistic and cultural nuances were preserved through bilingual coding and backward translation, ensuring integrity across languages. Collectively, these procedures establish a rigorous foundation for the trustworthiness of the study's findings.

Ethical Considerations

The study was conducted following approval (approval number Med. Dec. 2024/29) from the institutional review board at An Najah National University. All participants provided informed consent, receiving clear explanations of the study's purpose, voluntary participation, and confidentiality. Consent was indicated by participation, and participants were reminded of their right to withdraw at any time, ensuring ethical compliance and autonomy.

Researchers' Background and Positionality

This study was conducted by an interdisciplinary research team composed of scholars from diverse academic backgrounds and institutions across different countries. The team includes experts in medical education, English language studies, educational technology, and qualitative research methodology, with shared experience in the integration of AI tools in teaching, learning, and research. Members of the team are affiliated with universities in the Middle East and North Africa region, providing a transnational perspective on the evolving role of AI in higher education. The team's varied disciplinary expertise and familiarity with a wide range of learner populations—including undergraduate students, clinical educators, and faculty across Science, Technology, Engineering, and Mathematics (STEM) and humanities disciplines—helped ensure a nuanced and contextually grounded interpretation of the data. This interdisciplinary orientation aligns with the study's broader aim to explore AI dependency as a multidimensional and cross-sectoral phenomenon.

Results

Overview

To contextualize the qualitative findings, Table 1 presents the demographic characteristics of the 46 participants who took part in the study, including faculty from diverse medical and health sciences disciplines such as nursing, pharmacy, optometry, medicine, and dental sciences. Participants varied in gender, age, teaching experience, frequency of AI use, and level of AI familiarity, ensuring a wide range of perspectives on the phenomenon of AI dependency in academic practice.

Table . Demographic information about the participants in the semistructured interviews and focus group sessions.

Variable	Frequency (%)
Sex	
Male	20 (43.5)
Female	26 (56.5)
Age (years)	
25 - 35	5 (10.9)
36 - 45	15 (32.6)
46 - 55	18 (39.1)
56+	8 (17.4)
Frequency of gen AI[a] use	
Daily	21 (45.7)
Weekly	14 (30.4)
Monthly	7 (15.2)
Occasionally	4 (8.7)
Teaching experience	
1 - 5 years	16 (34.8)
6 - 10 years	6 (13.0)
11 - 15 years	15 (32.6)
16+ years	9 (19.6)
AI familiarity level	
Low	19 (41.3)
Moderate	16 (34.8)
High	11 (23.9)
Medical science discipline	
Nursing	8 (17.4)
Pharmacy	8 (17.4)
Optometry	9 (19.6)
Doctor of Medicine	7 (15.2)
Medical Laboratory Sciences	6 (13.0)
Doctor of Dental	8 (17.4)

[a]AI: artificial intelligence.

Building on this diverse dataset, the findings are structured and interpreted through the lens of the I-PACE model. This framework enabled a systematic mapping of themes across 4 interrelated components: institutional and individual pressures were aligned with person variables; anxiety and motivation reflected the affect dimension; cognitive offloading and creativity suppression were linked to cognition; and habitual overuse of AI tools corresponded to execution functions. Together, these findings illustrate how psychological, cognitive, and behavioral mechanisms interact to shape educators' dependency on AI technologies in higher education.

Research question #1*:* What key factors contribute to AI dependency among educators in higher education?

The first research question aimed to explore the factors influencing AI dependency among educators. The analysis revealed that AI dependency is shaped by institutional, psychological, cognitive, technological, and individual factors. Table 2 presents the coding book for the first research question.

Table . Coding book for the reasons for AI dependency research question.

Theme and subtheme	Quotation
Institutional factors	
Heavy workload and time constraints	*Without AI, I would spend hours grading assignments and drafting course materials. Now, I can do it in minutes*. [E5]
Institutional expectation of using AI[a]	*Our university expects us to use AI, but there's little guidance on how to do it effectively*. [E21]
Lack of institutional guidance	*There are no clear policies on how much AI use is appropriate, so I just use it however I think best*. [E8]
Psychological factors	
Anxiety and performance pressure	*Everyone around me is using AI, and I don't want to be left behind.* [E2]
Perfectionism and fear of errors	*I feel like I've lost my ability to draft a paper from scratch. I always turn to AI first*. [E6]
Cognitive factors	
Cognitive offloading	*I used to brainstorm lesson plans myself. Now, I ask AI, and it gives me something within seconds*. [E15]
Loss of pedagogical creativity	*I used to create my own case studies and interactive activities. Now, I just modify what AI generates*. [E17]
Technological factors	
Ease of access and automation	*Why spend hours writing something when AI can give me a great draft in seconds?* [E21]
Lack of AI literacy	*I know AI isn't perfect, but I don't always know how to verify the accuracy of what it generates*. [E18]
Feeling powerful and capable	*With AI, I can complete tasks that would have taken me hours in just a few minutes*. [E3]
Individual factors	
Academic self-efficacy	*AI helps me refine my ideas, making my work more professional and well-structured*. [E6]
Academic reputation	*I rely on AI in writing research papers due to my reputation and publication pressure*. [E9]
High performance expectations	*There's a lot of pressure to produce high-quality work, so I use AI to meet expectations*. [E11]
Low academic confidence	*I don't always trust my writing skills, so AI gives me the reassurance I need to finalize my work*. [E4]
Lack of scientific research engagement	*I rarely engage in deep scientific research anymore because AI provides quick summaries*. [E13]

[a]AI: artificial intelligence.

Institutional Factors

Heavy Workload and Time Constraints

Many participants viewed AI as essential for managing academic workloads, highlighting its role in reducing time spent on repetitive tasks like grading, report writing, and content creation.

> *Without AI, I would spend hours grading assignments and drafting course materials. Now, I can do it in minutes, which helps me keep up with my workload.* [E5]

Participants noted that institutional pressure to publish and show teaching effectiveness drives greater AI adoption. However, some—especially in the social sciences—found that unfamiliarity with AI increased their workload and added stress.

> *It's a double-edged sword—AI helps me finish tasks faster, but I sometimes feel I need more time to understand it, which increases the time I need to finish writing the tasks.* [E19]

Lack of Institutional Guidance

A recurring concern was the absence of institutional policies, support, or structured training for integrating AI responsibly. This lack of formal guidance often left participants unsure of how to use AI tools effectively and ethically.

> *There are no clear policies on how much AI use is appropriate, so I just use it however I think best.* [E8]

A few also expressed concern that future policy changes might disrupt their current dependency on AI.

> *I depend on AI now, but if my university decides to impose restrictions, I might struggle to adjust back to traditional methods.* [E5]

Psychological Factors

Anxiety and Performance Pressure

Several participants pointed out that AI helps them manage anxiety related to teaching and research expectations. Some also reported feeling pressured to stay updated with AI advancements and integrating AI tools in order to be adequately tech-savvy.

> *Everyone around me is using AI, and I don't want to be left behind. I feel like I need to use it to stay relevant.* [E2]

Nevertheless, a few participants argued that AI dependency sometimes increases stress, particularly when the accuracy of AI is uncertain.

> *I depend on AI, but at times, I worry that I might be using incorrect or biased information without realizing it.* [E9]

Perfectionism and Fear of Errors

Some participants described themselves as perfectionists, adding that AI helps them ensure accuracy in research, lesson planning, and assessment design. In addition, AI increases their confidence as it helps them refine content and eliminate errors.

> *I use AI to check everything. I don't want to submit anything that isn't polished and error-free.*

Conversely, a few expressed concern over the way AI dependency negatively impacts their academic and scholarly confidence.

> *I feel like I've lost my ability to draft a paper from scratch. I always turn to AI first.* [E 6]

Cognitive Factors

Cognitive Offloading

Most participants acknowledged that AI has become their default tool for information retrieval and content creation, reducing the effort required for critical thinking and problem-solving.

> *I used to brainstorm lesson plans myself. Now, I ask AI, and it gives me something within seconds.* [E15]

However, some educators worried that relying on AI too frequently might weaken their cognitive engagement with their work.

> *I wonder if I'm losing my ability to think critically because AI does the thinking for me.* [E 10]

Loss of Pedagogical Creativity

A few pointed out that AI-generated content makes teaching more convenient but limits their creativity in designing course materials.

> *I used to create my own case studies and interactive activities. Now, I just modify what AI generates.* [E17]

On the other hand, some educators mentioned that AI enhances their creativity by providing new perspectives and ideas they would not have considered otherwise.

> *AI gives me different angles to approach a topic, which actually improves my lesson planning.* [E22]

Technological Factors

Ease of Access and Automation

Many participants indicated that AI tools are readily available and easy to use, making them convenient for performing academic tasks. According to these participants, AI helps them save time, generate ideas, and organize content efficiently.

> *Why spend hours writing something when AI can give me a great draft in seconds?* [E21]

However, a few pointed out that the ease of access makes it tempting to rely on AI for everything, leading to unintentional dependency.

> *The more I use AI, the harder it becomes to work without it. It's like having a calculator for everything.* [E20]

Lack of AI Literacy

Some participants admitted that they lack a deep understanding of AI's inner workings**,** leading them to unquestioningly trust its outputs.

> *I know AI isn't perfect, but I don't always know how to verify the accuracy of what it generates.* [E18]

A few educators expressed concern that inadequate AI literacy might make them overly dependent on AI-generated insights.

> *I sometimes use AI without thinking critically because I assume it knows better than I do.* [E1]

Feeling Powerful and Capable

Some educators pointed out that AI empowers them and allows them to produce high-quality content more efficiently.

> *With AI, I can complete tasks that would have taken me hours in just a few minutes. It makes me feel more capable.* [E3]

Moreover, a few were concerned that this sense of control is misleading, as they might be overestimating AI's reliability.

> *AI makes me feel smarter, but I sometimes wonder if I'm just relying on it too much without questioning its accuracy.* [E 3]

Individual Factors

Based on the coding book (Table 2), individual factors include academic reputation, high performance expectation, low academic self-efficacy, and lack of scientific research engagement.

Academic Reputation

Most participants reported that academic reputation is a key driver of their reliance on AI, particularly for scientific research. One prominent researcher shared that, because of his demanding

teaching and research schedule, he relies on AI to assist with writing.

Academic Self-Efficacy

Some participants mentioned that using AI enhances their confidence in their academic abilities.

> *AI helps me refine my ideas, making my work more professional and well-structured.* [E6]

Other participants expressed concerns that relying on AI might affect their academic reputation, as AI-generated content could be perceived as lacking originality.

> *I worry that using AI too much might make others question the authenticity of my work.* [E7]

Low Academic Confidence

A few participants admitted that AI serves as a tool for procrastination, allowing them to delay tasks while still producing quick results when needed.

> *"I put off writing papers because I know AI can help me generate content at the last minute."*

On the other hand, some educators maintained that AI use compensates for their low academic confidence, making them feel more capable in completing their work.

> *"I don't always trust my writing skills, so AI gives me the reassurance I need to finalize my work."*

Research question #2: How does AI dependency impact educators' teaching autonomy, decision-making, and professional identity?

Findings from the second research question revealed that AI dependency has complex and varied consequences for educators. While participants acknowledged AI's efficiency and convenience, they also raised concerns about its negative effects. More than 30 subthemes emerged, categorized into 6 main themes: skills atrophy, pedagogical erosion, motivation decline, ethical and integrity risk, social fragmentation, and creativity suppression. Table 3 details these subthemes, which are outlined in the following sections.

Table . Consequences of AI dependency.

Main theme	Subtheme
Skills atrophy	• Loss of critical thinking • Weakened problem-solving abilities • Diminished writing and research skills • Reduced analytical skills • Loss of decision-making abilities • Reduced ability to synthesize independently • Weakened judgment
Motivational decline	• Over-reliance on AI[a] for simple tasks • Procrastination • Reduced motivation • Increased laziness • Reduced individual initiatives
Pedagogical erosion	• Erosion of pedagogical autonomy • Reduced active engagement with students • Weakened academic mentorship • Reduced self-confidence • Perceived professional inadequacy
Ethical and integrity risks	• Increased plagiarism rate • Increased copyright infringement • Increased academic misconduct • Diminished human responsibility • Increased misleading information
Social fragmentation	• Affects students' emotional state negatively • Diminished social development • Reduced human interaction • Decreased collaboration among humans
Creativity suppression	• Homogenization of knowledge production • Restrict creativity • Restrict information seeking

[a]AI: artificial intelligence.

Skills Atrophy

In this study, skills atrophy refers to the gradual decline of previously acquired skills and competencies due to lack of use or engagement. Related subthemes include weakened thinking skills, reduced problem-solving abilities, and diminished analytical synthesis.

All participants in the interviews and a few of the participants in the focus group discussions reported a decline in their skills in writing scientific research due to their frequent use of AI in scientific research. In addition, most participants reported that frequent reliance on AI has reduced their engagement in deep critical thinking.

> *I used to spend time reading multiple sources and forming my own analysis. Now, I just ask AI to summarize everything for me, and I take that as my starting point.* [EFG18]

Several participants in the interviews admitted that instead of independently evaluating and synthesizing information, they now trust AI-generated summaries and responses.

> *I don't challenge myself as much anymore. If AI gives me a structured answer, I don't always question it, I just go with it.* [EFG26]

In addition, several participants stated that using AI applications negatively affects their decision-making abilities, making them more reliant on automated solutions.

> *When I come across a difficult question in my field, my first instinct is to ask AI instead of thinking through possible solutions myself.* [EFG36]

A few participants pointed out that while AI speeds up the problem-solving process, it sometimes limits their ability to engage with complex academic challenges.

> *AI gives great answers quickly, but I worry that I'm losing my ability to navigate difficult academic discussions without its help.* [EFG13]

Most participants reported that AI dependence has weakened their academic writing and research skills. Some found it difficult to start writing without AI-generated drafts after extended use, while others rarely conduct extensive literature reviews themselves.

> *I used to write everything from scratch, but now I start with an AI-generated outline. I wonder if I'm losing my ability to structure my thoughts clearly on my own.* [EFG25]

A few participants mentioned that AI-generated summaries are convenient but may lead to a superficial understanding of academic topics.

> *Instead of reading full papers, I rely on AI to summarize them. I get the key points, but I feel like I'm missing the depth of the discussion.* [E17]

Motivational Decline

In the context of this study, motivation decline refers to the gradual reduction in an individual's drive, enthusiasm, or willingness to engage in various academic activities. Subthemes include procrastination, weaker intrinsic motivation, reduced individual initiatives, and overreliance on AI.

Several participants mentioned that AI has encouraged procrastination, as they know they can complete tasks quickly with AI assistance.

> *Before AI, I would start preparing my lectures well in advance. Now, I just rely on AI to generate material the night before.* [EFG28]

A few educators pointed out that while AI helps them meet deadlines, it sometimes leads to rushed and poor-quality work.

> *I meet my deadlines, but sometimes I feel like my work isn't as thoughtful as it used to be because I rely on AI to speed things up.* [E15]

A few educators mentioned that AI has made them more efficient but acknowledged that it can be tempting to take shortcuts.

> *I'm more productive with AI, but I also recognize that I use it to avoid thinking through certain problems myself.* [EFG13]

Pedagogical Erosion

In this study, pedagogical erosion refers to the gradual decline in the effectiveness, relevance, and innovation of teaching practices over time. Subthemes categorized under this theme include perceived professional inadequacy, erosion of pedagogy autonomy, reduced engagement with students, weakened academic mentorship, and reduced self-confidence.

Some participants pointed out that AI efficiently helps them improve the quality of their teaching material.

> *"AI gives me a strong starting point for my lessons. I still personalize them, but it definitely saves me time."*

According to a few participants, interactions with students became less personal since integrating AI into their workflow.

> *I used to spend more time giving individualized feedback. Now, I use AI-generated comments, and I feel like I'm not engaging with my students as much.* [E11]

On the other hand, some educators argued that AI allows them to focus on more meaningful discussions instead of wasting time on repetitive tasks.

> *AI handles the routine work, so I can dedicate more time to having deeper discussions with my students.* [E20]

Many participants admitted that AI has made them doubt their own expertise, as they often feel that AI-generated content is superior to their own in structure and insight.

> *Sometimes I feel like AI writes better than I do. It's unsettling to think that I might not be as good as I used to be.* [EFG35]

Similarly, some mentioned that they feel they must use AI particularly when completing research or complex writing tasks.

> *"If AI was suddenly unavailable, I don't know how I'd manage my workload. I've started to rely on it too much."*

However, a few pointed out that AI boosts their confidence by helping them refine their work.

> *AI isn't replacing my skills—it's just giving me an extra layer of support to make my work better.* [EFG14]

A few educators stressed that AI can and should be used wisely without hindering professional competence.

> *AI is a tool, not a replacement. As long as we use it strategically, we can avoid becoming too dependent.* [E16]

Ethical and Integrity Risks

Ethical and integrity risks in this study refer to the challenges that arise when AI influences academic practices. Subthemes that emerged under this category include increased plagiarism rate and copyright infringement, increased academic misconduct, decreased human responsibility, and increased misleading information.

Some participants expressed concerns that AI facilitates plagiarism and reduces students' accountability for their work.

> *It's so easy for students to copy-paste AI-generated responses without truly engaging with the material.* [E7]

Others pointed out that AI tools blur the lines of originality and authorship, making it difficult to differentiate between human and machine-generated work.

> *I worry that students are submitting AI-generated essays without understanding the concepts themselves.* [E12]

A few highlighted the fact that AI-generated content sometimes lacks accountability, as it can produce misleading or biased information.

> *AI sometimes generates convincing but factually incorrect statements, and students don't always verify them.* [EFG21]

On the other hand, some faculty members believe AI can be ethically leveraged if students are taught responsible AI use.

> *We should integrate AI literacy into our curriculum so students learn how to use these tools without compromising integrity.* [E26]

Social Fragmentation

Social fragmentation in this research refers to the weakening of human connections and interactions due to AIED. Subthemes include negatively impacting students' emotional state, diminishing social development, reducing human interaction, and decreasing collaboration among humans.

Many participants noted that students are becoming more isolated as AI tools replace traditional peer interactions in collaborative assignments.

> *Group discussions are not as engaging anymore because students rely on AI instead of exchanging ideas with their peers.* [E9]

However, some suggested that AI could be used to enhance social learning if implemented thoughtfully.

> *If we integrate AI strategically—such as using it to facilitate discussions rather than replace them—it can actually strengthen collaboration.* [E30]

Creativity Suppression

Creativity suppression refers to the risk that AI may homogenize knowledge production, restrict creativity, and limit students' ability to seek information. Subthemes include homogenizing knowledge production, restricting creativity, and limiting search for information from diverse sources.

Many participants reported that AI-generated content tends to produce generic, standardized responses, leading to a decline in original thought.

> *Students' assignments are starting to look the same because they rely on AI-generated structures.* [EFG15]

Some educators emphasized that AI discourages thorough research, as students may settle for AI-generated summaries instead of exploring diverse sources.

> *Before AI, students would read multiple papers. Now, they just use AI to summarize, and I feel like they're missing out on critical engagement.* [E14]

Research question # 3: What strategies can help educators balance AI use while maintaining pedagogical creativity and instructional effectiveness?

The third research question explored strategies educators use to balance AI integration with traditional teaching while maintaining effectiveness and autonomy. Findings show that most view AI as a valuable tool but use strategies to prevent overreliance and preserve human-centered teaching, with some embracing its efficiency and others expressing concerns about its effects on critical thinking, creativity, and student-teacher interactions. Key themes are summarized below.

Establishing Clear Boundaries for AI Use: Selective Use of AI for Instructional Tasks

Most participants said they use AI selectively, viewing it as a support tool rather than a replacement for their instructional role. They emphasized that core teaching activities—mentoring, leading discussions, and assessing student progress—should remain human-led.

> *AI helps with structuring lesson plans and summarizing content, but I make sure that my role as an educator remains central in guiding discussions and engaging with students.* [E4]

Some participants pointed out that AI is particularly useful for administrative tasks and content organization but should not dictate teaching methods.

> *I let AI handle routine tasks like scheduling and summarizing, but when it comes to interactive*

> *teaching, I rely on my own expertise and instincts.* [EFG33]

A few participants expressed concerns that without defined limits, educators might unconsciously begin to depend too much on AI-generated content.

> *I initially used AI just for support, but over time, I found myself relying on it more than I intended. Now, I consciously limit my AI use to avoid dependency.* [EFG28]

Encouraging Critical Engagement With AI: Verifying AI-Generated Content

Many participants stated that they actively verify and refine AI-generated outputs before using them in teaching, noting that AI can produce misleading, biased, or overly simplified content. This requires educators to serve as content curators rather than passive users.

> *I never use AI-generated content without reviewing it first. It can be a great starting point, but I always fact-check and refine the materials to align with my course objectives.* [EFG31]

Some educators pointed out that they encourage students to critically analyze AI-generated responses rather than accepting them at face value.

> *I tell my students that AI is a tool, not an authority. They need to critique what it produces, question its assumptions, and think beyond the outputs.* [EFG32]

On the other hand, a few participants expressed concern that not all educators take the time to evaluate AI content carefully, which could lead to inaccuracies in teaching.

> *One of my worries is that some educators might blindly trust AI-generated materials, which could introduce errors or outdated information into their lessons.* [EFG17]

Balancing AI With Human-Centered Teaching

Hybrid Intelligence

Most participants stressed that hybrid intelligence—integrating human and machine intelligence—is vital to prevent overreliance on AI. They defined it as critically assessing AI outputs, promoting deeper reflection and independent analysis rather than passive acceptance.

Prioritizing Interactive and Discussion-Based Learning

Most participants reported intentionally designing courses to prioritize live discussions, debates, and student-driven learning to counterbalance AI-generated content, emphasizing that human interaction is essential for deep understanding and critical thinking.

> *AI is great for providing structured information, but meaningful learning happens when students engage in discussions, challenge ideas, and interact with their peers and instructors.* [E15]

Some participants mentioned that they use AI to supplement discussions by generating diverse perspectives, but they ensure that students analyze and debate those perspectives rather than passively accepting them.

> *I sometimes use AI to provide multiple viewpoints on a topic, but I make sure my students critically evaluate and compare them rather than just absorbing the information.* [EFG25]

However, a few participants pointed out that some educators struggle to balance AI integration with traditional teaching, leading to a more passive learning environment.

> *I've seen cases where AI-generated lectures replace interactive teaching, and I worry that students might become passive learners rather than active thinkers.* [EFG32]

Maintaining Pedagogical Creativity: Using AI as a Spark for Innovation, Not a Substitute for Creativity

Many participants reported that they leverage AI to generate new ideas for lesson planning but ensure that their personal creativity remains the driving force. They view AI as a brainstorming partner rather than a content creator.

> *I use AI to generate multiple lesson ideas, but I always customize them to fit my teaching style and my students' needs.* [E3]

Some educators pointed out that AI helps them explore innovative approaches to teaching but emphasized that human creativity is irreplaceable.

> *AI can suggest engaging activities, but it's my job to refine them and add the human element that makes learning meaningful.* [E22]

On the other hand, a few participants expressed concerns that excessive AI use might lead to a decline in originality if educators become overly reliant on AI-generated content.

> *I fear that if we depend too much on AI, we might lose the uniqueness of our teaching styles. That's why I try to balance AI use with my own creative input.* [EFG26]

Fostering Student AI Literacy and Ethical Use: Teaching Students to Use AI Responsibly

Some participants expressed that they incorporate AI literacy into their courses to help students use AI effectively while avoiding over-reliance. They believe that educators should guide students in understanding AI's strengths and limitations.

> *I teach my students how to use AI as a research tool but also emphasize that they must engage critically with the results rather than just accepting AI-generated answers.* [EFG32]

Most participants reported that they actively discourage students from using AI for academic shortcuts, instead encouraging them to use AI as a means of enhancing learning.

> *AI can help students brainstorm ideas, but they need to put in the effort to analyze and expand on those ideas instead of just submitting AI-generated content.* *[EFG34]*

However, a few participants pointed out that some students misuse AI for assignments, and educators must establish clear guidelines on ethical AI use.

> *We need to teach students that AI is a tool to assist learning, not a way to bypass intellectual effort.* *[EFG11]*

Continuous Professional Development and Peer Collaboration: Engaging in AI Training and Professional Learning Communities

Several participants mentioned that they actively seek professional development opportunities to improve their AI literacy and refine their AI integration strategies. They believe that educators must continuously learn to ensure that AI is used responsibly and effectively.

> *I regularly attend AI workshops to stay updated on best practices. The more I understand AI, the better I can integrate it into my teaching without becoming dependent on it.* [E5]

Some educators pointed out that they collaborate with colleagues to share AI integration strategies, discuss ethical concerns, and develop guidelines for responsible AI use.

> *We have faculty discussions on AI use where we exchange ideas on how to integrate AI without compromising teaching quality. These discussions help us find the right balance.* [EFG36]

On the other hand, a few participants expressed that some institutions lack adequate AI training programs, leaving educators to navigate AI integration on their own.

> *I wish there were more structured AI training for educators. Right now, we mostly figure it out through trial and error.* [EFG35]

Discussion

Overview

The recent study examines the drivers and consequences of AI dependency among medical and health sciences faculty in Palestinian higher education, offering critical insights into over-reliance on generative AI and strategies for sustainable integration. This study contributes to the growing body of literature on digital transformation in medical education by identifying multidimensional factors that influence educators' reliance on AI tools and their implications for pedagogical integrity and professional agency.

Principal Findings

Institutional pressures—particularly workload intensity and a lack of clear AI governance—were identified as primary catalysts for increased AI reliance. These findings mirror previous studies [4,10] highlighting how time-saving AI applications appeal to overburdened faculty. Participants described using AI to manage grading, feedback, and administrative documentation, often without structured support or guidance. The absence of institutional frameworks creates ambiguity, allowing overuse and reinforcing dependency—a concern consistent with the findings of [7].

Psychological and individual factors also emerged as significant influences. Echoing previous research [8,9,32], educators reported that anxiety, performance pressure, and perfectionism motivated AI use as a coping mechanism. High expectations for output quality and academic reputation intensified AI reliance, particularly in competitive or high-stakes disciplines. While some participants viewed AI as a confidence booster, others reported reduced academic self-efficacy and increased procrastination, reflecting problematic patterns of technology use.

At the cognitive level, many educators admitted to cognitive offloading, allowing AI to complete tasks once handled through personal reflection or pedagogical creativity. These practices align with concerns from [33,34] about diminished analytical and innovative capacity when AI is used uncritically. Participants noted that AI-generated lesson plans increased efficiency but limited deep thinking and originality, a paradox especially concerning in health education where critical reasoning and ethical judgment are essential.

Technological factors, especially ease of access and automation, facilitated habitual AI use, often unconsciously. Similar to findings on digital tool overuse [25], educators recognized both the benefits and risks of AI ubiquity. Lack of AI literacy compounded the issue: while participants used GenAI tools regularly, many admitted limited understanding of how algorithms operate or how to evaluate their outputs critically [17]. This blind trust not only undermines informed decision-making but also amplifies the risk of propagating misinformation or algorithmic bias in academic work.

Consequences of AI Dependency

This study identified 6 major consequences of AI overreliance: skills atrophy, motivational decline, pedagogical erosion, ethical risks, social fragmentation, and creativity suppression. Faculty reported declining engagement in original writing, idea generation, and academic rigor—findings echoed by [8,34,35]. In some cases, AI was used as a substitute for personal initiative, weakening academic identity and self-reliance.

Social fragmentation was also discussed as educators expressed concern about diminished student-teacher interaction and reduced peer collaboration. This is consistent with [36] noting how digital tools can isolate learners. Our findings suggest AI can support collaborative learning by matching students for group work and distributing roles equitably, potentially countering its fragmenting effects.

Participants frequently cited ethical risks such as plagiarism, misinformation, and authorship concerns, expressing uncertainty about acceptable boundaries for AI use in assessment and publication. These concerns align with calls for regular AI audits [34], ensuring educational technologies are ethically vetted and contextually appropriate.

Comparison to Prior Work

The findings reinforce and expand on theoretical models such as the I-PACE framework [12], which links personality traits,

affective responses, and cognitive control to problematic technology use. This study shows that in Palestinian higher education, AI dependency is a systemic issue shaped by resource constraints and institutional pressures, not just individual behavior. It highlights the interplay between personal motivations and structural limitations in AI use.

Limitations and Future Research

This study's findings are limited by its focus on Palestinian higher education, which may affect transferability to other contexts. Variations in resources, policies, and academic cultures could lead to different experiences with AI dependency. Future research should explore these issues in diverse settings to broaden understanding.

Second, the use of self-reported data from 46 faculty members may introduce social desirability bias, with participants potentially misrepresenting their AI use. Conducting and translating interviews from Arabic to English may also have affected the preservation of linguistic and cultural nuances. Future studies should consider bilingual coding teams and cultural consultants for greater interpretive accuracy.

Third, this study focused solely on educators' perspectives, excluding student voices. Future research should examine AI dependency among students to understand its effects on motivation, learning outcomes, and academic integrity.

Furthermore, while this study examined AI dependency broadly, it did not address disciplinary differences. Faculty in humanities, social sciences, and STEM may experience unique challenges and opportunities with AI. Future research should compare disciplines to uncover domain-specific dynamics of AI dependency.

Finally, this study provides a snapshot of current practices but does not assess the long-term effects of AI dependency on faculty roles, creativity, or knowledge production. Longitudinal and mixed methods research is needed to track changes over time and evaluate the impact of institutional interventions on pedagogical autonomy and professional integrity.

Theoretical and Practical Implications

This study contributes to theoretical discourse on technology adoption in higher education by framing AI dependency as a multidimensional construct shaped by institutional, psychological, cognitive, and technological factors. Building on the I-PACE model, the findings demonstrate how overreliance on generative AI aligns with patterns of problematic technology use, particularly among faculty navigating high academic demands and limited institutional support. The study reinforces and extends the I-PACE framework by showing how its four components—Person, Affect, Cognition, and Execution—interact dynamically within educational environments to shape AI dependency.

Under the Person component, both individual (eg, academic self-efficacy, perfectionism, low confidence) and institutional drivers (eg, workload pressures, unclear policies) were identified as predisposing factors for AI overuse. These findings extend I-PACE by highlighting that external academic structures—not just personal traits—can significantly shape technology dependency. The Affect domain was reflected in emotional responses such as anxiety, fear of inadequacy, and pressure to meet performance expectations. Rather than being purely internal, these emotions were often shaped by systemic academic stressors, suggesting that affective triggers in the I-PACE model must be understood within broader socio-institutional contexts.

In the Cognition domain, participants frequently described cognitive offloading and declining engagement in creative and reflective tasks. Notably, this study introduces "creativity suppression" as a cognitive outcome not emphasized in the original model, pointing to the need for an update to account for AI's influence on ideation and pedagogical originality. The Execution component was evident in behavioral outcomes such as diminished teaching autonomy, motivational decline, and habitual reliance on AI. These confirm I-PACE's focus on maladaptive behavior patterns but also reveal participants' active strategies—like hybrid intelligence and critical engagement—to retain pedagogical agency.

Overall, the study affirms the I-PACE model's value while proposing a broader interpretation that incorporates institutional, technological, and cultural factors specific to under-resourced higher education systems. By doing so, it deepens our understanding of how AI transforms academic identity, decision-making, and autonomy in the evolving landscape of digital education.

On a practical level, the study offers several actionable recommendations:

Faculty Development

Higher education institutions should invest in personalized professional development to enhance AI literacy, ethical awareness, and pedagogical resilience. Training should include modules on AI ethics, data privacy, and algorithmic bias, tailored to each discipline's needs. Institutions can also use AI to personalize learning pathways for educators based on their backgrounds and evolving instructional needs.

Institutional Policy Design

Institutions must establish clear and adaptive AI governance frameworks to guide responsible AI use among faculty and students. These frameworks should define acceptable use policies, clarify the boundaries of AI-generated content, and promote transparency in AI-supported academic work. To uphold ethical standards—especially in high-stakes fields like medical education—regular audits of AI tools should be implemented to assess potential biases, misinformation, and integrity risks. Moreover, developing such policies should be a collaborative effort involving faculty members, administrators, IT professionals, and ethicists to ensure both institutional trust and community-wide compliance.

Student–Teacher Interaction in AI Contexts

To reduce risks of pedagogical erosion and social fragmentation, institutions should set guidelines that preserve student–teacher engagement in AI-rich environments. Human–AI collaboration, reflective use of AI, and AI-facilitated group work can enhance accountability and peer interaction. Prioritizing feedback, mentorship, and dialogic teaching ensures AI remains a

supplement, supporting balanced integration and safeguarding academic integrity.

Conclusion

This study provides a comprehensive exploration of AI dependency among educators, highlighting the institutional, psychological, and cognitive factors that contribute to reliance on AI in academic practices. While AI offers significant benefits in terms of efficiency, knowledge management, and academic productivity, unchecked dependence can pose risks to pedagogical autonomy, critical thinking, and professional identity. The findings emphasize the importance of hybrid intelligence as a strategy to balance AI use, ensuring that technology enhances rather than replaces human intellectual engagement. The study's contributions to the theoretical discourse on AI adoption extend existing models by integrating the concept of AI dependency within a broader framework of professional agency and academic integrity. From a practical standpoint, these findings underscore the need for institutional policies, faculty training, and AI literacy initiatives that foster responsible AI use. Ultimately, this study advocates for a balanced approach where AI serves as a tool to augment human intelligence rather than replace it. Future research should continue to explore AI's evolving role in higher education, examining its long-term impact on faculty development, student learning, and knowledge creation in an increasingly AI-driven academic landscape.

Abstract

Background: English for medical purposes (EMP) is essential for medical students as it serves as a foundational language for medical communication and education. However, students often undervalue its importance within the medical curriculum. Given their demanding schedules and workload, educational methods for EMP must align with their needs. Structured web-based learning offers flexibility and convenience, yet limited research has explored its exclusive application for EMP in undergraduate medical education.

Objective: This study aimed to evaluate medical students' perspectives on structured web-based EMP courses and assess their impact on medical English proficiency using objective and subjective measures.

Methods: Structured web-based EMP courses were developed based on evidence-based guidelines, addressing barriers to web-based learning during development and implementation. A cross-sectional study was conducted with 535 medical students who completed these courses. Data were collected via questionnaires, the learning management system, and the Khon Kaen University Medical English Test (KKUMET), which assessed proficiency in listening, reading, writing, and speaking. Data were analyzed using descriptive statistics.

Results: Of the 535 students, 452 (84.5%) completed the survey. Participants reported confidence in reading (mean 4.11, SD 0.87), vocabulary (mean 4.04, SD 0.84), and listening skills (mean 4, SD 0.89), but lower confidence in writing skills (mean 3.46, SD 1.07). The KKUMET results showed statistically significant improvements in all 4 language skills after course completion ($P<.001$). The top-rated benefits of the courses were convenience (mean 4.77, SD 0.59), sufficient instruction (mean 4.5, SD 0.85), and clear content (mean 4.41, SD 0.80).

Conclusions: Structured web-based EMP courses are relevant and well received by medical students. These courses significantly improve students' medical English proficiency, as evidenced by both subjective feedback and objective measures. Medical educators should consider integrating structured web-based EMP programs to better support students' language proficiency in medical contexts.

Introduction

Background

English is the international language of medicine [1,2]. It is the dominant language used in medical research and publications [1,3]. A growing number of medical journals worldwide have been published in English [4]. Almost 90% of the world's publications indexed in the MEDLINE database are published in the English language [3,5]. In addition, considering their high impact factors and citation scores, almost all quality research articles have been published in English-medium journals [1].

The language of medicine has shifted from Latin and Greek to English, influencing the development of modern medical terminology [3]. The use of English in a medical community involves communication with colleagues and staff, reading medical journals, giving conference presentations, or pursuing postgraduate education in English-speaking countries [1,3]. Therefore, the English language and literacy are essential in medical curricula [2,4,6].

General English focuses on overall language competency, emphasizing foundational grammar, vocabulary, and communication skills applicable to a wide range of everyday and academic contexts. English for medical purposes (EMP), on the other hand, is a specialized subset of English tailored to the medical field. It emphasizes medical terminology, reading and comprehension of medical texts and research articles, professional communication skills that are required for clinical and academic purposes, such as writing case reports, interacting with colleagues, and participating in medical discussions [7].

Approximately half of medical schools in the world use English as a medium of instruction [8]. The current status of English use with other languages in medicine is that "English is one lingua franca in medicine but speaks many tongues" [5]. This means that although medical teaching and patient interaction are in the local language, medical professionals still use medical languages with specialized vocabulary in their professional communication [3]. For students or professionals whose English is not their first language, using medical English for their professional-related activities is much more challenging and demanding than it is for those whose English is their first language [3].

The assessment of learning needs is considered fundamental to EMP curriculum design [2,4,7,9] and should be identified early [10]. The learner-centered approach is used to obtain needs from the learner's needs assessment. The learner-centered approach empowers learners to decide what, how, and where to learn, while teachers act as facilitators [11,12]. Learning needs assessments help define program goals and specific teaching objectives [7,13], which leads to the development of lesson plans, materials, tests, assignments, and activities. Many studies have examined the need for EMP [2,9,13-15]. Medical students need to read medical literature, listen to lectures, and write clinical reports and short essays, whereas practitioners need patient interaction and conference participation [1,7]. The development of EMP courses addresses specific language challenges that hinder medical students' learning, particularly in contexts where English is partially used as the medium of instruction, while local languages dominate communication between instructors, students, and patients [16].

Teaching an EMP course differs from teaching general English [7,14]. Instead of learning grammar and fundamental structures, the goal of learning English at this level is to apply the language to medical studies [7]. Previous studies have described the development of EMP courses, including detailed information about curriculum development processes based on students' learning needs [2,16-18], as well as EMP courses developed for international medical graduates [18] and undergraduate medical students [2,16,17]. However, these EMP courses were taught in medical curricula in countries where English was the official language or medium of instruction. In other countries, the EMP course design has not yet been clearly explored. As a result, the requirements of EMP for medical students must be investigated [19], and EMP instruction must be tailored to the intended audience needs. In addition, many studies have focused on preparing students with linguistic tasks for their future careers [9,15]. Less is focused on the design of EMP courses aiming to improve academic performance during undergraduate studies, preclinical years in particular, where basic science knowledge is most of the content rather than clinical application.

Educational methods for EMP should also be matched with learners' needs and preferences. Online and web-based educational methods have been adopted in medical education for the past decade [20]. Online teaching was the primary modality of instruction offered to undergraduate medical students during the COVID-19 pandemic [21]. The web-based education methods have been tested for their effectiveness [22-24]. The advantages of web-based educational methods include improving medical students' knowledge and skills [24]. However, prior meta-analyses have demonstrated that web-based learning is just as effective as the traditional learning methods [23,24]. There are few studies on the exclusive use of web-based learning techniques in EMP. One study explored students' readiness for internet-based learning in EMP [25] or internet- and computer-based as part of blended learning for general English [26,27]; however, none has solely used web-based educational methods in EMP courses for medical students.

Problem Statement

Despite the growing adoption of web-based learning methods in medical education [28], limited research has explored their exclusive use in teaching EMP, especially for preclinical medical students [24]. Web-based education, proven to be as effective as traditional methods [22,23,29,30], offers unique advantages such as flexibility and accessibility [24]. However, few studies have investigated the development and evaluation of structured web-based EMP courses tailored to students in non–English-speaking environments.

Thus, this study developed an exclusive structured web-based learning program for EMP and evaluated its effectiveness. Grounded in constructivist principles, the study emphasizes active, self-directed learning. The structured web-based EMP courses were designed to enable students to construct knowledge through interactive activities, scenario-based learning, and multimedia resources. These approaches foster engagement and empower learners to take ownership of their educational journey, ensuring the content is relevant and applicable to their academic and professional needs. The guiding research question for this study was whether a structured web-based learning program exclusively for EMP would be accepted, considered relevant, and meet the satisfaction of preclinical medical students. We hypothesized that learning EMP through structured web-based courses would be both relevant and well-received by preclinical medical students. This investigation formed the basis for evaluating the course. To comprehensively evaluate the course, the research is divided into 2 parts. The first part, the present study, focuses on assessing the relevance and acceptance of

structured web-based EMP courses based on students' perceptions of the web-based learning mode. The second part examines the effectiveness of the structured web-based EMP courses in improving students' medical English proficiency. To evaluate the first part, a cross-sectional descriptive study was conducted to assess the relevance and acceptance of the structured web-based EMP courses among participating medical students. Additionally, feedback from course instructors, gathered during the course design and development phases, was incorporated to capture their perceptions of the web-based EMP program. The findings from the second part are discussed in a separate article; however, this study included significant findings on the program's effects on students' medical English proficiency. The findings are intended for medical educators, curriculum designers, and policy makers in medical education, particularly those serving non–English-speaking regions.

Our Medical School Curriculum

Our medical school recruits students directly from high school through the Thailand University Central Admission System (TCAS). TCAS, implemented in 2018, is an admission framework consisting of 5 rounds held annually. Medical schools in Thailand often adopt unique criteria and processes within TCAS, reflecting their specific admission requirements and competitive nature [31]. With 288 students enrolled each year, our medical school is one of the regional institutions in northeastern Thailand. The undergraduate medical curriculum spans 6 years, including the first 3 years focused on medical sciences and the last 3 years on clinical practice [32]. Our 2019 updated medical curriculum states that medical students must earn 259 credits over 6 years of medical school. In the first year, premedical education courses (the majority are general education and general principles for medical sciences) account for 38.5 credits. In the second and third years, preclinical education courses comprise 76.5 credits. Clinical rotations, accounting for 48 credits, are conducted in the sixth year, while clinical education courses make up 96 credits across the fourth and fifth years [33]. The majority of the lecture slides, suggested texts, teaching and learning materials, and exam questions are in English, even though the instruction at our school is in Thai.

It is mandatory for Thais to learn English from primary school till higher education [34,35]. In Thailand, the English component taught in high school is of a very basic level, the general English proficiency is low and unsatisfactory [36,37], and by itself is not sufficient for medical professional courses. English proficiency is considered as a part of the entry criteria to the medical schools. Despite English proficiency being a part of the weighted formula for entering medical schools, at present, there is no specific cutoff score or a minimal standardized English language proficiency requirement for entering a medical school in Thailand [38]. English as a foreign language, therefore, is a requirement for students at our medical school [33]. Once students are admitted, they begin enrolling in English courses starting in their first year of study. During medical school, students are required to complete 6 English courses. Four general English courses are taken during the first 3 years of medical school and are taught by nonmedical staff from the university's language institute. They focus on foundational grammar, vocabulary, and communication skills, providing a general linguistic foundation for academic and social contexts. Two EMP courses are introduced in the second and third years of medical school. The content focuses on medical terminology and language skills necessary for academic and clinical tasks, such as reading medical literature, writing reports, and engaging in clinical communication. The curriculum shifts from general language acquisition in the initial years to specialized language skills tailored to medical contexts as students advance in their studies.

Annual feedback from our students consistently indicates that they perceive limited relevance of general English to their medical studies. This perception may stem from several factors. Despite years of English education, many students struggle with basic speaking skills due to insufficient vocabulary and grammar knowledge [39]. Additionally, a lack of intrinsic motivation often leads students to view general English as a mandatory requirement rather than a valuable skill for personal or professional development [40]. The culture within medical programs often emphasizes the need for English proficiency tailored to medical contexts, which shapes students' perceptions and priorities [41]. Therefore, they could not match learning general English in the medical curriculum.

The findings from our students' needs assessments revealed that our medical students needed to improve their English proficiency and wanted the school to organize a test for their English proficiency [42]. They preferred a self-directed web-based learning method and teachers who were both English language experts and medical professionals [42]. Based on the needs assessments, students value medical English because it directly aligns with their academic and professional goals. Unlike general English, medical English equips them with the specific skills needed to read medical literature, participate in clinical discussions, and engage effectively within global medical communities [41,43]. Needs assessments and feedback consistently emphasize students' preference for EMP courses over general English, highlighting the practical benefits they associate with EMP in their medical studies and future careers. Based on learning needs assessments, 2 additional EMP courses were developed while 2 general English courses were removed from the medical curriculum. The newly developed EMP courses were English for Medical Purposes I for the second-year medical students and English for Medical Purposes II for the third-year medical students, which were launched at the same time in the academic year 2021.

Proficiency in medical English is considered to enhance students' academic performance, evidenced by a positive correlation between English proficiency and academic success among medical students [44,45], and to support their development as independent learners [15]. However, evaluating the extent to which students achieve independent learning is beyond the scope of this study.

Methods

Study Objectives

This study aims to evaluate the relevance, acceptance, and satisfaction of structured web-based EMP courses among preclinical medical students.

Study Design

A cross-sectional study was conducted to explore medical students' opinions on learning EMP in a structured web-based course, and qualitative insights from instructors' feedback were obtained.

Participants

The participants were second-year medical students enrolled in the English for Medical Purposes I course and third-year medical students enrolled in the English for Medical Purposes II course at the time of the academic year 2021.

The WinPepi, a statistical software package, was used to calculate sample size based on the proportion of medical students who acknowledged web-based learning [46]. Assuming a proportion of 0.73, a population size of 535, a design effect of 1, and a significance level of 0.05, a total number of 121 was sufficient. However, all 535 students were included in this study to avoid a potential source of selection bias. It is important to clarify that this power analysis was performed for the broader research project, which consists of 2 parts. The first part, detailed in this manuscript, explores medical students' perceptions and experiences with web-based EMP learning. The second part examines the effects of the structured web-based EMP courses on changes in students' English language proficiency after course completion, which is reported in a separate article.

Development of Structured Web-Based EMP Courses

Based on our medical students' needs, EMP course objectives were set accordingly. The main objective of the EMP course was to enhance students' medical English proficiency in all 4 core English language skills (reading, writing, listening, and speaking) through structured, targeted, and interactive web-based practice.

An overview of the four main English language skills is as follows. (1) Reading: Defined as the comprehension of medical literature and academic texts relevant to the students' year of medical study. Instructional strategies include guided analysis of medical articles, scenario-based reading exercises, and formative assessments such as quizzes. (2) Writing: Focuses on effective medical note-taking and medical essays, emphasizing medical content, structure, vocabulary, readability, precision, and clarity. Instructional strategies involve structured writing guides, assignments, peer reviews, and scenario-based tasks such as summarizing patient cases. (3) Listening: Aimed at developing comprehension of medical conversations from case studies and lectures. Instructional methods include exposure to scenario-based audio materials, repeated listening tasks, and interactive multimedia resources. (4) Speaking: Enhances verbal communication in medical contexts, including explaining medical terms, conducting history taking, discussing treatment plans, and educating patients. Instructional strategies feature medical speaking guides, public speaking guides, role-play, video-recorded practice sessions, and feedback loops. Performance improvement for each skill is measured through targeted assessments conducted before and after the course. Standardized testing for reading and listening comprehension, comparison of baseline and final writing samples to assess coherence and technical accuracy, and evaluations of verbal communication in simulated scenarios are used to document and demonstrate progress effectively. These details ensure that the EMP course objectives are transparent and tied directly to improving students' proficiency in medical English through targeted and practical methods.

To develop an effective structured web-based course, we followed the steps of Hays and Veitch's recommendations [47] and applied Cook and Dupras's guide [48]. Key principles of Hays and Veitch emphasize the importance of conducting a thorough needs assessment to identify gaps in knowledge, skills, and practices while ensuring relevance to participants' professional roles and daily practices. They recommend interactive methods such as case studies, group discussions, and workshops to foster engagement and promote practical learning. Flexible delivery formats accommodate diverse learning preferences and schedules, while regular program evaluations ensure continuous improvement, sustainability, and adaptability to emerging needs and advancements in medical education. Cook and Dupras provide a guide specifically for developing web-based learning programs. Their framework focuses on conducting needs assessments, defining clear and measurable learning objectives, and designing content tailored to learners' needs. They highlight the importance of interactive and multimedia-rich content to enhance engagement, as well as ensuring usability and accessibility for diverse learners. Evaluation methods, including pre- and postassessments, combined with continuous feedback and iterative improvements, are essential to measure learning outcomes and maintain program quality. Together, these frameworks provide a robust foundation for creating effective, learner-centered programs that meet educational goals and align with the needs of preclinical medical students. Barriers to web-based learning were considered [49]. More details regarding the development of EMP courses are provided in Multimedia Appendix 1.

The EMP courses were uploaded to a customized web-based learning management system (LMS) developed by our medical school [29]. Each EMP course ran throughout the semester for approximately 48 weeks, and the students' learning schedule was approximately 3 hours per week. However, students can manage their time to study as scheduled or at any time that suits them (see more details on developing the web-based EMP course in Multimedia Appendix 1). Data from the LMS monitoring system were used to report student enrollment and completion of the EMP courses.

Data Sources, Questionnaire, and Assessment

To evaluate the course, questionnaires were used as tools to gather student perspectives on various aspects of the courses, including their confidence in medical English skills, satisfaction with the content, and perceived benefits of web-based learning. These tools provided quantitative data on student experiences

and attitudes. Additionally, feedback from instructors on course design and delivery was integrated into the evaluation process to ensure alignment with educational objectives and identify areas for improvement. Together, these methods offered both quantitative and qualitative insights into the evaluation of the web-based EMP courses.

An online administered questionnaire was developed based on the literature on the use and the evaluation of web-based learning [46,50,51]. The following constructs of web-based learning effectiveness and attitudes toward the structured web-based EMP course were included in the questionnaire: individual learners, confidence in medical English skills, perceived factors influencing web-based participation, perceived satisfaction with content and instructional designs, perceived ease of use, perceived advantages and barriers to web-based learning, and perceived outcomes and benefits of web-based EMP courses. The questionnaire included a 5-point Likert scale ranging from disagree to agree, which was used to assess learners' agreement with each item. For learners' confidence in their medical English skills, the constructs included a 5-point Likert scale ranging from not confident to strongly confident. For the factors influencing web-based learning participation, the constructs included a 5-point Likert scale, ranging from no influence to influence. For learners' perceived benefits of web-based EMP courses, the constructs included a 5-point Likert scale, ranging from not beneficial to strongly beneficial.

To ensure the face and content validity of the questionnaire, each item was evaluated thoroughly by 3 separate experts in the field of medical education at our school. Thirty students participated in a pilot test of the questionnaire, which led to revisions. The Cronbach α coefficient of the attitude and experience part of the questionnaire was 0.93.

The details of the course instructions, content, and materials are provided in Multimedia Appendix 1. The course media included PDF files, audio, videos, and external links for the downloads. The second-year medical students completed a 45-hour web-based asynchronous English for Medical Purposes I course. The third-year medical students completed a 45-hour web-based asynchronous English for Medical Purposes II course. The students would be considered to have completed the module if that module was accessed at least 50% of the total learning time for that module because the LMS has a double speed-up function for playing video or audio clips.

After participants completed the web-based EMP courses, they were invited to complete the questionnaire. A link to the online questionnaire on Google Forms was added at the end of each course. The students completed the questionnaire between December 2021 and April 2022. The questionnaire data were transferred from Google Sheets, and data from the LMS monitoring system were exported to Microsoft Excel. The data were then gathered and checked for completion before being transferred to IBM SPSS for Windows.

Of note, the summative assessment for medical English proficiency was conducted using the Khon Kaen University Medical English Test (KKUMET), which examined proficiency in listening, reading, writing, and speaking. Each component was assessed before and after completing the EMP courses. The baseline EMP proficiency of the participating students, as assessed before enrollment in the 2 EMP courses, revealed that more than two-thirds of the students were at beginner or intermediate levels. The instructional goal of these EMP courses was to enhance their proficiency to intermediate and advanced levels. This study focuses on highlighting final outcomes; detailed results of the EMP proficiency tests conducted before and after these web-based EMP courses are reported in a separate article.

Statistical Analysis

Data from questionnaires were analyzed using IBM SPSS for Windows version 26.0. A pairwise deletion strategy was applied to handle the missing data. The demographic data were described using descriptive statistics. The participants' responses on a 5-point Likert scale to a 42-item questionnaire on their web-based learning experiences were dichotomized by calculating the mean scores and SD. Mean scores of 3.5 and above were considered agreed upon.

Ethical Considerations

This study was approved by the Human Research Ethics Committee of Khon Kaen University (project number: HE631465). Students were recruited through the researcher's assistant, who invited volunteers to participate. Before completing the questionnaires, participants were informed that participation was voluntary and that they could drop out of the study at any time. They were informed that their opinions were important for enhancing the medical English courses and were therefore encouraged to express them. All students voluntarily agreed to participate without receiving compensation. The participants' privacy and identity were protected, and confidentiality was assured in that no identifying information was asked. The study objectives were explained to the participants, and the study was conducted according to the academic ethical code.

Results

Participating Medical Student Demographics

A total of 535 medical students completed the web-based EMP courses, 452 of whom started and returned the completed questionnaires (response rate: 84.5%). Table 1 presents the participants' demographic data. The numbers of male and female participants were relatively similar, as were the numbers of medical students each year.

Table . Demographic data of the participants.

Demographics	Values
Age (n=451), years	
Range	18 - 24
Mean (SD)	20.37 (0.74)
Sex (n=452), n (%)	
Male	219 (48.5)
Female	222 (49.1)
Prefer not to say	11 (2.4)
Year of study (n=450)	
2	231 (51.3)
3	219 (48.7)

Influence of Web-Based Learning Characteristics

Respondents rated the degree of influence of the characteristics of web-based learning on their participation in web-based EMP courses (Table 2). Convenience, flexibility, and accessibility were rated the highest, while facilitator interactions received lower ratings.

Table . Rating of the influence of web-based learning characteristics on participation in web-based EMP[a] courses (n=452).

Characteristics of web-based learning	The degree of influence on adoption of web-based EMP courses, mean[b] (SD)
The convenience of completion the courses at any time or place	4.82 (0.49)
Flexibility to complete and save small sections at a time	4.80 (0.56)
Easy to access the course content	4.60 (0.75)
Easy to use/complete the course	4.58 (0.71)
Access to other useful links and resources	4.53 (0.84)
Instant access to feedback and the right answers when completing quizzes	4.50 (0.85)
The quality of content	4.46 (0.75)
Accessibility to technical support if difficulties are encountered	4.35 (0.94)
The use of case-based information and discussion	3.99 (1.08)
Facilitator's regular input/participation	3.77 (1.17)
The opportunity to communicate/interact with the facilitator	3.75 (1.14)

[a]EMP: English for medical purposes.

[b]Mean was calculated using a 5-point Likert scale ranging from 1 (strongly no influence), 2 (no influence), 3 (neutral), 4 (influence), and 5 (strongly influence).

Confidence in Medical English Skills

Respondents' confidence in their medical English skills is shown in Table 3. The participating medical students reported feeling confident about medical English reading, vocabulary, and listening skills but were not sure about their writing skills.

Table . The participant's confidence in their medical English skills after completing the medical English courses (n=452).

Confidence in medical English skills after completing the modules	Values, mean[a] (SD)
Medical English reading skill	4.11 (0.87)
The use of medical English vocabulary	4.04 (0.84)
Medical English listening skill	4.00 (0.89)
Applying professional-specific knowledge and skills in English	3.92 (0.91)
Medical English speaking skill	3.50 (1.05)
Medical English writing skill	3.46 (1.07)

[a]Mean was calculated using a 5-point Likert scale ranging from 1 (strongly not confident), 2 (not confident), 3 (not sure), 4 (confident), and 5 (strongly confident).

Perceived Advantages, Barriers To, and Attitudes Toward Instructional Designs of Web-Based EMP Courses

The participants identified useful and beneficial aspects of web-based EMP courses. The top 3 highly rated participants agreed on the advantages of convenience, sufficient instructions, and clear and easy-to-understand content (Table 4). For the instructional designs of the web-based EMP courses, the participants agreed on the clarity and appropriateness of the overall design of the courses, including clear objectives and content, appropriate content, arrangement, instruction, media, delivery method, course assessment, and grading (Table 5).

Table . The participants' web-based learning experience of the medical English courses (n=452).

	Values, mean[a] (SD)
Advantages of the web-based medical English modules	
I was able to learn at any place	4.77 (0.59)
Overall, this web-based course provided me with adequate instruction	4.50 (0.85)
The content was easy to understand and clear	4.41 (0.80)
Overall, the course contents covered its objectives	4.30 (0.87)
I felt more comfortable learning in this web-based course than in the face-to-face session	4.19 (1.13)
Overall, the instruction I obtained from this web-based program was motivating	4.16 (0.99)
I knew how to contact the facilitator and the facilitator responses promptly to my questions	4.04 (1.02)
The web-based program fulfilled my learning needs to improve my medical English skills	3.93 (1.04)
If I had technical problems during participating in this program, I received adequate help with technical problems (n=66)[b]	3.30 (1.05)
Difficulties in accessing and completing the course	
There was too much basic, well-known information in the course	3.06 (1.14)
The module took too long to complete	3.03 (1.28)
I spent more time in access to a computer to access this web-based program	2.31 (1.46)
The internet connection was very slow	2.25 (1.42)
I spent more time in downloading external links	2.08 (1.35)
The course was not useful for me because I do not have adequate computer skills to complete the course	1.95 (1.41)

[a]Mean was calculated using a 5-point Likert scale ranging from 1 (Strongly disagree), 2 (disagree), 3 (neutral), 4 (agree), and 5 (strongly agree).

[b]When the participants were asked if they had technical problems during participating in this program, of the 452 participants, 66 (14.6%) had, while 386 (85.4%) had not.

Table . The participants' rating on the web-based medical English course contents and instructional designs (n=452).

The web-based course contents and instructional designs	Values, mean[a] (SD)
The course had clear learning objectives	4.48 (0.79)
The contents were complete, appropriate, and relevant to the objectives	4.41 (0.82)
The order of contents was arranged properly	4.41 (0.82)
The learning media (eg, audios, videos, and PDF files) were appropriate	4.39 (0.90)
Overall, the instructional design of the program was appropriate	4.38 (0.85)
The web-based teaching was appropriate	4.37 (0.86)
The course's assessments (formative assessments on listening, reading, writing, and speaking) were appropriate	3.97 (1.05)
Grading criteria were appropriate	3.74 (1.07)

[a]Mean was calculated using a 5-point Likert scale ranging from 1 (Strongly disagree), 2 (disagree), 3 (neutral), 4 (agree), and 5 (strongly agree).

Perceived Learning Outcomes

The participants agreed that their 4 main skills improved. They also believed that all types of teaching media and lectures benefited them (Table 6).

Table . The participants' perceived outcomes to and benefits of the web-based medical English courses after the course completion (n=452).

	Values, mean (SD)
The participants' perceived outcomes after the course completion[a]	
I improved my listening skills	4.37 (0.85)
I improved my reading skills	4.23 (0.90)
I gained knowledge on how to practice my medical English skills	4.21 (0.89)
I improved my writing skills	3.74 (1.15)
I improved my speaking skills	3.68 (1.21)
Benefits of the web-based medical English courses after the course completion[b]	
The audios to practice listening skills	4.45 (0.83)
The media for medical terms to learn medical terms and practice reading, speaking, and writing skills	4.36 (0.83)
The videos to practice reading, listening, and speaking skills	4.35 (0.91)
The lectures on listening and reading	4.34 (0.84)
The course was organized in the modules	4.28 (0.92)
The recommended reading articles to practice reading and writing skills	4.07 (0.99)
The lectures on scientific writing	4.07 (1.00)
The lectures on speaking	4.02 (1.04)

[a]Mean was calculated using a 5-point Likert scale ranging from 1 (strongly disagree), 2 (disagree), 3 (neutral), 4 (agree), and 5 (strongly agree).

[b]Mean was calculated using a 5-point Likert scale ranging from 1 (strongly not beneficial), 2 (not beneficial), 3 (neutral), 4 (beneficial), and 5 (strongly beneficial).

Learning Behaviors and Engagement Patterns (Data From the LMS Monitoring System)

The second-year students (n=263) completed the learning module ranging from 0 to 7 modules (mean 6.54, SD 1.41). The total learning time ranged from 172 to 24,439 minutes, with a mean of 925.02 (SD 1759.80) minutes. Regarding students' learning behaviors, 153 (58.2%) out of 263 students spent less than 10 hours on the course and often logged in to the course during the afternoon (1069/2993 logins, 35.72%) and evening hours (1005/2993 logins, 33.58%).

The third-year students (n=272) completed the learning module ranging from 0 to 7 modules (mean 6.61, SD 1.41). The total learning time ranged from 0 to 14,100 minutes, with a mean of 768.59 (SD 930.56) minutes. Regarding students' learning behaviors, 136 (50%) students spent less than 10 hours on the course and often logged in to the course during the evening

(1000/2962 logins, 33.76%) and morning hours (655/2962 logins, 22.11%).

Improvements in Medical English Proficiency

The summative assessment of medical English proficiency was conducted using KKUMET, which evaluates listening, reading, writing, and speaking skills. Each component was assessed before and after the EMP courses. The results showed statistically significant improvements in students' scores across all 4 skills, as well as in the total test scores (P<.001), underscoring the effectiveness of the courses. Additional details about the summative testing results are presented in a separate article.

Instructor Feedback on Course Design and Implementation

During the development and implementation of the structured web-based EMP courses, all course instructors actively participated in providing feedback. This feedback was gathered through regular meetings, written evaluations, and iterative reviews of course content and delivery methods. Instructors emphasized the importance of aligning the courses with medical students' academic and professional needs. Their insights directly influenced several key aspects of the course design.

First, scenario-based learning was integrated to make the content more applicable to clinical practice. Case-based scenarios were incorporated into reading and listening exercises to enhance the relevance and practicality of the material. Second, interactive assessments were adapted based on instructor feedback to emphasize practical application. These included the use of peer reviews for writing assignments and role-play activities for speaking exercises, allowing students to practice and refine their skills in realistic scenarios. Third, instructors highlighted the need for multimedia resources to create a more engaging learning experience. This led to the inclusion of audio clips, videos, and interactive tasks designed to cater to various learning preferences. Finally, adaptive scheduling was implemented to accommodate the heavy workloads of medical students. The courses were designed to be asynchronous, enabling students to learn at their own pace and manage their schedules effectively.

Instructors reported that the structured design of the courses, combined with the iterative feedback process, resulted in a cohesive program that effectively addressed students' learning needs. Their ongoing involvement ensured that the courses remained both relevant and practical for medical students.

Discussion

Principal Findings

This study explored the perspectives of preclinical medical students on structured web-based EMP courses and evaluated their proficiency improvements. A total of 535 students enrolled in and completed the courses by the published due dates, of which 452 (84.5%) students completed the questionnaire. The high response rate can be attributed to several factors. The survey's integration at the end of the web-based EMP courses ensured participants encountered it immediately after course completion, when their experiences were fresh and engagement levels were high [52]. The web-based format allowed flexibility, enabling participants to complete the survey at their convenience [53]. Clear instructions, the assurance of anonymity, and the perceived relevance of the survey further encouraged participation [54]. Additionally, students' satisfaction with the course content and instructional design likely motivated them to provide feedback [52].

The summative assessment, conducted using KKUMET, revealed statistically significant improvements across all 4 English language skills (listening, reading, writing, and speaking). Participants reported high confidence in reading, vocabulary, and listening skills but expressed lower confidence in writing and speaking skills. Students rated convenience, clarity of content, and sufficient instruction as the top benefits of the courses. These results affirm the relevance, acceptance, and satisfaction of structured web-based EMP courses for medical students, aligning with the primary objectives of improving proficiency and fostering recognition of EMP's importance in supporting their academic learning.

Evaluation of Course Effectiveness

The primary goal of the EMP courses was to improve students' proficiency in all 4 English language skills and introduce relevant medical terminology tailored to their academic content. This goal was achieved, as evidenced by measurable improvements in KKUMET scores and student-reported confidence levels.

We evaluated the effectiveness of web-based EMP courses, finding significant improvements in students' medical English proficiency across all skills, as measured by KKUMET scores, and increased confidence in reading, vocabulary, and listening. By comparing subjective learner feedback with objective results, we confirmed that reported confidence aligned with measurable gains, minimizing potential overestimation from cognitive biases like the Dunning-Kruger effect [55,56]. These findings underscore the importance of validating self-reported outcomes with objective data to ensure reliable assessments of learning impact [48,57], with future research recommended to explore the influence of cognitive biases and interventions to enhance learning outcomes [55,58].

Furthermore, the courses aimed to highlight the importance of EMP in supporting learning across other subjects, particularly through contextual and content-based design [7,15]. Students expressed initial difficulty in understanding the importance of general English and its relevance within the medical curriculum. However, they highly valued the structured web-based EMP courses and expressed satisfaction with the content, particularly due to its alignment with their academic and professional needs. This alignment was achieved by designing and developing courses that were self-directed and created by medical professionals, which students recognized as enhancing their engagement and acceptance of the educational approach. While students did not explicitly indicate a need for increased interaction with faculty facilitators, they expressed a preference for instructors who were both English language experts and knowledgeable about medical content. This preference suggests an implicit desire for contextualized guidance, highlighting the

value students place on instructors with dual expertise. The structured web-based EMP courses effectively met these needs, motivating them to integrate EMP learning into their study schedules, underscoring the importance of tailoring course design to align with student preferences.

Comparison With Previous Studies

The findings of this study align with existing research on the effectiveness of web-based learning in medical education while addressing gaps specific to EMP. Prior studies have emphasized the effectiveness of web-based learning in enhancing knowledge and skills in medical education [23,24]. Similarly, this study demonstrated statistically significant improvements in all 4 core English language skills (listening, reading, writing, and speaking) among medical students enrolled in structured web-based EMP courses. These findings confirm that well-designed web-based educational modalities can be as effective as traditional methods.

Students greatly appreciated the flexibility and accessibility offered by web-based courses, a perspective consistently supported in previous research [25,26,29,30]. Students appreciated the ability to learn at their own pace, access course materials conveniently, and engage with multimedia content tailored to their needs. The use of diverse teaching media, such as audio, video, and interactive exercises, aligns with widely recognized recommendations for enhancing learning engagement and retention [59,60]. This highlights the role of self-directed learning in increasing engagement and satisfaction.

Unlike previous studies focusing on blended learning or face-to-face instruction [25-27], this study uniquely explored the exclusive use of structured web-based courses for EMP. The findings underscore the potential of this approach to address the challenges faced by medical students in non–English-speaking regions, thereby filling a critical gap in the literature.

This study also found that students reported greater confidence in receptive skills (reading and listening) than in productive skills (writing and speaking), a pattern consistent with findings from previous research [7,15,17]. This underscores the need for targeted instructional strategies to support the development of productive language skills in EMP courses [2,17].

By situating the findings within the broader body of research, this study contributes to the evolving understanding of effective teaching strategies for EMP and web-based learning in medical education.

Implications of Findings for Practice

The findings of this study have important implications for curriculum development and teaching strategies in medical schools, particularly in non–English-speaking contexts. Structured web-based EMP courses significantly improved students' medical English proficiency, demonstrating their potential to meet academic and professional needs effectively. These results suggest that similar approaches could be adopted by other medical schools to enhance student engagement and learning outcomes.

Medical schools can leverage the flexibility and accessibility of web-based learning to design EMP courses that accommodate students' demanding academic schedules. By focusing on targeted skill development and incorporating medical terminology into course content, institutions can create tailored programs that address specific language needs [14,19]. The self-paced nature of web-based learning further enables students to manage their time effectively, aligning with their individual schedules and learning preferences. This adaptability can increase motivation and reduce barriers to learning, particularly in resource-constrained settings.

Integrating EMP with other areas of medical education, such as reading medical literature and writing clinical reports, can help students perceive medical English as an essential part of their academic and professional journey rather than as a standalone requirement. Additionally, structured web-based courses offer scalable and accessible solutions for institutions with large student cohorts, ensuring consistent, high-quality content delivery while reducing the resource burden on faculty and support staff.

Despite the benefits of self-directed learning, low engagement with "consultant hours" highlights the need for integrating opportunities for active faculty-student interaction within course designs. Addressing this issue could involve developing mechanisms that encourage and normalize faculty interaction, which may be especially beneficial in contexts where cultural preferences for independence or heavy academic workloads limit voluntary engagement with support services [23,24,26]. Such measures could enhance overall student support and satisfaction.

These insights underscore the value of structured web-based EMP courses as a model for improving language proficiency and supporting broader academic goals in medical education.

Strengths and Limitations

This study offers a comprehensive evaluation of structured web-based EMP courses, combining subjective learner feedback with objective proficiency measures. A key strength lies in the design of the courses, informed by needs assessments and evidence-based guidelines [47,48]. Moreover, the inclusion of summative assessments provides robust evidence of the courses' effectiveness. This study had a large sample size and response rate, which ensures robust findings. However, the study's scope was limited to a single medical school, potentially affecting generalizability [11,57].

Future research should focus on strategies to enhance productive skills (writing and speaking) while continuing to explore the impact of cognitive biases, such as the Dunning-Kruger effect, on the gap between perceived and actual proficiency [56]. Large-scale, multi-institutional studies are warranted to validate these findings and provide broader recommendations for integrating EMP into medical curricula. Additionally, research should investigate the long-term impact and scalability of such courses across diverse educational settings, as well as the development of adaptive learning technologies to customize course content based on students' baseline proficiency levels, effectively addressing specific skill gaps.

Conclusions

Structured web-based EMP courses are highly relevant, widely accepted, and well-received by medical students, demonstrating significant improvements in their medical English proficiency, particularly in reading, vocabulary, and listening skills, as evidenced by both subjective feedback and objective measures. The flexibility, accessibility, and practicality of structured web-based learning make it an effective approach to address the unique challenges faced by medical students with demanding schedules. By tailoring course content to meet students' academic and professional needs and incorporating engaging instructional designs, these courses provide a scalable and sustainable solution for medical education in non–English-speaking regions. Future developments in EMP course design should focus on enhancing productive language skills, such as writing and speaking, while maintaining the balance between self-directed learning and faculty support, integrating these courses into medical curricula as an essential component to equip students with the language skills necessary for academic success and global medical practice.

Abstract

Background: Doctor-to-Doctor (D2D) is a mobile learning app that aims to support continuous learning in health care, commonly known as continuing medical education. One of the metrics of success in mobile learning is the average amount of time spent each month on the app, which is a component of stickiness, the tendency of users to use apps repeatedly. Stickiness metrics are important because stickiness has a direct effect on user retention.

Objective: This study aimed to determine the factors influencing user stickiness of the D2D mobile learning app. The research framework was based on the stimulus-organism-response theory.

Methods: This study used a mixed methods approach, including a web-based questionnaire (quantitative data) and interviews (qualitative data). We recruited 520 health worker respondents, including general practitioners, dentists, specialists, and medical students, as users of the D2D app. Quantitative data processing was conducted using covariance-based structural equation modeling, whereas qualitative analysis was conducted on the data from 15 respondents using the content analysis method.

Results: On the basis of the web-based questionnaire (quantitative) results, we found that cognitive (P=.01) and emotional (P=.004) app relationship quality affected health workers' stickiness in mobile learning. On the other hand, factors related to the functionality of the app and health workers' experience were proven to affect cognitive and emotional app relationship quality (P<.005). In addition, according to interview (qualitative) data, the performance of apps for mobile learning is influenced by information quality and information processing speed, which are needed to deliver a more efficient learning process and reduce the possibility of misunderstanding in the interpretation of learning materials. The user experience is influenced by gamification factors to make the learning process more fun, especially for medical students who do not have to obtain professional credit units (referred to as *satuan kredit profesional* in Indonesia), unlike physicians or specialists.

Conclusions: The results of this study will help mobile learning service providers increase user stickiness in mobile learning, for example, through processing speed, the quality of the information presented, security features, personalized content recommendations, and gamification.

KEYWORDS

mobile health care learning; mobile learning; health worker; stickiness

Introduction

Background

To date, the health worker and medical student communities have used e-learning and tele-education to enable continuous education and training in the health sector, which is commonly known as continuing medical education (CME) [1]. One form of tele-education is mobile learning [2]. A 2020 report showed that the need to provide CME programs has increased; moreover, the number of medical personnel in Indonesia is always increasing [3]. In 2022, there was an increase in medical personnel in Indonesia by 3.3%, encompassing general practitioners, specialists, dentists, and specialist dentists [4].

Although the number of medical personnel has increased, Indonesia has a ratio of only 0.47 physicians per 1000 population [4]. One of the challenges faced by the health care sector in Indonesia is the uneven distribution of physicians—as many as 71,286 physicians, or approximately 57.63%, are located on the island of Java [5]. This challenge is exacerbated by the geography of Indonesia as an archipelagic country, which makes many physicians reluctant to work in remote areas due to inadequate regional infrastructure [5]. Thus, physicians in regions outside Java face challenges in providing health services and participating in CME programs, which are generally held only in big cities.

In Indonesia, the implementation of a CME program is regulated through Article 28 of Law 29 of 2004, which concerns medical practice. On the basis of that law, all physicians, dentists, and specialists are required to engage in continuous learning via programs conducted by professional organizations on current advancements in science and technology in their respective fields. The implementation of CME includes skill training, webinars, and various events through which attendees earn professional credit units (referred to as *satuan kredit profesional* [SKP] in Indonesia). On the basis of the Decree of the Minister of Health of the Republic of Indonesia HK.01.07/Menkes/1561/2024 concerning the *Guidelines for the Management of the Fulfilment of the Adequacy of Professional Credit Units for Medical Personnel and Health Workers*, SKP points are required to obtain or renew the certificate of expertise, namely, the Registration Certificate issued by the Indonesian Health Workers Council. In Indonesia, physicians and specialist physicians must obtain a score of 250 SKP points for 5 years and dentists and specialist dentists must obtain a score of 100 SKP points for 5 years for clinical (related to direct and indirect medical services) and nonclinical (eg, teaching, researching, conducting health managerial activities, and conducting professional or community service) activities. SKP points are reviewed by the chairman of the Indonesian physician association per region for general practitioners and by the chairman of the association of physicians for specialist physicians.

User stickiness to an app can be considered a key metric for evaluating the relationship between a user and an app [6]. It may influence their decision to adopt or discontinue the use of the app. According to Hsu and Tang [7], the stickiness of a mobile app is its ability to encourage continuous user interaction, which requires that the app maintain users' interest. Chen et al [8] argue that stickiness is the tendency of users to continue to visit apps or websites. One of the strategies that have been implemented to increase the retention rate (ie, stickiness rate) of apps is reinforcing the desire of the user to use the app. These efforts can take the form of direct promotion through webinars, recommendations and reviews by physicians and medical students, and reminder activity through the notification feature on the app [9].

The Doctor-to-Doctor (D2D) app (PT Global Urban Esensial), which competes with various other apps in Indonesia, including Docquity, Halodoc, and Alomedika, is a pioneer in obtaining SKP points for physicians. These 4 apps are the most popular mobile learning apps in Indonesia, especially regarding support for CME programs and webinars [10]. However, D2D is a pioneer in mobile learning and has high ratings and a large number of users in Indonesia compared to other apps. When developing health-related content for physicians, the materials are curated and validated by the company's internal medical team, where each piece of content is produced based on current and relevant medical topics [11]. Approximately 88% of D2D users are physicians practicing in Indonesia [11]. Physicians are also encouraged to engage in CME as part of their ongoing professional development. The D2D app offers various webinars tailored to specific target groups, such as webinars specifically designed for pediatricians [11].

The D2D app was first released in 2018, and to date, it already has >80,000 users on the Google Play Store and Apple App Store [11]. In addition, the D2D app is integrated with medical organizations in Indonesia, namely, the Indonesian Medical Association, and has been certified by the Indonesian Ministry of Health as one of the platforms that can be used to obtain SKP points [11]. Additional benefits for D2D users include access to the latest health content and information, up-to-date information on medical events, and the opportunity to attend free and certified webinars. Features of the D2D app include access to free webinars, health journals, medical discussion forums, and loyalty programs. However, the results of the study by Halim et al [12] show that D2D is only the fourth most frequently accessed app by physicians and medical students. Even though D2D is a pioneer in mobile learning and has amassed high ratings and a large number of users in Indonesia, this does not guarantee that the app will have a high level of user attachment or stickiness. Figures 1 and 2 show example webinar and CME features, respectively. The D2D app's health content is not limited to the D2D health worker community but can also be accessed by all health workers, which is not the case for its competitors such as Alomedika, as shown in Figure 3.

Figure 1. Webinar features of Doctor-to-Doctor.

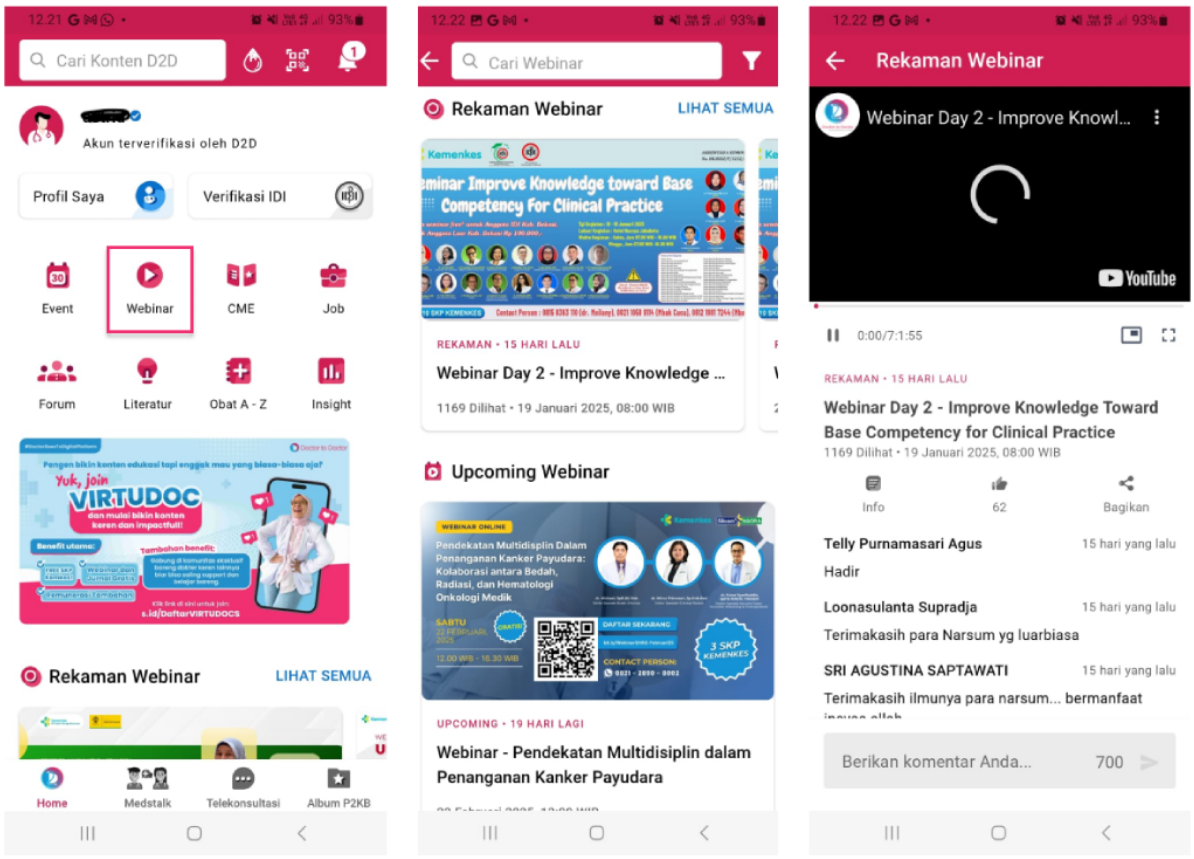

Figure 2. Continuing medical education features of Doctor-to-Doctor.

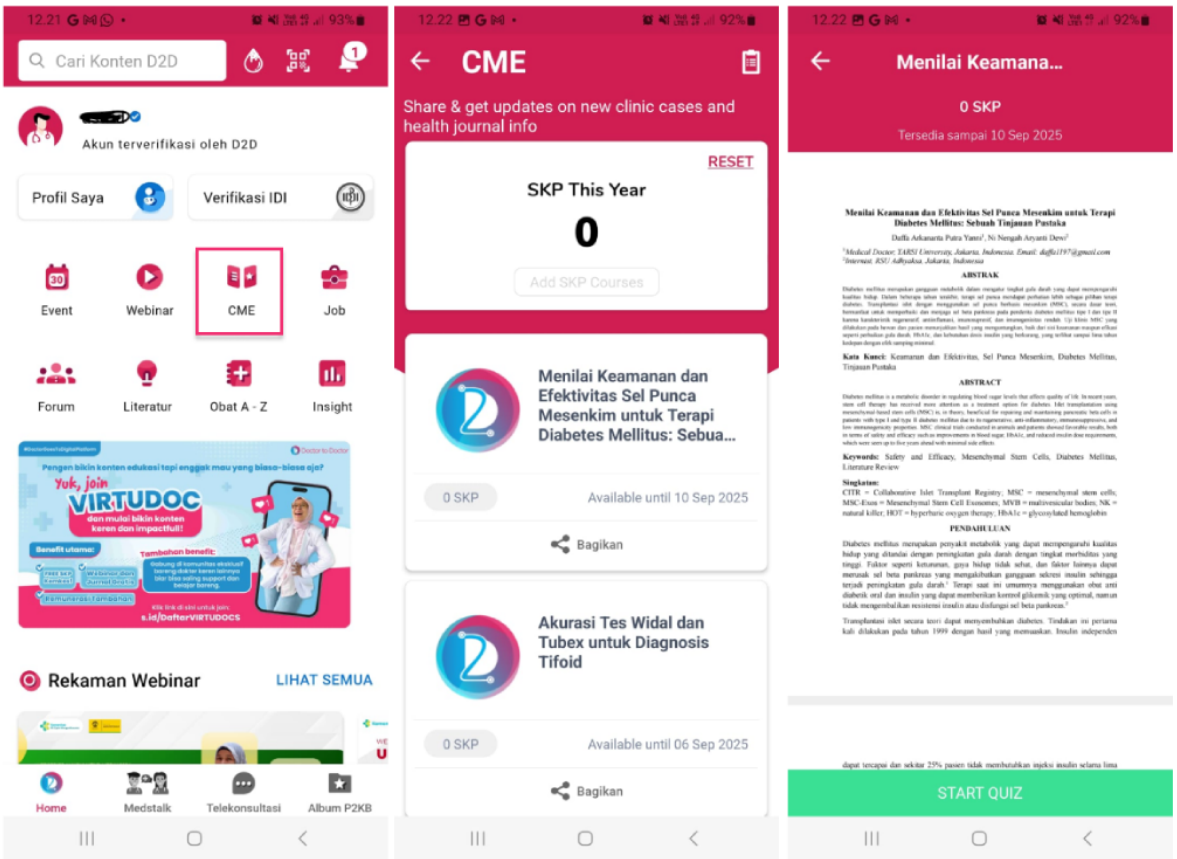

Figure 3. Webinar features of the Doctor-to-Doctor competitor.

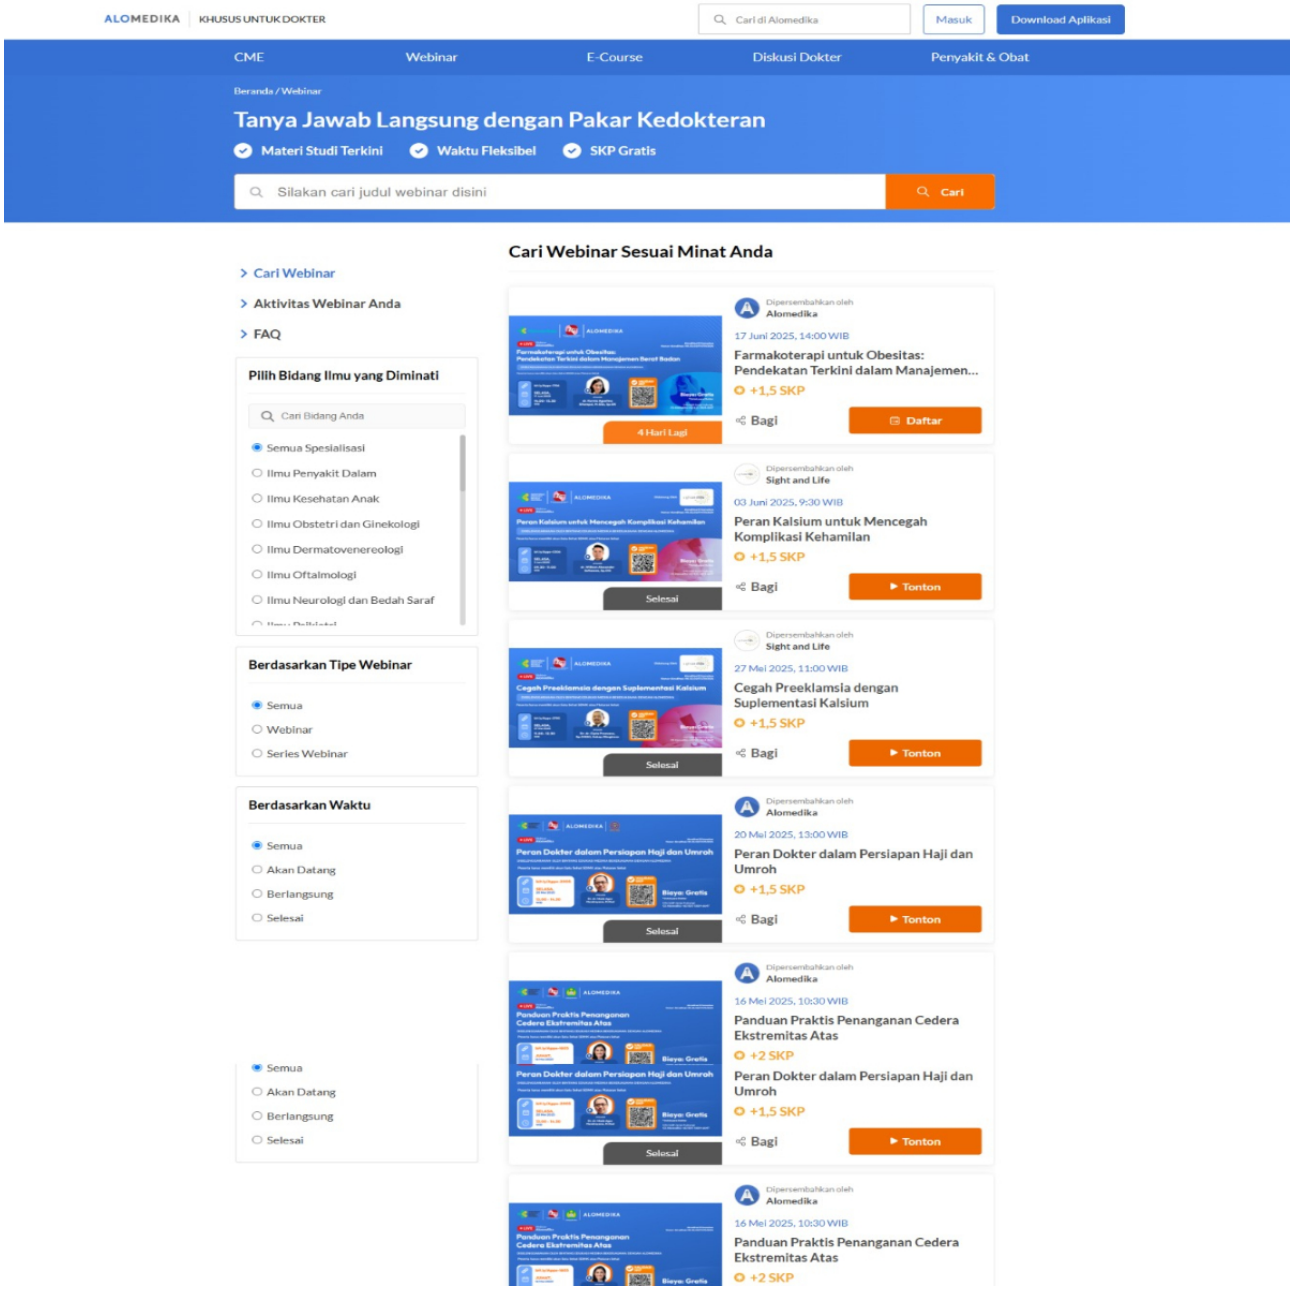


Objectives

In the context of e-learning, stickiness can also be affected by the emotions of the users when using an app, such as those that drive a user's decision to continue using or delete an app [13,14]. Moreover, the system performance of the mobile learning app plays an important role in user attachment, specifically in meeting user needs [9]. Thus, stickiness, which is related to both the user's emotions and the performance of the app, is an important benchmark for measuring the intensity of mobile learning use. However, research related to user stickiness is still focused on retail apps [6,15], massive open online courses [16-18], and fitness apps [9]. Therefore, this research sought to answer the following question: What factors affect health workers' stickiness regarding mobile learning apps? We used a web-based questionnaire and interviews to reach a large number of respondents and triangulated quantitative results with interview data to better understand the findings of this study. We formed the hypotheses underlying this study by analyzing the relationship between functional and experiential factors that could influence cognitive app relationship quality (CARQ) and emotional app relationship quality (EARQ), which influence app stickiness among users of mobile learning apps. The results of this study can provide guidance for mobile learning service providers to formulate strategies for improving stickiness rates.

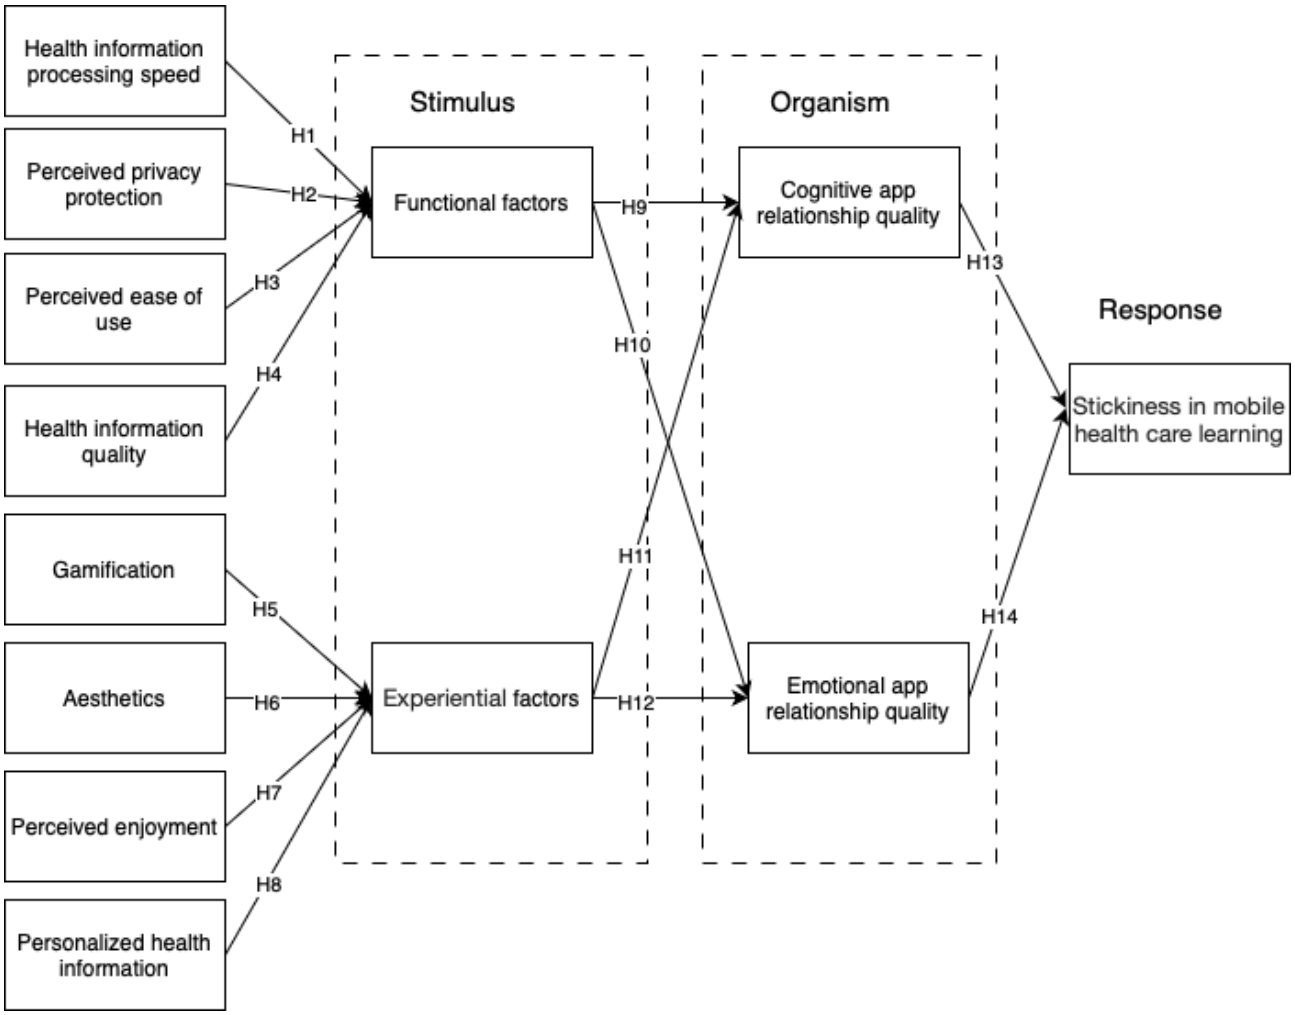
Methods

Research Model

This study's research model was based on the stimulus-organism-response theory [19] that explains the influence of a stimulus on the user assessment process and the relationship between the results of the individual assessment process and user habits [19]. The design of the proposed model

is referred to in multiple studies [6,13,20,21]. The selection of factors was adjusted to the scope of this study, namely, factors that affect user behavior regarding continuous use of an app (ie, user stickiness). This research focused on the theory of app relationship quality, namely, CARQ and EARQ, where the quality of the app relationship is driven by functional and emotional factors, respectively. Figure 4 shows the research model used in this study.

Figure 4. The proposed research model. H1 to H14: hypothesis 1 to hypothesis 14.



In this study, health information processing speed (HIPS) refers to the level of information processing speed in a given system [6]. This constitutes the ability of the system to process information, load pages, display content, or perform other functions [15]. The system speed is the speed at which a system can access information via an access link [22]. When an app can process user input or requests quickly and is able to present results without a delay, it becomes more convenient and efficient for users to carry out activities on the app [23]. Therefore, it can be concluded that the app response speed is one of the most important functional criteria for users of an information system. Indeed, Alnawas et al [6] mention that speed is one of the factors that affect product functionality. Thus, we propose the following hypothesis: HIPS influences functional factors in mobile learning performance assessment (hypothesis 1).

Perceived privacy protection (PPP) is defined as an app's ability to protect users' personal data [24]. This includes protection of data related to the users' browsing history and transaction history and other personal information [24]. On the other hand, PPP is also part of the security dimension of an app [6], and it can include the extent to which an app is able to protect users' personal data from unauthorized access by other parties [25]. Implementation of PPP can include notifying users that their personal data will not be shared with other parties [26]. Such implementation is also critical to preventing data problems caused by the unauthorized use of personal data [27]. Therefore, we propose the following hypothesis: PPP influences functional factors in mobile learning performance assessment (hypothesis 2).

Perceived ease of use (PEU) is defined as a user's assessment of an app based on its ease of use or performance [6]. PEU can also refer to the level of convenience that users feel when operating the app, such as not being confused when using or searching for information on the app for the first time [7]. The convenience that users feel will have a direct effect on their perception of the benefits obtained from the app [28]. The easier an app is to use, the greater the incentive for users to continue carrying out activities without feeling confused about the appearance or features [23]. Ease of use also reduces the time it takes for users to understand the app and its functionality and find solutions when facing problems with the app [25]. Previous research has shown that PEU has an influence on user

satisfaction and stickiness [29]. This is also supported by the work by Hsu and Tang [7], who included PEU in the top 5 factors considered to have the most influence on the user experience ratings of retail apps. PEU is also related to the functionality of an app as users prefer that an app be easy to operate—the app should be pleasing to use and should provide the requested information quickly and accurately [6]. Therefore, we propose the following hypothesis: PEU influences functional factors in mobile learning performance assessment (hypothesis 3).

Health information quality (HIQ) is defined as the level of information quality on an app, including the accuracy, reliability, clarity, and relevance of the content [29]. Such quality can be measured based on the speed at which the user reads the information and on the richness and reliability of the content (trusted sources) [29]. The content presented on an app must be informative and provide new insights to users [12]. Cognitive judgment is influenced by product functionality, an aspect of which is the ease with which users can find information [21]. In the context of mobile learning research, information is obviously a very important element in user learning [8]. The perceived usefulness (utilitarian benefit) of the information obtained during the learning process is the main focus of users of a given app [8]. Therefore, we formulate the following hypothesis: HIQ influences functional factors in mobile learning performance assessment (hypothesis 4).

Gamification is the implementation of game features in an app to increase motivation and interaction between users [13]. It can also refer to the adoption of a certain game design to influence self-awareness and individual behavior during the use of an app [13]. Gamification includes elements such as rewards or challenges that motivate users to continue interacting with an app [13]. Yang and Li [30] described the influence that gamification has on the user's experience and their decision to continue using a given mobile learning app. Aparicio et al [16] have similarly shown that gamification and personalization have a positive influence on the user app experience in massive open online courses. In the field of education, gamification features can encourage learners to become more involved in the learning process [16]. The adoption of gamification has been proven to encourage users to engage in more web-based learning activities, provide an enjoyable learning experience, and stimulate users to learn more [16,31]. Djohan et al [32] found that gamification also influences the user experience of an app. Hence, we propose the following hypothesis: gamification influences the experiential factors of the user's perceived experience of mobile learning (hypothesis 5).

Aesthetics, for the purposes of this study, are a perception produced by the visual appeal of an app through the selection of colors and illustrations, among other things [28]. Through the experience of visual beauty, aesthetics are indirectly able to attract the attention of users [33]. Aesthetics also provide immediate pleasure that is unrelated to the app's functionality or performance assessment [6]. According to Huang et al [33], users feel pleasure when they observe a beautiful app design display. What constitutes a beautiful display is influenced by a number of factors, including strategically arranged feature layouts, easy-to-reach search bar placement, feature placement design based on user need priorities, the use of unobtrusive colors and attractive icons, and the effective use of typography [24]. Huang et al [33] showed that the aesthetic value of an app has a significant influence on user experience. These findings are also supported by the work by Rose et al [34], who found that the aesthetic value of an app's display can affect the user's emotions while using the app. Therefore, we propose the following hypothesis: aesthetics influence the experiential factors of the user's perceived experience of mobile learning (hypothesis 6).

Perceived enjoyment (PE) is the user's perception of feeling happy or entertained or of enjoying the content or features provided by an app [7]. PE tends to be related to the user's emotions (eg, pleasure, happiness, and being entertained) while they are using the system. Pleasure or satisfaction in using an app is not determined by system performance alone but is more often influenced by the overall user experience [35]. On the basis of the work by Hsu and Tang [7], PE is one of the top 5 most important factors in creating a sticky app. The enjoyment that users feel can also increase interactivity when using an app [7]. Thus, we propose the following hypothesis: PE influences the experiential factors of the user's perceived experience of mobile learning (hypothesis 7).

Personalized health information (PHI) is a part of information personalization, the automatic provision of content based on user preferences and certain classifications [6,7]. Personalization refers to the app's ability to offer customized information, services, design, and content to meet user needs and preferences [36]. This helps users focus on what they want, determine the fitness of a product or service, and complete tasks efficiently [37]. Personalization provides customized content to improve the quality of the provided information and encourage users to complete certain tasks; personalization also encompasses user comfort [38]. The benefits offered by the adoption of personalization include the enjoyment that users feel [39], positive emotions [38], and feelings of joy [40]. Alnawas et al [6] found that personalization has a significant influence on the user experience. This is supported by the work by Cheng [13], who indicated that information personalization can affect the user experience and significantly affect the user's habit of using the app. Thus, we propose the following hypothesis: PHI influences the experiential factors of the user's perceived experience of mobile learning (hypothesis 8).

Functional factors are factors that directly affect the success of an app's performance [6]. Functionality is the main factor in evaluating the usefulness (ie, utilitarian benefit) of an app [41]. This is because app functionality influences the app's ability to help users achieve their goals safely and efficiently [6,41]. Cognitive assessment, the result of a comparison of expectations with app capabilities, can be conducted based on app functionality [7]. Wu [42] found that the main factor that significantly influences user engagement with an app is users' performance expectations. Therefore, we propose the following hypothesis: functional factors influence CARQ in the context of user assessment of the perceived usefulness of mobile learning (hypothesis 9).

Al-Nabhani et al [43] noted that functional factors also influence user satisfaction, which significantly affects users' emotions. The functionality of the app is another factor that users feel is related to their sense of pleasure or satisfaction with the app [44]. Responses related to the perception of emotions are called "judgment affective" responses and are related to EARQ [6]. Alnawas et al [6] state that a user's assessment of an app's functionality affects the emotional impact of a retail app, although not as strongly as its cognitive impact. Similarly, Molinillo et al [21] found that system functionality influences affective experience when using an app. Therefore, we propose the following hypothesis: functional factors influence EARQ in the context of user assessment of mobile learning based on emotional perception (hypothesis 10).

Experiential factors are defined as factors related to the user's subjective experience, including aspects such as perception, emotion, preferences, and user interaction with a product [6]. User experience can affect the sensation of using the app [23]. This refers to the psychological state experienced by users when evaluating the app, that is, the emotions felt while using the app [6]. Customer experience is subjective and contextual because it can differ among customers, cultures, and situations [32]. Each individual may have different feelings because their experience affects their assessment of the app [32]. Any emotions that users experience using an app generally affect the perception of pleasure and can encourage users to continue using the app [45]. Although user experience is not directly related to app performance, it affects the user's assessment of the usefulness of the system [6]. In this case, emotions become an important part of cognitive assessment, specifically related to processing the value of an experience, and can form the basis for a deep and intense relationship with the app [6]. User experience also significantly influences satisfaction and trust, to the point that experiences can form the basis for an emotional connection and a deep interest in a given product [6]. Thus, we suggest the following hypothesis: experiential factors influence CARQ in the context of user assessment of the perceived usefulness of mobile learning (hypothesis 11).

Experiential factors include users' emotions in relation to their assessment of the usefulness of an app [6]. Indeed, the emotions felt by users occur and are processed through human senses, especially those related to the appearance of the app [38]. User experience is the experience of users when they do something that involves them psychologically in activities requiring concentration, motivation, and enthusiasm [6,32]. This user experience includes aesthetic value, perception of pleasure (ie, enjoyment), and gamification [6,46]. Moreover, van Noort and van Reijmersdal [45] found that, if an app offers entertainment, it can produce a fairly good level of app performance satisfaction based on the user's emotional perception. User experience, derived from users' emotional assessments of a technology, plays a critical role in determining the use and benefits of the technology, including in the context of a mobile app [7]. Thus, we propose the following hypothesis: experiential factors influence EARQ in the context of user assessment of mobile learning based on emotional perception (hypothesis 12).

Alnawas et al [6] described how EARQ and CARQ affect the level of attachment of app users (ie, stickiness). Zolkepli et al [44] explained that this effect is related to differentiating user behavior based on feelings (affective) and thoughts (cognitive). Cognitive assessment is based on rational thinking, so it is more changeable and vulnerable to external influences such as other people's opinions [47]. The cognitive assessment of apps is usually related to the ease with which users can find factual information in accordance with their needs [48]. A relationship based on CARQ emphasizes analysis of the benefits obtained by the user, so it is necessary to conduct periodic evaluations of the usefulness of the available features [47]. In addition, it has been proven that user satisfaction with app performance—in the context of utilitarian benefits—positively affects the intensity of use of mobile apps [6]. Thus, both the quality of the app's performance and its emotional approach to the user experience can influence the user's desire to invest time and effort in using the app [49]. Therefore, we propose the following hypothesis: CARQ influences stickiness in mobile learning apps and determines the intensity of daily use (hypothesis 13).

Behaviors based on feelings tend to be more subjective because they relate to aspects of positive or negative judgment, whereas behaviors based on thoughts tend to be more objective and relate to notions of right or wrong [44]. As responses that arise due to feelings or emotions tend to be more subjective, it is quite difficult to change affective perceptions [21]. Emotional perceptions experienced while using mobile learning apps greatly affects app access intensity during the web-based learning process [13]. Perceptions that increase the duration of app access generally tend to be positive, such as feeling happy and entertained and enjoying using the app [50]. Nyffenegger et al [51] stated that user attachment to an app can be reflected through satisfaction and trust built based on the intensity of app use. User engagement with the app is the result of user assessments based on experience (ie, affective experience) [21]. Affective judgment is judgment based on the feelings of an individual, which makes influence by external forces more difficult [48]. Decisions based on experience are difficult to change as they shape individual beliefs and perceptions, including the use of apps [48]. Fernandes and Proença [47] explained that, when attitudes are dominated by feelings, individuals tend to behave habitually, making those feelings resistant to change and resulting in a much stronger response compared to attitudes based purely on rational thinking. Thus, we propose the following hypothesis: EARQ influences stickiness in mobile learning apps and determines the intensity of daily use (hypothesis 14).

Research Process

We used a quantitative approach to test the hypotheses and a qualitative approach to more deeply analyze the results of the hypothesis testing. An online questionnaire was used as a quantitative research instrument, and interviews were used to collect qualitative data. The focus of this study was on mobile learning, namely, the D2D app. We used purposive sampling, where all respondents involved in this study were D2D users—physicians, dentists, specialists, and medical students (eg, coassistants, residents, dental students, and medical undergraduate students). Furthermore, we asked the D2D company to help distribute the questionnaire links through push notifications on the D2D app. We also used social media

platforms such as WhatsApp, X (formerly known as Twitter), and Instagram, which are popular in Indonesia, to reach more health care workers.

We conducted a readability test on the questionnaire to ensure that the research instrument was easily understandable, in accordance with writing standards, and relevant to the context of the research. The readability test was carried out from February 1, 2024, to February 7, 2024. In total, 6 respondents participated in the readability test process. Most of the changes after the readability test were made due to ambiguous word choice or unclear syntax. After the readability test, a pilot study was conducted to test the reliability of the research instrument.

The pilot study was conducted to find whether participants experienced problems filling out the questionnaire before it was disseminated to more participants. The pilot study was conducted from February 19, 2024, to February 23, 2024, with a total of 50 respondents. The total Cronbach α value obtained in the pilot study was 0.981; thus, we distributed the questionnaire link to a larger number of respondents. Finally, based on the results of the quantitative analysis, hypotheses 2, 3, 6, 7, 8, and 12 were rejected. We used a qualitative instrument (semistructured interviews) to determine the reason for these rejections and obtain a deeper understanding of the results. Online and offline interviews were conducted with 15 respondents.

Research Instruments

The web-based questionnaire included demographic questions and measurement items. The preparation of the measurement items was carried out with reference to previous research, such as the studies by Alnawas et al [6], Chen et al [8], Cheng [13], Hsu and Chen [52], Huang et al [33], Elsotouhy et al [9], and Yang et al [53], and contextualized for this study, namely, mobile learning in health care. To make it easier for respondents to fill out the questionnaire, we translated the measurement items in Indonesian and tested them by conducting readability tests and pilot studies to ensure that respondents could understand the questionnaire. Each measurement item was given a code according to the variables it represented to make it easier to process the data. The assessment of the measurement items was then carried out using a 5-point Likert scale that included options ranging from “strongly disagree” to “strongly agree.” Multimedia Appendix 1 contains the questionnaire instrument and the 13 interview questions. We defined the interview questions according to the variables used in this study. The results of the questionnaire were analyzed using covariance-based structural equation modeling in SPSS Amos (version 24; IBM Corp).

In addition, the qualitative data were analyzed using content analysis. The results of the semistructured interviews were interpreted and linked to the hypotheses identified during the quantitative data analysis stage. The qualitative codification process was carried out using interview quotes that were grouped according to the specific hypotheses. Multimedia Appendix 1 provides the details of the qualitative results. An example of the codification results can be found in the Qualitative Results and Validity of Hypothesis Testing section.

Ethical Considerations

This study received approval from the research unit of the Faculty of Computer Science, University of Indonesia (reference S-17/UN2.F11.D1.5/PPM.00.00/2024). In line with university policy, the Research and Community Service Department, Faculty of Computer Science, University of Indonesia, adhered to the guidelines and procedures established by the faculty and provided ethics approval for this study. This study was also approved by the D2D company (reference 761/GUE/IX/2024/E). All respondent data were anonymized, all questionnaire respondents provided written informed consent, and all the interview participants provided verbal informed consent to take part in this study. Participants did not receive compensation.

Results

Quantitative Results

Respondents’ Demographics

Data collection for the primary study was carried out for approximately 25 days, from February 29, 2024, to March 21, 2024. The number of respondents who filled out the complete questionnaire was 520, which fulfills the requirements by Hair et al [54], where the minimum number of respondents required is the number of measurement items multiplied by 10. Detailed respondent demographic characteristics are shown in Table 1, and Table 2 shows the demographic characteristics of the interviewees. The interviews lasted between 30 and 60 minutes and took place between April 19, 2024, and April 27, 2024.

Table 1. Questionnaire respondents' demographic characteristics (N=520).

Variable	Respondents, n (%)
Gender	
Woman	311 (59.8)
Man	209 (40.2)
Age (y)	
<20	3 (0.6)
20-30	206 (39.6)
31-40	132 (25.4)
41-50	96 (18.5)
>50	83 (16)
Domicile	
Greater Jakarta	280 (53.8)
Java island outside Greater Jakarta	103 (19.8)
Outside Java island	137 (26.3)
Occupation	
General practitioner	358 (68.8)
Specialist	59 (11.3)
Dentist	4 (0.8)
Coassistant	46 (8.8)
Resident	7 (1.3)
Dental student	6 (1.2)
Medical undergraduate student	40 (7.7)
D2D[a] app use period (mo)	
<6	97 (18.7)
6-12	94 (18.1)
13-24	131 (25.2)
>24	198 (38.1)

[a]D2D: Doctor-to-Doctor.

Table 2. Summary of the interviewees' demographic characteristics.

Respondent	Gender	Age (y)	Occupation
1	Woman	23	General practitioner
2	Woman	25	General practitioner
3	Woman	23	Dentist coassistant
4	Man	23	Coassistant
5	Woman	19	Medical student
6	Man	24	General practitioner
7	Woman	23	General practitioner
8	Woman	23	Dentist coassistant
9	Man	25	General practitioner
10	Woman	20	Medical student
11	Woman	24	General practitioner
12	Woman	36	General practitioner
13	Woman	24	General practitioner
14	Man	19	Medical student
15	Man	19	Medical student

Measurement and Structural Model Testing

The average variance extracted (AVE) value is obtained from the sum of the squares of the values of the factor loadings of each indicator divided by the sum of the squares of the values of the factor loadings of each indicator, and this is added to the total measurement error of all indicators on one variable [55]. The AVE value of a variable is declared valid if it is >0.5 [54,55]. On the basis of the results, all variables in the research model passed the AVE value test (Table 3). The reliability test stage was carried out by checking the value of the composite reliability on each latent variable. The composite reliability of each latent variable is said to be valid if it has a value of >0.7 [54]. On the basis of the results shown in Table 3, all latent variables in this study passed the reliability test.

Table 3. Average variance extracted (AVE) and composite reliability (CR) test results.

Variables	CR	AVE
Stickiness in mobile learning	0.736	0.583
Cognitive app relationship quality	0.79	0.654
Emotional app relationship quality	0.991	0.983
Functional factors	0.99	0.979
Experiential factors	0.752	0.603
Health information processing speed	0.718	0.561
Perceived privacy protection	0.838	0.72
Perceived ease of use	0.989	0.979
Health information quality	0.739	0.588
Gamification	0.802	0.67
Aesthetics	0.849	0.585
Perceived enjoyment	0.814	0.687
Personalized health information	0.857	0.601

Hypothesis Testing

After the research model passed the validity and reliability tests, the next step was to check the goodness of fit (GOF) of the model. The GOF test consists of absolute fit indexes, incremental fit indexes, and parsimony fit indexes. Absolute fit indexes determine model compatibility by checking the values of the root mean square residual, GOF index, adjusted GOF index, and root mean square error of approximation. Incremental fit indexes are tests of normed fit index, comparative fit index, and Tucker-Lewis index values. Meanwhile, parsimony fit

indexes test the parsimonious normed fit index. The results of the GOF test are shown in Table 4.

The determination coefficient test was carried out to determine how well the endogenous variables simultaneously explained the exogenous variables [54]. The determination coefficient, which ranges from 0 to 1, is calculated from the square of the correlation (R^2) between its dependent and independent variables [54]. The R^2 value is categorized as strong if it is >0.67, moderate if it is between 0.33 and 0.67, and weak if it is >0.19 but <0.33 [54]. The results of the determination coefficient test are shown in Table 5.

In this study, we used a 2-tailed hypothesis test. If the *P* value was <.05, then the hypothesis was accepted; if the *P* value was >.05, the hypothesis was rejected [54]. The results of the hypothesis test are shown in Table 6.

Table 4. Goodness-of-fit test results.

Test	Requirement	Result	Description
Chi-square	>0.05	315.5	Good fit
Chi-square divided by *df*	<2.0	1.024	Good fit
Goodness-of-fit index	>0.9	0.949	Good fit
Root mean square error of approximation	≤0.08	0.008	Good fit
Root mean square residual	≤0.05	0.02	Good fit
Normed fit index	≥0.9	0.943	Good fit
Relative fit index	≥0.9	0.92	Good fit
Tucker-Lewis index	≥0.9	0.998	Good fit
Comparative fit index	≥0.9	0.999	Good fit
Parsimonious normed fit index	0-1	0.668	Good fit
Adjusted goodness-of-fit index	≥0.9	0.923	Good fit

Table 5. Results of the determination coefficient test (R2).

Variables	R^2 value	Description
Experiential factors	0.342	Moderate
Functional factors	0.201	Weak
Emotional app relationship quality	0.170	Weak
Cognitive app relationship quality	0.287	Weak
Stickiness in mobile learning	0.421	Moderate

Table 6. Hypothesis test results. The arrows represent the direction of influence.

Hypothesis	Estimate	*P* value	Result
Hypothesis 1: HIPS[a] →FFs[b]	0.282	.01	Accepted
Hypothesis 2: PPP[c]→FFs	0.055	.58	Rejected
Hypothesis 3: PEU[d]→FFs	−0.036	.49	Rejected
Hypothesis 4: HIQ[e]→FFs	0.177	.04	Accepted
Hypothesis 5: GM[f]→EFs[g]	0.337	.005	Accepted
Hypothesis 6: AE[h]→EFs	0.214	.07	Rejected
Hypothesis 7: PE[i]→EFs	0.081	.43	Rejected
Hypothesis 8: PHI[j]→EFs	0.071	.55	Rejected
Hypothesis 9: FFs→CARQ[k]	0.343	.006	Accepted
Hypothesis 10: FFs→EARQ[l]	0.505	.003	Accepted
Hypothesis 11: EFs→CARQ	0.143	.003	Accepted
Hypothesis 12: EFs→EARQ	0.102	.11	Rejected
Hypothesis 13: CARQ→SHL[m]	0.412	.01	Accepted
Hypothesis 14: EARQ→SHL	0.416	.004	Accepted

[k]EARQ: emotional app relationship quality.
[l]CARQ: cognitive app relationship quality.
[m]SHL: stickiness in mobile learning.

Qualitative Results and Validity of Hypothesis Testing

Hypothesis 1: HIPS and Functional Factors

This study showed that health information processing has an influence on functional factors (hypothesis 1). This is in accordance with the results of previous research related to the effect of stickiness on retail mobile apps, where information processing speed significantly affects app performance (functional factor) [6]. This is also supported by the work by Hsu and Tang [7], who found that response speed in an app is an important indicator of app functionality in terms of responsiveness. In health app studies, speed has an influence on the user's attachment and decision to continue using those apps [9]. In the context of mobile learning by medical students, the speed of information processing plays an important role in facilitating a more efficient learning process, allowing students to receive information faster, thereby reducing the possibility of misunderstandings in the interpretation of learning materials [1].

The results of the interviews showed that interviewees agreed that the speed of information processing was an important part of the functionality of the app—the app should be fast and meet user expectations:

> *The response speed of the app is very good and fast. There are no obstacles in accessing all the features in the D2D app.* [Respondent 1]

On the other hand, users were also happy if the presentation of the information was fast and occurred without advertisements:

> *Yes, it has to be fast and not load without ads.* [Respondent 4]

However, from the users' perspective, there were network constraints that sometimes made it difficult to access information or content on the mobile learning app:

> *...Never have experienced a loading failure on the app page or GT error. Most of all, what I have told you is that the network in my area is bad.* [Respondent 2]

Hypothesis 2: PPP and Functional Factors

PPP did not influence functional factors in this study (hypothesis 2). According to the *Harvard Business Review* [56], PPP is not a priority for users—because users are in a hurry to use the app, they do not pay much attention to the security aspect of personal data [56]. On the basis of the results of the interviews, there is a growing sense that users' trust in the app's ability to keep personal data secure does not affect their assessment of the app's functionality:

> *...Honestly, the functionality is more of a process to create a password and verify it is not complicated, which makes it easier for users. For data security, it's more about creating a sense of trust in users.* [Respondent 13]

Regarding the protection of personal data, users trusted the app more when it partnered with a trusted organization than when the capabilities of the security system were invisible in the user interface:

> *As long as the app is already partnering with a trusted organization.* [Respondent 8]

However, users also wanted the appearance and flow of the app to remain easy to understand even when there was a process of verification and password reset, which is generally considered to require more steps for security:

> *I think yes, the more requests the better. But on the other hand, I became very lazy because the process was too complicated.* [Respondent 4]

PPP plays a greater role in influencing user trust in the app. Although keeping personal data secure often involves a time-consuming process, users preferred simpler and faster verification processes and security settings.

Hypothesis 3: PEU and Functional Factors

In contrast with the study by Alnawas et al [6], this study showed that PEU has no significant effect on functional factors (hypothesis 3). This hypothesis was rejected because users are often not proficient in using the information system provided by the app. This finding is supported by respondents' answers regarding the main obstacles they encountered when accessing the app, namely, time limitations and a busy practice schedule, which were mentioned by 69.4% (361/520) of the respondents. According to Smith [57], PEU also has no effect on the assessment of system performance because users find it difficult to locate information that matches their preferences. This is further supported by the work by Rakhmadian et al [58], who found that users become unhappy if they only have limited access to the information provided by the system. According to the findings of the interviews, users experienced constraints and limitations in feature functionality when using mobile learning. First, users found it difficult to navigate the account verification and registration processes. Second, users often felt that notifications that suddenly appeared during the use of the app were somewhat annoying:

> *Sudden updates are often confusing.* [Respondent 10]

Third, users found it difficult to begin working within the app because there were often sudden account log-ins and exits that forced them to re-enter their medical ID number:

> *I have trouble quite often. Suddenly, go out and go in again. Suddenly, log out and log in to the account again.* [Respondent 12]

Hypothesis 4: HIQ and Functional Factors

The results of this study showed that HIQ has an influence on functional factors (hypothesis 4). This is also supported by the work by Elsotouhy et al [9], who stated that information quality, which is the result of a comparison between expectations and user perceptions of the presented information, is an indicator of functional factors. The quality of the information also determines the adequacy, relevance, thoroughness, and timeliness of user interpretation [59]. In a study of user stickiness regarding mobile news apps, it was found that the information quality affects the satisfaction and attachment of app users [29].

According to the interviewees, the existence of reliable references and sources can minimize misunderstandings or the spread of hoaxes:

> *...minimizing misunderstandings of hoax information because the source of information is not detailed and clear.* [Respondent 2]

Interview respondents were also happy with the information presented via D2D because it included references, clear titles, trusted speakers, and rewards such as certificates after completing a webinar. However, some interviewees mentioned shortcomings regarding the content presented on the app (eg, the health journal content was not as complete as on the journal's website: "...less complete than those available on the journal website" [Respondent 1]). In addition, it was also rare to find health articles written by physicians on the app:

> *Unfortunately in D2D, not all doctors are authors. Unfortunately, there are no results of doctors' research in D2D.* [Respondent 5]

This is in line with the work by Yang et al [53], who noted that the quality of the information affects system performance and user stickiness.

Hypothesis 5: Gamification and Experiential Factors

This study found that gamification has an influence on experiential factors (hypothesis 5). This result is in line with the work by Cheng [13], who described how gamification plays a role in the learning process and significantly affects the user experience, thus impacting emotional attachment to an app (EARQ). Gamification features of web-based learning include reward elements and leaderboards to encourage learners to participate [24]. In research related to stickiness in retail apps, gamification is an important element in attracting users and retaining app use [7]. Another study found that gamification has a high influence on experiential factors in mobile commerce apps [32].

The results of the interviews showed that gamification made using the app more fun:

> *It feels like a learning app with a gamification feature makes it fun and exciting. The collection of program points or SKP points is one of the motivations for me to access webinars or learn apps.* [Respondent 1]

However, it was unfortunate that the gamification in the D2D app focused more on the SKP point collection program. This did not incentivize users with medical student or dental student profiles to join the app program because they had no need to obtain SKP points:

> *Never made, because there is no need yet.* [Respondent 3]

In addition, physicians who still have internship status even though they have obtained a registration certificate as a physician cannot participate in the program:

> *Currently, there is no need to use SKP points because they are still using Internship [points]*. [Respondent 9]

Even so, gamification is an interesting feature of this mobile learning app because it presents a dashboard that is significantly more informative than that of its competitors:

> *I think this is one of the main factors for using D2D. Unlike the next app, which only tracks the number of SKP points—it cannot collect SKP points.* [Respondent 6]

Hypothesis 6: Aesthetics and Experiential Factors

This study found that aesthetics have no significant effect on experiential factors (hypothesis 6). This result is in contrast to those of Alnawas et al [6], who found a significant relationship between aesthetics and experiential factors in retail apps. Zhou [59], whose results also contrasted with those of Alnawas et al [6], noted that design trends are dynamic, which affects users' aesthetic preferences regarding a website's (also dynamic) appearance. This is also supported by the work by Chen et al [8]—an increased number of target users of an app can affect subjective judgments related to the appearance of the app interface. As demonstrated by the demographic results, this mobile learning app has a diverse target user pool that includes general practitioners, specialists, dentists, medical students, dental students, coassistants, and residents. Thus, hypothesis 6 was rejected due to the variety of app user personas, which leads to many subjective judgments related to the visual assessment of the app.

Most interviewees stated that, when making decisions about using a product, the visual appearance or aesthetic aspect of the product is an important factor that is based on subjective interest:

> *I think it's very important, if I am not attracted to it from the beginning, I'm lazy to open it again.* [Respondent 5]

However, the interviews also showed that the color selection in the mobile learning app is still too striking:

> *...don't use the color of the ring.* [Respondent 2]

In addition, it was found that the text displayed by the mobile learning app was too small, so it was difficult to read:

> *The selection of the size of the text is too small.* [Respondent 15]

Moreover, some users suggested emphasizing the app's superior features, namely, medical discussions, so that users are more interested in participating in them:

> *If possible, the superior features that are emphasized in the medical discussion so that it can be more interactive between users.* [Respondent 12]

Other users suggested adding animation elements, such as a mascot, to create a lively atmosphere on the app:

> *My suggestion is adding a mascot or other animation to make it interesting.* [Respondent 5]

Finally, users indicated that they expected periodic design improvements to prevent them from getting bored with the appearance:

> *...The design is also always updated so that you don't get bored.* [Respondent 15]

The interviews indicated that there are many possible improvements to the appearance of the app that the development team can consider. This reinforces the statement by Zhou [59] that it is necessary to continuously improve the appearance of an app. The appearance of the mobile learning interface should also be tailored to user preferences [17]. Recommendations for mobile learning service providers include evaluating the app design using more comprehensive methods such as heuristic evaluation or user experience design.

Hypothesis 7: PE and Experiential Factors

PE had no significant effect on experiential factors in this study (hypothesis 7). The interviews showed that users did not feel much enjoyment during the learning process on the D2D app; they accessed the app with clear goals in mind, such as obtaining the required SKP points or accessing the latest health information:

> *It's normal. Enjoy it, I access the app to read discussions, literature, forums.* [Respondent 9]

Due to the similarity of the features and the flow of the process of using the app, users can become accustomed to or feel bored by it:

> *It's actually normal because almost all learning apps have a similar flow, so it's just normal to me.* [Respondent 7]

The interviews revealed that users have different perceptions when using mobile learning apps and when using social media apps. They tend to use mobile learning apps for the purpose of learning, whereas social media apps are used for entertainment. Finally, enjoyment related to using the app was found to be influenced by the interactions between users within the app:

> *In addition, there are still few doctors, and the webinar is very interesting. But the interaction between fellow doctors is lacking.* [Respondent 12]

The interviews showed that interaction between users is still quite minimal, especially via the discussion feature. To further

encourage users to learn, the development team might consider including gamification within the app [13].

Hypothesis 8: PHI and Experiential Factors

PHI had no significant effect on experiential factors in this study (hypothesis 8). These results are not in accordance with those of either Alnawas et al [6] or Hsu and Tang [7]; the latter stated that personalization significantly affects experiential factors. Information personalization is important because it connects the app user with the information provided on the app in accordance with the needs and interests of the user [29].

On the basis of the interviews, if the app's content is in accordance with users' needs and preferences, it will have an impact on the intensity of use:

> *From me, it is certain, because it is according to my needs, and I will continue to access it.* [Respondent 2]

In addition, users with student profiles noted having difficulty finding health information, journals, and webinars aimed at students:

> *I think it is still lacking because I want D2D to be able to categorize the material. If it can be divided by topic according to the station, it can be a children's station, so I can use it more comfortably.* [Respondent 4]

The interviews highlight the disappointment of respondents regarding the suboptimal implementation of personalization. Currently, D2D stores only users' work profiles, and the app has not optimized content personalization. Finally, it is important to remember that, when implementing personalization, it is necessary to consider the user's privacy and ensure that previous approval is granted [60].

Hypothesis 9: Functional Factors and CARQ

This study showed that functional factors do not have a significant influence on CARQ (hypothesis 9). This is in contrast to the work by Alnawas et al [6]. According to Zhampeissova et al [61], offering too many features or too much information via mobile learning increases the user's cognitive process load. Therefore, even if the system's ability to present information is very good, too much variety of that information can distract users from learning [18]. Wilmer et al [62] explained that users' attention when accessing mobile apps is generally diverted by additional features, resulting in a distraction from the users' original purpose. Wardaszko and Podgórski [63] stated that the success of cognitive processes is not entirely influenced by the success of the implementation of mobile learning. This is because each individual has different learning styles and cognitive needs, so a given app functionality may be beneficial for certain groups but not for others [63].

In the context of mobile learning, the interviews showed that users accessed the app with a clear purpose of obtaining the latest medical information:

> *I still need to find a reliable place or platform that can support my learning needs.* [Respondent 7]

However, users felt that the material provided to support their cognitive needs was unsuitable:

> *...But unfortunately, it is still rare for information for dentists.* [Respondent 3]

In addition, it is known that users obtain information in various ways, such as by reading various platforms, by preparing for an examination, and through videos:

> *To be honest, I cannot learn at this time from only this one platform, because my type of learning has to read as much as possible to understand better.* [Respondent 7]

Finally, the interviews made clear that users focus more on utilitarian benefits that can be felt directly, such as features that support learning, the collection of SKP points, the quality of the articles and medical information, and the speed of information processing:

> *Personally, I prioritize the usefulness of the app over the user experience.* [Respondent 14]

The interviews support that the functionality of the app does not have much effect on the cognitive process because what the user focuses on is the usefulness of the information to support the learning process. This is in line with the work by Cheng [13], who argued that information personalization is a very important part of directing users toward progress in the learning process.

Hypothesis 10: Functional Factors and EARQ

This study showed that functional factors affect EARQ (hypothesis 10). Previous research has shown that functional factors affect the emotions felt by users when using retail apps [6]. Furthermore, if the service provider focuses on achieving ease of operation and high performance, this affects the user's emotions and attitude toward using the app [47]. Chen et al [8] explained that technological capabilities, which implicitly include system performance, have a significant impact on the level of satisfaction with the use of technology in the web-based learning process. Good app performance capabilities, such as information processing speed, can make users feel satisfied and happy because they feel that the app is useful [44]. On the basis of the interviews, the emotions felt by users due to the quality of the app's functionality significantly affected their decisions regarding continued app use:

> *...The better the functionality of the app, the more it will meet my expectations, which has an impact on me being happy and likely to keep the app.* [Respondent 15]

Hypothesis 11: Experiential Factors and CARQ

Experiential factors affected CARQ in this study (hypothesis 11). In the context of mobile commerce, user experience has a significant influence on the level of ease of use when operating the app features [8]. Experiential factors are also related to the ease of information collection, which is one of the utilitarian benefits [6]. Dastane and Haba [17] explained that experiential factors can influence a user's perception of the benefits of the available features either directly or indirectly. Interviewees agreed that the appearance of the app affects the user's level of

trust and their perception of the process of obtaining information:

> *On the other hand, a good user experience can also make it easier for users to use their features and find information more easily.* [Respondent 10]

The experience provided by the app also affects the user's decision to continue using it:

> *Of course I will move to another one also if it looks bad.* [Respondent 9]

User considerations in the context of mobile learning still include utilitarianism and the experience provided:

> *But still in terms of performance, you also have to look at the performance of the app, at least not very slow, it's still okay for me to use it.* [Respondent 11]

One of the insights obtained from the interviews is that, if the app provides a suboptimal user experience but the features have a high benefit value, users will still use the platform. However, if a competitor is able to present similar features with a better user experience, users are more likely to switch to them.

Hypothesis 12: Experiential Factors and EARQ

Experiential factors were found to affect EARQ in this study (hypothesis 12). Alnawas et al [6] explained that user experience has a significant influence on the relationship between app quality and the emotional judgment of retail app users. Experiential factors also influence the users' emotions because they provide hedonistic benefits [43]. Improving the user experience is one way to shape the interaction between users and apps; user responses to interacting with an app or service can include emotions, perceptions, preferences, behaviors, and enjoyment [7]. The user experience then affects pleasure during purchasing activities and can encourage users to engage with the app [45]. The interviews showed that a good user experience on the app affects feelings of happiness when using it. Users will also be more interested in using the app if the experience is memorable:

> *But on the other hand, they will be more interested if the app has good coloring and a cute design.* [Respondent 4]

In addition, users will also have increased trust in apps that have a good design:

> *The experience on the app also affects me, so I have more trust in the app.* [Respondent 7]

Hypothesis 13: CARQ and Stickiness in Mobile Learning

This study found that there is a relationship between CARQ and stickiness in mobile learning in health care (hypothesis 13). This result is in accordance with previous research showing that CARQ has a significant influence on stickiness in retail apps [6]. In the context of mobile commerce apps, the results of previous research have shown that the cognitive relationship with apps affects user experience, such as satisfaction levels, and this satisfaction affects the user's desire to use apps in the future [34,64]. The cognitive relationship dimension includes the ease of searching for information [64] and the ease of efficiently purchasing goods [34]. In addition, CARQ has been proven to have a significant effect on learning persistence in the context of the web-based learning process using massive open online courses [13,65].

The interviews showed that one of the drivers of using the app continuously was users' desire to obtain the latest medical information:

> *In my opinion, if from me, the cognitive desire that I usually feel for the learning app is to get new information in the world of health.* [Respondent 14]

The ability of features to meet user needs also greatly affected the satisfaction that users felt and the intensity of their app use:

> *So if the app I consider not to provide benefits for me, yes, I also rarely have access intensity.* [Respondent 13]

However, there were also external factors that affected the intensity of app use, such as busy schedules or poor mobile network quality.

Hypothesis 14: EARQ and Stickiness in Mobile Learning

Finally, this study discovered a relationship between EARQ and stickiness in mobile learning (hypothesis 14). In retail app research, it is known that EARQ has a significant effect on user stickiness [6]. The user's decision to use an app is influenced by the level of emotional satisfaction that they feel [66]. Similar findings were obtained in the study by Souiden et al [67]. In understanding the decision-making process of retail app users, it is important to consider how users feel when shopping in both offline and online stores. In the context of mobile learning, learners' emotional involvement can positively influence their intention to continue using web-based courses [21]. Zolkepli et al [44] stated that the emotions felt when using an app are affective responses that can be positive or negative and affect the intensity of app use. The emotions felt during app use were found to be related to the user's desire to continue to use the app regularly:

> *The feeling I felt while using the D2D app for learning is happy, because the health information provided is quite complete in the app, so it makes me want to continue using the app.* [Respondent 15]

The sense of pleasure obtained from the experience encouraged users to become more willing to use the app:

> *I think maybe yes because I'm already happy, so I should at least be willing to use the app.* [Respondent 7]

Discussion

Principal Findings

This study showed that the cognitive and emotional connections with an app affect user stickiness in mobile learning. The user's EARQ is positively influenced by the performance of the app (functional factors) and the user experience (experiential factors), whereas the CARQ is influenced by user experience factors (experiential factors). App performance can affect emotional assessments triggered by feelings that arise when using apps (hedonic benefits), resulting in subjective

assessments. However, the experience that users have when using the app (experiential factors) has an effect on their emotions or feelings. In addition, user experience has an impact on cognitive assessments related to the ease of app use.

This study provides an overview of the influence of the relationship between app relationship quality, namely, EARQ and CARQ, and stickiness in mobile learning. In this study, the organismic variables are EARQ and CARQ, which represent the process of user assessment of app relationship quality [6,13]. EARQ was found to have a greater effect on stickiness in mobile learning apps than CARQ. The emotions felt during the use of an app were found to be related to the user's desire to continue using the app regularly, and the sense of pleasure obtained from the experience encouraged users to become more dependent on using the app. This is relevant to the results of previous research where, in retail apps, users were more inclined to build affective or emotional-quality relationships than cognitive-quality relationships [6,21]. The results of this study are relevant to the work by Alnawas et al [6] on retail apps, in which the relationship between CARQ and EARQ was found to affect user stickiness. Previous mobile learning research has produced similar results—cognitive and emotional connections were proven to affect users' desire to continue using apps in the web-based learning process [21]. However, this study showed that functional factors have no effect on CARQ. This is because the app provides diverse information without factoring in users' information needs.

Mobile learning service providers can use the results of this study to continue to develop features that improve user stickiness in mobile learning. Service providers must pay attention to app quality based on cognitive and emotional aspects when developing features in mobile learning apps. In addition to the usefulness of features, the experience of using the mobile learning app is an important aspect in encouraging ongoing user dependence. Service providers can improve the quality of mobile learning app functionality by focusing on several important aspects, especially the processing speed and quality of the information presented. Processing speed is a critical factor that affects the user experience as responsive and fast apps can improve user satisfaction and efficiency. In addition, the information presented in the mobile learning app must be accurate, relevant, and easily accessible to users. Quality information will help mobile learning app users make better decisions and increase trust in the app. Thus, improvements in these two aspects are expected to encourage user stickiness and ensure sustainable use of mobile learning apps.

Mobile learning service providers can improve the app's security in the context of personal data protection. To accomplish this, they can present the terms and conditions of the app and privacy policy in a clear and easy-to-understand manner. The purpose of this step is to show the seriousness of the mobile learning service provider regarding safeguarding users' personal data and building trust with users. In addition, mobile learning service providers can educate users on how to protect their personal data. This education can include instructions not to provide information to unknown parties and on maintaining the confidentiality of personal data.

Furthermore, mobile learning service providers can implement personalized content recommendations and health information tailored to mobile learning users' interests and information needs. This recommendation feature can be realized by using data on the user's profession. However, it is important to note that mobile learning user data are confidential and should be protected under the data privacy policy. Important components to consider in the implementation of this feature include effective communication, transparency, engagement, and an attractive value proposition. To increase user enjoyment and interaction during the learning process, mobile learning service providers can improve the gamification features on their apps. This can be accomplished by adopting several game elements, such as missions, rewards, dashboard rankings, and leveling. In addition, gamification provides a good user experience by supporting the learning process and increasing learning persistence.

Because most D2D app users are physicians, there are several external factors that affect the duration of app access. On the basis of the questionnaire, the biggest obstacle was limited time due to a full practice schedule (361/1120, 32.23%). This was also supported by most respondents providing more than one answer related to the location of their practice, the most common being physicians practicing in clinics (267/649, 41.1%), hospitals (117/649, 18%), and private practices (106/649, 16.3%).

Strength, Limitations, and Future Work

This study enriches previous studies on mobile learning for the Indonesian context using the stimulus-organism-response theory. Another strength of this study is the involvement of medical students, general practitioners, and specialist physicians. However, a limitation of this study is that the research respondents were primarily general practitioners and mobile learning users with an age range of 20 to 30 years; thus, future work should add more specialist respondents. On the basis of the interviews, further research can identify other factors that affect user stickiness, namely, perceived behavioral control and social influence as there were many obstacles users experienced such as busy activity schedules or network quality constraints. In addition, based on the interviews, an in-depth analysis is needed to determine whether encouragement from one's social environment also affects the desire to continue using an app.

Future work can examine whether there is an influence of moderation factors such as the age, gender, and occupation of mobile learning app users on the relationship between app relationship quality and user stickiness in mobile learning. Future research could also include comparative results based on the age and occupation of mobile learning app users. Further research can explore related factors that affect the app use experience by examining users' perception of usefulness after learning to use the app.
