Conclusions: During the COVID-19 pandemic, there was an increased engagement for our EM board review podcast and website platform over a long-term period, specifically through website visitors and the number of podcast plays. Medical educators should be aware of the increasing usage of web-based education tools, and that asynchronous learning is favorably viewed by learners. Limitations include the inability to view Spotify (Spotify Technology S.A.) analytics during the study period, and confounding factors like increased popularity of social media inadvertently promoting the podcast.

KEYWORDS

asynchronous learning; medical education; podcast; COVID-19; emergency medicine; online learning; engagement; web-based; online study; online class; videoconferencing; assessment; effectiveness; challenges; knowledge retention; performance; virtual learning; pre-pandemic; post-pandemic

Introduction

As the field of medical education evolves, web-based media and digital study tools are finding larger audiences each year [1]. The COVID-19 pandemic dramatically changed the landscape of medical education. Suddenly in March and April 2020, all learning was switched to remote platforms, greatly challenging educators and hastening the switch to web-based media [2-4].

Previous studies have demonstrated that podcasts have positive effects on knowledge retention and test performance [5,6]. Multiple studies have previously been published on the effectiveness of remote learning during the COVID-19 pandemic via remote learning and web-based modules [7,8]. Most recently, 1 study aimed to measure podcast and blog utilization during the early months of the COVID-19 pandemic [9]. This study found an increase in blog page views during the early months of the pandemic, but no statistical change in podcast usage. However, this study had a short measurement period (January to May 2020). In addition, the study made measuring educational content related to COVID-19 a secondary outcome. As asynchronous teaching continues to increase in popularity among students in the wake of the pandemic, medical educators should be curious about the popularity of such materials during a time in which in-person education was severely limited or paused altogether. The purpose of this study was to assess the level of engagement for an emergency medicine (EM) board review podcast and platform, comparing before COVID-19 to during the COVID-19 pandemic over a period of 34 months. Our secondary outcome was to measure important website variables that have previously not been mentioned in medical education literature, especially in the setting of the pandemic. We hypothesized that the pandemic would increase the number of website visitors, page views, and podcast episode plays.

Methods

Overview

This retrospective analysis was conducted from March 5, 2022, to April 30, 2022. Data were collected by the study authors from July 11, 2018, when the first podcast episode was released, to December 31, 2021. Emergency Medicine Board Bombs (EMBB) was launched by 2 academic EM physicians in July 2018. The goal of this asynchronous educational platform was to increase first-time pass rate among residents and attendings taking their in-service exam and boards, respectively. EMBB is a peer-reviewed resource and functions at no cost to the learner. EMBB has never been formally assigned to any formal, academic curriculum; its educational platform is entirely free and open access to all learners. The website has podcasts and printable study guides that function as summaries of various common pathologies encountered in the emergency department and on-the-board exams.

Platform Development

Each podcast episode was structured to quickly cover one multiple-choice question, a discussion of correct and incorrect answers, and the relevant subject matter. Audio-editing was conducted using Apple Garageband, a free service provided to those who own Apple hardware. The podcast was available for free streaming on a designated website, emboardbombs, as well as dedicated podcast platforms (Apple Podcasts, Soundcloud [SoundCloud Global Limited & Co KG], and Spotify [Spotify Technology S.A.]). Questions for each episode were modeled after the American Board of Emergency Medicine (ABEM) certification exam. The Model of the Clinical Practice of Emergency Medicine (EM Model), serves as the basis for ABEM content and was followed in drafting podcast episodes [10]. A peer review process was used to develop multiple-choice questions. Each question was written by an EM physician with an academic appointment and was shared with 2 other academic physicians for review before it was featured on the podcast.

Medical source material was derived from *Tintinalli's Emergency Medicine* as well as UpToDate and EB Medicine [11-13]. The educational platform was self-funded by the creators and developed on their own time and schedule. No financial support or aid was received. In terms of dedicated time and monetary investment, the cost of equipment and software totaled nearly US $400 annually. In terms of hourly commitment, approximately 5 - 10 hours weekly is needed to record, edit, and publish podcast episodes, as well as write and publish study guides. The podcast was not formally added to any curriculum. It was disseminated by word of mouth. No marketing or paid advertising was used.

Variable Definitions

Podcast analytics were derived from Apple Podcasts Connect which is a free service provided for all Apple Podcast hosts. It provides data on total listeners, engaged listeners, and number of plays [14]. Listeners were defined by Apple as the number of unique devices that played more than 0 seconds of an episode. Engaged listeners were defined as the number of devices that played at least 20 minutes or 40% of an episode within a single session. Of note, pausing or stopping an episode did not count as starting a new session. Number of episode plays was based on the number of unique devices where the play duration is more than 0 seconds. At the time of our data collection during the pandemic, Spotify did not publish podcast statistics, and therefore, their user data could not be obtained.

The website learning platform was hosted on Squarespace. Website traffic analytics were derived from Squarespace, which measured traffic using variables such as website visits, website bounce rate, website unique visitors, and website page views [15]. Visits were defined as the total number of browsing sessions per visitor on the website within a 30-minute period. A browser cookie from Squarespace was used to track views within a 30-minute period. The bounce rate was defined as the number of visitors who navigate away from the website after viewing 1 page. Unique visitors were defined as the total number of new IP addresses that visited the website. Page views were defined as the total number of views across all pages on the website. Page views count the number of times a page is viewed. Furthermore, 1 visit consists of 1 or more pages.

Data Collection

Website traffic and podcast analytics from July 11, 2018, to February 28, 2020, were compared with those from May 1, 2020, to December 31, 2021. May 1, 2020, was chosen as the transition date because, during March and April 2020, various schools and residency programs began switching to remote learning. As the pandemic evolved, medical schools and graduate medical education sites began suspending in-person rotations. The Accreditation Council for Graduate Medical Education announced in mid-March that all in-person educational activities, meetings, and site visits were to migrate to virtual occurrences only [16]. By the end of April 2020, all nonessential, in-person educational activities had ceased [17].

Statistical Analysis

All collected data were organized in a Microsoft Excel spreadsheet and analyzed using statistical software JMP Pro 16.0.0 (SAS Institute Inc) in March 2022. All numerical data were summarized using mean and SD. Variations in monthly data from before COVID-19 and during COVID-19 periods were compared using the Levene test, whereas the means per month were compared using a 2-sample *t* test after accounting for differences in variations if any [18,19]. In addition, a nonparametric Mann-Whitney *U* test was also used to compare analytics from 2 time periods. Time series plots were used to study trends in monthly data. A significance level of 0.05 was used to determine the significance of outcomes.

Ethical Considerations

The Institutional Review Board was approached for ethics approval but reported that the study did not meet the criteria for human candidates research, and therefore, no approval was required.

Results

During the study period from July 11, 2018, to December 31, 2021, a total of 132 podcast episodes and 93 study guides were created. The first podcast episode was released on July 11, 2018.

From July 11, 2018, to February 28, 2020, 68 episodes were released, along with 30 study guides. From May 1, 2020, to December 31, 2021, 59 podcasts were released, and 53 handouts were published. Note that 5 episodes and 10 handouts were released during March-April 2020, which were also available to learners during the COVID-19 pandemic. This resulted in a total of 225 postings (132 podcasts and 93 handouts) being available to learners during the COVID-19 pandemic (Table 1).

Table . Number of podcasts, handouts, and total postings before, in-between, and during COVID-19 periods.

Period	Podcasts, n	Handouts, n	Postings, n
Before COVID-19	68	30	98
In-between period	5	10	15
During COVID-19	59	53	112
Total	132	93	225

The time series presented in Figure 1 show month-to-month changes in podcast and website visit analytics before the COVID-19 and during COVID-19 periods and differences in changing patterns. Although higher outcomes were observed during the COVID-19 period in all 6 podcast and website visit measurements compared with before the COVID-19 period, not all changes showed linear patterns of increase. In fact, the number of unique visitors, visits, and page reviews showed decreasing trend after reaching a peak around the middle of the COVID-19 period. However, at the end of the 20-month period, they still remained higher than before the COVID-19 level. During the before the COVID-19 period, number of listeners per month steadily increased from 39 to 338. During the COVID-19 period, it continued to increase, reaching a maximum number of listeners at 672. A similar trend was observed for number engaged per month, increasing from 28 to 289 during the before the COVID-19 period and reaching a maximum of 555 during the COVID-19 period. Although a similar trend was observed for the total number of plays with an increase from 412 to 11,879 during the before the COVID-19 period, a sharp drop was observed during the period of uncertainty (March-April 2020). Again, during the COVID-19 period, total number of plays increased from 4547 to 14,296. Number of visits during the before the COVID-19 period increased from 218 to 1064; there was further increase in the COVID-19 period, reaching 4664 in January 2021. The number of visits started declining thereafter, reaching a low of 1879. The number of unique visitors and page views showed patterns similar to that of the number of visits. The number of unique visitors increased steadily during the before the COVID-19 period from 138 to 620. It increased to 3222 in January 2021 but started declining to a low of 2293. The number of page views also increased steadily during the before the COVID-19 period from 610 to 3405; in the COVID-19 period, it increased to 11,326 in November 2020, only to steadily decrease to a low of 5389 in December 2021. Note that all measures showed a decrease from November 2021 to December 2021.

Comparison of podcast and website visit analytics are presented in Table 2. It shows that regardless of differences in the number of podcasts and handouts available during the 2 time periods, variation in analytics from month to month did not differ significantly during the 2 time periods under study except for bounce rate and number of visitors. Significantly higher variation as measured by SD was observed in bounce rate (0.07 vs 0.05; Levene test, P=.036) and number of unique visitors (523.45 vs 179.62; Levene test, P=.0049) during COVID-19 pandemic compared with the before the COVID-19 period. Percent increase in mean analytics from before the COVID-19 period to during the COVID-19 period ranged from 24% (bounce rate, 0.55 to 0.30 per 100 postings, n=20) to 539%

(unique visitors, 3.74 to 10.41 per posting, n=20) with the mean number of unique visitors showing the highest percent increase and the bounce rate the lowest. The number of visits increased by 504% (5.85 to 15.39 per posting, n=20) whereas the number of listeners, engaged, and total plays each increased by more than 200% (listeners: 2.11 to 3.77 per podcast, n=20; engaged: 1.72 to 3.09 per podcast, n=20; total plays: 42.54 to 69.23 per podcast, n=20). Percent increases in the average monthly analytics indicate considerable increase in visits and usage of podcasts from before COVID-19 to during the COVID-19 period.

Figure 1. Monthly change in podcast and website visit analytics before COVID-19 and during COVID-19 periods. The arrowhead marks the start of the pandemic.

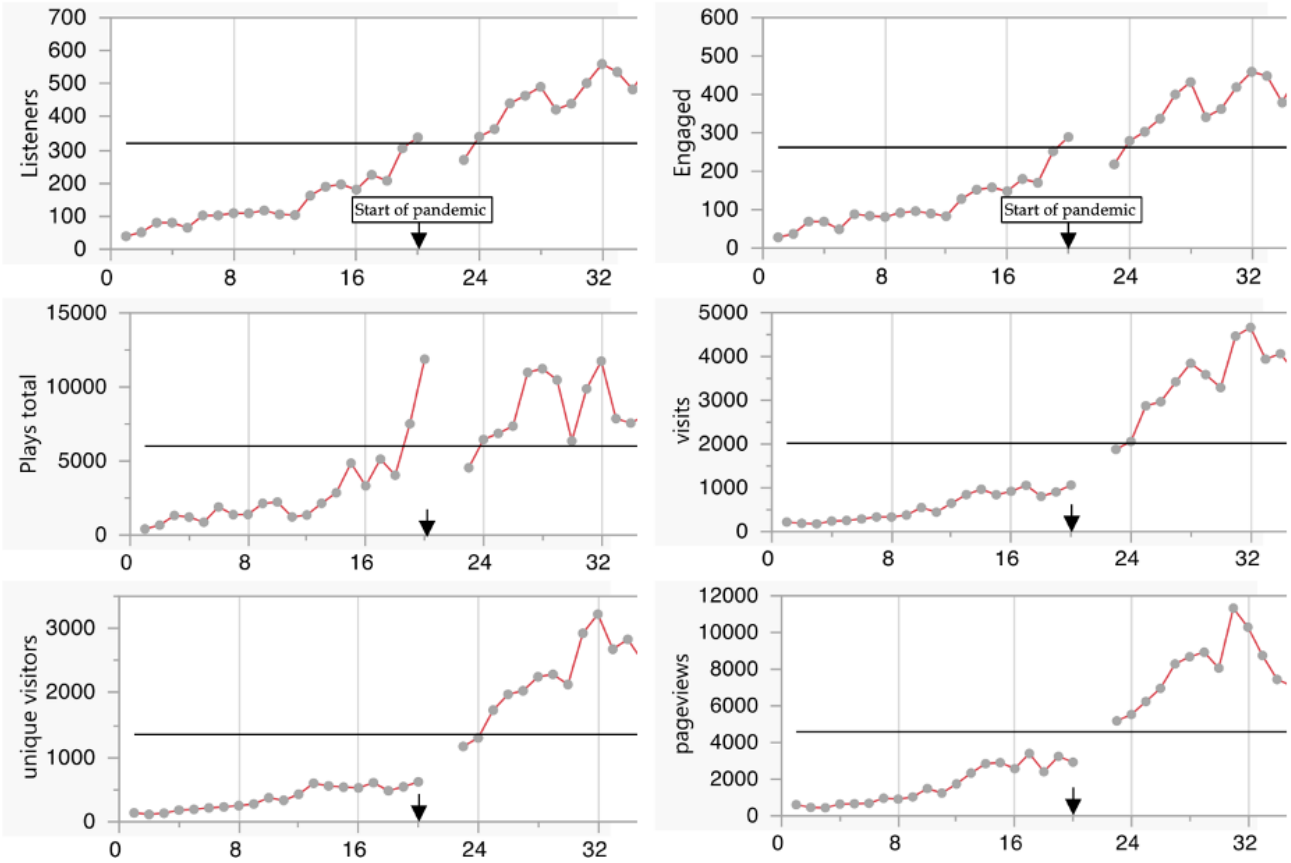

Table . Comparison of podcast and website visit analytics before the COVID-19 and during the COVID-19 periods.

Aspect and period	n	Mean (SD)	Range	*P* value (Levene test)	*P* value (*t* test)	Increase in mean, %
Listeners				.54	<.001	247.31
Before COVID-19	20	143.20 (80.93)	39-338			
During COVID-19	20	497.35 (99.84)	270-672			
Engaged listeners				.48	<.001	247.84
Before COVID-19	20	117.15 (68.17)	28-289			
During COVID-19	20	407.50 (82.19)	218-555			
Number of total episode plays				.95	<.001	215.88
Before COVID-19	20	2892.85 (2764.59)	412-11,879			
During COVID-19	20	9137.80 (2315.19)	4547-14,296			
Website visits				.06	<.001	504.3
Before COVID-19	20	573.20 (321.17)	178-1064			
During COVID-19	20	3463.85 (689.29)	1879-4664			
Website bounce rate				.03	<.001	24.07
Before COVID-19	20	0.54 (0.05)	46%-62%			
During COVID-19	20	0.67 (0.07)	52%-75%			
Website unique visitors				.004	<.001	538.99
Before COVID-19	20	366.55 (179.62)	114-620			
During COVID-19	20	2342.20 (523.45)	1170-3222			
Website page views				.27	<.001	346.6
Before COVID-19	20	1678.60 (1041.70)	443-3405			
During COVID-19	20	7496.65 (1577.68)	5183-11,326			

Although periods of similar length (ie, 20 months each) were used for comparison, the number of postings available during these 2 periods differed considerably because as new postings were made available, the earlier postings were still available for review for visitors. To account for the differences in the number of postings, analytics were adjusted by computing outcome per posting available. For example, number of listeners per podcast was computed as follows:

- Before COVID-19: # of listeners/podcast = # listeners/68
- During COVID-19: # listeners/podcast = # listeners/132

Note that this accounts for all podcasts that were available to listeners. Before COVID-19 accounts for all podcasts put out during that time and during COVID-19 used all podcasts available, that is, those that were put out before COVID-19, in-between, and during COVID-19 periods. Number of engaged and total plays were adjusted similarly by number of podcasts. Number of visits, unique visitors, and page views were adjusted similarly using all postings (ie, podcasts plus handouts). Bounce rate was adjusted similarly using per 100 postings because rate of per posting resulted in very small numbers and this change from per posting to per 100 postings does not affect the outcome of statistical tests.

Resulting comparisons of outcomes are listed in Table 3, which shows a significant increase in mean rates for all analytics except mean bounce rate per 100 postings from before COVID-19 to during COVID-19. Bounce rate per 100 postings showed a significant decrease from before COVID-19 to during

COVID-19 (0.55 to 0.30 per 100 podcasts; *t* test, *P*<.001). Mean number of listeners per podcast increased significantly from 2.11 (SD 1.19) to 3.77 (SD 0.76; *t* test, *P*<.001), mean number engaged per podcast increased from 1.72 (SD 1.00) to 3.09 (SD 0.62; *t* test, *P*<.001), and mean number of plays per podcast increased from 42.54 (SD 40.66) to 69.23 (SD 17.54; *t* test, *P*=.0122). Similarly, mean number of visits per posting increased from 5.85 (SD 3.28) to 15.39 (SD 3.06; *t* test, *P*<.001), mean number of unique visitors per posting increased from 3.74 (SD 1.83) to 10.41 (SD 2.33; *t* test, *P*<.001); and mean number of page views per posting increased from 17.13 (SD 10.63) to 33.32 (SD 7.01; *t* test, *P*<.001). Even nonparametric comparisons using Mann-Whitney *U* test gave the same results.

Table . Comparison of podcast and website visit analytics rates per posting available to viewers before COVID-19 and during COVID-19 periods.

Aspect and period	n	Mean (SD)	Range	Median (IQR)	*P* value (*t* test)	*P* value (Mann Whitney *U* test)
Listeners per podcast					<.001	<.001
Before COVID-19	20	2.11 (1.19)	0.57-4.97	1.60 (1.26-2.86)		
During COVID-19	20	3.77 (0.76)	2.05-5.09	3.83 (3.34-4.27)		
Engaged per podcast					<.001	<.001
Before COVID-19	20	1.72 (1.00)	0.41-4.25	1.34 (1.06-2.30)		
During COVID-19	20	3.09 (0.62)	1.65-4.20	3.22 (2.62-3.47)		
Number of total episode plays per podcast					.0122	<.001
Before COVID-19	20	42.54 (40.66)	6.06-174.69	29.71 (18.36-56.81)		
During COVID-19	20	69.23 (17.54)	34.45-108.30	69.95 (56.13-81.99)		
Website visits per posting					<.001	<.001
Before COVID-19	20	5.85 (3.28)	1.82-10.86	5.07 (2.68-9.08)		
During COVID-19	20	15.39 (3.06)	8.35-20.73	15.64 (13.80-17.41)		
Website bounce rate per 100 postings					<.001	<.001
Before COVID-19	20	0.55 (0.05)	0.47-0.63	0.54 (0.51-0.59)		
During COVID-19	20	0.30 (0.03)	0.23-0.33	0.30 (0.27-0.32)		
Website unique visitors per posting					<.001	<.001
Before COVID-19	20	3.74 (1.83)	1.16-6.33	3.60 (2.03-5.53)		
During COVID-19	20	10.41 (2.33)	5.20-14.32	10.65 (9.14-11.84)		
Website page views per posting					<.001	<.001
Before COVID-19	20	17.13 (10.63)	4.520-34.745	13.98 (6.85-28.35)		
During COVID-19	20	33.32 (7.01)	23.036-50.338	32.49 (28.39-38.13)		

Discussion

Principal Findings

The results demonstrate that our online EM board review podcast and platform experienced significantly increased levels of engagement during the COVID-19 pandemic. Our learning platform included multiple media, such as PDF study guides, video and picture-based modules, and online question banks. The aim was for the podcast and handouts to be integrated into an asynchronous study plan, as the platform provided easy accessibility and use.

Implication of Findings

The COVID-19 pandemic disrupted medical education, forcing learners in both medical school and residency to navigate vast amounts of information, largely in isolation. This shift from interactive, in-person learning raised concerns about students overextending themselves, leading to only a surface-level understanding of the material. One study comparing first and second-year medical student education during the pandemic highlighted the importance of face-to-face learning, finding that the first-year medical students in isolation performed worse than the previous year's first-year medical students [20]. Another retrospective study performed at the University of Hawaii Burn School of Medicine demonstrated that fourth-year medical students who were enrolled during the pandemic displayed improved note-taking with a 9-point increase in exam scores, yet worse physical examinations in their standardized patient encounters with a 12-point average decrease in scores [21].

In response, many innovative educational tools have emerged to attempt to provide asynchronous learning. Online resources like the one in this study are unique. Diverse topics are integrated into a single, cost-effective, and efficient platform, with podcast episodes <20 minutes, as well as downloadable PDF handouts. This model is beneficial for both visual and auditory learners.

While other learning platforms were not analyzed during this study period, valuable information was collected from this study's podcast. EMBB offers a humanistic aspect to learning with the dual physician hosts, pertinent banter, and narrative medicine aspect, of which may anthropomorphize the learning despite pandemic isolation.

Comparison With the Literature

Podcasts have been welcomed by those looking for a nontraditional method of learning in recent years, most notably those practicing in EM, where it is the most represented specialty that regularly hosts podcasts [22-24]. A survey in 2014 showed EM residents devote more time to podcasts than journals, citing podcasts as "the most beneficial" for education [22]. In another large survey, 80% of EM residents had listened to medical podcasts at least once [25].

Traditional lectures continue to be replaced by various digital teaching methods and this was hastened by the arrival of COVID-19. Podcasts' major benefit is their customization to fit learner's educational goals as well as time constraints, allowing users to optimize their study goals while balancing work and private life.

Feasibility of Implementation

In terms of feasibility, the podcast required a dedicated amount of time and monetary investment. The cost of standard microphones, basic recording software, and a website to host the podcast required approximately US $300 to 400 annually. As discussed in the methods section, the hourly commitment was close to 5 - 10 hours weekly.

Next Steps

A review of "Learning Through Listening: A Scoping Review of Podcast Use in Medical Education" examines podcasts for learning across many specialties, most often referencing anesthesia, with some reference to EM [26]. The data cited an increase in retention of information pre- and posttest for medical students, who are not specialized in EM compared with the level of a resident or attending physician. The review briefly mentions a podcast that improved EM in-training exam scores and a podcast that reportedly worsened in-training exam scores. The data gleaned from this study are of interest, but due to varied in-training exam scores, a comparative study is needed that examines test performance matching which podcast was used most for learning. Another future area of study will be to observe if the effects of the COVID-19 pandemic on asynchronous web-based learning are long-term.

Limitations

Our study is limited in generalizability due to it only measuring one specific podcast and website platform. A restricted sample size is one limitation of this study. Spotify and Android (Google) do not publish podcast statistics nor track individual usage, and therefore user data from both these platforms could not be obtained. According to Reuters in a survey of 2012 listeners, 20% used Apple Podcasts as their app of choice from 2019 - 2020, which is the second largest market share [27]. Previous studies have used podcast episode downloads as a metric for engagement. Despite the appeal of using number of downloads as a measurement, accurate analytics are difficult to obtain and fraught with bias. Downloads are defined differently depending on the podcast host. In addition, there have been reports that these numbers can be unreliable due to bot traffic and there can be manipulation of download data by hosts [28,29].

Another limitation is association versus causation. Given the retrospective study design and nature of COVID-19, it is difficult to completely credit the pandemic for increased podcast engagement. Confounding variables could also be a limitation, such as increased usage of social media during quarantine resulting in better promotion of the podcast and website.

One potential confounding variable was the launch of a procedural module in May 2020. This web-based learning instruction was an airway module, with recorded intubation videos and a pre- and postassessment. However, when reviewing website analytics, this was not a frequently viewed page on the website, accounting for only 2.59% of total website page views. It cannot entirely account for the sudden increase in website

visitors and podcast listeners. Thus, in this study, we can only establish differences observed in analytics between 2 time periods.

No quantitative data were tracked regarding listener exam performance, in particular in-training or board examinations. The purpose of this study was to assess the level of engagement for an EM board review podcast and website platform, before and during the COVID-19 pandemic. Future research should be aimed at assessing whether this educational intervention is an effective form of test preparation.

Conclusion

During the COVID-19 pandemic, there was an accelerated level of engagement for our EM board review podcast and website platform over a long-term period. This educational platform is a feasible, low-cost asynchronous study tool. Medical educators should be aware of the increasing usage of web-based education tools, and that asynchronous learning is favorably viewed by learners.

Abstract

Background: Many national medical governing bodies encourage physicians to engage in continuing professional development (CPD) activities to cultivate their knowledge and skills to ensure their clinical practice reflects the current standards and evidence base. However, physicians often encounter various barriers that hinder their participation in CPD programs, such as time constraints, a lack of centralized coordination, and limited opportunities for self-assessment. The literature has highlighted the strength of using question-based learning interventions to augment physician learning and further enable change in practice. CPD By the Minute (CPD-Min) is a smartphone-enabled web-based app that was developed to address self-assessment gaps and barriers to engagement in CPD activities.

Objective: This study aimed to assess the app using four objectives: (1) engagement and use of the app throughout the study, (2) effectiveness of this tool as a CPD activity, (3) relevance of the disseminated information to physicians' practice, and (4) acceptability to physicians of this novel tool as an educational initiative.

Methods: The CPD-Min app disseminated 2 multiple-choice questions (1-min each) each week with feedback and references. Participants included licensed staff physicians, fellows, and residents across Canada. A concurrent multimethods study was conducted, consisting of preintervention and postintervention surveys, semistructured interviews, and app analytics. Guided by the Reach, Effectiveness, Adoption, Implementation, and Maintenance framework, the qualitative data were analyzed deductively and inductively.

Results: Of the 105 Canadian anesthesiologists participating in the study, 89 (84.8%) were staff physicians, 12 (11.4%) were fellows, and 4 (3.8%) were residents. Participants completed 110 questions each over the course of 52 weeks, with an average completion rate of 75% (SD 33%). In total, 40.9% (43/105) of participants answered >90% of the questions, including 15.2% (16/105) who completed all questions. Moreover, 69% (52/75) of participants reported the app to be an effective and valuable resource for their practice and to enhance continuous learning. Most participants (63/75, 84%) who completed the postsurveys reported that they would likely continue using the app as a CPD tool. These findings were further supported by the interview data. Three key themes were identified: the practical design of the novel educational app facilitates its adoption by clinicians, the app was perceived as a useful knowledge tool for continuous learning, and the app's low-stakes testing environment cultivated independent learning attitudes.

Conclusions: The findings suggest the potential of the app to improve longitudinal assessments that promote lifelong learning among clinicians. The positive feedback and increased acceptance of the app supports it as an innovative tool for knowledge retention and CPD. Future research efforts should prioritize evaluating the app's long-term sustainability and its impact on physicians' practice, as well as exploring alternative approaches (such as artificial intelligence–based tools) for generating questions.

Introduction

Background

According to the Accreditation Council for Continuing Medical Education, continuing medical education (CME) supports physicians and health care teams in their lifelong learning and engagement in self-directed learning and quality improvement, leading to better care for patients and communities [1]. Continuing professional development (CPD) learning activities generally consist of a selection of educational and developmental activities, including group learning, self-directed learning, and self-assessment activities [1,2]. Such CPD activities for specialist physicians in Canada are overseen by the Royal College of Physicians and Surgeons (RCPSC) using the Maintenance of Certification (MOC) program [3]. Traditional CPD activities have been shown to have a limited impact on physicians' performance and patient outcomes [3]. Furthermore, experts suggest that systems-integrated CME activities that use a longitudinal multimodal approach allow for organizational improvements, as well as positive change in practice and patient health outcomes [4,5]. However, implementing longitudinal CME is not without challenges, including limited availability of objective practice data, inaccurate physician self-assessment, and ineffective CPD activities [5-7].

Longitudinal assessments have successfully been used in medical education where multiple-choice and short-answer questions are delivered at spaced intervals on a computer or mobile device [5,8]. More recently, this type of longitudinal assessment has been used for CPD of physicians [5,8]. One approach that has been shown to be effective in supporting clinicians' CPD is question-based learning interventions, such as test-enhanced learning (TEL) [9]. TEL has been shown to promote knowledge retention and information retrieval from memory [9]. As part of the learning sciences, spaced repetition and intentional recall are effective techniques for enhancing knowledge retention [10-13]. The process of recalling information for testing purposes further consolidates the material in the long-term memory and helps strengthen the memory trace when it is repeatedly tested [13]. In addition to repeated testing, feedback after retrieval attempt has been shown to increase the effects of TEL, as it reinforces the correct material in the long-term memory and retention [14]. This can promote reflective learning, as health care professionals can identify their strengths, weaknesses, and knowledge gaps that require further learning. Several studies have found that incorporating TEL and spaced repetition in CME programs enhances knowledge retention among clinicians [15-17].

The American Board of Anesthesiology (ANES) has developed a program of web-based multiple-choice questions (MCQs) that have been used for recertification in ANES, replacing their recertification examination [18]. This type of recertification allows ANES health care professionals to stay up-to-date on the latest developments and best practices in their field, improving their performance and patient outcomes. Furthermore, the use of this web-based MCQs CME provides an opportunity to be integrated into organizations and organizational workflows, as an effective strategy for promoting ongoing learning and development among health care professionals [1]. However, the question of how this approach could be used beyond the MOC remains largely unanswered. What is the role of digital approaches such as this one in the promotion of self-assessment, reflective learning, personalized learning, lifelong learning, and practice improvement?

Digital tools have increasingly been adapted to support pedagogies for CPD and have the potential to address limitations of self-assessment identified in existing CPD programs for specialist physicians in Canada [19,20]. Self-assessment CPD tools effectively promote lifelong learning through spaced longitudinal question-based assessments and reflective learning [4]. A team of clinicians and researchers at the University Health Network (UHN) developed a web- and mobile-based app, called CPD By the Minute (CPD-Min), that disseminates weekly self-assessments to specialist clinicians in Canada. A prototype of this progressive web-based app was initially developed by the team to assess the feasibility and utility of this concept in a Canadian setting. The prototype was first tested by 17 members

of the University of Toronto's (UofT) Department of Anesthesiology to demonstrate the feasibility of the app and to evaluate user experience, educational experience, and perceived efficacy [21]. The mobile app format was positively received, with 88% of users likely to continue using the app and 76% of users citing the app as an effective learning tool [21]. The tool was recognized for its ease of use, accessibility, and minimal time commitment. Users suggested the addition of a feedback feature to allow them to compare their performance to a peer group [21].

This Paper

On the basis of the feedback from the feasibility study, the CPD-Min pilot study was launched to further explore the efficacy of the app among ANES clinicians. This paper assesses the CDP-Min app using the four objectives related to the deployment of CDP-Min in the ANES context: (1) the effectiveness of this tool as a CPD activity; (2) ANES residents', fellows', and staffs' acceptability of this novel tool as an educational initiative; (3) relevance of the disseminated information to physicians' practice; and (4) engagement and use of the app throughout the study.

Methods

Study Design

The CPD-Min pilot study was a prospective, concurrent multimethods study, with assessment components implemented throughout the study. This multimethod evaluation of the app was guided by the Reach, Effectiveness, Adoption, Implementation, and Maintenance (RE-AIM) framework in the development of the survey and interview questions [22]. The RE-AIM framework was used to assess the design and development of the app as well as the efficacy of the intervention.

Ethical Considerations

This study was approved by the UHN Research Ethics Board (20-5883), the UofT Research Ethics Board (00040879), and the UofT CPD committee for CME credits. Participants in the study were required to review and sign the consent form sent via email by the study coordinator. The consenting process specified that participation entails agreeing to the terms of use and engaging with the CPD-Min application for the entire study duration, completing preintervention and postintervention surveys, and participating in an optional follow-up interview. The consent form outlined the voluntary nature of participating in this study, the benefits and risks, and data handling and storage. Participants were able to withdraw from the study at any time without penalty. The survey and interview data gathered were stored on confidential databases on secured UHN servers or encrypted and password-protected UHN devices. Interview transcripts were deidentified before analysis. After the transcripts have been verified for accuracy and data coding is complete, the audio recordings were destroyed. Data from the surveys were entered into a database on the UHN network shared drive, where only study team members have access. Only aggregated and thematically analyzed data were shared with study collaborators.

Education Intervention

The CPD-Min app was developed at UHN by a multidisciplinary team of clinicians, researchers, and software developers. Before the launch of the study, members of the research team (ie, experts and associate deans with relevant academic and professional backgrounds in the field of CPD) engaged in usability testing to assess and approve the app's design.

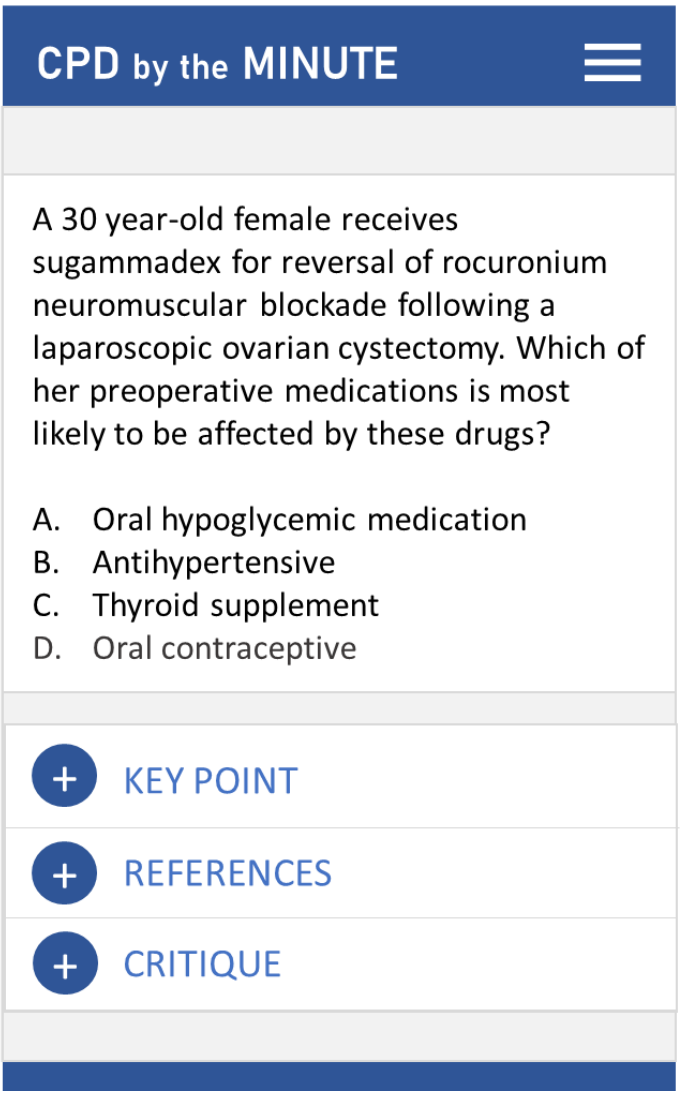
Description of the CPD-Min App

The CPD-Min app is a smartphone-enabled web-based app that administered 2 questions (1 min each) each week over a 52-week period. Following participants' response to the question, the app provided detailed feedback, including the correct answer, critiques of the wrong answer, key points, and references. This provided the participants with an opportunity to identify gaps in their knowledge and further explore these topics using the resources provided. In addition to answering the questions, participants were asked to rate each question based on their confidence (ie, very confident, somewhat confident, or not at all confident) and its relevance (ie, very relevant, somewhat relevant, or not relevant) to their practices. Moreover, an aggregated summary of all participants' responses and reflection ratings of each question were available for them to review after each week on the app's dashboard. This feature allowed participants to compare their performance to their peers and reflect on their performance accordingly. Finally, 2 knowledge assessments were conducted, at the midpoint (T1) and the end point (T2) of the study, where 5 questions were recycled back to participants if answered incorrectly or omitted.

Question Development

A total of 7 residents and staff from the UHN and UofT ANES departments were recruited to assist with question development; research associates provided guidance to ensure the consistency and quality of questions. A peer-review process involving 2 content experts was then conducted to validate, refine, and provide feedback on the content, quality, and relevance of the questions to CPD. Each question was multiple choice and contained a question stem, 4 to 5 answer choices, a key point, a critique of incorrect answers, and references (Figure 1). Questions developed were used to assess health care professionals' knowledge of important practice standards and guidelines and to stimulate problem-solving in 23 general and specific subspecialty topics, such as critical care and resuscitation, cardiology and cardiovascular surgery, neurology and neurosurgery, and general complications. The MCQs developed were a mixture of clinically related case-based questions as well as calculation and statistical questions. Approximately 100 ANES-based questions were developed and reviewed. The number of questions developed was based on the size of the anesthesiology specialty in Canada. A Microsoft OneNote database was created to allow for collaboration and monitoring of questions developed in real time. The questions were developed iteratively over a 6-month period to disseminate new practice information as the emerging needs of clinical practice continuously evolve.

Figure 1. A CPD By the Minute mock-up of a clinical pharmacology question for anesthesiology.



App Development and Usability Testing

Usability testing was conducted to assess and approve the design of the CPD-Min app as well as to identify opportunities to improve the user experience before the release of the final version of the app and the launch of the pilot study, thereby optimizing the app for better user engagement. A total of 7 experts and associate deans with relevant academic and professional backgrounds in the field of CPD were recruited for usability testing (including a pre- and postsurvey) via purposive sampling. Each testing session took place, via Microsoft Teams, due to COVID-19 public health restrictions. Furthermore, the Post Study System Usability Questionnaire, including 3 subscales—system usefulness, information quality, and interface quality—was administered after the usability test to evaluate the usability of the app and their perceived satisfaction. Data from the sessions were evaluated using the 10 Usability Heuristic Principles and Severity Scale by Nielsen [23].

Recruitment

Recruitment materials (email invitations with consent forms, digital posters, and a recruitment video) developed by the research team were sent out to anesthesiologists through the UofT's departments of ANES and specialty society organizations (Association of Canadian University Departments of Anesthesia, Continuing Education and Professional Development) across Canada, where a snowball sampling approach was used for recruitment.

Before conducting the study, participating ANES physician staff, fellows, and residents gave their written informed consent via electronically signed documents. The study was conducted in 2 sequential cohorts over a 52-week period, initiated in October (cohort 1) and November 2021 (cohort 2).

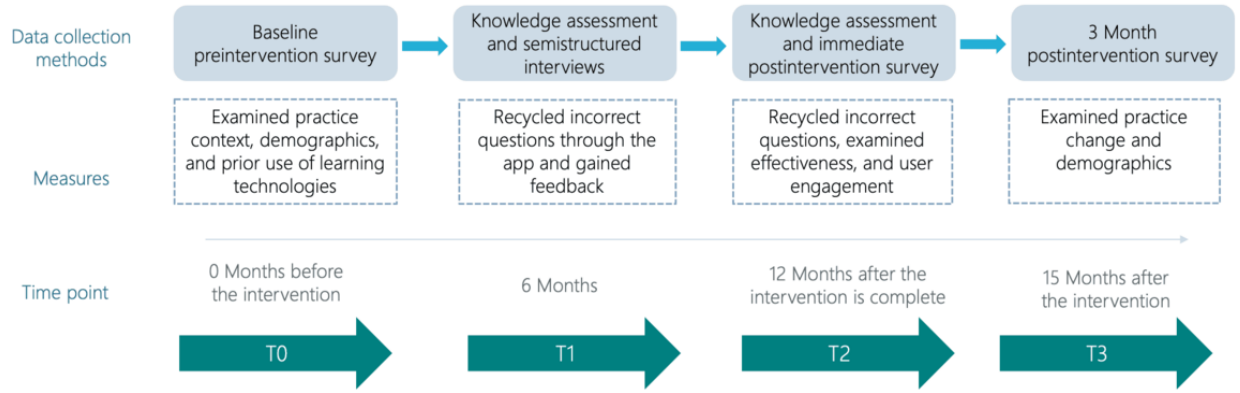
Data Collection

Data collection occurred throughout 4 distinct time points of the study (T0, T1, T2, and T3) and included electronic preintervention and postintervention surveys, knowledge assessments, and semistructured interviews with participants who had consented (Figure 2). The 3 surveys (preintervention, postintervention and 3 months after the intervention) were administered via REDCap (Research Electronic Data Capture; Vanderbilt University). The preintervention survey was administered before participants' engagement with the app (T0), and it included questions on practice context and demographics and prior use of learning technologies.

At the midpoint of the study (T1), semistructured interviews were conducted and recorded on Microsoft Teams with participants from ANES who provided consent. They were on average 17 (SD 0.29) minutes in duration, with questions on acceptability, relevance, expansion, and potential impact of CPD-Min. At weeks 26 and 52, the app recycled a maximum of 5 questions back to participants based on previous user responses using a random selection process. If ≥1 question was answered incorrectly before the first knowledge testing time point (T1), a maximum of 5 questions were randomly selected from a list of incorrectly answered questions for a second attempt. Recycled questions that were either omitted or incorrectly answered at T1 were carried forward as part of the pool or list of eligible questions to be revisited once more during the final knowledge testing week (T2). For the users who exhibited perfect scores at either T1 or T2, there was no knowledge testing. In addition, app analytics (eg, number of questions answered, correct questions, and time spent answering questions) were collected throughout the 52-week study period.

The postsurvey was sent to participants at the end of the pilot program (T2), and it included questions on the effectiveness and appeal of the app, influence of peer comparison, user engagement behavior, quality assessment, app design, and the System Usability Scale (SUS; Multimedia Appendix 1). The questions were designed by the research team based on peer-reviewed literature, and a subset of them was pilot-tested during the feasibility study. The SUS is a widely used 10-item questionnaire designed to assess the usability and effectiveness of a digital tool [24]. For example, participants rated various aspects of the app, such as the ease of use, functionality integration, the need for technical support, and overall complexity, on a scale from 1 to 5, ranging from "strongly disagree" to "strongly agree." A survey was sent to participants 3 months after the intervention (T3) with questions recapturing demographics and others exploring practice change or improvement.

Figure 2. Data collection tools and measures.



Data Analysis

Quantitative Analyses

All quantitative data were cleaned and analyzed using SPSS (IBM Corp). Preintervention and postintervention survey data were analyzed for descriptive statistics and correlational findings. With regard to the knowledge assessments, descriptive results were used to describe the extent of learning due to question recall. This included the number of correct or incorrect responses, the number of responses that timed out or were not started, question relevance, response times, and perceived confidence in answering questions. A series of paired 2-tailed *t* tests were conducted to compare knowledge assessments' mean scores and evaluate change in question responses at different time points. In addition, Spearman rank correlation tests were conducted to assess the relationship between the proportion of participants who answered correctly or incorrectly and degrees of confidence and relevance. A *P* value of <.05 was used to determine significance throughout.

Qualitative Analysis

For the semistructured interviews, data were transcribed by a professional transcription service and cleaned for clarity and to remove any identifying information. Data were deductively and inductively analyzed using NVivo (Lumivero) following the thematic analysis process by Braun and Clarke [25]. Participant interviews were first deductively analyzed using the RE-AIM framework to code the data. Following the deductive analysis, the step-by-step process developed by Braun and Clarke [25] was used to inductively generate themes from the coded data by searching the data to capture participants' thoughts and perceptions of the app and reviewing the preliminary themes before defining and describing them.

Finally, in addition to the RE-AIM framework being used to frame the findings from this pilot study, the continuing education outcome framework by Moore et al [26] was used to evaluate the learner's experience and the app as a CPD activity (Table 1).

Table 1. CPD By the Minute (CPD-Min) outcome measures using the Reach, Effectiveness, Adoption, Implementation, and Maintenance (RE-AIM) framework.

RE-AIM framework components	Pilot study outcome measures
Reach	• Number of American Board of Anesthesiology participants taking part in the CPD-Min program study • Demographics of participants
Adoption	• Participant completion rates were tracked throughout the 1-year pilot study
Effectiveness	• Satisfaction using the CPD-Min app • Mean scores from questions attempted throughout the program • Mean scores from knowledge assessments
Implementation	• Quality assessment of the content and delivery modes for the program
Maintenance	• Prospective measure of self-reported continued use of the app • Self-reported recommendation of the app

Results

Study Demographics: Reach

A total of 105 ANES participants were recruited for both cohorts to participate in the CPD-Min app study. Out of the 105 ANES participants in the study, there were varying response rates for the surveys administered preintervention, postintervention, and 3 months after the intervention. The response rate for the presurvey was 8.6% (9/105), while the response rate for the postsurvey was 71.4% (75/105). Due to the low response rate in the presurvey, a 3-month postsurvey (41/105, 39% response rate) was administered to gather information on demographics and practice change.

Of the 105 participants, there were 89 (84.8%) staff, 12 (11.4%) fellows, and 4 (3.8%) residents who took part in the study. Of the 89 staff, 40 (45%) reported on their years of practice with a variety of practice experience, but most reported <5 practice years (11/41, 27%) or 20 to <30 practice years (8/41, 20%). Most participants were in the age categories of 36 to 45 years (14/41, 34%) and 46 to 55 years (12/41, 28%), with most of them identifying as a cisgender man (33/41, 81%). Table 2 shows more details on participants' demographics.

A large proportion of participants recruited were practicing in the Greater Toronto Area (eg, Mount Sinai, Humber River Hospital, Sunnybrook Health Sciences Centre, and UHN). Others were from hospitals and universities in Quebec, Manitoba, and British Columbia. Most participants (29/41, 71%) from the survey indicated that they practiced at an academic health sciences center or a teaching hospital, with varying participation in CPD activities, such as attending departmental rounds (39/41, 95%), meeting informally with colleagues (35/41, 85%), attending and presenting in conferences and courses (34/41, 83%), and many more (refer to Table 2 for the full list).

Table 2. Demographics and continuing professional development (CPD) activities of the CPD By the Minute app participants from the 3-month postsurvey (N=41).

Characteristics	Participants, n (%)
Staff (years of experience)	40 (98)
<5	11 (27)
5 to <10	6 (15)
10 to <15	5 (12)
15 to <20	7 (17)
20 to <30	8 (20)
>30	3 (7)
Fellow (year 3)	1 (2)
Practice setting	
Academic health science center or teaching hospital practice	29 (71)
Community-based hospital practice	12 (29)
Age (years)	
26-35	6 (15)
36-45	14 (34)
46-55	12 (29)
56-65	7 (17)
>65	2 (5)
Gender	
Cisgender Man	33 (80)
Cisgender Woman	7 (17)
Transgender Person	1 (2)
Annually practiced CPD activities	
Attending formal case conferences to discuss patient care	29 (71)
Performing chart audits or reviewing performance data	14 (34)
Meeting informally with colleagues	35 (85)
Attending journal clubs	27 (66)
Attending departmental rounds	39 (95)
Attending and presenting in conferences and courses	34 (83)
Engaging in online activities or courses	33 (80)

Research Objective 1: Engagement and Use of the App Throughout the Study—Adoption

The *adoption* of the app was measured by looking at participants' completion rate and use of the app throughout the 52-week pilot study (first-level of the framework by Moore et al [26] - participation). The app was assessed based on its effectiveness as a CPD activity and participants' perceptions of their use of the app with regard to the *effectiveness* outcome.

The CPD-Min app sent out 110 questions to participants throughout the 52 weeks. In total, 40.9% (43/105) of participants responded to more than 90% of the questions, with 15.2% (16/105) completing every question. Participants had an overall high mean completion rate of 75% (SD 33%) throughout the study. However, there was a significant difference in the average response rate before and after the midpoint assessment at 26 weeks (t_{104}=−5.06; P<.001, 2-tailed). On average, the premidpoint response rate was 5 questions higher than the postmidpoint response rate (95% CI −7.07 to −3.05). Normality was assumed by visually inspecting Q-Q plots and considering the larger sample size (n=104) in accordance with the central limit theorem.

Research Objective 2: Effectiveness of This Tool as a CPD Activity—Effectiveness

Overview

The average number of questions answered per participant was 82 (SD 32.9; range 0-110) questions, with a mean correct response of 43 questions per participant (SD 19.5; range 0-76). They spent an average of 35.3 (SD 5.9; range 14-48) seconds

to provide an answer to each weekly question. Spearman rank correlation tests (r_s) showed weak positive correlations between questions answered correctly and both participants' confidence (r_s=0.272; P<.001) and relevance (r_s=0.143; P<.001) rating of those correct questions.

Semistructured Interviews

A total of 15 ANES participants were interviewed from both cohorts. On the basis of the thematic analysis of the interview data, the following themes regarding participants' thoughts and perceptions on the CPD-Min app were generated: (1) the practical design of the novel educational app facilitated its adoption by clinicians, (2) the app was perceived as a knowledge tool for continuous learning, and (3) the app's low-stakes testing environment cultivated independent learning attitudes.

Theme 1: The Practical Design of the Novel Educational App Facilitates Its Adoption by Clinicians

The convenience and practicality of this novel app facilitated participants' adoption of the learning tool (second-level of the framework by Moore et al [26] - satisfaction). Participants noted that both the practicality and convenience of having this continuing learning tool in an app format, along with its short time commitment, helped them maintain their participation and engagement throughout the study period and possibly beyond:

> *There's a practicality to the app and to the timeframes required by the question-based module, which is interesting and fun. There's something practical about having bite-size elements of CPD that can be done anywhere at any time, which is very practical.* [ID 109]

According to participants in the interview, they were consistent with using the app throughout the program, taking approximately 5 minutes to answer questions and review materials if necessary. In addition, most participants found the weekly reminder emails to be useful in prompting them to answer the question right away or to schedule a time to do it during the week. When it came to the design of the app, while most participants noted the ease of use and practicality of it, there were a few suggestions on improving some features within the app. One participant suggested improving access to previous questions and resources by integrating a quick search function to refer to in the future if needed.

Research Objective 3: Relevance of the Disseminated Information to Physicians' Practice (Theme 2: The App Was Perceived as a Useful Knowledge Tool for Continuous Learning)

The app provided health care professionals with an opportunity to engage in a continuous learning experience. Most participants mentioned using the app as a tool to identify gaps in their knowledge by reflecting on their scores and the content of the app. The CPD activity was described as a "refresher" of previous knowledge for the licensing exams by several participants. Moreover, a few participants expressed that although some of the subspecialty content was not relevant to their practice, it was useful in identifying subspecialty gaps and providing an overview of clinical topics within different subspecialties in the field:

> *Some of the content is not necessarily relevant to my practice. But I think as an anesthesiologist, you never know what's going to come up. So, it's good to keep a broad overview of things, even if you're not doing them every day.* [ID 85]

For some participants, having a broad range of subspecialty topics provided them with a refreshing overview of knowledge regardless of its relevancy to their practice. By contrast, a few participants reported that they would have appreciated a more tailored approach to the content of the app. Specifically, 1 participant reported that the number of questions that did not relate to their practice "did not necessarily increase [their] learning." As a recommendation, a few participants suggested having the option to choose specific topics of interest at the start of using the app. Moreover, interview participants reported engaging in the supplementary material and feedback provided to them; some used the references provided to them to further explore specific topics they were interested in.

Research Objective 4: Acceptability Among ANES Residents, Fellows, and Staff of This Novel Tool as an Educational Initiative (Theme 3: The App's Low-Stakes Testing Environment Cultivates an Independent Learning Attitude)

The app uses low-stakes repeated testing to cultivate lifelong learning among health care professionals. Participants noted that low-stakes and repeated testing design of the app was useful in keeping them engaged throughout the program and further cultivated their lifelong learning:

> *Doing the CPD is extremely low stakes. I do this because, well, I want to keep lifelong learning. I like to learn. I care to be as good of an Anesthesiologist as I can. And just as well to keep on practicing and learning and reviewing the material. And this, in a way, forces you or at least prompts me to do it, in an easy bite-sized manner. The low stakes is what keeps me in. If I knew that if I failed this, I'd lose my license, I be slightly more worried. This is only win-win. I need to do CPD. I do CPD. It's easy. Why not?* [A109]

Similar to the themes generated, findings from the postsurvey confirmed participants' perceptions during the midpoint interviews, where participants highlighted the effectiveness of the app as an educational tool, as it not only tests their current knowledge but also exposes them to the newest guidelines, studies, and information related to their practice. Concurrently, while exploring the quality of the app's content in the postsurvey, most respondents (57/75, 76%) were satisfied with the variety of topics offered, and even more participants (64/75, 85%) reported the quality of the questions and supplementary material as above average (ie, excellent or good).

The themes generated from the interview data were further supported by the survey findings (Table 3), as over one-third of the participants (29/75, 39%) reported that they would *always* or *often* check after answering correctly, while even more

(57/75, 76%) reported *always* or *often* checking the feedback after incorrect responses. More than half of the participants (43/75, 57%) did not report any more engagement with the app after answering correctly rather than incorrectly. Furthermore, most participants (58/75, 77%) were intrigued to find out the answers to the questions asked of them weekly. Most participants (45/75, 60%) were *occasionally* motivated to seek out additional, related self-directed learning external from the app. The CPD-Min app was reported as a frequent, low-stakes knowledge testing platform by most participants (62/75, 83%). Most participants (65/75, 87%) did not perceive the 2 knowledge assessment weeks to be too stressful or anxiety inducing.

With regard to participants' learning, on average, participants scored 16% (SD 33.1%) less on their end point knowledge assessment compared to their midpoint knowledge assessment. From the final survey results, most participants (38/41, 93%) reported that the app enhanced their clinical knowledge and helped them identify gaps in their learning (third level of a framework by Moore et al [26] - learning). They also found the knowledge assessments helpful. Furthermore, it provided them with adequate resources to further their learning. For most participating clinicians (35/41, 85%), the app helped them improve or change their practice, and for some (31/41, 76%), it also contributed to their confidence with their clinical knowledge.

Table 3. Postsurvey response on user engagement (Likert scale) by users of the CPD By the Minute app (N=75).

	Always or strongly agree, n (%)	Often or agree, n (%)	Occasionally or neither agree nor disagree, n (%)	Rarely or disagree, n (%)	Never or strongly disagree, n (%)
How likely are you to review the supplementary materials provided (eg, key points, references, and critiques) after a correct response?	10 (13)	19 (25)	28 (37)	15 (20)	3 (4)
How likely are you to review the supplementary materials provided (eg, key points, references, and critiques) after an incorrect response?	32 (43)	25 (33)	13 (17)	3 (4)	2 (3)
I was more likely to engage with the app if a previous question was correct rather than incorrect.	2 (3)	4 (5)	26 (35)	19 (25)	24 (32)
The results I received after answering a question motivated additional, related self-directed learning external to the app.	4 (5)	19 (25)	45 (60)	6 (8)	1 (1)
I was intrigued to find out the answers to the questions asked of me.	26 (35)	32 (43)	15 (20)	2 (3)	0 (0)
Participating in either the routine weekly questions or KA[a] weeks was too stressful and induced anxiety.	0 (0)	2 (3)	8 (11)	26 (35)	39 (52)

[a]KA: knowledge assessment.

Implementation of the CPD-Min App

With regard to the *implementation* component of the CPD-Min app, the delivery or format of the app was assessed using both the interviews and postsurvey. Participants spoke positively about the CPD-Min app's format, content, and delivery method (Table 4). Participants noted that the weekly question count was manageable within their workload and helped them stay consistent in using the app. Several participants also highlighted that the weekly reminders were beneficial in prompting them to complete their questions for the week. Moreover, the questions were mostly relevant to realistic case scenarios that were applicable to their practice. Finally, many participants positively described the appropriateness of the format for CPD and continuous learning.

Likewise, the findings from the postsurvey regarding the quality and usability of the app concur with the abovementioned findings from the midpoint interviews. Most postsurvey participants (49/75, 65%) reported the format and layout (eg, character count, image, and font size) of the questions in the app to be appropriate for a time-sensitive response. The app's usability was measured using the SUS, and the mean scale score as reported by participants was 77.7 (SD 6.7; range 60-88). The usability score was rated on a scale of 100, with an average score being 68 and a score >80 considered above average [24]. A score of 77 indicated that the CPD-Min app was fairly usable; however, there were still areas that could be improved to enhance the overall user experience.

While majority of participants (51/75, 68%) found the peer reflection feature of the app (ie, being able to compare their performances to their peers) helpful and about half of the participants (30/75, 40%) thought it was important, most participants (54/75, 72%) reported *never* discussing the results or material with their peers. Almost one-third of the participants (21/75, 28%) reported discussing their results with their peers from once a week to less than once a month. This was concurrent with findings from the interview, as most interview participants reported never discussing the material or content from the app with colleagues. When asked to elaborate, a few interview participants highlighted that the CPD activity in this app format

did not facilitate discourse and discussion among peers and colleagues. Participants found themselves using the app as a self-guided learning tool as opposed to other CPD activities, such as conferences. A few participants (2/15, 13%) suggested integrating an in-app feature that allowed interaction or discussion with other CPD-Min users.

Table 4. Postsurvey responses on quality assessment (Likert scale) by users of the CPD By the Minute app (N=75).

	Strongly agree or excellent, n (%)	Agree or good, n (%)	Neither agree nor disagree or average, n (%)	Disagree or below average, n (%)	Strongly disagree or poor, n (%)
I was satisfied with the variety of topics and subject matter.	12 (16)	45 (60)	12 (16)	4 (5)	2 (3)
The quality of questions and supplementary materials offered was (poor to excellent).	21 (28)	43 (57)	9 (12)	2 (3)	0 (0)
While answering a given question, I felt the format and layout were appropriate for a time-sensitive response.	9 (12)	40 (52)	8 (11)	14 (19)	4 (5)

Maintenance

CPD-Min program's *maintenance* feature focused on the individual level, exploring participants' likelihood of continued use of the CPD-Min app and recommendation to peers and colleagues (Table 5). Most participants (63/75, 84%) who reported that they were likely to continue using the CPD-Min app, also reported that they would continue using it as an ongoing CPD activity (61/75, 81%). Most participants (67/75, 89%) reported that they would likely continue using the app if they received section 3 MOC (self-assessment) CME credits. Similarly, 89% (67/75) of the participants reported that they would continue using the CPD-Min app for >12 months. Most participants (52/75, 69%) found the app to be an effective learning tool for their practice, with about 28% (21/75) reporting that the app was *somewhat* effective as a learning tool. In terms of recommending the app to colleagues, 79% (59/75) of the participants said that they would recommend the app to their colleagues, and 81% (61/75) said that they would specifically recommend it to residents and fellows.

Table 5. Postsurvey responses on appeal and effectiveness (Likert scale) by users of the CPD By the Minute (CPD-Min) app (N=75).

	Very likely or effective, n (%)	Likely or effective, n (%)	Somewhat, n (%)	Not very, n (%)	Not at all, n (%)
How likely are you to continue using the CPD-Min app?	43 (57)	20 (27)	8 (11)	4 (5)	0 (0)
How likely are you to continue using the app as an ongoing CPD[a] activity?	40 (53)	21 (28)	9 (12)	4 (5)	0 (0)
Would you likely continue using the app if you continued receiving section 3 MOC[b] (self-assessment) CME[c] credits?	53 (71)	14 (19)	6 (8)	1 (1)	0 (0)
How effective is this as a learning tool for your practice?	19 (25)	33 (44)	21 (28)	2 (3)	0 (0)
How likely are you to recommend the app to your colleagues?	34 (45)	25 (33)	15 (20)	1 (1)	0 (0)
How likely are you to recommend the app to residents or fellows?	36 (48)	25 (33)	9 (12)	3 (4)	2 (3)

[a]CPD: continuing professional development.

[b]MOC: Maintenance of Certification.

[c]CME: continuing medical education.

Discussion

Principal Findings

The CPD-Min app disseminated 110 peer-reviewed questions to 105 ANES clinicians over the span of 52 weeks. Upon the evaluation of this app as a CPD tool, three major themes were identified: (1) the practical design of the educational app facilitated its adoption by clinicians, (2) the app was perceived as a useful knowledge tool for continuous learning, and (3) the app's low-stakes testing environment cultivated independent learning attitudes. In addition to clinicians' positive perceptions of the CPD-Min app, they noted that using it helped them identify gaps in their clinical knowledge. The implementation of a longitudinal self-assessment activity such as CPD-Min has various strengths, enabling health care professionals to assess their own knowledge and identify areas where they may need to improve. CPD is essential to maintaining and improving clinical practice among physicians. It allows health care professionals to stay up-to-date with the latest developments in their field and to acquire new skills and knowledge that can help them deliver better care to their patients. However, traditional CPD activities are associated with several limitations in their implementation (eg, lack of time, cost, and reliance on self-assessments) and rate of dissemination [2-4].

Among the ANES clinicians who participated in the survey, 63% (26/41) were aged between 35 and 55 years and 80% (33/41) were male. The age of this sample was comparable to the general ANES population according to reports from the Canadian Medical Association, noting that >50% of the

Canadian ANES population was aged between 35 and 55 years [27]. However, our sample had slightly more ANES clinicians identifying as a cisgender man (33/41, 80%) compared to the general population (67%) [27]. Similarly, our population's work setting was comparable to the general Canadian ANES population. According to the 2019 Canadian Medical Association report, most ANES clinicians reported academic health science centers and community hospitals as their top primary work settings [27].

The CPD-Min pilot program had high engagement as participating ANES clinicians had an average of 75% (SD 33%) completion rate through the entire year of the study program. The average clinician participation rate in the CPD-Min program was consistent with participation levels from 10 previously evaluated educational delivery programs for health care professionals, as explored in a systematic review by Phillips et al [28]. Clinician participation levels in self-assessment CPD programs could be attributed to a number of factors, including clinical relevance, optimal number of questions per day, and their spacing [29]. In addition, the decrease in participant response rate over the course of the program is not an uncommon occurrence, as the drop in participation over time could be due to fatigue, lack of motivation, or other personal or external factors [30-32].

With the CPD-Min app, clinicians' adoption of the app and participation in the program could be attributed to the ease of use and ability to quickly adapt to this microlearning pedagogy method. The app provided specialized physicians with an opportunity to participate in continuous learning in a flexible and accessible manner that encouraged sustained engagement [33]. The microlearning style presented by this CPD app was a helpful format for continuous learning and development for physicians, as they were able to be consistent with using the app throughout the program, taking approximately 5 minutes to answer questions and review materials if necessary [34]. Clinicians' responses to the CPD-Min app echoed key takeaways of mobile-microlearning pedagogy within workplaces that highlight the usefulness and demand of just-in-time learning, which provides clinicians with bite-sized lessons that can be immediately applied within their clinical practices [33,35-37]. In addition, this nontraditional mode of CPD allows for spatial and temporal flexibility among clinicians with demanding workloads who are seeking to engage in CPD. For instance, participating clinicians report being able to engage in learning "on the go," allowing them to seamlessly integrate their continuous learning within their workflows. Participating clinicians noted that they were always able to find time to do it throughout their working days (eg, during a coffee break or free time waiting in the operating room).

The app's low-stakes testing environment encouraged independent learning attitudes. Participants reported low anxiety and stress while using the app and actively engaged with supplementary resources and feedback provided after each question. While the use of the app seemed to encourage continued learning through the just-in-time low-stakes learning environment, the structure of the app did not facilitate discussion of the material with colleagues, as highlighted by participants. The facilitation of discussion and interaction during CPD uptake provides clinicians the opportunity to reflect on their performance and knowledge in reference to their peers. Although the CPD-Min app did not facilitate collaboration and peer interaction, a key feature of the app was its weekly summary. This summary, detailing participants' and their colleagues' performance, served as a tool for reflection and played a crucial role in motivating clinicians to remain actively engaged with the app. This finding aligns with previous literature that emphasizes the importance of clinician reflection in CPD activities, helping them identify gaps in performance and knowledge [38,39].

The CPD-Min app disseminated information to clinicians in a timely manner [40]. The app used the declarative knowledge state with key features such as feedback, key critiques, and references to translate knowledge to clinicians' practice [41]. This finding is consistent with a recent study that reported the benefits of immediate feedback for knowledge retention [42]. With the rapidly evolving research knowledge in health care, there seems to be a slow rate in knowledge uptake and dissemination into practice [43]. The well-received engagement with the CPD-Min app and uptake in knowledge, as well as engagement with the resources, indicates the potential of using such a mobile question-based app to translate and disseminate new and innovative knowledge in the field. Repeated testing has been shown to enhance knowledge retention and promote higher-level cognitive processing more effectively than traditional learning methods [42,44].

The CPD-Min app aimed to address gaps in CPD self-assessment for clinicians and facilitate their ability to identify knowledge gaps using just-in-time learning, which prioritizes meeting clinicians' current learning needs. While the purpose of this app was not to test knowledge, it served the purpose of a self-assessment tool for clinicians. Many participants (38/41, 93%) noted that the app helped them identify knowledge gaps and enhanced their clinical knowledge. In addition to participants' self-assessment of their knowledge, they reported that the app played a role in improving their practice by guiding their learning and highlighting the overall effectiveness of the intervention. Similar findings were reported in a pilot study of family physicians, indicating that most clinicians continued to integrate the longitudinal assessment as a form of continuous learning and changed their practice because of participating in the program [45]. Interestingly, another study found that in high-stakes assessment, participants were more accurate but less confident in their responses [44]. Low confidence could be attributed to the high-stakes nature of the assessment [44]. Overall, the results of the CPD assessment program suggested that the CPD-Min app was an important learning pathway for anesthesia clinicians and was perceived as a useful knowledge tool for continuous learning. However, further research is needed to explore the effectiveness of the app in promoting knowledge retention and the accuracy of physicians' self-assessment of their knowledge. Integrating this form of longitudinal assessment into organizational workflows could enhance physician performance and, ultimately, improve patient outcomes.

Participants found the CPD-Min app to be an effective tool for their practice as it helped them identify knowledge gaps in their

practice. Overall, based on the findings from both the survey and interviews, participants perceived the app to be useful for their practice. Regarding the perceived ease of use, the high SUS score suggests that the app is well designed and user-friendly, which could lead to its adoption and integration into clinical practice.

Limitations

This study has a few limitations, which should be acknowledged. The generalizability of the study is limited because the study population focused only on one medical discipline (ie, ANES), and thus, the findings may not be applicable to other medical specialties. Future studies should replicate the study design in various medical fields to determine the app's generalizability and usefulness in different contexts. In addition, study recruitment and intervention were administered during the COVID-19 pandemic, which limited the recruitment diversity of clinician roles and significantly impacted the participants' engagement with the study's intervention. Although the intervention was conducted remotely, the COVID-19 pandemic may have influenced clinicians' work schedule and stress levels, ultimately affecting their overall engagement with the study intervention. Another limitation of the study was that the question development process was labor intensive. Large language models could be used to rapidly prototype the questions in the future. Finally, due to the randomized nature of the questions disseminated through the app, inferences could not be made from the knowledge assessment findings, as it would require controls such as exact questions and spacing in administration. The highlighted limitations should be considered when interpreting these findings. Future research should aim to address these limitations to provide a more comprehensive understanding of the app's effectiveness as a continuous learning tool for clinicians.

Conclusions

The CPD-Min app was positively received and accepted as an educational initiative by ANES clinicians, and its practical design encouraged continued use of the app by the clinicians. Furthermore, the information was extremely relevant to participants' practices while also allowing them to brush up on knowledge from subspecialties they might not frequently practice. The CPD tool allowed ANES clinicians to recognize knowledge gaps and promote continuous learning. This app uses a practical longitudinal approach to incorporating CPD into the workflow and provides opportunities to facilitate the dissemination of new clinical information and updates across health care organizations. Integrating mobile microlearning activities into the workflow allows health care professionals to engage in ongoing learning and development more easily, leading to improved performance and outcomes. While the initial results are promising, further evaluation of the app is necessary to fully understand its long-term implications and the sustainability of the app over time. Another key area of evaluation is assessing practice changes among clinicians using the app and its impact on organizational workflows. In summary, while the CPD-Min app has shown promise in enhancing learning and knowledge retention, further evaluation is needed to understand its long-term implications. This includes examining the sustainability of the CPD activity and assessing the impact on clinical practice and patient outcomes.

Acknowledgments

The authors wish to thank Ms Tran Truong, Mr Alex Zisman, Mr Herm Sidhu, and Ms Katherine Sue at Techna, University Health Network for developing the mobile app. The authors also thank Dr Allan Okrainec, Dr Dave Davis, Mr Spencer Williams, and Ms Sophia Li for their support with the study. The authors would like thank the Southeastern Ontario Academic Medical Organization for its generous support of this work through the AHSC AFP Innovation Fund.

Abstract

Background: Since the COVID-19 pandemic, residency candidates have moved from attending traditional in-person interviews to virtual interviews with residency training programs. This transition spurred increased social media engagement by residency candidates, in an effort to learn about prospective programs, and by residency programs, to improve recruitment efforts. There is a paucity of literature on the effectiveness of social media outreach and its impact on candidates' perceptions of residency programs.

Objective: We aimed to determine patterns of social media platform usage among prospective residency candidates and social media's influence on students' perceptions of residency programs.

Methods: A cross-sectional survey was administered anonymously to fourth-year medical students who successfully matched to a residency training program at a single institution in 2023. These data were analyzed using descriptive statistics, as well as thematic analysis for open-ended questions.

Results: Of the 148 eligible participants, 69 (46.6%) responded to the survey, of whom 45 (65.2%) used social media. Widely used social media platforms were Instagram (19/40, 47.5%) and Reddit (18/40, 45%). Social media influenced 47.6% (20/42) of respondents' opinions of programs and had a moderate or major effect on 26.2% (11/42) of respondents' decisions on program ranking. Resident-faculty relations and social events showcasing camaraderie and wellness were the most desired content.

Conclusions: Social media is used by the majority of residency candidates during the residency application process and influences residency program ranking. This highlights the importance of residency programs in leveraging social media usage to recruit applicants and provide information that allows the candidate to better understand the program.

Introduction

Since the 2020‐2021 residency application cycle, the Association of American Medical Colleges and Liaison Committee on Medical Education have recommended that programs conduct virtual interviews exclusively for residency applicants [1,2]. This recommendation allows for a more equitable residency application process, as it offloads financial and time burdens from the applicant involved with traveling, the applicant pool, bias, and interview flexibility; however, having an exclusively virtual process also comes with a loss of applicants developing rapport with faculty and residents and appreciating resident camaraderie, program culture, and what resident daily life is like [1,3].

Students and residency programs have both turned toward social media to lessen this void. Residency applicants turn to social media to gather more information about residency programs, such as details about the work environment and facilities, and residency programs use social media to promote their programs and institutions and highlight their culture, personnel, and network [4-8]. This has been shown to increase the number of programs applicants can apply to [9]. Residency programs must embrace this digital shift to adapt to the postpandemic landscape and efforts to enhance diversity and equity in medical education. Thus, social media remains an important platform for residency applicants and programs alike.

Despite its widespread usage, there is a lack of information on the impact that applicants across different specialties derive from residency programs' social media accounts. There have been single-specialty studies that have shown that social media is used by prospective applicants during the residency recruitment process, but limited studies across specialties have

been performed [4,10-12]. In this study, we performed a survey across multiple specialties to elucidate the patterns of social media consumption and its influences on medical students' selection of a residency program.

Methods

Population and Setting

The study population consisted of fourth-year medical students who graduated in 2023 from an allopathic medical school in Massachusetts and who participated in the residency match program during the 2022 - 2023 cycle.

Ethical Considerations

The survey was approved by the institutional review board and deemed not human research (STUDY00001121). The survey contained a description containing the risks of participation in the study, and completion of the survey implied voluntary, informed consent. No personally identifiable information was collected, and no incentives were offered.

Survey Development and Distribution

We developed the survey based on guidelines by Artino et al [13]. After a literature review, a focus group was held to learn more about medical students' use and opinions of social media. This information was synthesized, and survey items were created using a combination of a Likert scale, yes or no, and open-ended questions; the survey explored demographic data, the use of social media and types of platforms, preferred social media content, and the impact of social media on residency programs. The survey was reviewed by faculty and fellows and assessed for acceptability, feasibility, and content validity of survey questions. We performed cognitive interviews for the questions and then piloted and revised the survey for clarity based on user feedback from medical students. The survey had a total of 5 pages with 6 or less questions per page, and answers could be changed. The survey was then distributed to all students at our institution who graduated in May 2023.

All fourth-year medical students who graduated in 2023 at UMass Chan Medical School were eligible for the survey and emailed a link to the anonymous electronic survey (Multimedia Appendix 1). Study data were collected and managed using the Qualtrics XM platform. The survey was distributed in May 2023 and was open for 28 days. In total, 5 reminders were sent to nonrespondents and nonfinishers at 3, 7, 14, 18, and 23 days. To avoid duplicates, each participant was sent an individual link via Qualtrics.

Outcomes Measured

The outcomes measured included demographic data; social media platform use (platforms that were used daily, platforms used for residency programs, and the influence of social media on stages of the residency application process); content posted on social media platforms (student content that was trusted, not trusted, desired, deterrents, and then helpful); nonsocial media resources used for learning about residency programs; and reasons why participants did not use social media.

Data Analysis

We performed simple descriptive statistics for survey questions. Nominal variables were reported as percentages and frequencies. Ordinal variables were presented as percentages. Data analysis was conducted using Prism GraphPad (version 9.5.1).

We performed a thematic analysis using an inductive constructivist approach on deidentified responses to open-ended questions of fully completed questionnaires [14,15]. Coders (SJ and JLC) independently reviewed responses via open coding, systematically generating a preliminary list of codes for each question. Using methods outlined by Nowell et al [15], these were merged into concepts, and themes were generated via constant comparison, returning to raw data, and iterative modification to develop a consensus on themes.

Results

There were 69 respondents out of 148 eligible students in our study. Of these, 5 were excluded from the analysis because of incomplete survey responses, with a completion rate of 92.8%. The median age of survey respondents was 27 years old (range 24 - 39; IQR 27 - 29 years). In this cohort, 42.9% identified as a man and 57.8% identified as a woman. Further, 100% of respondents matched in the 2022 - 2023 cycle, and 73.4% matched in the Northeast Region. The most popular specialties were internal medicine (25%), pediatrics (15.6%), and emergency medicine (9.4%) (Table 1).

Table . Demographic characteristics.

Characteristics	Participants, n (%)
Gender	
Women	37 (57.8)
Men	27 (42.9)
Transgender or nonbinary	0 (0)
Race or ethnicity	
American Indian or Alaska Native	0 (0)
Asian	13 (20.3)
Black or African American	0 (0)
Native Hawaiian or other Pacific Islander	0 (0)
Hispanic White	2 (3.1)
Non-Hispanic White	44 (68.8)
Other-Hispanic	2 (3.1)
Multiracial-Asian or White	3 (4.7)
Specialty	
Anesthesiology	3 (4.7)
Emergency medicine	6 (9.4)
Family medicine	4 (6.3)
Internal medicine	15 (25.0)
Internal medicine—pediatrics	1 (1.6)
Neurological surgery	1 (1.6)
Neurology	1 (1.6)
Obstetrics-gynecology	5 (7.8)
Ophthalmology	2 (3.1)
Orthopedic surgery	2 (3.1)
Otolaryngology	1 (1.6)
Pathology	1 (1.6)
Pediatrics	10 (15.6)
Psychiatry	4 (6.3)
Radiation oncology	1 (1.6)
Radiation—diagnostic	3 (4.7)
Surgery—general or preliminary	3 (4.7)
Region matched	
Northeast	47 (73.4)
Southeast	1 (1.6)
West	3 (4.7)
Southwest	7 (10.9)
Midwest	6 (9.4)
Social media platforms daily use	
Discord	3 (4.7)
Facebook	20 (31.8)
Instagram	46 (73.0)
Reddit	12 (19.1)

Characteristics	Participants, n (%)
Snapchat	18 (28.6)
Twitter (X)	10 (15.6)
TikTok	14 (22.2)

The primary social media platform used was Instagram, with 73% (46/63) reporting daily use, followed by Facebook (20/63, 31.8%) and Snapchat (18/63, 28.6%) (Table 1). Among the respondents, 65.2% (45/69) reported using social media to learn about prospective residency programs. The most frequently used platforms for this purpose were Instagram, Reddit, and YouTube (Figure 1). Facebook, Snapchat, and TikTok were rarely or never used to learn about residency programs.

Social media had a moderate or major effect on 47.6% (20/42) of respondents' opinions about programs, while it had a lesser effect on respondents' decision to apply (6/42, 14.3%) or interview (5/42, 11.9%) at a program. However, 26.2% (11/42) of respondents indicated that social media had a moderate or major effect on their decision to rank a program (Figure 2).

Figure 1. Frequency of social media platform usage when learning about residency programs.

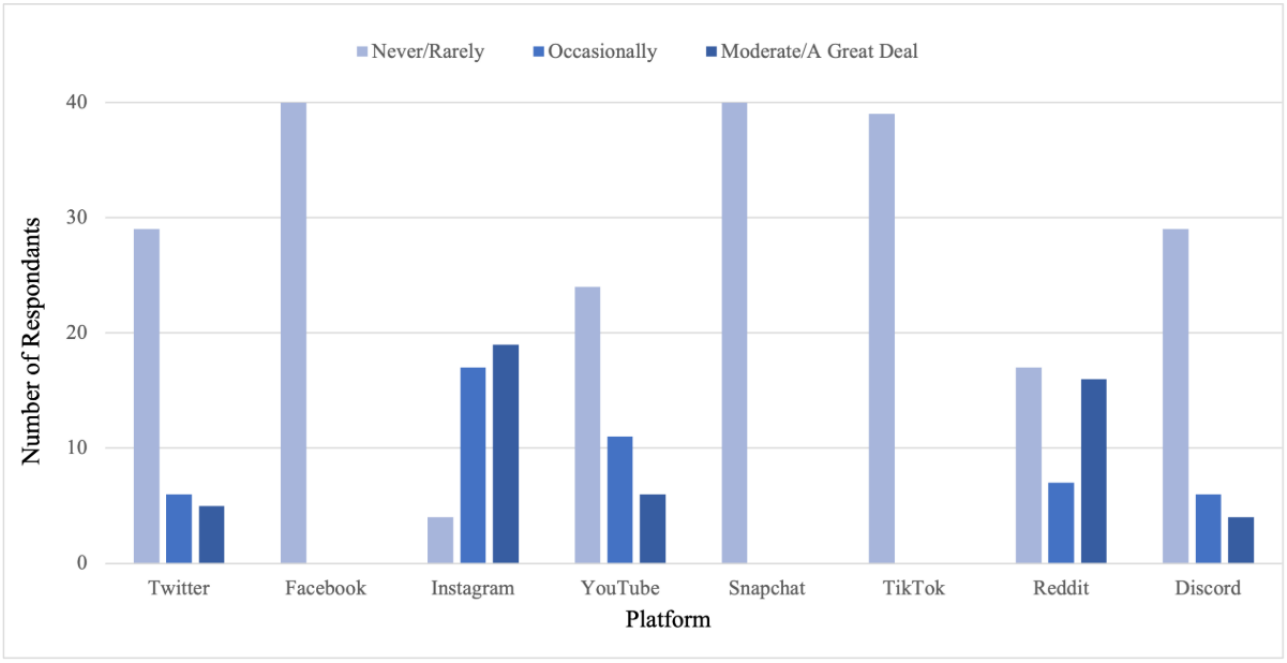

Figure 2. Social media influence on students' residency application process.

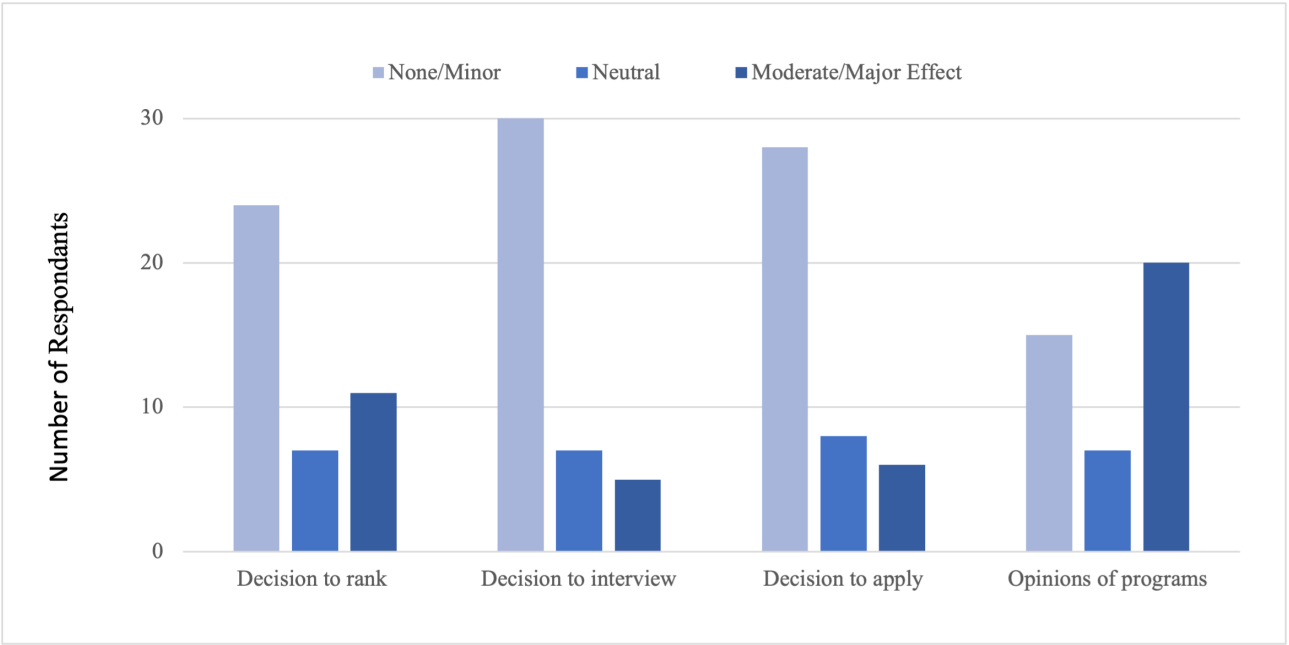

Among the 34.4% (22/64) of respondents who did not use social media, common reasons for abstaining included a perception that information could be easily distorted, social media can lead to mistrust and misrepresentation of the programs, lack of personal social media accounts, and limited usefulness or applicability of information resulting from the variable quality of social media posts. The sources trusted were the official program website, Fellowship and Residency Electronic Interactive Database Access (FREIDA), word of mouth, and personal contacts (Table 2).

Table . Resources used and reasons that students did not use social media.

	Themes
Resources used	• Program website • FREIDA[a] • Word of mouth • Current or past residents • Institutional contacts
Reasons that students did not use social media	• Mistrust of social media • Programs could be misrepresented • Irrelevant and not applicable postings that were unhelpful • Posts were not authentic • Respondents did not have or use social media personally and professionally • Variability in posts

[a]FREIDA: Fellowship and Residency Electronic Interactive Database Access.

The content deemed most valuable was resident and faculty relations (89.5%), followed by social events (86.8%) and education (60.5%) (Table 3). Thematic analysis revealed that students were attracted to posts emphasizing camaraderie, diversity, resident wellness, a genuine representation of the program's personality, and program and curriculum information. Participants particularly valued "Day in the Life" posts that visually depicted people, facilities, and location, as well as content that focused on personal experiences or resident wellness, highlighted unique attributes of the program, and provided information on the application process (Table 4).

Table . Desired social media content when researching residency programs.

Content	Participants, n (%)
Social events	33 (86.8)
Research	13 (34.2)
Didactics	12 (31.6)
Education	23 (60.5)
Resident and faculty relations	34 (89.5)
Other	2 (5.3)

Table . Themes and quotes of content that students deemed helpful, attractive, deterrents, trusted, and not trusted.

Themes		Quotes
Content that attracted students to a program		
	Camaraderie among residents and faculty; diversity of the program	"Seeing the residents spending time together and enjoying it, even if they were posting them working on the floor together"
	Resident wellness	"Camaraderie evident on posts"
	Content invoking a genuine feeling and showcasing its personality; informational content about the program and curricula	"Multiple social events with residents of all classes, photos with attendings and residents together"
Content that students deemed helpful in learning more about programs		
	Visualizing people, facility, and location; showcasing program's unique features; informational posts on the program; "Day in the Life"; resident wellness including what they do in their time off; personal experiences about a program; focus on advocacy	"When it was active, showed personality of programs/residents"
Content that deterred students		
	Minimal to no social media posts; lack of representation of multiple resident and faculty; negative personal anecdotes	"Less activity or presence on social media left an impression of overworked residents who didn't have time to post, or programs with less wellness/bonding activities to show off"
	Perception of ingenuine postings	"Too much of one person"
	Lack of types of content: photos and resident highlights	"No photos of residents and attendings"
Content trusted by students		
	Personal endorsements; resident-driven content; perspectives from residents and applicants; anonymous online platforms	"Reddit, student doctor network, because people post anonymously and be honest about the negative aspects of their program"
Content not trusted by students		
	Curated social media posts	"Social media posts are curated, and I don't trust that it's a true reflection of the day-to-day or vibe of the program"
	Program websites; promotional videos	"The promo videos for each program on the website because you can highlight very small parts."
	Nonanonymous content (subject to bias)	"Statements about the quality of the program, if they are happy, etc. I would not trust because the residents know the recordings will be posted. Hard to be honest when you can't be anonymous."
	Reddit, Discord, and chat/discussion boards (subject to bias)	"Chat/discussion boards due to potential for bias"
	Content from individuals outside the program; content from nonprogram accounts	"Message boards like Reddit I consider less reliable as anyone could share their experience with a good versus bad interview, I find these sites are very polarizing good or bad."

In a thematic analysis among all participants, anonymous digital platforms such as Reddit and Discord were considered trustworthy by some (n=3), although others perceived them as subject to bias and could be polarizing (n=15). Respondents also reported that nonanonymous content could also be subject to bias, noting that individuals posting may not want to be honest about negative aspects of a program when posting anonymously. Content from individuals outside the program and from nonprogram accounts was generally not trusted, as content could be posted and "filled with trolls," individuals who post intentionally provocative or inflammatory content. Finally, curated social media posts, program websites, and promotional videos were also listed among content that was not trusted (n=8), as it may only highlight certain aspects of the program (Table 4).

Discussion

Principal Findings

Our study revealed that Instagram was the most commonly used social media platform within our cohort. Instagram has experienced the greatest growth among new residency-specific social media accounts since March 2020, and its predominant demographic characteristics are similar to those of most prospective residents [12,16-18]. It has also been cited to be the most used platform, compared to Facebook and Twitter [19].

Interestingly, although the majority of students in this cohort reported using Facebook daily or weekly, it was almost never used to learn about residency programs by our respondents. Despite Facebook being commonly cited and compared to other platforms, it was only used more than Twitter by family medicine applicants. Otolaryngology, anesthesia, and plastic surgery applicants all used Facebook less than Twitter, with all specialties citing Instagram as the most used platform [4,7,19-21]. Facebook as a platform was shown to have the least growth, the least total number of accounts across specialties, and the least utilization among most specialties in comparison to Instagram and Twitter [17,19,20]. It is unclear why students did not use Facebook to learn about residency programs, despite their overall frequent use. One possible reason is the lack of Facebook posts by residency programs. To maximize the effectiveness of their social media presence, programs might consider focusing on Instagram rather than Facebook or linking the 2 platforms, thereby reaching 2 platforms with 1 post.

We found Reddit to be the second most popular platform. Reddit has been used by anesthesia and emergency medicine applicants as sources of information but was not this highly ranked by prior studies [20,22]. Its design facilitates ease of information exchange, and its built-in anonymity affords users the opportunity to post content without fear of repercussions. Students acknowledged that while anonymity introduces the potential for bias, anonymous online chat and discussion boards still have the potential to be trustworthy sources of information. Additionally, it is worthwhile for programs to note that negative anecdotes published on Reddit or similar platforms can deter students from programs and can be seen by those without social media accounts. The increasing popularity of Reddit suggests that it is a worthwhile avenue for social media outreach during the residency application season [22].

As social media influence the residency process, respondents are affected by their opinion and rank of a program. Social media can positively influence the opinions of programs, congruent with prior urology, otolaryngology, and plastic surgery studies, with a quarter of students' decisions affected by social media when creating their "rank list" [7,8,23]. However, as compared to Naaseh et al [9], who found 74% of respondents increased the number of programs they applied to due to social media, we found no significant effect when applying to programs found in our study despite the positive overall impression of the program in our study along with anesthesia, general surgery, and family medicine [4,9,11,20]. Based on studies, social media can influence opinion and rank of a program, which may ultimately change where a student matches for residency and whether a residency program is able to fill all its residency positions.

Regardless of surgical or nonsurgical specialty, posts that showcase resident and faculty relations, social events, and educational material are seen as the most desired content. As seen in our study, applicants desire a sense of camaraderie and resident wellness where "the residents are spending time together and enjoying it even if they were posting them working on the floor together" [19,21]. Consistent with prior studies, applicants are interested in the resident life in and outside of the hospital [19]. "Day in the Life" posts, where residents showcase a typical working day, can help students understand what their day-to-day life will be like at a particular program. They can also help to showcase aspects of the program that are difficult to show within the virtual interview setting, such as personnel interactions, diversity, and wellness [11,21]. Finally, they can be an adjunct to highlight specific program information, including curricula, electives, rotations, research, conferences, and even interview-specific information. These are all aspects sought by students in their evaluation of a program's social media presence and can be leveraged in the recruitment of residency candidates.

Importantly, social media can also have a negative influence on prospective applicants. Our study shows that social media accounts that do not consistently post or save content can leave the "impression of overworked residents who did not have time to post, or programs with less wellness or bonding activities to show off," consistent with prior investigations [24]. Negative anecdotes and comments left on anonymous platforms by single individuals, although possibly isolated, nonrepresentative experiences, can have a profound negative influence on an applicant's perception of a program, and it can be exceptionally difficult to correct these views. Programs must keep in mind that the amount and content a program posts and anonymous negative anecdotes can contribute to a negative opinion of a program, potentially affecting the application and rank process.

In our cohort, approximately one-third of the applicants did not use social media and reported using other resources. Thus, it is imperative to ensure that the official program website and Google are updated and accurate. Traditional resources include FREIDA, Doximity, word of mouth, current and past residents, and contacts within the institution [4,11,12]. These are all highly trusted content used by both social media users and nonusers.

With Instagram being the most popular social media platform, residency programs would likely benefit the most from using Instagram as their main social media platform [9,12,19,20]. Although an exact threshold is unknown, students associate less frequent Instagram posts with decreased resident wellness, and frequently posting information about residents, faculty, and program information is important for a program's image. High-impact posts might feature a particular resident for a "Day in the Life," social activities both inside and outside of the work environment, and highlights from resident wellness days and resident-faculty interactions. These can be categorized and saved, enabling prospective applicants to easily view them at later dates. Efforts should focus on creating authentic posts that showcase the people, diversity, and culture of the program in a

fun manner while taking care to avoid professional, ethical, and legal violations [25]. Students want a glimpse of what it is like to be a resident at a particular program, and posts containing pictures and videos can enable them to see and understand the program better in the current landscape of recruitment.

Limitations

As this is a survey-based study, the survey is subject to selection and response bias, with potential inaccuracies in the participants' recollection of their social media usage and influence in the residency application process. However, this is the first survey across specialties to delve into the social media usage throughout their residency application process; it has to be done after Match day. We attempted to limit response bias by ensuring anonymity and distributing this survey between match day and prior to graduation to all students in this class. We had no responses that indicated they did not match and did not ask whether any applicants went through the SOAP (Supplemental Offer and Acceptance Program) process. Thus, it is possible that those likely to respond may have been those who used social media throughout the application process and those who did not have to go through the SOAP process. Further studies could look at social media use in those that matched during the NRMP (National Resident Matching Program) or the SOAP process to see if there was a difference. Questions could also directly ask about positive and negative influence to gain more information on the drawbacks of social media while being a neutral question stem.

Although the survey was developed based on the guidelines of Artino et al [13], it needs to be further validated in the future. This was a single-center study from an allopathic medical school, limiting the generalizability of the findings, as social media patterns may vary among regions and medical schools. Thus, a multi-institutional study that examines applicants' use of social media throughout their application, interview season, and ranking process is needed to further elucidate information to be used by programs. Studies could delineate the widespread use of social media by specialties, as well as whether the applicants matched into their specialty of choice or not. Specific content that students are interested in could also be looked at for specialty (ie, procedural-based vs non–procedural-based specialties or adult vs pediatric specialties).

Conclusions

This study offers important insights into the effects of social media on residency recruitment from the student perspective. Students use social media platforms, specifically Instagram, to make informed decisions in their residency application process; therefore, programs can use these platforms to augment their recruitment. This information can help programs develop their social media platforms to cater to their target audience and mitigate the potential negative influence of social media. With the increasing popularity of social media among this generation of applicants, its use in the residency match process is expected to increase, with the current leading social media platforms being Instagram and Reddit.

Abstract

Background: Social media (SM) has become an integral part of many medical students' lives, blurring the lines between their personal and professional identities as many aspects of their medical careers appear online. Physicians must understand how to responsibly navigate these sites.

Objective: This study aimed to identify how medical students use SM and their awareness and adherence to ethical guidelines of e-professionalism.

Methods: This is a cross-sectional study delivered as an online voluntary survey to senior medical students at King AbdulAziz University Hospital in Jeddah, Saudi Arabia. We investigated how many students used SM, their privacy settings, their possible breaches of ethical standards, and their portrayal of their training institute online.

Results: A total of 400/1546 (26%) senior medical students responded to our survey. Among the participants, 95/400 (24%) had public SM accounts, while 162/400 (41%) had both private and public accounts. As for breaches in e-professionalism, 11/400 (3%) participants posted a picture of a patient on SM without their permission, while 75/400 (20%) posted part of an excised organ or x-ray on SM without their permission, and 60/400 (16%) discussed a patient. With regards to sharing medical school information, 108/400 (29%) discussed an incident at their medical school, and 119/400 (31%) participants shared a lecture online without the presenter's permission. Approximately 66% of the participants reported that they were unaware if their institution had a professional code of conduct for SM use, and 259/371 (70%) did not receive training on the professional use of SM.

Conclusions: Medical students must be taught to recognize inappropriate online behavior, understand their role as representatives of their medical school, and know the potential repercussions of unprofessional conduct on SM. This could be accomplished by providing workshops, regular seminars on e-professionalism, and including principles of SM conduct in existing ethics courses.

Introduction

Since its founding in 2006, the number of active users of Twitter (currently known as X) has increased to 237.8 million worldwide as of January 2023 [1]. Many medical students have grown up with online social media (SM) profiles. Studies conducted in Saudi Arabia have demonstrated that 75% - 87% of medical students use SM [2,3]. Owing to built-in camera-equipped smartphones, these students can now document their entire lives through pictures and videos and share them online like a public diary. Therefore, medical school is an integral part of their lives, and aspects of it are bound to find their way onto their SM profiles. However, do medical students understand the rules and implications of sharing that information online?

In the past decade, medical students have transitioned from discussing complex patient details with a few colleagues in the hospital's breakroom to doing so with hundreds of "followers" worldwide. During the COVID-19 crisis, SM played a major role by building bridges across health care communities, allowing physicians and patients to connect worldwide, exchange experiences, access the latest health recommendations, and provide and receive emotional support [4-6]. SM has even been used as an educational resource, with studies showing that most students use it to access or share learning material; 30% do not even use a textbook [7-9]. In addition, students may also share patient encounters, conflicts between staff, recordings of lectures, and other occurrences on these SM sites. These medical student posts eventually become a reflection of their profession and institution. The images they share are not always

complimentary. A cross-sectional study in the United States revealed 9 incidents of medical students posting negative information about their medical school online [10]. Furthermore, the same study revealed that 13% of those schools described a violation of patient confidentiality, and 4% of those incidents were reported by the patients or their families. Health care workers' online posts have also led to dismissals and lawsuits [4,11,12]. Moreover, several articles document unprofessional behavior by medical students online, including drinking and illicit drug use [4,10,12,13].

We hypothesize that many medical school curricula emphasize disease management and patient care, which are undeniably important. However, they have not fully evolved to address the complexities of the modern social and digital landscape, leaving students underprepared to navigate these challenges effectively. This gap can inadvertently contribute to lapses in judgment because students face situations for which they may not have been adequately equipped. Against this background, our study aimed to determine whether medical students shared unprofessional content related to patients or their medical school that could impact public perception of their institution or profession. Additionally, we sought to assess their awareness of and adherence to ethical standards of e-professionalism. A further objective was to compare our findings within the context of Saudi culture to those reported in previously published Western studies.

Methods

Study Design

This is a cross-sectional study that includes senior medical students and interns at King AbdulAziz University (KAU). Medical school in KAU lasts 6 years in addition to an internship year. We defined senior medical students as those in their 4th to 6th years of training. This group was selected because the earlier years of medical education focus primarily on lecture-based and laboratory-based basic sciences, with no direct patient exposure. We developed a 2-part, 19-item survey and included 3 demographic questions (age, gender, and year of training). The question content and design were based on our primary and secondary research goals. We developed our research questions through an extensive review of the literature, aiming to identify common challenges, breaches, and issues faced by medical students and medical schools in the context of SM use [4,10,12,14]. We identified common issues among medical students, including the sharing of confidential patient information—both textual and visual—on SM, as well as the dissemination of negative encounters experienced in their hospitals. Additionally, this study found that numerous lecturers faced consequences for remarks or actions during lectures that were unknowingly recorded by students and shared publicly [15-17]. This prompted us to investigate the frequency of teaching sessions being recorded without the lecturer's permission. Our survey questions were regarding sharing images of patients, parts of patients, colleagues, and lectures without permission. We also included questions on whether they discussed patients or incidents at their medical school online. To identify the effects students' online behavior may have on their professional image, we included questions that addressed students' profiles' privacy or anonymity (eg, Do you use your real name? Is your profile picture a clear image of yourself?), and link to their profession (eg, Do you mention the name of your institution? Do you identify your profession?). We revised the survey to ensure that the final questions were relevant, contained appropriate wording, and appeared in a logical order. A questionnaire was developed using the website Survey Monkey. The results could only be accessed by the principal researcher under a password-protected online account. We shared the survey with 10 medical students from the target group to ensure that all respondents would similarly interpret the questions as well as the usability and technical functionality of the survey platform. After piloting the survey, some questions were modified (in the question "what social media platform do you use regularly?" we added options such as Telegram, Discord, and Reddit). We also changed the wording of some questions to improve clarity. These 10 students were not included in this study's group. The final questionnaire consisted of 19 questions distributed over 4 pages (Multimedia Appendix 1). The questionnaire does not allow multiple responses for the whole duration of this study. If a student attempts to take the survey again using the same browser, they will see a message that they already took the survey. After final approval of the questionnaire and design, we invited senior medical students from years 4, 5, and 6 and the internship year to participate in the survey voluntarily through an open link. Members of the research team contacted the chief students of each academic year in person to explain the purpose and details of this study to share with all students in their year of training. Then, they sent the chief students a link to the survey via a WhatsApp (Meta Platforms, Inc) message to distribute to all students in their year individually. This message included the name and contact information of the principal researcher, the duration of the survey (3 min), and a link to the survey. The message also informed the students that their responses would be kept confidential, participation was completely voluntary, there was no incentive, and their evaluation and training would not be affected by their decision to participate in the study. We also included a QR code link on the last slide of anesthesia lectures given to the target group and invited the students to this study. The survey link was opened on August 10, 2022, and closed on June 16, 2023.

Descriptive statistics of variables were presented as counts and percentages to summarize the characteristics of the participants, including gender, age, and year of medical school. Chi-square tests assessed associations between categorical variables, and Fisher exact tests, as indicated. Univariate and multivariate logistic regression analyses were performed to identify predictors of cyberbullying exposure, with odds ratios (ORs) and 95% CI reported for each predictor. Variables included in the regression models were gender, age category, year of medical school, SM privacy status, time spent on SM, and training on the professional use of SM. Statistical analyses were performed using Stata (version 12.1 software, StataCorp LP). Cronbach α was used to measure internal consistency (0.75).

Ethical Considerations

We obtained institutional review board approval to conduct the study from KAU's Ethics Committee (reference #414-‐22). The online survey began with an informed consent statement that explained the purpose of the questionnaire and assured participants that all information would be kept confidential with no names or contact details recorded in the survey. Participation was entirely voluntary, with no reward for completing the survey and no penalty for choosing not to participate. The data were stored securely under password protection, and only the principal researcher had access.

Results

We distributed the survey to 1546 participants, of whom 400 responded, yielding a response rate of 26%. Survey completion rate was 86% and both incomplete and complete surveys were used in analysis. Approximately half of the participants were sixth-year students (194/400, 49%), and two-thirds were women (246/400, 62%), as illustrated in Table 1. Snapchat was the most used platform (287/400, 72%), followed by Twitter (275/400, 69%) and Instagram (256/400, 64%). Facebook was the least used platform (8/400, 2%), and only 8/400 (2%) of the participants reported not using any SM platform at least once a week.

Table . Characteristics of the participants (N=400).

Characteristic	Value
Gender, n (%)	
Male	154 (38.5)
Female	246 (61.5)
Age (years), n (%)	
18‐20	3 (0.8)
21‐25	378 (94.5)
26‐30	18 (4.5)
>30	1 (0.2)
Year of medical school[a], n (%)	
Fourth	16 (4)
Fifth	142 (35.5)
Sixth	194 (48.5)
Intern	48 (12)
Platform used at least once a week, n (%)	
Facebook	8 (2)
TikTok	184 (46)
Snapchat	287 (71.8)
Twitter	275 (68.8)
Instagram	256 (64)
Reddit	32 (8)
Discord	30 (8)
Telegram	247 (61.8)
Own YouTube channel	25 (6.3)
None	8 (2)

[a]Has missing value for 1 participant.

Only 95/400 (24%) of the participants had public SM accounts, whereas 162/400 (41%) had a combination of private and public accounts. Most of the participants (307/400, 77%) used their real names on SM, and one-third used their own photos for their profile image (118/400, 30%). Approximately half of the participants used SM for more than 3 hours a day (180/400, 47%), whereas only 15/400 (4%) used it for less than 1 hour a day (Table 2). Most of the participants used SM for entertainment (340/400, 85%); some used it for networking with other professionals worldwide (91/400, 29%) and for staying in touch with family and friends (300/400, 75%).

Table . Description of social media use among the participants (N=400).

Variable	Participants
Privacy status of social media account, n (%)	
Public	95 (23.8)
Private	139 (34.8)
Some public, some private	162 (40.5)
Do not use social media	4 (1)
Privacy practices in social media use, n (%)	
Use of real name on social media	307 (76.8)
Use of a clear photo of self as a profile image	118 (29.5)
Identify as a King AbdulAziz University student	76 (19)
Identify as a medical student	127 (31.8)
None of the above	69 (17.3)
Time spent on social media, n (%)	
Less than 1 h/d	15 (3.9)
1 h/d	27 (7.1)
2 h/d	71 (18.6)
3 h/d	88 (23.1)
More than 3 h/d	180 (47.2)
Reason for social media use, n (%)	
Networking with other medical students or professionals worldwide	91 (22.8)
Keeping in touch with family or friends	300 (75)
Providing medical advice and advocacy	30 (7.5)
Entertainment	340 (85)
Medical education	172 (43)

Institution-related SM use practices are presented in Table 3. Regarding the professional use of SM, only 125/371 (34%) of the participants said they were aware that their institution had a professional code of conduct for SM use. Additionally, just 112/371 (30%) recalled having received training in the professional use of SM. Approximately one-third of the participants reported checking SM while rounding on patients (138/382, 36%), discussing an incident that occurred at their institution online (108/371, 29%), or uploading the content of a lecture or workshop online without the lecturer's permission (119/382, 31%). Only 11/380 (3%) posted pictures of patients on SM after obtaining the patient's permission, while 75/381 (20%) posted pictures of parts of a patient (x-ray, excised organ, etc) on SM without obtaining their permission.

Table . Number of participants who answered yes to questions regarding institution-related social media use practices, code of conduct, and training on social media use among the participants.

Survey question	Number of respondents[a], n	"Yes" response, n (%)
Does your institution have a professional code of conduct or protocol that addresses the use of social media?	371	125 (33.7)
Did you receive any training during medical school or residency on the rules and regulations for the professional use of social media?	371	112 (30.1)
Checked your social media account while rounding on patients	382	138 (36.1)
Posted a picture of a patient on social media without their permission	380	11 (2.9)
Posted an image of part of a patient (including excised tumors or organs) or a radiographic image of a patient without a patient's permission	381	75 (19.7)
Posted an image of a work colleague or senior without their permission	382	25 (6.5)
Uploaded a video or image of a lecture or workshop online without the lecturer's permission	382	119 (31.2)
Discussed an incident that happened in your institution online	371	108 (29)
Discussed a patient you saw at your institution online	372	60 (16.1)

[a]Some of the values do not add up to the total because of missing values.

Furthermore, many participants used apps to search for medical information (Table 4). The most common apps were YouTube (314/340, 92%; Google LLC) and AMBOSS (301/340, 75%; AMBOSS GmbH), followed by Osmosis (250/340, 74%; Elsevier) and UpToDate (235/340, 70%). Wikipedia (35/340, 10%; Wikimedia Foundation, Inc) and Medline (40/340, 12%; Medline Industries, LP) were the least commonly used sources.

Table . Applications used among the participants to look up medical information (N=340).

Application	Participants, n (%)
YouTube	314 (92.4)
Medline	40 (11.8)
UpToDate	235 (69.1)
Wikipedia	35 (10.3)
AMBOSS	301 (75.3)
Osmosis	250 (73.5)
Other:	40 (11.8)

Other sources were BMJ, Board and Beyond (McGraw Hill), Dr. Najeeb (DrNajeebLectures.com), MedED (PW MedEd), Kaplan, Google, ChatGPT (OpenAI), Lecturio, OnlineMedEd, Mayo Clinic (Mayo Foundation for Medical Education and Research [MFMER]), Medscape (WebMD LLC), Medicosis Perfectionalis, Radiopaedia, Healthline (Healthline Media LLC), NCBI StatPearls (National Library of Medicine), Orthobullet (Lineage Medical, Inc), WikEM, Telegram (Telegram FZ-LLC), and Twitter (X Corp).

The associations between SM use practices and gender are presented in Table 5. Women were more likely than men to have private SM accounts (96/248, 39% and 43/154, 28%, respectively; P<.001) and were less likely than men to use a clear photo of themselves for a profile image (45/248, 18% and 73/154, 47%, respectively; P<.001).

Table . The association between cyberbullying, social media privacy status, social media privacy practices, and gender among the respondents (N=400).

Survey question	Male	Female	*P* value
Experienced cyberbullying, n (%)			.13[a]
No	118 (80.3)	194 (86.2)	
Yes	29 (19.7)	31 (13.8)	
Social media privacy status, n (%)			.001[b]
Public	53 (34.4)	42 (17.1)	
Private	43 (27.9)	96 (39)	
Some public, some private	56 (36.4)	106 (43.1)	
Do not use social media	2 (1.3)	2 (0.8)	
Privacy practices in social media use, n (%)			
Use of real name in social media	117 (76)	190 (77.2)	.77[a]
Use of a clear photo of self as a profile image	73 (47.4)	45 (18.3)	<.001[a]
Identify as a King AbdulAziz University student	30 (19.5)	46 (18.7)	.85[a]
Identify as a medical student	46 (29.9)	81 (32.9)	.52[a]
None of the above	29 (18.8)	40 (16.3)	.51[a]

[a]Chi-square test.

[b]Fisher exact test.

Of all the participants, 60/400 (16%) reported experiencing cyberbullying. In univariate analyses, participants with private SM accounts were less likely to experience cyberbullying compared to those with public accounts (OR 0.40, 95% CI 0.2-0.9). Additionally, those spending more than 3 hours per day on SM had significantly higher odds (OR 3.36, 95% CI 1.0-11.5) of experiencing cyberbullying compared to those spending 1 hour or less per day. Same findings were found in multivariate analyses but became borderline significant (all had confidence intervals that narrowly include the null value).

Table 6 presents the association between patient privacy practices among the participants and the privacy status of the SM accounts. Participants who reported posting an image of part of a patient (including excised tumors or organs) or a radiograph were more likely to have a mix of public and private accounts (39/75, 52%) than public (21/75, 28%) or private accounts (15/75, 20%; *P*<.001). Among the participants who reported posting an image of a colleague without obtaining permission, 12/25 (48%) had a public account, whereas 8/25 (32%) and 5/25 (20%) had mixed and private accounts, respectively (*P*<.001). Moreover, participants who uploaded the content of a lecture online without the lecturer's permission were more likely to have a public account (37/119, 31%) than mixed (54/119, 45%) or private (28/119, 24%) accounts.

Table . Association between the privacy status of social media accounts and patient privacy practices.

Survey question	Privacy status of participants who answered "yes" to social media accounts			*P* value
	Public, n (%)	Private, n (%)	Mixed, n (%)	
Posted a picture of a patient on social media without their permission	5 (45.5)	2 (18.2)	4 (36.4)	.24
Posted an image of part of a patient (including excised tumors or organs) or a radiographic image of a patient without a patient's permission	21 (28)	15 (20)	39 (52)	.01
Posted an image of a work colleague or senior without their permission	12 (48)	5 (20)	8 (32)	.01
Uploaded a video or image of a lecture or workshop online without the lecturer's permission	37 (31.1)	28 (23.5)	54 (45.4)	.004
Discussed an incident that happened in your institution online	29 (26.9)	36 (33.3)	43 (39.8)	.68
Discussed a patient you saw at your institution online	20 (33.3)	20 (33.3)	20 (33.3)	.14

Discussion

Our study reveals that a substantial portion of students frequently share medical school-related content online, with notable instances of ethical breaches such as discussing patients and posting images without consent. While most published studies examine unprofessional online content posted by students, we investigate how often aspects of their medical school that may affect public perception appear on their profiles. These results underscore the urgent need for enhanced e-professionalism training. Of the students who responded to our survey, 246/371 (66%) were unaware of institutional guidelines addressing the use of SM, and 259/371 (70%) felt they had not received training on the professional use of SM. However, most students in our study (389/400, 97%) refrained from posting images of a patient online despite not having received e-professional training. Probably, they recognized this as a breach of the well-known Hippocratic oath.

This study did uncover some breaches of professionalism. Of the students who participated in our survey, 60/372 (16%) discussed patients online, and 75/381 (20%) posted pictures of a patient's excised organ or radiological image. Their intention was likely to share clinical experiences and demystify rare medical conditions, possibly unaware that they may be violating privacy regulations. Even if the information is deidentified using the Health Insurance Portability and Accountability Act's "safe harbor" technique, it may not be anonymous [18]. If the clinical scenario is unique enough, the patient might be recognized or even appear in the local news [19]. Furthermore, patients or their families may find the case description or the public's online comments hurtful or offensive. In response to several incidents, the Saudi Ministry of Health developed guidelines requiring physicians to obtain the patient's consent before sharing their images or health information online or submitting it to a journal [20,21]. Any breach of these guidelines carries a hefty penalty.

When a personal profile is linked to a profession or institution, it becomes part of its public image, brand, and professional identity. In our study, in the participants' SM profiles, 127/400 (31.8%) indicated that they were medical students, and 76/400 (19%) indicated the name of their university. Among them, 91/400 (22.8%) used their accounts to network with other professionals worldwide, making them representatives of their institutions and professions. Furthermore, students used YouTube (314/340, 92%) as a clinical reference more than websites with verified peer-reviewed content, such as UpToDate (235/340, 69%) and AMBOSS (301/340, 75%). Among our participants, 162/400 (41%) had both a public and private profile (one profile may have reflected a professional identity and the other a private one). Female students in our study are more likely than male students to have private profiles (96/248, 39% and 43/154, 28%, respectively; $P<.001$) and less likely to use a clear photo of themselves for their profile image (45/248, 18% and 73/154, 47%). This gender difference could stem from the conservative culture in Saudi Arabia or the universally higher vulnerability of women to online criticism and cyberbullying [22,23]. Regardless of privacy settings, medical students must be cautious when deciding what to post on their SM profiles since the content can be leaked.

Among the students, 119 (37 with a public profile) uploaded recordings of lectures or workshops without obtaining the presenter's permission. This behavior is concerning, as comments and expressions made by educators or attendees may be taken out of context by worldwide viewers. Educators often tailor teaching material to their intended audience. They also ensure the cultural appropriateness of their expressions and

comments while observing the audience's social norms. If educators are aware that their work will be shared with a wider online audience, they may decide to change their appearance, behavior, and lecture content. They may also choose to avoid comments that may cause controversy among other groups. These fears have led many UK universities to implement lecture capture policies to manage the recording and dissemination of lecture content [24]. The policies address concerns related to intellectual property rights, emphasizing the need for the lecturer's consent before recording and sharing materials. Furthermore, in our study, 108 students (29 with a public profile) discussed online incidents that had occurred at their institutions. These incidents may have been unintentionally misrepresented by these students. Studies have proven that eyewitness accounts are not always accurate [25]. Additionally, these incidents may have been exaggerated online for comedic or dramatic purposes or unintentionally reveal confidential patient information. Unfortunately, public criticism of these online posts will be directed at the students' profession and medical school [26,27].

Our findings contribute to the growing body of literature on medical students' SM use by highlighting specific behaviors and awareness levels in the context of the Kingdom of Saudi Arabia. While many of our results align with previous studies, notable differences were also observed. For instance, similar to a French study, most of our students used YouTube for medical education [28]. Although, our numbers (314/340, 92%) are much higher than those in France (504/762, 66%). However, only 172/400 (43%) of our students use SM for education compared to 42/63 (67%) of Canadian students in 2015 [29]. Additionally, 60% - 92% of medical schools in the United States have also experienced unprofessional online behavior by medical students [10,14]. Most students in both regions reported using restrictive privacy settings, with only 20% - 37% of US students failing to do so [30,31]. However, unlike our American counterparts, our students are less likely to use a clear profile photo, with female students being less likely than male students to do so. By contrast, an American study found that 57% of medical students had a clear profile photo, with females being more likely to display one than males [31]. While in India, 80% of students used a clear profile photo [32]. This discrepancy may reflect cultural differences in SM use. In Saudi Arabia, where our study was conducted, cultural norms and societal expectations may influence their online behaviors. These findings emphasize the importance of contextualizing SM behaviors within cultural and geographical frameworks to develop targeted interventions that address both universal and region-specific challenges.

This study's findings are consistent with the results of other studies suggesting that medical school curricula should be regularly updated and adapted to the constantly changing clinical environment, which now includes the internet [4]. Developing guidelines alone would not be sufficient, as evidenced by the fact that 51% of US medical schools that reported incidents already had policies in place addressing online content [10]. Based on our findings, medical schools must integrate e-professionalism training into their curriculum. This refers to attitudes and behaviors that reflect traditional professionalism paradigms but are manifested through digital media [33]. These guidelines should not be restricted to patient privacy but must also emphasize respect and consideration for their professors, colleagues, and medical school. We recommend that medical schools (1) develop comprehensive e-professionalism guidelines, (2) implement mandatory training sessions on SM use, (3) regularly update curricula to reflect the evolving digital landscape and its impact on professional practice, (4) introduce regular audits and feedback sessions where students' SM activities are reviewed and constructive feedback is provided, and (5) develop an anonymous reporting system for unprofessional behavior, ensuring students can report concerns without fear of retribution.

The limitations of our study include the use of a voluntary questionnaire that depended on self-reporting. Additionally, the generalizability of the findings may be limited due to the single institution sample and cultural context. The potential impact of self-reporting bias must be acknowledged, as participants might underreport unprofessional behavior. Moreover, this study did not account for other possible confounding variables such as the influence of peers or external SM trends. Two of the researchers are associate professors and 3 of them are students at the institution which may have influenced their study design and interpretation of results. Furthermore, we did not examine the specific content of medical students' posts. We are, therefore, unaware if shared patient information followed Health Insurance Portability and Accountability Act guidelines and if posts positively or negatively depicted their school. Future studies should include content analysis of SM posts as that could provide deeper insights into the types of information shared and help identify specific areas for intervention. This analysis involves categorizing posts into themes such as educational content, patient confidentiality breaches, and professional interactions.

In conclusion, this study reveals significant gaps in medical students' online behavior that can affect their medical schools' image, patient care, and reputation. To foster students' understanding of these issues, e-professionalism must be included in training curricula and assessments. This curriculum should include workshops, regular seminars on e-professionalism, and integration of SM conduct into existing ethics courses. Now, more than ever, medical schools should ensure that students develop a sense of belonging and pride in their institution and care about how it is represented worldwide. Information-sharing guidelines should strive to strike a balance between clinical knowledge sharing, protecting patients' privacy, and reflecting an institution's values and public image.

Abstract

Background: Student development is currently taking place in an environment governed by new technologies and social media. Some platforms, such as Instagram or X (previously known as “Twitter”), have been incorporated as additional tools for teaching and learning processes in higher education, especially in the framework of image-based applied disciplines, including radiology and pathology. Nevertheless, the role of social media in the teaching of core subjects such as histology has hardly been studied, and there are very few reports on this issue.

Objective: The aim of this work was to investigate the impact of implementing social media on the ability to learn human histology. For this purpose, a set of voluntary e-learning activities was shared on Instagram as a complement to traditional face-to-face teaching.

Methods: The proposal included questionnaires based on multiple-choice questions, descriptions of histological images, and schematic diagrams about the subject content. These activities were posted on an Instagram account only accessible by second-year medical students from the University of Malaga. In addition, students could share their own images taken during the laboratory practice and interact with their peers.

Results: Of the students enrolled in Human Histology 2, 85.6% (143/167) agreed to participate in the platform. Most of the students valued the initiative positively and considered it an adequate instrument to improve their final marks. Specifically, 68.5% (98/143) of the student body regarded the multiple-choice questions and image-based questions as the most useful activities. Interestingly, there were statistically significant differences between the marks on the final exam (without considering other evaluation activities) for students who participated in the activity compared with those who did not or barely participated in the activity (P<.001). There were no significant differences by degree of participation between the more active groups.

Conclusions: These results provide evidence that incorporating social media may be considered a useful, easy, and accessible tool to improve the learning of human histology in the context of medical degrees.

Introduction

Social media platforms are web-based technologies particularly suited to facilitate the exchange of ideas through collaboration, interaction, and discussion. The accessibility and low cost of internet access, together with the high number of users of these platforms, make social media one of the easiest and most effective ways to disseminate information. In fact, 4.65 billion people, equivalent to 58.4% of the world's population, use social media [1]. In addition, most current medical students are far more knowledgeable and experienced with emerging technologies than preceding generations. Unlike traditional media (journals or television), social media emphasizes interactivity, motivation through social connections, and immediacy [2]. In this sense, the "social constructivism theory" states that interaction and socialization may help students learn and construct their knowledge and personal learning processes, supporting the use of social media for educational activities as a different tool for teaching and learning [3]. For all these reasons, social media platforms have progressively been incorporated into health care and medical education [4].

Technological advances have enabled rapid dissemination of medical updates through social networks such as Facebook, X (previously known as Twitter), or Instagram. Thus, students often have access to significant amounts of information, including content taught during traditional classes. Nevertheless, this information has not always been rigorously verified or is outdated, representing a formative disadvantage for medical students. Moreover, there is a lack of engagement and even dropout from classes because traditional education methodology is considered by the student body to be boring, unnecessary, or repetitive. Therefore, the faculty must adapt to meet their specific needs, changing traditional teaching styles and implementing new e-learning technologies [5].

Recently, the COVID-19 pandemic forced teaching staff to move further into a virtual education environment and highlighted the importance of communication between educators and learners through social media platforms. The rapid and efficient dissemination of information during the pandemic illustrated the significant influence of social media in the dissemination of medical literature and knowledge, not only among health care professionals but also among the student body [6,7]. For instance, Chan et al [8] demonstrated the benefits of using tools such as infographics posted on social media platforms (such as X and WeChat) to educate frontline health care workers about respiratory tract management and infection control in the setting of COVID-19. Thus, the pandemic prompted a paradigm shift in learning for students and medical residents by using different platforms (eg, YouTube, Zoom, Microsoft Teams) as e-learning tools under the new circumstances. Although face-to-face teaching is possible and desirable today, the use of social networks as educational instruments must continue with apps such as Instagram and aim to share image-based educational content to complement the classes.

Histology has long been an integral part of the medical curriculum [9] and continues to provide key information about biological tissues, physiology, and disease; it is therefore highly valued in clinical medicine and research. Furthermore, histopathology is a fundamental tool for diagnosis and prognosis. In addition, a thorough knowledge of histology is necessary for the surgical field and in general practice. However, histology and its nomenclature can be complex to understand for novice medical students, and consequently, it is often perceived as a secondary subject without clinical relevance [10]. From a pedagogical point of view, one of the main goals of histology courses is to ensure that students acquire the competencies necessary to understand histophysiology. For example, histology requires students to develop pattern recognition skills. Specifically, they must be able to identify what they are observing based on specific histologic features. Consequently, histology courses commonly include laboratory practices for students to train and develop these abilities. In this context, the study of histology through digital imaging might be a relevant alternative for the development of their curricula.

Instagram is a social networking service owned by Meta Platforms Inc that was launched in October 2010. Instagram allows photo and video sharing accompanied by text. The information can be shared either publicly or privately. Followers can archive shared posts, and the account's owner can track the number of people reached and give feedback to their followers. The literature shows that this social network is being used for educational purposes in medical schools, predominantly in imaging-related subjects such as radiology [11], ophthalmology [12], dermatology [13], anatomy [14], fertility [15], pathology [16], plastic surgery [17], dentistry [18], and (with very few proposals) in histology [19]. Understanding how students interact with these novel social media–based teaching environments and their approaches during e-learning processes is a matter of high relevance [20]. On the other hand, there is a lack of evidence on how the use of social networks impacts the learning and follow-up of Spanish medical students in the first years of their formation in the field of histology. In the first courses, the curricula of a Spanish medical degree include a basic thematic area with fundamental core subjects to obtain the essential knowledge for the subsequent study of pathological alterations. Among these subjects, some necessarily require the use of images, such as anatomy, cytology, histology, and microbiology. For that purpose, an educational experience was carried out using the social network Instagram to make the subject more attractive to the students of the official degree of Medicine at the University of Malaga in Spain during the 2022-2023 academic year. Our main objective was to test whether the use of Instagram might facilitate knowledge acquisition and increase engagement with histology, leading to a positive impact on students' qualifications. Additionally, we aimed to elucidate which type of visual material was more useful

for medical students. Finally, we determined students' perceptions of the integration of this tool in medical education.

Methods

Content of Histology in the Degree of Medicine at the University of Malaga

According to the syllabus for the degree in Medicine at the University of Malaga, histology is divided into 2 subjects (Human Histology 1 and 2) that are taught during the first and second years, respectively. The different didactic content is distributed sequentially, progressively increasing the theoretical difficulty (Table 1). First-year students learn general histology along with some special histology topics (eg, the immune system). The remaining systems and organs are studied during the second school year in the subject Human Histology 2. Some of the potential skills to be developed during these courses are knowledge about the architecture, morphology, and function of the different tissues or systems; recognizing the morphology and structure of tissues by microscopy and imaging techniques; and how to handle basic laboratory equipment and methodology. In addition, our curricula include the acquisition of some transversal competencies such as the capacity for analysis and synthesis, problem-solving or critical reasoning, and analysis, together with other abilities and skills (autonomous work, information management, and oral or written communication skills).

Table 1. Curricula content of the human histology subjects in the degree in Medicine at Malaga University.

Content	Issues dedicated to each topic, n
Human Histology 1	
Tissues (epithelial, muscle, osseous, connective, nervous)	17
Stem cells	1
Blood and hematopoiesis	3
Circulatory system	1
Immunity and lymphoid tissues	5
Human Histology 2	
Digestive system	6
Respiratory system	2
Urinary system	2
Genital apparatus	6
Tegumentary system	1
Endocrine system	6
Nervous system and neurosensorial organs	12

Sample Size

This study was carried out with 167 students enrolled in the subject Human Histology 2 in the degree in Medicine at the University of Malaga during the 2022-2023 academic year. The final examination was performed by most of the students (153 students), of which 143 participated until the end of the Instagram experience. Thus, only 10 (6.5%) of the 153 involved students did not follow our account.

Design of the Instagram Profile

After downloading the free app on a smartphone, a private Instagram account (username: @histologiauma) was created for the subject Human Histology 2 at the University of Malaga. The Instagram profile was linked to an institutional email address created to receive questions and comments from the student body of this subject. Students were notified of the availability of this account and were informed about the procedure to participate. For instance, they had to register by giving their real first name and last name. Once we checked they belong to the subject, the students were accepted as followers of @histologiauma.

Virtual Microscope Images

The images published in @histologiauma belong to the image bank of the Histology Unit of the Department of Human Physiology, Human Histology, Anatomical Pathology and Physical-Sports Education of the Medical School at the University of Malaga. During the COVID-19 pandemic, we introduced a highly interactive, web-based digital microscope system to view histological images during online practical lessons, either from classroom or personal computers. This virtual microscope is currently based on the digitalization of 66 slides, providing the element of real-time dynamic microscopy and offering students a truly innovative experience at exceptionally high resolution. Interestingly, this virtual microscope offers the possibility to capture specific tissue areas and use these pictures to formulate specific questions.

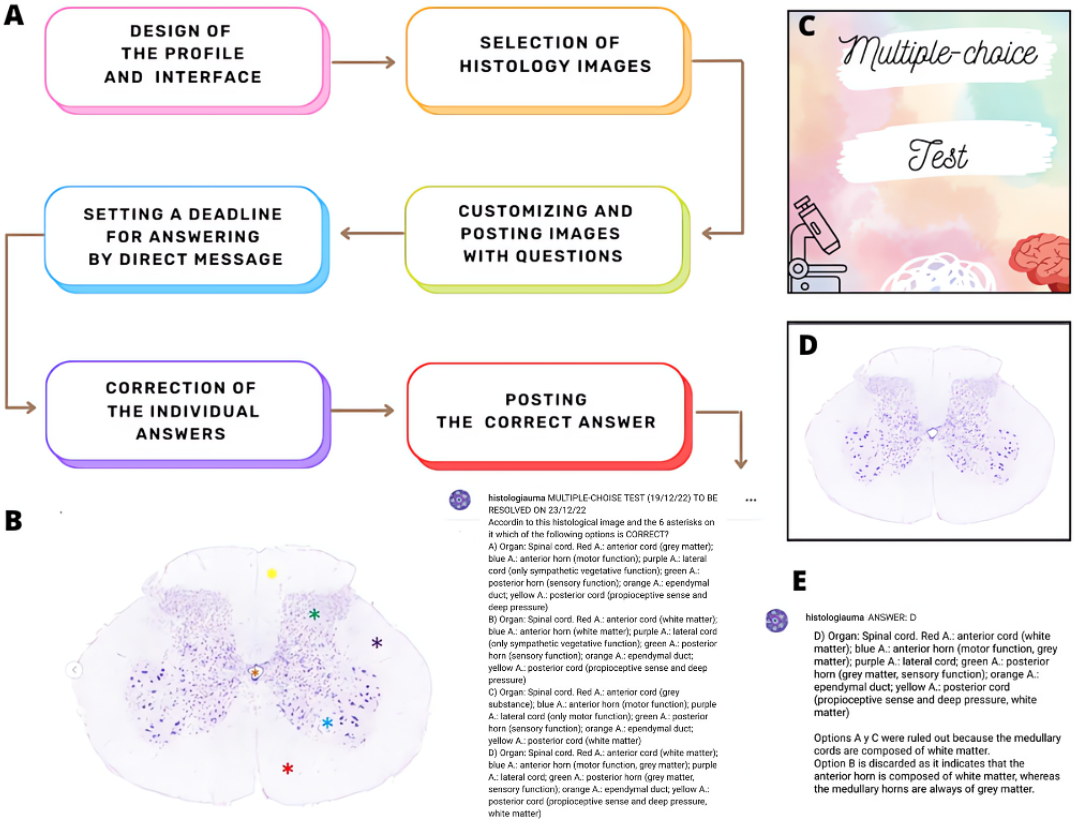
Account Content Feed

Two software applications were used to design the images: Canva and Microsoft Office PowerPoint. The free basic mode of Canva offers access to thousands of templates and 1 million free photos. Both applications allow drag-and-drop operations familiar to both average users and design professionals and

feature templates, photo filters, images, icons, and shapes useful for customizing histological images (eg, including different shapes to highlight structures or cells within a tissue, adding numbers or letters).

During a 3-month trial period, 35 posts were published, of which 5 were announcements about the account rules. The general process for uploading new content to @histologiauma account is summarized in Figure 1.

Figure 1. (A) Workflow for uploading a post in @histologiauma account, (B) screenshot of a post from @histologiauma account, (C) multiple-choice test interface, (D) image of a spinal cord transversal section with Klüver-Barrera staining, and (E) a student's direct message including a reasoned correct answer.



Ethical Considerations

The repository of digital images is composed of scanned slides with anonymized tissue remnants from Virgen de la Victoria University Hospital, whose patients provided signed informed consent for educational purposes.

The account @histologiauma was created as a private profile to be exclusively accessed by those second-year students of the degree in Medicine at the University of Malaga who voluntarily requested to participate. Images displaying captures from @histologiauma have been edited to make students' profiles unidentifiable. Moreover, all the surveys were anonymously filled out by students.

The manuscript is a retrospective case report that does not require ethics committee approval at our institution since no demographic nor clinical data from patients were used.

Type of Questions Posted on @histologiauma

The following sections were included in the Instagram platform for human histology education.

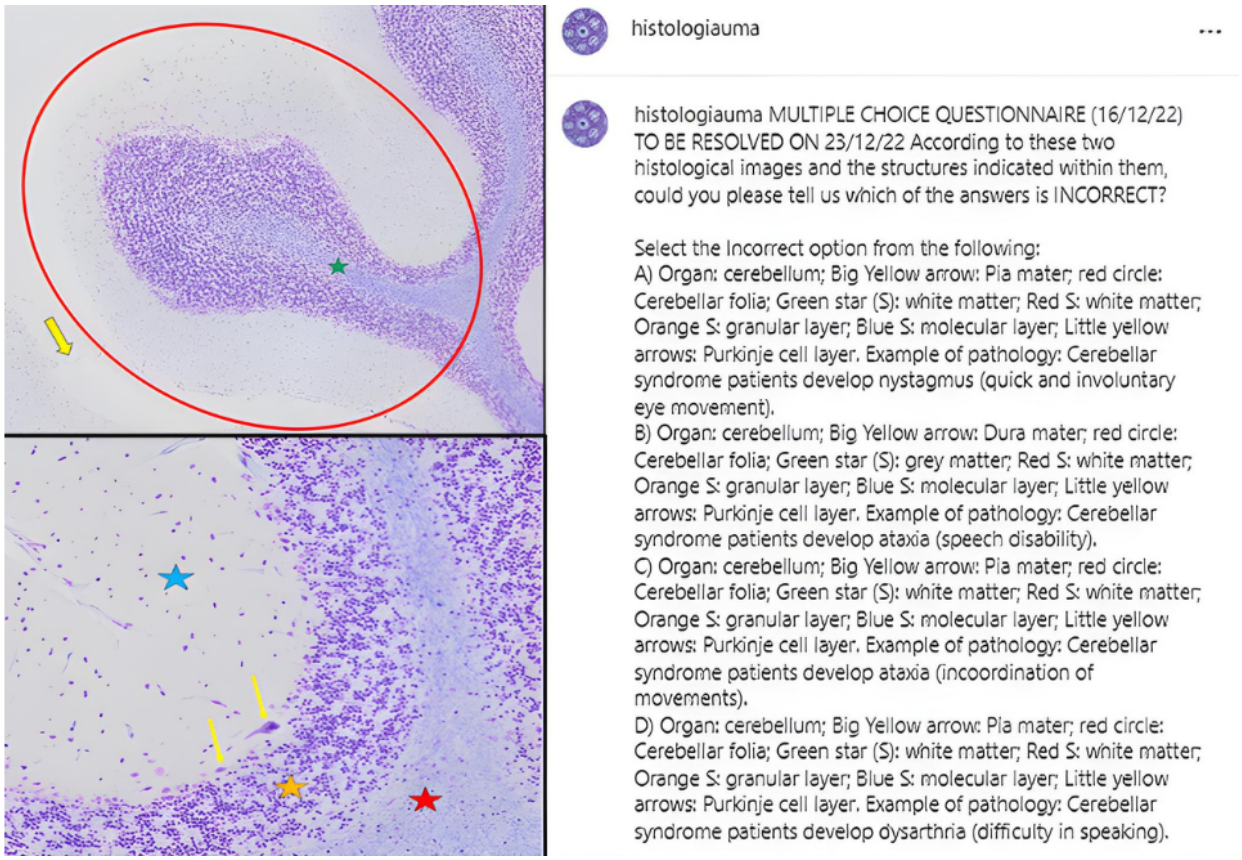
Image-Based Multiple-Choice Questions

There were 13 posts with image-based multiple-choice questions (Figure 2). Histological images of several organs studied during the academic year were posted. Different structures or cells were highlighted with arrows or other shapes (eg, stars, circles, asterisks). Multiple-choice questions with a single correct answer were posted, and 4 options were marked with labels A, B, C, and D in each question. For example, Figure 2 shows a post that asked students to select the incorrect option from the following answer choices: "A) Organ: cerebellum; Large yellow arrow: Pia mater; Red circle: Cerebellar folia; Green star: white matter; Red star: white matter; Orange star: granular layer; Blue star: molecular layer; Small yellow arrows: Purkinje cell layer. Example of pathology: Cerebellar syndrome, nystagmus as a quick and involuntary eye movement is included. B) Organ: cerebellum; Large yellow arrow: Dura mater; red circle: Cerebellar folia; Green star: gray matter; Red star: white matter; Orange star: granular layer; Blue star: molecular layer; Small yellow arrows: Purkinje cell layer. Example of pathology: Cerebellar syndrome, ataxia as a problem to speak is included. C) Organ: cerebellum; Large yellow arrow: Pia mater; red circle: Cerebellar folia; Green star: white matter; Red star: white matter; Orange star: granular layer; Blue Star: molecular layer; Small yellow arrows: Purkinje cell layer. Example of pathology: Cerebellar syndrome, ataxia or incoordination of movements is included. 4) Organ: cerebellum; Large yellow arrow: Pia mater; red circle: Cerebellar folia; Green star: white matter; Red star: white matter; Orange Star: granular layer; Blue star:

molecular layer; Small yellow arrows: Purkinje cell layer. Example of pathology: Cerebellar syndrome patients develop dysarthria (difficulty in speaking).” The correct answer is B.

No negative scores were given in the case of wrong answers. All questions had a single correct answer. Each student provided their answer, including a brief justification in the form of a private message on Instagram. They were then notified about their success or encouraged to try again in case of failure. The answers were made public 5 days later in a comment, accompanied by a summary of the most common mistakes.

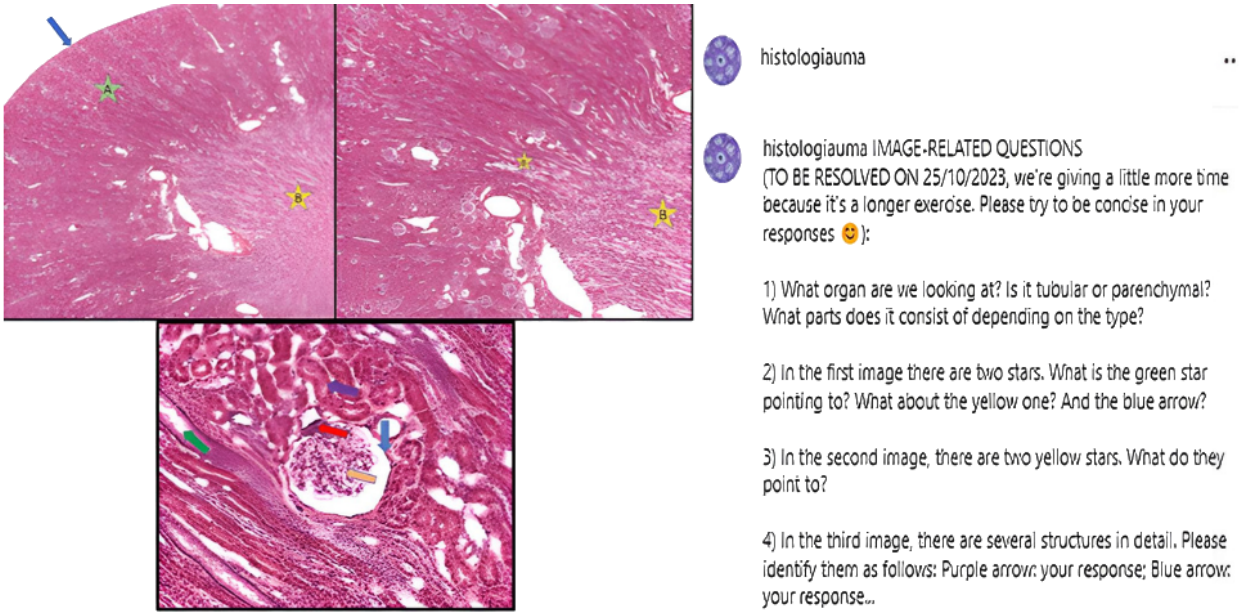
Figure 2. Screenshot of an image-based multiple-choice question about the cerebellum from the account @histologiauma.



Descriptions or Questions Associated With Histological Images

This section, consisting of 10 posts, showed histological images pointing out different structures and components to be identified by the students. For example, Figure 3 shows a post that included the following questions: “1) Identify the organ shown in the image. Is it a tubular or a parenchymatous organ? 2) What is the green star (A) pointing at? And the yellow star (B)? And the blue arrow?” Occasionally, comparisons between pathological and healthy tissues were posted, along with an introduction to clinical medicine. This section was conceived in accordance with the curricular competency entitled “From Histology to Medicine,” which aims to highlight the clinical aspects of human histology. The correct answer was published 5 days later as a comment on the post, and feedback was given to the students, as explained for the multiple-choice questions.

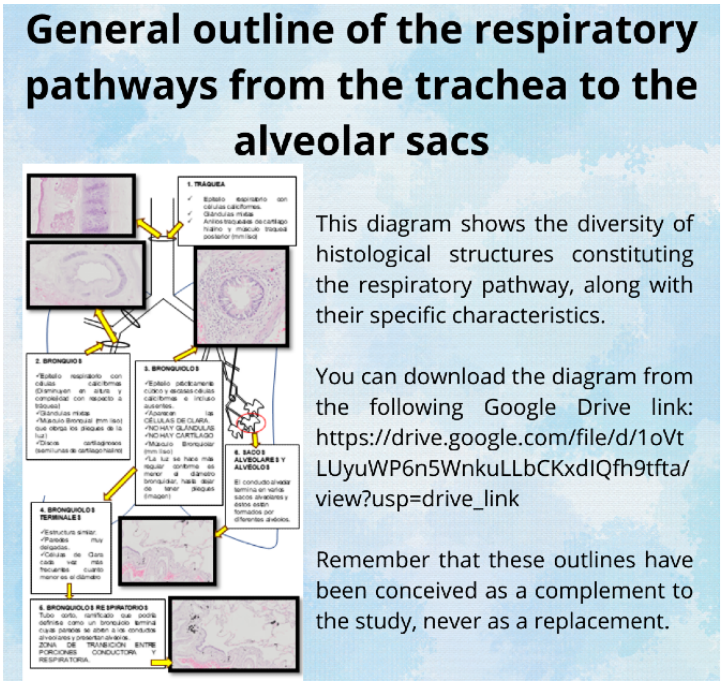
Figure 3. Screenshot of a histological image section (kidney) with the accompanying questions.



Didactic Schemes

This section included 7 posts based on student requests for visual or explanatory diagrams of the content they found most difficult. Teachers then prepared specific outlines based on these requests, avoiding the inclusion of new content. An example is shown in Figure 4. Diagrams were created using free-design and educational software, such as PowerPoint or Canva and stored in a shared Google Drive folder. The link to access the content was posted on the Instagram account and made available for 1 week. The content of these diagrams was derived from the theoretical material already provided to the students, as they were conceived as a complementary tool to the study. Students were also encouraged to make their own schemes to learn how to summarize concepts.

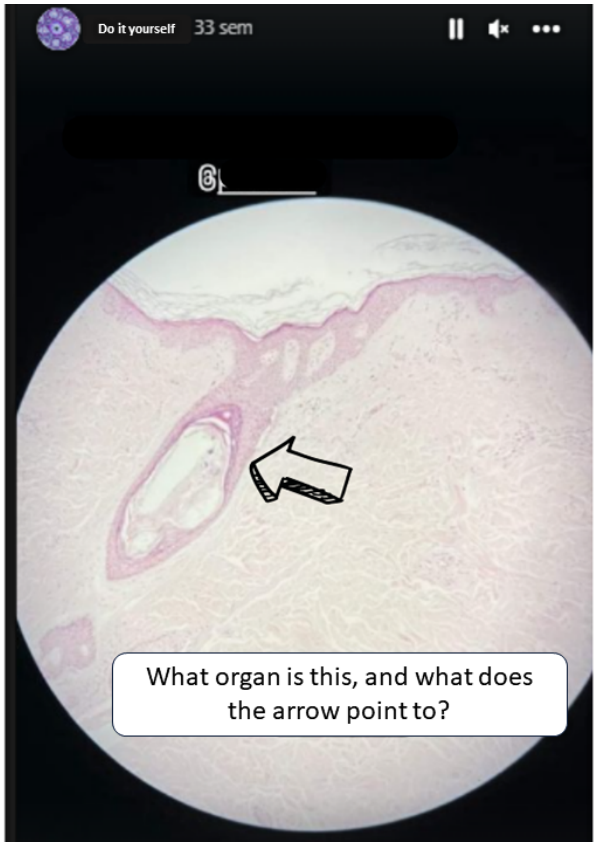
Figure 4. Screenshot of a scheme requested by students about the respiratory tract.



"Do It Yourself" Section

During the practical classes, students were encouraged to take images of histological slides through the eyepiece of the microscopes with their own smartphones. Later, they posted the images for 24 hours in the form of a story on @histologiauma accompanied by a specific question to be solved by their classmates. In total, 25 images were shared as stories, and an example is shown in Figure 5.

Figure 5. Screenshot of a "Do it yourself" section depicting a histological section of skin that was taken and elaborated on by one of the students.



Teaching Commitment

The teaching staff played a crucial role in providing feedback to the students, notifying them about their successes or mistakes through private messages and designing diagrams. Overall, 1 hour of work was required daily during the experience.

Rating

The activity was conceived as a voluntary pilot study. Students who actively participated could add a maximum of up to 0.50 points to their final mark, regardless of whether their interventions were successful. Thus, students earned points in proportion to their level of participation. A score of 10 was assigned to students who answered 100% of the questions. The student body was organized in 4 groups according to the rewards received on @histologiauma (group 1=0-4.4 points; group 2=4.5-6.5 points; group 3=6.5-8.5 points; group 4=8.5-10 points). Therefore, these points served as an indicator of participation.

Evaluation of the Activity as an Educational Innovation

To explore the influence of this innovative learning tool, data on student engagement and perceptions were collected during the lectures and at the end of the course through a final evaluation. The results were gathered throughout the academic semester with 3 anonymous surveys using a 5-point Likert scale. Each topic in the surveys covered a gradient of agreement with the statement presented (1=strongly disagree, 5=strongly agree). All questions were designed in Spanish by members of the teaching staff (AES, RSV, and DB) and later translated into English for publication.

At the beginning of this educational experience, the opinions of students about the inclusion of new technologies and the implementation of social media in our medical school were assessed through a first survey (called the pre-experience survey; Textbox 1).

This first survey also included specific questions regarding students' perceptions of the use of Instagram in the histology course (Textbox 2).

The second survey (middle experience; Textbox 3) was conducted 2 months after the start of the project. This questionnaire focused on the general operation of the account and their early perceptions of the experience. The third and final survey contained the same questions (Textbox 3) and was carried out during the last week of theory classes.

Textbox 1. General questions in the initial survey (pre-experience).

1. The university's educational systems are up to date and adapted to the times.
2. Most teachers use social networks as an educational resource.
3. Currently, the use of alternative educational tools is essential.
4. Bringing the basic subjects of a medical degree closer to the reality of professional practice is essential.
5. In general, teachers are concerned about updating educational tools.

Textbox 2. Specific questions for the initial survey (pre-experience).

1. Instagram facilitates access to educational content on histology.
2. Accessing Instagram allows me to consult the content anywhere at any time (eg, bus, train).
3. Test questions are a useful tool to review theoretical or practical content.
4. Downloading the subject outlines helps me to complete histology concepts.
5. I expect to improve my academic grades thanks to this academic experience.

Textbox 3. Specific questions for the 2nd (mid-experience) and 3rd (end of the experience) surveys.

1. I followed the @histologiauma updates daily.
2. I answered test questions.
3. I answered questions shared in the @histologiauma stories.
4. I shared some photographs in the “Do it yourself” section.
5. I answered the image-associated questions.
6. I used @histologiauma when traveling by public transport.
7. I used @histologiauma during class exchanges.
8. The test questions were adequate.
9. The schemes were useful.
10. We received highly personalized attention.
11. Circle the most useful sections of @histologiauma: “Do it yourself,” image-associated questions,” “multiple-choice questions,” “schemes.”
12. I will use @histologiuma to prepare for my final exams.

Statistical Analysis

Raw data from the survey responses were collected and analyzed using SPSS v.24 (IBM Corp). Descriptive statistics were used to characterize the data, with a frequency study carried out for each of the variables evaluated in the different surveys. Homoscedasticity (equality of variances) and normal distribution of the data were checked. Data corresponding to students’ marks (score range 0-10) are expressed as mean (SD). Mann-Whitney tests were conducted to compare overall grades from different cohorts (groups from different academic years or current cohort with the extra points versus the cohort without the extra points). The comparisons between the marks of the different groups (previously categorized into groups 1-4 according to the level of participation) and the degree of acquired knowledge evidenced by the final exam (global marks) were conducted using 1-way ANOVA followed by a post hoc Bonferroni test. Pearson correlation coefficients were calculated using the individual scores according to the students’ participation in @histologiauma and their final grades. An $r>1$ indicated a positive linear correlation between the 2 variables. The significance was set at 95% of confidence.

Results

Participant Demographics

From the very first post, 73 of 167 students enrolled in Human Histology 2 followed the account. At the end of the learning experience, there were 143 followers (143/167, 85.6%), of which 106 students had actively participated during the entire period. Analytics from these 143 students showed that 76.2% (109/143) were women and 23.8% (34/143) were men. Most (133/143, 93%) of them were 18 years to 22 years old and in their second year of the medical degree (139/143, 97.2%). There were only 4 repeaters of this subject, who were concomitantly in the third year of the degree. Full-time students represented 97.9% (140/143) of the respondents. The full demographic profile of the students is shown in Table 2.

Table 2. Student demographic data (N=143).

Characteristics	Results, n (%)
Gender	
Female	109 (76.2)
Male	34 (23.8)
Age (years)	
18-22	133 (93)
23-26	7 (4.9)
27-30	2 (1.4)
31-40	1 (0.7)
Academic year	
2	139 (97.2)
3	4 (2.8)
Enrollment	
Complete	140 (97.9)
Partial	3 (2.1)

Pre-Experience Test About Students' Perceptions of the Use of Social Media and New Technologies in Medical School Curricula

Of the participants, 83.9% (120/143) considered that the current educational system requires a significant update. Thus, 97.9% (139/143) of them strongly believed that the use of social networks should be significantly improved. Of the students, 99% (141/143) considered that using alternative educational tools is relevant, and 77.1% (110/143) of the students agreed that the use of social media such as Instagram facilitates access to the didactic content. Thereby, 95% (133/143) of the respondents found the subject more accessible thanks to @histologiauma, and 99.5% (142/143) believed they might improve their academic marks thanks to this experience.

Survey About the Students' Perceptions During the Experience

Multiple-choice questions (65/143, 45.7%) and image-based questions (33/143, 22.8%) were the students' favorite sections, with 96.5% (138/143) and 99.3% (142/143) of the students, respectively, considering them highly useful for learning the subject. In contrast, the schemes and "Do it yourself" sections were the favorite sections for 12.6% (18/143) and 0.8% (1/143), respectively, of the students. The remaining 18.1% (26/143) reported a stated preference for combinations of the different sections (multiple-choice questions + image-based questions: 17/143, 11.8%; multiple-choice questions + schemes: 5/143, 3.9%; image-based questions + schemes: 3/143, 2.4%). No other activities were included in the experience. Additionally, 96.7% (138/143) of the students felt well-supported and guided by the teaching staff throughout the experience. In addition, students showed no preference between public transport or the exchange of classes for visualizing the didactic content available on Instagram.

Impact of the Experience on Final Marks

The average grade obtained by the students from the Histology course during the academic year prior to the implementation of the experience (2021-2022: n=158 students) was 6.49 (SD 1.87) out of 10, whereas marks from the 2022-2023 cohort were significantly higher (mean 7.13, SD 1.68; $P<.002$; n=153), regardless of the extra points for participating in the experience. Once the earned points were included, the final outcome was not significantly different (2022/2023 without extra points: mean 7.29, SD 1.70; 2022/2023 with extra points: mean 7.13, SD 1.68; $P=.03$). Furthermore, the mean final grade from the 4 previous academic courses showed homogeneity in terms of having lower results (mean 6.12, SD 0.27; n=628 students) in comparison to our cohort. Overall, our data support that the use of social media produced a positive impact on students' performance, even without considering the points for participating in @histologiauma.

Interestingly, a positive linear correlation between individual participation scores and final marks (not including the extra reward points) was found ($r=0.439$, $P<.001$). Moreover, the ANOVA showed significant differences between students' marks according to their degree of participation ($P<.001$; Table 3). There was a trend of higher ratings according to the level of participation. The Bonferroni test showed that group 1 (the least engaged group with 0-4.4 points) achieved significantly lower global mean scores than the other 3 groups (all $P<.001$). Finally, there were no significant differences among groups 2 to 4 (all $P=.99$).

Table 3. Students' global marks (without the extra points) and rating obtained according to the degree of participation in @histologiauma.

Group	Global score, mean (SD)
Group 1 (0-4.4 points)	5.43 (2.65)
Group 2 (4.5-6.5 points)	7.44 (0.93)
Group 3 (6.5-8.5 points)	8.04 (0.51)
Group 4 (8.5-10 points)	8.27 (1.32)

Discussion

Background

Histology is one of the first morphological disciplines faced by medical students. Since it is necessary to integrate basic knowledge from other fields (eg, anatomy, cytology, biology, biochemistry) with spatial awareness, histology is perceived as a difficult subject by most learners. Moreover, students consider histology as irrelevant on their board examination (ie, "Spanish Specialized Health Training examination") and even for their future clinical practice [21,22]. Most current medical students use social networks daily and demand considerable effort from educators to make the subjects more attractive and dynamic. Creating a social media account is a free educational option that enables access to information and allows users to easily connect with others [23]. Thus, in this work, we analyzed the impact of using a specific Instagram account (@histologiauma) as a teaching resource during a histology course (2022-2023).

Principal Findings and Implications

Overall, our data demonstrate that medical students who followed and interacted with @histologiauma improved their exam scores compared with those who did not. In fact, a complete lack or a low level of participation generated significant differences in comparison with students who actively engaged with the activity. Most importantly, the enhancement of final grades compared with previous cohorts was not a direct consequence of the extra points awarded to the participants. Thus, improved test performance may serve as indirect and tangible evidence of better long-term knowledge acquisition [24]. These results are supported by the previous opinion of the majority of our students about the positive impact of this experience on academic results. In the first instance, the pre-experiment survey already showed that most of our students believed that social media is rarely used in educational contexts and considered that it may be relevant to include social media platforms as teaching tools, not only to increase accessibility to the content but also to improve their marks. In fact, the results demonstrated a positive disposition toward this innovative approach, since 99.5% of the participants believed they could improve their academic grades thanks to this experience even before participating in it.

Research on the strength or quality of motivation as a predictor of academic success has yielded both definitive and inconclusive findings. In this work, higher engagement and interaction with the content through the proposed interactive activities may have helped in the learning process, which was later reflected in the scores. Indeed, motivation is a determining factor not only for medical students but also for all students to develop sophisticated and successful learning strategies. A study on small group learning found that increased knowledge and understanding of subject matter increase students' motivation for studying and interest in the course content [24]. The "social constructivist theory" states that socialization can also help students during their personal learning processes [3]. In this sense, social media facilitates active interaction and collaboration by enabling instant communication and motivation [24,25].

Furthermore, our Instagram activities also served as additional virtual tests. Testing is no longer considered as only a tool for evaluation but also for learning [26,27]. Thus, using Instagram for educational purposes incorporates not only these phenomena in the process (as it could have been done through a virtual platform like Moodle) but also other factors that are particularly relevant for current young students: direct interaction with their classmates and immediacy, in addition to their own behavior and daily routine with smartphones and social media. We believe that all these factors increased the motivation and engagement of students with histology, leading to greater retention of the content that was finally reflected as higher scores.

Unfortunately, the information available on social media platforms might not be updated or subjected to peer review; thus, it may be invalid, incorrect, or even false. Conversely, @histologiauma is a platform controlled by our group of specialized teachers, prepared to guide learners toward appropriate knowledge according to the content of the subject. Therefore, the creation of a platform adapted by the teaching staff to the curricular content is ideal not only to boost interest but also to prevent students from accessing unreliable information [28].

Additionally, it is essential to comprehend the preferences of learners in order to create a quality digital learning environment [29,30]. During the experience, the image-based questions, multiple-choice questions, and histological descriptions were considered very useful by the students. Ultimately, this knowledge may help teachers to understand the strengths and weaknesses of the subject matter as well as its impact on adherence.

Comparison With the Literature

Numerous social media accounts disseminate information about many different types of pathologies to the general public. Although our work focuses on a course within the medical degree program, it is evident that Instagram serves as an optimal and cost-effective platform for capturing attention through passive learning in the field of histology and pathology [31]. In this sense, Nguyen et al [14] reported that 92.5% of students visit Instagram for educational purposes. Accordingly, 97.9%

of our respondents strongly believed that social networks should be implemented in higher education.

As far as we know, many accounts share educational content about pathology [16,32], but very few are specifically targeted at histology and assessing the impact of sharing this information on social media on medical students. Another novelty of our approach is that we used Instagram as an educational tool specifically tailored to our students, offering personalized content directly aligned with the course curriculum. Although many other studies have examined the use of social media in education, few have focused on how a targeted, image-based platform like Instagram can enhance engagement and learning outcomes in medical education, particularly in a subject highly reliant on visual materials.

For instance, Essig et al [19] from the School of Medicine at the University of North Carolina created an experience with the Instagram profile @InstaHisto in 2020, which is the most similar to our work in the existing literature. However, one of the main differences between these profiles could be summarized by the word "personalization." Our private account was created solely and exclusively for second-year students in the medicine degree program at the University of Malaga, in contrast with their public profile. Moreover, they examined the impact of the posts based on the number of views, not focusing on student interaction but rather on the general public. Instead, our work aimed to potentiate students' knowledge acquisition and to increase engagement with the subject. We also intended to understand students' perceptions about this educational tool. Similarly, the work by Essig et al [19] focused on the National Board of Medical Examiners final exams, reporting that 77% of their students found the histology content from @InstaHisto useful for passing the test. In this line, our survey data reflected a high degree of satisfaction with the utility in the educational environment of these virtual activities (96.5% and 99.3% with multiple-choice questions and image-based questions). More recently, Prabhu and Munawar [11] evaluated 49 Instagram profiles dedicated to the dissemination and teaching of radiology, concluding that it is indeed a better application of this image-based social media platform due to its easy accessibility and appeal to students. In this line, our data reflect that 95% of students believe that using Instagram would enhance their perception of the course and its appeal.

Limitations

In this work, rating grades increased after use of @histologiauma, even before adding the points awarded for students' participation in Instagram. It is noticeable that scarce involvement led to no or low improvement, and although there was no significant difference between the most active groups (G2 to G4), we did find a trend toward higher ratings according to the level of participation. In this sense, we cannot completely rule out the influence of other factors masking the impact of this experience, including other curricular or extracurricular activities performed during the school year or personal preferences regarding social media. Nevertheless, as far as we are concerned, standard students from the same academic course share identical academic schedules. All other activities performed during the histology course (such as problem-based learning or the section "From Histology to Medicine") were developed during theoretical classes or practice and were mandatory. However, we are aware that every academic group is different and repeating the experience during additional academic years would yield more reliable data. Relevant to this, the algorithm used by social media platforms like Instagram tends to favor posts from accounts with which users interact more frequently or with related content, creating information bias for customers [33]. Given this scenario, it is reasonable to interpret that students who interacted with @histologiauma above a threshold were later shown our account or similar profiles in their private feed more often than those who barely engaged or did not participate in the voluntary activity. This interaction likely results in students passively reviewing content each time they visit this platform, which finally positively impacts their acquisition and assimilation of knowledge and therefore their final results. However, this may also minimize the differences between the most active groups.

Another specific limitation of this work is that participating in these activities was not mandatory, which may have led to potential selection bias. We cannot rule out that students following the @histologiauma account were more eager to participate in additional activities than the general medical students. However, the high participation rate (85.6% of students enrolled) notably reduced the impact of this possibility. Even so, eliminating the optional nature of this activity would have yielded clearer data. In addition, it is possible that some of our students do not have an Instagram account because they do not find social networks attractive. Nevertheless, this was rarely the case, since we detected very few exceptions of students who performed the final exam without participating in Instagram (10 of 153 students). For future editions, we intend to propose @histologiauma as an educational instrument in a public mode, encouraging users to create their own hashtags and check the transcendence of the posts.

On the other hand, the use of social media platforms during the educational process of histology should be recommended only as a complement for regular teaching. Evidence that social media is not a panacea was provided in a separate analysis of 131 students who were using the microblog X during class with the aim of fostering student-faculty interaction on two campuses. Although it facilitated discussion, 71% of students found it distracting [34]. For this reason, it is important to find a balance between the usual lecture-based methodology and the inclusion of social media in higher education, not only to meet the curricular needs of students but also to ensure their engagement with their studies.

For future research, the sample size may be broadened to increase the validity and reliability of our findings and include cohorts from other courses or health science degrees such as podiatry, physiotherapy, or nursing. Moreover, specific tests about the content shown on the Instagram account could be implemented. The inclusion of a longitudinal study to track students' performance and engagement over multiple semesters would allow better understanding of the long-term impact of Instagram-based learning. Although, in general, we detected typical mistakes of pattern recognition of histological structures, a range of accuracy-based rewards could be incorporated into

the activity to avoid participation without true commitment. Finally, future experiences could explore the impact of different types of Instagram content (eg, video, live question-and-answer sessions, different quizzes).

Conclusions

Medical students consider there is inadequate use of social networks for teaching purposes, probably due to a lack of updated methodological approaches in the context of university subjects. Compared with the conventional educational system, social media platforms have a considerable impact on both teachers and students as they offer the possibility to easily connect and collaborate. In fact, one of the main objectives of medical education is to capitalize on the engaging nature of social media tools as part of an overall strategy to use a learner-centered approach. In addition, to increase student engagement during the first year of the degree in Medicine, it is desirable to use attractive didactic methods for learning histology. In this regard, the visual nature of histology is particularly appropriate for the introduction of new image-based tools. Thus, the aim of this study was to investigate an innovative online educational approach for histology based on an Instagram account specifically designed for medical students. In this work, we showed that the use of Instagram has great potential to improve not only the knowledge but also the scores of students of human histology. Our results provide evidence that this teaching strategy boosts students' learning motivation. In the near future, the classical practical lessons based on the physical microscope might not be enough to meet the needs of medical students. Therefore, Instagram may be considered as a relevant tool for current students to achieve their curricular objectives in a more dynamic, friendly, and enjoyable way under the supervision of the faculty.

Abstract

Background: Clinical internal medicine practice training traditionally relies on case-based teaching. This approach limits the development of students' clinical thinking skills. It also places significant pressure on instructors. Virtual standardized patients (VSPs) could offer an alternative solution. However, evidence on their feasibility and effectiveness remains limited.

Objective: This study aims to use the “VSPs in general practice” interactive diagnostic and teaching system, which uses VSPs to provide 3D virtual simulated patients and mimic virtual clinical scenarios. Medical students are trained through system-preset cases. This study aims to establish the clinical application of VSPs through a “VSPs in general practice” system and compare its effectiveness with traditional teaching in improving students’ clinical thinking ability.

Methods: A randomized controlled trial was conducted from October 20, 2022, to October 20, 2024. A total of 60 medical students interning at Quzhou People’s Hospital were enrolled and divided into 2 groups: the experimental group receiving VSP training (30/60, 50%) and the control group receiving traditional academic training (30/60, 50%). The teaching effectiveness was evaluated using basic knowledge assessments and virtual system scoring. After completing the course, students were surveyed with a questionnaire to assess their satisfaction with the course.

Results: All enrolled medical students completed the study. In the evaluation of training effectiveness, the experimental group showed significantly greater improvement in theoretical scores compared to the control group (mean 17.07, SD 4.24 vs mean 10.67, SD 4.91; $F_{1, 59}$=29.20; Cohen *d*=1.15; 95% CI 12.43-15.31; *P*<.001); the total score improvement in the virtual clinical thinking training system test was also significantly better in the experimental group than in the control group (mean 42.60, SD 9.56 vs mean 31.63, SD 7.24; $F_{1, 59}$=25.10; Cohen *d*=1.09; 95% CI 34.51-39.72; *P*<.001). Specifically, improvements in consultation skills (mean 8.76, SD 1.67 vs mean 7.66, SD 2.08; $F_{1, 59}$=31.09; Cohen *d*=0.55; 95% CI 7.70-8.70; *P*<.001), overall objective improvement (mean 11.97, SD 2.77 vs mean 8.15, SD 2.62; $F_{1, 59}$=30.08; Cohen *d*=1.16; 95% CI 9.21-10.91; *P*<.001), initial diagnostic ability (mean 8.74, SD 1.67 vs mean 7.66, SD 2.08; $F_{1, 59}$=4.91; Cohen *d*=0.55, 95% CI 7.70-8.70; *P*=.03), and ability to provide patient treatment (mean 7.23, SD 2.41 vs mean 5.72, SD 2.19; $F_{1, 59}$=6.42; Cohen *d*=0.63; 95% CI 5.85-7.01; *P*=.01) were significantly higher in the experimental group than in the control group. The questionnaire results indicated that 90% (27/30) of the students who participated in the VSPs’ training believed it could enhance their clinical thinking abilities.

Conclusions: VSPs reinforce the foundational knowledge of internal medicine among medical students and enhance their clinical thinking abilities, as well as improve their capacity for independent work. The VSP system is feasible, practical, and cost-effective, making it worthy of further promotion in clinical education.

KEYWORDS

virtual standardized patients; clinical competence; clinical thinking ability; medical education; medical students

Introduction

Against the backdrop of the continuous expansion of higher medical education, clinical skills training is facing multiple developmental challenges. On one hand, medical schools are under real pressure to address the shortage of millions of health care professionals, urgently needing to scale up the training of high-quality clinical physicians [1]. On the other hand, they are constrained by the relative scarcity of high-quality teaching resources, leading to significant regional disparities in the quality of medical talent cultivation [2]. Clinical reasoning ability, as the core competency for medical students transitioning into qualified clinical physicians, essentially requires the integration of multidimensional clinical information such as patient history

collection, physical sign identification, laboratory data interpretation, and imaging analysis [3]. However, the current clinical thinking training system still has significant shortcomings, primarily relying on traditional teaching methods in ward practice. This approach not only lacks opportunities for students to independently construct clinical reasoning frameworks but also fails to stimulate the cultivation of critical thinking and clinical decision-making abilities [4].

Driven by the rapid development of information technology, virtual simulation technology is deeply reconstructing the medical education ecosystem. Virtual standardized patients (VSPs), defined as artificial intelligence (AI)–driven, interactive virtual humans that simulate real patient encounters in 3D environments, offer a scalable alternative. As a product of the deep integration of computer multimedia technology and clinical medicine, VSPs have become an important carrier for revolutionizing clinical thinking training paradigms by accurately simulating real diagnosis and treatment scenarios through intelligent interactive systems [5-7]. Unlike static case studies, VSPs dynamically respond to learners' actions, replicating nuanced clinical scenarios, from history-taking to diagnostic decision-making. With the rise of generative AI, modern VSP systems can now leverage natural language processing and machine learning to mimic diverse patient phenotypes, pathologies, and even emotional states, providing a near-lifelike training experience. In the field of international medical education, mature application systems like the DxR Clinician, developed by Southern Illinois University School of Medicine, have established benchmarks through AI-driven virtual patient simulations, dynamic clinical decision trees, and intelligent feedback mechanisms, making it a gold standard for clinical thinking training [8-10].

In contrast, VSP teaching in China is still in the exploratory stage of localization and adaptation and has not yet formed a large-scale application system. From the perspective of teaching implementation, the VSP system reconstructs the clinical competency development path through 3 core mechanisms [11]: first, constructing a full lifecycle disease spectrum database, covering typical and rare cases from newborns to the older population; second, creating a human-computer interactive consultation environment that requires learners to independently complete the entire process of medical history collection, physical examination operations, auxiliary examination selection, and treatment plan formulation; finally, relying on intelligent evaluation algorithms, millisecond-level feedback is provided to operational nodes, marking logical vulnerabilities and providing evidence-based medical treatment recommendations. This closed-loop system of "simulation practice, instant feedback, correction, and improvement" effectively breaks through the time and space limitations and ethical dilemmas of traditional bedside teaching.

Clinical empirical research shows that VSPs have unique advantages. In terms of diagnostic thinking, through the dynamic deduction of complex cases such as diabetic ketoacidosis, cultivate the ability to make timing decisions for differential diagnosis. In terms of treatment decision-making, individualized treatment plans based on drug metabolism characteristics are established through scenario simulations such as antibiotic tiered use [12]. In terms of humanistic literacy, a role-playing system for patients with depression is used to train their ability to analyze the social and psychological factors behind symptoms. This teaching paradigm of integrating reality and virtuality is reshaping the new landscape of clinical competence cultivation [13]. In recent years, the demand for medical safety in society has been constantly increasing, and the professional pressure on physicians has also increased accordingly. The long training period, heavy social responsibility, and high professional risks of physicians make it a key issue for medical education to improve skill levels in high-pressure environments. The virtual patient system provides a secure practice platform for medical students, allowing them to make mistakes in the virtual environment and learn from them, thereby reducing future medical errors in real clinical environments. This "trial and error learning" model not only helps cultivate high-level medical workers, but also provides new directions for the reform of medical education [14].

Traditional clinical internal medicine training heavily relies on case-based teaching, which often limits the development of students' clinical reasoning skills and places substantial demands on instructors [15]. While VSPs offer a promising alternative, empirical evidence regarding their feasibility and effectiveness in enhancing clinical thinking remains limited. This study aimed to evaluate whether VSP-based training outperforms traditional methods in improving medical students' clinical thinking abilities. Specifically, we addressed the following questions: (1) Does VSP training lead to greater improvements in theoretical knowledge and practical diagnostic skills compared to conventional case-based teaching? (2) Which components of clinical thinking are most influenced by VSPs? (3) How do learners perceive the utility of VSPs in their training? We hypothesized that the "VSPs in general practice" system, a 3D virtual platform simulating patient interactions, would significantly enhance clinical thinking metrics due to its immersive, repeatable scenarios. To test this, we conducted a randomized controlled trial (RCT) comparing VSP training with traditional teaching, assessing outcomes via standardized knowledge tests, virtual system scoring, and posttraining surveys. By rigorously evaluating VSPs, this study provides actionable insights into scalable, cost-effective alternatives to traditional clinical education, addressing gaps in evidence-based teaching innovations.

Methods

Trainee Recruitment

Based on the pilot data, we determined the sample size for this study to be 60 medical students. From a total pool of 85 eligible fifth-year undergraduate medical students interning at Quzhou People's Hospital (affiliated with Wenzhou Medical University and Zhejiang University of Traditional Chinese Medicine), we recruited 60 participants via consecutive sampling between October 20, 2022, and October 20, 2024 (.

Inclusion and Exclusion Criteria

We selected fifth-year undergraduate medical students from Wenzhou Medical University and Zhejiang University of Traditional Chinese Medicine who were interning at our

hospital. The exclusion criteria were (1) participants who had received VSP or standardized patient training, (2) participated in courses related to clinical thinking skills, and (3) failure to comply with the research plan or withdrawal from the study.

Randomization

Using computer-generated randomization, participants were randomly assigned to either the experimental group or the control group in a 1:1 ratio. Random grouping is conducted by individuals who have not had contact with the participants.

Training Curriculum and Setting

The control group received traditional clinical thinking training through a combined problem-based learning and real-patient exposure approach. Supervisors selected patients from routine admissions in the Department of Internal Medicine who met the criteria for typical clinical cases outlined in the teaching syllabus, prioritizing broad alignment with the VSP curriculum while preserving real-world clinical heterogeneity. No further screening for specific attributes was applied to maintain ecological validity. Students were divided into small groups (10 per group) to: (1) conduct standardized clinical workflows (history-taking, physical examinations, and interpretation of laboratory and auxiliary tests); (2) formulate preliminary diagnoses and treatment plans; (3) participate in structured problem-based learning discussions based on these real medical records. Supervisors provided systematic theoretical explanations and feedback throughout the process. All patient interactions adhered to hospital protocols, with explicit consent obtained for student involvement. While exact case matching with the VSP group was logistically unfeasible, supervisors ensured thematic consistency to mitigate exposure variability between groups.

The experimental group used the VSPs of the "VSPs in general practice" interactive diagnosis and treatment teaching system for teaching. The study used the HIWILL VSP System (version 2.1; Huawei Medical Technology), an interactive 3D clinical simulation platform designed for clinical thinking training. Each student in the experimental group completed 12 standardized VSP cases during the training period, with each case representing a different common clinical scenario in internal medicine. Students were allowed up to 3 attempts per case to achieve optimal performance, with immediate feedback provided after each attempt. The operation process of the VSP teaching system is shown in Figure 1.

Figure 1. Operation procedures of the virtual standardized patient system.

Selection and Improvement of VSPs

By using the VSPs included in the "VSPs in general practice" interactive diagnosis and treatment teaching system, the chief complaints, disease descriptions, consultations and physical examinations, laboratory and auxiliary examinations, as well as clinical cases required to be mastered in the treatment and teaching syllabus of VSPs are organically combined.

Application of Virtualization Teaching Software

Implement VSP teaching for experimental group students, and teachers provide guidance and training on software usage methods for students. Students form small groups of 10 and complete the entire clinical diagnosis and treatment process through interaction with VSPs. Obtain the patient's condition description, chief complaint, and abnormal signs in a virtual clinical environment. Based on the obtained consultation information, perform examinations on VSPs, including physical examination, laboratory examination, and, if necessary,

histopathological examination. Students conducted a preliminary diagnosis of VSPs, provided corresponding diagnostic criteria, and then treated the disease. Teachers provide guidance and systematic explanations and training on relevant professional theoretical knowledge. All teachers supervising VSP sessions completed a standardized 8-hour training program that included: technical operation of the VSP system, standardized facilitation techniques, methods for providing consistent feedback, and protocols for troubleshooting technical issues. Instructors were required to pass a competency assessment before supervising sessions (Multimedia Appendix 1).

Evaluation of Training Effectiveness

All students underwent medical record analysis exams and assessments of relevant professional theoretical knowledge upon enrollment. A 50-item multiple-choice exam covering core internal medicine topics was developed by a panel of 5 senior clinicians. And their clinical thinking abilities were evaluated through the intelligent module of the "VSPs in general practice" interactive diagnosis and treatment teaching system. The system evaluated performance across 4 domains: consultation skills (history taking and communication), diagnostic accuracy (initial and differential diagnoses), treatment planning (evidence-based interventions), and overall clinical reasoning (logical progression and efficiency). The score was recorded as the base score F_0, and they entered group teaching. After completing the teaching tasks, all students underwent medical record analysis exams and assessments of relevant professional theoretical knowledge again, and their clinical thinking abilities were reevaluated through the intelligent module of the "VSPs in general practice" interactive diagnosis and treatment teaching system. The score was recorded as F_1-score. Traditional case-based evaluations were structured to mirror the VSP domains but used paper-based scenarios. Both groups were assessed by blinded instructors using identical criteria.

The VSP system test primarily encompassed 4 components, with the medical interview section accounting for 25 points. This section evaluated the student's ability to gather relevant medical history through human-computer dialogue. The condition examination section was worth 30 points, comprising a physical examination worth 15 points and auxiliary examinations worth 15 points. It assessed the student's capability to perform necessary physical examinations based on the collected information and to select relevant tests and laboratory investigations required for diagnosis and differential, including histopathological examinations when necessary. The diagnosis and differential section carried 25 points, consisting of an initial diagnosis worth 16 points and a differential diagnosis worth 9 points. This section tested the student's ability to choose the correct diagnostic criteria based on known information to make an accurate diagnosis and to analyze inclusion and exclusion criteria to complete the differential diagnosis. The treatment plan section was worth 20 points, with medication management accounting for 17 points and nonpharmacological interventions for 3 points. It evaluated the student's competence in providing the correct treatment plan for the condition.

Reference Standard for VSP Scoring

The VSP scoring algorithm was cross-validated against blinded expert evaluations (3 senior clinicians) who reviewed 20% of randomly selected VSP sessions. Interrater reliability (Fleiss κ=0.81) confirmed consistency between automated and manual scoring. Discrepancies were resolved by consensus.

Feedback Questionnaire

Based on the characteristics of this study and reference literature, a self-designed learning effect questionnaire was used to investigate the effectiveness of prehospital emergency training among students. It mainly includes 5 questions, namely (1) beneficial for improving the ability to collect medical history, (2) it is conducive to improving the ability to analyze the condition, (3) beneficial for improving diagnostic and differential diagnostic capabilities, (4) beneficial for improving clinical treatment capabilities, and (5) it is conducive to improving clinical thinking ability. The evaluation criteria are divided into 4 levels: full agreement, agreement, partial agreement, and disagreement, which are filled in by students based on their true feelings. Those who fully agree or agree in the questionnaire will be considered as positive reviews, and the overall positive review rate and individual positive review rate will be comprehensively calculated. In addition, we conducted a questionnaire survey on 6 teachers responsible for clinical training to evaluate the potential impact of VSP courses on their work.

Statistical Analysis

SPSS 26.0 statistical software (IBM Corp) was used to perform statistical processing on the data obtained from this study, analyzing the differences in scores between each group of students before and after teaching, and analyzing the differences in F_0 and F_1-scores between the 2 groups of students, in order to evaluate the differences in clinical thinking ability between students before and after teaching and under 2 different teaching modes. Continuous variables are represented as mean (SD), while categorical variables are represented as frequency or percentage. All continuous outcomes were analyzed using independent *t* tests, reporting mean differences, 95% CIs, and Cohen *d* as effect size measures. For categorical outcomes, Chi-square tests with odds ratios (ORs) and 95% CIs were used.

Ethical Considerations

This study, which involved medical students as participants in an educational intervention evaluation, was granted a formal exemption from requiring full ethical review by the Quzhou People's Hospital Medical Ethics Review Committee (review number: 2025 - 004). This exemption is in full compliance with the institution's policy, as well as the institutional guidelines for educational research. Specifically, the study was deemed to fall under the category of low-risk educational interventions that are part of the normal evaluation of curriculum quality and teaching methods. The anonymity of the participants was ensured, and the data were collected and analyzed in an aggregated manner for research purposes only, posing minimal risk to the participants. All participants provided written informed consent before participating in the study and received

corresponding remuneration according to hospital regulations after the study ended.

Results

The Basic Characteristics of Participants

There were 30 students in the control group, including 18 females and 12 males, with a mean age of 21.73 (SD 0.85) years. The experimental group consisted of 30 students, including 16 females and 14 males (mean age 21.60, SD 0.73) years (Figure 2). The prehospital emergency training for both groups is 6 months, and the training teachers for both groups are the same 6 teachers (2 bishops and 4 assistants). The average credit scores of the 2 groups of students were 3.66 (SD 0.36) points and 3.58 (SD 0.32) points, respectively. There were no statistically significant differences between the control group and the experimental group in terms of gender, age, average credit scores, training time, and training teachers, as shown in Table 1.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flow diagram. SP: standardized patient training; VSP: virtual standardized patient.

Evaluation of Training Effectiveness

Systematic Knowledge Test

Figure 3A displays the theoretical performance results of 2 groups of trainees before and after training. Prior to clinical training, there was no significant difference in the theoretical performance between the experimental group and the control group (mean 65.83, SD 7.11 vs mean 66.57, SD 7.17; $F_{1, 59}$=0.16; Cohen *d*=0.10; 95% CI 64.36-68.03; *P*=.69). After the training, the theoretical performance of the experimental group was significantly better than that of the control group (mean 82.63, SD 5.76 vs mean 77.07, SD 5.89; $F_{1, 59}$=13.71; Cohen *d*=0.87; 95% CI 78.19-81.51; *P*<.001). Additionally, the improvement in theoretical scores was significantly greater in the experimental group compared to the control group (mean 17.07, SD 4.24 vs mean 10.67, SD 4.91; $F_{1, 59}$=29.20; Cohen *d*=1.15; 95% CI 12.43-15.31; *P*<.001).

Figure 3. Results of formative evaluation, including (A) theoretical score, (B) VSP training system improvement score, (C) medical interview improvement score, (D) score improvement for physical examination and auxiliary examination, (E) physical examination improvement score, (F) pathological examination improvement score, (G) improvement of identification and diagnostic abilities, (H) improvement of primary diagnosis ability, (I) improvement of differential diagnosis ability, (J) improvement of treatment plan ability, (K) enhancement of drug treatment plan ability, and (L) enhancement of nondrug treatment plan ability. VSP: virtual standardized patient. *P<.05, **P<.01.

Clinical Skill Test

The test results of the virtual clinical reasoning training system are shown in Figure 3B. Before the clinical training, there was no significant difference in the total scores of the virtual clinical reasoning training system test between the experimental group and the control group (mean 35.90, SD 8 vs mean 35.70, SD 9.55; $F_{1, 59}$=0; Cohen *d*=0.01; 95% CI 33.5-38; *P*=.96). After 4 weeks of training, the total scores of the virtual clinical reasoning training system test in the experimental group were significantly higher than those in the control group (mean 78.30, SD 7.98 vs mean 67.43, SD 8.74; $F_{1, 59}$=25.27; Cohen *d*=1.09; 95% CI 70.30-75.44; *P*＜.001). Additionally, the improvement in the total scores of the virtual clinical reasoning training system test was significantly greater in the experimental group compared to the control group (mean 42.60, SD 9.56 vs mean 31.63, SD 7.24; $F_{1, 59}$=25.10; Cohen *d*=1.09; 95% CI 34.51-39.72; *P*＜.001).

Medical Interview

Figure 3C illustrates the scores of medical history-taking abilities for both groups of medical students before and after the training. After 4 weeks of training, the medical history-taking ability scores of the medical students in the experimental group (mean 20, SD 2.33 vs mean 15.45, SD 5.70; $F_{1, 59}$=49.61; Cohen *d*=1.35; 95% CI 16.86-18.60; *P*<.001) and the improvement in medical history-taking ability scores (mean 12.30, SD 3.43 vs mean 7.77, SD 2.84; $F_{1, 59}$=31.09; Cohen *d*=1.17, 95% CI 9.04-11.04; *P*<.001) were significantly higher than those in the control group.

Physical Examination and Auxiliary Examination

Figure 3D-F displays the scores of the ability to conduct patient examinations for both groups of medical students before and after the training. After 4 weeks of training, the medical students in the experimental group showed significantly greater improvement in physical examination ability (mean 5.86, SD 1.44 vs mean 4, SD 1.34; $F_{1, 59}$=26.41; Cohen *d*=1.11; 95% CI 4.50-5.36; *P*<.001) and in auxiliary examination ability (mean 6.11, SD 1.74 vs mean 4.15, SD 1.63; $F_{1, 59}$=20.36; Cohen *d*=1.01; 95% CI 4.63-5.63; *P*<.001) compared to the control group. Additionally, the total improvement in objective examination scores was significantly higher in the experimental group than in the control group (mean 11.97, SD 2.77 vs mean 8.15, SD 2.62; $F_{1, 59}$=30.08; Cohen *d*=1.16; 95% CI 9.21-10.91; *P*<.001).

Diagnosis and Differentiation

Figure 3 depicts the scores of the ability to diagnose and perform differential diagnoses for both groups of medical students before and after the training. After 4 weeks of training, the medical students in the experimental group showed a significantly greater improvement in initial diagnosis scores (mean 8.74, SD 1.67 vs mean 7.66, SD 2.08; $F_{1, 59}$=4.21; Cohen *d*=0.55; 95% CI 7.70-8.70; *P*=.045) compared to the control group. However, there was no significant difference between the 2 groups in the improvement of differential diagnosis ability (mean 2.37, SD 1.24 vs mean 2.33, SD 1.09; $F_{1, 59}$=0.01; Cohen *d*=0.03; 95% CI 2.05-2.65; *P*=.91).

Treatment Plan

Figure 3J-L displays the scores of the ability to administer treatment to patients for both groups of medical students before and after the training. After 4 weeks of training, the medical students in the experimental group showed significantly greater improvement in medication management ability (mean 5.69, SD 2.27 vs mean 4.51, SD 2.14; $F_{1, 59}$=4.29; Cohen *d*=0.62; 95% CI 4.51-5.69; *P*=.04) and in nonpharmacological treatment ability (mean 1.54, SD 0.47 vs mean 1.21, SD 0.43; $F_{1, 59}$=7.85; Cohen *d*=0.68; 95% CI 1.25-1.50; *P*=.007) compared to the control group. Additionally, the improvement in the overall ability to provide treatment to patients was significantly higher in the experimental group than in the control group (mean 7.23, SD 2.41 vs mean 5.72, SD 2.19; $F_{1, 59}$=6.42; Cohen *d*=0.63; 95% CI 5.85-7.01; *P*=.01). The medium-large effect size (*d*=0.75) suggests that VSP training is not only statistically significant but also practically important in improving clinical reasoning. However, the wide CI (0.55-1.17) for Cohen *d* suggests that there is uncertainty about the true effect size and further validation is needed.

Questionnaire

After the training, 2 groups of clinical medicine students who participated in the training were invited to conduct a satisfaction survey. As shown in Table 2, 29 of 30 medical students (96.7%) in the experimental group believe that VSP training is beneficial for improving their ability to collect medical history and analyze medical conditions. The experimental group of 27 of 30 medical students (90%) believes that VSP training is beneficial for improving diagnostic and differential diagnostic abilities, clinical treatment abilities, and clinical thinking abilities.

Table . Results of the learning effectiveness questionnaire.

Questionnaire content	Control group, n	VSP[a] group, n	Chi-square (*df*)	*P* value
Beneficial for improving the ability to collect medical history			31.86 (59)	<.001
Strongly agree	5	22		
Agree	11	7		
Neutral	12	1		
Disagree	2	0		
Beneficial for improving the ability to analyze the condition			23.17 (59)	<.001
Strongly agree	12	27		
Agree	8	2		
Neutral	6	1		
Disagree	4	0		
Beneficial for improving diagnostic and differential diagnostic capabilities			22.35 (59)	＜.001
Strongly agree	7	23

[a]VSP: virtual standardized patient.

Discussion

Principal Findings

This study found that VSPs can consolidate the basic knowledge of internal medicine among medical students, improve their clinical thinking ability, and enhance their ability to work independently. Clinical reasoning ability is one of the essential core competencies for medical students, requiring not only a solid theoretical foundation but also continuous accumulation through clinical practice by interacting with patients. Unlike clinical skills, which can be improved through repeated training on models, the VSPs in the “VSPs in general practice” interactive diagnostic and therapeutic teaching system are characterized by immersion, interactivity, and conceptualization [16]. The system establishes a simulated human model based on real clinical cases, incorporating various multimedia elements, such as images, sounds, and text to realistically recreate clinical environments. It allows real-time interaction through natural methods like vision and touch, simulating the clinical diagnosis and treatment processes. The system enables virtual examinations and treatments, including medical interviews, electrocardiogram examinations, physical examinations, laboratory tests, imaging studies, clinical interventions, medication administration, and device-based interventions [17]. All examinations performed by trainees on the virtual patients automatically provide feedback on the results. The VSPs present the patient’s condition and physical signs through lifelike 3D imaging, creating an immersive experience. Through an open diagnostic and therapeutic model, the system fully cultivates trainees’ ability to identify and solve problems, fostering clear, rigorous, and efficient thinking patterns. A comprehensive assessment system objectively evaluates the trainees’ clinical reasoning logic and mastery of basic skills. Under the premise of ensuring medical safety, it provides trainees with practice opportunities that closely resemble real clinical scenarios [15,18].

With the advancement of technology, VSPs have gradually become an important tool in medical education. VSPs are computer-based and AI-driven simulation tools designed to cultivate clinical reasoning abilities in medical students. By

simulating real clinical cases and providing an interactive learning environment, VSPs help medical students improve their diagnostic, therapeutic, and communication skills [7,19,20]. This study suggests that, compared to traditional clinical training, VSP-based training may enhance medical students' consolidation of theoretical knowledge and improve their abilities in clinical history-taking, physical and auxiliary examinations, diagnosis and differential diagnosis, as well as treatment planning. The findings indicate that virtual patient systems could contribute to reforming medical education curricula and support the goal of cultivating clinically competent professionals. VSPs offer several potential advantages: they can be reused indefinitely, allowing students to practice repeatedly in various scenarios without being influenced by the emotions or physical conditions of real patients, thus providing a safe practice environment. Additionally, VSPs may offer personalized feedback and guidance based on students' learning progress and performance. While the initial development costs are high, VSPs could, in the long term, reduce the overall costs of medical education.

This RCT compared the teaching effectiveness of virtual training and traditional academic training for more than 4 weeks. The results suggest that students experienced less stress in the simulated clinic environment, which may have allowed them to dedicate more time to learning. Through repeated practice in a safe setting, they appeared to become more familiar with diagnostic and therapeutic processes. By the midterm assessment, students in the VSP group showed improvement in comprehensive abilities such as medical interviewing and clinical judgment compared to the control group. However, further research is needed to validate these findings across diverse educational settings and larger cohorts. Summative evaluation results also indicated that the VSP simulation system might enhance students' theoretical knowledge, medical interview skills, syndrome differentiation, and treatment capabilities. Compared to traditional academic training, the use of standardized patient teaching appeared to improve students' interpersonal communication skills, potentially helping them establish more harmonious doctor-patient relationships in future practice. While these findings are promising, additional studies are required to assess the long-term impact of VSP training on clinical performance and patient outcomes. Despite some technical and methodological challenges, ongoing advancements in virtual simulation technology are expected to further refine VSPs, potentially making them a valuable tool in medical education. However, their full integration into curricula will depend on continued validation and adaptation to different learning environments.

Limitations

Content and Design Limitations

First, the VSP system primarily focuses on textbook-style disease presentations, potentially neglecting case variations and atypical scenarios encountered in real clinical practice. Additionally, the predefined decision-tree branches may restrict students' exploration of alternative diagnostic hypotheses, limiting the simulation's flexibility. Future research should enhance VSPs' realism and adaptability to better mimic clinical complexity.

Methodological Constraints

This study relied on self-reported data and lacked objective external evaluation, which may introduce instructor-dependent variability. While the sample size was adequate for detecting primary outcome differences, it limited subgroup analyses. Furthermore, the control group's nonstandardized patient pool, though intentionally designed to reflect real-world clinical training environments, could lead to confounding due to uneven case exposure. Multicenter studies with larger, standardized samples are needed to validate these findings.

Assessment and Long-Term Validity

The VSP-embedded assessment provided real-time metrics, but its alignment with the intervention might introduce measurement bias. To address this, we cross-validated results with standardized exams and faculty evaluations; however, future studies should incorporate third-party assessment tools. Moreover, while the study demonstrated significant short-term improvements in clinical knowledge and skills, the lack of long-term follow-up and direct validation with real patient interactions leaves the clinical relevance of these gains uncertain. Structured evaluations in real-world settings are warranted to confirm the predictive validity of VSP training.

Conclusions

This RCT demonstrates the feasibility of VSPs in improving the clinical competence of medical students. VSPs deserve more attention and promotion. Therefore, future research aims to improve the VSPs system to more effectively enhance the clinical thinking ability of medical students. Future studies should use a hybrid evaluation approach, where trainees first complete VSP training and are then assessed with standardized real patient encounters, to establish the translational validity of virtual training to clinical practice.

Funding

This study was funded by the Teaching Reform Project JG2022153 of Wenzhou Medical University, Quzhou Science and Technology Plan Project (2022015), and research projects of Quzhou People's Hospital in 2022 (YNB21 and YNB19).

Authors' Contributions

LX had full access to all the data in the study and took accountability for data integrity and the accuracy of data analysis. LX, QX, and CL conceptualized and designed the study. BC obtained and analyzed data. LX drafted and revised the article. CW obtained funding.

Abstract

Background: Although technology is rapidly advancing in immersive virtual reality (VR) simulation, there is a paucity of literature to guide its implementation into health professions education, and there are no described best practices for the development of this evolving technology.

Objective: We conducted a qualitative study using semistructured interviews with early adopters of immersive VR simulation technology to investigate use and motivations behind using this technology in educational practice, and to identify the educational needs that this technology can address.

Methods: We conducted 16 interviews with VR early adopters. Data were analyzed via directed content analysis through the lens of the Unified Theory of Acceptance and Use of Technology.

Results: The main themes that emerged included focus on cognitive skills, access to education, resource investment, and balancing immersion. These findings help to clarify the intended role of VR simulation in health professions education. Based on our data, we synthesized a set of research questions that may help define best practices for future VR development and implementation.

Conclusions: Immersive VR simulation technology primarily serves to teach cognitive skills, expand access to educational experiences, act as a collaborative repository of widely relevant and diverse simulation scenarios, and foster learning through deep immersion. By applying the Unified Theory of Acceptance and Use of Technology theoretical framework to the context of VR simulation, we not only collected validation evidence for this established theory, but also proposed several modifications to better explain use behavior in this specific setting.

Introduction

Background

As technology rapidly advances in immersive virtual reality (VR) simulation, there is a growing interest among educators to develop VR simulation curricula for health professions education. However, there is a paucity of literature to guide these efforts, and there are no accepted best practices for the development or implementation of this technology. While experts anticipate the potential for VR to transform medical education [1], without a better understanding of the role VR will play in our training programs, these statements may amount to nothing more than vague future promises. Therefore, characterization of the early use of VR is imperative to clarify its evolving role and gain insights that will allow us to implement this technology to its fullest potential.

VR Simulation Technology

Immersive VR creates a simulated environment, allowing users to “step inside” a computer-generated world and engage authentically with their surroundings [1]. VR offers several potential benefits for health professions education, including facilitating distance learning and providing training that is difficult to deliver via traditional simulation [2]. In addition, VR shows comparable educational outcomes to high-fidelity mannequin simulation with more cost-effectiveness [3-7]. Many institutions are enthusiastic about VR simulation and are already piloting or studying VR curricula [1,8] However, there is still

much to learn in order to best guide the development and implementation of these curricula.

While prior research has concentrated on individual VR usage-scenarios or software evaluations [9,10], effective educational interventions require a broader understanding of the context of our learners [11]. Therefore, we must study VR user needs across a wider spectrum to guide development that aligns with the context of health professions training. By analyzing current VR educational practices, we can better identify the gaps that this technology can bridge, and move toward a consensus about how best to use VR simulation in the future. Without a better understanding of these gaps, we risk pouring resources into technology for technology's sake—a solution looking for a problem [12].

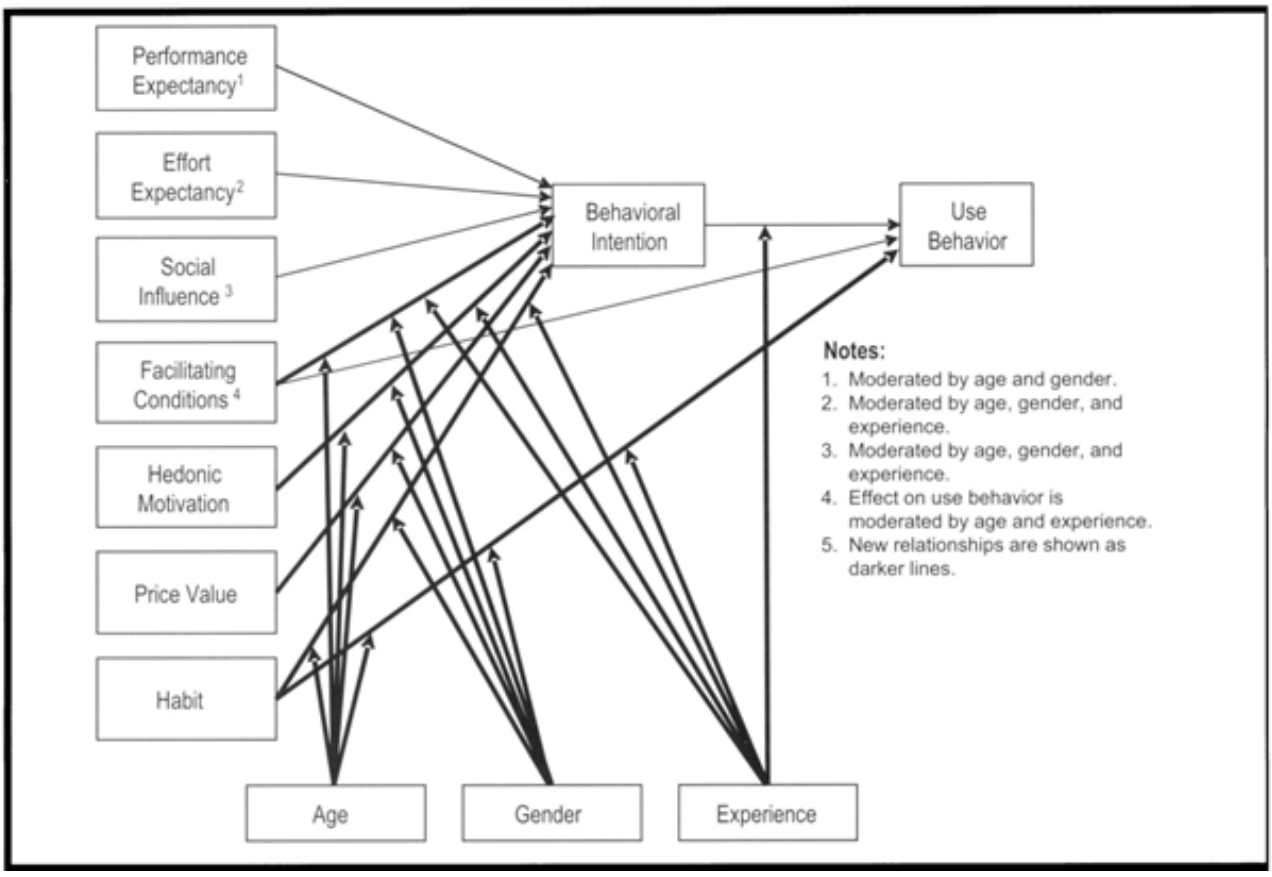
Study of Early Adopters

The technology adoption life cycle categorizes users into 5 groups based on their likelihood to adopt new technology: innovators, early adopters, early majority, late majority, and laggards [13]. Our study focuses on early adopters, as they represent educational stakeholders pioneering the implementation of VR within authentic educational environments and collaborating with VR innovators to adapt the technology to their needs. They therefore have expertise evaluating VR technology, but unlike the innovators, their experience is more practical than theoretical.

Unified Theory of Acceptance and Use of Technology

The Unified Theory of Acceptance and Use of Technology (UTAUT) explains factors that affect the adoption of new technologies and predicts future technology use [14]. UTAUT provides a robust theoretical framework for understanding the drivers incentivizing early adopters to embrace VR as an educational strategy. The original theory described 4 constructs as direct determinants of technology usage behavior (Figure 1): performance expectancy (user expectation that the technology improves performance), effort expectancy (ease associated with using the technology), social influence (user perception that others believe they should be using the technology), and facilitating conditions (organizational and technological infrastructure for technology implementation). These determinants are modified to varying degrees by user gender, age, or experience [14]. Extensively applied across multiple fields for assessing new technologies [15], the UTAUT was expanded to the Unified Theory of Acceptance and Use of Technology 2 (UTAUT2) with 3 additional constructs: hedonic motivation (pleasure derived from using the technology), price value (perceived cost of the new technology), and habit (degree of automatic use of the technology) [16].

Figure 1. The UTAUT2 from Venkatesh et al [16], used with permission. UTAUT2: Unified Theory of Acceptance and Use of Technology 2.



With validity evidence across multiple fields since 2003, UTAUT has become one of the most developed and intensive models to test new technologies [15]. In addition to being well-validated in multiple settings, UTAUT is an ideal theoretical framework to explore and better understand thoughts and behaviors associated with the use of VR simulation technology. While other theoretical frameworks have been used to approach VR simulation research, few will allow the isolation of factors associated with VR specifically rather than those that apply to simulation in general. Even fewer might facilitate the

prediction of its use in the future. For example, constructivist learning theory has been applied to VR simulation because learners can manipulate a problem and construct learning from active participation in an engaging experience [17]. Experiential learning has also been used to contextualize VR simulation because it provides a safe and forgiving training environment that facilitates learning by doing [3]. However, these theoretical frameworks serve better to characterize simulation in general rather than to focus on the specific experience provided by VR technology. The use of UTAUT2 on the other hand provides a structured framework by which we can distinguish the features of VR technology from other modes of simulation, and by which we can attempt to predict its future use.

Prior VR research using UTAUT2 focuses primarily on understanding learner experience and learner acceptance [18,19]. While these concepts are critical for the successful adoption of evolving technological innovations [20], we must progress further by investigating how VR simulation can address specific educational needs and gathering validation evidence for its most effective future role in the evolving landscape of health professions education.

Study Aims

To fill this gap in our understanding, this study interviews early adopters of VR simulation in health professions education, with the following aims: (1) characterize how early adopters are adapting VR to meet their educational needs, (2) define the educational problems or gaps that early adopters are trying to address with VR, and (3) explore factors influencing the ability of early adopters to meet their needs with VR.

Methods

Ethical Considerations

This study was approved by the New York University Langone Institutional Review Board (22‐01346). Informed consent was obtained from all study participants, and participants had the ability to opt out or withdraw from the study at any time. Interview transcripts were deidentified for confidentiality. Participants were not compensated.

Study Design

This is a qualitative study using thematic analysis of semistructured interviews. The research methodology is directed content analysis, starting with a limited code book of 7 a priori codes defined through the lens of the UTAUT2 theoretical framework, followed by an exploratory coding phase [21,22]. The research paradigm is postpositivist. Reporting was completed following the Standards for Reporting Qualitative Research guidelines [23].

Semistructured Interview Guide

We iteratively developed a semistructured interview guide based on our research questions and grounded in the UTAUT2 theoretical framework [24,25] (Multimedia Appendix 1). The interview guide was piloted with local stakeholders to ensure capture of meaningful data within the 45-minute interview timeframe.

Recruitment and Sampling

We recruited educational stakeholders who were identified as "early adopters" of immersive VR simulation technology. Inclusion criteria were experience educating, implementing, or researching with VR. Exclusion criteria included technology developers without educational practice experience, and participants with experience limited to 360° video, augmented reality, or nonsimulation immersive learning.

The first 3 participants were recruited as a convenience sample, as they were known to our research team based on their work with the American College of Chest Physicians to develop and pilot an immersive VR simulation program teaching endotracheal intubation. These participants were recruited as an entry into the community of VR early adopters, with subsequent recruitment by snowball sampling. We sought to map the terrain of VR use-cases by recruiting for maximal diversity. We asked if participants could identify additional early adopters who had different experiences (ie, worked with a different company, in a different learner setting, at a different institution, or who had differing perspectives on VR technology). We estimated a sample size of 12‐18 interviews. Data were iteratively analyzed for thematic saturation, and recruitment was terminated upon achieving saturation of meaning [26].

Interviews and Data Analysis

Each participant completed a 45-minute semistructured interview via Zoom videoconferencing. Interviews were audio-recorded and transcribed verbatim into a written document via Speechmatics software with manual verification. Transcripts were imported to ATLAS.ti (ATLAS.ti Scientific Software Development GmbH) web, which was used for iterative qualitative data coding and analysis. First-round coding was performed via an a priori coding template corresponding to the UTAUT2 domains. Any additional codes used process coding and descriptive coding. All codes were approved by 2 independent reviewers (JT and DP) with deliberation over any discrepancies. Second-round coding then checked all codes against the initial coding template, collapsing as necessary to capture any new domains not described by the UTAUT2 framework. Field notes and memos were maintained by both reviewers. Themes were identified and their interrelationships characterized [27]. Themes were then shared with study participants via member checking to ensure the accuracy of our analyses.

Reflexivity

JT and DP are Pulmonary/Critical Care Medicine physicians. JT has worked with technology companies and educational technologists researching immersive VR simulation, but is relatively suspicious of new technology unless it fulfills a specific need. DP is also an early adopter, who is a self-described "gamer" and owns a VR headset for recreational use. JT, DP, and MF are simulation educators at New York University. All authors kept memos to practice reflexivity throughout this study's period.

Results

Overview

We completed 16 semistructured interviews. Coding saturation occurred after 11 interviews and thematic saturation after 12 interviews. Four additional interviews were completed to ensure saturation of meaning [26]. Participant demographics are described in Table 1. Our study population included early adopters from diverse health professions whose educational interventions targeted the following groups of learners: physician trainees (premedical students, medical students, residents, and fellows), advanced practice providers (nurse practitioners and physician assistants), nurses and nursing students, respiratory therapists, pharmacists, and emergency service members (emergency medical technician students and paramedical students).

Table . Demographics of interview participants (N=16).

Demographics of interview participants	Values (n)

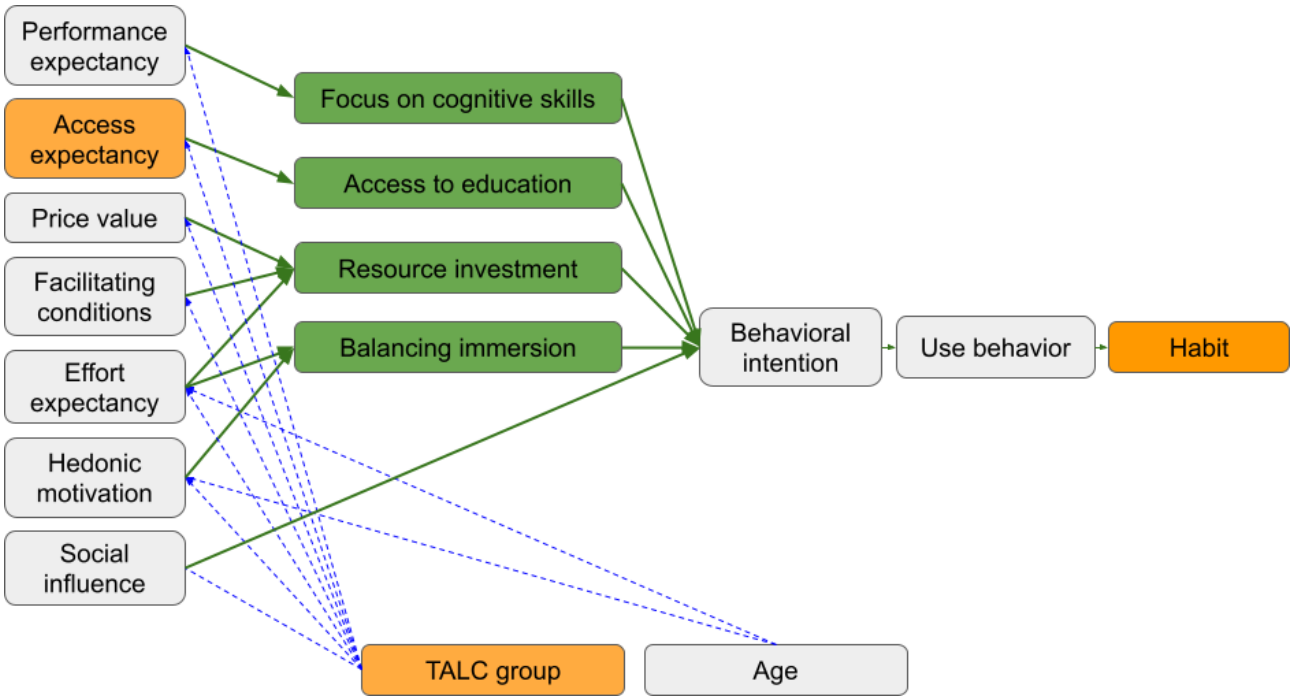
Coding and Themes

First-round coding generated 38 unique codes: 7 from the a priori coding template corresponding to UTAUT domains, and 31 new codes via process and descriptive coding. Four themes were identified and examined for their interrelationships. The resulting synthesis and validation evidence for the UTAUT2 framework are depicted in a thematic map (Figure 2).

Figure 2. Thematic map of results. The thematic map illustrates our results and changes we have made to the theoretical framework. Themes (green boxes) are superimposed between each UTAUT construct and the resulting behavioral intention. The new addition of access expectancy is highlighted in orange. Green arrows illustrate which theme most strongly relates to which UTAUT construct. Blue arrows represent effect modifying relationships. TALC: technology adoption lifecycle; UTAUT: Unified Theory of Acceptance and Use of Technology.



Theme 1: Focus on Cognitive Skills

Study participants focused on VR simulation for the development of cognitive skills, including communication, teamwork, clinical reasoning, situational awareness, and interdisciplinary skills, occasionally referred to as "soft skills."

> *It's really just about talking to each other, right? And sharing that mental model…I think that's where you can really benefit from VR because it's not really about the tasks you're doing. It's how are you communicating…I think if you look at a lot of the sentinel events or the near misses that happen, it's based on communication.* [Participant #4]

For procedural skills, the role of VR simulation was limited to building procedural knowledge or situational awareness.

> *It does help you remember the different steps. You know, don't forget the suction at the head of the bed or, you know, [we will] have the patient vomit…and maybe they won't forget it now.* [Participant #4]

However, participants found the teaching of fine psychomotor skills, such as laryngoscopy or peripheral intravenous placement, to be limited in VR.

> *We knew that you cannot teach the fine motor skills of intubating a patient in virtual reality. It is very difficult to do with the kind of tools that are available right now. And so it was more about the thinking…I truly believe that the mental process of approaching an airway is just as important, if not more important, than the fine tuning of technical skills.* [Participant #1]

The most common barrier to teaching psychomotor skills in the VR environment was haptic technology, noted unanimously by every interview participant.

> *What it doesn't do well? One is teaching people how to do things that require them to use their hands and fine motor skills, even just like how to use tools. It's really challenging to teach somebody how to hold a laryngoscope, how to hold the endotracheal tube…I think the big limiting factor is the fact that you have to use controllers because the controllers only work a certain way. You must hold it this way. These are the few buttons that you have. You're not using your hands the way you would in real life.* [Participant #1]

In addition to limitations in simulating authentic tools, participants noted limitations in simulating the weight or feel of human anatomy necessary to learn fine psychomotor skills.

> *You put the [laryngoscope] blade in their mouth, the vocal cords show up on the screen and you just drop the tube and it just clicks right in. But right now, we don't have…that feedback where you feel your scope in your hand or you feel the weight of the jaw when you're going to lift up.* [Participant #8]

Many participants discussed the development of haptic gloves which can allow users to simulate touch and contact experiences. However, most found current solutions either cost-prohibitive or inadequate.

> *I don't see that type of fine motor feedback, you know, where I know how to put the needle into an arm for an IV, for example. That's not going to happen for - I would say that's decades away. Easily. I don't think there are good solutions right now in even the most*

> *expensive labs with experimental haptics for that.* [Participant #16]

Therefore, to teach psychomotor and procedural skills, participants turned to other forms of simulation technology such as mixed reality or mannequin simulation. Several participants offered learners a blended experience, using VR to create an immersive scenario, followed by a task trainer to simulate any necessary fine motor tasks.

Theme 2: Access to Education

The ability of VR simulation to facilitate distance learning was seen as a significant driver of use behavior for most participants.

> *We wanted to break down the barriers of requiring learners to physically come to a place to get this type of education. We want this education to be deliverable over long distances to people in other parts of the world.* [Participant #1]

In areas without the resources for a high-fidelity mannequin-based simulation laboratory, VR was seen as expanding access to high-quality simulation learning from expert educators.

> *Places that don't have simulation labs and all of those resources…available at academic medical centers, at [professional society] headquarters…But outside of large centers or hospitals that have access to a sim lab - and I think probably the majority of hospitals in the country do not - those hospitals don't have access to that type of education.* [Participant #1]

VR simulation was also used as a solution to reduce the cost, inconvenience, and sometimes danger associated with traveling to simulation centers.

> *The ability to do remote simulation at a much lower cost than requiring travel, that's a huge benefit…If you've got employees spread across the country, even across the state - and I'll use Wyoming, for example… everything's 8 hours away. It's icy half the year. So if…you've got students all over the state that are part of your paramedic program, and you have these guys driving throughout the winter to come to your simulation center. Like, what are the chances of something bad happening there? Pretty high to be honest.* [Participant #8]

Even in centers with existing high-fidelity simulation laboratories, participants found a role for VR in facilitating collaboration and standard-setting at a national or international level.

> *As people adopt these headsets…somebody from [University] could do the same ACLS training as somebody at [University] and it would be the same across institutions. And there's crosstalk - so different learning points and different perspectives and shared information and shared values in terms of education.* [Participant #6]

Finally, VR simulation also expanded access to education during the COVID-19 pandemic, responding to the need for social distancing, and significantly accelerating VR adoption.

> *If heaven forbid there was another pandemic, now we are set up that. If our students were at home on lockdown, as long as they had a headset, their learning would not be interrupted.* [Participant #13]

Overall, VR afforded a distance learning advantage, providing equitable access to high-quality simulation education to centers in diverse settings and learners in adverse scenarios.

Theme 3: Resource Investment

Implementation of a VR simulation curriculum required extensive resources, particularly upfront costs (funding and time commitments).

> *There is a capital purchase that has to be made just for the equipment itself. But…how do you develop that program in a manner that somebody is not spending tons and tons of time to bring one little educational module to fruition.* [Participant #3]

These upfront costs also related to the process of cocreation with technology companies.

> *There was generally some frustration during the build process because we're all clinicians and we're like, 'yeah, this thing needs to be this way'. And you're trying to communicate that with someone who has no medical experience and is a software programmer… We speak one language and they speak a different language, and there was some inability to communicate that effectively.* [Participant #3]

Once the programming was complete, participants also described an ongoing cost to maintain the software through updates or licensing.

> *Keeping these things alive is really…the cost to maintain software…for servers and engineers and updates and things like that. So without some sort of continued funding from somewhere, it will become a useless pile of code as soon as the next [operating system] update hits.* [Participant #9]

The investment required to develop novel VR programming was frequently more resource-intensive than anticipated, and the risk of failed investment was wasted time and money.

> *I've seen many cases of projects that are developed and they're just abandoned…I would walk into my office every morning and I had a stack of 16 boxes of headsets we didn't use.* [Participant #10]

Therefore, participants wanted more opportunities for creative collaboration and sharing of software programs. However, some felt limited by the current state of technology.

> *There's no great way to share content yet. So a lot of stuff is just getting reinvented over and over again, which is a really expensive way to do things.* [Participant #12]

Others felt restricted by the current incentives within the VR marketplace, concerned by compatibility between different software or hardware companies.

> *There needs to be an ability for me to use multiple vendors within my one headset without having to pay*

> *millions of dollars to do so…I don't know about everybody's budget. On my budget, I cannot afford to pay four different guys for completely different programs.* [Participant #8]

Generally, participants desired to use pre-existing software that was universally relevant for multiple institutions and multiple users, and compatible with a variety of hardware.

Theme 4: Balancing Immersion

The immersiveness of VR was a powerful experience associated with learner enjoyment.

> *Being in virtual reality is an immersive experience, and it's just hard to describe in words until you try it. But when people try it, it's like seeing a new color.* [Participant #1]

At its best, immersion increased learner presence, stimulated intellectual curiosity, and accelerated learning.

> *When you go in and you see an environment in 3D that looks exactly like your cardiac ICU…you immediately have a 'wow' thing. And what I love about that is immediately when I start this scenario, I never really hear like, 'Wait, what do you want me to do? Are we starting now? Is the patient supposed to have pulses?'…It's so immersive that people immediately feel like they're in a football game and it's kickoff.* [Participant #7]

Participants also valued VR immersion for minimizing distractions more than other simulation technologies.

> *The thing that's nice about virtual reality is you put the headset on and that's what you're doing, right? So you're not looking at your phone or checking your email while someone's trying to teach you.* [Participant #3]

However, immersion could also create extraneous cognitive load, detracting from learning. Participants described unnecessary environmental elements that distracted from learning objectives, along with some tasks that were frustrating to simulate in VR.

> *The picking up of items in the ICU was difficult always…With the limited controller toggles, it was not always intuitive how to pick something up. And even when they told you what to do, it still sometimes fell on the floor and stuff like that.* [Participant #2]

Sometimes immersive scenarios became more about navigating the VR environment than mastering intended learning objectives.

> *You're never going to drop some instrument on the tray 6 times…Like is the goal to learn to pick the scope up, or to [learn the procedure]?…I think a lot of people try and make the virtual world exactly like the real world…but I think you have to simplify the haptics…If it's just so frustrating because you're an intensivist and you can't pick up the needle drivers, then forget it. There shouldn't be a five minute learning curve on how to pick up needle drivers, right?* [Participant #12]

Participants found an ideal immersive balance when the virtual world accomplished the intended learning objectives, but was not overly complex to create frustration in navigating the environment. In this way, there was constructive alignment between the intended learning outcomes and the virtual learning activities.

Validation Evidence for the UTAUT2 Framework

Codes were confirmed for each previously described construct within the UTAUT2 framework [16]. Performance expectancy was the most frequently coded driver for use intention with VR technology. We also found age to modify the effect of certain constructs, with the younger generation more easily adapting to VR technology (effort expectancy) and demonstrating greater VR learning enjoyment (hedonic motivation).

> *I think the current generation of learners is…becoming more and more comfortable with virtual reality. So I think the buy-in of our new generation of learners is going to be really quick…And so I think they're going to help drive the need for this type of education.* [Participant #5]

The UTAUT2 theoretical framework was able to explain patterns in use behavior and intention related to VR simulation, and provided conclusions relevant to educational practice. However, we modified the UTAUT2 model, most notably adding "access expectancy" as an independent driver of behavioral intention. The importance of distance learning, expanded access, and equity in educational experience was sufficient to qualify as an independent construct. To illustrate its relative importance, there were more instances of coding for access expectancy than hedonic motivation, habit, or social influence. This may reflect that the UTAUT was initially described in the individual consumer marketplace while "access expectancy" applies more to the context of the educational technology marketplace. Further research would be necessary to explore this hypothesis.

The other notable change was seen in the UTAUT modifier "gender." There were no instances of coding applicable to gender by either independent reviewer, and themes identified did not differ by participant gender. We found no signal for gender as a modifier of any UTAUT2 construct. We suggest that this is a reflection of both time and context. The initial publication of the UTAUT was in 2003, wherein it was discussed that effort expectancies may be more salient to women than men, and that women may be more sensitive to others' opinions than men [16]. We believe this contextualization of gender roles and social norms to be antiquated and due for revision. Furthermore, in this cohort of career medical educators, we found no differences in motivating factors between men and women related to their intention or use behavior with simulation technology. Therefore, we eliminated "gender" from our thematic map.

Discussion

Principal Findings

Participating early adopters have adapted their use of VR to meet specific educational needs. Whether it be the need for

distance learning during the pandemic, the need to bridge geographical or institutional divides, or the need for wide dissemination of teaching to address gaps in knowledge or skills, early adopters are implementing VR as a method to expand access to high-yield educational interventions. In terms of the role that VR served among the studied population, it was used primarily to teach cognitive skills as opposed to psychomotor or procedural skills. The most common factors that affected how successful any given implementation of VR would be is related to how educators managed their resources (funding, time, and design effort) and the degree to which they were able to foster learning through deep immersion.

The results of this study establish drivers of use behavior, providing practical insights into the educational gaps that VR might address in the future. Furthermore, this study contributes validity evidence for the UTAUT framework in studying the evolving role of immersive VR simulation in health professions education. This study represents an advancement to the literature in this field as it encompasses a wider variety of VR use cases than prior work, and it uses a well-validated theoretical framework to reflect on the perspectives of a diverse population within the health professions education community.

Implications for Future Research

Based on our findings, we synthesize a set of research questions that may help define best practices for future VR development and implementation (Table 2). We also list example study ideas corresponding to each research question in order to provide additional context and encourage reflection. These examples are not meant to be comprehensive or prescriptive, but rather to demonstrate how researchers might approach these questions with a variety of different methodologies and paradigms that could advance the literature in this field.

Table . Suggested research questions for immersive VR[a] simulation technology.

Themes from this study and suggested research questions		Example future research study
Focus on cognitive skills		
	How can we best implement immersive VR simulation given its strength in teaching cognitive skills (eg, communication, teamwork, clinical reasoning, situational awareness, and interdisciplinary skills)?	Multi-institutional study comparing 2 different VR implementation methods and using a validated assessment for cognitive skills
	What innovations can improve the teaching of fine psychomotor tasks in the VR environment?	Validation study using novel haptic gloves for VR simulation and assessing learning outcomes
Access to education		
	How can VR be most effectively leveraged to provide distance learning?	Mixed methods (quantitative or qualitative) needs assessment for distance simulation learning in post-COVID health professions education
	How can VR be used as a tool to create equity of educational experience?	Comparative study of learner outcomes at highly resourced centers versus resource-limited training programs for VR simulation
	How can VR facilitate collaboration on a larger scale (eg, national or international)?	Descriptive study demonstrating feasibility of an international VR curriculum offered by a professional society
Resource investment		
	What are the upfront investments and preparation processes necessary to start a new VR simulation program?	Focus group study of early adopters with concentration on preparation and upfront costs for establishing a VR simulation program
	How can we increase availability and decrease barriers for using pre-existing VR software programs?	Thematic analysis of focus groups after piloting a VR multi-case library targeting undergraduate medical education learners
	What processes facilitate the creation of novel VR software that is relevant to external users, institutions, and learner groups?	Systematic review and subsequent guideline development project to describe best practices in creation of VR curricula
Balancing immersion		
	How can we achieve sufficient immersion to accomplish intended learning objectives without creating extraneous cognitive load and frustrating part-tasks?	Comparative study of learning outcomes in a high-fidelity versus low-fidelity VR environment

[a]VR: virtual reality.

Much ongoing VR simulation research focuses on demonstrating that VR is equally or more effective than traditional simulation modalities [3-6,28]. While this is an important question, it risks overshadowing other questions that are raised by early adopters

in this study: how might we improve the ability of VR technology to teach psychomotor skills? How can we use VR simulation to create equity between learner populations? What solutions exist for shared and collaborative creation of VR software? How can we leverage the incentives of the marketplace for VR technology companies? These questions could significantly impact the future use of this technology in health professions education.

Study Limitations

This study has several limitations. First, early adopters tend to be optimistic about the advantages of new technologies, sometimes underemphasizing associated challenges. To account for this bias, we designed our interview guide with prompts targeted equally toward the advantages and challenges of VR technology, and we practiced reflexivity among this study's team to appreciate the effects of any personal biases. Future studies should examine perspectives from early majority, late majority, and laggards, but these groups are not yet readily identifiable.

Second, this study used nonprobability sampling, which harbors potential for bias toward participants with similar experiences and perspectives. However, the small size of the VR educator community limits the feasibility of random sampling. We therefore attempted to compensate by seeking participants with diverse experiences, working with different software applications, different VR companies, or different learner populations. To further assure accuracy and freedom from bias, future studies should attempt triangulation of this data, for example via data source triangulation using focus groups or via theory triangulation, analyzing this data through a different theoretical lens [29].

Third, while we targeted diversity, all health professions were not represented. Our sample included only individuals from the United States and Canada, and participants from rural workplace settings were underrepresented. These considerations may be important, particularly if geography is found to independently affect use behavior.

Finally, regarding the UTAUT modifier "experience," our sample size was inadequate to analyze its role as a modifier of use behavior. Therefore, we did not include experience in our thematic map and further research will be necessary to explore how experience may affect use behavior with VR simulation.

Conclusion

We used the UTAUT2 framework in a directed content analysis using semistructured interviews to investigate the role of immersive VR simulation in health professions education. We identified 4 key themes elucidating use behavior related to VR simulation, suggesting its optimal applications include teaching cognitive skills, expanding access to educational experiences, offering a collaborative repository of relevant simulation scenarios, and enhancing immersion for intended learning objectives. These themes may help to inform best practices for the future development and implementation of immersive VR simulation programs.

As immersive VR simulation technology continues to evolve in health professions education, the VR educator community will continue to grow alongside the rapid technological advancements. Therefore, defining best practices for integrating this technology into training programs is critical. Future research should focus on leveraging VR simulation's unique capabilities as compared to traditional simulation modalities.

Abstract

Background: With the increasing recognition of the importance of simulation-based teaching in medical education, research in this field has developed rapidly. To comprehensively understand the research dynamics and trends in this area, we conducted an analysis of knowledge mapping and global trends.

Objective: This study aims to reveal the research hotspots and development trends in the field of simulation-based teaching in medical education from 2004 to 2024 through bibliometric and visualization analyses.

Methods: Using CiteSpace and VOSviewer, we conducted bibliometric and visualization analyses of 6743 articles related to simulation-based teaching in medical education, published in core journals from 2004 to 2024. The analysis included publication trends, contributions by countries and institutions, author contributions, keyword co-occurrence and clustering, and keyword bursts.

Results: From 2004 to 2008, the number of articles published annually did not exceed 100. However, starting from 2009, the number increased year by year, reaching a peak of 850 articles in 2024, indicating rapid development in this research field. The United States, Canada, the United Kingdom, Australia, and China published the most articles. Harvard University emerged as a research hub with 1799 collaborative links, although the overall collaboration density was low. Among the 6743 core journal articles, a total of 858 authors were involved, with Lars Konge and Adam Dubrowski being the most prolific. However, collaboration density was low, and the collaboration network was relatively dispersed. A total of 812 common keywords were identified, forming 4189 links. The keywords “medical education,” “education,” and “simulation” had the highest frequency of occurrence. Cluster analysis indicated that “cardiopulmonary resuscitation” and “surgical education” were major research hotspots. From 2004 to 2024, a total of 20 burst keywords were identified, among which “patient simulation,” “randomized controlled trial,” “clinical competence,” and “deliberate practice” had high burst strength. In recent years, “application of simulation in medical education,” “3D printing,” “augmented reality,” and “simulation training” have become research frontiers.

Conclusions: Research on the application of simulation-based teaching in medical education has become a hotspot, with expanding research areas and hotspots. Future research should strengthen interinstitutional collaboration and focus on the application of emerging technologies in simulation-based teaching.

(JMIR Med Educ 2025;11:e71844) doi:10.2196/71844

KEYWORDS

medical education; simulation-based teaching; bibliometrics; visualization analysis; knowledge mapping

Introduction

In the rapidly evolving landscape of medical education, the integration of simulation-based training has emerged as a pivotal innovation. Simulation in medical education encompasses a broad spectrum of methodologies, including high-fidelity mannequins, virtual reality, standardized patients, and computer-based simulations [1,2]. These techniques aim to enhance clinical skills, decision-making, and teamwork among medical professionals without the direct involvement of real patients.

The adoption of simulation in medical training addresses several critical challenges [3,4]. First, it provides a safe and controlled environment where learners can practice and refine their skills. This is particularly crucial in high-stakes scenarios such as emergency medicine, surgery, and critical care, where errors can have severe consequences [5,6]. In addition, simulation allows for repetitive practice and immediate feedback, facilitating a deeper understanding of complex procedures and concepts.

Over the past few decades, there has been a significant increase in research focused on the effectiveness and impact of simulation-based education in the medical field [7,8]. This growing body of literature reflects the widespread recognition of simulation as a valuable educational tool. However, the rapid expansion of this field necessitates a comprehensive review and analysis to understand its development, trends, and future directions.

Several bibliometric analyses have been conducted on simulation in medical education [9,10], highlighting its growing importance and impact. However, these studies often focus on specific aspects of simulation, such as surgical training or virtual reality. Our study complements this body of research by providing a comprehensive overview of the entire field, including emerging technologies like 3D printing and augmented reality (AR), and by analyzing collaborative networks and thematic trends over a 20-year period.

A bibliometric analysis provides an ideal approach to systematically evaluate the literature on simulation in medical education. By using quantitative methods to analyze publication patterns, citation networks, and research themes, bibliometric studies can offer valuable insights into the evolution of this field. Such an analysis can identify key contributors, influential publications, and emerging trends, thereby guiding future research and practice.

This study aims to conduct a bibliometric analysis of the literature on simulation in medical education. By examining the scope, growth, and impact of research in this area, we seek to elucidate the current state of the field and identify potential gaps and opportunities for further investigation. Specifically, this analysis will focus on the following objectives:

1. To map the overall publication trends and growth in simulation-based medical education research.
2. To identify the most influential journals, articles, and authors contributing to this field.
3. To explore the thematic evolution and emerging trends within the literature.
4. To assess the collaborative networks and geographical distribution of research activities.

Through this comprehensive bibliometric analysis, we hope to provide a clearer understanding of the trajectory and impact of simulation in medical education, ultimately contributing to the enhancement of educational practices and outcomes in the medical field.

Methods

Data Acquisition and Search Strategy

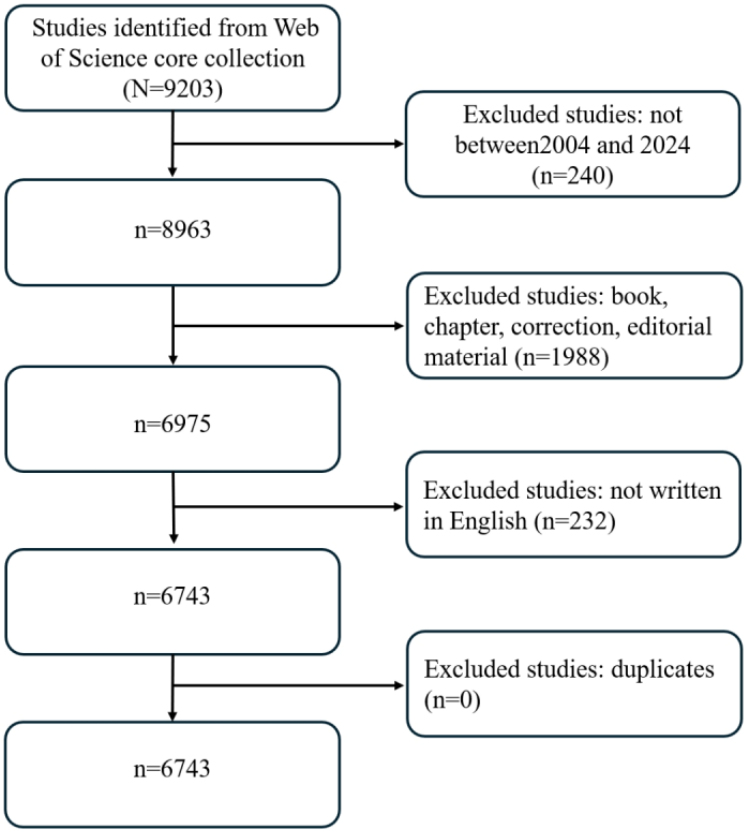
The search was conducted in the Web of Science Core Collection (WoSCC) database, which is widely recognized for its comprehensive coverage of high-quality, peer-reviewed literature [11,12]. While we acknowledge that including additional databases such as PubMed or Scopus could provide a more comprehensive dataset, the WoSCC was chosen for its superior bibliographic accuracy and extensive coverage of medical education research. Therefore, we opted to perform our search within this database. We conducted a search in the Web of Science for all relevant papers published between January 1, 2004, and December 31, 2024. The time frame from January 1, 2004, to December 31, 2024, was selected because it marks the period when simulation-based medical education began to gain significant traction in the literature, reflecting the growing recognition of its importance in medical training. In medical education, we define “simulation” as a teaching and training method that encompasses high-fidelity mannequins, virtual reality, standardized patients, and computer-based simulations.

The search formula “TS=(Medical education) AND TS=(Simulation)” was used. The inclusion criteria were as follows: (1) full-text publications related to simulation in medical education, including original research articles and review articles; (2) articles written in English; and (3) papers published between January 1, 2004, and December 31, 2024. We excluded conference abstracts, theses, dissertations, and nonpeer-reviewed articles to ensure the quality and relevance of the data. The exclusion criteria were (1) topics not related to simulation in medical education and (2) papers in the form of conference abstracts, theses, dissertations, and non–peer-reviewed articles to ensure the quality and relevance of the data. A plain text version of the papers was exported.

General Data

Between January 1, 2004, and December 31, 2024, the WoSCC database recorded a total of 6743 publications concerning simulation in medical education. This body of literature included contributions from 121 countries and regions, 510 institutions, and 858 authors. Figure 1 shows the process of literature searching and bibliometric analysis.

Figure 1. The workflow of data collection and bibliometric analysis.



Data Analysis

We used GraphPad Prism (version 8.0.2; Dotmatics) to illustrate annual publication trends. The methodological approach was validated through the use of CiteSpace and VOSviewer, both of which are widely recognized and extensively used in bibliometric research [13,14]. These tools have been shown to provide robust and reliable analyses of large-scale bibliometric data.

VOSviewer, a Java-based software developed by van Eck and Waltman in 2009, facilitates the construction of various types of network maps, such as bibliographic coupling, cocitation, and coauthorship networks. CiteSpace, developed by Professor Chaomei Chen, provides a dynamic platform for identifying and visualizing patterns and trends in scientific literature, enabling the exploration of knowledge domains and predictive analysis of research trajectories [14]. Our methodological approach involved setting specific parameters for network density (eg, keyword co-occurrence density of 0.0127), node inclusion thresholds (eg, minimum occurrence frequency of keywords), and time-slicing techniques to analyze temporal changes. The references corresponding to the software applications were verified against our citation list to ensure accuracy [13,14]. When using VOSviewer and CiteSpace for bibliometric analysis, we established standards for defining international collaboration. This was done by examining the authorship of papers, specifically the first and corresponding authors, to ensure a comprehensive capture of collaborative efforts from researchers across different countries.

Burst detection in CiteSpace is based on the Kleinberg algorithm, which models document streams using infinite-state automata to extract meaningful structures [15]. These analyses can reveal rapidly growing topics over extended periods as well as short-term themes.

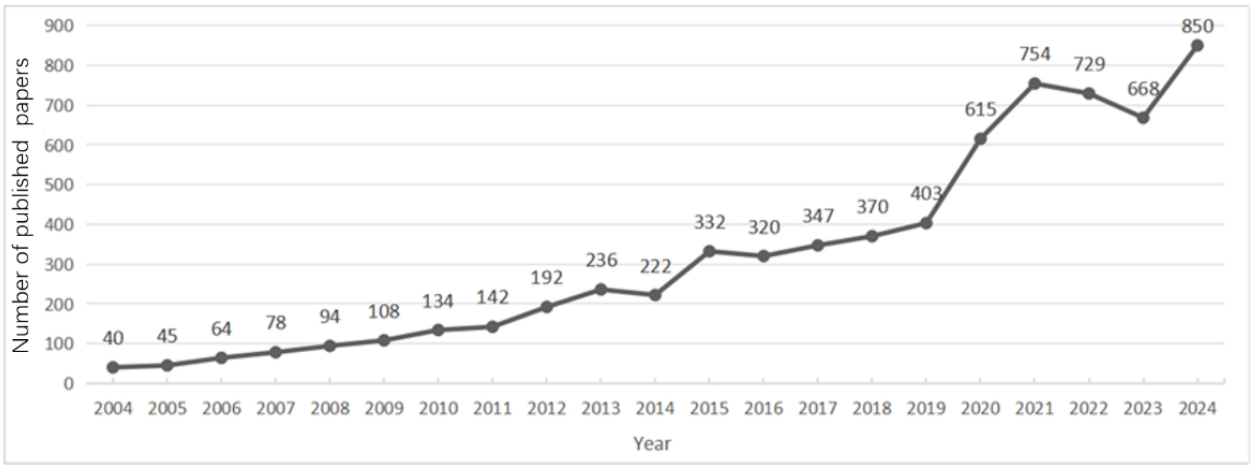
The rationale for selecting these techniques lies in their widespread application and effectiveness in bibliometric research. They provide robust and complementary insights into productivity, impact, and collaboration patterns within research fields.

Results

Publication Trend

Figure 2 shows that from 2004 to 2008, the annual number of publications on simulation teaching in medical education did not exceed 100 articles, indicating that research in this field was still in its nascent stage. Since 2009, the number of publications in this field has steadily increased, showing a trend of fluctuating growth. Specifically, the number of publications in 2015 surpassed 300 for the first time, and by 2020, this number had exceeded 500. This significant increase marks the growing attention and interest of scholars and researchers in the field of simulation teaching in medical education. Since 2020, the annual number of publications in this field has consistently remained above 500, reaching a peak of 850 articles in 2024. This further highlights the vigorous development and extensive influence of research in the field of simulation teaching in medical education.

Figure 2. Trend chart of publications in the past 20 years.



Country or Region and Institution Contributions

According to Figure 3A, the connections between circular nodes representing different countries to some extent reflect the existence of relationships and collaborations between these countries. Furthermore, the density of these connections in the network can serve as an important indicator of the closeness of collaborative relationships between countries. Among them, the countries with the highest number of publications are the United States (3083 articles), Canada (776 articles), England (510 articles), Australia (381 articles), and China (375 articles) (Table 1). In addition, countries such as Italy, the Netherlands, Sweden, and Belgium have numerous connections, indicating a complex network of relationships, which suggests that these countries have relatively close research collaborations with other regions.

Using the CiteSpace software, an institutional collaboration network diagram was obtained, as shown in Figure 3B. Upon statistical analysis, it was found that there are a total of 510 research institutions forming 1799 connections, with Harvard University being the central hub. The diagram reveals that the network density is 0.0139, indicating relatively weak collaborative relationships between research institutions, with a significant portion of them operating in a relatively independent research state. In terms of research output, the top-10 institutions by the number of publications are Harvard University, the University of Toronto, the University of California System, the University System of Ohio, Harvard Medical School, Mayo Clinic, Northwestern University, Feinberg School of Medicine, the University of Copenhagen, and Pennsylvania Commonwealth System of Higher Education (Table 2).

Figure 3. Network graph of national and institutional collaborations. (A) Network graph of national collaborations. (B) Network graph of institutional collaborations. The bubble size represents the number of publications.

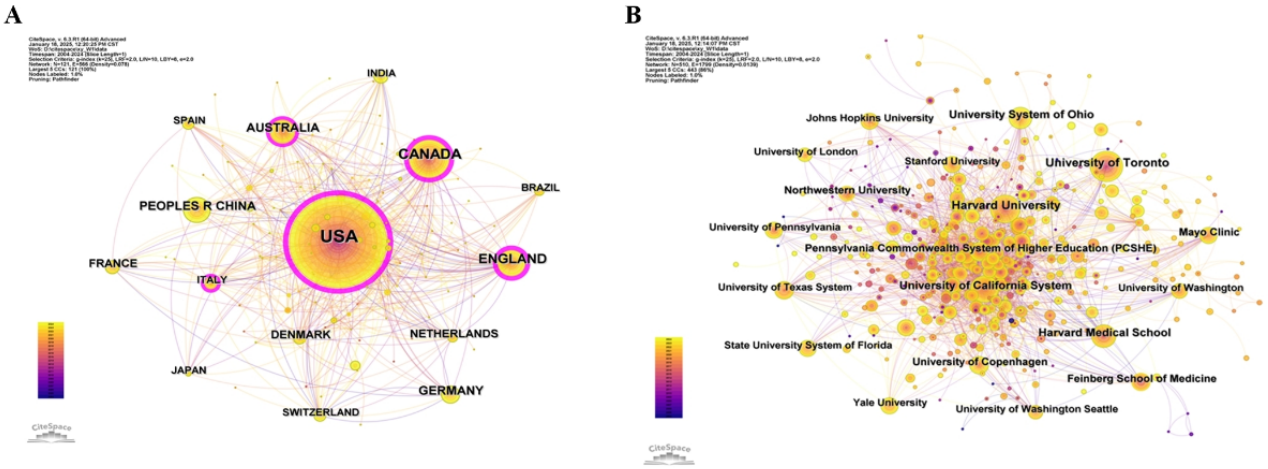


Table 1. Top-10 most productive countries or regions.

Rank	Country or region	Articles, n	Centrality	Percentage	Half-life
1	United States	3083	0.51	45.71%	14.5
2	Canada	776	0.22	11.52%	13.5
3	England	510	0.25	7.57%	15.5
4	Australia	381	0.12	5.64%	15.5
5	China	375	0.02	5.56%	15.5
6	Germany	340	0.05	5.04%	16.5
7	France	189	0.03	2.8%	15.5
8	Denmark	184	0.05	2.73%	15.5
9	The Netherlands	164	0.1	2.43%	15.5
10	Switzerland	142	0.05	2.1%	16.5

Table 2. Top-10 most productive institutions.

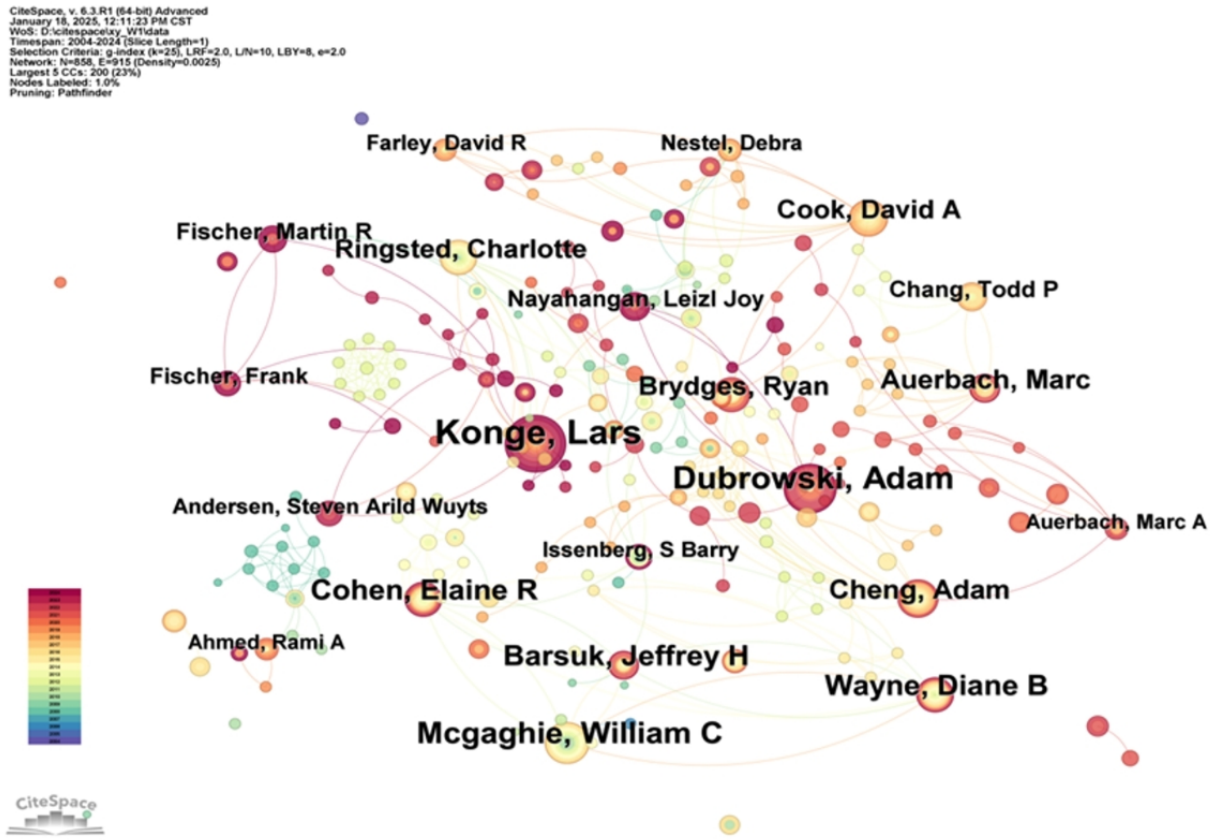
Rank	Institution	Country	Studies, n	Centrality	Half-life
1	Harvard University	United States	167	0.06	13.5
2	University of Toronto	Canada	153	0.04	11.5
3	University of California System	United States	125	0.01	12.5
4	University System of Ohio	United States	118	0.04	11.5
5	Harvard Medical School	United States	82	0.09	13.5
6	Mayo Clinic	United States	68	0.03	12.5
7	Northwestern University	United States	66	0.01	10.5
8	Feinberg School of Medicine	United States	65	0.01	10.5
9	University of Copenhagen	Denmark	61	0.01	14.5
10	Pennsylvania Commonwealth System of Higher Education	United States	60	0.02	13.5

Author Collaborations

The sample data were processed using CiteSpace, and the resulting author co-occurrence map is shown in Figure 4. In this map, each node represents a different author. The size of the node indicates the author's publication frequency, meaning the larger the node, the more publications the author has. When nodes are presented in the form of annual rings, the bandwidth of the color band corresponding to a particular year represents the number of papers published by the author that year, with a wider ring indicating more publications. The lines between nodes represent collaborative relationships between organizations or authors, with the thickness of the lines indicating the degree of collaboration.

Among the 6743 core journal articles, a total of 858 authors were involved. The top-10 authors by publication volume are Konge, Lars (69 papers); Dubrowski, Adam (50 papers); McGaghie, William C (37 papers); Wayne, Diane B (33 papers); Cohen, Elaine R (33 papers); Barsuk, Jeffrey H (30 papers); Auerbach, Marc (26 papers); Cheng, Adam (24 papers); Cook, David A (23 papers); and Ringsted, Charlotte (22 papers). Authors with 7 or more publications, a total of 44 individuals, were classified as the core author group, which accounts for only 5.1% of the total authors. In addition, there are 915 collaboration lines among the authors on the map, with a collaboration density of 0.0025, indicating a low-density level. The number of lines is relatively sparse, and the collaboration network map shows a relatively dispersed pattern. The largest collaboration network system is formed by the research team centered around Dubrowski, Adam; Nayahangan, Leizl Joy; Cheng, Adam; Auerbach, Marc A; and Cook, David A. The scale of collaboration is mainly presented in the form of individual or small-scale research teams, indicating that the core research team in this field has yet to be fully established.

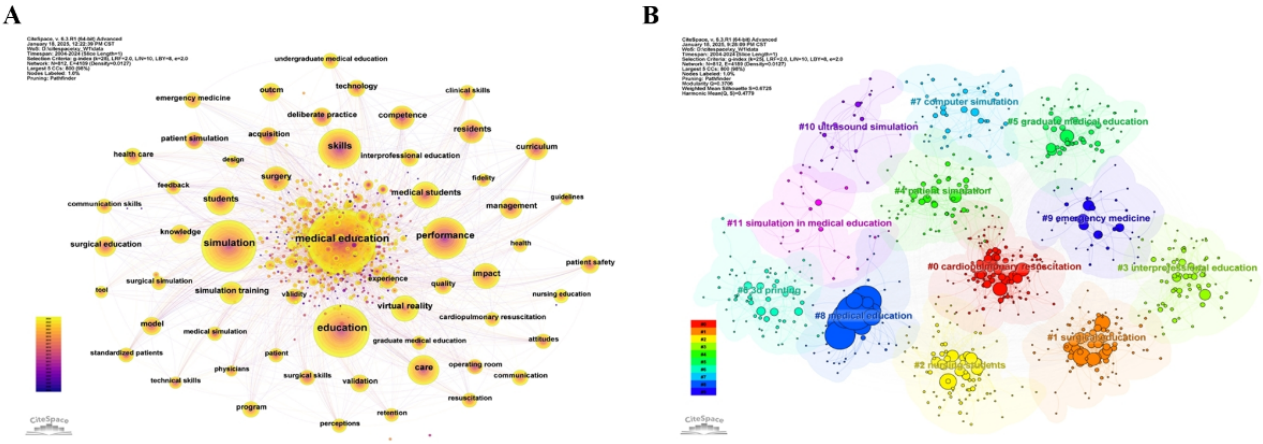
Figure 4. Network diagram of author collaborations. The bubble size represents the number of publications.



Keyword Co-Occurrence and Cluster

Using CiteSpace software to conduct a keyword co-occurrence analysis on the sample, the constructed keyword co-occurrence map is shown in Figure 5A. From the keyword co-occurrence analysis, a total of 812 common keywords were identified, forming 4189 connections, with a network density of 0.0127. The most frequently occurring keyword is “medical education,” accounting for 7.9%. This is followed by “education” and “simulation,” which account for 5.48% and 5.14%, respectively. The keywords “performance” and “skills” account for 3.49% and 3.29%, respectively. These keywords represent the current research hotspots and status in the field of simulation teaching in medical education.

Figure 5. Keyword co-occurrence and keyword clustering map. (A) Keyword co-occurrence map. (B) Keyword clustering map. The bubble size represents the number of publications.



Based on the keyword co-occurrence map, the log-likelihood ratio algorithm was used to cluster the keywords, resulting in a keyword clustering co-occurrence map. The Q value is 0.3707 (>0.3), and the S value is 0.6725 (>0.5), indicating a significant clustering structure and a high degree of clustering match. The map displays a total of 10 clustering areas, among which “cardiopulmonary resuscitation,” “surgical education,” “nursing students,” “interprofessional education,” and “patient simulation” are the five largest clusters (Figure 5B). Specifically, medical simulation teaching has become an important

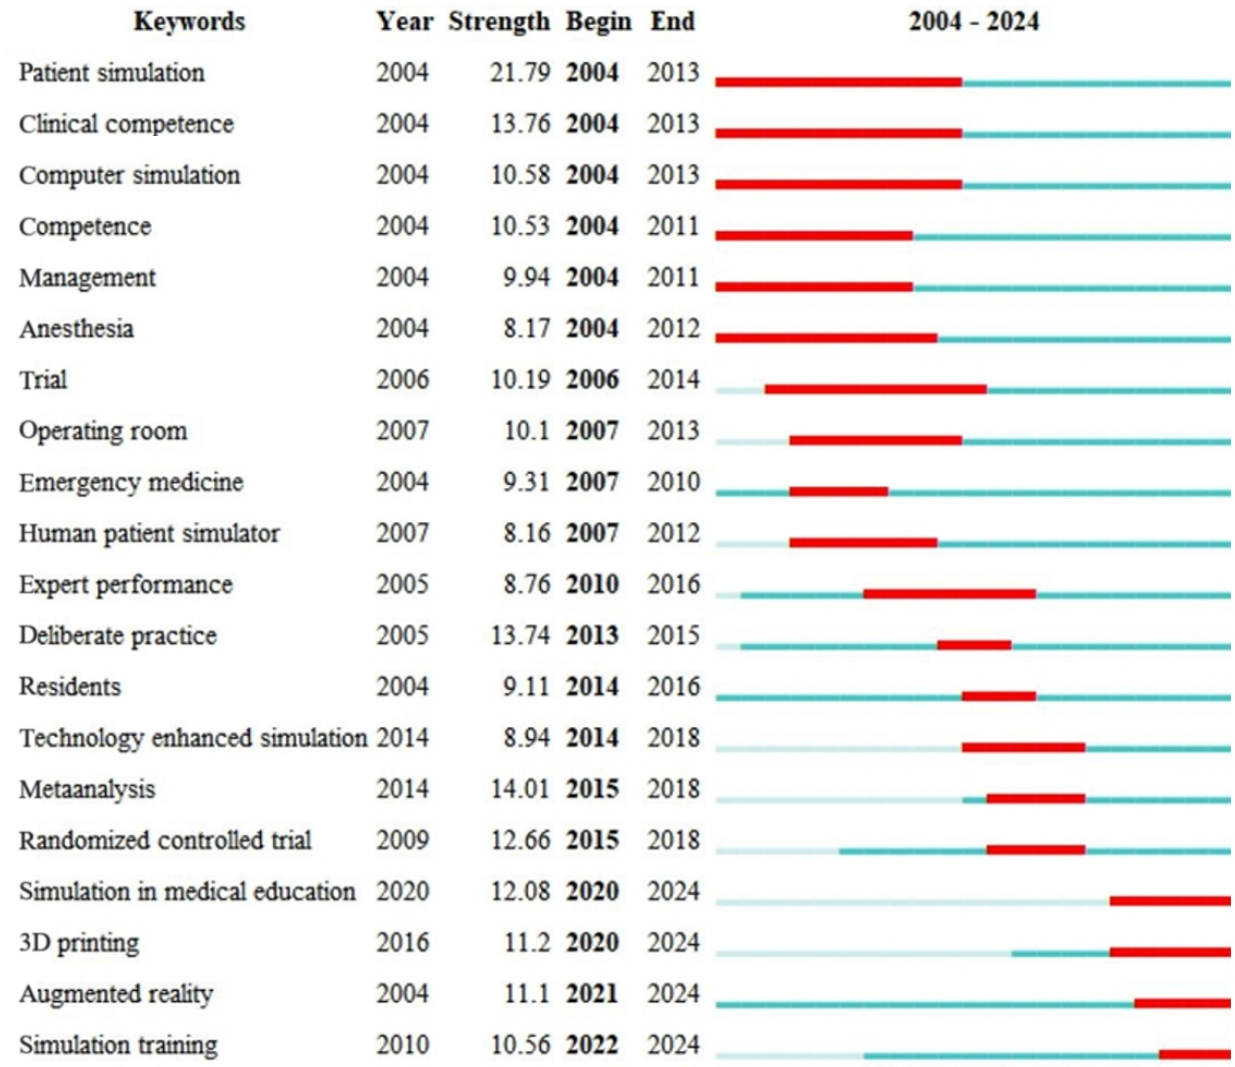
component of medical education, widely applied in various fields including cardiopulmonary resuscitation, surgical education, and nursing student training.

Keyword Citation Bursts

The keyword burst visualization analysis identified a total of 20 keywords in the field of simulation teaching in medical education from 2004 to 2024, along with their emergence intensity and start-end years. The relevant literature on keyword emergence is shown in Figure 6.

It can be observed that the keywords with high emergence intensity include "patient simulation," "randomized controlled trial," "clinical competence," and "deliberate practice." Meanwhile, the research area began to focus on "patient simulation" as early as 2004, which, along with "clinical competence" and "computer simulation," became one of the keywords with the longest duration of emergence. In recent years, researchers have increasingly focused on themes such as "trial" and "expert performance." The keywords that are still emerging represent the current research frontiers and trends, which include "simulation in medical education," "3D printing," "augmented reality," and "simulation training." The emergence of "3D printing" reflects the growing interest in using patient-specific anatomical models for surgical planning and training, offering a more personalized and immersive learning experience. Similarly, "augmented reality" signifies the integration of advanced technologies to create interactive and realistic training environments, enhancing the acquisition of clinical skills. These emerging trends highlight the transformative potential of technology in medical education, paving the way for more innovative and effective teaching methodologies.

Figure 6. Keyword burst graph (sorted by the beginning year of the burst). The blue bars denote the reference has been published; the red bars denote citation burstiness.



Discussion

Principal Findings

The results of our bibliometric analysis provide a comprehensive overview of the evolution, collaboration patterns, and thematic focus of simulation-based education research in the medical field. Key trends include a steady increase in publications from 2004 to 2024, particularly a surge after 2009, indicating a growing recognition of simulation's importance in medical education. By 2024, the publication count had peaked at 850, highlighting a transition of simulation from a novel approach to a staple in medical education. In addition, the United States emerged as the leading contributor with 3083 articles, reflecting substantial investment in education and research. Harvard University is a central hub for simulation-based medical education, despite a fragmented institutional landscape. Prominent authors like Lars Konge, Adam Dubrowski, and William C McGaghie drive the field, though the low density of collaborative networks suggests room for enhanced inter-institutional teamwork. Keyword analysis underscores the focus on competency-based education and practical skill acquisition, with emerging technologies like 3D printing and AR shaping future directions.

Comparison to Literature

Our findings are consistent with existing literature [16,17], which also highlights the increasing role of simulation in medical education over the past two decades. Previous studies have documented the rise in publications and the central role of the United States and key institutions like Harvard in advancing this field. However, our analysis provides a more granular look at the collaborative networks and thematic focuses, revealing a fragmented institutional landscape and the emergence of cutting-edge technologies that are less emphasized in earlier reviews.

Implications of Findings

The implications of these findings are multifaceted. The robust growth in simulation-based medical education research indicates a broad acceptance of its efficacy in improving medical training. The strong international collaboration suggests that best practices and innovative methodologies are being shared globally, potentially standardizing and enhancing simulation protocols. The emergence of new technologies like 3D printing and AR points to a future where simulation-based education will be more immersive and technologically advanced [18-20], which could significantly enhance learning outcomes and patient care. The integration of 3D printing and AR into simulation-based training can significantly improve clinical outcomes. 3D-printed anatomical models enable patient-specific simulations, allowing surgeons to practice complex procedures before operating on real patients, thus enhancing precision and reducing errors [21]. Similarly, AR creates immersive training environments, providing real-time feedback and interactive learning to enhance clinical skill acquisition [22]. However, challenges such as the high cost of equipment and the need for specialized training for educators and learners may limit their widespread adoption. Future research should explore cost-effective solutions to overcome these barriers and ensure broader access to these technologies in medical institutions.

The emergence of "cardiopulmonary resuscitation" as a major research hotspot reflects its critical importance in medical education and clinical practice. Cardiopulmonary resuscitation is a high-stakes procedure where errors can have severe consequences, making it an ideal candidate for simulation-based training [23]. Simulation allows learners to practice cardiopulmonary resuscitation in a controlled environment, receive immediate feedback, and refine their skills through repetitive practice [24]. This not only enhances individual competence but also improves team dynamics and communication during real-life emergencies.

Similarly, the focus on "surgical education" underscores the need for advanced training methods to prepare surgeons for complex procedures. Simulation-based training in surgical education has been shown to improve technical skills, reduce operative time, and enhance patient safety [25]. These findings highlight the transformative potential of simulation in addressing critical gaps in medical education and improving clinical outcomes.

Limitations

While the bibliometric analysis provides valuable insights, it has several limitations. First, the data might not capture all relevant publications, particularly those in non-English languages or those in less accessible databases, which could introduce selection bias. Second, the analysis relies on citation metrics, which may not fully reflect the quality or practical impact of the research. For instance, highly cited articles may not always represent the most impactful studies in terms of educational outcomes. Third, the low density of collaborative networks suggests that our findings might underrepresent the potential for interinstitutional synergy and innovation. Finally, a limitation of this study is the reliance on a single database (WoSCC), which may not capture all relevant publications. Future studies could expand the search to include additional databases such as PubMed and Scopus to enhance the robustness of the findings.

Suggestions

To address the identified limitations and enhance the impact of simulation-based education research, we suggest the following:

1. Increasing efforts to include diverse and international publications in future analyses.
2. Encouraging more interinstitutional collaborations to create a more cohesive research landscape.
3. Fostering larger, integrated research teams to deepen the scope of studies and drive innovation.
4. Embracing and further investigating emerging technologies to stay at the forefront of educational advancements.

Conclusions

In conclusion, the bibliometric analysis of simulation in medical education research reveals a dynamic field characterized by rapid growth, strong international collaboration, and evolving thematic focuses. The increasing trend in publications, significant contributions from leading countries and institutions,

and the integration of new technologies underscore the impactful nature of this research area. Moving forward, enhancing collaboration among institutions and expanding the core author network will be crucial. Future research should focus on integrating emerging technologies, such as 3D printing and AR, into medical education. For instance, studies could explore how 3D-printed anatomical models can enhance surgical training by providing realistic, patient-specific simulations.

Data Availability

All datasets generated for this study were included in the manuscript.

Authors' Contributions

HB conceived and designed the ideas for the manuscript. HB, LZ, XH, and SL participated in all data collection and processing. HB was the major contributor in organizing records and drafting the manuscript. All authors proofread and approved the manuscript.

Abstract

Background: Simulated programs provide health care professionals (HCPs) with a learning opportunity to develop clinical competencies and improve patient outcomes in a safe and controlled environment. While the benefits of simulation training are well established, there is a paucity of research assessing its differential impact, if any. SIMBA (Simulation via Instant Messaging for Bedside Application) provides simulation-based learning through WhatsApp and Zoom (Zoom Video Communications, Inc) to increase HCPs' confidence in managing various medical conditions.

Objectives: This study aims to explore whether there are differences in the clinical performance of HCPs participating in SIMBA sessions based on gender, country of work, and training grade.

Methods: This study assessed participants in 17 SIMBA sessions from May 2020 to June 2022. WhatsApp chats containing participants' approach to the simulated scenarios were graded using an adapted version of the Global Rating Scale consisting of 6 domains: eliciting history; physical examination; investigations, diagnostic tests, and imaging; interpretation of investigations and imaging; clinical judgment; and management and follow-up or discharge plan. These domains were rated using a Likert-type scale of 1 (not done) to 5 (excellent) prior to the session based on expert inputs. All WhatsApp transcripts were evaluated against the scale postsimulation session. Unadjusted and adjusted means and 95% CIs of the scores for the 6 performance variables were calculated using multiple linear regression models. The *P* value for heterogeneity between the mean performance scores was calculated using likelihood ratio tests by using an analysis of variance.

Results: A total of 289 participants across 49 countries who completed pre-SIMBA and post-SIMBA surveys in the 17 simulation sessions were included in the analysis. Participants from high-income countries scored higher in all categories of the Global Rating Scale (GRS) except the physical examination and interpretation score. Junior-grade participants scored significantly higher in history taking (junior=4.2, middle=3.7, and senior=3.7; *P*=.003) and physical examination (junior=4.0, middle=3.7, and senior=3.5; *P*=.068), but this was not significantly different. There were no statistically significant differences in GRS scores between male and female participants.

Conclusions: The significant differences in clinical performance scores between low- and middle-income countries and high-income countries highlight the need for better medical education resources to bridge existing gaps in health care globally. The decrease in some clinical competency scores following career progression could be addressed by simulation-based training to maintain the same quality of history taking and physical examination skills. These outcomes, including no gendered differences in simulation-based learning, hold profound implications for tailoring medical education strategies, fostering equitable training, and elevating patient care standards on a global scale. The need for targeted interventions and capacity-building efforts via context-specific training and tailored approaches to health care education is emphasized.

Introduction

Understanding the multifaceted global health care disparities is crucial for ensuring access to high-quality medical education [1]. The most common barriers to high-quality medical education are due to financial, resource, and accessibility inequities [2]. There is a shortage in the training resources to recruit and retain health care professionals (HCPs) in low- and middle-income countries (LMICs), leading to disparities in clinical learning opportunities compared with HCPs in high-income countries (HICs) [3]. This was further exacerbated following the COVID-19 pandemic [4,5].

E-learning and distance virtual simulation sessions can provide case-based learning and support the training of medical professionals in LMICs [6]. Specifically, initiatives using accessible technology platforms to develop high-quality educational programs can enhance postgraduate health care training [7,8]. Simulated programs provide HCPs with a learning opportunity to develop clinical competencies and improve patient outcomes in a safe and controlled environment [9,10]. However, there is an unequal distribution of simulation-based learning across LMICs, due to misconceptions regarding the cost and availability of programs [11]. Also, while the benefits of simulation training are well established, there is a paucity of research studying the differences, if any, in the clinical performance of HCPs from HICs and LMICs in simulation-based case scenarios. Understanding the similarities and differences in clinical performance can help identify areas for improvement in health care education and resource allocation in LMICs.

SIMBA (Simulation via Instant Messaging for Bedside Application) is a simulation-based learning model that uses WhatsApp and Zoom (Zoom Video Communications, Inc) platforms to improve HCPs' confidence in managing various medical conditions [12,13]. The model is built on the principles of Kolb's experiential learning theory and simulation gaming theory [14]. Kolb's experiential learning theory emphasizes the importance of learning through reflection on doing, where learners actively engage in a cycle of concrete experience, reflective observation, abstract conceptualization, and active experimentation. This framework guided the design of our SIMBA sessions, ensuring that participants were exposed to real-world scenarios and encouraged to reflect on their actions and apply new knowledge in future simulations. Simulation gaming theory further shaped our curriculum by integrating gamelike elements to create an immersive and interactive learning environment. Using realistic clinical cases, role-playing, and feedback loops in our sessions aligns with the theory's emphasis on learning through interaction and problem-solving within a simulated context. This approach fosters engagement and enhances skill development, making the learning process dynamic and participatory. It helped deliver and sustain good quality medical education during the COVID-19 pandemic [15]. It also provided alternative work experiences for premedical students [16] and a platform for medical students and junior doctors to improve teamwork and leadership skills [17]. Our previous work described how SIMBA provided equitable and high-quality postgraduate medical education to health care physicians in the LMICs and HICs [18].

As health care systems strive to provide safe and effective medical services, understanding the nuances of clinical competence among different training grades becomes a pivotal aspect of medical education and professional development. Exploring the clinical performance variations across various stages of HCP training offers valuable insights into how educational strategies and experiential learning impact the acquisition and application of clinical competencies. The need for such exploration is underscored by the potential ramifications these findings may have on patient care. An HCP's ability to accurately diagnose, interpret diagnostic tests, make informed clinical judgments, and formulate appropriate management plans can vary across different training grades. These variations can impact patient safety, the quality of health care services, and the overall effectiveness of medical teams [19-21]. In addition, as health care systems increasingly seek to bridge global disparities in medical education and patient outcomes, it is imperative to identify how training grade–related differences influence clinical performance across diverse settings.

In this study, we explore the differences in the performance and outcomes of HCPs participating in SIMBA sessions based on gender, country of work, and training grade. This study addresses this critical knowledge gap by examining the disparities among training grades within a single context and how the geographic context of HICs and LMICs influences these disparities. The inclusion of gender as a parameter is aligned with the aspiration to tailor medical education to the diverse needs of HCPs, while also acknowledging the broader societal implications of gender-sensitive health care delivery. The study's findings hold the potential to influence medical training practices, curriculum development, and professional mentorship in ways that are more attuned to the nuances of gender-specific experiences and perspectives.

Methods

Conducting SIMBA Sessions

The preparation and delivery of SIMBA sessions, including detailed flowcharts and examples, have been described in detail in our previous publication [12]. Each SIMBA session featured 4-6 clinical case scenarios representing a range of medical presentations commonly encountered in secondary care. These sessions were promoted via social media, junior doctor bulletins, and supporting organizations' websites.

The case scenarios were adapted from real-life cases with all patient-identifiable information removed. They included

comprehensive details such as presenting complaints, medical history, examination findings, clinical observations, investigation results (eg, blood tests and imaging), differential diagnoses, management strategies, and follow-up plans. Experts chairing the sessions rigorously reviewed and approved the case transcripts to ensure scientific accuracy and alignment with current medical guidelines.

Participation in the sessions was voluntary and free of charge. Participants registered in advance by providing their email addresses and WhatsApp numbers. Emails were used for presession communication, while WhatsApp facilitated real-time interaction during the simulations, providing access to all necessary session details and resources.

Before the simulation, participants completed a presimulation survey, which included informed consent, sociodemographic data collection, and self-assessment of their confidence in managing various clinical scenarios. This survey established a baseline measure of their confidence levels, covering both the session scenarios and the similar medical presentations.

During the simulation, HCPs from HICs and LMICs participated concurrently via WhatsApp. Moderators guided participants through the scenarios, encouraging them to interact as they would during real-life patient encounters. WhatsApp was also used to share key resources, such as links to surveys, investigations, and meeting invitations.

After completing all simulated cases, participants joined a Zoom meeting led by an expert. This interactive session provided an opportunity to discuss the cases, ask questions, and gain additional insights. Experts facilitated peer-to-peer discussions in the Zoom chat, fostering collaborative learning and ensuring a thorough exploration of each case.

After the simulation, participants completed a postsimulation survey, which included the confidence-rating questions from the presurvey to assess changes in confidence levels. The survey also collected feedback on their experience, highlighting successful aspects of the session and identifying areas for improvement.

WhatsApp interactions were recorded and later analyzed. Participants' performance was objectively assessed using a GRS [22], validated by experts prior to the session. The scale evaluated 6 domains: eliciting history, physical examination, investigations and diagnostic tests, interpretation of findings, clinical judgment, and management and follow-up plans. Each domain was scored on a Likert-type scale from 1 (not done) to 5 (excellent) [23], with total scores ranging from 6 to 30. This assessment measured participants' knowledge, accuracy, and thoroughness in handling the cases.

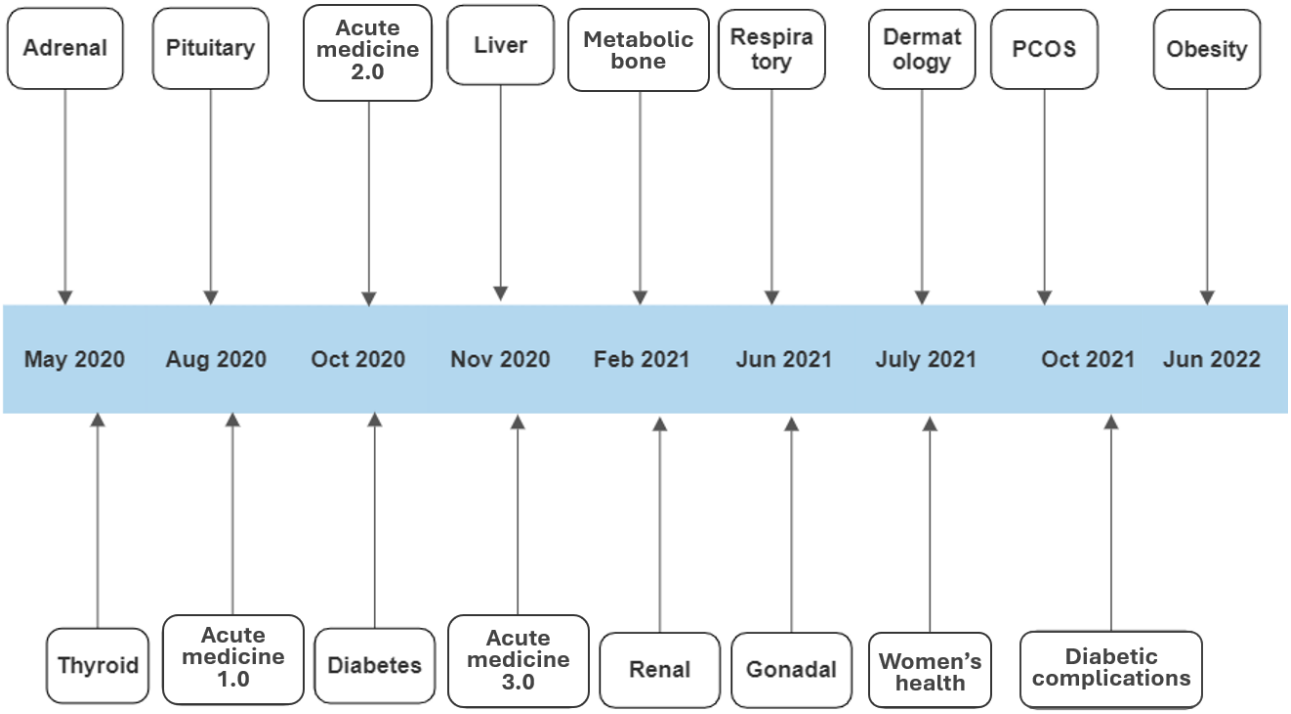
In addition, moderators provided personalized feedback using Pendleton's feedback model [24,25]. Feedback highlighted participants' strengths and offered constructive guidance for improvement, aiming to enhance their skills and confidence in managing similar scenarios in the future.

Data Collection

This study assessed participants in 17 SIMBA sessions from May 2020 to June 2022. The topics simulated included a wide range of medical specialties, as seen in Figure 1. All participants were invited to complete both the pre-SIMBA and post-SIMBA surveys voluntarily. The pre-SIMBA survey, distributed just before the session began, gathered basic sociodemographic information and self-reported confidence levels in managing simulated cases. The post-SIMBA survey, shared immediately after the expert case discussion, included similar questions on self-reported confidence in managing these cases. It also sought participants' feedback on their experience in the session. Each survey was administered at a single time point rather than as part of a test-retest design.

In addition, following each SIMBA session, WhatsApp chats containing the participants' approach to the simulated scenarios were graded using an adapted version of the GRS [22], which is reviewed by experts to confirm their appropriateness for the simulated case. Our assessment tool consisted of 6 domains (eliciting history; physical examination; investigations, diagnostic tests, and imaging; interpretation of investigations and imaging; clinical judgment; and management and follow-up or discharge plan), which are rated using a Likert-type scale of 1 (not done) to 5 (excellent) [23]. Moderators calculated the participant's score between a minimum of 6 and a maximum of 30, measuring the participant's knowledge, accuracy, and completeness in approaching the simulated case and assessing the patient. In addition to a numerical score, moderators provided participants with written feedback based on Pendleton's feedback model [24,25]. Pendleton's model is a structured approach to feedback that aims to create a positive and constructive learning environment. The model emphasizes a balanced feedback process by first highlighting the learner's strengths, then identifying areas for improvement, and finally engaging the learner in self-reflection. This structured feedback process encourages active learning and helps participants gain a deeper understanding of their performance, making it an effective tool for clinical education. GRS scores and feedback were emailed to participants 24 - 48 hours after the session. In the case of any queries, participants were provided with the contact details of the SIMBA team. To ensure uniformity and fairness across scoring, all moderators attended training sessions where they were taught how to use our assessment tool by experienced moderators. Any uncertainties that arised during the scoring process were resolved by discussion with experienced moderators.

Figure 1. Timeline of SIMBA (Simulation via Instant Messaging for Bedside Application) sessions held from 2020 to 2022. PCOS: polycystic ovary syndrome.



Statistical Analysis

Participants who completed both pre-SIMBA and post-SIMBA surveys were included in the analysis. This pre-post test design with presurvey and postsurvey specifically focused on assessing changes over time rather than the consistency of responses. Participants self-reported their country of residence during surveys, and the data (countries) were grouped into HICs and LMICs according to their country of residence based on the 2022 World Bank report [26]. Participants were classified as junior, middle, and senior grades based on their work experience. Junior-, middle-, and senior-grade HCPs had 0 - 2 years, 2 - 5 years, and >5 years of work experience, respectively.

Unadjusted and adjusted means and 95% CIs of the scores for the 6 performance variables (history taking, physical examination, investigation, interpretation, judgment, and management) by economic classification (HIC or LMIC), level of training (junior, middle, or senior grade), and gender (male or female) were calculated using multiple linear regression models, adjusting for gender, country, training, and number of WhatsApp messages (continuous), as appropriate. The mean (95% CI) difference of the pairwise comparisons between each performance score was calculated using paired *t* tests. The *P* value for heterogeneity between the mean performance scores was calculated using likelihood ratio tests by using an ANOVA. Two-sided *P* values of <.05 were considered statistically significant. We did not adjust the *P* value for multiple comparisons. All statistical analyses were performed using the Stata statistical software package (version 27.0; StataCorp).

Ethical Considerations

SIMBA was approved as an educational modality for postgraduate medical education by the Health Education West Midlands Diabetes and Endocrinology Specialist Training Committee. The study was approved by the Science, Technology, Engineering and Mathematics Ethics Committee at the University of Birmingham (ERN_2023 - 0495 and ERN_2023 - 0544). The study complied with all relevant ethical guidelines and institutional regulations throughout its design, implementation, analysis, and dissemination. Informed consent was taken from each participant and participation was voluntary. Participants were provided with an information sheet outlining the purpose of the study, the estimated duration of their involvement, the nature of the data collected, the identity of the investigators, and the storage and retention details. All data were anonymized at the point of analysis and stored on a secure, restricted access online drive. No identifiable patient data were used. No financial or material compensation was offered for participation.

Results

Overview

A total of 289 participants completed both pre-SIMBA and post-SIMBA surveys in the 17 simulation sessions. A total of 281 participants provided their country of residence. These participants worked in 49 countries across 5 continents, of which 36.7% (18/49) were classified as HICs, whereas 63.2% (31/49) were LMICs. Most participants worked in HICs (HICs: 191/281, 67.9%; LMICs: 90/281, 32.0%). Overall, the mean (SD) scores for the cohort were history taking: 3.6 (SD 3.9), physical examination: 3.5 (SD 3.7), investigation: 3.3 (SD 3.5), interpretation: 2.6 (SD 2.9), judgment: 3.1 (SD 3.3), and management: 2.6 (SD 2.8) (Table 1).

The values with the footnotes are the mean (95% CIs) for that particular score. Other values and corresponding *P* values are the mean difference (95% CIs) for the pairwise comparisons between scores taken from a paired *t* test for the 264 participants

who had a value for all 6 outcome scores. The difference is for the performance measure on the column compared with the performance measure on the corresponding row.

Table . Mean and 95% CIs difference between various performance measures using the global rating score for those participating in Simulation via Instant Messaging for Bedside Application (SIMBA).

	History	*P* value	Physical examination	*P* value	Investigation	*P* value	Interpretation	*P* value	Judgment	*P* value	Management
History	3.7 (3.6 - 3.9)[a]

[a]These values are the mean (95% CIs) for that particular score.

Comparing the Performance Between Participants From HIC and LMIC

After adjusting for sex, training, and number of WhatsApp messages, there were statistically significant differences in performance that were identified in the categories of history taking (HIC vs LMIC: 3.8 [3.7 - 3.9] vs 3.5 [3.3 - 3.7]; *P*<.01), investigations (3.6 [3.5 - 3.7] vs 3.1 [2.9 - 3.2]; *P*<.01), clinical judgment (3.4 [3.3 - 3.5] vs 2.9 [2.7 - 3.1]; *P*<.01), and management (2.9 [2.7 - 3.0] vs 2.3 [2.1 - 2.5]; *P*<.01) (Table 2 and Multimedia Appendix 1). A slight difference, although not statistically significant, was also found in physical examination (3.7 [3.5 - 3.8] vs 3.5 [3.2 - 3.7]; *P*=.13) and interpretation (2.8 [2.6 - 3.0] vs 2.6 [2.3 - 2.9]; *P*=.23).

Table . Mean and 95% CIs of various performance measures using the global rating score for low- or middle- and high-income countries for those participating in the SIMBA (Simulation via Instant Messaging for Bedside Application).

Performance measure	Unadjusted and adjusted	Low and middle income	High income	*P* value[a]
History taking	Unadjusted	3.5 (3.2 - 3.7)	3.8 (3.7 - 4.0)	<.01
	Adjusted[a]	3.5 (3.3 - 3.7)	3.8 (3.7 - 3.9)	<.01
Physical examination	Unadjusted	3.4 (3.2 - 3.6)	3.7 (3.5 - 3.8)	.05
	Adjusted[a]	3.5 (3.2 - 3.7)	3.7 (3.5 - 3.8)	.13
Investigation	Unadjusted	3.1 (2.9 - 3.2)	3.6 (3.5 - 3.7)	<.01

	Adjusted[a]	2.9 (2.7 - 3.1)	3.4 (3.3 - 3.5)	<.01

[a]Adjusting for country, level of training, and the number of WhatsApp messages

Comparing the Performance Between Participants Based on Their Training Grade

A total of 213 participants provided their training grade in pre-SIMBA and post-SIMBA surveys, of which we classified 28.2% (60/213) as junior grade, 55.9% (119/213) as middle grade, and 16% (34/213) as senior grade. Junior-grade participants scored significantly higher in history taking (junior vs middle vs senior: 4.2 [4.0 - 4.5] vs 3.7 [3.5 - 3.9] vs 3.7 [3.4 - 4.0]; *P*<.01). Otherwise, there was no significant difference across the training grade for the rest of the domains (physical examination: 4.0 [3.7 - 4.2] vs 3.7 [3.5 - 3.9] vs 3.5

[3.1 - 3.8]; *P*=.07; investigation: 3.5 [3.3 - 3.7] vs 3.4 [3.3 - 3.6] vs 3.6 [3.3 - 3.8]; *P*=.53; clinical interpretation: 2.6 [2.3 - 2.9] vs 2.5 [2.3 - 2.8] vs 3.1 [2.7 - 3.6]; *P*=.08; clinical judgment: 3.4 [3.1 - 3.6] vs 3.3 [3.1 - 3.4] vs 3.4 [3.1 - 3.7]; *P*=.63; and management: 2.8 [2.5 - 3.0] vs 2.7 [2.6 - 2.9] vs 2.8 [2.5 - 3.1]; *P*=.94) (Table 3 and Multimedia Appendix 2).

Table . Mean and 95% CIs of various performance measures using the global rating score by level of training for those participating in SIMBA (Simulation via Instant Messaging for Bedside Application).

Performance measure	Unadjusted and adjusted	Junior grade	Middle grade	Senior grade	*P* value[a]
History taking	Unadjusted	4.2 (4.0 - 4.5)	3.7 (3.6 - 3.9)	3.6 (3.3 - 3.9)	<.01
	Adjusted[a]	4.2 (4.0 - 4.5)	3.7 (3.5 - 3.9)	3.7 (3.4 - 4.0)	<.01

Comparing the Performance Between Participants Based on Their Gender

A total of 199 participants provided their gender identity in pre-SIMBA and post-SIMBA surveys (male: 83/199, 41.7%; female: 116/199, 58.3%). There were no statistically significant differences in GRS scores between male and female participants (male vs female; history taking: 3.7 [3.5 - 3.9] vs 3.8 [3.6 - 3.9]; *P*=.53; physical examination: 3.7 [3.5 - 3.9] vs 3.6 [3.4 - 3.7]; *P*=.30; investigation: 3.4 [3.3 - 3.6] vs 3.4 [3.3 - 3.6]; *P*=.93; clinical interpretation: 2.9 [2.7 - 3.2] vs 2.7 [2.5 - 2.9]; *P*=.12; clinical judgment: 3.3 [3.1 - 3.5] vs 3.3 [3.1 - 3.4]; *P*=.75; and management: 2.8 [2.6 - 3.0] vs 2.7 [2.5 - 2.8]; *P*=.42) (Table 4).

Table . Mean and 95% CIs of various performance measures using the global rating score by number of WhatsApp messages for those participating in SIMBA (Simulation via Instant Messaging for Bedside Application).

Performance measure	Unadjusted and adjusted	Men	Women	*P* value[a]
History taking	Unadjusted	3.7 (3.4 - 3.9)	3.8 (3.6 - 4.0)	.52
	Adjusted[a]	3.7 (3.5 - 3.9)	3.8 (3.6 - 3.9)	.53
Physical examination	Unadjusted	3.7 (3.5 - 3.9)	3.6 (3.4 - 3.8)	.35
	Adjusted[a]	3.7 (3.5 - 3.9)	3.6 (3.4 - 3.7)	.30
Investigation	Unadjusted	3.4 (3.3 - 3.6)	3.4 (3.3 - 3.6)	.89
	Adjusted[a]	3.4 (3.3 - 3.6)	3.4 (3.3 - 3.6)	.93

Discussion

Principal Findings

Overall, participants scored higher in history taking and physical examination skills, while their scores were lower in interpretation and management skills. This information is valuable for fine-tuning future simulation programs to focus on improving interpretation and management abilities.

GRS is a validated tool for assessing clinical competencies across 6 critical domains: eliciting history, physical examination, investigations and diagnostic tests, interpretation of findings, clinical judgment, and management and follow-up plans. Although the GRS was not used to evaluate participants' abilities before the curriculum, it served as an objective measure during the simulation to assess performance and track growth. Combined with presimulation and postsimulation surveys, it allowed us to analyze changes in confidence levels and skill application.

The Pendleton model was adopted to provide structured feedback for the GRS output. This approach starts with positive reinforcement by highlighting what participants did well and then constructive guidance on areas for improvement. This approach ensures supportive feedback and facilitates skill enhancement.

Demographic data were collected during the presimulation survey to contextualize participants' backgrounds and identify trends in performance or confidence changes across demographic groups. While these characteristics are static, integrating them into a pre-post framework enabled us to correlate them with dynamic variables such as confidence and skill development.

The significant differences in clinical performance scores between LMICs and HICs highlight the need for better medical education resources to bridge existing gaps in health care across the globe. A recent analysis by the General Medical Council has identified a substantial attainment gap between international medical graduates from LMIC and candidates from the United Kingdom working in the National Health Service [27]. Subsequent recommendations advise the need for tailored approaches to tackle inequality and ensure consistent quality of medical education to trainees. Free and accessible programs, such as SIMBA, can facilitate this.

The observed differences in clinical performance between HCPs from HICs and LMICs can be attributed to various factors. HCPs from HICs often benefit from better infrastructure, advanced technology, and comprehensive training programs. In contrast, LMIC professionals face limited access to resources, inadequate training opportunities, and contextual factors that may impact their clinical performance. The comparative analysis highlights the need for context-specific training and tailored approaches to health care education in LMICs. Of note, a commonly identified issue with technology-enhanced simulation is the cost of simulators and limited understanding of the use and limitations of artificial intelligence or embedded computer algorithms [28,29]. SIMBA bypasses these hurdles as it has minimal costs, and the sessions can be conducted virtually.

Whilst all training grades performed similarly across investigation, clinical judgment, and management domains, significant differences were noted in history taking and physical examination scores. The decrease in these scores following career progression suggests the need for simulation-based training for senior trainees to maintain the high quality of history taking and physical examination skills. These insights hold implications for refining medical education approaches and optimizing patient care delivery. In an era of global health care parity, comprehending training grade–related performance disparities is instrumental in fostering contextually apt and universally equitable medical training standards. A study validating the use of smartphone accelerometers in neurosurgical simulations found higher acceleration scores among junior doctors than among senior registrars and consultants, suggesting improved technical performance in junior HCPs [30]. However, our findings also contrast with findings from a study of the American Board of Internal Medicine patient satisfaction questionnaire, which found a systematic improvement in the quality of consultations in directly observed clinical skills in senior attending physicians compared with junior residents [31]. The decline in history and examination skills may stem from increased workload, encouraging reliance on diagnostic investigations over thorough assessments. Deskilling—reduced use of certain skills in practice—also contributes to a decline in history and examination skills. The potential reason for contrast with findings from various national and international educational boards likely arises from differences in settings; formal assessments occur in controlled environments, encouraging conscious performance. In contrast, SIMBA sessions reflect real-life scenarios without direct observation, emphasizing authentic application of skills, which may reveal different trends.

Recommendations by Health Education England highlight the growing role of simulation-based education in core medical training, including procedural and emergency presentation learning sessions [32]. Its widespread use and implementation of a clear framework across all National Health Service trusts may allow physicians to further develop their skills and knowledge in line with up-to-date guidelines throughout their careers.

We did not find a significant difference in GRS between male and female participants. This is consistent with previous findings, which showed no significant gender-related differences in simulation assessment scores among emergency medicine residents assessed against 2 simulation cases related to the emergency medicine curriculum [33]. Similarly, simulation-based learning has been shown to eliminate gender differences in a virtual surgical training course in endoscopic proficiency [34]. However, while gender differences in the simulation were investigated, the translation of simulated skill to physical performance in the endoscopy suite was not investigated. Consequently, further prospective studies are required to assess the impact of gender on clinical performance. Previous studies have further demonstrated the role of simulation-based education in developing interpersonal communication skills and teamwork among medical students and HCPs [35,36]. Therefore, simulation-based learning may

provide objective and standardized scenarios to help remove gender-based differences in clinical outcome scores.

While mobile simulation-based learning appears to be widely accessible, reliable web access and cost of access continue to pose a barrier to virtual learning in many LMICs [37]. This is a particular issue in remote areas of the world, which may be subject to unscheduled power cuts [38]. Although communication platforms such as WhatsApp serve as low-cost initiatives for delivering medical education, emphasis must be placed on data security and confidentiality [39]. Consequently, standardized guidelines concerning the use of instant messaging in health care education are required to ensure its sustainability [40].

Limitations

We did not assess the change in perception toward virtual education over time. This may have influenced the findings of experience and difficulties that the participants encountered with web-based education from both LMICs and HICs. Future longitudinal studies must determine whether subsequent clinical decision-making is improved in real-life scenarios. Brain drain, that is, migration of doctors usually from LMICs to HICs for better opportunities and other varied reasons, is another important factor that needs to be considered as this phenomenon may have skewed the results. As SIMBA sessions are currently conducted only in English, it is a potential language barrier. As all the data collected were self-reported rather than objectively verified or tested, it is an inherent limitation of the study.

Regarding the physical examination, participants requested specific types of examinations, such as general physical examination, abdominal examination, or limb examination, and the corresponding findings were provided to them. The virtual clinical physical examination was not performed by the participants themselves, which is a limitation of our study. As we collected minimal identifying data, we do not have further information on the career breaks taken by a doctor for any reason that may have led to inaccurate classification as a junior, middle, or senior-grade doctor. Moreover, given the growing role of virtual learning in medical education, future work should focus on user perception of the feasibility of remote simulation-based training in LMICs.

Conclusions

Future simulation programs should enhance interpretation and management skills by incorporating customized content, feedback mechanisms, and real-world scenarios for HCPs. The significant differences in clinical performance scores between LMICs and HICs highlight the need for better medical education resources to bridge existing gaps in health care globally. The decrease in some clinical competency scores following career progression could be addressed by simulation-based training to maintain the same quality of history taking and physical examination skills. These outcomes, including no gendered differences in simulation-based learning, hold profound implications for tailoring medical education strategies, fostering equitable training, and elevating patient care standards on a global scale. The need for targeted interventions and capacity-building efforts via context-specific training and tailored approaches to health care education is emphasized.

Acknowledgments

The authors thank all the health care professionals who participated in this study. They thank all the moderators, session chairs, and endorsing organizations for their contribution and continued support. During the preparation of this work the authors used ChatGPT to improve language and readability. After using this tool or service, the authors reviewed and edited the content as needed and take full responsibility for the content of the publication.

Abstract

Background: Training of health care professionals and their participation in continuous medical education are crucial to ensure quality health care. Low-resource countries in Sub-Saharan Africa struggle with health care disparities between urban and rural areas concerning access to educational resources. While e-learning can facilitate a wide distribution of educational content, it depends on learners' engagement and infrastructure.

Objective: This study aims to assess knowledge, attitude, practice, and access to infrastructure related to e-learning among health care professionals in primary health care settings in Ethiopia.

Methods: In April 2023, we carried out a quantitative, questionnaire-based cross-sectional study guided by the knowledge, attitudes, and practice framework, including additional items on available infrastructure. The scores in each category are defined as "high" and "low" based on the median, followed by the application of logistic regression on selected sociodemographic factors. We included health care professionals working in general and primary hospitals, health centers, and health posts.

Results: Of 398 participants (response rate 94.5%), more than half (n=207, 52%) reported feeling confident about their understanding of e-learning and conducting online searches, both for general (n=247, 62.1%) and medical-related content (n=251, 63.1%). Higher levels of education were associated with better knowledge (adjusted odds ratio [AOR] 2.32, 95% CI 1.45-3.68). Regardless of financial and personal efforts, we observed a generally positive attitude. Almost half of the participants (n=172, 43.2%) reported using the internet daily, compared to 16.8% (n=67) of participants who never used the internet. Higher education (AOR 2.56, 95% CI 1.57-4.16) and income levels (AOR 1.31, 95% CI 1.06-1.62) were associated with higher practice scores of e-learning-related activities. Women, however, exhibited lower practice scores (AOR 0.44, 95% CI 0.27-0.71). Regular access to an internet-enabled device was reported by 43.5% (n=173) of the participants. Smartphones were the primarily used device (268/393, 67.3%). Common barriers to internet access were limited internet availability (142/437, 32.5%) and costs (n=190, 43.5%). Higher education (AOR 1.56, 95% CI 0.98, 2.46) and income (AOR 1.50; 95% CI 1.21-1.85) were associated with increased access to infrastructure, while it was decreased for women (AOR 0.48, 95% CI 0.30-0.77).

Conclusions: Although Ethiopian health care professionals report mixed levels of knowledge, they have a positive attitude toward e-learning in medical education. While internet use is common, especially via smartphone, the access to devices and reliable internet is limited. To improve accessibility, investments in the digital infrastructure and individual digital education programs are necessary, especially targeting women and those with lower income. Due to their widespread availability, e-learning programs should be optimized for smartphones.

Introduction

Background

Importance of Continuous Professional Development

Medical education is a fundamental part of a country's health care system [1]. Continuous professional development (CPD) and continuous medical education are used to regularly update and enhance health care professionals' knowledge and skills [2,3]. While CPD programs are seen as beneficial in low-and middle-income countries (LMICs) [4], their availability is often limited due to financial and personnel resources. This shortage of training opportunities for health care professionals affects the quality of medical care and sets patients' health at risk [5].

e-Learning as a Globally Endorsed Strategy

The World Health Organization (WHO) endorses e-learning as a key component of their learning strategy, with the goal of reaching 3 million health care professionals by 2028 through approximately 260 courses. This offer leverages advanced multilingual technology and strategic partnerships to ensure accessible, culturally relevant, and impactful health education worldwide [6]. The WHO has established the "WHO Virtual Campus," which offers tailored training programs, emphasizing the importance of conducting thorough needs assessments involving local health authorities and stakeholders prior to implementing e-learning initiatives [7]. The United Nations Online Learning Framework emphasizes the importance of understanding learners' background, experiences, motivations, and infrastructural conditions before implementing online learning [8].

Advantages of e-Learning

The advantages of e-learning include improving the access to education [9], particularly in geographically or economically isolated areas [10], and being cost-effective, easy to update while improving the user's performance and knowledge [11,12]. In addition, as a CPD strategy, e-learning has proven effective in enhancing both knowledge and procedural skills. Studies indicate that medical, surgical, and pharmaceutical (partly blended) e-learning courses received high levels of satisfaction and were considered useful by participants, even in low-resource settings [13-15]. e-Learning approaches have advanced health care quality and accessibility on a global scale [16].

Barriers in LMICs and Africa

Nevertheless, e-learning approaches are not universally suitable for all learners due to the diverse and individual nature of learning styles [17]. Their implementation often faces challenges in many LMICs with unique aspects in Africa compared to other parts of the world [18]. One of the main hurdles to implementing e-Learning projects on the continent is the low internet coverage of 43.2%, compared to 66% worldwide (2021) [18-20]. In Ethiopia, the internet penetration rate has slightly increased in recent years, reaching 19.4% in 2024 [6]. There is also a strong disparity in access to grid electricity between rural and urban areas. While almost all urban residents (95.7%) have access, only 43.6% of residents in rural areas are covered (2023 [21]). The lack of technical devices further disadvantages rural populations compared to urban residents [22], and as educational strategies shift toward distance learning, individuals in rural areas face even greater challenges in accessing education [23,24]. Further common barriers are costs, a lack of digital skills and knowledge, and computer fear [11,25-28]. The literature notes that Ethiopian educational institutions and students are insufficiently prepared for e-learning and have only used these platforms to a limited extent. This is mainly due to their focus on traditional education systems, which has resulted in a lack of efficient e-learning approaches. As a consequence, the development and adoption of modern digital learning methods remain restricted [21,22]. A systematic review (published in 2023) of challenges associated with e-learning in Sub-Saharan Africa noted that existing problems remained similar since 2016 without notable structural improvements [29].

Implementation Efforts in Africa

Several studies report on piloting and partly adopting e-learning in medical education. In Uganda, despite relevant efforts, nationwide implementation remains limited, with progress largely dependent on the commitment of individual institutions and educators, leading to uneven advancement across the country [30]. Many e-learning pilot projects are insufficiently adapted to local environments in LMICs [1], for example, addressing unreliable access and limited technological infrastructure [31]. This includes the usage of appropriate digital platforms and providing user support for a successful learning experience. Despite this, recruiting skilled personnel capable of managing and using e-learning effectively requires additional financial investment [9]. A baseline and needs assessment of the target group and area, as well as pretests, can identify strengths and limitations of e-learning tools and enable their adjustment to specific settings. Since e-learning is anticipated to be used increasingly in medical education worldwide, efforts are needed to be worthwhile to understand the target groups [32].

Rationale

The knowledge, attitudes, and practices (KAP) framework is a widely used approach to assess target groups in the context of public health [33]. It can be used to identify educational gaps and inform the design of targeted interventions, such as e-learning strategies. KAP studies provide a valuable foundation for tailoring digital learning tools to the specific needs, perceptions, and practices of diverse user groups. In our literature review, we did not find publications from LMICs or Sub-Saharan Africa specifically concerning the perspective of health care professionals regarding e-learning, highlighting the

need to address this gap [34]. The existing literature mainly focuses on students enrolled in universities and colleges during the COVID-19 pandemic [28,35,36], as well as individuals among the general population [37].

Objective

Our study aims to assess knowledge, attitude, practice, and access to infrastructure (KAP-Infrastructure) related to e-learning courses among health care professionals working at the primary health care level in Central and Southern Ethiopia. Our study provides an opportunity to offer insights and address the existing gaps and missing information in this area and setting.

Methods

Overview

We conducted a data collector–supported self-administered cross-sectional survey among health care professionals working as general practitioners, health officers, nurses, midwives, or health extension workers in 45 health facilities between April 3 and 28, 2023. The study was set in the Oromia region and the former Southern Nations, Nationalities, and Peoples Region (SNNPR), which was reorganized in August 2023 after the data collection. The study regions are now part of the South Ethiopia Regional State and the Central Ethiopia Regional State. More than 85% of residents in Oromia and 89% of residents in the former SNNPR live in rural areas [38,39]. The selection of the health care facilities (2 general hospitals, 3 primary hospitals, 14 health centers, and 26 health posts) was based on partner settings in a collaborative cervical and breast cancer care project between the Addis Ababa University School of Public Health, Ethiopia and the Martin Luther University Halle-Wittenberg, Germany. Ethiopia has a 3-tier health care system with specific responsibilities on each level to enable continuous care in the country (Multimedia Appendix 1). At the primary health care level, health posts, health centers, and primary hospitals deliver essential health care services, particularly in rural areas [23], where 77.4% of the Ethiopian population is resided. General and referral hospitals, as part of the secondary health care level, provide a wider range of medical services and treatments. Specialized hospitals form the tertiary level and provide extensive services for comprehensive health care [40]. We included 2 general hospitals as part of the secondary health care level to perform a sensitivity analysis comparison between health care levels (see Multimedia Appendix 1). Our study area is located approximately 150 km to the south and southwest of the capital, Addis Ababa, in a radius of about 100 km.

Outcome Variables

We investigated the 4 KAP-Infrastructure constructs, building items based on the following definitions (1) “Knowledge” assessed the health care professionals’ self-perceived practical abilities related to e-learning tasks. (2) “Attitude” represented participants’ motivation and expectations toward e-learning to support their professional education. (3) “Practice” concerned the conduct of activities related to e-learning. Finally, (4) “Access to infrastructure” covered individual and work-related infrastructural conditions of the health care professionals.

Questionnaire

The questionnaire contained questions on sociodemographic characteristics as well as the participants’ perspectives on e-learning based on the KAP model [33]. The KAP items had 5-step Likert scale answering options [41].

Besides using the United Nations Online Learning Framework as an orientation, we covered relevant aspects of e-learning by using items described in a systematic review outlining enablers and barriers affecting e-learning in health sciences [11]. We added a category “access to infrastructure” (KAP-Infrastructure) as a relevant aspect for e-learning conduct. We based this section on the European Union’s “Community survey on ICT usage in households and by individuals (2020)” [42], with additional items adapted from a community survey on information and communication technology [35,37] and a KAP study on online learning by college students in India [35].

The questionnaire contained 10 sociodemographic, 10 knowledge, 13 attitude, 8 practice, and 7 infrastructure items. It was initially developed in English and then translated into the Amharic and Afan Oromo languages. A blind back-translation into English ensured accuracy. Discrepancies were addressed and discussed. The main translation process involved 5 native speakers of Amharic and Afan Oromo, all of whom were proficient in English and had a medical background.

Due to the lack of a topically fitting validated research instrument, the questionnaire was developed by an interprofessional team of health scientists from Martin Luther University Halle-Wittenberg and Addis Ababa University based on comprehensive initial literature research. We performed pretests according to the Concurrent Think Aloud Method and adapted the questionnaire accordingly, ensuring its comprehensibility, suitability, and validity. Two rounds of pretests were conducted in Addis Ababa in March 2023, including 38 health care professionals in 2 health centers. These participants represented approximately 9% of the overall sample, closely meeting the targeted 5% per health care center. The items were tested for understandability and clarity in the Amharic and Afan Oromo languages. The received feedback was then reviewed and discussed by interdisciplinary teams in both Germany and Ethiopia, resulting in the exclusion or rephrasing of certain questions and answer choices, as well as modifications to the consent section. The process was guided by “Surveys and Questionnaires in Health Research” by Schofield and colleagues [43,44].

Sample Size and Sampling Technique

Before collecting the data, the sample size was calculated using the single population proportion formula. The level of KAP of health care professionals on e-learning in Ethiopia has not been studied yet. Therefore, the sample size was calculated with the some assumptions, including 50% proportion of the outcome among health care professionals, 5% marginal error, and 95% CI. Under these circumstances, the sample size is 384, and after adding a 10 % nonresponse rate, the final sample size was 423. For comparison, we also calculated the sample size to estimate a 2-sided CI for one proportion for the target variable “internet access” as a representation for the objective “infrastructure.”

With this frame we calculated a sample size of 395, including a 10% nonresponse rate. Since the calculated sample size of infrastructure was smaller than the sample size of KAP, we decided to achieve a larger sample size of 423. We selected participating health care professionals working in the affiliated health facilities using the convenience sample method and reached a final sample size of 398 participants (response rate 94.1%). All health care professionals, including general practitioners, health officers, nurses, midwives, and health extension workers present during data collection, were included in the study. However, those who were unavailable at that time and any professionals not listed above were excluded from the study. Ensuring a balanced participation between all occupations, we considered a proportional allocation for each health facility.

Data Analysis

First, we conducted basic descriptive statistics. After building sum scores for each KAP-Infrastructure category, the median was used to define "low" and "high" scores in each category, which were considered as binary response variables in downstream analyses (Multimedia Appendix 2). In order to detect potential monotonic relationships (collinearity) among predictor variables, we used Spearman rank correlation coefficient (ρ) [45] (refer Multimedia Appendix 3). This preliminary diagnostic analysis yielded a high correlation between the variables "health facility" and "occupation" (ρ=0.982). As a ρ above 0.9 is generally considered very high, we proceeded to remove the variable "occupation" from all multivariate logistic regressions in order to avoid redundancy and ensure convergence of statistical modeling. The remaining 7 explanatory variables were kept in all multivariate logistic regressions. We divided the participants into 5 similar-sized income groups (monthly income less than US $94, US $94 - US $115, US $115 - US $130, US $130 - US $151.2, and more than US $151.2 USD), according to the World Bank's country income classifications [46]. We applied a more precise breakdown that is often used in household or individual-level analyses by adding middle income. The income thresholds were established to produce comparable income ranges across different income-level groups. We defined regular usage of the internet and internet access as an available internet service in terms of messaging, browsing, downloading, and purchasing in the last 3 months for at least once a week [47-49]. Data imputation was carried out based on Spearman correlation indices among the variables. It was done for 0.7% of data points in the "religion" and "sex" variables and for 3.8% of data points in the "income" variable. The correlation indices among the components of the dependent variable (KAP-Infrastructure scores) were used to allow imputation as well, which led to 1.1% of data points in the dependent variables being imputed. We then investigated the relationship between KAP-Infrastructure score and multiple explanatory factors (age, sex, education level, income, and type of health facility) by calculating odds ratios (ORs) and adjusted ORs (AORs) and the corresponding 95% CI with a logistic regression, using SPSS version 28 (IBM Corp) [50]. An OR greater than 1 indicates that the factor is associated with higher KAP-Infrastructure scores. We tested each category for internal consistency by calculating Cronbach α (knowledge 0.897; attitude: 0.688; practice: 0.899; access to infrastructure: 0.810) [51]. The results indicated acceptable or high internal consistency. Furthermore, we assessed the fit of a logistic regression model using the Hosmer-Lemeshow test [52].

Ethical Considerations

We received approval from the Addis Ababa University Research Ethics Committee in Addis Ababa, Ethiopia (Prev: 423), and the ethics committee of the Martin Luther University Halle-Wittenberg-Medical Faculty (processing number 2023 - 003). Participant information was collected anonymously, and written consent was obtained in the questionnaire. Participants did not receive any compensation.

Results

Overview

We included a total of 398 participants (response rate, 94.1%). Overall, 25 health care professionals declined due to workload, unwillingness, or undisclosed reasons. Male (195/394, 49.5%) and female (199/394, 50.5%) participants were equally represented. The mean age was 31.0 (SD 7.0) years. Half of the health care professionals were nurses (200/398, 50.3%). In total, 86.7% (345/398) of the participants chose the Amharic version of the questionnaire. The mean income per month was US $138 (SD $57). Among the participants, 4 out of 5 worked in primary facilities (316/398, 79.4%; Table 1).

Table . Sociodemographic information.

Characteristic and category	Value
Region (N=398), n (%)	
SNNPR[a]	252 (63.3)

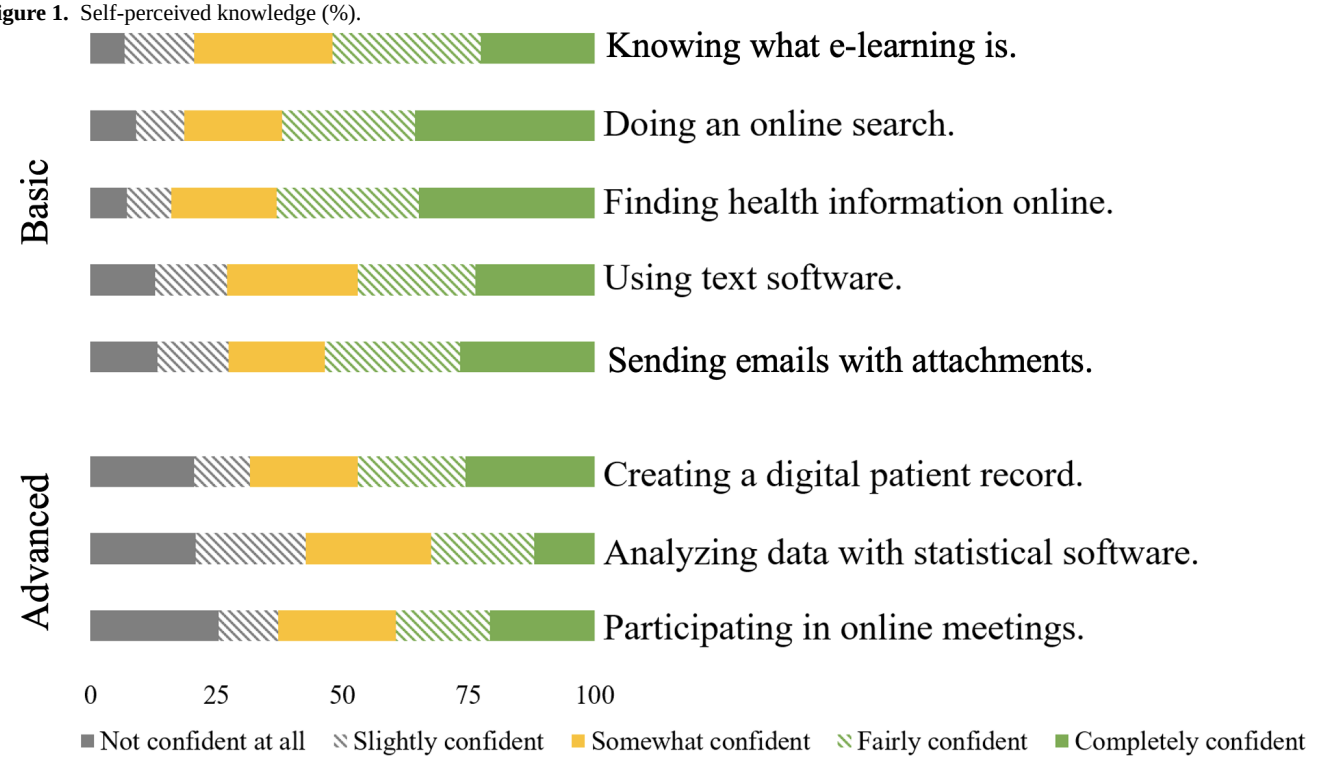
Knowledge

About half of the health care professionals were completely (90/398, 22.6%) or fairly confident (117/398, 29.4%) in knowing what e-learning is. Almost two thirds of them described a self-perceived competence in doing general (247/398, 62.1%) and medical-related (251/398, 63.1%) online searches. Over one-third were not or slightly confident in their ability to participate in online meetings (157/398, 37.2%; Figure 1).

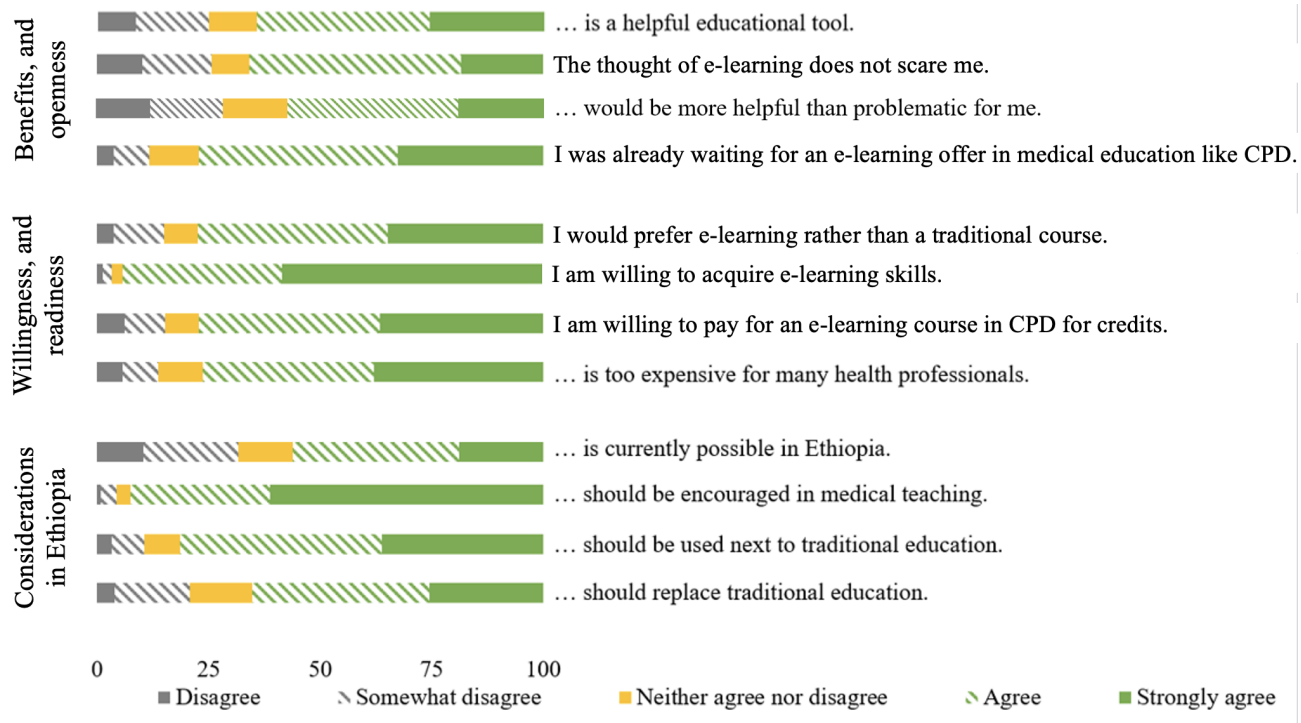
Figure 1. Self-perceived knowledge (%).



Attitude

Health care professionals predominantly had a positive attitude toward e-learning, with 94.2% (375/398) willing to put effort into acquiring e-learning skills. More than half (224/398, 56.2%) believed that e-learning is possible in rural parts of Ethiopia. Almost all health care professionals were in favor of integrating e-learning in medical teaching institutions (368/398, 92.5%). Some participants expressed fear (102/398, 25.7%) or perceived e-learning as more problematic than helpful (113/398; 28.4%; Figure 2).

Figure 2. Health care professionals' attitude toward e-learning (%). CPD: continuous professional development.

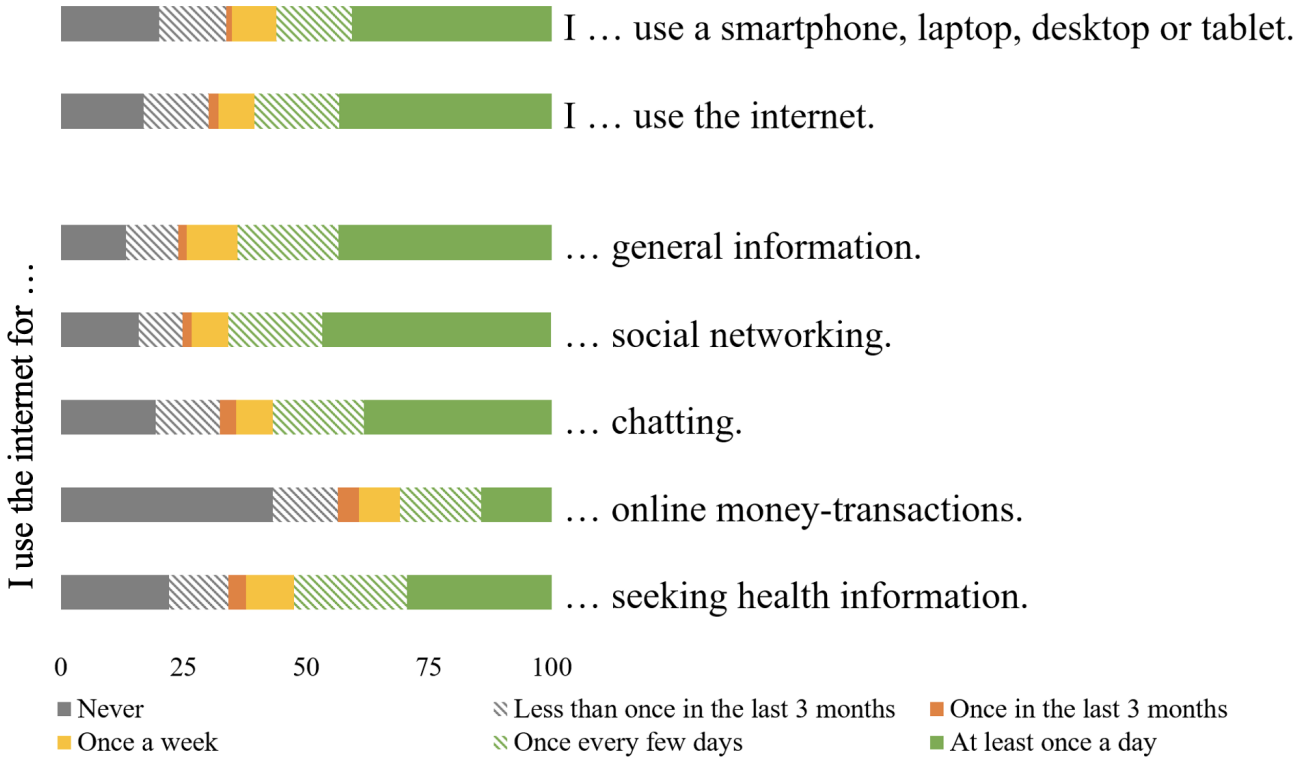


Practice

Daily internet usage was reported by 172/398 (43.2%) participants and 67/398 (16.8%) participants never used it. More than half used the internet for general (255/398, 64.1%) and medical-related searches (209/398, 52.5%), social networking (262/398, 65.8%), and chatting (226/398, 56.8%). In total, 2 out of 3 health care professionals stated a regular usage (at least

once a week) of an internet device (259/398, 65.1%) and pointed out smartphones as the most used device (268/393, 67.3%; Multimedia Appendix 4 and Figure 3).

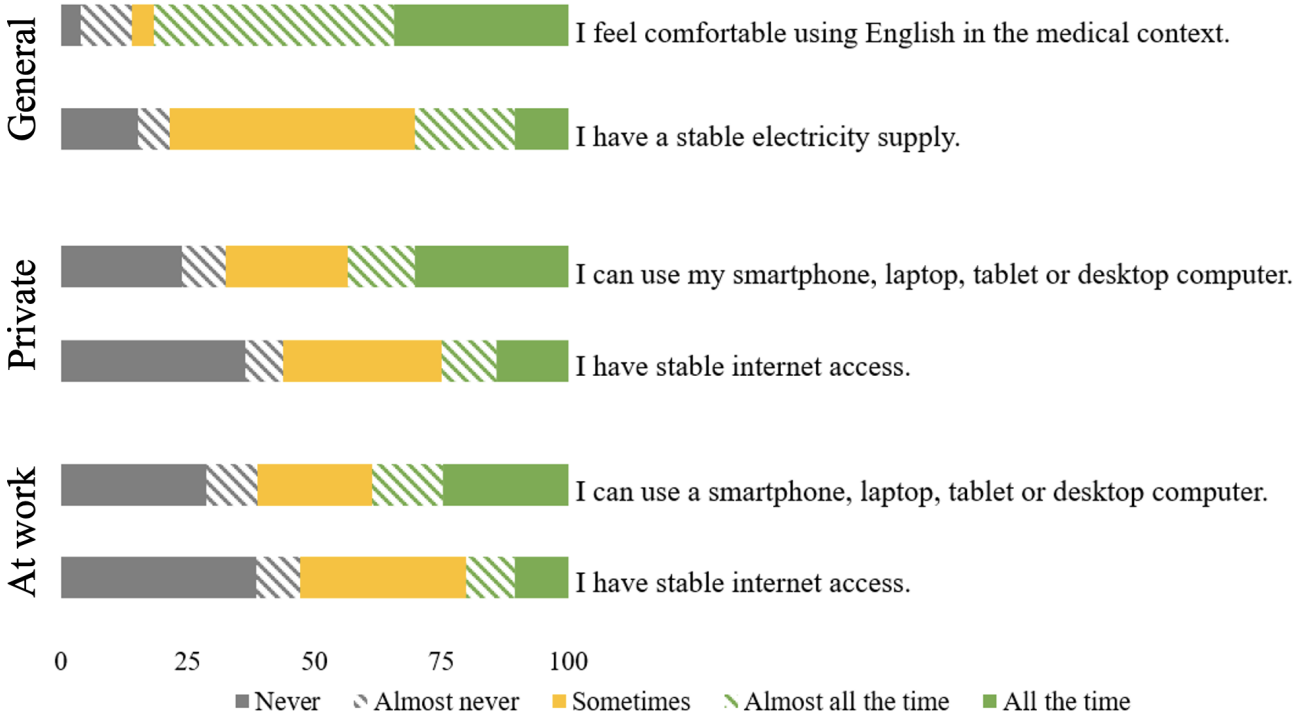
Figure 3. Practice of e-learning (%).



Access to Infrastructure

Access to digital devices (154/398, 38.7%) and stable internet (80/398, 20.1%) at the participants' workplace was less common than at home (access to private devices [173/398, 43.5%] and stable internet [99/398, 24.9%]). Common barriers included problems with internet availability (142/437, 32.5%) and internet costs (190/437; 43.5%; Multimedia Appendix 5 and Figure 4).

Figure 4. Health care professionals' access to infrastructure (in %).



Factors Associated With Knowledge, Attitude, Practice, and Infrastructure

Higher levels of education were associated with increased knowledge (AOR 2.31, 95% CI 1.45-3.68), whereas higher age was associated with lower knowledge (AOR 0.94, 95% CI 0.91-0.97). Health care professionals with a higher education level (AOR 2.56, 95% CI 1.57-4.16) and income group (AOR 1.31, 95% CI 1.06-1.62) were more likely to have higher practice scores. Female (AOR 0.44, 95% CI 0.6-0.71) and older participants (AOR 0.91, 95 % CI 0.87-0.95) were likely to report lower practice scores. Participants from higher income groups (AOR 1.50, 95% CI 1.21-1.85) had increased odds of having higher access to infrastructure. For detailed information see Table 2 and Multimedia Appendices 6 and 7.

Table . Factors associated with knowledge, attitude, practice–infrastructure.

Variable	Self-perceived knowledge, AOR[a] (95% CI)	Attitude, AOR (95% CI)	Practice, AOR (95% CI)	Access to infrastructure, AOR (95% CI)
Age (years)	0.94 (0.90-0.97)	1.01 (0.98-1.04)	0.91 (0.87-0.95)	0.94 (0.91-0.98)
Female sex[b]	0.69 (0.43-1.11)	1.01 (0.65-1.56)	0.44 (0.67-0.71)	0.48 (0.30-0.77)
Higher education level[c]	2.31 (1.45-3.68)	1.19 (0.78-1.82)	2.56 (1.57-4.16)	1.56 (0.98-2.46)
Higher income group	1.16 (0.95-1.41)	1.06 (0.88-1.28)	1.31 (1.06-1.62)	1.50 (1.21-1.85)
Health facility[d]				
Health post	2.00 (0.86-4.66)	1.48 (0.65-3.38)	0.70 (0.25-2.00)	0.31 (0.11-0.90)
Primary hospital	0.66 (0.39-1.09)	1.12 (0.69-1.78)	0.61 (0.36-1.04)	0.55 (0.33-0.91)
General hospital	1.97 (1.08-3.60)	0.60 (0.34-1.03)	1.01 (0.54-1.86)	1.08 (0.59-1.98)

Discussion

Principal Findings

The majority of the participants knew about e-learning and viewed themselves as competent in different e-learning-related activities. Still, we found difficulties in relevant knowledge aspects like participating in online meetings or searching for medical information. Moreover, a high proportion of workers had a positive attitude toward the use of e-learning. Almost half of the participants stated using the internet daily, whereas 16.8% (67/398) never use the internet. Infrastructure, such as technical devices and stable internet, was more often available at home than at work. The availability of stable internet was reported at below 25% (at home: 24.9% and at work: 20.1%).

Health care professionals with higher levels of education and income and those working in general hospitals had better KAP of e-learning and better access to infrastructure. Older health care professionals, women, and those working in health posts and primary hospitals reported reduced access to infrastructure.

Strengths and Limitations

First, the included health facilities show differences in terms of health service quality, with some having been rewarded international awards and not necessarily representing the typical peripheral hospital in Ethiopia. However, this diversity is part of the primary health care setting and should be represented in the study.

Second, during the data collection, we observed that some participants were confused about the definition of a smartphone, occasionally mistaking it for a tablet. These cases were clarified by the data collectors. Despite verification and testing of the translated questionnaire, we cannot completely rule out cases of misinterpretation. However, it is not expected to significantly affect the results.

Third, the health care facilities are exclusively located in Oromia and the former SNNPR region. Therefore, the results may not be generalizable for Ethiopia. While future research should investigate regional differences, it is reasonable to assume that our data from the context of primary health care settings are relevant and transferable to other parts of the country to a certain extent. Given the absence of studies in comparable settings, our data offer valuable insights for the development and implementation of effective e-learning courses.

Comparison With Prior Work

Participants report mixed levels of confidence regarding knowledge or e-learning–related tasks. More than 3 quarters of the health care professionals are at least somewhat confident in understanding the concept of e-learning (316/398, 79.4%), in performing basic digital tasks, such as general online searches (324/398, 81.4%), in finding professional health information on the internet (334/398, 83.9%), or in using writing programs, such as Microsoft Word (290/398, 72.9%). We did not find literature specifically targeting the knowledge of e-learning of health care professionals in LMICs, but the Ethiopian health care professionals were less confident in basic tasks, such as sending email attachments (53.5%) and conducting online searches (62.1%) compared to medical undergraduate students in India. Both studies identified creating patient records as

particularly challenging [36]. College students in India and Pakistan reported experiencing technical difficulties due to a lack of knowledge on e-learning. Nevertheless, they had an overall acceptable level of knowledge regarding media content and communication [28,35,53]. Possible reasons could include the higher internet penetration rate in India (52.4%) compared to Ethiopia (26.7%; 2024) [54,55]. This could be one of the reasons consequently leading to this difference.

Moreover, the lack of digital knowledge remains a significant challenge, further widening the digital divide between rural and urban areas [56,57]. Addressing these barriers is essential. Therefore, offering basic digital training programs can play a crucial role in bridging this gap [56]. Older health care professionals, those with lower education, and participants working outside general hospitals should be supported when implementing e-learning programs. A study from Kenya offers a further perspective on e-learning knowledge. Medical trainees faced difficulties in completing the courses due to limited technical skills and a lack of engagement from trainers and institutions responsible for developing the content. In addition to the extensive volume of e-learning materials and frequent online meetings, the courses contributed to feelings of being overwhelmed among the students. Approximately half of the students included in the study did not finish the course. Consideration should be given not only to the participants' knowledge but also to the content creators' [58].

Despite these mixed results, the overall attitude among Ethiopian health care professionals remains positive, and many even consider making financial and personal investments to support its implementation. In contrast, students from Uganda and Turkey showed an overall negative attitude toward e-learning. Participants' income, internet quality, ownership of technical devices, and previous use of academic sites were associated with attitude scores [59,60]. In Pakistan, similar issues did show, including technical and infrastructural challenges, limited technical skills, and the general disadvantages of e-learning, such as decreased connection and interaction with other participants, led to widespread dissatisfaction among the surveyed students. Consequently, 50% of them frequently missed e-learning classes. Nearly 80% considered e-learning less effective than traditional classroom instruction, particularly when it comes to acquiring practical skills [61]. Health care professionals in urban Taiwanese settings had a less positive attitude compared to those in rural settings but still valued the increase in knowledge, time saving, and diverse, and wide offer of information [62]. Medical students in Sudan favored a combination of electronic and traditional teaching methods [63]. Similarly, most of our participants (81.4%) are in favor of e-learning as an addition to traditional courses, even expressing a preference of e-learning over traditional workshops and lectures (77.4%). Overall, our results indicate that Ethiopian health care professionals are motivated to use e-learning for their professional development.

These positive attitudes can support the success of educative efforts [64], including e-learning [65]. e-Learning requires a higher level of self-motivation compared to other educational concepts [66], especially for participants with limited experience [67]. Incorporating feedback and evaluation is crucial in addressing these issues [11]. In addition, the rapidly evolving technical standards necessitate a positive attitude to continuously improve one's skills [68]. However, since a relevant share of health care professionals expressed fear, preparatory courses are advisable [1].

Regarding the practice of e-learning-related activities, almost half of the health care professionals (172/398, 43.2%) reported using the internet daily, which is less frequent than nursing students (68.1%) and comparable to patients from Gondar, Ethiopia (47%) [69,70]. Similar to our findings, being young, male, more educated, and with an urban residence is associated with increased internet use [70]. In rural communities in Sub-Saharan Africa, the internet is primarily used for browsing (13.9%) and email communication (13.2%), followed by information search (12.5%), chatting (10%), social networking (9.6%), and video conferencing (5.8%) [71]. Undergraduate students from Ethiopia with a rural background predominantly used the internet for social media [69]. Similarly, our participants most commonly used the internet for social networking and chatting, but also for general and medical searches. While a majority of primary health care professionals reported frequent internet use and engagement in e-learning–related digital activities, there is a relevant share of health care professionals (39.5%) who reported less frequent internet use, hinting at potential difficulties in handling online learning formats. To address this, targeted support for lower-income groups, women, and less-educated health care professionals is recommended.

Notably, smartphones emerged as the most commonly used device for accessing infrastructure, which aligns with findings from other Ethiopian settings [70]. Mobile phone ownership and usage has increased in countries of the global south, including rural communities in Sub-Saharan Africa, although access is not ubiquitous [70,72]. Mobile phones were among the least commonly used devices for use in our study, ranking lower than smartphones, tablets, laptops, and other devices. Smartphones are becoming increasingly important and prevalent as part of mobile health (mHealth) initiatives [73]. The WHO [25], along with other authors [19,26,74] recommends smartphones as a possible platform for e-learning to reach remote parts of countries with low resources. Health extension workers and midwives working in primary health care facilities in Ethiopia perceived the use of mobile devices in an mHealth program as easy and beneficial. The program was implemented for both the health care providers themselves as well as for the patients [75]. The Ethiopian Ministry of Health also introduced a community-based health extension program, which incorporates mHealth [76]. Nevertheless, rural communities in Sub-Saharan Africa used the mobile phone majorly for receiving (89.8%) and making calls (88.5%) and the least for internet browsing (27.3%) [71]. A study conducted in 4 primary hospitals in Ethiopia in 2018 revealed that 12.1% of health care professionals had internet access and 25.6% had access to a computer at work. Private computers were more often accessible at 33.3% [53]. Our study similarly showed higher accessibility to private internet and technical devices compared to work. Lacking bandwidth and stable internet access are common limitations, resulting in slow speed and low quality of e-learning

programs that may create difficulties for users to load digital content [9]. Power issues, shortage of skilled personnel for support, the cost of internet and necessary devices, and problems of viruses and malware can additionally hinder access to online education [77]. In addition, South Africa reports socioeconomic challenges that widen the digital divide and are thereby hindering the implementation of e-learning across various settings of the country [78]. For these reasons studies suggest e-learning courses with downloadable offline versions may help to establish accessible e-learning programs [79]. This increased accessibility and attempt to include students from different socioeconomic backgrounds, and in turn, positively influenced students' acceptance of e-learning in Amhara, Ethiopia, by enhancing their perceived ease of use [80].

Regarding possible gender differences, female health carecprofessionals had lower scores in knowledge, practice, and access to infrastructure while displaying a similar attitude. This is consistent with reports on the digital divide, both globally and in Ethiopia, which can in part be attributed to gender inequality [81]. For example, in Ethiopia, 14% of females used the internet, compared to 20% of males [82], and women faced lower computer literacy and access to infrastructure [19]. To reduce these disparities, supporting women, including the development of knowledge and skills, as well as addressing aspects of the costs of communication technology is necessary [83,84].

Conclusion

Health care professionals report mixed levels of knowledge in e-learning-related task while generally having a positive attitude toward e-learning in medical education. More than half use the internet regularly, especially via smartphones, while the access to digital infrastructure and reliable internet remains limited. Efforts should be made to improve access to internet access and technological infrastructure, as well as the adaptation of e-learning courses to the local needs. This could include the provision of introductory trainings, particularly for women and health care professionals with lower income and educationl; provision of downloadable offline learning options; and the adaptability of the course to smartphone use.

Abstract

Background: Nursing students' motivation in clinical learning is very important not only for their academic and professional achievement but also for making timely, informed, and appropriate decisions in providing quality and cost-effective care to people. However, the increased number of students and the scarcity of medical supplies, equipment, and patients, just to mention a few, have posed a challenge to educators in identifying and navigating the best approaches to motivate nursing students to learn during their clinical placements.

Objective: This study primarily used descriptive and analytical methods to examine undergraduate nursing students' desire for clinical learning both before and after participating in the program.

Methods: An uncontrolled longitudinal quasi-experimental study in a quantitative research approach was conducted from February to March 2021 among 589 undergraduate nursing students in Tanzania. Following a baseline evaluation, nursing students were enrolled in an interactive web-based clinical practice monitoring system by their program, institution, names, registration numbers, and emails via unique codes created by the lead investigator and trainers. The system recorded and generated feedback on attendance, clinical placement unit, selected or performed clinical nursing procedures, and in-between and end-of-shift feedback. The linear regression was used to assess the effect of the intervention (interactive web-based clinical practice monitoring system) controlled for other correlated factors on motivation in clinical learning (outcome) among nursing students. Nursing students' sociodemographic characteristics and levels of motivation in clinical learning were analyzed descriptively while a 2-tailed paired sample *t* test established a comparative mean difference in motivation in clinical learning between the pretest and the posttest. The association between variables was determined using regression analysis set at a 95% CI and 5% statistical significance.

Results: The mean age of study participants (N=589) was 23 (SD 2.69) years of which 383 (65.0%) were male. The estimated effect (β) of a 3-week intervention to improve nursing students' motivation in clinical learning was 3.041 (*P*=.03, 95% CI 1.022-7.732) when controlled for other co-related factors. The mean score for motivation in clinical learning increased significantly from the baseline (mean 9.31, SD 2.315) to the postintervention (mean 20.87, SD 5.504), and this improvement presented a large effect size of 2.743 (*P*<.001, 95% CI 1.011-4.107).

Conclusions: Findings suggest that an interactive web-based clinical practice monitoring system is viable and has the potential to improve undergraduate nursing students' motivation for clinical learning. One alternative clinical pedagogy that educators in

nursing education can use to facilitate clinical learning activities and develop motivated undergraduate nursing students is the integration of such technology throughout nursing curricula.

Introduction

Owing to changes in population, technology, and communicable and noncommunicable diseases, the uncertain nature of health care provision necessitates improvements in health care systems and the teaching and learning environment across health disciplines, including nursing [1]. Clinical nursing education, in particular, has become a fundamental aspect of the nursing profession that informs educators about the best and most innovative pedagogical strategies that are navigated into technology to increase nursing students' motivation in clinical learning and thus ensure consistent clinical attendance and passionate clinical learning around the world [2]. In clinical learning, motivation refers to an individual's inner drive toward an activity or behavior that defines his or her achievements, in this case, the attainment of skills and competence required in the nursing profession among nursing students [3]. Scholars have shown that motivated students can demonstrate metacognition, metacompetencies, and a sense of independence when providing high-quality, cost-effective health care to a diverse population [4-6].

Educators in nursing education are important individuals in both classroom and clinical teaching and learning activities to enhance nursing students' motivation in clinical learning during clinical placements for meta-competencies in diagnosing and making informed and appropriate decisions in providing quality and cost-effective care to people. Educators in nursing education are expected to be developed and empowered with pedagogical competencies to cope with advanced science and technology, increased rates of nursing student enrollments in middle and higher education institutions, scarcity of medical supplies and equipment, unimproved clinical teaching and learning environments, and availability of clients or patients as important individuals in clinical nursing education [7,8]. Empowering educators with knowledge and skills for facilitating clinical teaching and learning activities for nursing students may be intimately related to their pedagogical competencies in creating, supporting, mentoring, coaching, supervising, monitoring, and assessing nursing students [9,10].

Nursing students, developed by competent educators in nursing education, are believed to share their learning experiences with both educators and peers. They show motivation in their clinical learning activities and client or patient care provision as they demonstrate a sense of independence, a positive professional identity, and the attitude, skills, and values of lifelong learners and professionals [11]. Motivating nursing students to learn has risen to be prominent in clinical nursing education because it is regarded as a critical component in promoting consistent clinical attendance and learning [12]. Investing in the motivation of nursing students also ensures the development of competent nursing graduates who can demonstrate safe, ethical, and legal practices, which are foundational and essential aspects of clinical nursing education [6,13]. Contrary to what is expected of educators in nursing education in the twenty-first century, their current clinical nursing education practices are more traditional, with pedagogics such as bedside tutorials, lectures, demonstrations, discussions, case studies, portfolios, and nursing meetings, to name a few, being widely used [11,14,15]. However, due to the increased enrollment rate of nursing students with the unchanging pedagogical trend, a shortage of academic faculty, and a limited number of trained clinical instructors, the aforementioned clinical pedagogics are doubted to be able to enhance interactive communication between educators in nursing education and students.

Nevertheless, they are doubted on their abilities to establish teaching and learning feedback or experiences from students and nursing students' motivation in clinical learning [16]. Moreover, they demonstrate weaknesses in not developing them with clinical meta-competencies for providing quality and cost-effective care to people [17]. Scholars have linked the permanent implementation of conventional clinical nursing education pedagogics to a lack of interactive communication, teaching and learning feedback from students, and clinical absenteeism as remarkable signs of unmotivated nursing students worldwide [18]. The work by Rahman et al [12] has demonstrated that clinical absenteeism has been linked to an unsatisfactory clinical learning environment as well as a shortage of competent educators in nursing education. Nevertheless, the implementation of conventional clinical supervision, mentorships, support, monitoring, and evaluation measures such as registration books and follow-up books fail to manage a large group of nursing students in clinical settings [19]. Nursing students' avoidance and lack of enthusiasm in attending their daily practical activities during their clinical placements result in substandard care delivered to clients or patients alongside unethical professional conduct and poor customer care [20].

This work is based on the belief that understanding and implementing novel clinical pedagogical strategies will assist educators in nursing education in grasping and navigating the best ways to inspire unmotivated students to learn in a clinical context over conventional pedagogies. Adoption and integration of technology have been prioritized and have proven to be timely, quick, cost-efficient, long-term, and beneficial in enhancing students' motivation in their learning activities [21,22]. Authors of this work agree with other scholars that it appears to be timely for clinical nursing education to transform its pedagogics to technology-based ones to fill educational gaps demonstrated by conventional pedagogics for enhancing nursing

students' motivation in clinical learning, particularly in low- and middle-income countries such as Tanzania [23]. As it has worked elsewhere, web-based learning is currently becoming an increasingly vital instructional tool in nursing education, as it offers the potential to promote motivation to learn among students [24].

Scholars including Mico et al [25] have highlighted that the web-based learning approach, which has been endorsed as an essential educational tool, responds effectively and efficiently to nurses' needs and experiences in their clinical practices. Web-based technology in education is linked with a networking interactive model to promote communication with a feedback mechanism to enhance active learning between the users [26]. However, little about the integration of technology in clinical nursing education has been documented in Tanzania to mentor, supervise, support, monitor, and evaluate nursing students during their clinical placement [27]. If the situation remains unattended, nursing students will continue to be developed conventionally and continue to be unmotivated in their clinical learning, gaining little clinical competencies to work independently and confidently to deliver ethical, quality, and cost-effective care to people.

Therefore, this study intended to fill the gap by primarily using descriptive and analytical methods to examine undergraduate nursing students' desire for clinical learning both before and after participating in the program.

Methods

This study was conducted by taking into consideration international and national research standards and ethics. Moreover, it was informed by the institutional postgraduate guidelines and regulations of The University of Dodoma [28].

Study Location

The study was conducted in Dodoma Regional Referral Teaching Hospital in Tanzania, which accommodates a large number of nursing students from different nursing training institutions within Dodoma region. Some previous scholars [11,29,30] suggest that proximity to the research environment where the intervention is being piloted or implemented aids in receiving rapid input from the consulted experts, trainers, and participants, and ensuring periodic monitoring of its integrity. Aside from the availability of nursing students, the location was chosen because of the availability and accessibility of the consulted experts and trainers for their evaluation and appraisal of the web-based clinical monitoring system throughout the design and piloting procedures.

Study Design and Approach

As it has also been used by some previous scholarly works [31], this study used an uncontrolled longitudinal quasi-experimental design (pre-post tests) with a quantitative research approach among 589 randomly selected undergraduate nursing students in Tanzania from February 2021 to March 2021. The study began with a screening method to choose individuals who satisfied the inclusion criteria and were willing to engage in the study, followed by a baseline assessment to determine their initial level of motivation in clinical learning. Following the intervention, the same participants were exposed to the system for 3 weeks, with 1 week set apart for the end line evaluation (posttest) after the intervention as a follow-up assessment.

Study Population

To maximize the diversities of an intervention's effects, the study recruited undergraduate nursing students in diploma and bachelor's degree programs from 2 middle and 2 higher training institutions in the Dodoma region of Tanzania's central region.

Sample Size Determination

The minimum sample size of this study was determined based on the findings from previous studies [5]. Their findings revealed a baseline mean score of knowledge about how to plan learning activities of 53.10, whereas the end line mean score was 54.21. The following formula was used to determine the minimum sample size as suggested by previous studies [29,31] to be used when researchers wish to conduct an uncontrolled quasi-experimental study design:

where n=minimum sample size

$Z\alpha$: Tabulated Z value set at 95% (1.96) CI

$Z\beta$: Tabulated Z value set at 80% (0.84) power to demonstrate a statistical difference between pretest and posttest.

σ: Polled SD = 7.511399669835177

SD_1: SD 1 (from previous studies = 10.21)

SD_2: SD 2 (from previous = 11.02)

δ: Mean difference $(M_2 - M_1)^2 = 0.11$

M_1: Mean 1 (from previous studies = 53.10)

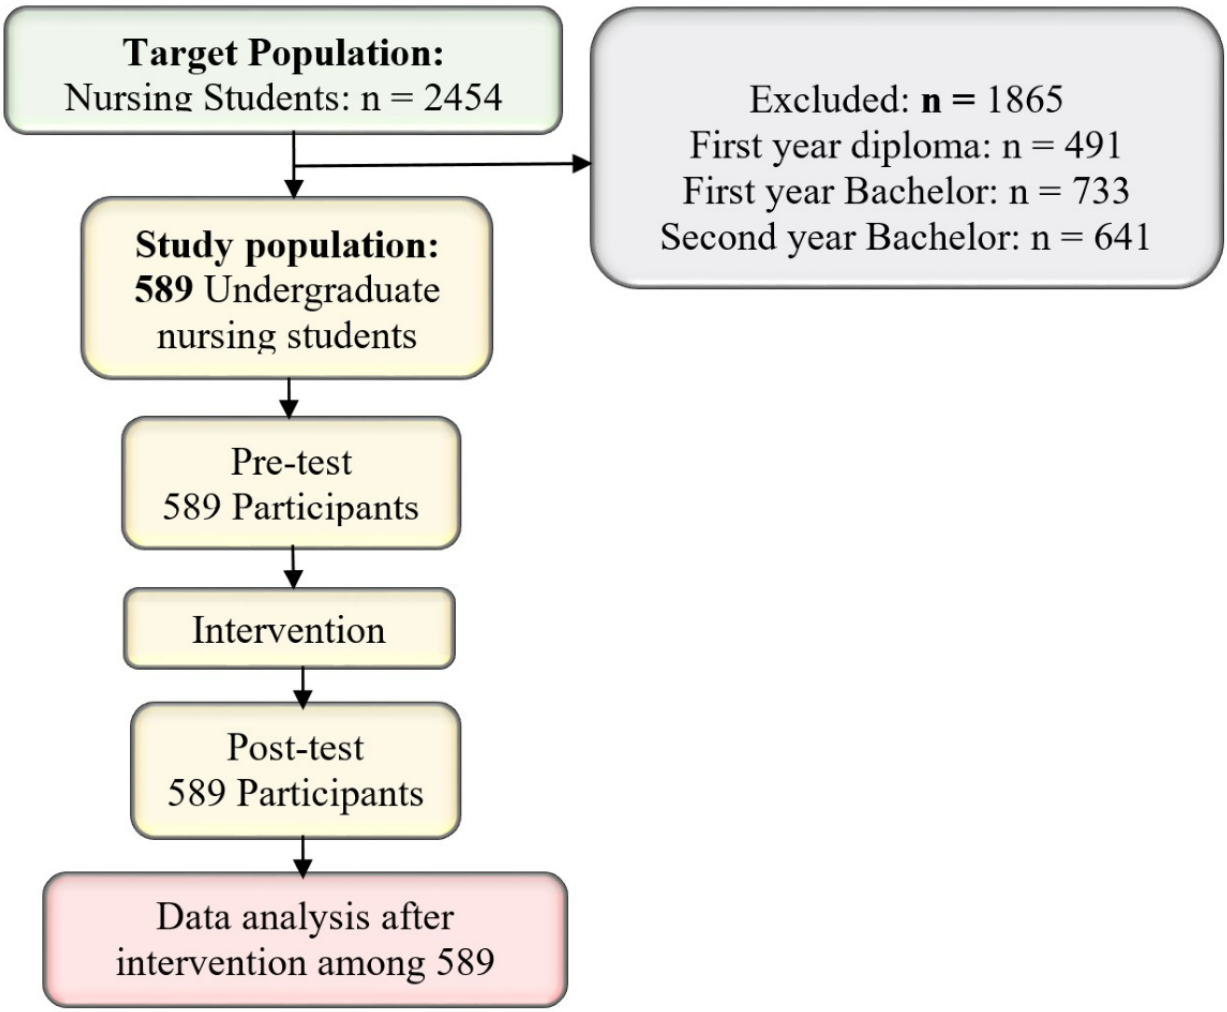
M_2: Mean 2 (from previous studies = 53.21)

With the addition of a 10% attrition adjustment of the calculated sample size (n=54) = (535+54) = 589. Therefore, the minimum sample size of this study was 589 nursing students.

Recruitment Procedures of the Study Participants

The framework of recruiting study participants has been benchmarked from some previous scholarly works [11,32-37]. As shown in Figure 1, 2454 nursing students were eligible to join the study. However, 589 nursing students met the inclusion criteria and participated in the study, assessed at baseline, at end line, and their data analyzed. Sums (1865/2454, 76%) were excluded due to various reasons including not having started clinical placements (first-year diploma in nursing [n=491], a first-year bachelor of science in nursing [n=733], and a second-year bachelor of science in nursing [n=641]). There was no loss to follow-up among nursing students who joined the study and thus the completion rate was 100%.

Figure 1. A flow pattern of sampling procedure among nursing students. From field data (2021).



Eligibility Criteria

Inclusion Criteria

Nursing students were recruited for this study based on their willingness after being informed about the purpose, benefits, and drawbacks of participating in this study. The study recruited second-, third-, and fourth-year undergraduate nursing students who were in clinical placements at the time of this study. In addition, undergraduate nursing students with Information and Communication Technology literacy and those with iPhones or iPads were recruited for the study.

Exclusion Criteria

Nursing students who reported being unwell and unable to converse or participate in the study were excluded from the study. Students without institutional registration numbers, those unable to use computers or smartphones, and nursing students recruited for other studies or projects were not eligible to participate in this study.

Sampling Procedures

As recommended by previous scholars [38-41], probability sampling techniques through multistage sampling methods were used to reach and study nursing students in this study. Stage 1: a simple random sampling technique by lottery method was used to select regions and districts. Stage 2: As shown in Tables 1 and 2, stratified sampling methods were used to select higher training institutions (institutions A and B). On the other hand, lower training institutions (institutions C and D) were randomly selected using a stratified sampling technique.

Nevertheless, a stratified random sampling technique was used to select the nursing program (diploma in nursing and bachelor of science in nursing) and classes (who are in their clinical placement). The training health facility was selected purposely because it is only a major regional referral hospital in the Dodoma region used by multiple training institutions for training nursing students in clinical settings. Stage 3: systematic sampling methods were used to select the study participants. As shown in Tables 1 and 2, a proportionate formula: $n=[P_i \times (n/p)]$ was used to determine a minimum sample size of nursing students per training institution and their program, respectively, whereas n_i is the proportional sample size, P_i is the total targeted population, n is the number of nursing students, and P is the minimum sample size of the study.

Table 1. Proportionate sample size by the sampled training institutions[a].

Name of training institution	Total population, n	Proportionate, n
Institution A	968	232
Institution B	998	239
Institution C	367	88
Institution D	121	30

[a]From Study plan (2021). Total number of nursing students among the sampled training institutions = 2454 ($P_i \times n/P$).

Table 2. Proportionate sample size by training nursing program[a].

Training institution	Nursing program	Total population, n	Proportionate ($P_i \times n/P$)
Institution A	Diploma in nursing	230	55
Institution A	Bachelor in nursing	738	177
Institution B	Bachelor in nursing	828	198
Institution B	Diploma in nursing	171	41
Institution C	Diploma in nursing	367	88
Institution D	Diploma in nursing	121	30

[a]From Study plan (2021).

Intervention

The intervention was completed in 3 weeks, with 1 week set aside for the final evaluation (posttest). It was carried out on a daily basis (6 hours a day), per the clinical rotation and placement schedules established by the nursing students' respective training institutions. Within the 3 weeks of the intervention, all students were expected to perform and complete the assigned clinical learning task or activities and models on a daily basis and within 6 hours of their duty shifts. The primary aim of the intervention was to descriptively and analytically measure a change in motivation in clinical learning among undergraduate nursing students before and after participating in the program. Trained research trainers who also had clinical nursing education competence implemented the intervention. As illustrated in Figure 2, the system included a welcoming window as well as several menus or nodes such as clinical instructors, academic staff, clinical nursing procedures, clinical attendance, evaluation forms, announcements, code generator, professional programs, clinical library, system feedbacks and reports, and students' node, which included students' profiles, clinical notes, attendance, evaluation forms, and announcement menus.

Referring to Figure 3, nursing students were required to arrive at their shift very early each day before the tuned time in the system, which was 7:30 AM (East African time), to be assigned codes of a specific day or date generated by the trainers. The generated codes allowed them to log in to the system and sign out in the presence of the trainer at the end of the shift, which was tuned at 1:30 PM (East African time). Any student who arrived late for his or her shift and who did not provide web-based feedback on his or her performance of the chosen clinical nursing procedure in the presence of clinical instructors or trainers in between shifts, or left the shift before the fixed time of signing out was considered absent in that particular shift. The system provided a daily shift attendance report that included the dates, students' names and registration numbers, department, ward or unit, duty shift, clinical nursing procedure executed, and evaluation score for each student.

Nonetheless, as shown in Figure 4, several nursing clinical procedures were imported into the system, including giving and receiving reports; patients admission; changing patients' positions on a bed; counseling; bed making; administration of intravenous, intermuscular, and oral medications; catheterization; kangaroo mother care; administration of oxygen to patients (oxygen therapy); cardiopulmonary resuscitation; management of patients with preeclampsia or eclampsia; blood transfusion; per-vagina examination; wound dressing; mouth care; management of postpartum hemorrhage; assessment of placenta; management of pregnant women in a first and second stage of labor; assessment of new-born babies; history taking during labor; and vital sign assessment. After selecting a clinical nursing procedure for a particular duty shift, nursing students had to adhere to the 6 stages of conducting it including identification of the patient alongside getting informed consent; preparation of the environment; one-self; equipment appropriate for the chosen procedure; and performing and finishing the procedure. Each clinical nursing procedure was featured in several activities, which nursing students were supposed to follow, adhere, and implement chronologically.

Figure 2. A welcoming window, menu window, and nursing students' node with various menus in the system. From field data (2021).

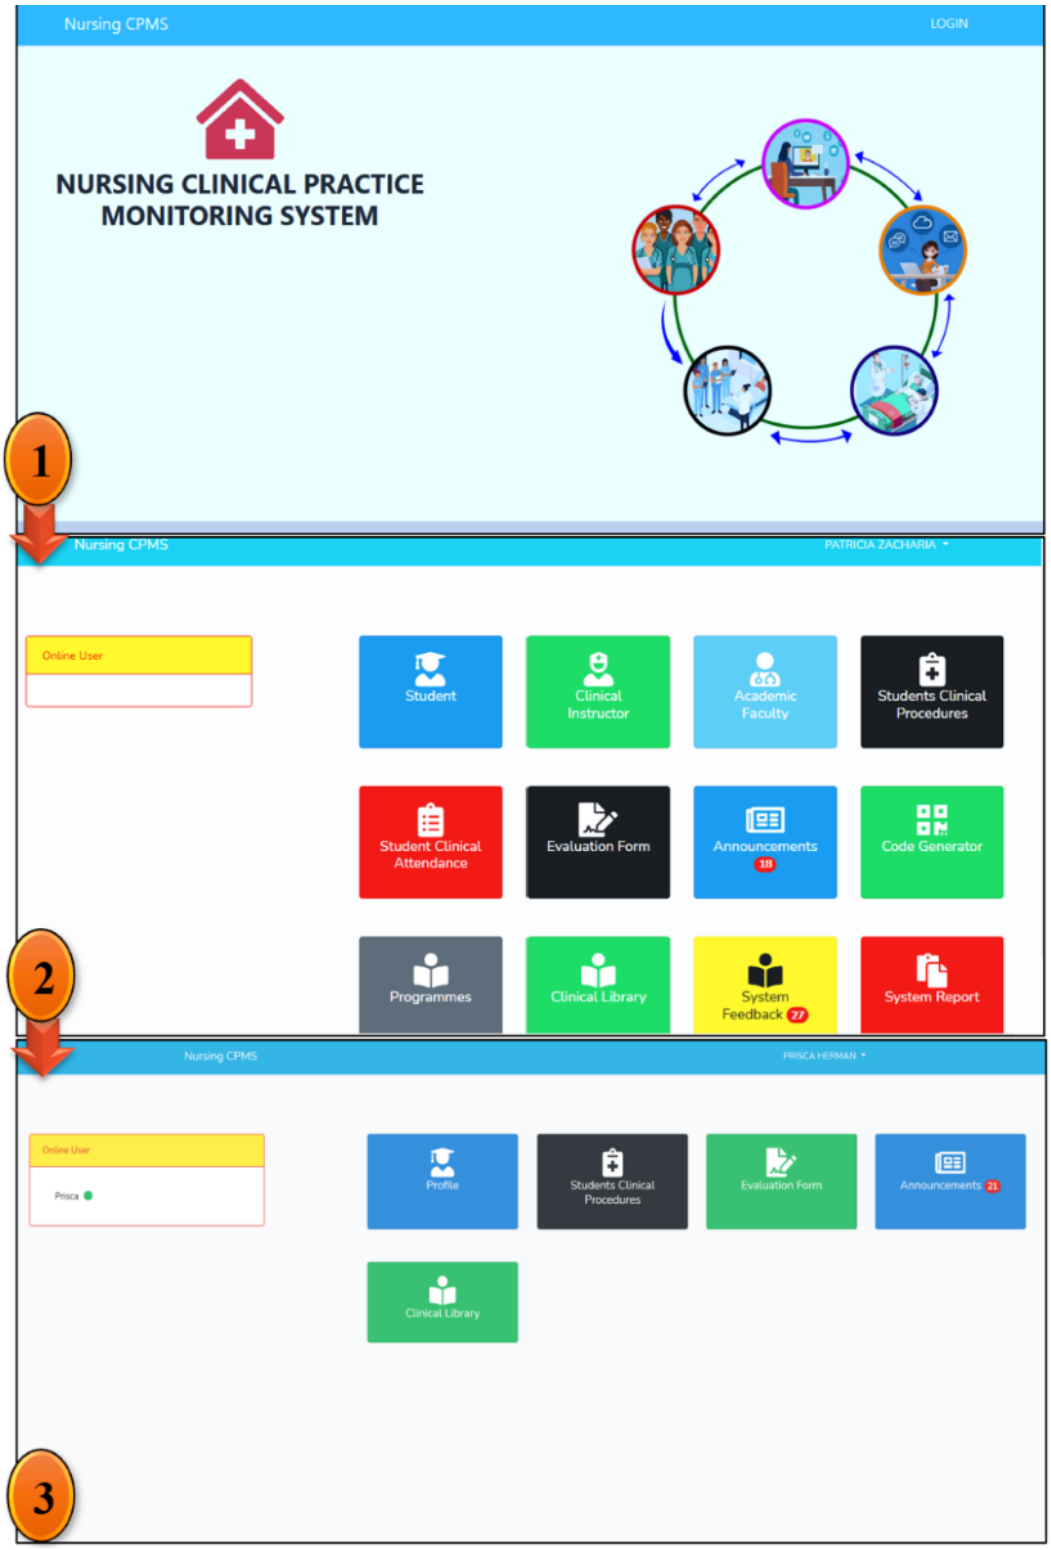


Figure 3. Code generator window, nursing students' login window, and an example of a system-generated report. From field data (2021).

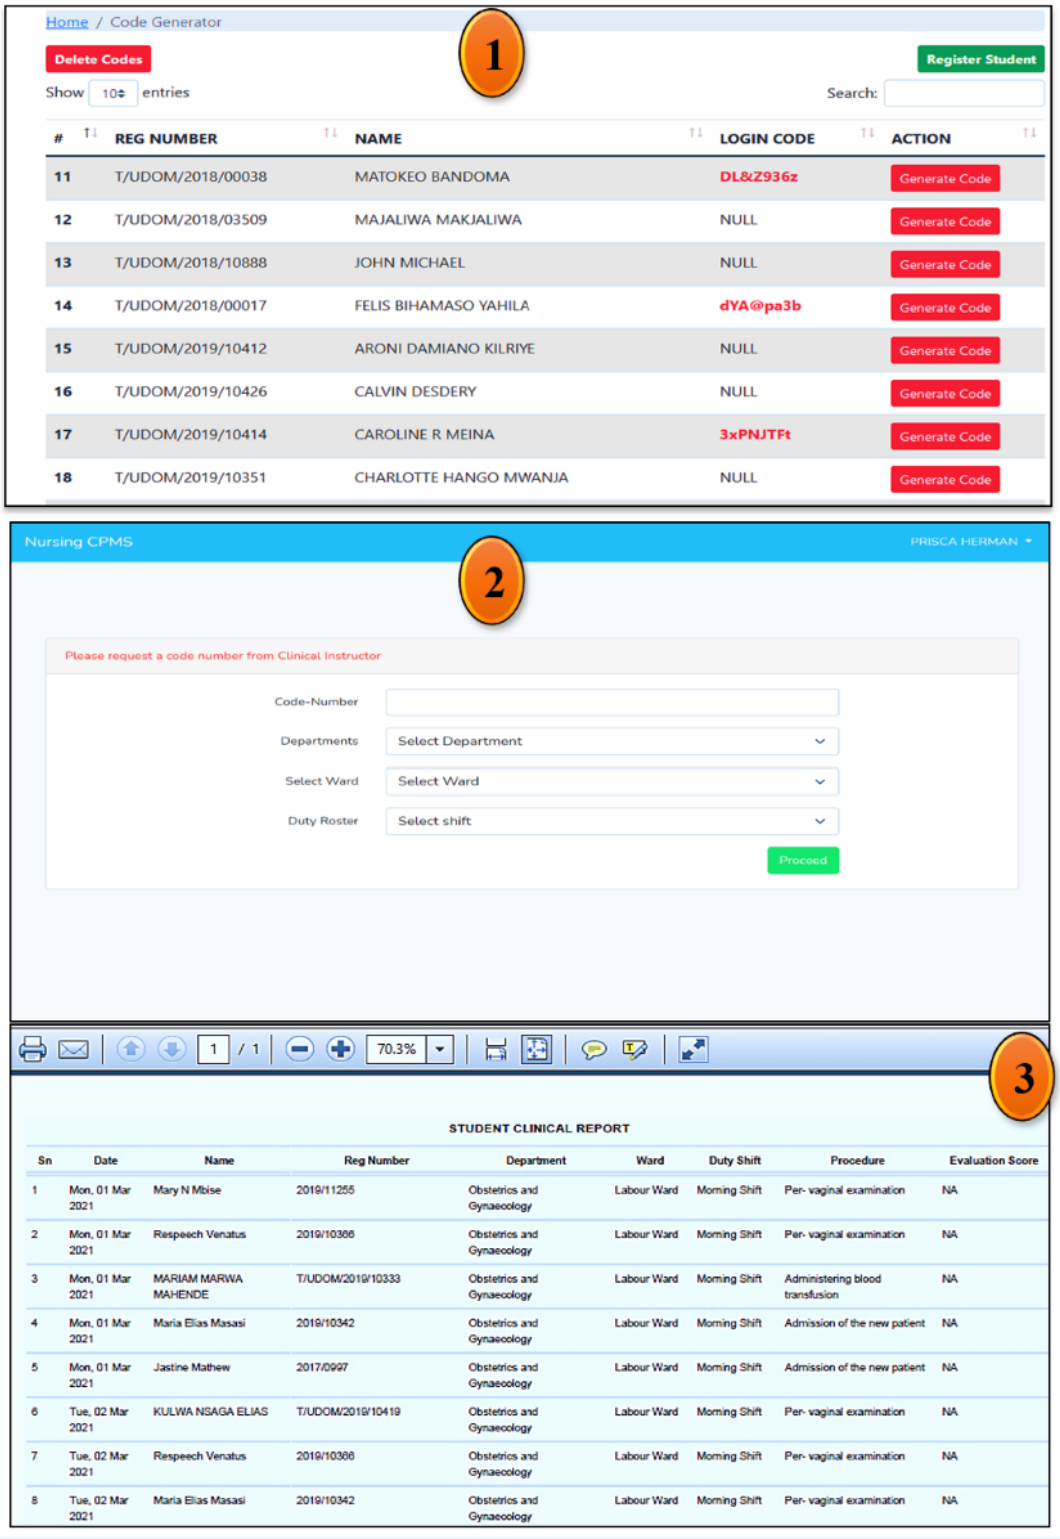

Figure 4. Variety of clinical nursing procedures, stages, and activities imported into the system for nursing students. From field data (2021).

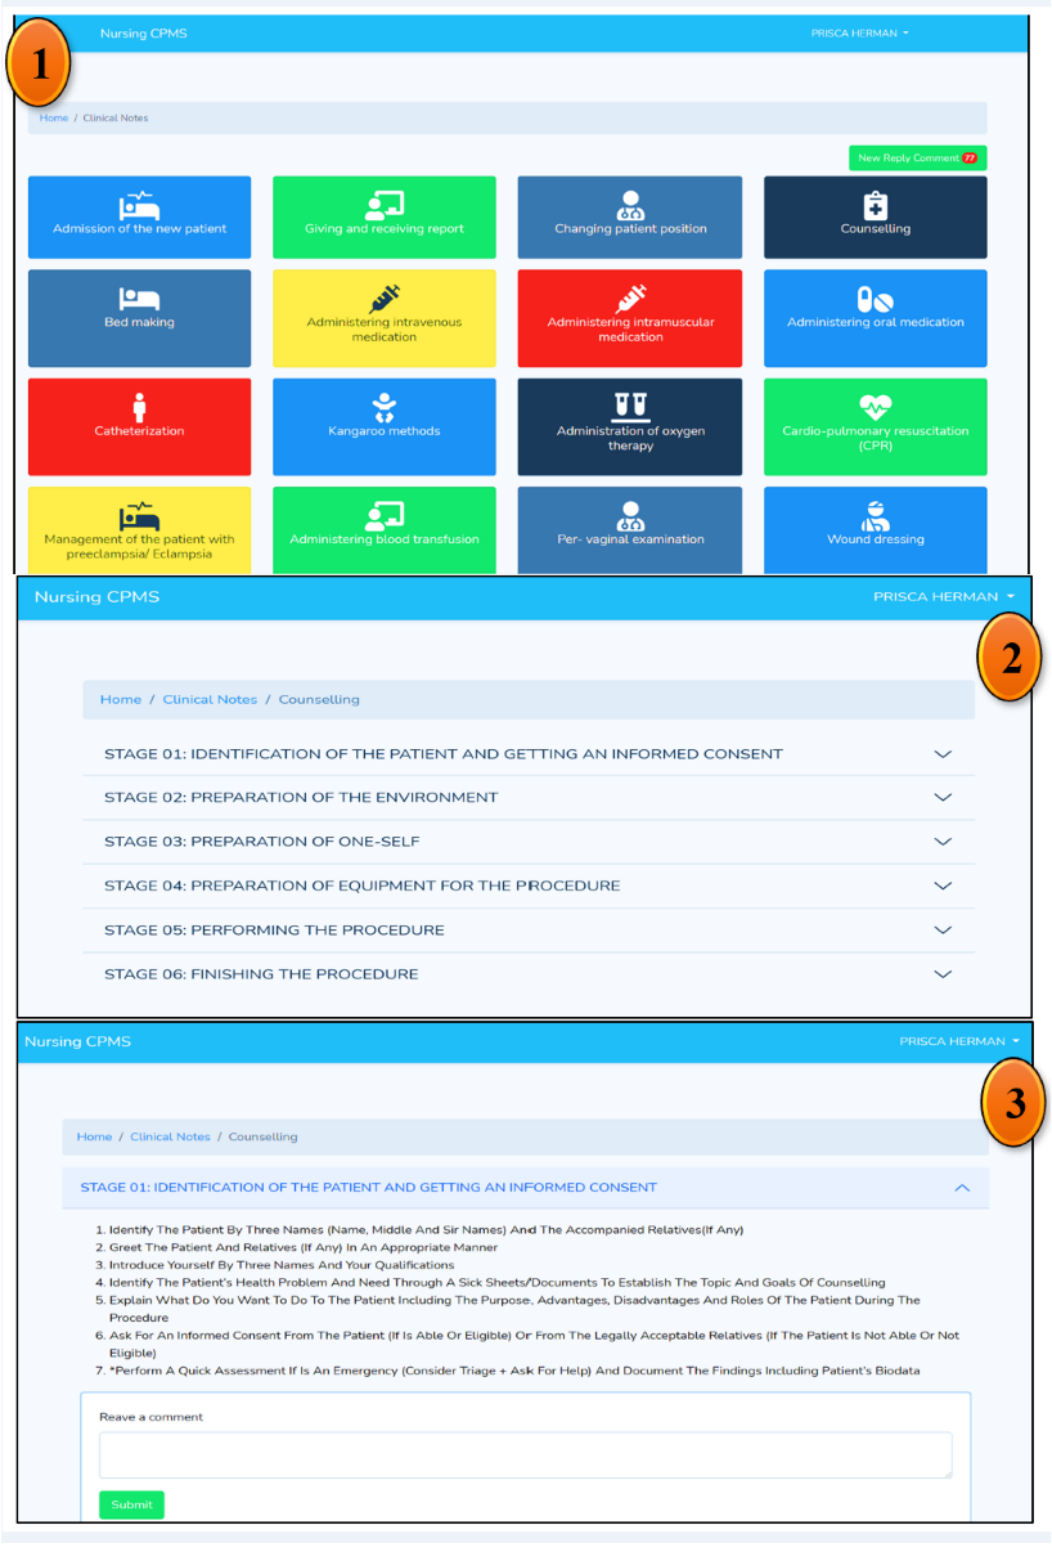


Procedures for Getting Nursing Students Into the System, Supervising, Supporting, Monitoring, and Evaluating Them

Undergraduate nursing students were recruited based on their units of clinical placements including the emergency unit, labor and postnatal ward, pediatric ward, and male medical ward within Dodoma Regional Referral Hospital. Resources such as computers, smartphones or iPads, electricity, web connectivity, clinical nursing procedure checklists, duty rosters, notebooks, pens, and shift objectives were the requirements for the intervention. Nursing students' institutional registration numbers were used as username identities during the login procedures into the system.

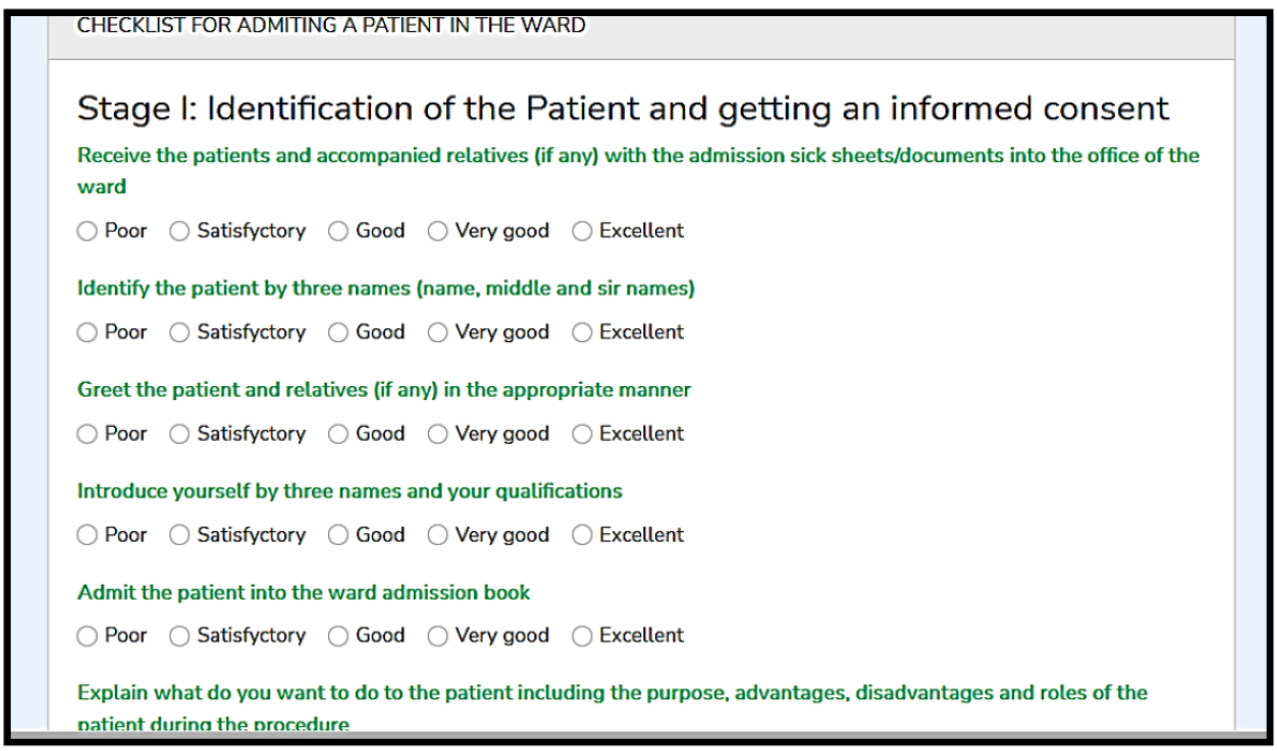
Clinical nursing procedures and evaluation checklists were imported into the system during the intervention to allow nursing students and clinical instructors to access them and have an interactive room to identify and discuss them before starting to

care for the patients on that particular day. Nursing students had to ask for a system-generated code in the presence of a (system implementers) clinical instructor to be able to log in to the system and counted to have reported timely in a particular duty shift as the mode of monitoring and keeping clinical attendance reports among them. Furthermore, after the successful registration of nursing students into the system, system implementers had to confirm the presence of nursing students throughout the specified duty shift.

A shift progress Min-reports (brief or summary report of what a student has done for a particular time of a shift) was posted by nursing students in the system including patients' progress after performing the procedure. On the other hand, trained research trainers had the role of periodically posting announcements into the system to enhance interactive and reciprocal communication among nursing students and academic faculty. They also had the role of summing up nursing students' clinical signs of progress and filling the evaluation forms at the end of a duty shift. All clinical teaching and learning activities performed by the trained research trainers and nursing students were tracked, monitored, and sometimes addressed by the principal investigator (PZH) through a system WebTop. All self-rated evaluations on the performed clinical procedures, day feedback, and experiences of the interactive web-based clinical practice monitoring system among nursing students and system implementers were captured through the system before they signed out at the end of the duty shift.

Only 1 session (morning duty shift) was preferred for the intervention as negotiated by hospital administration and system implementers. The intervention was implemented for 6 hours equivalent to 1 duty shift in a day with a duration ranging from 7:30 AM to 1:30 PM (East African time) among nursing students. Each student had to carry out and finish one of the aforementioned clinical nursing procedures every day for 3 weeks for learning to take place. This amounted to about 20 clinical nursing procedures in total. All students finished the same clinical nursing procedures during the intervention's 3-week duration including giving and receiving reports; patients admission; changing patients' positions on a bed; counseling; bed making; administration of intravenous, intermuscular, and oral medications; catheterization; kangaroo mother care; administration of oxygen to patients (oxygen therapy); cardiopulmonary resuscitation; management of patients with preeclampsia or eclampsia; blood transfusion; per-vagina examination; wound dressing; mouth care; management of postpartum hemorrhage; assessment of placenta; management of pregnant women in first and second stages of labor; assessment of newborn babies; history taking during labor; and vital sign assessment. Assessment of nursing students' motivation in clinical learning was performed using academic motivation questionnaires that were administered to them as pretests and posttests. As shown in Figure 5, the evaluation of the system was performed through nursing students' and system implementers' experiences feedback inventory that was posted in the system and filled out before signing out of the system.

Figure 5. An example of a self-rated evaluation form imported into the system for nursing students. From field data (2021).



Strategies Used to Maintain Adherence to the Intervention Among Nursing Students

This section describes the measures used to increase nursing students' adherence during intervention implementation in the field. Throughout the intervention, nursing students' registration numbers were used as identifiers during system deployment. Being unidentified and acknowledged by name would most likely make nursing students feel at ease and confident in their clinical learning privacy, allowing them to feel free and inspired

to follow the intervention regimen. Furthermore, with the assistance of academic faculty and clinical instructors, the study was carried out under the training institutional clinical rotation schedule, which most likely aided this study in ensuring that nursing students adhered to the intervention because they had to attend their shifts accordingly. The use of technology to assist clinical learning among nursing students appeared to impress them, particularly the ways interactive communications and physical contact were assured to them. Nursing students and system implementers have enhanced adherence to the intervention among nursing students by posting various announcements, peer teaching and learning, and self-evaluation forms.

Data Collection Procedures

The focus of the current effort was mostly on presenting the study's quantitative findings. Quantitative data were gathered at two-time intervals, baseline, and end line (directly postintervention), in different unoccupied rooms, as agreed upon by the administrative authority of the respective training institutes. The research assistants were chosen on purpose based on their eligibility criteria, which included at least 1 year of data-gathering experience. Nursing students were given a brief explanation of completing the questionnaire before having copies provided by research assistants. The researcher and assistants were present throughout the process to supervise and address the overstretched immediate and long-term problems before collecting all copies of completed surveys and protecting them as part of nursing students' confidentially. Before leaving the room, nursing students were informed of the timetable and method for intervention.

Research Tools and Instruments

The data collection tool for the quantitative part of the work consisted of 2 parts: the sociodemographic characteristics profiles and the part that measured nursing students' motivation in clinical learning. Gender, age, marital status, interest, motive for joining the nursing profession, accommodation, and marital status were all part of the sociodemographic profile. The study used a 5-point Likert scale to assess motivation in clinical learning using an Academic Motivation Scale composed of 28 items adopted from previous scholarly works [5,42-44]. The 5-point Likert scale ranged from 1=strongly disagree to 5=strongly agree. Its subscales included intrinsic motivation which was assessed by 12 items, extrinsic motivation (12 items), and amotivation (4 items) of which the findings were dichotomized into an "Agree" (assigned a value of "1") response that described the action to have been performed by the participant; otherwise, "Disagree" ("0" value) for unperformed action or behavior.

Before data collection, the principal component analysis was performed at a measure of Keiser-Meyer-Olkin and Bartlett test value of >0.5 and a significance level of ≤5% to measure the weight of each item. The findings revealed that all 28 items scored >0.3, and thus, they were all retained for data collection. Scoring the variable of motivation in clinical learning was adopted in a study conducted by Millanzi and Kibusi [6] that nursing students who scored 0-16 were categorized into low motivation in clinical, those who scored 17-24 had moderate learning motivation, and nursing students who scored 25 and above demonstrate high motivation in clinical learning.

Validity and Reliability of the Study

The validity and reliability tests were performed first before subjecting the tool to the actual field for data collection. The tool was shared with the subject matter and statistician for suitability of the items, reliability, and ambiguity to fit for knowledge to undergraduate nursing students. The pretest of research tools was conducted among 60 nursing students at a location that was different from the sampled study setting. The finding of a pretest was subjected to the exploratory factor analysis to determine the weight of each item to assess the outcome of interest and the reliability scale analysis to determine the internal consistency of the tool and presented using Cronbach α values as recommended by previous studies [45]. The findings of the scale analysis on motivation in clinical learning were found to be Cronbachα=0.840 (>0.7), which was statistically reliable for the actual data collection.

Data Analysis

An SPSS software program (version 23; IBM Corp) was used to analyze data. Before data analysis, cleaning was done to ensure the completeness, accuracy, and clarity of the information in the questionnaires. A normality test was performed to determine the distribution of data to opt for the mode of data analysis. Findings of the normality test revealed that data motivation in clinical learning was approximately normally distributed, and thus, parametric statistical measurements were adopted. Descriptive statistic was used to establish participants' sociodemographic characteristics profiles of the study participants such as age, sex, program, and year of study, just to mention a few, and the motivation in clinical learning. For inferential statistics, a 2-tailed paired *t* test was performed to determine a comparative mean score change and difference in motivation in clinical learning among nursing students between the pretest and the posttest.

The multiple linear regression analysis model by considering the control of other factors as independent variables such as sociodemographic characteristics profiles and the intervention (interactive web-based clinical practice monitoring system) was performed to establish the extent of association with the outcome variable of interest (motivation in clinical learning). The multiple linear regression was opted for because several factors were controlled during analysis and the outcome variable of interest was treated as a scale variable. The goal of this study was to determine the net effect of the intervention by taking into account and controlling for the sociodemographic characteristic profiles of nursing students, as it was hypothesized that these profiles would also have an impact on the outcome of interest (motivation in clinical learning) over the intervention. Findings of inferential statistics were presented in tabular forms by means, of SDs, *t* values, significance level (<5%), and 95% CI. The following logistic regression model was used:

where Y is dependent variable; a is intercept; b, c, d, and e are slopes; X_1, X_2, X_3, and X_4 are independent (explanatory) variables; and e is residual (error).

Ethical Considerations

This study conformed to The University of Dodoma institution's postgraduate guidelines and regulations after being approved and given an ethical clearance (number MA.84/261/02/81) by the institutional research ethics review committee. All participants provided written informed consent after being explained about the study and their freedom to participate in it. Data collection procedures were performed in separate and unoccupied venues that were available in the respective institution premises. Participants' names were not included in the data collection tools and their information was secured by the principal investigator (PZH) using folders with passwords. Given that participants were in their academic clinical rotations calendar for clinical learning activities, there were no compensations of either time or monetary incentives throughout the study.

Results

Proportional Distribution of Nursing Students by Their Sociodemographic Characteristics Profiles

The completion rate of the study was 100% of the studied participants. Findings in Table 3 indicate that 65.0% (383/589) of nursing students were males while 79.6% (469/589) of the sample were younger than 24 years, with a mean age of 23 (SD 2.689, range 19-50) years. Accommodated participants in their respective training institutions' hostels accounted for 71.5% (421/589) while 63.7% (375/589) of them were enrolled in bachelor of science in nursing and 33.6% (198/589) and 30.1% (177/589) of them were in their fourth and third year of studies, respectively. A majority of nursing students 69.4% (406/589) were not interested in joining nursing programs. However, those who were interested in joining nursing education were driven by a belief that it is a secure profession (567/589, 96.3%), caring to save peoples' lives (491/589, 83.4%), autonomy to practice (478/589, 81.2%), and generous salary and employment benefits (438/589, 74.4%). Other findings were found as shown in the table.

The Overall Distribution of the Level of Motivation in Clinical Learning and Their Domains Among Nursing Students

The findings from Table 4 revealed that there was no significant difference between the proportion of nursing students with low and moderate motivation in clinical learning (261/589, 44.3%; and 328/589, 55.7%, respectively). However, baseline findings indicated that none of the nursing students demonstrated high motivation in clinical learning 0.0% (n=0). On the other hand, baseline findings of the motivation domains indicated that 94.7% (558/589) of nursing students were not intrinsically motivated in clinical learning contrary to the end line findings, which indicated that 90.5% (533/589) demonstrated inner motive in clinical learning. Highly motivated nursing students to learn in clinical settings accounted for 67.7% (399/589) while only 4.9% (29/589) of them demonstrated lower motivation in clinical learning. Other findings were observed as shown in Table 4.

Overall Mean Score Change and Mean Difference in Motivation in Clinical Learning Between Pretest and Posttest Among Nursing Students

As shown in Table 5, there was a statistically significant increase in mean scores changes of motivation in clinical learning from mean 9.31 (SD 2.315) at baseline to mean 20.87 (SD 5.504) at the end line. A comparative analysis of motivation performance among nursing students between pretest and posttest was found to be statistically significant (mean 11.566, SD 5.667; t_{588}=49.496; P<.001; 95% CI 11.107-12.025). The findings suggest that nursing students scored high on motivation in clinical learning in the posttest as compared with the pretest. Moreover, the findings in Table 5 indicated that there was an increase in mean scores among nursing students per domain of motivation to clinical learning between the pretest (mean 3.74, SD 1.231) and the posttest (mean 9.53, SD 2.762).

Table 5. Overall mean score change and mean difference in motivation in clinical learning between pretest and posttest among nursing students (N=589)[a].

	Pretest, mean (SD)	Posttest, mean (SD)	Mean difference, mean (SD)	*t* test (*df*)	*P* value	95% CI	Effect size (Cohen *d*)	95% CI
Motivation in clinical learning	9.31 (2.315)	20.87 (5.504)	11.56 (5.667)	49.496 (588)	.001	11.107-12.025	2.743	1.011-4.107
Domains of motivation in clinical learning								
Intrinsic	3.74 (1.231)	9.53 (2.762)	5.800 (2.968)	47.421 (588)	.001	5.559-6.040	N/A[b]	N/A
Extrinsic	4.49 (1.42)	8.77 (3.325)	4.276 (3.474)	29.845 (588)	.001	3.994-4.557	N/A	N/A
Amotivation	2.57 (1.1871)	1.08 (1.392)	1.492 (1.644)	22.031 (588)	.001	1.359-1.625	N/A	N/A

[a]From field data (2021).

[b]N/A: not applicable.

Moreover, they also demonstrate higher scores in their extrinsic motivation to learning in clinical settings at the end line (mean 8.77, SD 3.325) than at baseline (mean 4.49, SD 1.42) while amotivation performance decreased from mean 2.57 (SD 1.187) at baseline to mean 1.08 (SD 1.392) at the end line. The effect size of the intervention on motivation in clinical learning among nursing students was computed using Cohen *d* formula (mean 2 minus mean 1 divided by a pooled SD). Findings showed that the intervention demonstrated an effect size of 2.74 (*P*<.001; 95% CI 1.011-4.107), which is a high effect size based on Cohens *d* classifications of effect sizes [46].

The Estimated Effect of an Intervention (Interactive Web-Based Clinical Practice Monitoring System) Controlled for Other Co-Related Factors on Motivation in Clinical Learning Among Nursing Students at Posttest

About 58.5% variation in motivation in clinical learning scores is explained by the explanatory variables included in the model. The overall model was statistically significant (*f*=25.6; *P*=.001). Findings in Table 6 indicate that reasons to join the nursing profession such as due to the opportunity to demonstrate autonomy (β=1.590; *P*=.02; 95% CI 0.279-3.901), the opportunity to travel around the world (β=1.648; *P*=.04; 95% CI 0.583-4.713), job availability (β=1.409; *P*=.001; 95% CI 1.046-5.772), and other corelated factors were statistically significantly associated with motivation in clinical learning among nursing students against their counterparts. The estimated effect (β) of a 3-week intervention to improve nursing students' motivation in clinical learning was 3.041 (*P*=.03, 95% CI 1.022-7.732) when controlled for other correlated factors.

Table 6. The estimated effect of an intervention (interactive web-based clinical practice monitoring system) controlled for other corelated factors on motivation in clinical learning among nursing students at posttest (N=589)[a,b].

Discussion

Principal Findings

In terms of the study's focus and objective, the implementation of an interactive web-based clinical practice monitoring system for nursing students' motivation in clinical learning was feasible and practical in a clinical setting with consistent electricity supply and web connectivity. Nursing students indicated moderate to high levels of motivation in clinical learning after 3 weeks of system implementation, compared with when they were not exposed to it. Nursing students demonstrated a capacity to plan, identify, and access academic resources and help, as well as participate in clinical practices with minimal support from clinical instructors, trainers, and academic faculty, according to the end line assessment. Nonetheless, contrary to the existing practices where nursing students are not allowed formally to use electronic devices in clinical settings, the use of electronic devices while students are in clinical settings such as smartphones, iPads, and computers would most likely extrinsically motivate nursing students to attend their daily duty shifts.

The posttest results show that nursing students who are mentored, supported, monitored, supervised, and evaluated using an interactive web-based clinical practice monitoring system are more efficient in terms of clinical attendance and completing clinical activities on time. The findings of this study indicated that nursing students showed a readiness to stick to their clinical duty roster, report on the clinical environment on time, receive and give reports, and complete their assigned responsibilities using an interactive web-based clinical practice monitoring system. Furthermore, students expressed a desire to ask questions and locate clinical resources to help them learn not just to win a prize or a grade but also to broaden their knowledge and skills. Despite a significant change in clinical learning motivation among nursing students, the system improved clinical attendance as an indicator that it motivated and enhanced their interest and willingness with a sense of being confident, independent, and autonomous to engage in clinical learning activities than when conventional clinical pedagogies such as attendance books, bed tutorials, or assignments were predominantly used.

Similarly to the findings from other previous scholars [2,21], the implementation of an interactive web-based clinical practice monitoring system would allow nursing students to interact with one another while performing clinical nursing procedures, as well as interact instantly and timely with trainers, clinical instructors, or academic faculty for any support or mentorship. Nonetheless, as argued by some previous scholars [5,47] that individuals' behaviors are sometimes shaped by their personalities, this study found that nursing students' motivation in clinical learning was partly attributed to what motivated them to join nursing education programs, such as challenges in job availability, opportunities to demonstrate autonomy in nursing, and opportunities to travel around the world when individuals enrolled in the nursing profession. Such corelated aspects to the intervention would most likely drive nursing students to study nursing programs extrinsically rather than intrinsically to match their academic and living goals.

Referring to the findings from some previous scholarly works on students' abilities to demonstrate an interest in their learning activities becomes a precursor for them to be motivated to identify and locate learning resources and thus engage in learning activities actively [48,49]. Similarly, scholars' [6,50,51] low motivation in clinical learning has been linked to uninteresting clinical teaching techniques, an uncomfortable learning environment, a lack of interest, and unclear clinical objectives, all of which contribute to clinical absenteeism among nursing students. This study's findings on motivation to learn are consistent with those found by Millanzi and Kibusi [6], for example, who argued that innovative pedagogy has the potential of improving learning motivation among nursing students.

Nevertheless, Allvin et al [52], claimed that while the clinical environment is important for nursing students' academic achievement, students' learning motivation is positively correlated with an adequate number of competent and qualified clinical instructors who use innovative clinical pedagogies that enhance their motivation in clinical learning, including the prescription and integration of interactive web-based clinical practice monitoring system in nursing curricula. In the same way, Aghajari et al [53] observed that the majority of nursing students lack academic motivation during clinical placement practices because the clinical learning environment, as well as clinical teaching and learning pedagogies, does not motivate them to learn and meet their clinical academic potential as lifelong learners. This study's and prior research findings indicate to underline that a favorable, learner-centered, and technology-based innovative clinical pedagogy may positively boost clinical learning motivation among nursing students in nursing education.

Limitations of the Study

The study did not involve a control group to maximize the validity of findings on the efficacy of interactive web-based clinical practice monitoring systems on the outcomes of interest. The use of a single group may obscure the interpretation of the effect size on the outcome variables because standard clinical teaching pedagogies would also produce effects on the outcome of interest. Therefore, findings on the effect of interactive web-based clinical practice monitoring systems need to be interpreted cautiously by considering this limitation. The study suffers from a methodological limitation, as it did not adopt a randomized controlled trial (a true intervention) to estimate the random effect of the interactive web-based clinical practice monitoring system on the outcome variables over the standard clinical teaching pedagogies. Therefore, findings need to be treated and interpreted cautiously by considering that with a quasi-experimental design random effect of the intervention on the outcome, variables would not be established without outweighing its effect over the standard clinical teaching pedagogy (control group) if it could be involved.

Conclusions

The findings of this study demonstrate that it is possible to teach, mentor, supervise, support, monitor, and assess nursing students throughout their clinical placements by adopting, implementing, and evaluating an interactive web-based clinical practice monitoring system. As a minimum exposure of at least 3 weeks of the interactive web-based clinical practice monitoring system, nursing students may demonstrate nursing students' attendance and motivation in clinical learning by their will than is now performed, where sanctions and other associated techniques are used to force them to attend their daily clinical duty shifts accordingly. Incorporating technology into clinical nursing education pedagogics nursing curricula can be an alternative educational technique for educators in nursing education to facilitate clinical learning activities to develop motivated and passionate undergraduate nursing students to engage and learn efficiently and effectively during their clinical placements. Nonetheless, managing a big group of nursing students was proven to be achievable with the use of an interactive web-based clinical practice monitoring system.

Furthermore, an interactive web-based clinical practice monitoring system was feasible to not only mentor, supervise, monitor, and support nursing students but also record students' clinical attendance and the type and number of clinical nursing procedures learned and practiced, as well as generate clinical formative evaluation reports. In other words, an interactive web-based clinical practice monitoring system can be used as an innovative clinical pedagogical approach in clinical teaching and learning to improve nursing students' motivation in clinical learning as a precursor to clinical competence for quality and cost-effective care to people.

Abstract

Background: Virtual reality (VR)–based simulation is an increasingly popular tool for simulation-based medical education, immersing participants in a realistic, 3D world where health care professionals can observe nuanced examination findings, such as subtle indicators of respiratory distress and skin perfusion. However, it remains unknown how the VR environment affects participant behavior and attention.

Objective: This study aimed to describe clinician attention and decision-making behaviors during interprofessional pediatric resuscitation simulations performed in VR. We used video-based focused ethnography to describe how participant attention and behavior are altered in the VR environment and reflect how these changes may affect the educational profile of VR simulation.

Methods: The research team analyzed scenarios with the question, "How does a completely virtual reality environment alter participant attention and behavior, and how might these changes impact educational goals?" Video-based focused ethnography consisting of data collection, analysis, and pattern explanation was conducted by experts in critical care, resuscitation, simulation, and medical education until data saturation was achieved.

Results: Fifteen interprofessional VR simulation sessions featuring the same scenario—a child with pneumonia and sepsis—were evaluated. Three major themes emerged: Source of Truth, Cognitive Focus, and Fidelity Breakers. Source of Truth explores how participants gather and synthesize information in a VR environment. Participants used the patient's physical examination over ancillary data sources, such as the cardiorespiratory monitor, returning to the monitor when the examination did not align with expectations. Cognitive Focus describes the interplay between thinking, communicating, and doing during a VR simulation. The VR setting imposed unique cognitive demands, requiring participants to process information from multiple sources, make rapid decisions, and execute tasks during the scenario. Participants experienced increased task burden when virtual tasks did not mirror real-world procedures, leading to delays and fixation on certain actions. Fidelity Breakers reflects how technical and environmental factors disrupted focus and hindered learning. Navigational challenges, such as unintended teleportation and difficulties interacting with the virtual patient and equipment, disrupted participant immersion. These challenges underscore the current limitations of VR in reproducing the tactile and procedural aspects of real clinical care.

Conclusions: Participants' focus on the physical examination findings in VR, as opposed to the cardiorespiratory monitor, potentially indicates simulation of an identical, more patient examination-centered approach to clinical data gathering. In addition, the multiple data sources allowed for participant cognitive load and task burden that may better mirror real-life clinical care. However, technical features that required straying from real-world task completion, as well as other navigational and interactional challenges in VR, led to breaks in fidelity and shifted focus away from the learning objectives. These findings underscore the need for continued research on how simulation modality, fidelity, and technical challenges may influence participant attention and behavior, to allow thoughtful alignment between desired learning objectives and mode of training.

Introduction

Simulation-based medical education (SBME) emerged as a way to practice skills without placing patients at risk [1]. Simulation has been shaped by the tools and technology available and has primarily consisted of ever-evolving computerized manikins designed to represent a patient. Computerized manikins have been well aligned with training toward and evaluation of specific goals and behaviors, such as practicing high-quality cardiopulmonary resuscitation [2], enhancing team dynamics [3], and establishing procedural competency [4]. Recently, technological advancements have allowed SBME to move beyond computerized manikins. Digital simulation environments can allow for a simulated patient to exist in 3D space as a virtual patient. These new approaches to simulation change the way participants perceive and interact with the patient during training scenarios [5-10].

Institutions have begun to explore the use of several digital-based simulation modalities, including augmented reality (AR) and virtual reality (VR)–based simulation. AR simulation places a 3D virtual patient in an actual physical space [11]. This virtual patient can either exist alone or as a superimposed image anchored onto a physical manikin [12]. AR passthrough technology obviates the need to replicate a physical environment in a virtual space, since the simulation occurs in the physical world. However, the technology needed to allow a seamless passthrough AR experience remains limited [13].

Immersive VR places participants in a fully digital 3D environment. This environment can be a digital twin of the actual clinical space used by the participants [12,14] or a completely novel training environment [8]. Achieving high-fidelity physical interactions and closely matching real-life clinical skills in VR remains challenging [15].

SBME is built upon the foundational presumption that the training environment, and the associated degree of realism and fidelity, impacts learning through the quantity and complexity of cognitive tasks required (ie, cognitive load theory) [16], as well as through allowing new knowledge construction through experiences and interactions (ie, constructivism) [17]. Augmented and VR, which significantly change the environment where participants engage, learn, and grow, could influence the attention (ie, directed cognitive engagement) and behaviors (ie, observable participant actions) exhibited by participants. In addition, while some of this influence may be purposeful (ie, realistic presentation of clinical findings), it is unknown whether there are additional influences that may be inherent to the training modality and independent of the clinical context and learning objectives. While these new and innovative tools present opportunities for training and assessment, an understanding of their influence on trainee attention and behavior is necessary to optimize our ability to use them to achieve ideal educational outcomes.

Our previous findings found that participant behaviors differed substantially between an AR-enhanced and a manikin-based simulation of an identical clinical scenario. The modality influenced the observed communication dynamics, participant behaviors, and fidelity breakpoints that influenced participant attention [5]. However, a similar description of attention and behavior in a VR clinical simulation currently does not exist. As these digital training modalities are becoming increasingly accessible, addressing this gap is crucial for supporting educators in developing and implementing precision training that is potentially more impactful through thoughtful alignment between learning objectives and chosen training modality. This study aimed to identify and categorize provider attention and behavior during VR SBME to aid in establishing which educational objectives are best addressed through this novel simulation modality.

Methods

Theoretical Framework

This study is anchored in the theoretical construct that the inherent characteristics of a simulation modality may influence participant attention and behavior. In addition, understanding that influence is key to ensuring that specific learning objectives are feasible to accomplish with the use of a given simulation modality. This aligns with the educational theory of constructivism, which posits that learners actively build knowledge by engaging in “hands-on” experiences, experimentation, and reflection within authentic contexts [17]. In a VR simulation, these authentic contexts are approximated by realistic clinical environments that include realistic digital patients and equipment to encourage exploration, role adoption, and collaborative decision-making. However, the same immersive features that make VR engaging (eg, richly detailed visuals, interactivity, and collaboration) may also impose additional cognitive demands (eg, technical work-arounds or deviations from reality) that could influence the construction of knowledge in unintended ways. The impact of those cognitive demands can best be understood through the lens of cognitive load theory, which highlights the limited capacity of working memory and its subsequent impact on knowledge or skill acquisition [16]. With VR simulations, expanded data sources in the form of virtual patients, equipment, environments, or other assets will influence the cognitive load burden on participants and potentially influence their behavior and subsequent learning. At the same time, novel controls and interface complexity may inadvertently add additional cognitive load, drawing learners’ mental resources away from essential clinical tasks and therefore potentially diminishing their bandwidth for the desired learning objectives. The integration of constructivism and cognitive load theory allows for a theoretical framework that aims to capture how participants effectively manage mental resources while constructing new knowledge through immersion, as well as identify when extraneous load hinders that process. This blended theoretical lens guided our data analysis and interpretation of observed learner behaviors in VR-based pediatric resuscitation simulations.

Study Design

We used video-based focused ethnography [18,19] to study a cohort of video-recorded VR simulations. Focused ethnography is a methodological adaptation of traditional ethnography, offering a targeted and time-efficient approach to studying

specific phenomena within specific contexts. This research strategy prioritizes depth of understanding over breadth, using concentrated data collection and a clear research question to describe particular social, cultural, or organizational processes. For this study, the goal was to understand how VR-based simulation affects participant attention and behavior. With this goal in mind, the research team was primed with the initial research question [19]: "How does a virtual reality simulation influence participant attention and behavior, and how might these changes impact educational goals?"

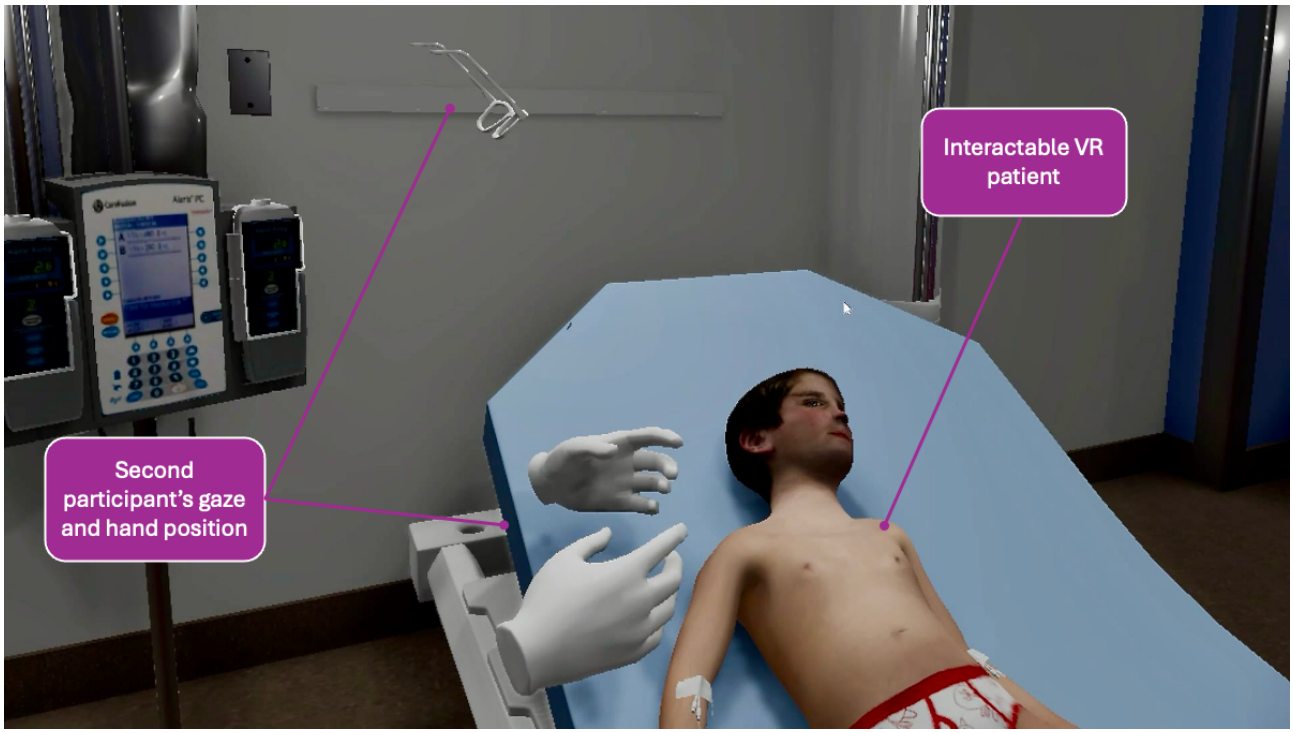
During this focused exploration, the team first identified and classified the data, then described and analyzed the specific behaviors, and finally moved to pattern explanation [18,19]. This study was approved by the Institutional Review Board at Cincinnati Children's Hospital Medical Center. It was funded, in part, by the Laerdal Foundation.

Data Corpus

Our research team, composed of an interdisciplinary group with combined expertise in critical care (DL, KE, and MZ), resuscitation (DL and MZ), simulation (DL, KE, and JS), and medical education (DL, JS, and MZ), reviewed a series of VR simulation recordings captured during a validation study of a specific VR curriculum [20]. The simulation took place in a virtual environment that mirrored a typical high-acuity room, as might exist in an emergency department or intensive care unit. Participants in the simulation included pediatric critical care and emergency medicine attendings and fellows, and pediatric intensive care unit and emergency department nurses. Each physician-nurse dyad had no previous exposure to the scenario and completed it only once.

The virtual patient was located on a hospital bed within a room that included a vital sign monitor, an intravenous pole with fluids, an oxygen delivery device, a stethoscope, a thermometer, a syringe for drawing blood samples, and a large fluid-filled syringe for triggering administration of a fluid bolus. A representative first-person perspective of the VR environment can be found in Figure 1. The virtual patient was an 8-year-old male with pneumonia and sepsis. The rationale for this scenario was that pneumonia frequently progresses to sepsis, and key stakeholders regarded this as a realistic scenario for clinical assessment and management training. The clinical status of the virtual patient changed throughout the simulation, conveying alterations in mental status (ranging from conversant to altered), perfusion (mottled skin that progressed to poor perfusion and cyanosis), and respiratory status (superimposed retractions and tachypnea).

Figure 1. First-person perspective of the virtual reality (VR) experience.



The scenario was coded in Unity (Unity Technologies) and accessed via an Oculus Rift headset connected to a VR-capable laptop, which allowed 2 participants within the same simulation to move freely and interact with the scenario and each other, including communicating regarding shared findings in real time. The purpose of the simulation was to assess the participants' ability to recognize, describe, and begin to treat a patient with developing shock. A detailed description of this VR simulation was previously described by Zackoff et al [20]. Participants received a 5-minute orientation to navigation in the VR environment and the functionality of the virtual patient and equipment from a trained VR simulation facilitator. They then received the case description and were instructed to begin their assessment and management of the patient as they would in real life. The VR simulation facilitator was present in the VR environment for the orientation and then exited the VR but remained present in real life to address questions and provide feedback throughout the remainder of the simulation session.

First-person audiovisual data recorded from the perspective of both users (a nurse and a physician) were stored in a password-protected, encrypted server, annotated via Vimeo (Vimeo, Inc), and coded in Microsoft Excel. Multiple audiovisual feeds, capturing the perspective of both participants within the virtual environment, allowed for data triangulation [21].

Research Team

Considering reflexivity [22] and the desire for analytic triangulation [21], the research team was composed of a heterogeneous group of experts in resuscitation team leadership and medical education (DL), resuscitation bedside nursing (KE), and SBME (JS). DL is a practicing pediatric critical care physician as well as a simulation educator. KE is a simulation educator and former critical care nurse. JS is a simulation educator and a former pediatric emergency department nurse. The data analysis was also overseen by MZ, a pediatric critical care physician and education scientist with expertise in designing, implementing, and evaluating SBME using innovative modalities such as VR and AR. MZ served as a senior consultant, providing guidance and expertise at scheduled intervals and during critical decision points where consensus within the research team was required.

Focused Research Question

The research team reviewed the data, primed with the following generative question [23], "How does a virtual reality simulation influence participant attention and behavior, and how might these influences impact achievable educational goals?"

Using a focused ethnographic approach is particularly suited for foundational research in which little is known about how subjects interact with a new environment (or, more specifically, a technology that places subjects in a new environment). Rather than measure changes against a specific baseline or control group, a focused ethnographic approach provides foundational descriptions of behaviors [18]. Instead of benchmarking against manikin-based or live simulations, our goal was to capture and interpret emergent behaviors, areas of challenge, and decision-making processes that may be uniquely influenced by VR-based training.

Phased Qualitative Analysis of Participant Attention and Behavior

To investigate participant attention and behavior within a virtual environment, we conducted a 3-phase analysis of VR simulations [18,24]. We followed a focused ethnographic strategy [18,19,24] incorporating inductive coding techniques [25]. This approach was chosen to (1) provide in-depth, context-specific insights into participant behavior in VR and (2) allow unanticipated themes to emerge from the data rather than imposing pre-existing hypotheses.

Phase 1: Identification and Classification

The initial phase involved exposing the research team to the VR scenarios. All participants were oriented to the technology, simulation, and virtual environment. The team then watched an initial group of scenarios to further familiarize themselves with the simulation and VR environment. For each study video, each researcher took independent field notes [26]—timestamped observations documenting participant statements, team dynamics, and points of interest [18]. These notes were stored, compiled, and subsequently treated as data and shared during collective analysis sessions.

The units of analysis for these notes were discrete, timestamped episodes of participant behavior. Team members independently categorized these notes into two broad types: (1) verbal events: any distinct verbalization by a participant (eg, "I'm going to give a bolus," or "He looks cyanotic") and (2) Interaction events: any observed action in the VR environment (eg, checking capillary refill, reaching for oxygen supplies, and teleporting to a different location). This unit of analysis helped capture how participants directed attention, interpreted clinical cues, and engaged with the virtual environment.

During the collective analysis sessions, the research team met together and used triangulation techniques to reconcile discrepancies in individual coding and ultimately reach consensus during the development of a comprehensive codebook. The team compared individual code lists, resolved discrepancies through discussion, and compiled a unified preliminary codebook. During this stage, our theoretical framework served as a sensitizing concept, alerting us to phenomena related to the active construction of knowledge and influence of cognitive load (eg, repeated attempts to use virtual equipment, indicating extraneous load on top of the active construction of clinical assessment knowledge).

This codebook served as a standardized tool for subsequent research phases (Phase 2: Description and Analysis and Phase 3: Pattern Explanation). Following the consolidation of the codebook, the research team independently applied it to each VR simulation session video recording. After coding each simulation session, the team reconvened to discuss and refine the codebook further as needed. This iterative process continued until data saturation [27] was achieved.

Phase 2: Description and Analysis

After achieving data saturation, the research team transitioned to the second phase—description and analysis. A rigorous review of the developed codebook was conducted to identify recurring patterns in participant attention and behavior across the reviewed simulated scenarios, guided by the focused research question.

The recurring findings were subsequently organized into distinct clusters to inform themes, providing a comprehensive overview of participant engagement during the VR simulations. To ensure the validity and consistency of these themes, an independent researcher (MZ) again triangulated the data.

Phase 3: Pattern Explanation

The final phase used the established themes to facilitate a descriptive analysis of the potential ramifications of using VR as an educational tool. By exploring the patterns of attention and behavior exhibited during VR-based simulations, we identified unique advantages and limitations associated with this modality. We reflected on how these insights may aid

educators in determining which educational objectives are best aligned with VR training.

Ensuring Code Validity

We used multiple strategies to enhance the credibility and dependability of our findings. First, we used analyst triangulation [21,28] by involving researchers with diverse backgrounds in critical care, nursing, and simulation education. Each analyst independently reviewed and coded selected video segments, then convened to discuss and reconcile any discrepancies. This iterative group process helped refine the codebook, ensuring that multiple perspectives were integrated and minimizing the influence of individual bias. We also maintained reflexive memos [22] to document personal assumptions or theoretical leanings; these memos were revisited throughout data analysis to encourage ongoing reflection on how our backgrounds might shape interpretations.

In addition, we created an audit trail [29] that outlined key decisions made during coding and theme development. This trail included records of coding updates, consensus discussions, and rationale for code merging or splitting, providing a transparent account of how the analysis evolved. By combining triangulation, reflexivity, and rigorous documentation, we sought to strengthen the trustworthiness of our findings and facilitate replicability of the study's analytic approach.

Ethical Considerations

The primary study and this secondary analysis received approval from the Cincinnati Children's Hospital Institutional Review Board, which granted a waiver of documentation of informed consent in accordance with 45 CFR 46.116(d). This waiver was permissible because the research posed no more than minimal risk to participants, did not compromise their rights and welfare, could not be feasibly conducted without the waiver, and would provide subjects with additional relevant information after participation, when appropriate. Given its educational focus and the absence of risk to participants, the study met these criteria. Participation in the simulations was voluntary, with no compensation provided. All data on participant performance were stored securely on a password-protected server.

Results

Overview

The ethnographic analysis was conducted on the recordings of 15 interprofessional teams of 2 users (a nurse and a physician) who completed the VR simulation. The simulations were recorded from both the perspective of the nurse and the team lead. This analysis revealed 3 major themes and associated subthemes that offer insights into the interplay between simulation modality and participant attention and behavior (Table 1).

Table . Ethnographic analysis results.

Themes, subthemes, and their examples	Illustrative descriptors and quotes
Source of Truth	
Initial reliance on virtual cues	
Observing movements	• The nurse and team lead observe the virtual patient swatting at the team with his hands and struggling to breathe. The nurse states, "Pending a [blood gas to confirm], we are probably looking at assisting ventilation one way or another." [N11]
Mental status	• "Quick cardiopulmonary assessment–His mental status is down; his airway is open. I need to take a listen to him, but I can see him breathing, cap refill is about 3 - 4 seconds, he looks like crap… I am thinking shock, likely sepsis." [P8] • "Timmy? HELLOO?" Meanwhile, the team lead Interacts with the virtual patient's foot and then performs a sternal rub. [P6]
Linking physical examination to clinical progression	• After evaluating the patient, the team lead states, "Airway seems to be ok. He seems to be a little more alert." Asks the virtual patient, "How you doing buddy?" The team lead taps on that patient's chest, and while sounding stressed, says, "He isn't responding." As the virtual patient starts to respond, the team lead sounds calmer. [P13] • Team lead says the virtual patient has bounding "femoral" and "jugular" pulses as he palpates them sequentially. [P2]
Dynamic reliance based on response	
Increasing reliance on the cardiopulmonary monitor when the examination does not change as expected	• "[After receiving fluid, the] blood pressure is still a little low, so that may be the cause of his tachycardia, but he also has fever, so…(provider does not finish sentence)." [P5] • Midway through the simulation, the team lead notes that the patient still has poor perfusion and is still working hard to breathe. He recognizes that about half of the fluid bolus is in, yet the patient has not improved. He then turns to the monitor, remarking on the tachycardia and hypoxemia. He asks for vancomycin to be added while staring at the monitor. [P10]
Cognitive Focus	
Task burden and scenario complexity	
Synthesizing large amounts of information quickly	• Team lead listens to the lungs, looks at the monitor, and states, "He looks kind of like ass... why is his face purple?" [P3] • After giving a fluid bolus, the team lead reports, "His heart rate is trending down nicely." [P5] • The nurse responds, "His perfusion in his hands is 3 - 4 seconds." [N5] • The team lead leans over the virtual patient and watches the cap refill animation.
Transitioning from interpretation to action	• "He looks sick, he is a little cyanotic...can you put oxygen on him?" [P13] • The team lead requests, "septic workup stuff." Quickly asks for several interventions, and then asks the nurse for suggestions. [P8]
Cognitive demands as an unexpected consequence of simulation modality	
Completing examination in VR[a]	• The team lead reaches for the stethoscope on the table so she can listen to the lungs. She struggles initially to grab it, but quickly figures it out. She then moves the stethoscope to the virtual patient but struggles to use it in the VR environment. Meanwhile, communication between the nurse and team lead stops while the team lead is task-burdened with learning how to perform an assessment of the lungs in the VR environment. [P4]

Themes, subthemes, and their examples	Illustrative descriptors and quotes
Completing interventions in VR	• The team lead asks the nurse to give the patient a fluid bolus. The nurse moves to follow the order and realizes that she does not know how to perform the action in the VR environment. The facilitator then proceeds to walk her through the process. [N10]
Fidelity Breakers	
Navigational challenges	
Unintended teleportation	• The team lead puts the headset on but finds himself in the ceiling of the virtual environment. He attempts to correct but ends up in the floor, spending several moments trying to get in the correct position. [P13]
Trouble walking	• The team lead accidentally teleports to a different location in the room, but is able to quickly get back to her original location without assistance. [N9]
Interaction challenges	
Applying interventions to patient	• The team has accidentally taken off the mask while attempting a sternal rub. The entire team is discussing how to get the mask back on and struggle to get it appropriately positioned. The facilitator interrupts, acknowledges the attempt to place the mask, and instructs the team to move on as if the mask has been applied. [P11]
Triggering animations	• The team is struggling to get the capillary refill animation to trigger. At first the nurse attempts and is unable, then the team lead then joins. Together, they spend 140 seconds trying to trigger the capillary refill animation in several locations—the foot, the hand, and the sternum. Meanwhile the virtual patient has globally poor perfusion, low blood pressure, and tachycardia, which is not addressed because the team is stuck on trying to trigger the animation. [P8, N8]

[a]VR: virtual reality.

Theme 1, Source of Truth, outlines the hierarchy of informational sources for participants analyzing clinical scenarios, including subthemes related to initial reliance on virtual cues and dynamic reliance based on responses. Theme 2, Cognitive Focus, describes the interplay between thinking, communicating, and doing, with subthemes of dynamic task burden based upon scenario complexity and the cognitive demands of the virtual environment. Theme 3, Fidelity Breakers, explores moments where the boundary between real life and simulation becomes most pronounced, leading participants to deviate from their typical behavior in real-life encounters. Subthemes within this theme relate to navigational and interactional challenges.

Theme 1: Source of Truth

Participants face novel challenges in a VR medical simulation that they may not have encountered in previous traditional simulation experiences. They are immersed in a completely virtual environment, with real-world objects replaced with digital replicas. This immersion requires participants to reorient themselves to the virtual room and their ability to move and interact within it. We gained insights into how participants navigate this new environment and identify reliable sources of information to guide their actions within the simulated medical case.

Subtheme 1.1: Initial Reliance on Virtual Cues

The VR environment offers a visually realistic virtual patient within a replicated clinical environment. This immersive environment replaces the real world with a digital replica, requiring participants to acclimate briefly before focusing on dynamic elements within the room. As participants acclimated to the virtual environment, their focus aligned to three major sources of information: (1) the virtual manikin, (2) the cardiorespiratory monitor, and (3) other participants in the same simulation.

After orientation to the VR environment, participants consistently prioritized soliciting data from the virtual patient. This early prioritization was evident in their frequent comments on the patient's movements, mental status, and perfusion. The recorded first-person perspective showed that participants spent the majority of their time looking at the patient.

Subtheme 1.2: Dynamic Reliance Based on Response

Though initially focused on the virtual patient, participants did use the cardiorespiratory monitor as a secondary source of information. They checked the monitor periodically for brief durations; however, this behavior changed when the patient's response to interventions deviated from expectations. For example, if the virtual patient's perfusion did not improve after administration of a fluid bolus, participants shifted to a heavier reliance on the monitor readings, potentially discounting some

qualitative physical examination cues in favor of objective data. In such cases, participants became more reliant on the monitor readings, devoting greater attention for extended periods. This shift suggested a transition from using the monitor for confirmation to using it as a primary source of information guiding decision-making.

When both the patient's presentation and the monitor readings deviated from expected responses to interventions (eg, no immediate improvement in perfusion or heart rate after an intravenous fluid bolus), participants would collaborate to review the case. When working together, participants made decisions based on a combination of group consensus, individual opinions, and real-life clinical algorithms applicable to the context of the simulation (ie, treatment of pneumonia or sepsis). Nonverbal communication was limited due to simulation constraints. Only the participants' virtual hands and glasses (corresponding to their headset orientation) were visible in the simulation, and thus participants could not assess eye contact or body language as markers of consensus or concern, which is a major deviation from real-life interactions.

If no alternative explanation existed for the perceived incongruity, the participant might seek clarification from the facilitator as the final source of objective data, ranging from asking for clarification on the VR simulation's functionality to attempting to draw the facilitator into the clinical scenario as an additional participant.

Theme 2: Cognitive Focus

Participant attention is finite, and the dynamic interplay between the VR environment and participants' cognitive load unfolded during the simulated scenario. By introducing an entirely virtual world and placing participants in it, VR introduces unique features that may impact the cognitive load and task burden placed upon the participant [30,31]. We observed how the virtual environment affected participants' ability to process information, make decisions, and execute actions within the simulation. These effects occurred both as an intentional part of the design and as unintended consequences of the VR simulation's technical limitations.

Subtheme 2.1: Task Burden and Scenario Complexity Dynamically Influenced Cognitive Demands

In the initial phase of the simulation, participants faced a high cognitive load as they synthesized the clinical situation while simultaneously familiarizing themselves with the complexities of the VR environment. Participants needed to integrate information from multiple sources: the virtual patient's visual presentation, physiological data displayed on the monitor, and communication with other team members. As noted in Theme 1, participants initially focused heavily on the virtual patient and the data it provided to anchor their navigation of the clinical scenario.

As the scenario progressed, a critical shift in cognitive demands occurred. The focus transitioned from understanding the patient's condition to taking decisive actions. Participants needed to execute physical assessments, such as auscultation and capillary refill checks, alongside tasks that included applying supplemental oxygen and initiating intravenous fluid resuscitation. This transition, in many cases, aligns with the natural progression of patient care, moving from initial assessment to formulating and implementing a treatment plan.

Subtheme 2.2: Cognitive Demands as an Unexpected Consequence of the Virtual Environment

Cognitive demands as an unintended consequence of the virtual environment (ie, additional demands due to unique VR functionality that differs from real life) impacted participant experience at times. When virtual tasks differed substantially from their real-world counterparts in terms of complexity or intuitiveness, participants appeared to experience increased task burden. We inferred this increased task burden primarily through observed behaviors, such as repeated attempts to perform a task, expressions of frustration, or prolonged fixation on a single action. Certain actions, such as administering a fluid bolus, were intentionally simplified for VR programming feasibility, as it was seen as outside the stated objectives of the training exercise. However, this simplification created a discrepancy from real-world procedures. Experienced nurses, accustomed to a specific bolus administration technique, appeared frustrated by the VR version. This frustration led to disproportionate task fixation on what would otherwise have been a rudimentary task for the team, resulting in excessive focus on technical skills that may have impeded uptake of the simulation's core learning objectives.

Theme 3: Fidelity Breakers

Factors intrinsic to the VR environment appeared to challenge participant immersion and disrupt their sense of "being there." These disruptions, termed Fidelity Breakers, appeared to break participants' engagement with the simulation and shift their focus from clinical reasoning to technical troubleshooting. The identified Fidelity Breakers fell into the 2 main categories of navigational challenges and interactional challenges.

Subtheme 3.1: Navigational Challenges and Learner Adaptations—Limitations in Movement Within the Virtual Space

Participants began each session positioned at the foot of the virtual patient's bed. Given their starting positioning relative to the patient and the equipment, participants universally tried to move around the room to complete a physical examination or use equipment. However, limitations in the VR system at times disrupted these efforts. Several instances of unintended teleportation were observed: rather than smoothly walking to their desired location via the hand-held controller, participants would inadvertently press a button that transported them to an unintended spot—sometimes on the opposite side of the bed or even partially on top of the patient (refer to Table 1, Fidelity Breakers). Such abrupt relocations caused noticeable confusion and delays while participants struggled to reposition themselves.

As a workaround, several participants elected to lean or reach instead of fully reteleporting to examine the patient more closely. Although this approach facilitated some aspect of examination, it also compromised realism by limiting participants' freedom to perform typical bedside maneuvers—such as placing a stethoscope on the chest or palpating a pulse—which would otherwise be straightforward

during an actual patient encounter. Conversely, some participants became completely fixated on these limitations and spent an outsized amount of time just trying to move around the room, rather than participating in the simulation.

Subtheme 3.2: Interaction Challenges—Difficulties Interacting With the Virtual Patient or Equipment

Interactions with the virtual patient and equipment at times appeared to challenge the authenticity of the simulation. Some key examination maneuvers were difficult for participants to perform in VR. For instance, some participants experienced collision detection problems when interacting with the patient. An example includes attempts to apply a supplemental oxygen mask to the virtual patient, which would sometimes accidentally pass through the face (clipping) or fail to trigger the animation altogether. This deviation from real-world actions hindered the intervention and assessment process. Reliance on VR controllers for interactions, as opposed to one's hands, additionally presented participants with a learning curve that occasionally led to repeated difficulties performing core physical examination skills. A prime example was the challenge of triggering the capillary refill animation, a vital step in evaluating the patient's hemodynamic status. In some cases, participants became fixated on manipulating the controllers to achieve this specific action, neglecting other aspects of the simulation for several minutes.

Discussion

Principal Findings

This study identified 3 major themes regarding the impact of a headset-based VR simulation on participant attention and behavior. VR was found to influence participants to rely primarily on the virtual patient for clinical data and decision-making; however, the participants' reliance on "Theme 1: Source of Truth" shifted to the cardiorespiratory monitor when the expected patient response to interventions did not occur. In addition, learner behaviors in the VR environment closely reflected the natural progression of patient care, moving from initial assessment to formulating and implementing a treatment plan, allowing closer approximation of the "Theme 2: Cognitive Focus" experienced during clinical care. Finally, participants faced navigational and procedural challenges that were "Theme 3: Fidelity Breakers," skewing participant attention to the simulation's technical details rather than the intended learning objectives.

Participant Reliance on Patient-Centered Data

Practicing medicine in a completely virtual environment is an unfamiliar experience for most medical staff and can be disorienting. In this constructed environment, participants primarily relied on the patient examination as their source of objective data, with focus shifting to the cardiorespiratory monitor only when the virtual patient did not respond as expected to interventions. This grounding of the patient as the center of the simulation, as opposed to a primary reliance on ancillary data, represents a key potential benefit of VR training—reinforcing the patient examination as central in the practice of medicine. Although these observations suggest that VR might help draw learners' attention to direct patient cues, this conclusion is tentative without a direct comparison to other simulation modalities. While VR could reinforce the patient examination as central in the practice of medicine, further research should verify whether this pattern is unique to VR or equally present in other simulation approaches.

Limitations of the VR Environment for Procedural Training

Though participants focused on the patient examination, this examination was at times limited. Due to the unique learning curves and inherent technological limitations for movement within the environment and physical manipulation of the patient and equipment, participants often relied primarily on audiovisual cues. In addition, technological glitches causing accidental teleporting and clipping resulted in participants electing to limit their movement around the room, favoring leaning and reaching over moving around the environment, as highlighted through the examples listed in Table 1, Fidelity Breakers. These challenges and resultant learner adaptations suggest that VR might have limitations for learning objectives focused on examination maneuvers or procedures requiring "hands-on" skill development. Until there is no need for technical workarounds or deviations from reality to perform skills in VR, as observed in this study, experience with these tasks in VR may not support skill acquisition that can be directly applied to real-life clinical care. In addition, the cognitive load added by navigating these workarounds may distract from or prevent the acquisition of other learning objectives. Alternatively, these skills may be better learned, practiced, or assessed with alternative modes of simulation, such as computerized manikin-based or AR-enhanced simulation, and thus specific studies examining specific skill acquisition in different modes of simulation are needed.

Task Fidelity and Cognitive Load Considerations

A virtual patient has the advantage of being able to portray a broad and realistic range of physical findings, as well as dynamic responses to therapy. However, inherent to VR is the requirement of creating digital content for the participant's entire field of view and expected actions—extending to the environment, equipment, and the interactions with said equipment. Though education and design teams can meticulously craft a virtual environment, any deviations from the real-world environment risk distracting the participant from the primary objectives of the training exercise. This dissonance extends from observable deviations from the real world to divergences in how to perform tasks. Although this VR simulation was designed to focus on recognizing and treating shock, participants were at times distracted by activities outside of that direct focus, such as needing to relearn how to administer a fluid bolus in VR. This intervention was intentionally simplified to reduce the technical learning curve of the simulation, but this simplification had the unintended effect of distracting the learners from the primary focus of the simulation. Future work might explore balancing necessary simplifications with realistic task fidelity to minimize extraneous cognitive load in VR.

Interface-Specific Training Requirements

VR-based simulation demands additional orientation and training that differ from what is typically provided in manikin-based scenarios. Because certain actions—such as administering a fluid bolus in this scenario (refer to Table 1, N10)—are not replicated 1:1 from real-life procedures, participants must allocate some cognitive load to learning the VR mechanics. This interface-based burden can divert attention from the core clinical objectives, underscoring the importance of structured, VR-specific training sessions before learners engage in complex clinical tasks, and considering these extraneous loads when targeting specific learning objectives.

Communication and Team Dynamics

Decision-making when treating critical illnesses must be quick to be effective. In VR simulations, team leads made decisions based on a combination of group consensus, individual opinions, and real-life clinical algorithms. Group discussions were frequent, and team communication dynamics appeared to significantly impact decision-making. The VR scenarios included only two participants (plus a facilitator), making decision-making conversational. However, nonverbal communication was limited for this VR simulation, as only participants' virtual hands and glasses were visualized, which limited assessment of body language and eliminated the ability for eye contact. For this specific VR simulation, the modality encouraged verbal communication around shared observations and findings but lacked feasible options for nonverbal communication. While this reliance on explicit verbal communication may facilitate clarity in certain respects, we cannot determine whether it is more frequent or effective than in traditional simulations without further comparative research. Finally, despite the presence of ongoing communication, individual parallel assessments continued, suggesting that participants processed information independently. A more complex environment or scenario, with potentially a larger team of clinicians and staff, might result in different communication dynamics than what we observed. Assessing the attention and behavior of larger teams in more complex clinical contexts represents key future work for our team.

Limitations

While our study sheds light on important aspects of VR training for pediatric resuscitation, several limitations warrant consideration. First, the data originated from a single institution over a limited timeframe, encompassing only 15 simulations. While this sample size is relatively small, the participants represent a significant portion of the pediatric resuscitation team at a major academic medical center, potentially fostering generalizability to similar institutions. In addition, data saturation was achieved after analyzing 15 scenarios, indicating that further analyses would not likely yield novel findings. Second, the focused ethnography approach involves inductive analysis, meaning the researchers' experience and expertise are inherently woven into the methodology. This strengthens the analysis by adding depth and richness to the conclusions drawn. Notably, the research team was purposefully assembled to leverage their expertise in simulation and resuscitation, allowing them to inject diverse perspectives into data analysis and enrich the interpretation of findings.

However, this methodological approach lacks a direct comparator or control group. Because our objective was to describe behaviors in a previously unexamined context, fully immersive VR, we did not measure change from a standard baseline (eg, manikin-based or live simulations). This limitation was partially mitigated by providing rich, context-specific observations from multiple angles, coupled with cross-disciplinary analyst triangulation. Future studies may build on these findings by including mixed method comparisons across different simulation platforms to quantify how VR might augment or hinder specific learning objectives. In addition, there is currently no literature that describes the focus of interdisciplinary teams during real-life clinical care—a key future direction for our team to enhance our ability to align participant behaviors during simulation with those expected during real life.

Finally, this study used a single VR scenario, and thus the conclusions drawn must be considered in relation to the specific technical design and functionality of that scenario. However, while there are a range of VR systems and approaches at various stages of development and availability, the foundational principles of navigating and interacting in a virtual world are likely similar across platforms. As VR technology advances, limitations in movement within the virtual space may be resolved. For example, wireless head-mounted displays allow for easier movement in the VR space by untethering users from stationary computers. Yet even at its best, VR can only approximate—rather than fully replicate—the fidelity of genuine hands-on, kinesthetic practice. Further research can help clarify how these core elements influence participants' clinical reasoning, teamwork, and skill acquisition, enabling educators to better tailor VR-based simulations to specific learning objectives.

Conclusions

The conclusions drawn from this study provide a comprehensive understanding of how a VR-based simulation may influence participant attention and behavior, revealing both strengths and limitations of this training modality. Our findings indicate that VR simulations create a unique environment where participants predominantly rely on virtual patient assessments and audiovisual cues. This setup prioritizes patient-centered data over ancillary information, fostering focused clinical decision-making. However, the constraints of VR, such as limited physical interaction and navigational challenges, can impact the authenticity of the training experience, suggesting that VR may be better suited for clinical assessment or cognitive objectives over physical skill–based objectives.

As the landscape of SBME evolves, it is crucial to recognize the potential and limitations of VR simulations compared to other modalities. The ability to create a fully immersive, yet controlled, environment offers significant training advantages for objectives that focus on rapid decision-making and patient assessment. Nevertheless, the technological constraints that limit physical interactions highlight the persistent need for complementary simulation modalities, such as AR and

computerized manikin-based simulations, which may better support hands-on skill development. Next steps include the delineation of how the growing armamentarium of simulation modalities and tools can be optimally leveraged to best train a broad range of clinical skills.

Acknowledgments

We would like to acknowledge the Laerdal Foundation for its funding contribution to this research. All the authors are responsible for this manuscript and have participated in the conceptualization, drafting, or revision of the manuscript and have seen and approved the final version submitted. This study was funded, in part, by project support from the Laerdal Foundation. Matthew Zackoff received previous project support through the Place Outcomes Research Award Program at Cincinnati Children's Hospital Medical Center to create the video dataset analyzed in this study.

Data Availability

The datasets generated and analyzed during the study are not publicly available due to the video consent, which stipulates that the collected videos cannot be used outside the current research study, and because individual participant identifiers are included in the field notes. The datasets are available from the corresponding author on reasonable request.

Authors' Contributions

Abstract

Background: Discussing weight remains a sensitive and often avoided topic in health care, despite rising prevalence of obesity and calls for earlier, more compassionate interventions. Many health care professionals report inadequate training and low confidence to discuss weight, while patients often describe feeling stigmatized or dismissed. Digital simulation offers a promising route to build communication skills through supporting repeatable and reflective practice in a safe space. VITAL-COMS (Virtual Training and Assessment for Communication Skills) is a novel simulation tool designed to support health care professionals in navigating weight-related conversations with greater understanding and skill.

Objective: This study aimed to assess the potential of VITAL-COMS as a digital simulation training tool to improve weight-related communication skills among health care professionals.

Methods: A mixed-method feasibility study was conducted online via Zoom (Zoom Video Communications) between January to July 2021, with UK-based nurses, doctors, and dietitians. The intervention comprised educational videos and 2 simulated patient scenarios with real-time verbal interaction. Pre- and posttraining self-assessments of communication skills and conversation length were collected. Participants also completed a feasibility questionnaire. Descriptive statistics were used to analyze the feasibility questionnaire, and open-ended feedback was analyzed using content analysis. Paired-samples *t* tests were used to assess changes in communication skills and conversation length before and post training.

Results: In total, 31 participants completed the study. There was a statistically significant improvement in self-assessed communication skills following training (mean difference=3.9; 95% CI, 2.54 - 5.26; t_{30}=−5.76, *P*=.001, Cohen *d*=1.03). Mean conversation length increased significantly in both scenarios: in the female patient scenario, from 3.73 (SD 1.36) to 6.08 (SD 2.26) minutes, with a mean difference of 2.35 minutes (95% CI, 1.71 - 2.99; t_{30}=7.49, *P*=.001, Cohen *d*=1.34); and in the male scenario, from 3.61 (SD 1.12) to 5.65 (SD 1.76) minutes, a mean difference of 2.03 minutes (95% CI, 1.51 - 2.55; t_{30}=8.03, *P*=.001, Cohen *d*=1.44). Participants rated the simulation positively, with 97% (95% CI 90% - 100%) supporting wider use in health care and 84% (95% CI 71% - 97%) reporting emotional engagement. Content analysis of feedback generated two themes: (1) adapting to this form of learning and (2) recognizing the potential of simulation to support reflective, skills-based training. A minority, 13% (95% CI 1% - 25%) expressed a preference for alternative learning methods.

Conclusions: VITAL-COMS was feasible to implement and acceptable to a diverse group of health care professionals. Participants demonstrated significant improvements in self-assessed communication skills and patient-scenario engagement. The simulation was perceived as realistic, emotionally engaging, and well-suited for training in sensitive conversations. These findings support further development and integration of VITAL-COMS into health education programs. Next steps include the translation of the insights identified in this study to inform a tool supported by generative artificial intelligence.

Introduction

Obesity is a leading contributor to chronic disease and reduced quality of life [1,2]; yet, weight remains a sensitive and often avoided topic in clinical settings [3,4]. Despite national and global policy goals and clinical guidelines calling for earlier, more compassionate intervention [5-7], many health care professionals (HCPs) report inadequate training, lack of confidence, and fear of damaging the patient relationship when discussing weight [8-11]. Patients, in turn, often describe feeling stigmatized, misunderstood, or dismissed when seeking support for weight-related concerns [12-15] Addressing this training gap requires more than knowledge transfer—it requires practical, reflective skills development in how to talk about weight [16-18].

Digital or virtual simulation offers a flexible and scalable route to delivering communication skills training [19-21]. Simulation-based training enables learners to rehearse conversations in a safe environment and build confidence through repetition, feedback, and debrief [22]. When designed with behavioral science and communication theory, virtual simulations can foster the deeper understanding needed to engage patients with empathy and nuance [23-25]. For weight-related communication, where misalignment between HCP intention and patient perception is common [26-28], virtual simulation tools offer a safe space to surface and reflect on these tensions.

VITAL-COMS (Virtual Training and Assessment for Communication Skills) was developed to address the misalignments between HCPs and patients when discussing weight. The tool presents HCPs with simulated patient scenarios to practice sensitive, weight-related conversations, guided by principles from the COM-B (communication, opportunity, and motivation) model to support behavior change [23], Hargie's skilled interpersonal communication model [24], and the theory of deliberate practice [25]. The full development of VITAL-COMS is described elsewhere [26-32]. This study focuses on the preliminary findings of the feasibility study.

VITAL-COMS uses the Wizard of Oz (WoZ) method to control the simulated patient's responses. In this design technique, a human operator (FQ) manages the system's output to mimic intelligent responses that do not yet exist technologically [33,34]. WoZ allows designers to prototype complex interactions and gather authentic user feedback without the cost or limitations of fully developed artificial intelligence (AI) [35]. WoZ allows design ideas to be tested when the technology and AI do not yet exist or if it would take too much time or expense to explore a new idea. The virtual patient character in the simulator is operated by the primary author (FQ) using a WoZ controller designed for the simulation. In VITAL-COMS, this means tailoring verbal feedback from the virtual patient in real time to match the learner's communication, offering a high-fidelity, emotionally resonant training experience. More detail on the WoZ controller and how VITAL-COMS works can be found in Multimedia Appendices 1 and 2.

WoZ methods have been successfully used in health care education to simulate patient interactions, particularly where natural language, emotion, and timing are crucial [36]. This approach offers a flexible and iterative way to explore what kinds of digital communication training are most effective, while also revealing learners' needs and reactions [37]. As HCPs continue to navigate the challenges of supporting patients living with obesity, tools like VITAL-COMS provide a timely and evidence-based approach to addressing the training gaps.

Aim

The aim of this pilot feasibility study was to assess the potential of the VITAL-COMS digital simulation training tool to improve weight-related communication skills among HCPs.

Research Questions

This feasibility study addresses the following research questions Textbox 1:

Textbox 1. Primary and secondary questions.

Primary research question

- Does the VITAL-COMS (virtual training and assessment for communication skills) virtual simulator improve weight-related health communication skills?

Secondary research questions

- What is the perceived fidelity of the Wizard of Oz–based simulation from the participants' perspective?
- What is the perspective on VITAL-COMS leading to improvement in health care practice?

Methods

Design

A pre-post, mixed methods feasibility study was conducted to evaluate the viability of a virtual simulator designed to enhance weight-related health communication skills (VITAL-COMS). The study is reported following the CONSORT (Consolidated Standards of Reporting Trials) statement: extension to pilot and feasibility trials [38].

Technical Design

The VITAL-COMS virtual simulator was developed using the Unity 3D game engine (version 2019.3.5f). Development incorporated a suite of Unity's C# libraries to construct the user interface and implement speech simulation for the virtual patients. 3D character models were generated using Adobe Mixamo, and the Unity add-on components SALSA Lip-Sync, EmoteR, and Eyes were integrated to facilitate realistic speech articulation and emotional expression in the virtual patients. The tool comprised a pretraining stage of watching short educational videos on obesity science, weight-related communication, and weight stigma, then using the simulation tool (Multimedia Appendices 1 and 2).

Participants and Recruitment

This study used purposive and snowball sampling strategies to obtain a sample of 31 participants. This sample size aligns with recommendations for feasibility trials, which suggest total sample sizes ranging from N=24 to 50 [39]. The overall sample comprised both UK-based undergraduate and postgraduate allied health professionals and qualified doctors, nurses, and dietitians. Undergraduate and postgraduate students (n=2) were recruited via an email distributed by course directors at Ulster University. Targeted courses included undergraduate Nursing, Physiotherapy, Dietetics, and Occupational Therapy, as well as the MSc in Advanced Practice Nursing. Eligibility for participation was determined by enrollment in courses with curricula specifically addressing lifestyle factors related to the prevention, management, and recovery of ill health.

Qualified doctors, nurses, and dietitians (n=29) were recruited using purposive and snowball sampling. Eligibility for professional participants was contingent upon current practice within United Kingdom primary or secondary care settings and documented clinical experience in weight management counseling. Recruitment involved a social media advertisement posted on Ulster University's Twitter (currently known as X) and Facebook (Meta) accounts. The advertisement was subsequently disseminated through snowball sampling by tagging UK-based health care organizations and obesity charities. All participants provided informed consent before participation.

Procedure and Materials

Quantitative Data Collection

Upon obtaining informed consent, a participation date was arranged. Participants were subsequently provided with a secure, password-protected Zoom (Zoom Video Communications) meeting link via email before the scheduled session. Participants were invited to complete a brief demographic questionnaire, "About You." Participants also completed a self-reported knowledge assessment questionnaire on weight-related communication skills. The questionnaire was developed in relation to the existing literature and piloted with an advisory group (Multimedia Appendix 3).

The training intervention was delivered in 2 sequential parts, with participants offered the option of a brief break between sessions. In part 1, participants engaged in simulated consultations with 2 virtual patient scenarios, 1 male and 1 female. During these scenarios, participants interacted verbally with the virtual patient characters. In part 2, participants repeated the same scenarios, but with the addition of supplementary educational videos designed to enhance communication skills within each scenario (Multimedia Appendices 4 and 5). Following the completion of part 2, participants repeated the knowledge assessment questionnaire to evaluate potential changes in self-reported weight-related communication knowledge and skill levels. The temporal data associated with the primary author's activation of the WoZ controller buttons were recorded to facilitate an analysis of the author's controller operation during the simulated patient interactions.

The training concluded with a feasibility questionnaire, adapted from the technology acceptance model [40] and the digital simulation literature. Piloted and refined with the advisory group, it included yes or no items such as "I'd like to see this type of training used more in healthcare" and "I can see other uses for this type of training." Feasibility was assessed by calculating the percentage of "yes" responses.

Qualitative Data Collection

The feasibility questionnaire included one open-ended question, where participants were asked to add any other thoughts on the training.

Data Management and Analysis

Quantitative Data

Descriptive statistics were calculated for participant characteristics at baseline, including demographic data from the "About You" questionnaire, feasibility questionnaire responses, and WoZ controller button activation timestamps. All questionnaire data were collected online via the Qualtrics survey platform. To address the aims of the feasibility study, the primary focus was on descriptive data. However, exploratory significance testing using paired-samples *t* tests was conducted to evaluate within-group mean differences in weight-related communication skills between pre- and posttraining knowledge self-assessment responses. Data were analyzed using SPSS (version 28; IBM Corp, 2021).

Qualitative Data

Qualitative data from the open-ended feasibility questionnaire responses were analyzed using a systematic content analysis methodology [41]. The primary author initiated the analysis by familiarization with the textual data. A coding system was developed, informed by the initial patterns identified within the data. This coding scheme was then applied to code the data, facilitating the identification of recurrent themes and patterns.

The identified themes were reviewed with another author (LR) to ensure alignment with the raw data. Finally, these themes were interpreted to explain key participant perspectives and experiences.

Ethical Considerations

Ethical approval for this study was granted by the Ulster University Communications and Media Ethics Filter Committee in December 2020 (reference number: CMFC-20-012). Signed, written informed consent was obtained from all participants via email after they responded to study advertisements and confirmed eligibility. Participants completed the study in private settings of their choosing via Zoom. Data from the online Zoom meetings were transcribed from downloaded audio recordings and anonymized using participant identification numbers. All identifiable information was removed, and data were stored securely in password-protected files accessible only to the research team. No compensation was provided to participants.

Results

Overview

Participant attrition was observed during the feasibility study. Among student participants, a 33% dropout rate occurred between the consent and completion stages. For HCPs, a 68% attrition rate was noted from initial expression of interest via social media to the provision of informed consent. Among those HCPs who provided consent, 20% did not complete the study. Participant reports indicated that the COVID-19 pandemic significantly impacted their available time, contributing to attrition. In addition, some participants reported a perceived lack of content knowledge influencing their decision not to complete the study.

Participant Characteristics

A total of 31 participants, comprising a UK-wide cohort of male and female nurses, doctors, dietitians with varying levels of professional experience, and dietetic students from Ulster University, completed the feasibility study (Table 1). The sample was predominantly female (29/31, 94%) and exhibited a significant proportion of participants with over 10 years of professional practice (21/31, 68%).

Table . Characteristics of participants who completed the feasibility study.

Participant characteristics and professions		Participants, n (%)
Profession		
	Nurse	8 (26)
	Doctor	9 (29)
	Dietitian	12 (39)
	Student (dietitian)	2 (6)
Gender		
	Male	2 (6)
	Female	29 (94)
Years in practice		
	1 - 5	6 (20)
	6 - 10	2 (6)
	10+	21 (68)
	Student (dietitian)	2 (6)
Work area		
	Primary care	16 (52)
	Secondary care	9 (29)
	Other	4 (13)
Location		
	Northern Ireland	9 (29)
	Scotland	4 (13)
	Wales	2 (6)
	England	16 (52)
Previous training or experiences in weight management		
	Yes	19 (61)
	No	12 (39)
Previous experiences of eLearning simulations		
	Yes	8 (26)
	No	23 (74)

Descriptive Statistics

All dietitians (12/12, 100%) reported previous training in weight management. Few doctors (2/9, 23%) and 50% (4/8) of nurses reported training in weight management. Dietitians and nurses were more likely to have reported training in weight management than doctors. Students were less likely to participate in the study (2/31, 6%). Only 26% (8/31) of participants had previous experience with simulation-based learning. Most participants were from England (16/31, 52%), while the smallest proportion came from Wales (2/31, 6%).

Participants' usage time for the VITAL-COMS tool ranged from 18.1 to 41.4 minutes. The mean duration was 24.6 (SD 5.4, median 24.0) minutes. Most participants completed the tool within 20 to 30 minutes, though one participant took over 40 minutes, which may represent a mild outlier.

Inferential Statistics

A paired-samples *t* test revealed a statistically significant improvement in participants' self-assessed weight-related communication skills following training (t_{30}=−5.76, *P*=.001). Specifically, mean scores increased from 28.36 (SD 7.6) pretraining to 32.35 (SD 5.7) post-training, with a mean difference of 3.9 (SD 3.7; 95% CI 2.54 - 5.6). The effect size, as measured by Cohen *d*, was 1.03, indicating a strong effect. Doctors and nurses demonstrated the most substantial improvements, while dietitians showed the least.

Paired-samples *t* tests revealed statistically significant increases in conversation length following training for both the female (*P*=.001) and male virtual patient scenarios (*P*=.001). For the female scenario, the mean conversation length increased from 3.73 (SD 1.36) minutes pretraining to 6.08 (SD 2.26) minutes post training, representing a mean difference of 2.35 (SD 1.75, 95% CI 1.73 - 2.97) minutes. This increase was statistically

significant (t_{30}=7.49, P=.001) with a large effect size (Cohen d=1.34). Similarly, for the male scenario, the mean conversation length increased from 3.61 (SD 1.12) minutes pretraining to 5.65 (SD 1.76) minutes post training, with a mean difference of 2.03 (SD 1.41, 95% CI 1.53 - 2.53) minutes. This increase was also statistically significant (t_{30}=8.03, P=.001) and demonstrated a large effect size (Cohen d=1.44).

Fidelity of VITAL-COMS and the WoZ-Based Simulator

Following completion of the feasibility questionnaire, participants were invited to provide open-ended feedback on their experience with VITAL-COMS. Content analysis of the 84% (26/31) of participants who responded yielded two overarching themes: (1) "Getting used to this type of learning" and (2) "What this type of learning can do for people."

"Getting Used to This Type of Learning"

Participants generally reported positive reactions to the VITAL-COMS tool, though many noted an initial adjustment period. Some participants could immediately engage, while others found the lack of facial expression in the characters difficult to adjust to. Participants perceived a favorable balance between realism and learning stimulation, as illustrated by the comment

> *An enjoyable experience – enough verisimilitude to be meaningful and to stimulate learning, but not so real that it felt uncomfortable or threatening.* [Doctor, male]

This balance is referred to as effortful learning and is often a criticism of poorly designed eLearning content – that is, poorly designed digital learning does not challenge the user enough. Participants also reported initial feelings of awkwardness, stating, "It was very different to anything I have done before and I felt awkward, but if more used to it, I think it would be really useful" (Nurse, female). Despite this, the tool's overall effectiveness was consistently acknowledged.

"What This Training Does for People"

Participants reflected on who might benefit most from the tool, how the tool might help them to think and reflect, and the difference between this type of training and classroom-based training. Training for undergraduate students was mentioned frequently as a potential use for the tool. This seemed to be because it helped participants to practice sensitive conversations without the risk of failure in real life -

> *I think it is great to have this type of training as a "no risk" forum for practicing sensitive topics - the opportunity to do so has been limited to 'real life' where there is often more harm than good whilst people are upskilling.* [Nurse, female]

Mentions of reflection and making participants think were common from most participants. From the educational videos, the use of examples and good questions to ask was valued as a practical approach to engage with patients. The scenario-based learning approach and being able to try again seemed particularly helpful to prompt thinking and reflection,

> *Interesting to do this. Made me think about what I was saying and also already thinking about how I would respond differently again.* [Dietitian, female]

Comparisons between this type of virtual training and classroom training were drawn by many participants. Some felt that the addition of a facilitator for group discussions would add to the realism and ability to reflect. Participants suggested a combined or blended learning approach might be useful:

> *I think it would be good to have in combination with other training as we miss the emotional/ feelings and body language side which is important.* [Dietitian, female]

Participants' Perspective of the Feasibility Study

Poststudy feasibility questionnaire results indicated a predominantly positive reception among participants. Specifically, a substantial majority expressed a desire for increased usage of such tools within health care settings (97%, 95% CI 91% - 100%) and identified potential applications beyond the study context (97%, 95% CI 91% - 100%) Furthermore, 90% (95% CI 80% - 100%) of participants anticipated colleagues benefiting from the tool's implementation. Notably, 84% (95% CI 71% - 97%) reported experiencing emotional engagement during the simulation, suggesting a high degree of perceived fidelity in the learning experience. The use of simulated training for sensitive topics, such as weight management, was favorably received by 84% (95% CI 71% - 97%) of participants. While a majority (74%, 95% CI 59% - 90%) preferred scenario-based simulated learning for skills development, a minority, 13% (95% CI, 1% - 25%) expressed a general dislike for this pedagogical approach. In addition, 19% (95% CI 5% - 33%) indicated a preference for alternative learning modalities.

Discussion

Principal Findings

This study evaluated the feasibility and preliminary efficacy of VITAL-COMS, a previously developed and usability-tested weight-related communication training tool for HCPs. Participants demonstrated statistically significant improvements in self-assessed weight-related communication skills following training with VITAL-COMS. This was accompanied by a significant increase in the duration and engagement level of conversations with virtual characters. Specifically, doctors and nurses exhibited the greatest improvement, likely due to their comparatively limited previous formal training in this domain, while dietitians, who possess greater baseline expertise in weight-related communication, showed smaller, albeit still statistically significant, gains. These findings suggest VITAL-COMS is effective in enhancing both communication confidence and consultative engagement among health care professionals.

Most participants rated the training as realistic and appropriately challenging. Only 13% of participants reported disliking the training modality, and 19% expressed a preference for alternative learning approaches. Several participants suggested a blended model, combining simulator-based training with

subsequent peer or patient role-play. This highlights the importance of adaptable delivery formats to optimize engagement and satisfaction. The tool's real-time feedback functionality contributed to longer, more detailed conversations, demonstrating its potential for direct application in real-world clinical settings.

The observed lower levels of improvement among dietitians may reflect their pre-existing confidence and familiarity with weight-related communication. Consequently, future iterations of VITAL-COMS should incorporate more advanced content tailored to meet specific developmental needs of this professional group.

Low student participation, likely attributable to pandemic-related pressures, academic workloads, and hesitancy to engage with sensitive topics, was a notable limitation. This was corroborated by feedback from participating students. Future iterations could address this by integrating the training into course curricula, offering greater flexibility in scheduling, and providing novice learners with more comprehensive introductory guidance on navigating difficult conversations.

VITAL-COMS directly addresses common barriers to effective weight-related health care communication, particularly misalignment between HCPs' assumptions and patient needs. Through educational videos and real-time feedback, the tool facilitates the reduction of misunderstandings that can compromise communication quality. Posttraining feasibility questions and feedback interviews indicated that participants engaged in reflexivity, recalling previous patient interactions and identifying emotionally challenging encounters. This process is a recognized driver of behavioral change and quality improvement in health care [42,43].

Furthermore, the tool also addresses weight stigma by drawing participants' attention to the impact of weight stigma in the educational videos (Multimedia Appendix 5). Weight stigma is a well-documented barrier in clinical settings [4,7,16]. By foregrounding patient experiences and modeling empathetic communication, VITAL-COMS aims to mitigate patient anticipation of judgment or internalized weight stigma, both of which contribute to disengagement in weight-related care [44,45].

Implications of Findings

The VITAL-COMS training offers a precision-based approach and nuanced approach to weight-related communication training, moving beyond traditional weight management messaging such as "eat less, move more." By fostering the exploration of complex etiological factors contributing to weight gain, including biological, environmental, and psychosocial determinants, VITAL-COMS facilitates a more individualized and respectful patient-centered dialogue. This approach aligns with national and international health policy initiatives, such as the NHS (United Kingdom) health service long-term plan [46] and other international guidelines and calls to action [47-49], which emphasize the importance of enhanced nutrition and weight stigma education among health care professionals. VITAL-COMS supports these objectives by promoting in-depth patient discussions encompassing eating behaviors, appetite regulation, stress management, and sleep hygiene. Furthermore, the tool's inherent adaptability allows for future customization, including scenario diversification and integration into broader health care curricula.

Although most participants completed the VITAL-COMS tool within 20 - 30 minutes, one participant spent over 40 minutes using it. This longer duration likely reflects individual variation in communication style and clinical practice. In this case, the participant was an experienced dietitian working in secondary care, where consultations may be longer and more complex. Compared to others, the participant incorporated more patient-centered techniques, including taking a detailed weight history and using more open-ended questions to explore the patient's perspective. This suggests that while the tool is generally time-efficient, practitioners with more in-depth communication approaches or working in specialist settings may require additional time. It highlights the flexibility of VITAL-COMS to adapt to different clinical styles and patient needs, rather than being a rigid script.

The observed minority of participants who expressed negative feedback regarding the training modality mirrors findings from other studies evaluating digital simulation and virtual reality-based interventions, where user preferences and technological comfort levels exhibit heterogeneity. As demonstrated by Chang et al (2023) [50], perceived ease of use and digital confidence significantly influence the acceptance and usage of simulation-based training tools. This observation is consistent with the technology acceptance model [40], which posits that perceived usefulness and usability are critical determinants of technology adoption. Consequently, the implementation of hybrid learning models that integrate digital and interpersonal learning strategies may enhance engagement and satisfaction across diverse learner profiles.

Comparison With Previous Work

VITAL-COMS represents a novel, skills-based, communication-focused digital simulation tool specifically designed, tested, and evaluated for weight-related conversations. This innovation builds upon the growing body of research demonstrating the efficacy and acceptability of virtual character or virtual human interventions in health care communication training [51-53]. The scalable, immersive, and interactive nature of VITAL-COMS aligns with recent advancements in this area. Ryan et al (2024) [53] established a behavioral framework delineating essential training needs for health care professionals in weight-related communication and obesity science, many of which were also evident in the design of VITAL-COMS. However, VITAL-COMS distinguishes itself through its robust training needs analysis [30,31] and nuanced approach to modality (instructional videos, repetition, and guided feedback) and evaluation. This comprehensive methodology facilitates a more targeted and effective learning experience compared to recent progress.

Significant gaps remain in scalable weight-related communication skills training, particularly given the urgent need to address the rising prevalence of obesity [54,55]. This is shown through the current most available digital learning approaches as they often exhibit limitations in their scope and

delivery. For instance, Logue et al [56], 'Small talk, big difference' intervention, while grounded in the COM-B behavioral theory, provided only a single one-hour online session and lacked opportunities for practical skill development and reflective learning. Similarly, the INTERACT study in Germany [57], which incorporated eLearning and motivational interviewing content, failed to demonstrate sustained improvements in key patient outcomes. In contrast, VITAL-COMS emphasizes experiential learning through practice, repetition, and reflection. Developed using the Unity 3D simulation platform, VITAL-COMS facilitates ongoing development of nuanced communication strategies and allows for adaptability to a wider range of patient scenarios. This focus on experiential learning represents a significant advancement in equipping health care professionals to address weight stigma and engage in sensitive weight discussions with confidence. Comparative platforms such as the Royal College of GPs' obesity hub [58] and the global SCOPE training program [59] offer valuable educational material. However, these platforms typically lack immersive and interactive components. The inclusion of hands-on, realistic role-play with VITAL-COMS distinguishes it from these existing resources, thereby enhancing its potential for impactful translation into clinical practice.

Strengths and Limitations

The limited sample size, combined with recruitment challenges among students, likely exacerbated by the COVID-19 pandemic and the sensitive nature of the training topic, constrains the generalizability of the findings. Furthermore, while the communication self-assessment tool demonstrated preliminary promise, it requires further validation against established competency frameworks. The reliance on self-report measures, while common in communication skills training, introduces recognized limitations associated with subjective reporting bias. To mitigate potential inconsistencies arising from human facilitation, a recognized limitation of WoZ methodologies, the research team implemented a rigorous protocol to standardize instructions and ensure a consistent participant experience. This approach adhered to core principles of WoZ design experiments. Nevertheless, the potential for residual variability in human facilitation remains a consideration when interpreting the study's findings.

Future Work

VITAL-COMS, as an advanced prototype, used a WoZ methodology to simulate real-time natural language interaction with virtual patient characters, a functionality that was not readily available at the time of development. The findings of this feasibility study provide valuable insights for the potential integration of emerging technologies, such as generative AI chatbots, which now offer real-time natural language interaction and feedback capabilities. These advancements present a promising alternative to the WoZ approach, potentially enabling broader and more scalable training delivery. Furthermore, the feasibility of automated AI-driven assessment should be explored in future iterations of VITAL-COMS, addressing the inherent limitations associated with self-report assessment measures. Future development of VITAL-COMS includes expanding the range of characters and scenarios, adapting content for different health care settings and professional groups, incorporating advanced technologies, and ultimately, informing the development of the next iteration of the VITAL-COMS prototype driven by generative AI.

Conclusion

This study found that VITAL-COMS was acceptable to a diverse group of HCPs and it improved weight-related communication skills. While most participants were enthusiastic about the real-time simulation, some also recognized its potential value when used alongside more traditional learning methods. Further development is needed to tailor the training to different professional groups. The findings from this study will be used to inform the next iteration of the VITALS-COMS communication skills training tool driven by generative AI.

Acknowledgments

The authors wish to acknowledge the contribution of the study advisory group whose input was invaluable in the design of the training tool VITAL-COMS. We also wish to thank the study participants who provided their valuable time to take part in the feasibility study.

This study was funded as part of a PhD by the Department for the Economy Northern Ireland.

Abstract

Background: Virtual reality (VR) has emerged as a promising tool in medical education, particularly for fostering critical skills such as empathy. However, how VR, combined with perspective-taking, influences affective empathy in nursing education remains underexplored.

Objective: This study investigates the influence of VR and perspective-taking on affective empathy in nursing education, focusing on 4 psychological factors: perceived self-location, narrative transportation, emotional engagement, and affective empathy.

Methods: A 2×2 between-subjects design was used, involving 69 nursing undergraduates from two Midwest universities. The participants engaged with a narrative-focused video game, That Dragon, Cancer, in either VR or non-VR conditions and from the perspective of either parents or clinicians.

Results: VR significantly enhanced perceived self-location (*P*=.01), while adopting a clinician's perspective amplified emotional engagement (*P*=.03). However, VR did not significantly influence narrative transportation (*P*=.35). An interaction effect was found between the platform and player's perspective on narrative transportation (*P*=.04). Several indirect effects of media elements on affective empathy were observed via other psychological factors, though the direct effect of VR on affective empathy was not significant (*P*=.84).

Conclusions: These findings underscore the potential of VR in medical education, suggesting that perspective-taking should be carefully considered when designing immersive learning experiences. The study advocates for broader integration of VR technologies into medical curricula to enhance instruction quality and patient-centered care.

nursing education; narrative transportation; presence; virtual reality; game-based learning; affective empathy

Introduction

Background

The domain of health care education is currently undergoing a monumental shift, facilitated by advancements in immersive technologies such as virtual reality (VR). Immersive technologies have demonstrated significant potential in transforming medical and health education, including enhanced training in surgical procedures [1,2], improved understanding of complex biomedical processes through immersive visualization [3,4], and more empathetic patient care through simulated patient interactions [5,6]. Despite its promise, VR technology faces challenges such as system fidelity and presence, which can impact user experience and learning outcomes [7]. Addressing these challenges is essential for the effective design and implementation of VR training modules.

Moreover, VR provides a safe and controlled environment for students to practice and make mistakes without direct consequences on actual patients, increasing their confidence and proficiency before real-world clinical scenarios [8,9]. Concurrent with this paradigm shift, immersive technologies like VR have emerged as an effective tool in the instruction of empathy among nursing students [10-12]. Empathy, being a fundamental aspect of the nursing profession, has been shown to improve patient adherence to treatment plans [13], satisfaction levels [14], and overall health outcomes [15]. Specifically, being

immersed in virtual narratives allows students to navigate and process their own emotions, as well as respond appropriately within simulated scenarios [16]. This innovative approach offers a safe space for students to handle the emotional complexities associated with patient care, thus better preparing them for future clinical encounters involving nuanced emotional interactions.

VR simulation has also been studied in the context of nursing education [17-21]. In our recent study [22], we found that VR-based role-playing games enhanced cognitive empathy among nursing students. However, affective empathy remains underexplored in VR-based nursing education. Cognitive empathy involves understanding another's perspective, whereas affective empathy refers to sharing and responding to another's emotional states [23]. A recent meta-analysis revealed that VR has a significant effect on perspective-taking outcomes (cognitive empathy) but lacks impact on affective empathy [23]. Therefore, the objective of the current research is to investigate the potential of VR to influence affective empathy among nursing students by exploring narrative-related psychological factors.

Research on immersive media indicates that perceived self-location (ie, being there in a virtual environment) is a key mechanism that explains the impact of VR on empathy [24,25]. VR-based empathy training programs often contain a story with plots and characters to help users experience a situation first-hand [26]. They comprise both medium-based (ie, of the virtual environment) and message-based (ie, of the narrative) elements [27].To understand how VR might enhance affective empathy, we explore specific psychological mechanisms: perceived self-location and narrative transportation.

Perceived self-location refers to the sensation of "being there" in a virtual environment, enhancing users' immersion and empathy [24,25], which we hypothesize will lead to greater empathy by allowing users to more deeply understand and share the feelings of virtual characters. Narrative transportation is the cognitive and emotional absorption into a story, where individuals lose awareness of their physical surroundings and form intense connections with the narrative and characters [28,29]. This deep absorption can lead to significant shifts in attitudes and empathy toward others [30]. Research has found that VR narratives lead to higher levels of transportation compared with traditional media, which in turn enhance empathetic responses [31]. Therefore, we hypothesize that VR will enhance narrative transportation, significantly impacting affective empathy.

A noteworthy characteristic of VR-based empathy training programs is their ability to feature multiple characters, thus allowing users to experience a narrative from varying character perspectives [32,33] The perspective-taking aspect significantly impacts users' emotional engagement with the character [34]. Research has found that users are more likely to experience emotional engagement toward characters that are portrayed positively [33] and are similar to them [35]. Therefore, we hypothesize that character perspective will impact emotional engagement, with higher engagement when viewing from the clinician's perspective compared with the parents' perspective due to character-user similarity, subsequently influencing affective empathy.

Moreover, we propose that perceived self-location, narrative transportation, and emotional engagement will form a sequential mediation model to account for the effect of VR-based training. Previous research on video games has found that the feeling of "being there" in the game is a predictor of flow, an experience similar to narrative transportation [36,37]. A recent study obtained similar findings: spatial presence predicted narrative transportation in a VR storytelling experience [38]. Furthermore, existing work suggests that narrative transportation is associated with an increase in emotional responses [39,40]. Hence, we predict that perceived self-location, enhanced by VR, will foster narrative transportation, which will, in turn, promote emotional engagement. Emotional engagement will then lead to affective empathy.

Hypotheses and Research Questions

Based on the literature review, the following hypotheses were proposed to explore the interconnected roles of perceived self-location, narrative transportation, and emotional engagement in enhancing affective empathy through VR interventions:

1. Hypothesis 1: VR conditions will enhance (1) perceived self-location and (2) narrative transportation compared with non-VR conditions.
2. Hypothesis 2: the participants will experience higher emotional engagement when viewing the narrative from a clinician's perspective compared with a parent's perspective.
3. Hypothesis 3: perceived self-location will positively predict narrative transportation in VR-based training programs.
4. Hypothesis 4: narrative transportation will positively predict emotional engagement within VR-based experiences.
5. Hypothesis 5: emotional engagement will positively predict affective empathy.

In addition to these hypotheses, we proposed the following research questions to explore potential interaction and indirect effects:

1. Research question 1: Are there interaction effects between the media platform (VR vs non-VR) and character perspective (clinician vs parents) on psychological factors such as perceived self-location, narrative transportation, and emotional engagement?
2. Research question 2: Do perceived self-location, narrative transportation, and emotional engagement mediate the relationship between the media platform and affective empathy?

Methods

Design

The proposed conceptual framework of this study is illustrated in Figure 1. This study used a 2×2 between-subjects experimental design to investigate the effects of the platform (VR vs non-VR) and perspective (parents vs clinicians) on nursing undergraduates' empathy levels. Participants were randomly assigned to 1 of 4 conditions: VR parents, VR

clinicians, non-VR parents, or non-VR clinicians. Figure 2 shows the 4 conditions of the study.

Figure 1. The proposed conceptual framework.

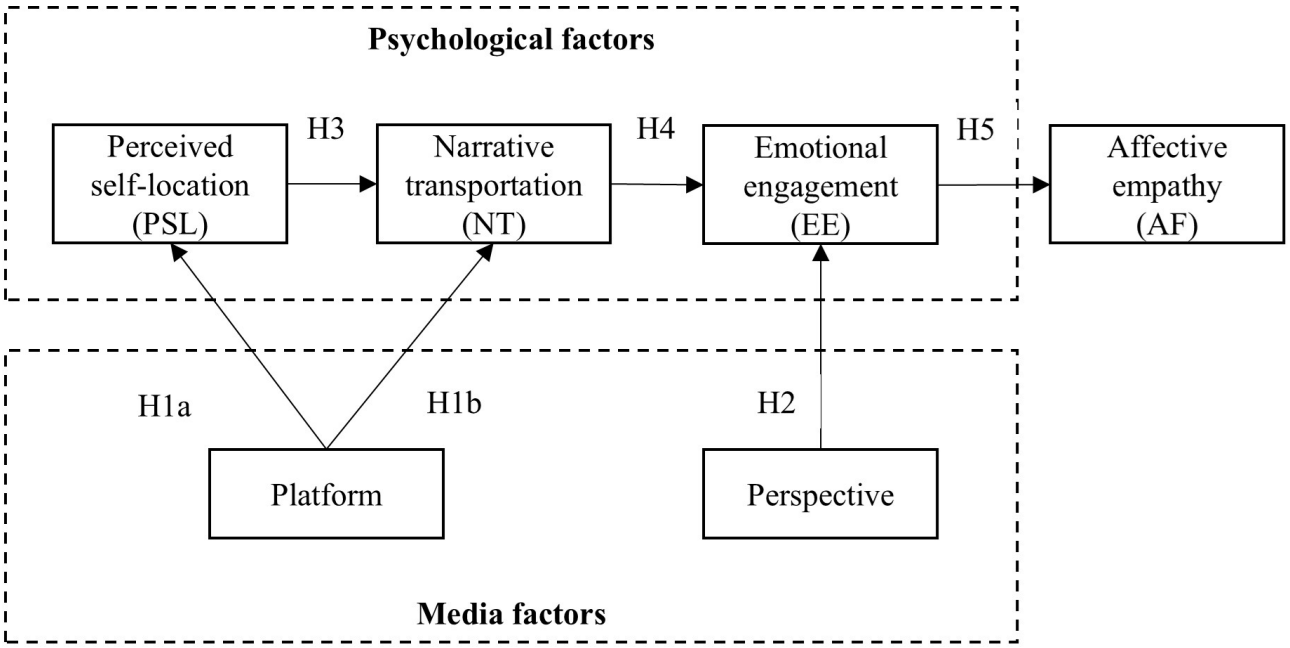

Figure 2. Four conditions of the study.

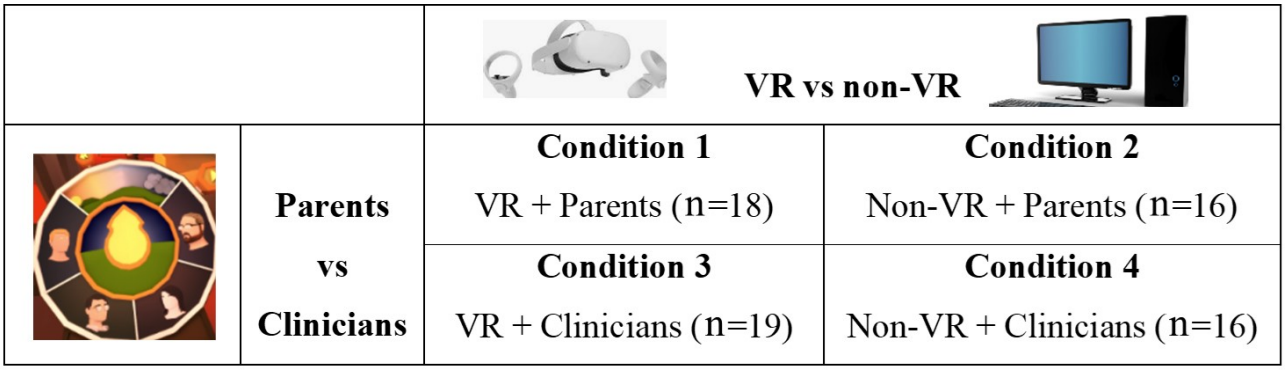


Participants

A total of 69 nursing undergraduates from two Midwest universities participated in the study, predominantly female (57/69, 82.6%) and White (57/69, 82.6%), mostly juniors (39/69, 56.5%; sophomores: 24/69, 34.8%; seniors: 6/69, 8.7%). The average age was 22.13 (SD 3.70) years. The participants were recruited via university mailing lists and classroom announcements, with inclusion criteria requiring them to be nursing undergraduates aged 18 years or older. Most participants (54/69, 77.6%) reported they were not familiar with VR.

Before participation, all were screened for visual impairments and susceptibility to motion sickness; those with significant issues were excluded to avoid adverse effects during the VR experience.

Randomization was done through a drawing process, assigning participants to 1 of 4 conditions, ensuring balanced allocation between VR and non-VR platforms and the perspectives of parents or clinicians. Given the sample size and complexity of the 2×2 design, the study may be underpowered to detect small effects. No a priori power calculations were conducted; however, this exploratory research aims to investigate initial effects and generate hypotheses for future studies with larger samples.

Experimental Procedures and Stimulus

Upon arrival at the research lab, participants provided informed consent and completed a short pretest questionnaire. They were then assigned to 1 of the 4 gameplay conditions as per the randomization process described above. The participants were informed that they could stop or report at any time if they experienced motion sickness or visual discomfort.

The participants engaged with the seventh chapter of the narrative-focused video game That Dragon, Cancer, titled “I’m Sorry Guys, It’s Not Good.” That Dragon, Cancer is an interactive narrative game developed by Numinous Games (Mainframe Studios) [41] that tells the real-life story of a family’s experience with their son’s terminal cancer diagnosis. The game is designed to evoke emotional responses and foster empathy through immersive storytelling [42]. This chapter was selected based on prior research demonstrating its efficacy in increasing empathy among medical students [42]. The gameplay allowed participants to experience a pivotal moment when Joel’s parents were informed of his terminal cancer diagnosis,

navigating the scene from 4 unique perspectives: dad, mom, doctor, and nurse. The game is designed as a point-and-click adventure, which allows participants to trigger conversations and access a selected character's inner thoughts.

The participants in the VR conditions used Oculus Go headsets, seated in a quiet room to minimize distractions. The headsets provided a 360-degree immersive experience with built-in headphones for audio. For the non-VR conditions, the participants used Dell laptops or iPads (Apple, Inc) with over-ear headphones, seated at a desk in the same room to ensure consistent environmental conditions. The game was presented on a standard screen, and the participants interacted using a mouse or touchscreen, replicating typical non-VR gameplay settings. The gameplay lasted approximately 10 minutes. The selection of this exposure time was based on previous studies indicating that brief VR experiences can effectively elicit emotional and empathetic responses [43]. Immediately after the gameplay, participants completed a posttest questionnaire assessing their empathy and gaming experience. This immediate administration was intended to capture their reactions and reduce potential recall bias.

Instrument

Several validated scales were used to measure the constructs of interest. These measures are specifically applicable to our study's context in nursing education and VR-based empathy training. First, the Spatial Presence Experience Scale, developed by Hartmann et al [44], was used to evaluate self-location and assess nursing students' immersion in the simulated clinical scenarios. This validated scale, widely used in diverse media environments, measures 2 facets of the spatial presence experience: perceived self-location and potential actions, while also considering key factors that influence spatial presence. The study's transportation scale was an adaptation from Green and Brock [28], which measures students' absorption of patient stories that may foster empathy. In addition, the Emotional Engagement scale used in the study was sourced from Knol and Van Linge [45], which captures students' emotional connection with virtual characters, vital for developing affective empathy. Affective empathy was assessed with 3 items from the validated empathy scale by Batson et al [46]. The participants responded to items on a 7-point Likert scale ranging from 1 (strongly disagree) to 7 (strongly agree). The results of these items were averaged to produce a composite score for data analysis. Covariates such as participants' gender, age, race, and university affiliation were included in the following statistical analyses. Descriptive statistics, the items used, and reliability estimates for all scales are presented in Table 1.

Table . List of items used in the study and the descriptive statistics (N=69).

Variable	Statistics	Items
Perceived self-location [44]	• Mean 5.19 (SD 1.12) • Cronbach (α=0.88)	• I felt like I was actually there in the environment of the presentation. • It was as though my true location had shifted into the environment in the presentation. • I felt as though I was physically present in the environment of the presentation. • It seemed as though I actually took part in the action of the presentation
Transportation [28]	• Mean 5.77 (SD 0.93) • Cronbach α=0.83	• I could picture myself in the scene of the events described in the story. • I was mentally involved in the story while watching it. • I wanted to learn how the story ended.
Emotional engagement [45]	• Mean 5.83 (SD 0.98) • Cronbach α=0.83	• The story affected me emotionally. • During the media experience, when the characters suffered in some way, I felt sad. • I felt sorry for some of the characters in the story.
Affective empathy [46]	• Mean 5.65 (SD 1.24) • Cronbach α=0.93	• Did watching/playing this video make you feel __ • softhearted • sympathetic • compassionate

Statistical Analysis

Data analysis was performed using SPSS 29 statistical software. Hypotheses H1, H2, and RQ1 were assessed through a series of analyses of covariance (ANCOVA), controlling for covariates such as participants' gender, age, race, and university affiliation. Covariates such as participants' gender, age, race, and university affiliation were included in the ANCOVA because these demographic factors have been shown to influence empathy levels and responses to VR experiences [23]. Including these covariates helps control for potential confounding variables, ensuring that the effects observed are attributable to the

experimental manipulations rather than demographic differences. Hypotheses H3-H5 and RQ2 were tested with mediation analyses using the PROCESS macro, following a bootstrap estimation approach with 5000 samples, based on Hayes' Process Model 6 [47]. Control variables were also included in these analyses to control for potential confounding influences.

Ethical Considerations

This study was approved by the Institutional Review Board at Ball State University (approval number 1386023 - 1). All participants provided informed consent before data collection. To acknowledge their participation, they received extra course credits as compensation. Confidentiality and privacy were maintained, and participants had the right to withdraw at any time without consequences.

Results

Descriptive Statistics and Correlation Analysis

The descriptive statistics for each condition, including mean and SD, are presented in Table 2. In addition, skewness and kurtosis values were assessed to check the normality of the data distribution, and the results were within the acceptable range confirming the appropriateness of the data for further analysis. A correlation analysis was conducted to identify any potential multicollinearity issues among the variables. The results indicated that while variables were correlated, they did not exceed the threshold that would suggest multicollinearity, thus ensuring the independence of predictors. The means for all variables were above the midpoint of the scale, indicating generally high levels of perceived self-location, narrative transportation, emotional engagement, and affective empathy among participants. The SD values ranged from 0.83 to 1.24, suggesting moderate variability in responses.

Table . Means and SEs by experimental conditions (N=69). Participants' race, gender, school year, and university affiliation were controlled.

Platform and perspective	Perceived self-location	Narrative transportation	Emotional engagement	Affective empathy
VR, mean (SE)				
Parents (n=18)	5.58 (1.07)	6 (0.87)	5.85 (0.72)	5.76 (1.43)
Clinicians (n=19)	5.66 (0.98)	5.81 (1.07)	6.02 (1.04)	5.84 (1.15)
Non-VR, mean (SE)				
Parents (n=16)	4.50 (1.34)	5.27 (1.16)	5.31 (1.26)	5.23 (1.41)
Clinicians (n=16)	4.89 (0.65)	5.96 (0.59)	6.13 (0.7)	5.75 (0.9)

Analysis of Covariance

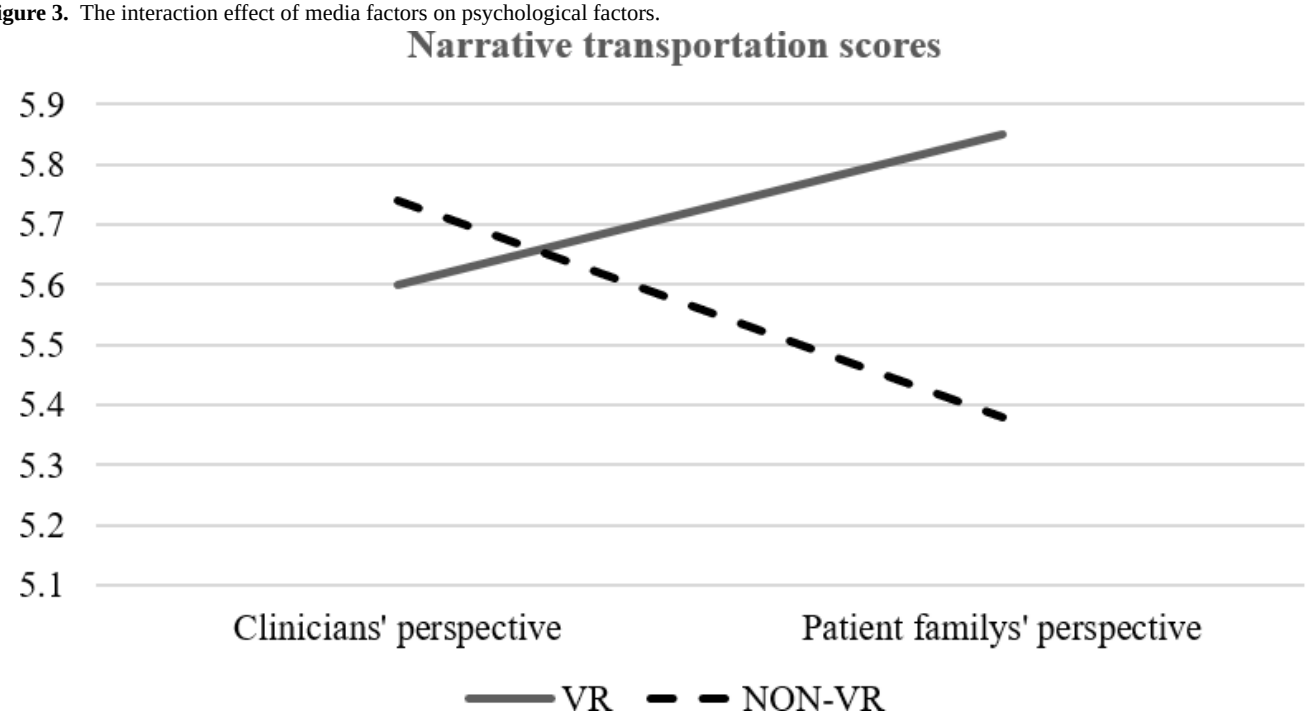
The analysis of covariance (ANCOVA) included checks for assumptions such as homogeneity of variances, assessed using the Levene test. The results of these tests confirmed that the assumptions of ANCOVA were met across all variables of interest. Specifically, Levene test results for homogeneity of variances were $F_{3,65}$=2.146, P=.10 for self-location; $F_{3,65}$=1.566, P=.20 for narrative transportation; $F_{3,65}$=0.904, P=.44 for emotional engagement; and $F_{3,65}$=0.620, P=.60 for affective empathy. These results suggest that the variances of the residuals were not significantly different from each other across groups for each variable, thus fulfilling one of the key assumptions for conducting ANCOVA and lending validity to the subsequent analyses.

Based on our findings (Table S1 in Multimedia Appendix 1), the platform of the game had a significant influence on perceived self-location ($F_{1,61}$=6.60, P=.01, partial η^2=0.098), indicating that VR has a stronger influence on perceived self-location compared with non-VR environments. This substantial difference in perceived self-location depending on the platform used provided support for hypothesis H1a, suggesting VR's unique capacity to enhance users' sense of presence within the virtual environment. We also examined the effect of the adopted perspective on participants' emotional engagement. The results revealed a significant effect ($F_{1,61}$=4.76, P=.03, partial η^2=0.072), indicating that participants who assumed the clinician's perspective exhibited greater emotional engagement compared with those adopting a patient's perspective. This finding supported hypothesis H2, highlighting the importance of perspective in influencing emotional responses in VR settings. However, the effect of VR on narrative transportation did not yield significant results ($F_{1,61}$=0.90, P=.35, partial η^2=0.014), thereby not supporting hypothesis H1b.

To answer the first research question, we also test whether there is an interaction effect of media factors on psychological factors. The results revealed that the platform and perspective had an interaction effect on narrative transportation ($F_{1,61}$=4.68, P=.04, partial η^2=0.070). The post hoc analysis indicated that participants experiencing the game from the perspective of patients' families in a non-VR platform exhibited the lowest level of narrative transportation. This nuanced finding sheds light on how different combinations of platform and perspective can uniquely affect the immersive experience of users. These interaction effects are further elucidated in Figure 3, providing

a visual representation of these dynamics. Specifically, the narrative transportation scores for clinicians and patient families under VR (solid line) and non-VR (dashed line) conditions showed diverging trends between the two perspectives.

Figure 3. The interaction effect of media factors on psychological factors.

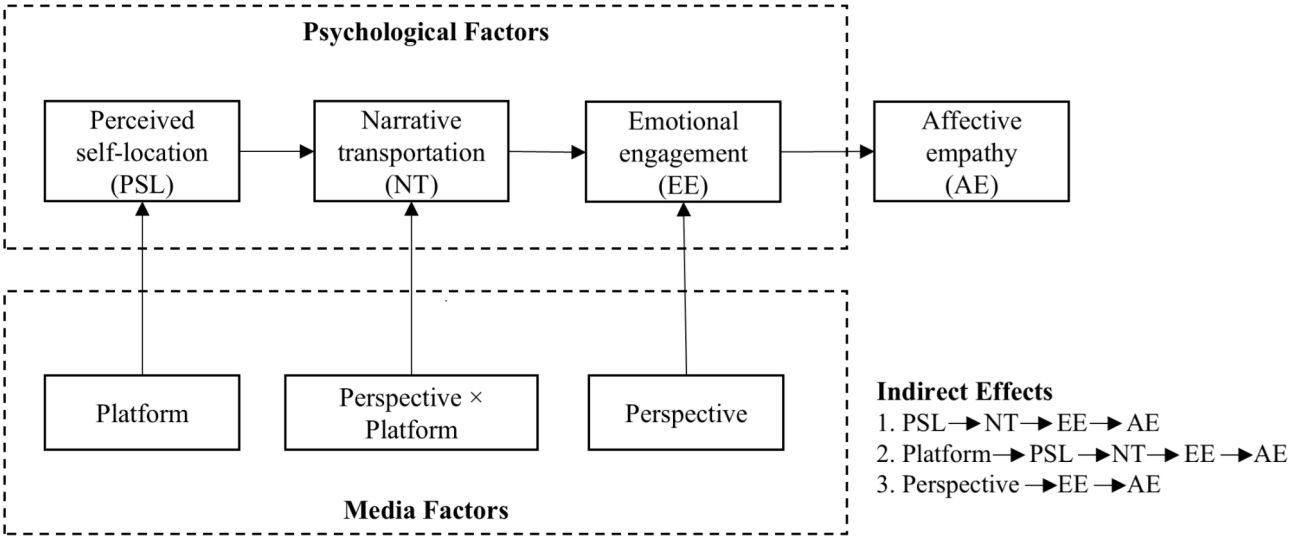


Mediation Analysis

The mediation analyses using Hayes' PROCESS model 6 revealed several direct and indirect effects. Regarding direct effects, self-location was found to have a significant positive effect on transportation (b=0.54, P<.001). Transportation had a positive effect on emotional engagement (b=0.74, P<.001). Emotional engagement was found to have a strong positive effect on affective empathy (b=0.84, P<.001). These findings, supporting H3-H5, illustrate the psychological process from self-location in VR, through narrative transportation and emotional engagement, to the ultimate development of affective empathy. We used 5000 bootstrap samples to generate bias-corrected confidence intervals for the indirect effects. The significance of the mediation pathways was determined by examining whether the confidence intervals excluded zero. All variables were included in the model simultaneously, and control variables were accounted for in the analysis. The model fit was assessed, and all pathways were found to be significant, confirming the validity of the mediation pathways.

The results also uncovered three sets of indirect effects, which answered our second research question. First, perceived self-location exerted an indirect effect on affective empathy through narrative transportation and emotional engagement (indirect effect=0.25, 95% CI 0.0610-0.5048). Second, the platform had an indirect effect on affective empathy through perceived self-location, narrative transportation, and emotional engagement (indirect effect=0.25, 95% CI 0.0610-0.5048). Finally, the perspective adopted by the participants was found to have an indirect effect on affective empathy through emotional engagement (indirect effect=0.27, 95% CI 0.0059-0.6153). These indirect effects, along with the direct effects, are represented in the revised conceptual framework presented in Figure 4.

Figure 4. The revised conceptual framework.



Discussion

Summary and Interpretations of the Findings

The study investigates the impact of media platforms and players' perspectives on perceived self-location, narrative transportation, emotional engagement, and affective empathy within medical education, which capture key psychological processes essential for developing empathy in clinical practice. The results indicate that all psychological factors were influenced by media elements, albeit through different mechanisms.

Our hypothesis H1a was supported, demonstrating that playing the game in VR (vs non-VR) significantly increased perceived self-location. This finding is consistent with prior studies [24,25]. However, contrary to our hypothesis H1b, VR (vs non-VR) did not differ in narrative transportation, which echoes findings from a recent meta-analysis [27]. This nonsignificant finding suggests that while VR enhances the sense of presence or self-location, it may not necessarily increase narrative transportation compared with non-VR platforms. One possible explanation is that narrative transportation is more strongly influenced by the quality of the narrative itself rather than the medium through which it is delivered [28]. It is possible that the narrative content was equally engaging in both VR and non-VR formats, resulting in similar levels of transportation. Future research could explore how different narrative structures or content types interact with VR to affect narrative transportation.

Regarding our hypothesis H2 adopting a clinician's perspective during the VR experience significantly influenced emotional engagement, the result is consistent with previous research [32,33]. This insight emphasizes the value of learning from other clinicians in strengthening emotional ties with patients, thereby fostering affective empathy. The findings showed the potential of VR in medical education by enhancing perceived self-location, which can improve empathy toward patients. The significant influence of perspective adopted by players reiterates its role in enhancing emotional engagement, crucial for fostering empathy in health care professionals.

The proposed direct relationships between psychological factors and affective empathy (H3-H5) were all supported. The findings demonstrate that a sense of perceived self-location in VR can enhance narrative transportation, leading to increased emotional engagement. In turn, this fosters affective empathy, a critical skill for health care professionals to understand and respond to patients' emotional experiences effectively, a critical skill for health care professionals to understand and respond to patients' emotional experiences effectively. This sequential process confirms the potential of VR in facilitating immersive, emotionally engaging learning experiences in medical training, promoting the development of affective empathy.

The exploration of the research questions (RQ1 and RQ2) yielded compelling insights. The first research question investigates potential interaction effects. Our findings indicate a significant interaction effect among these conditions, specifically revealing that scores on narrative transportation were significantly lower in the condition using non-VR with a patient's perspective compared with the other 3 conditions. This interaction effect suggests that the combination of platform and perspective plays a crucial role in influencing narrative transportation. One possible explanation is that adopting the patient's perspective in a non-VR environment may not provide sufficient immersion or sensory cues to facilitate deep engagement with the narrative. In contrast, VR may compensate for the less immersive perspective by enhancing sensory immersion, while adopting a clinician's perspective may align more closely with the students' professional identity, facilitating engagement even in non-VR settings. This finding indicates that the effectiveness of narrative transportation may depend on the congruence between the medium, the perspective adopted, and the user's own identity and experiences. Future studies could explore how personal relevance and role identification influence narrative engagement across different platforms.

For the second research question, the study uncovered 3 indirect effects: perceived self-location impacted affective empathy via narrative transportation and emotional engagement, the platform influenced affective empathy through self-location, narrative transportation, and emotional engagement, and the perspective affected affective empathy through emotional engagement.

Theoretical Contributions and Practical Implications

This study makes significant theoretical contributions to the fields of empathy research and narrative communication. It demonstrates how VR can influence affective empathy through mechanisms such as perceived self-location, narrative transportation, and emotional engagement, thereby deepening our understanding of the integral role immersive technologies play in fostering critical emotional competencies. By identifying the sequential mediation of these psychological factors, our findings extend existing theories on empathy development and immersive media, providing empirical evidence within the context of nursing education.

These findings add valuable empirical evidence to empathy research and highlight the importance of immersive, technology-enabled experiences in shaping affective responses. Specifically, our study fills a gap in the literature by focusing on affective empathy rather than cognitive empathy, which has been less examined in VR research. Furthermore, by exploring the interaction between character perspective and affective empathy within VR environments, the study offers a novel perspective on empathy development and enriches narrative communication research. This contributes to a more nuanced understanding of how perspective-taking in VR can differentially impact emotional engagement and empathy outcomes, which has practical implications for designing effective educational interventions.

From a practical standpoint, the findings offer actionable insights for integrating VR into nursing education. We propose that nursing programs should incorporate VR experiences that emphasize perspective-taking from a clinician's viewpoint to enhance emotional engagement and affective empathy among students. To address potential barriers such as cost, accessibility, and technological limitations, nursing programs could start by incorporating affordable VR solutions like stand-alone VR headsets or 360-degree video experiences, which are more feasible than high-end VR systems or simulation stations. For accessibility, it is important to ensure that VR experiences are also designed for students in the classroom settings. Technological limitations, such as a lack of technical expertise among faculty, can be mitigated through training workshops and technical support services. In addition, curricula should be designed to seamlessly integrate VR experiences into existing courses, perhaps starting with pilot programs to evaluate effectiveness before broader implementation. By proactively addressing these barriers, educators can more effectively leverage VR technology to enhance empathy training in nursing education. By implementing these recommendations, educators and institutions can leverage VR technology to significantly enhance the quality of medical education and training, especially in the domain of empathy development.

Limitations and Future Research Directions

This study has several limitations. First, while the sample size was sufficient to yield statistical power, it was relatively small. The participants were primarily female, white nursing undergraduates from two Midwestern universities. The small sample size may have also limited our ability to detect smaller effect sizes. The homogeneity in gender and race may have influenced the results, as previous research suggests that empathy levels and responses to VR experiences can vary across different demographic groups. For instance, gender differences have been observed in emotional processing and empathetic responses, which could affect how participants engage with VR-based empathy training. Therefore, our sample may limit the generalizability of the results.

Future studies should prioritize recruitment strategies that enhance demographic diversity to ensure the broader applicability of findings. One approach is expanding outreach to institutions with more diverse student populations, such as historically Black colleges and universities, Hispanic-serving institutions, and community colleges. Establishing partnerships with nursing programs in urban and rural areas can also help reach a wider range of participants with different socioeconomic and educational backgrounds. In addition, leveraging professional nursing associations, student organizations, and social media platforms can improve the recruitment of participants from underrepresented groups. Providing flexible participation options, such as internet-based study components or varied scheduling, may further increase accessibility and encourage participation from nontraditional students, working professionals, or those with caregiving responsibilities. Implementing these strategies can enhance inclusivity and variability, ultimately strengthening the generalizability of future research.

Second, the research design offered only a brief, single-session exposure to VR and non-VR platforms and varying character perspectives. This short exposure duration may not have allowed sufficient time for participants to fully immerse themselves in the VR experience or for the effects on empathy to fully manifest. This limited interaction may not fully capture the potential effects of extended VR-based training on empathy. Longer or repeated exposures could provide a more accurate assessment of VR's impact on empathy development. Therefore, longitudinal studies are recommended to investigate the long-term effects of VR on empathy, providing insights into the sustainability and potential long-term integration of VR into medical education.

Third, while we used self-reported scales that have been validated and widely used, these measures may introduce a certain level of response bias. Self-reported data can be influenced by social desirability or participants' subjective interpretations of the questions, which may affect the accuracy of the results. Future investigations could stand to gain significantly from incorporating more objective evaluative methods, such as physiological and behavioral observations, that would serve to substantiate the self-reported data. For example, using biometric measures like heart rate variability or skin conductance could provide objective insights into emotional engagement and empathy responses. In addition, behavioral assessments during simulated interactions could offer tangible evidence of empathy development. Implementing mixed-method approaches would mitigate reliance on self-reports and enhance the validity of future research findings.

Finally, although the usability of the VR interface is important, our study did not assess usability using standard questionnaires

such as the System Usability Scale [48] or the Usefulness, Satisfaction, and Ease of use [49] questionnaire. Future research could incorporate these usability measures to provide a more comprehensive evaluation of VR interfaces in educational settings. Usability testing plays a crucial role in ensuring that VR interventions in nursing education are intuitive, user-friendly, and meet the needs of learners. A system that is difficult to navigate or provides a poor user experience can disrupt engagement and limit the effectiveness of the intervention. Future research should integrate standardized usability assessments, such as the System Usability Scale or Usefulness, Satisfaction, and Ease of use questionnaire, to systematically evaluate the user experience. These measures will help identify areas for improvement, offering insights into how the VR interface aligns with learning goals and how usability affects student engagement and comprehension. By incorporating such evaluations, design improvements can be made—whether refining the interface, enhancing interaction features, or adjusting the VR experience to better suit diverse learning styles. Ultimately, addressing usability issues can improve the practical application of VR in nursing education, ensuring that immersive learning experiences are both accessible and impactful for real-world clinical practice.

Conclusion

In this study, we explored the interactive roles of media platforms and perspective-taking in shaping key psychological factors, including perceived self-location, narrative transportation, emotional engagement, and affective empathy, in nursing education settings. The initial findings provide empirical evidence for the potential of immersive technologies as applicable pedagogical tools, particularly in teaching and training future health care providers. The capacity of virtual reality to facilitate the feeling of presence, build emotional engagement, and foster empathy among nursing students shows the potential to foster a greater degree of patient-centered care. Therefore, this study advocates for a wider consideration of integrating technologies into health care education curriculum design and development. The potential benefits and financial viability of VR technologies could enrich pedagogical experiences and pave the way for the emergence of competent health care professionals, well-equipped to navigate different scenarios in health care delivery.

Abstract

Background: Teaching severe pelvic trauma poses a significant challenge in orthopedic surgery education due to the necessity of both clinical reasoning and procedural operational skills for mastery. Traditional methods of instruction, including theoretical teaching and mannequin practice, face limitations due to the complexity, the unpredictability of treatment scenarios, the scarcity of typical cases, and the abstract nature of traditional teaching, all of which impede students' knowledge acquisition.

Objective: This study aims to introduce a novel experimental teaching methodology for severe pelvic trauma, integrating virtual reality (VR) technology as a potent adjunct to existing teaching practices. It evaluates the acceptability, perceived ease of use, and perceived usefulness among users and investigates its impact on knowledge, skills, and confidence in managing severe pelvic trauma before and after engaging with the software.

Methods: A self-designed questionnaire was distributed to 40 students, and qualitative interviews were conducted with 10 teachers to assess the applicability and acceptability. A 1-group pretest-posttest design was used to evaluate learning outcomes across various domains, including diagnosis and treatment, preliminary diagnosis, disease treatment sequencing, emergency management of hemorrhagic shock, and external fixation of pelvic fractures.

Results: A total of 40 students underwent training, with 95% (n=38) affirming that the software effectively simulated real-patient scenarios. All participants (n=40, 100%) reported that completing the simulation necessitated making the same decisions as doctors in real life and found the VR simulation interesting and useful. Teacher interviews revealed that 90% (9/10) recognized the VR simulation's ability to replicate complex clinical cases, resulting in enhanced training effectiveness. Notably, there was a significant improvement in the overall scores for managing hemorrhagic shock (t_{39}=37.6; 95% CI 43.6-48.6; P<.001) and performing external fixation of pelvic fractures (t_{39}=24.1; 95% CI 53.4-63.3; P<.001) from pre- to postsimulation.

Conclusions: The introduced case-based VR simulation of skill-training methodology positively influences medical students' clinical reasoning, operative skills, and self-confidence. It offers an efficient strategy for conserving resources while providing quality education for both educators and learners.

Introduction

Severe pelvic trauma is characterized by unstable pelvic fractures resulting from high-energy impacts, typically accompanied by complications such as fatal massive bleeding and organ injuries. The mortality rate in China is as high as 10%-30% [1-3]. Managing pelvic fractures with hemodynamic instability poses a significant challenge within the orthopedic surgery discipline [4,5]. The current gap that exists in the field of the effectiveness of severe pelvic trauma clinical skill training is multifaceted. It includes the inaccessibility of clinical teaching in hospitals and the constraints of traditional classroom instruction. In addition, owing to the complexity, unpredictability of treatment locations, the rarity of typical cases, reluctance to cooperate, and ethical concerns surrounding clinical teaching, traditional methods of clinical skill training in diagnosing and treating severe pelvic trauma are limited to theoretical instruction and mannequin-based simulation. These methods face limitations, including disproportionate teacher-student ratios, high model consumption, insufficient training spaces, the absence of comprehensive and immediate feedback, and inadequate training overall. Specifically, on-site mentoring can be challenging to achieve effectively and efficiently. Therefore, a teaching model for severe pelvic trauma needs to integrate new teaching strategies and computer technology to address these issues. This study addresses gaps in the current training methods and tools for managing severe pelvic trauma by designing an innovative virtual reality (VR)–based simulation platform.

In recent years, VR technology has gained widespread acceptance in orthopedic surgery education because of its multisensory immersive experience, the convenience of real-time interaction, and a psychologically secure experimental environment [6,7]. These technologies have mitigated the limitations of time, space, and teaching resources in orthopedic surgery education and addressed issues such as simulated patients and the difficulty of repeated practice. To some extent, this has enhanced the efficiency and quality of clinical practice. Digital patient simulators have become valuable tools in medical education, offering a standardized method of patient simulation [8,9]. However, virtual patients typically only exhibit clinical symptoms and signs, with minimal explanation of the underlying fundamental medical knowledge of primary symptoms and positive or negative signs. Furthermore, there is a scarcity of research on virtual simulation teaching models that integrate basic and clinical medicine for severe pelvic trauma. To mimic the real teaching scenario of the disease and capture the sudden and variable condition of patients in clinical settings, we developed an electronic standardized patient (ESP) for severe pelvic trauma, capable of replicating both macroscopic changes, such as monitor display data, and microscopic changes, including alterations in blood circulation, organs, tissues, and cells. The ESP model facilitates the integration and application of clinical and basic knowledge. The original design and technology of the ESP were conceived by Professor Xing Ya Gao's team at Nanjing Medical University, Department of Physiology [10]. An ESP is grounded in contemporary theories of human systems physiology and incorporates relevant clinical literature and data through analog circuits, physics, and other methods to formulate a mathematical model. Artificial intelligence and data analytics are used to refine and adjust the simulation data. In summary, the ESP represents a web-based intelligent standardized patient, enabling students to interact with it in a virtual hospital setting from a physician's perspective. To date, the ESP has not been fully used in the clinical skills education for severe pelvic trauma.

Case-based learning (CBL) is recognized as an effective teaching strategy in clinical skills training [11,12]. CBL is particularly valued in orthopedic surgery education for its ability to enhance learner participation, foster active learning, and develop critical thinking and problem-solving skills [13]. CBL is an educational method designed to analyze medical records, recreate real clinical scenarios, and engage learners in addressing actual clinical challenges, thereby stimulating their curiosity and promoting active learning [14].

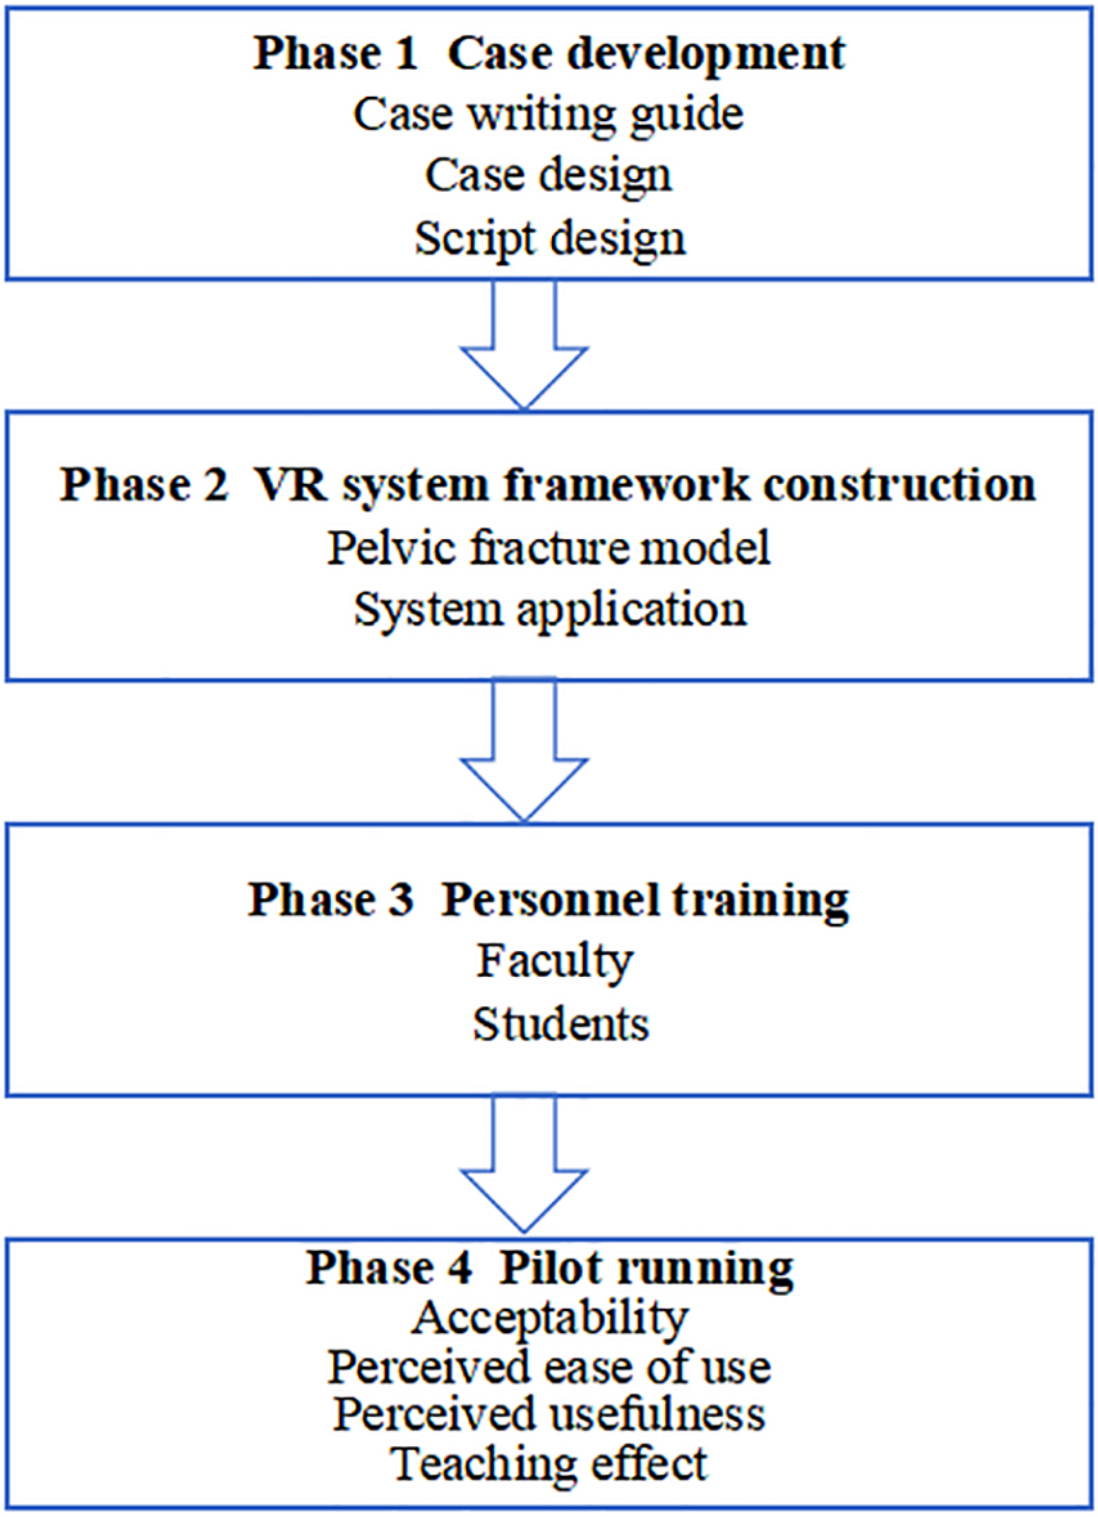
CBL, combined with VR simulation technology, has been successfully applied in midwifery laboratory courses, with its effectiveness widely acknowledged by students [15]. However, the application of these combined methodologies in teaching clinical skills for severe pelvic trauma has yet to be explored. Therefore, in this study, we introduced a case-based digital skill training program for severe pelvic trauma and conducted mixed methods to evaluate its acceptance among users. Additionally, we implemented a pretest-posttest design to investigate the potential impact of this clinical skills training on undergraduate and graduate students. We hypothesize that the case-based VR simulation teaching method will effectively complement current training practices for severe pelvic trauma, enhancing knowledge, procedural skills, and confidence, while also improving instructional efficiency and effectiveness for educators.

Methods

Study Design

We conducted a 4-phase study (Figure 1). First, we created the simulated teaching case base and adapted typical clinical cases based on the case writing guide [16,17]; subsequently, the case script was developed. Next, we established the framework of the VR system, comprising 3 ports and 3 system modules. To facilitate the effective implementation of the teaching system, we formulated a comprehensive training plan for department administrators, course instructors, and medical students. A pilot test of the system was conducted on a limited scale, followed by a 1-group pretest-posttest design to assess its acceptability, potential application, and existing limitations.

Figure 1. A flow diagram illustrating the steps involved in developing a case-based VR simulation for severe pelvic trauma clinical skill training. VR: virtual reality.



Phase 1: Case Development

Case Design

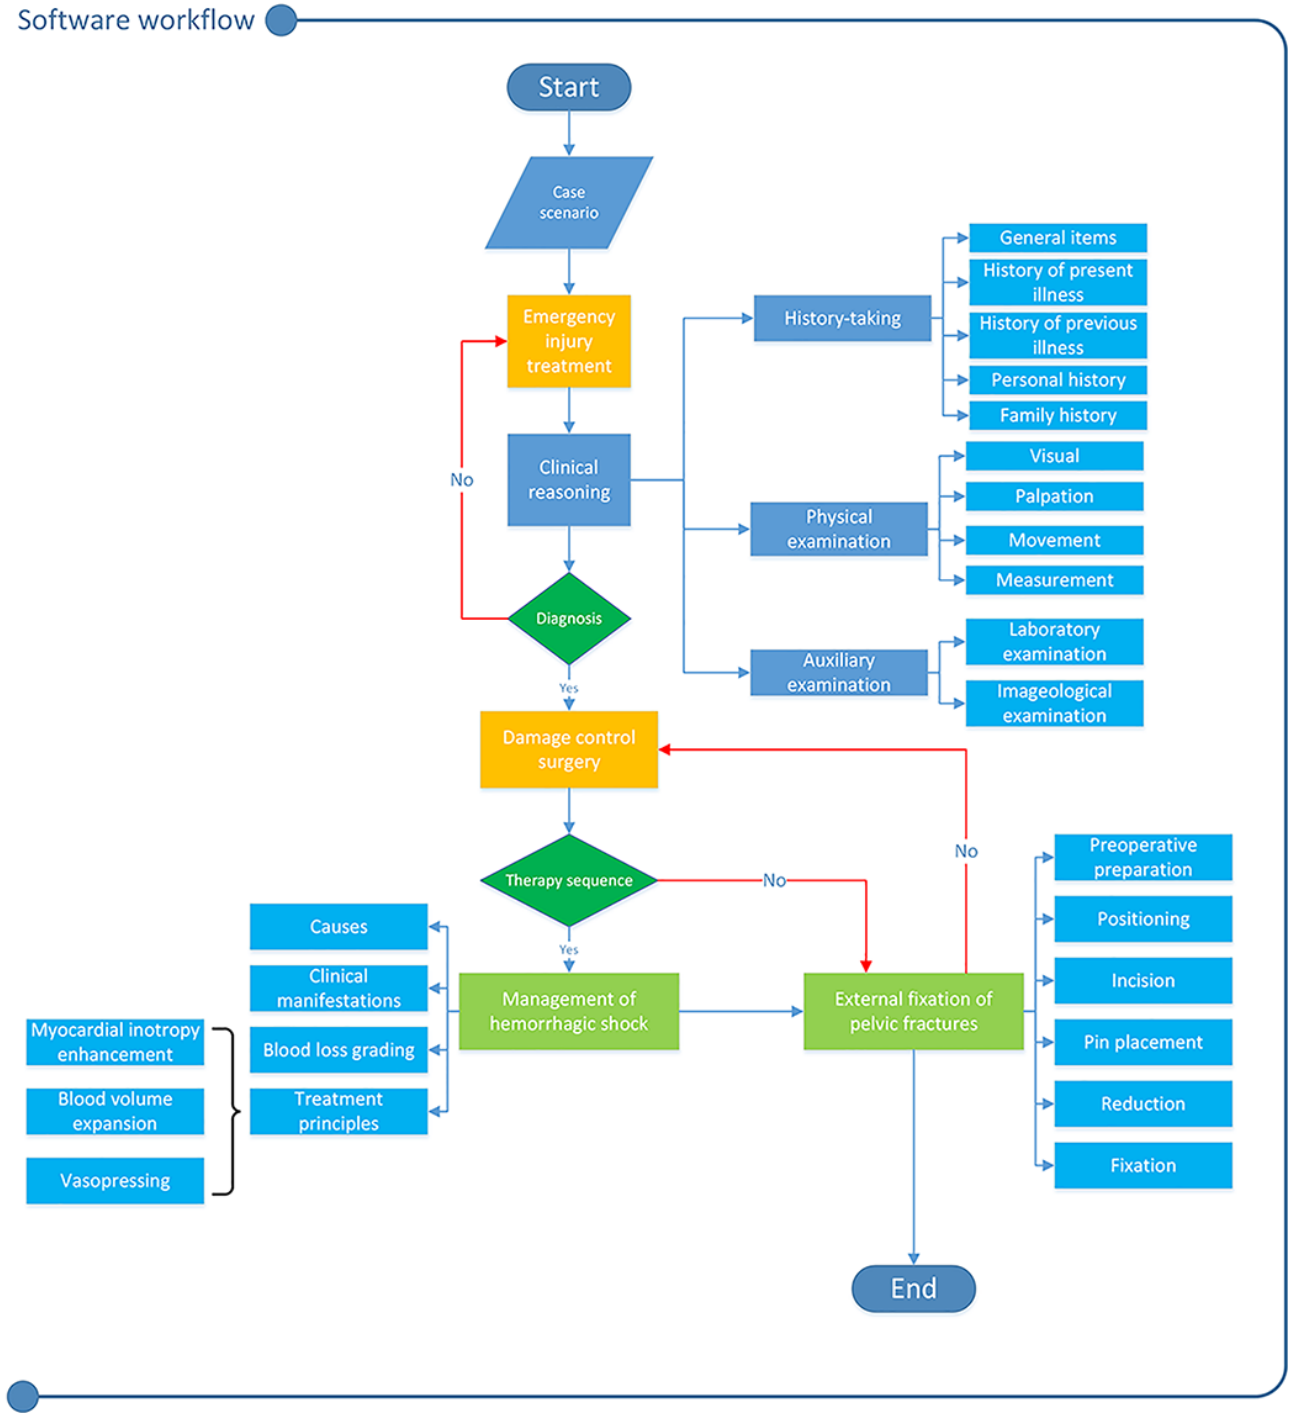
Specialists in basic and clinical medicine, drawing on a literature review, real patient cases, and the course syllabus, designed the cases. A representative case involved a worker who fell from a high platform and was sequentially evaluated in the emergency department, admitted to the intensive care unit, and taken to the operating room as his condition worsened. The diagnostic and treatment processes for this condition were standardized. Learners were guided through different scenarios to acquire both declarative and procedural knowledge for managing patients with severe pelvic trauma. We developed 3 initial cases, each representing a different stage of trauma and treatment approach (Table 1). Learning paths for diagnosis and treatment were outlined in a flowchart (Figure 2), based on clinical

treatment guidelines [18,19] to serve as a framework for evaluating student performance. We collected clinical manifestations, relevant imaging, and laboratory examination results of real patients.

Table 1. Three cases with patients diagnosed with pelvic trauma.

	Case 1	Case 2	Case 3
Diagnosis	Pelvic fracture	Pelvic fracture with mild hemorrhagic shock	Pelvic fracture with severe hemorrhagic shock
Injury evaluation	Mild	Moderate	Severe
Diagnostics	Standard	Plus computed tomography of the pelvis	Plus computed tomography of the pelvis and abdomen
Therapy	Surgery	Antihemorrhagic shock therapy, surgery	Antihemorrhagic shock therapy, surgery

Figure 2. An optimal template for the diagnosis and treatment process of severe pelvic trauma (blue arrows for the correct path, red arrows for the wrong path).



The 3 cases varied in the severity of pelvic trauma, necessitating different diagnostic and treatment strategies.

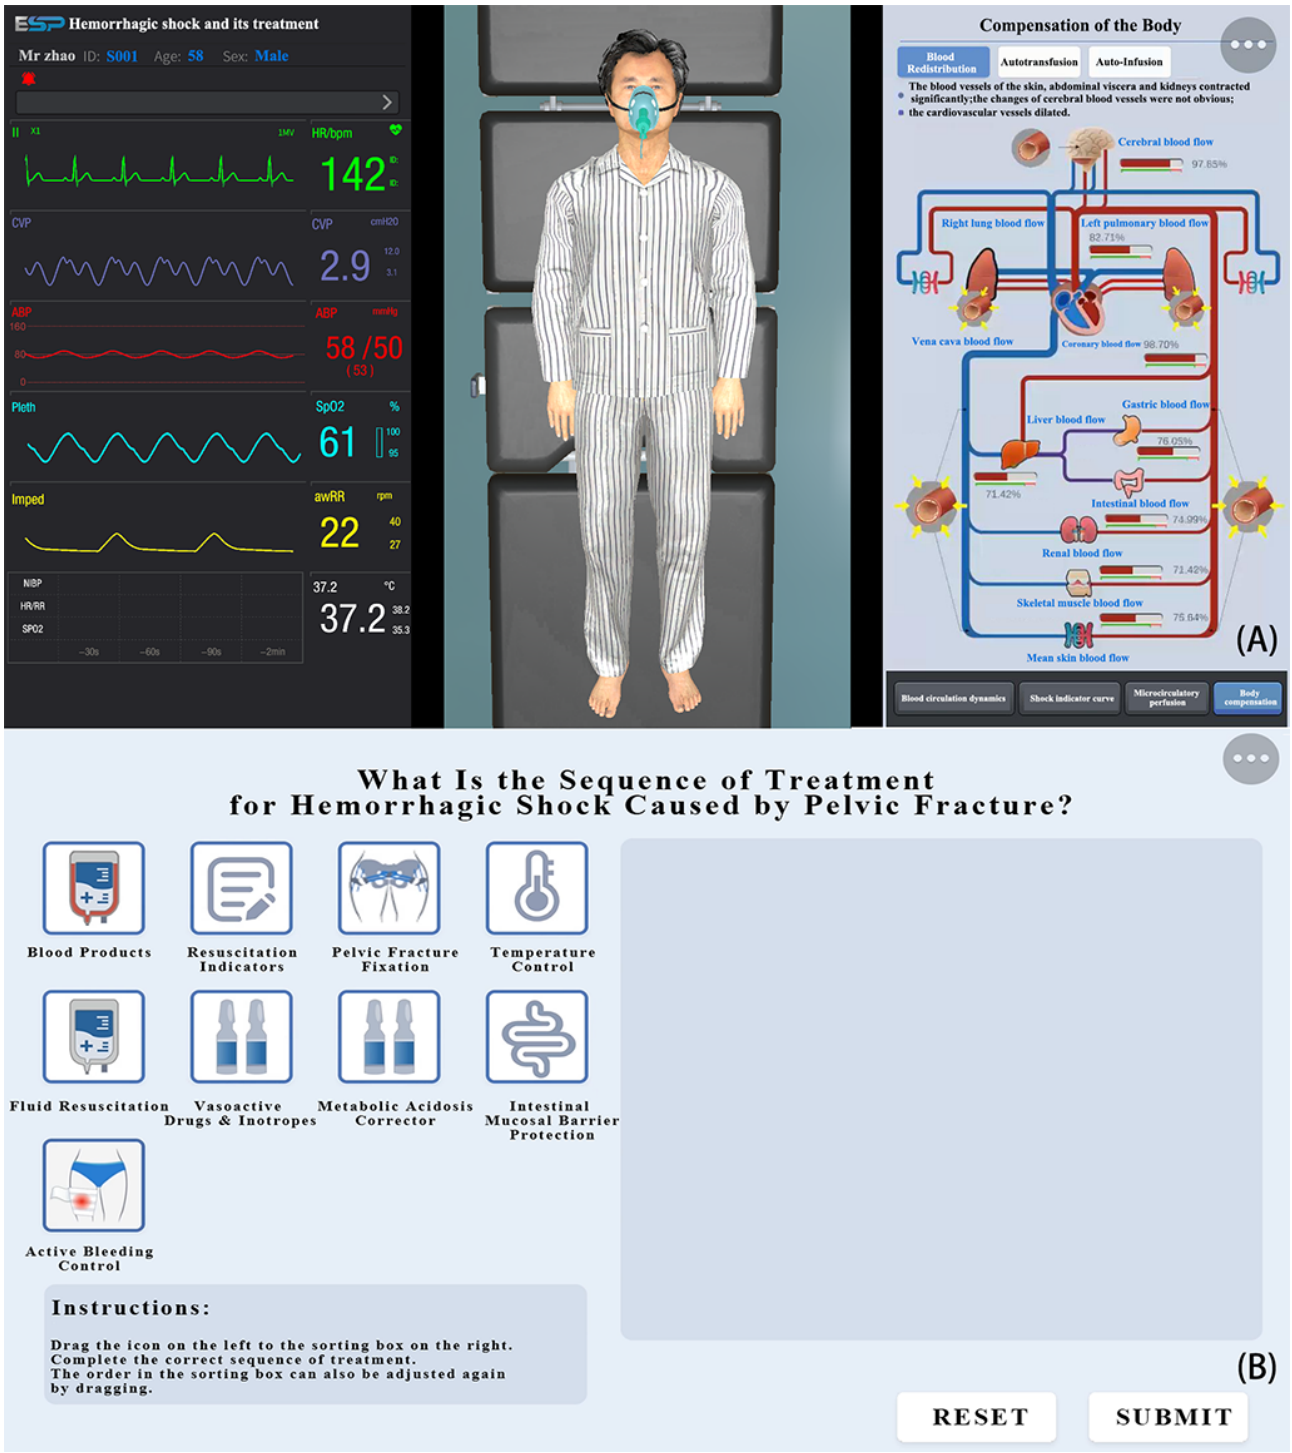
Script Design

Scripts focused on scenarios in emergency rooms, intensive care units, and operating rooms. In a virtual emergency room, users could interact with the ESP, using various diagnostic and treatment methods, such as history taking, physical examination, and auxiliary examination, to formulate a preliminary diagnosis based on evidence gathered during the process. Learners engaged with the ESP through text input or voice chat during the history-taking session. They then entered pertinent information into the system's modules for general items, history of present illness, personal history, marital history, and family history. The system evaluated 4 aspects: completeness of the inquiry framework, logical order of inquiries, communication skills, and awareness of humanistic care, assigning scores based on the accuracy of the information collected. The system also recorded the total duration of inquiries and the time spent on each module for later analysis. Physical examination, a fundamental skill for diagnosing diseases, involves comparing and identifying positive signs. The system assessed the patient examination position, completeness and sequence of operational steps, standardization of procedures, comprehensiveness of examination content, accurate reporting of results, and basic professional quality. Auxiliary examination, crucial for diagnosis and treatment planning, involves evaluating laboratory tests and computed tomography images. Upon completing these steps, students made a preliminary diagnosis and a prioritized list of differential diagnoses. Correct diagnoses led to immediate treatment initiation; otherwise, students continued trial and error in this module (Figure 3).

Figure 3. Screenshot of the emergency room. (A) The user acts as a doctor in the emergency room while interacting with the ESP by selecting different diagnoses and treatment icons. (B) Trainees can choose the present history module in history taking to communicate with the ESP. (C) During the physical examination session, students can use a tape measure to measure the distance between the bilateral anterior superior iliac spine and the xiphoid process to determine whether the pelvis was displaced. (D) The students order a computed tomography scan to evaluate the location and severity of the ESP's injury. ESP: electronic standardized patient. Please note that a higher resolution version of this image can be found in Multimedia Appendix 1.

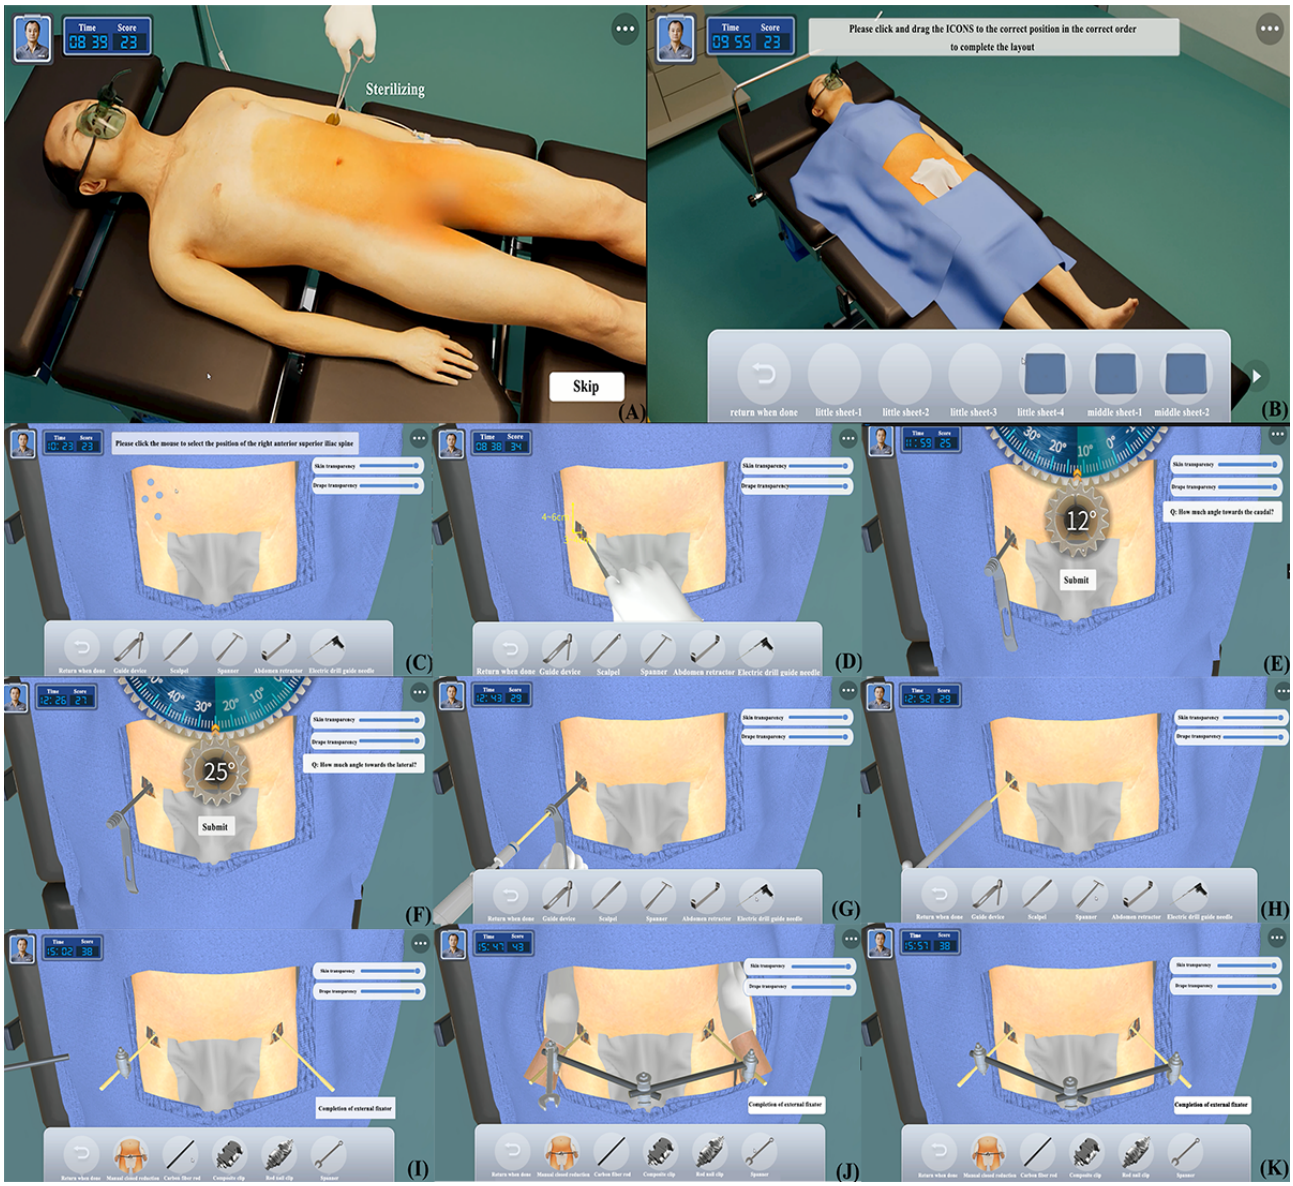
Upon initiating appropriate immediate treatment measures, the ESP was transferred to the intensive care unit. Vital sign monitors reflected real-time changes based on the condition and treatment progression. In this module, users learned about the causes, clinical manifestations, severity classifications, and management of hemorrhagic shock (Figure 4).

Figure 4. Screenshot of hemorrhagic shock and its treatment. (A) Monitors in the intensive care unit show decreased blood pressure, increased heart rate, and subnormal central venous pressure and arterial oxygen saturation in the ESP. By users' observation, the ESP at this time showed pallor, decreased urine output, and cold sweats. Users can also learn about the compensatory mechanisms of ESP in terms of blood redistribution, autotransfusion, and auto-infusion at the system, organ, and tissue levels after hemorrhagic shock. Screenshot of treatment principles for severe pelvic trauma. (B) In this module, the user should drag the corresponding icons from all the treatment measures given on the left to the right blank according to the treatment principle. When the dragged content matches the built-in answer of the system, the next section will be entered. ESP: electronic standardized patient. Please note that a higher resolution version of this image can be found in Multimedia Appendix 1.



During the surgical procedure for external fixation of a pelvic fracture, users first completed preparatory tasks such as handwashing and donning surgical attire. Then, the ESP underwent anesthesia, sterilization, positioning, drilling, and bracket installation according to surgical standards (Figure 5).

Figure 5. Screenshot of the surgical procedure of external fixation of pelvic fractures. (A) According to the sequence of operation, the users need to complete disinfection, (B) laying, (C) positioning, (D) incising, (E,F) positioning and protection of the guide, (G) electric insertion of screw, (H) manual insertion of screw, (I) use of rod-nail clamp and composite clamps, and (J,K) adjustment of the external fixator after manual reduction. Please note that a higher resolution version of this image can be found in Multimedia Appendix 1.



Phase 2: Framework Construction

Construction of Pelvic Fracture Model

To provide learners with a comprehensive understanding of pelvic anatomy and fracture morphology, we collaborated with software engineers to develop the relevant content. The development process involved several steps. Initially, 3D modeling data of pelvic fractures were extracted from real clinical cases, and a preliminary geometry was constructed using the Maya (Autodesk) development tool to complete the foundational model of pelvic fractures. Subsequently, the ZBrush (Pixologic) tool was used to sculpt and refine the fracture site shape, fracture line position, and bone surface structure of the basic pelvic fracture model, minimizing the detailed morphology of the pelvic fracture. Next, we used the support model subdivision level adjustment feature to enhance the pelvic fracture model's subdivision level, showcasing the complex structure of the fracture site. The addition of materials and textures in Maya, such as bone texture and skin color and texture, further improved the visual realism. The established skeletal system was then integrated into the pelvic fracture model, and animations were created based on real pelvic fracture case data, including the degree of fracture displacement and the relative position of fracture blocks. Finally, the pelvic fracture model was exported from Maya to Unity (Unity Technologies) for digital and real-time rendering, allowing learners to interact with a pelvic fracture model in a virtual environment to simulate actual surgical procedures. The development and construction process of the pelvic fracture model is elaborated in Multimedia Appendix 2.

Construction of System Application

The digital simulation system was segmented into 3 ports: the department administrator, course leader, and user ports, constructed on a website platform. The department's primary role is to create the appropriate courses in the system, either

compulsory or optional. Once the courses are established, they should be linked to the digital simulation skills training system, and relevant instructors assigned to teach all enrolled students for the semester. Course instructors are responsible for preparing preview materials, learning videos, self-assessment questions, and postclass surveys. They also review experimental outcomes and evaluate their performance within the system. Users can engage with the digital simulation system for severe pelvic trauma by enrolling in or attending a scheduled course. Upon system login, the interface offers 2 modes: training and assessment. Due to the digital simulation experiment teaching integration with the virtual simulation experiment teaching sharing platform of Nanjing Medical University, campus users are not required to register or authenticate before use, thanks to unified identity verification and experimental data integration.

Phase 3: Personnel Training

Faculty Training

Faculty training targeted course directors and instructors from various disciplines within basic and clinical medicine, aiming to familiarize them with the digital simulation experimental teaching system. They received training on case materials, experimental teaching objectives, principles, teaching processes and methods, steps, outcomes, and conclusions. Additionally, they learned to address technical system issues, respond to student inquiries, and interact with students on the platform during experiments.

Student Training

Before software utilization, students were informed about the operating system and hardware configuration requirements. The application runs on a Windows 7 64-bit or higher PC, equipped with a 3.60 GHz Intel i5 processor, 8 GB RAM, NVidia GTX 2060 graphic card, and a 1920×1080 display resolution. The application supports various browsers on different operating systems, such as Google Chrome, the 360 browser, and Firefox. After accessing a specific URL, users must install MengooLauncher, requiring less than 100 MB of plug-in capacity, as indicated. Before proceeding to the autonomous training or assessment interface, users familiarize themselves with the experimental teaching objectives and principles through introductory and instructional videos.

Phase 4: Pilot Running Evaluation of Digital Simulation Software

Design

A self-controlled teaching comparison study was conducted at Nanjing Medical University, China, from October 2023 to January 2024, to examine the impact on knowledge, skills, and confidence before and after using virtual simulation experimental teaching software. All participants underwent a knowledge assessment of equal difficulty before and after system engagement.

In the initial design phase, the teaching and research teams sought input from the software development team and feedback from various users through internal reviews. A case-based VR simulation of severe pelvic trauma was tested by students majoring in clinical medicine, clinical teachers, and basic medicine instructors. We distributed the ESP digital simulation teaching web link via WeChat (Tencent) to pertinent users, soliciting face-to-face or written feedback on case and script design and software development, including aspects related to clinical and basic medicine education. Additionally, the teaching research group reviewed classical cases of severe pelvic trauma and questionnaire responses.

Sampling and Recruitment

The recruitment criteria were as follows: (1) students must have completed courses in diagnostics, internal medicine, and surgery; (2) they needed to have a laptop for the study; (3) they should not have participated in any form of digital simulation software training for clinical skills prior; and (4) they agreed to participate in the pilot study and signed an informed consent form. We invited a purposive sample of 20 fourth-year undergraduates and 20 first-year graduate students majoring in clinical medicine from the First Clinical Medical College of Nanjing Medical University to test the case-based VR simulation software. Based on sample size requirements previously reported in the literature for evaluating data collection materials, a minimum of 10 samples is necessary to ensure the adequacy and validity of the assessment instrument [20]. The evaluation sought feedback from a diverse group of users, including undergraduate and graduate students, as well as teachers with various professional titles. The qualitative study used a representative population most familiar with the study topic, comprising 5 orthopedic teaching teachers and 5 basic medicine teachers.

Data Collection

Participants were required to complete the training and assessment using the digital simulation software for severe pelvic trauma treatment. Our data collection involved a repeated measurement approach to assess knowledge test scores before and after the simulation. Feedback on the simulation teaching tools was collected through a single questionnaire. Participation in the survey was entirely voluntary, and students were informed that their decision to participate would not impact their academic standing. The survey distribution was conducted independently, with no direct or known ties between the distributors and the students, ensuring an unbiased and pressure-free environment for participants. Participants were recruited and invited to complete the survey through the WeChat platform using the Wenjuanxing applet. The survey was administered anonymously to encourage honest feedback on their experience with the VR simulation software.

Outcome Assessment

Although evaluation questionnaires are commonly used to compare learning tools, there is a dearth of validated tools for assessing the ESP digital simulation software as a learning instrument. Consequently, the questionnaire was adapted from a validated assessment tool in educational literature, offering a resource for future research on the perception in clinical medical professional education. The questionnaire comprised 15 Likert-scale statements (1=strongly disagree to 5=strongly agree), assessing accessibility and usability. The teaching team and subject experts reviewed the questionnaire. Cronbach α for the questionnaire was 0.85 (n=15). The questionnaire was

adapted from a validated assessment tool widely used in educational literature for clinical medical professional education [21]. The instrument used for assessing system acceptability was based on a modified version of the Technology Acceptance Model questionnaire, with validation provided by Balki et al [22]. The Cronbach α coefficient, which reflects internal consistency, was calculated jointly for both the usability and acceptability surveys, yielding a consistent value for both aspects.

Data Analysis

Descriptive analysis was applied to the quantitative data obtained from the Likert scale. For qualitative data, which included responses to 7 open-ended questions, we used a validated content analysis method as described by Elo and Kyngäs [23]. All participant comments were transcribed and imported into Excel (Microsoft Corp) for coding. The content analysis process consists of several steps: (1) familiarizing oneself with the data and the hermeneutic spiral, (2) dividing up the text into meaning units and subsequently condensing those meaning units, (3) formulating codes, and (4) developing categories and themes [24]. Initially, the primary investigator analyzed the content, and the research team subsequently reviewed and discussed the codes to achieve consensus. In cases of disagreement, group discussions were held, and, if necessary, a third-party opinion was sought to ensure triangulation and enhance reliability. The 7 open-ended survey questions are provided in Multimedia Appendix 3 for reference.

For user acceptance analysis of the ESP platform among undergraduates, graduates, and tutors, descriptive statistics were used. To compare the mean rating scales of each survey item between groups, an independent 2-tailed *t* test was performed with a significance threshold of $P<.05$. Prior to conducting parametric tests, we verified the assumption of normality using the Shapiro-Wilk test, confirming that the data met the requirements for a parametric approach. This method was chosen over nonparametric tests due to the normal distribution of the data, making it suitable for our sample size and study design.

Ethical Considerations

The Nanjing Medical University ethics committee approved this study (2023418). During the informed consent process, participants were made aware that no incentives were provided for participation in the survey. All methods were implemented in accordance with the Helsinki declaration. All participants were voluntary in the study.

Results

Demographic Results

Of the 56 students enrolled in the optional course on the integrated case of severe pelvic trauma in October 2023, 40 students consented to participate in the pilot study. Among these participants, 50% (n=20) of the students were senior-year undergraduates, 50% (n=20) of the students were first-year graduates (n=20), 45% (n=18) of students were men, and 55% (n=22) of the students were women. The mean age was 22.9 (SD 1.3) years. Among the undergraduate participants (n=20), there were 10 male and 10 female students, with a mean age of 21.9 (SD 0.9) years. For the graduate participants (n=20), there were 8 male and 12 female students, with a mean age of 24.0 (SD 0.8) years. Ten faculty members with at least 5 years of teaching experience in orthopedic surgery or basic medicine were also invited to participate. Neither the students nor the faculty had prior experience with this type of digital simulation platform. All participants were required to complete the questionnaire shortly after finishing the training tasks.

Questionnaire Results

A 5-point Likert scale assessed perceptions of the acceptability, effectiveness, and applicability, summarized in Table 2.

Table 2. Average rating scores of survey questions (Q1-Q15) by all students.

Survey questions	Average rating scores, mean (SD)	
	Undergraduate students	Graduate students
(1) The digital software provides a simulation of a real patient	4.40 (0.66)[a]	4.80 (0.40)
(2) During the simulation, I felt like a doctor taking care of this patient	3.90 (0.99)	3.90 (1.14)
(3) When I finished the simulation, I felt I had to make the same decisions as doctors in real life	4.55 (0.50)	4.80 (0.40)
(4) The VR[b] simulation is interesting and useful	4.85 (0.36)	4.70 (0.46)
(5) The difficulty of the VR simulation is appropriate to my own level of knowledge and skills	4.10 (0.94)[a]	4.60 (0.49)
(6) The feedback from the system adequately reflected my actual performance	4.80 (0.40)	4.60 (0.66)
(7) The goals of scenario simulation are clear and easy to understand	4.55 (0.59)	4.80 (0.40)
(8) I can access the system anytime and anywhere for simulation training	4.75 (0.54)	4.90 (0.30)
(9) The VR simulation can help me to use basic medical knowledge to explain clinical manifestations of clinical reasoning skills	4.80 (0.40)[c]	4.20 (0.87)
(10) The ESP[d] simulator can help me develop clinical operation skills	4.30 (0.78)	4.60 (0.49)
(11) I feel more confident about working with hospital colleagues	4.40 (0.80)	4.70 (0.46)

(13) The VR simulation can support courses and exams	4.60 (0.49)	4.75 (0.43)
(14) Compared with traditional teaching practice training methods, VR simulation can reduce my training cost and risk	4.90 (0.30)[c]	4.50 (0.50)
(15) In general, this VR simulation training should enhance my learning	4.80 (0.40)	4.80 (0.40)

[a]$P<.05$ compared to the graduate student group.

[b]VR: virtual reality.

[c]$P<.01$ compared with the graduate student group.

[d]ESP: electronic standardized patient.

The respondents showed strong agreement; 95% (n=38) agreed or strongly agreed that the interactive software simulated a real patient scenario (Q1 in Figures 6 and 7). However, 68% (n=27) agreed or strongly agreed that “During the simulation, I felt like a doctor caring for this patient” (Q2), with 18% (n=7) neutral and 15% (n=6) disagreeing. All students (n=40, 100%) felt they had to make real-life doctor decisions by the end of the simulation (Q3) and found the VR simulation interesting and useful (Q4).

Figure 6. Acceptability, effectiveness, and applicability of the case-based VR software by undergraduate students. ESP: electronic standardized patient; VR: virtual reality. Please note that a higher resolution version of this image can be found in Multimedia Appendix 1.

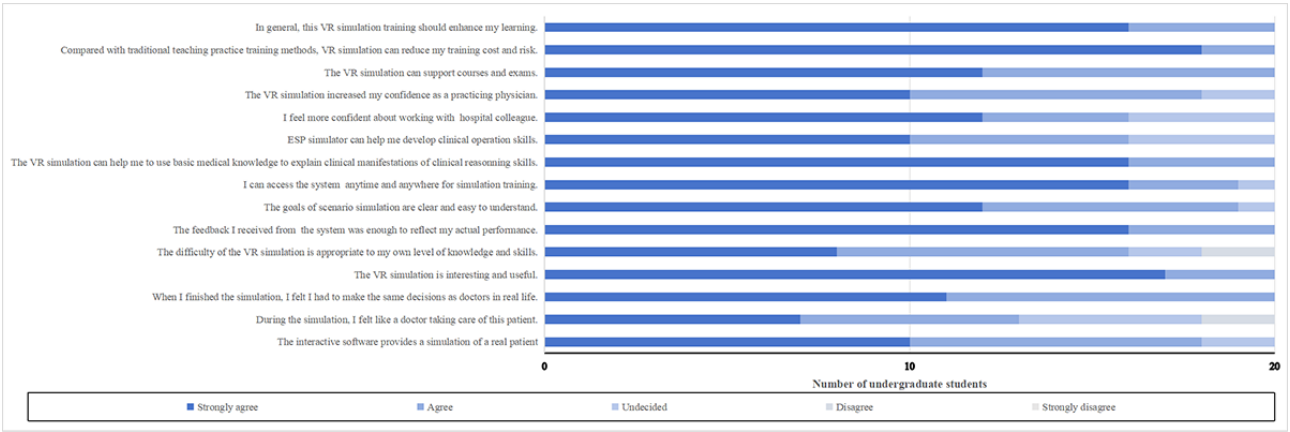

Figure 7. Acceptability, effectiveness, and applicability of the case-based VR software by graduate students. ESP: electronic standardized patient; VR: virtual reality. Please note that a higher resolution version of this image can be found in Multimedia Appendix 1.

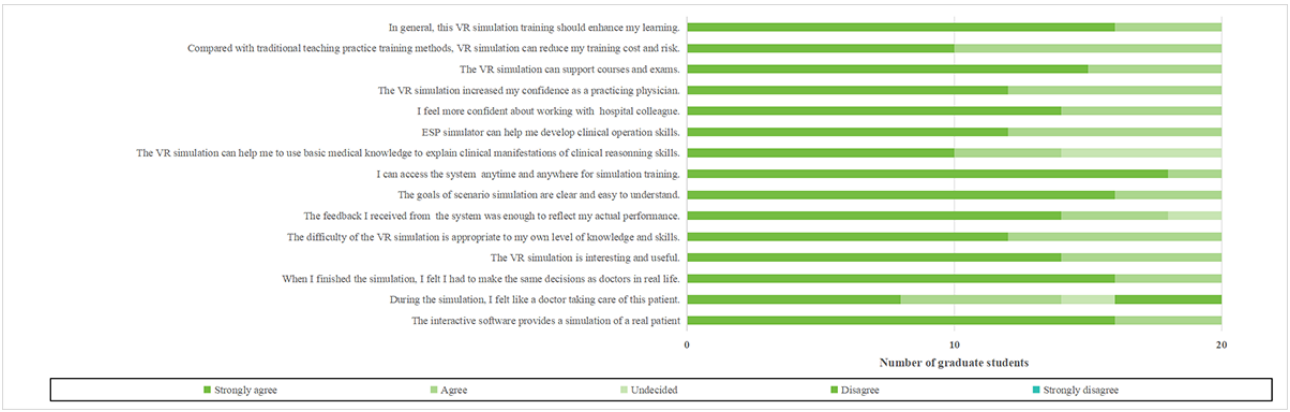

Additionally, 90% (n=36) believed the VR simulation's difficulty was appropriate for their knowledge and skills (Q5), while 5% (n=2) disagreed. Moreover, 95% (n=38) reported that the feedback from the system sufficiently reflected their performance (Q6). Most students (95%, n=38) understood the goals of the scenario simulation clearly (Q7). Nearly all students (98%, n=39) could access the system anytime for training (Q8), and 98% (n=39) agreed that "The VR simulation can help apply basic medical knowledge to clinical reasoning skills" (Q9).

When inquired if the ESP simulator aided in developing clinical operational skills (Q10), 85% (n=34) agreed. Regarding confidence in collaborating with hospital colleagues (Q11) and functioning as practicing physicians (Q12), 90% (n=36) agreed or strongly agreed. All students (n=40) concurred that the VR simulation supports courses and exams (Q13), is cost-effective compared to traditional training (Q14), and enhances learning overall (Q15).

Impact of Training Level on Questionnaire Answers

Finally, a 2-tailed *t* test was used to compare the average rating scales between undergraduate and graduate students. This analysis aimed to determine if the responses varied according to their academic level. Specifically, for Questions 1 and 5, undergraduate students exhibited significantly stronger disagreement than their graduate counterparts, as indicated by the *P* values (Q1, *P*=.03; Q5, *P*=.047). Moreover, when compared to graduate students, a larger proportion of undergraduates believed that VR simulation could enhance their clinical reasoning abilities (Q9, *P*=.009) and decrease their training costs and associated risks (Q14, *P*=.004). Additionally, all participants indicated a low level of agreement with the statement "During the simulation, I felt like a doctor taking care of this patient" (Q2, *P*=.99). No significant differences were observed in responses to the remaining questions when analyzed based on academic level.

Qualitative Analysis

Overview

The members of the research team conducted a 1-to-1 structured interview with the participating teachers around the interview outline of 7 open questions formulated in advance, as shown in Table 3.

Table 3. Themes of teacher groups' interview on the application and research of digital simulation teaching curriculum system.

Theme	Teacher
Perceived benefits of systematic teaching	"As one of the most complex and urgent diseases in orthopedics, severe pelvic trauma often fails to receive on-site teaching from teachers in the tense emergency treatment site. In addition, due to the long treatment period of this disease, it takes a long time to fully learn the diagnosis and treatment process of this disease. However, in real life, learners only spend limited time rotating with one department and cannot follow through the entire disease process and treatment course. By creating typical cases of severe pelvic trauma and constructing a virtual clinical diagnosis and treatment environment based on ESP, this system shortens the learning cycle of students, enables learners to experience different treatment settings, allows a large scale concurrent online participation breaking through the limitations of traditional teaching in time and space and improving the efficiency of teaching organizations."
The appropriateness of case application subjects	"It helps me conduct classified teaching according to the basic knowledge level of undergraduates and postgraduates. The basic medical and clinical medical knowledge involved in the disease set in the system is suitable for students at different undergraduate and postgraduate levels to learn. At the same time, the extensibility of the system enriches the flexibility and innovation of students' training and assessment."
The extendibility of course application	"The teaching design of this case is very suitable for the objective structured clinical examination scenario, which is closer to reality than traditional simulation training scenario. In addition, it introduces ESP, without the need for on-site re-placement of exam environments and standardized patient training."
The limitations of systematic research	"In the early stage of communication and interaction with the ESP speech inquiry, it was found that the ESP lacked a large sample of language training model library, so it could not recognize the semantics of the trainer. In addition, the ESP has not achieved the language style characteristics of different types of characters at this stage."
Recommendations for enhancing systematic research	"To enhance the virtual ESP simulation system, five improvements were suggested: enlarging the ESP case database, incorporating a feature for automatic and manual responses to technical queries, broadening the range of disease diagnosis and treatment simulations, expanding the ESP history collection database, and advancing the ESP's artificial intelligence for inquiry processing."

Theme 1: Perceived Benefits of Systematic Teaching

Participants noted that the digital simulation experimental teaching system for severe pelvic trauma significantly improved teaching efficiency and effectiveness, overcoming the traditional teaching constraints related to time and space.

Theme 2: The Appropriateness of Case Application Subjects

Most participants pointed out the variable difficulty of teaching cases within the system for different learning groups, highlighting the advanced design. The freedom for students to interact with the ESP in the system underscores its innovative development. The immersive simulation for diagnosis, treatment training, and assessment allowed students to thoroughly apply their theoretical knowledge and skills, presenting a notable challenge.

Theme 3: The Extendibility of Course Application

The majority of participants regarded case-based digital simulation systems as potent educational tools for both undergraduate and graduate training. A substantial number of participants viewed the system as suitable for integration into an objective structured clinical examination.

Theme 4: The Limitations of Systematic Research

Some limitations of the digital simulation software were reported by participants, particularly issues with the ESP not always accurately recognizing the semantics and tone of the inquiries.

Theme 5: Recommendations for Enhancing Systematic Research

A large case base, different training paths, and smarter ESP interaction can enhance the freshness, challenge, and realism of the ESP experience for the trainers.

Theoretical Knowledge Level of Severe Pelvic Trauma

A comparison of theoretical examination scores before and after participants used the digital simulation software for severe pelvic trauma showed significant improvements in their overall scores for diagnosing and treating the condition, making preliminary diagnoses, the sequence of disease treatment, emergency management of hemorrhagic shock, and performing external fixation of pelvic fractures (Table 4). The IQR box plots for the theoretical knowledge levels of severe pelvic trauma, both pretest and posttest, are provided in Multimedia Appendix 4.

Table 4. Mean scores at presimulation and postsimulation for the 5 uncoached assignments.

Severe pelvic trauma clinical skill training	Presimulation score, % (SEM)	Postsimulation score, % (SEM)	Mean difference[a] (95% CI)	*t* test (df=39)	Cohen *d*	*P* value[b]
Order of diagnosis and treatment	49.9 (2.0)	85.5 (1.4)	35.5 (32.7-38.3)	25.9	3.4	.001
Make a preliminary diagnosis	45.1 (1.4)	89.4 (1.0)	44.4 (42.2-46.5)	41.8	6.0	.001
Order of disease treatment	69.4 (1.8)	95.2 (0.5)	25.8 (22.2-29.5)	14.3	3.2	.001
Emergency treatment of hemorrhagic shock	39.7 (0.9)	85.8 (0.8)	46.1 (43.6-48.6)	37.6	8.5	.001
External fixation operation of pelvic fracture	32.7 (2.3)	91.1 (0.7)	58.4 (53.4-63.3)	24.1	5.3	.001

[a]The analysis included only paired data. The mean difference is the difference in mean presimulation score and mean postsimulation score.

[b]*P* value obtained from a paired 2-tailed *t* test.

Discussion

Principal Findings

This study yielded 3 primary findings. First, we developed a case-based digital simulation teaching system for severe pelvic trauma, incorporating principles of basic and clinical medicine. In contrast to traditional training methods, the VR system allows students to engage in repeated practice at their own pace, providing immediate and standardized feedback after each interaction. This feature overcomes challenges like high teacher-student ratios and insufficient feedback, which are common in traditional training environments. Furthermore, the use of a computer model to demonstrate physiological hemodynamic changes has been shown to aid in understanding the connection between clinical phenomena and underlying knowledge. Second, the software's acceptability, perceived ease of use, and perceived usefulness were highly regarded by users. Finally, the application of this digital simulation teaching system resulted in a significant improvement in all participating knowledge and skill scores. These findings contribute to the innovation in severe pelvic trauma skills training and may offer guidance for the development of enhanced training strategies and the revision of orthopedic surgery training standards.

Comparison to Prior Work

Although severe pelvic trauma is relatively rare in China, our hospital, being an orthopedic center of excellence, sees a higher incidence, treating over 100 patients annually and performing more than 20 external pelvic fixation procedures. The design of our case-based VR simulation curriculum for severe pelvic trauma draws from real cases, expert consensus, and literature reviews. Although previous research has demonstrated the efficacy of integrated learning [25], simulation training [26,27], traditional CBL [13], online learning [28], and digital patient simulator-assisted learning [29] in orthopedic clinical skills training, few studies have combined these methodologies. To our knowledge, this research is the inaugural study to amalgamate these proven effective training methods to enhance severe pelvic trauma clinical skill training, using a hybrid approach to assess the digital simulation efficacy.

Participants' acceptance of this clinical skills training was evident in several areas. Most participants felt the simulation training provided a compelling immersion experience, was accessible at any time and location, and had clear and understandable case scenario goals. Previous studies indicate that digital simulation software can significantly impact learning success [30]. Moreover, the degree of immersion is crucial in VR software, as identification with a digital character directly influences learning motivation and effectiveness [31]. Concerning the utility, all students concurred that the self-directed exploration learning method facilitated a deeper understanding of the knowledge and skills necessary for treating severe pelvic trauma and bolstered their confidence in handling similar conditions in real-life scenarios.

However, acceptance of clinical skill training was lower in certain aspects. A minority of trainees felt that the digital simulation technology's construction of the clinical environment and ESP allowed for experimentation within a safe psychological space. Studies suggest that digital simulators are effective for training doctor-patient communication skills [32]. Nevertheless, the discrepancy between virtual scenarios and real-life situations led to challenges in caring for actual patients. In our pilot study, most learners reported difficulty in direct communication with the ESP in the virtual environment, including eye and body language, and in discerning the nuances of the real language environment (such as tone and intonation); hence, they did not fully practice effective doctor-patient communication skills. Future educational efforts in all hospital departments should prioritize teaching doctor-patient communication skills to students.

Differences in the efficacy of case-based VR in pelvic trauma clinical skills training were observed between undergraduate and graduate students. Undergraduate respondents felt that after undergoing training with the digital simulation system, they solidified their basic medical knowledge and mastered the diagnostic and treatment processes for severe pelvic trauma; however, they expressed a lack of confidence in performing pelvic fracture external fixation. Graduate respondents believed that systematic training deepened their understanding of the diagnosis, treatment, and operational procedures for antihemorrhagic shock therapy and pelvic fracture external fixation. These variances are attributable to their respective stages of learning: undergraduates possess a stronger foundation in basic medical knowledge, while graduates have more opportunities to apply clinical knowledge in practice. Furthermore, undergraduate students outperformed graduate students in retaining disease-related knowledge due to their firmer grasp of basic medical principles. Conversely, their skills

were slightly inferior to those of graduate students, a disparity linked to the latter's greater internship experience and the number of surgical procedures conducted in the hospital. Thus, the training focus should be tailored to each need during severe pelvic trauma clinical skill training.

Quantitative outcome analyses revealed an overall improvement in pass rates at crucial assessment points posttraining with the digital simulation system, with external fixation of pelvic fractures displaying the most significant enhancement. Participants identified the realism and interactivity of the pelvic fracture model within the virtual environment as pivotal in elevating their learning experiences and assessment scores. Despite this, scores for external fixation of pelvic fractures were not the highest due to the inherent complexity and the necessity for interns to rotate through the orthopedic department to gain familiarity with patient care and the surgical technique [33]. Although the scores for diagnosing and treating the disease were the lowest presimulation, participants' scores in these 2 categories were the highest.

Personal interviews confirmed that teaching software facilitates large-scale online student learning in terms of ease and effectiveness. Tailoring cases to different learner groups introduced high levels of order, innovation, and challenge. The experiment also addressed challenges such as prolonged real-world teaching durations, access to actual patients, and teaching environment constraints. However, 1 instructor cautioned that this innovative skill training should complement, rather than replace, traditional teaching methods, a sentiment echoed by other educational research [21,34].

Implications

The digital simulation software for severe pelvic trauma provides undergraduates with an immersive learning experience that bridges theoretical knowledge and practical skills. For graduate students, it offers targeted preclinical training, preparing them for real-world trauma care. This approach enhances skill acquisition and promotes standardized training, potentially improving patient outcomes in severe trauma cases.

Limitations

Limitations include the inability to directly compare the digital simulation teaching system for severe pelvic trauma with traditional teaching models. Moreover, being self-controlled, participants' preexisting knowledge about the digital simulation system may have biased the outcomes. Although the participant count was sufficient for statistical analysis in this pilot study, the sample size remains limited.

Conclusions

Case-based VR simulation of skill training is an effective educational approach for medical students learning about severe pelvic trauma. It presents a potentially resource-efficient approach to delivering high-quality education for both educators and learners.

Acknowledgments

We express our gratitude to the 2021 first-class undergraduate curriculum project at Nanjing Medical University for its financial support. Additionally, we thank the undergraduate and graduate students of the First Clinical Medical College of Nanjing Medical University for their involvement, as well as the teaching development teams of the First Clinical Medical College and the Basic Medical College for their role in instructional design, software development, and production. The corresponding author may be contacted via email for further details or to request permission for educational tool use. Our appreciation also extends to Editage for their assistance with English language editing.

Data Availability

The datasets generated during or analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

All the authors (PT, YX, KQ, ML, and JH) were involved in the study design and methods. PT conducted the investigation and formal analysis of the data and was responsible for writing the first draft of the manuscript. ML and JH supervised the study. All the authors contributed to and approved the final manuscript.

Abstract

Background: The use of extended reality (XR) technologies in health care can potentially address some of the significant resource and time constraints related to delivering training for health care professionals. While substantial progress in realizing this potential has been made across several domains, including surgery, anatomy, and rehabilitation, the implementation of XR in mental health training, where nuanced humanistic interactions are central, has lagged.

Objective: Given the growing societal and health care service need for trained mental health and care workers, coupled with the heterogeneity of exposure during training and the shortage of placement opportunities, we explored the feasibility and utility of a novel XR tool for mental health consultation training. Specifically, we set out to evaluate a training simulation created through collaboration among software developers, clinicians, and learning technologists, in which users interact with a virtual patient, "Stacey," through a virtual reality or augmented reality head-mounted display. The tool was designed to provide trainee health care professionals with an immersive experience of a consultation with a patient presenting with perinatal mental health symptoms. Users verbally interacted with the patient, and a human instructor selected responses from a repository of prerecorded voice-acted clips.

Methods: In a pilot experiment, we confirmed the face validity and usability of this platform for perinatal and primary care training with subject-matter experts. In our follow-up experiment, we delivered personalized 1-hour training sessions to 123 participants, comprising mental health nursing trainees, general practitioner doctors in training, and students in psychology and medicine. This phase involved a comprehensive evaluation focusing on usability, validity, and both cognitive and affective learning outcomes.

Results: We found significant enhancements in learning metrics across all participant groups. Notably, there was a marked increase in understanding (P<.001) and motivation (P<.001), coupled with decreased anxiety related to mental health consultations (P<.001). There were also significant improvements to considerations toward careers in perinatal mental health (P<.001).

Conclusions: Our findings show, for the first time, that XR can be used to provide an effective, standardized, and reproducible tool for trainees to develop their mental health consultation skills. We suggest that XR could provide a solution to overcoming the current resource challenges associated with equipping current and future health care professionals, which are likely to be exacerbated by workforce expansion plans.

mental health; training; consultation; extended reality; virtual reality; augmented reality

Introduction

As the demand for mental health services in health care systems continues to rise, the need for skilled professionals capable of providing effective mental health consultation and support also increases [1,2]. In the face of changing workforce training requirements (coupled with significant health care workforce expansion plans), there is a growing recognition that the effective implementation of emerging technologies could help overcome some of the logistical and resource-related barriers involved in education and training.

Mental health nursing, in particular, faces distinct challenges that necessitate specialized training solutions. Mental health nurses encounter unique stressors, including high levels of emotional exhaustion, moral distress, and exposure to patient-initiated violence, all of which contribute to job dissatisfaction and high turnover rates [3], which in turn negatively impact workforce stability, patient outcomes, and overall health care service quality [4]. Additionally, mental health nurses often report insufficient opportunities for continuing professional development and limited support from leadership, further compounding retention challenges. Addressing these issues through targeted and innovative training approaches is essential for fostering resilience, enhancing job satisfaction, and improving workforce retention.

Beyond specialist mental health settings, primary care physicians or general practitioners (GPs) also play key roles in managing mental health conditions, with more than a third of general practice consultations involving mental health issues [5]. Effective communication and therapeutic relationships have been shown to significantly influence outcomes, emphasizing the need for better training in interpersonal and empathetic skills for managing mental health conditions in primary care. However, variability in the ability of GPs to detect and manage mental health issues highlights gaps in current training models [6]. As communication forms a central part of mental health treatment, poorly trained clinicians may inadvertently block disclosure of emotional distress, potentially delaying critical interventions [5]. Therefore, innovative training approaches are crucial not only for mental health nurses but also for GPs and other health care professionals involved in mental health consultations.

Traditional training for health professionals in managing mental health problems typically relies on a combination of in-person placements, which employ observation-based learning, and actor-based simulations. While in-person placements provide valuable real-world experience, they often present challenges, such as unpredictable exposure to a diverse range of patient demographics, risks to both students and vulnerable service users, and limited opportunities for structured feedback. Actor-based simulations, on the other hand, are difficult to scale and standardize due to variability in actors' interpretations of scripts and inconsistencies in their familiarity with specific case studies. These limitations make it challenging to provide health care professionals with the comprehensive training necessary to handle the complexities of mental health consultations. Effective and compassionate mental health consultations require more than procedural knowledge. They demand the ability to empathize, engage in therapeutic communication, and establish a strong patient-provider relationship. To address these needs, training must focus on promoting empathy and compassion while preparing health care professionals to navigate the diverse backgrounds and emotional experiences of patients. However, traditional training methods often struggle to meet these goals due to ethical concerns around exposing students to sensitive cases and the inherent difficulty in replicating the unpredictable dynamics of real-life mental health scenarios.

Advances in a suite of new immersive technologies that go under the banner of extended reality (XR) and include virtual reality (VR) and augmented reality (AR) could be particularly well-suited to address these challenges by providing interactive, standardized, repeatable learning experiences that bridge the gap between theory and practice. VR presents users with a computer-generated environment that immerses them in a fully digitally simulated environment, while AR overlays virtually generated elements onto the real world. The value of XR for health care training has already been demonstrated across various domains, such as surgery [7], physical rehabilitation [8], anatomy [9], and the training of practical skills in nurses [10]. However, the implementation of XR in the training of mental health professionals has lagged.

Given the importance and complexity of training for mental health consultations, coupled with the increasing workload pressure on GPs and mental health nurses to meet the population's mental health support needs [7], we set out to test whether XR technology could be used to create a training environment to support the development of mental health consultation skills. We reasoned that the ability to deliver standardized repeatable experiences of varied patient encounters (including more rare presentations) in a safe and controlled environment could provide a learning experience that nurtures confidence and competence in consultation skills that augment traditional training.

To assess the potential efficacy of XR in mental health consultation training, we focused on perinatal mental health

training, a subspecialty supporting women navigating mental health challenges during pregnancy or the initial postpartum year. This is an area of the mental health service with an urgent training need. The recent report of the Royal College of Psychiatrists [8] highlighted a critical need for comprehensive perinatal training programs across both specialized and general health care services. There is also a notable lack of confidence among perinatal mental health nurses in their capacity to deliver care to women with perinatal mental health challenges, with only a quarter feeling well-equipped to support these women [9]. Trainees also have relatively limited opportunities to train, with a shortage of placement opportunities. A recent review of perinatal mental health education across 32 UK medical schools [10] found that perinatal mental health was not considered a core curriculum topic. Instead, it was typically incorporated as a subtopic within broader topic areas, such as lectures on depression. Given the shortage of staff and limited placements in perinatal mental health, a new training tool that could support the development of the next generation of health care staff could have an immediate impact.

Here, we report on the validation and evaluation of a novel XR training tool developed through a collaboration between software developers and health care staff, including nurses specializing in perinatal mental health and GPs. The simulation presents an interactive virtual patient ("Stacey") with severe perinatal mental health problems. Stacey is a mother of 2 children, with her youngest child only 4 weeks old, and has a record of mild postnatal depression following her first birth. Low mood, suicidal ideation, and episodes of psychosis add complex layers to her clinical presentation. Users interact with Stacey verbally, and her responses are selected by a human instructor from a range of prerecorded voice-acted clips in an audio repository. We explore the utility of this tool for supporting social and emotional interactions with the simulation, investigate the ease of use for trainers and trainees, and evaluate the impact on cognitive and affective learning.

Methods

Overall Approach

We undertook a 2-stage evaluation process that included a pilot study exploring feasibility and a subsequent evaluation of the perinatal mental health XR training experience in terms of learning outcomes and perceptions. In this section, we introduce the simulation platform and training experience and subsequently detail the methods and procedures common to and distinct for each phase of the experiment. It should be noted that the authors involved in developing the content played no role in the evaluation. The analysis was carried out independently by the authors KH, LT, and FM.

This study was not designed as a head-to-head comparison with traditional training approaches. Some participants, particularly those in mental health nursing, had previously received standard training methods (eg, classroom-based teaching, in-person clinical placements, or actor-based role plays), but these forms of training were not systematically assessed here. Instead, the primary aim was to evaluate the feasibility and potential impact of XR as a supplementary training tool. We have thus included the details of traditional training experiences for context but did not incorporate a direct comparative arm in this work.

XR Simulation

The simulation was built on a platform ("JoinXR") created by the software developer Fracture Reality. The JoinXR platform was designed to enable multi-user simulation training environments over a range of head-mounted VR or AR displays. In the evaluation, we used the Meta Quest 2 headset (Meta Platforms, Inc) for the VR version of the platform and Microsoft HoloLens 2 (Microsoft Corp) for the AR version.

The human-computer interface within the JoinXR platform was central to facilitating immersive lifelike interactions with the virtual patient. The interface allowed learners to engage through natural voice-based dialogue, processed in real time using instructor-guided responses. The integration of audio feedback, gesture recognition (HoloLens 2), and hand controllers (Meta Quest 2) enabled users to navigate the virtual space intuitively. Learners interacted directly with Stacey, the patient avatar, whose responses, including eye contact, subtle emotional cues, and body movements, were programmed to mimic real-world patient behavior, creating a realistic and contextually relevant learning experience. Users engaged with the simulation through natural voice-based dialogue and through VR controllers (Meta Quest 2) or hand-tracking gestures (HoloLens 2). Nonverbal communication, such as the avatar's facial expression, body language, and spatial audio, enhanced the simulation's realism.

The JoinXR platform was designed to be a conversational engine enabling "human to digital avatar" interactions in a multi-user, real-time environment. In this way, it could facilitate remote participation by learners, instructors, and observers, supporting the practice and refinement of nonroutine clinical skills. The learner-instructor dynamic was a crucial component of the simulation, incorporating both real-time guidance and postsimulation feedback. Instructors played an active role during the interaction by interpreting learner inputs and controlling Stacey's responses using a soundboard system (Figure 1B). This allowed for dynamic adaptations, where learners could engage organically with the avatar and explore different conversational pathways. After the simulation, instructors conducted debrief sessions using performance analytics that tracked response accuracy, emotional sensitivity, and decision-making, providing learners with targeted feedback to refine their clinical competencies.

Figure 1. Development of the learning platform. (A) Wireframe of the patient avatar, Stacey; (B) Soundboard for instructors to control Stacey's responses; (C) Setting for the consultation, showing the learner (blue) and the patient avatar.

During the simulation, learners interacted with Stacey by asking questions that were either processed by conversational artificial intelligence (AI) or directly controlled by the instructor for tailored responses. Stacey's reactions were designed to simulate real-world patient behaviors, including nuanced emotional expressions and gestures. Figure 2B illustrates an example consultation scenario in which the learner uses voice input to ask about Stacey's symptoms, prompting verbal and nonverbal responses (eg, maintaining eye contact and gesturing to emphasize a point).

Learners using VR devices (Meta Quest 2) could navigate the virtual consultation room using handheld controllers to manipulate objects, such as a clipboard or a stethoscope, or to adjust their position relative to Stacey. In contrast, AR users (HoloLens 2) experienced a blended environment where Stacey's avatar appeared within a real-world room.

The clinical simulations were developed through collaboration between Fracture Reality and a panel of subject-matter experts from the National Health Service (NHS), including mental health clinicians, GPs, and psychologists specializing in perinatal mental health. These experts supported the design of all aspects of the simulations, from character development and storyline construction to ensuring the accurate portrayal of medical conditions. Prior to the present evaluation, the development process included an iterative feedback process involving clinicians with primary care and perinatal mental health experience, software developers, and intended end users.

The specific focus of our evaluation is the first clinical simulation scenario developed using this new platform (Figure 1). The simulation is centered around a female patient avatar ("Stacey"). The aforementioned clinical experts contributed to the development of her patient history and personal attributes. Digital reference photos were then gathered to build a montage of the patient. A base model was built by taking a full body scan of a human model and was modified using a combination of 3D modeling software. The 3D models were created using a combination of Maya (Autodesk) and Blender (Blender Foundation). Clothing was designed, and then, the digital model was dressed. Bespoke custom lighting and skin rendering pipelines were developed to deliver realistic digital human features that could be rendered on headsets using low-powered graphics processing units.

Multiple script iterations were recorded, and the dialogue was reviewed and refined for clinical authenticity by the Fracture Reality team in consultation with the aforementioned subject-matter experts. Auditions were held to select actors. Studio sessions and spatial audio engineering rebalanced vocals to realistically imitate the patient avatar. Animations combined motion capture, hand animation, and lip-syncing for seamless responses. A custom Unity system facilitated quick and accurate lip-syncing to facial expressions and body poses (Figure 2). Reference photos from NHS facilities were used, and lighting was tailored for realistic environments, focusing on meaningful prop placement.

Two scenarios were designed, each tailored to address the needs of 2 primary but distinct target groups: mental health nursing students and primary care trainees (postgraduate doctor in GP training). While both scenarios feature a patient named Stacey presenting with a similar mental health condition, contextual variations were introduced to align more closely with the necessary professional capabilities of the respective trainee groups.

In the mental health nursing scenario, Stacey Morris is introduced as an emergency referral from her GP for a comprehensive assessment. Stacey, a 32-year-old mother of 2 children, with a 4-week-old newborn, has a history of postpartum depression following the birth of her first child. The primary objective for the student in this scenario is to conduct an initial mental health examination of Stacey.

In the primary care scenario, following a telephone conversation with her husband, Josh, who expressed concerns about her behavior, the postgraduate doctor in GP training agrees to meet Stacey in her home. Stacey in this scenario has a similar profile as in the mental health nursing scenario. She is a 32-year-old mother of 2 children, with her youngest child being 4 weeks old. In this context, the role of the postgraduate doctor in GP training centers on conducting a comprehensive mental health assessment with Stacey.

For each context, specific learning outcomes were defined by subject-matter experts. For the mental health nursing scenario, learners were expected to (1) understand and reflect on the lived experience of assessing the mental health of a patient with perinatal mental health problems; (2) identify signs and symptoms of perinatal mental ill health in acute assessment presentation; (3) apply the skills, knowledge, and abilities relevant to one's own profession in the assessment of mental health; and (4) have an appropriate reflected and evaluated performance of the task in a supported reflection. For the primary care setting, learners were expected to be able to (1) take history from a patient presenting with an acute psychotic illness; (2) ascertain and evaluate information relating to safeguarding; and (3) assess suicide and homicide risk.

Figure 2. Development of the verbal storyboard and voice integration for patient avatar interactions. (A) Demonstration of the process of integrating voice actors' performances into the patient avatar through a custom Unity-based lip-syncing system. Multiple iterations of dialogue scripts were recorded, and voice actors were selected via auditions, with audio engineering applied to simulate realistic patient speech patterns. Motion capture, hand animation, and spatial audio balancing enhanced the avatar's authenticity. (B) Demonstration of the verbal storyboard for the virtual patient, displaying categorized responses covering key clinical themes such as psychosis, self-harm, and family concerns. The storyboard guided the avatar's realistic conversational flow, informed by clinical expertise and reference material from National Health Service facilities to create immersive training scenarios.

General Methods

Following study advertisement, interested participants were screened for physical conditions that would exclude them from participation, including physical and auditory impairments and epilepsy. Included participants met with the instructor for a one-to-one session in a quiet room located on the university campus or at a local NHS hospital. Multimedia Appendix 1 outlines the study procedure. At the beginning of the session, participants had the opportunity to read the information sheet

and ask questions related to the study. Participants provided their consent to the study once they had been informed of their right to withdraw.

After consenting, participants were asked to complete a baseline questionnaire, capturing demographic and attitudinal data. Participants were then randomly allocated to 1 of 2 immersive environments: VR (Meta Quest 2) or mixed reality (HoloLens 2). Participants were subsequently exposed to either "primary care" Stacey (targeted at medical students and postgraduate doctors in GP training) or "mental health" Stacey (for mental health nursing or psychology students), contingent upon their current training program. These simulations share identical features, with the sole distinction lying in the introductory context of the consultation process. Both simulations were configured to align with the familiar protocols of health care trainees, specifically in terms of patient reception. Importantly, the responses of Stacey and the trajectory of the consultation remained consistent across the 2 scenarios.

Trainees verbally interacted with Stacey, who was in turn controlled by an instructor through the navigation of a soundboard, which triggered prerecorded audio clips from Stacey (see Figure 1B). The conversation journey would typically begin with general introductions; discussion of Stacey's relationships with her daughter, son, and husband; discussion of her birthday; discussion of experiences of psychosis and self-harm; and finally, formulation of a care plan. If the instructor felt the student was unable to lead the conversation or the student expressed having difficulty conversing with the avatar, prompts could be provided within the simulation. Multimedia Appendix 2 shows the prompts available for the early, mid, and late stages of the conversation that could be made visible to the students by the instructor.

Following the experience, the instructor carried out a postexperience debrief session with the trainee, including a critical discussion of the experience and the participant's performance. Following this, participants completed a postexperience survey measuring attitudinal domains and career considerations alongside measures of usability, presence, discomfort, and preference. The total session lasted approximately 1 hour (Multimedia Appendix 1).

Pilot Study

Participants

In the pilot study, we recruited 9 subject-matter experts from primary care and mental health disciplines. This included a consultant perinatal psychiatrist, a GP, 4 mental health nurses, a specialist perinatal mental health nurse, a psychiatry trainee (ST4), and a mental health nursing lecturer. All had more than 5 years of experience in their respective fields, with 8 having 10 or more years of experience. The purpose of this study was to formally test face and content validity and usability, and to support the latter, we included 5 undergraduate university students (mean age 22.4 years, SD 0.8 years).

Participants followed the procedure outlined in Multimedia Appendix 1. We evaluated face and content validity, usability, and utility as reported by a group of nonnursing or medical students and subject matter experts in the postexperience questionnaire. Face validity was assessed using a scale applied previously to expert evaluations of VR health care training [11]. This original 13-item scale was adapted to this study, and 11 items analyzed the ease of use, effectiveness, and immersion of the XR simulation on a 4-point Likert scale (strongly agree to strongly disagree).

In addition, the Lawshe method [12] also known as the content validity ratio (CVR) method was used. This is a method used to assess the content validity of a measurement instrument or a test, especially in the context of psychological, educational, or health care research, using expert opinion. Here, experts rate each item on a 3-point scale: (1) Essential: if the item is crucial and necessary for measuring the construct; (2) Useful but not essential: if the item is relevant but not critical for measuring the construct; and (3) Not necessary: if the item is irrelevant or not needed for measuring the construct. The CVR is calculated using the equation:

where *Ne* represents the count of experts who have deemed the item as "essential," and *N* denotes the total number of experts who have participated in the rating process. The CVR is a numerical value that quantifies the consensus among experts regarding the essential nature of the items under consideration. The critical value is a benchmark used to assess the appropriateness of items included in a content validity assessment. If the number of experts who agree on the relevance of an item meets or exceeds the critical value, the item is deemed valid; otherwise, it may be considered for revision or removal from the assessment. According to the values calculated previously [13] with a panel of 8 subject matter experts, this study's critical value was 0.75. Thus, constructs must surpass a CVR of 0.75 to be deemed essential to the procedure.

We also captured usability through the 10-item System Usability Scale (SUS) [14] as it has widely been used to evaluate XR as a tool for health care training [15-17]. Scores of more than 80 indicate excellence, between 70 and 80 are considered good, and less than 50 are not acceptable [18].

We assessed user discomfort through the Virtual Reality Sickness Questionnaire (VRSQ) [19]. As a more context appropriate adaptation of the validated Simulator Sickness Questionnaire (SSQ) [20], the VRSQ was designed to minimize burden on participants. The VRSQ sums the scores of oculomotor and disorientation discomfort items to generate an overall total. While there are no widely agreed bounds of acceptability for the VRSQ, we set out to compare the scores of the Meta Quest 2 and HoloLens 2 to assess relative differences in physical discomfort between the 2 devices.

Experiment

Following the demonstration of the feasibility of the use of XR in consultation training, we undertook a larger-scale evaluation. Here, we continued to collect measures of usability and supplemented them with surveys exploring cognitive and affective learning, training preference, presence, and career considerations.

Participants

The experiment involved 123 participants (mean age 24.3 years, SD 7.86 years; 97 female participants, 22 male participants, 3 nonbinary or third gender participants, and 1 who did not disclose gender). No participants had known health conditions, such as epilepsy, or visual, auditory, or cognitive disorders that would prevent participation in XR-based activities. They were drawn from a range of health care disciplines, including postgraduate doctors in GP training (n=18; mean age 38.2 years, SD 6.38 years), mental health nursing students (n=30; mean age 25.9 years, SD 7.6 years) from the Universities of Leeds and Huddersfield, and undergraduate medical students (n=28; mean age 19.8 years, SD 3.12 years) and psychology students (n=47; mean age 19.8 years, SD 3.2 years) recruited from the University of Leeds.

Participants were approached via their institutions, through the distribution of emails including information sheets. Participants were offered a monetary voucher incentive where appropriate (ie, for registered students), while clinical staff were asked to undertake the study voluntarily with no remuneration. Participants were randomly allocated to the AR (n=63, 51.2%) and VR training groups (n=60, 48.8%).

Measures

In phase 2, the VRSQ and usability continued to be evaluated as described in the pilot study. The experiment extended the evaluation to capture attitudes, cognitive and affective learning, career aspirations, presence, and conversation fluency. These self-reported measures were implemented to provide insights into the user's social and emotional interactions with the simulation, as well as any reported enhancements in knowledge, understanding, motivation, learning satisfaction, and learning confidence, further assessing the effectiveness of XR mental health consultations.

Attitudes

Cognitive Learning

Success and confidence in practical situations are often predicted by possessing knowledge, familiarity, and understanding of the themes and techniques embedded in a course curriculum [21]. Conversely, a deficiency in such familiarity may hinder the ability to apply theoretical knowledge in practice [22].

To capture this, a 14-item Perinatal Mental Health Familiarity and Awareness Scale (PMHAFS) (Multimedia Appendix 3) was developed by the study team with subject-matter experts. Participants were asked to evaluate their knowledge with, awareness of, and understanding of the perinatal mental health assessment conditions and care on a 5-point Likert scale (strongly disagree to strongly agree).

Affective Learning

Intrinsic and extrinsic motivation for learning was assessed through a 6-item scale [23], developed based on the Motivated Strategies for Learning Questionnaire Manual [24]. Evaluating intrinsic and extrinsic constructs provides a holistic examination of the influences of learner engagement from within the learner and from the learning environment [25]. Higher scores on each item suggest a greater motivation for learning.

To assess self-confidence and learning satisfaction, a 12-item variant [26] of the original Student Satisfaction and Self-Confidence in Learning Scale was used [27]. This instrument has been shown to be highly reliable, with a Cronbach α of .92 for the presence of features and .96 for their importance. Each item on the Likert scale was coded from 1 to 5 (strongly disagree to strongly agree), with 5 items reverse coded to prevent acquiescent responding. Higher scores on the scale indicate greater satisfaction and self-confidence with learning [28].

Career Attitudes

To assess students' considerations of health care specialization, we assessed 9 items across 3 affective domains of motivation, preparedness, and sense of support toward perinatal mental health specialization. Higher scores on each 5-point Likert scale indicate a greater desire to consider perinatal mental health upon graduation.

Presence

The construct of presence is regularly evaluated in studies involving virtual environments. Defined as the subjective experience of being in one place or environment, even when physically in another [29], there has been an active debate on its contribution to learning [30-32]. High levels of presence are speculated to be associated with deeper cognitive engagement, a cornerstone for effective learning [29], increasing intrinsic motivation and creating an environment where learners are more likely to integrate and retain new information [32]. A high degree of presence may help to minimize the impact of real-world distractions, allowing learners to fully immerse themselves in the task at hand [33]. Presence has also been proposed to be instrumental for the transfer of skills from the virtual to the real world [31]. We sought to measure presence through the previously validated iGroup Presence Questionnaire (IPQ) [34,35], a 14-item scale capturing spatial presence, realness, and involvement.

Ethical Considerations

Approval for the study was granted by the School of Psychology Ethics Committee (approval number: PSYC-615; date of approval: November 13, 2022). Consent was obtained from participants at the beginning of the session.

Statistical Analysis

ANOVA tests were performed to examine the effect of the XR training tool on the ratings of improvement in cognitive learning of conditions, assessment, and care. This same technique was applied to attitude changes in career motivation, support and preparedness, learning confidence, and learning satisfaction. Where appropriate, a between-subjects variable was introduced in the ANOVA when comparing population groups: GP postgraduate doctor in training, mental health nursing student, psychology student, or medical student.

For presence, specific data items related to presence were filtered and selected to include measures, such as "general," "spatial," "involvement," and "realism," as defined in the IPQ. The presence scores were reported across different devices and groups, examining how users experienced each of these presence

measures. An ANOVA assessed differences in presence scores between devices and measures (device [AR vs VR] × iGroup construct [general vs spatial vs involvement vs realism]). Post-hoc tests were applied to decompose interaction effects for VR and AR where appropriate.

For each family of tests (per construct), *P* values were corrected for multiple comparisons using the Bonferroni method. Corrected *P* values below an α threshold of .05 were considered statistically significant. All data analyses were performed in R (version 4.2.2) using RStudio (version 2022.12.0.353; Posit).

Results

Pilot Study

All experts, across both VR and AR systems (n=9, 100%), felt actively involved and in charge of the situation. The simulation software responded adequately and did not lag according to 8 of the experts, while all 9 experts reported that it was easy to learn how to interact with the software. Notably, all were interested in the progress of events throughout the simulation, suggesting high engagement. Additionally, all stated that it was easy to move around in the virtual environment, and the same amount of people reported that the controller buttons responded adequately.

Using the Lawshe method, we calculated the CVR for each step of the simulation process. These steps were: briefing instructions, medical notes, in-simulation prompts, instructor prompts, and postsimulation debrief. Briefing instructions provided the user with the necessary context for the forthcoming consultation. Medical notes, collaboratively developed with subject-matter experts, provided a comprehensive medical history for the virtual character, Stacey, to enhance the contextual richness of the consultation. In-simulation text prompts, illustrated in Multimedia Appendix 2, could be administered within the XR environment by the instructor, without verbal disruption to the ongoing consultation. In contrast, instructor prompts denoted verbal interventions made by the instructor at any time during the simulation. The postsimulation debrief is an opportunity for the user to reflect and for both the user and instructor to critically evaluate the consultation. The critical value in our study for the content validity of a construct and the component part of the simulation was 0.75. The obtained CVR scores for simulation outcomes, briefing instructions, and postexperience debrief were all 1, indicating that these processes were all rated as essential by all experts.

Some parts of the procedure, including previewing medical notes and using prompts during sessions, were considered optional by design. Our evaluation revealed that all content experts rated it as either essential or useful. In the case of in-simulation and instructor prompts, the majority found them essential or useful, but some considered them “not necessary,” as indicated by a score of 0.75.

The SUS scores were 78.75 for VR and 73.75 for AR, indicating good usability for both systems. The VRSQ scores were 0 for VR and 4.17 for AR, suggesting a negligible amount of discomfort for participants.

Pilot Study Summary

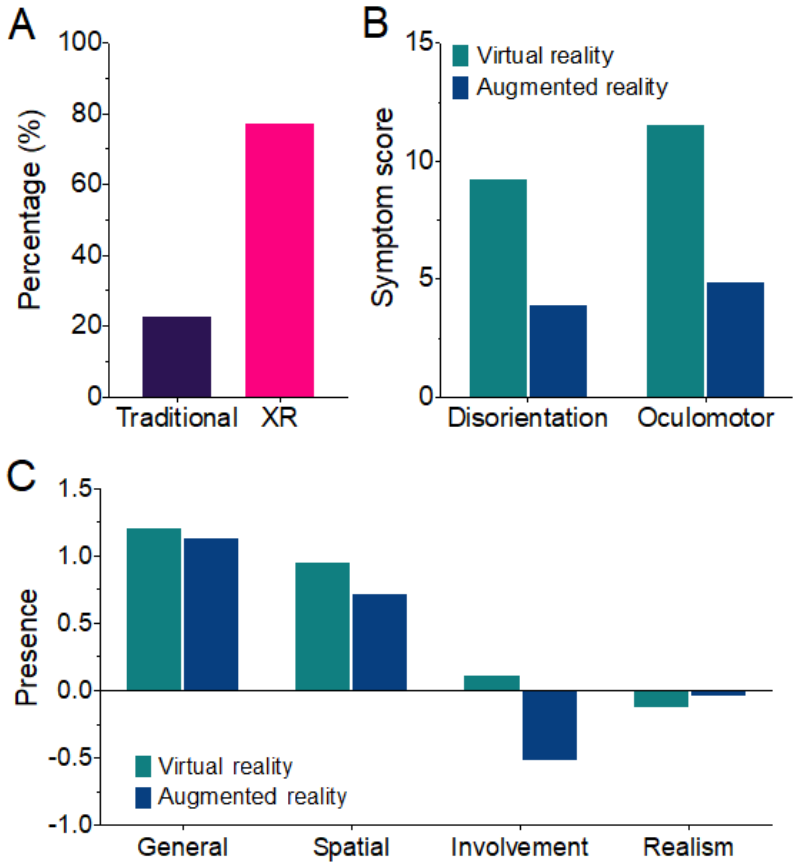
Participants provided positive feedback, reporting high usability levels for both VR and AR systems and minimal discomfort. Subject-matter experts rated the XR simulation highly in terms of engagement, involvement, and simulation quality, particularly within the context of perinatal training. They found the content and procedures valid, aligning with their expectations for an effective training session. These results suggest that the XR simulation has the potential to serve as a learner-centered training tool and provide the basis for conducting a larger-scale evaluation with health care trainees.

Experiment

Preference

Participants were asked whether they preferred the XR simulation or traditional approach to training that they had been exposed to. Overall, 77.2% (95/123) of participants preferred XR over traditional training methods (28/123, 22.8%) (Figure 3A).

Figure 3. Usability and preference. (A) User preference toward traditional learning for perinatal mental health or the integration of extended reality (XR) to augment perinatal mental health learning. (B) Symptom scores for the disorientation and oculomotor domains of the Virtual Reality Sickness Questionnaire for virtual reality (VR) and augmented reality (AR). (C) Self-reported experience of presence, illustrating that participants felt less involved in AR relative to VR. Error bars represent ±1 SEM.



Feasibility

The overall SUS score was 81.6 (SD 11.1), with no difference (t_{73}=0.75; *P*=.45) between the scores for AR (mean 82.3, SD 10.9) and VR (mean 80.3, SD 12.8), which translates to an excellent usability rating for both systems.

Simulator Sickness

In an analysis designed to understand the impact of different devices on simulator sickness, a 2-way ANOVA revealed a significant interaction between device and symptom ($F_{3,312}$=6.41; *P*<.001). There were greater sickness scores in the disorientation domain in VR (mean 9.22, SD 1.06) than in AR (mean 3.92, SD 0.81) (t_{208}=3.47; *P*<.001) and greater scores in the oculomotor domain in VR (mean 11.53, SD 1.33) than in AR (mean 4.89, SD 1.01) (t_{208}=4.34; *P*<.001). The analysis suggests that VR is more likely to cause symptoms of disorientation and oculomotor discomfort than AR.

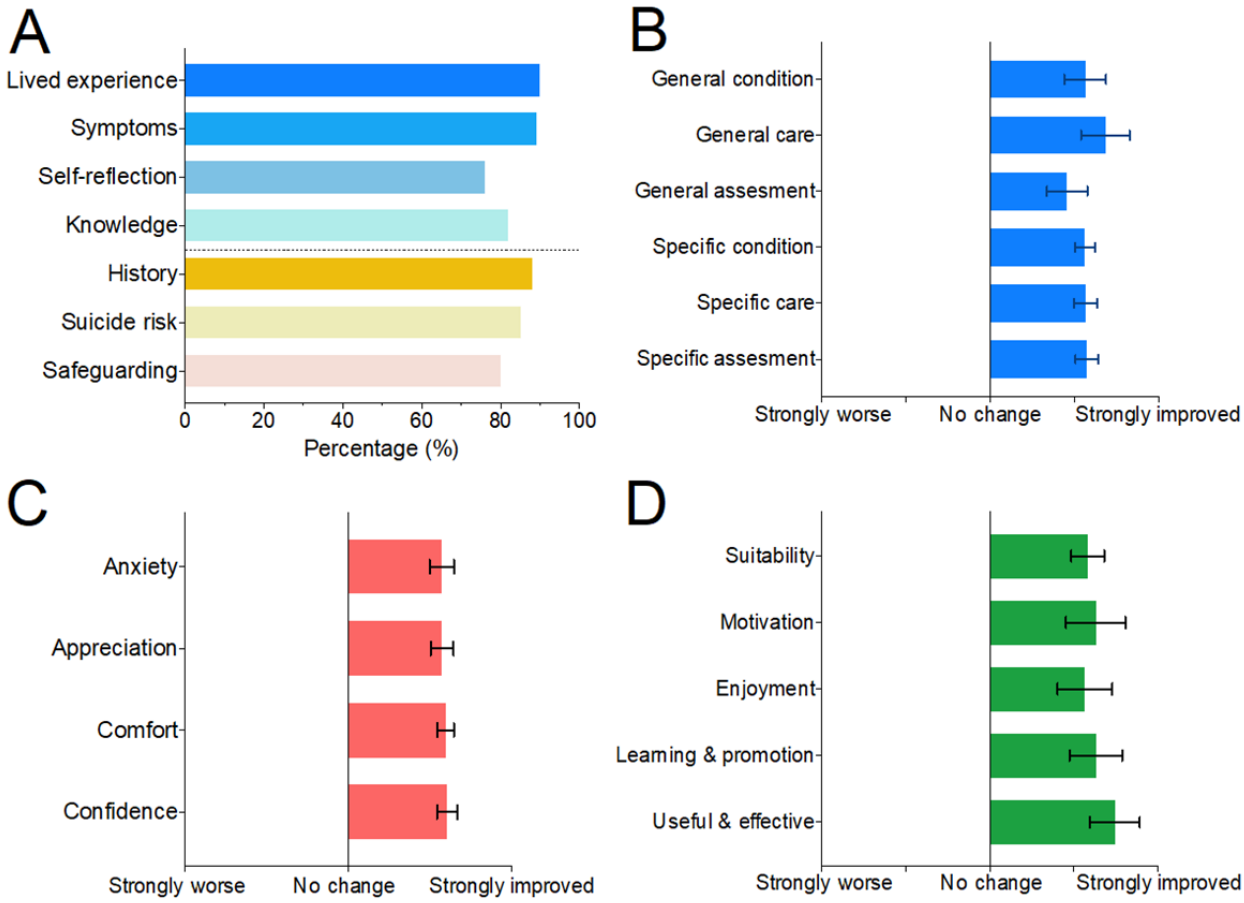
Presence

IPQ scores were compared between VR and AR. There was a statistically significant interaction between presence measure and device ($F_{3,327}$=5.78; *P*=.02; η^2_G=0.025). Post-hoc analysis revealed a statistically improved sense of involvement for those using VR relative to AR (t_{484}=3.18; *P*=.002). There were no significant differences between the systems in general (t_{484}=0.13; *P*=.90) and in the spatial (t_{484}=–1.11; *P*=.27) and experienced realism (t_{484}=1.17; *P*=.24) domains of presence.

Learning Outcomes

For the 2 simulations evaluated in this study, specific learning outcomes were defined by subject matter experts from perinatal mental health and primary care. We report these separately for each group. Figure 4A shows the percentage of sessions in which the learning outcome was achieved across all groups, as reported by the instructor.

Figure 4. Learning outcomes, cognitive and affective changes, and learning satisfaction. (A) Percentage of achievement of learning objectives for perinatal mental health and primary care simulations within sessions across all participants. (B) Improvements in understanding across perinatal conditions, assessment, and care domains following the simulation for general practitioner (GP) trainees, and improvements in understanding across perinatal conditions, assessment, and care domains following the simulation for mental health nursing students. (C) Improvements in the affective domains of confidence, comfort, appreciation for the challenges in providing support to perinatal cases, and reduction in anxiety among perinatal cases for GP trainees. (D) Improvements in the utility and feasibility domains for mental health consultation training following XR simulations compared with the current training approach. Error bars represent the SEM for domain change responses.



In the primary care simulation, instructors rated that they were able to achieve learning objective 1 (able to take history from a patient presenting with an acute psychotic illness) in 100% of sessions, learning objective 2 (able to ascertain and evaluate information relating to safeguarding) in 80% of sessions, and learning objective 3 (able to assess suicide and homicide risk) in 80% of sessions.

In the perinatal mental health simulation, instructors rated that they were able to achieve learning objective 1 (understand and reflect on the lived experience of assessing the mental health of a patient with perinatal mental health problems) in 100% of sessions, learning objective 2 (identify the signs and symptoms of perinatal mental ill health in acute assessment presentation) in 90% of sessions, learning objective 3 (apply the skills, knowledge, and abilities relevant to one's own profession in the assessment of mental health) in 89% of sessions, and learning objective 4 (have appropriate reflected and evaluated performance of the task in a supported reflection) in 80% of sessions.

Changes in Cognitive and Affective Attitudes

Primary Care

At baseline, 22% of participants stated that they had "no experience" with perinatal mental health cases, 61% expressed "little experience," and only 17% expressed "some experience." Understanding of complex mental health (general) and perinatal mental health (specific) was measured at baseline, revealing that 59% of GP trainees expressed an understanding of complex mental health at a general level and 58% expressed an understanding of perinatal mental health specifically.

Regarding affective constructs, 44% of trainees expressed anxiety around complex mental health cases and 50% expressed anxiety around perinatal mental health cases. Following the simulation, participants reported a statistically significant improvement in cognitive attitudes (mean 0.91, SD 0.86; t_{17}=4.47; P=.003; d=1.05).

Participants further reported a statistically significant improvement in affective attitudes following the simulation (mean 0.92, SD 0.74; t_{17}=5.27; P<.001; d=1.17). Across the affective domain, participants reported an improvement in confidence (mean 0.83, SD 1.04; t_{17}=3.39; P=.004; d=0.79),

comfort (mean 0.89, SD 0.76; t_{17}=4.97; P<.001), appreciation for the challenges of providing perinatal mental health support (mean 0.94, SD 1.00; t_{17}=4.01; P=.001; d=0.95), and reduced anxiety toward perinatal mental health cases (mean 1.00, SD 1.09; t_{17}=3.91; P=.001; d=0.92).

Medical Students

Following the simulation, medical students reported an improvement in cognitive attitudes (mean 1.38, SD 0.40; t_{27}=18.14; P<.001; d=3.42). This group also reported a statistically significant improvement in affective attitudes (mean 1.35, SD 0.46; t_{27}=10.01; P<.001; d=1.89). Across the affective domain, students reported an improvement in confidence (mean 1.64, SD 0.58; t_{27}=13.45; P<.001; d=2.54), comfort (mean 1.39, SD 0.57; t_{27}=13.00; P<.001; d=2.46), appreciation (mean 1.29, SD 0.90; t_{27}=7.59; P<.001; d=1.43), and reduced anxiety toward perinatal mental health cases (mean 1.25, SD 0.97; t_{27}=6.84; P<.001; d=1.29).

Mental Health Students and Psychology Students

Mental health and psychology students reported a significantly improved understanding of perinatal mental health conditions (mean 1.01, SD 0.62; t_{76}=14.26; P<.001; d=1.63), assessment (mean 1.21, SD 0.74; t_{76}=14.60; P<.001; d=1.62), and care (mean 1.09, SD 0.65; t_{26}=14.82; P<.001; d=1.69) following the simulation.

Within the mental health student group, improvements were seen following the simulation across the domains of perinatal mental health conditions (mean 0.86, SD 0.65; t_{29}=7.26; P<.001; d=1.32), assessment (mean 0.91, SD 0.67; t_{29}=7.41; P<.001; d=1.35), and care (mean 0.76, SD 0.60; t_{29}=6.88; P<.001; d=1.26).

Improvements were also seen in the psychology group across the domains of conditions (mean 1.11, SD 0.59; t_{46}=12.85; P<.001; d=1.87), assessment (mean 1.39, SD 0.73; t_{46}=13.10; P<.001; d=1.91), and care (mean 1.31, SD 0.59; t_{26}=15.32; P<.001; d=2.23).

Across all mental health and psychology students, we found a significant increase in learning confidence (mean 1.14, SD 0.49; t_{76}=20.32; P<.001; d =2.32). Students further reported a significant increase in learning satisfaction (mean 1.33, SD 0.69; t_{76}=16.51; P<.001; d=1.88). There was a similar finding within groups, as mental health students reported a significant increase in learning confidence following the simulation (mean 1.13, SD 0.57; t_{29}=10.83; P<.001; d=1.98). Psychology students also reported a significant increase in learning confidence following the simulation (mean 1.13, SD 0.43; t_{46}=15.32; P<.001; d=2.61).

For learning satisfaction, mental health students reported a significant increase following the simulation (mean 1.25, SD 0.82; t_{29}=8.33; P<.001; d=1.52), and psychology students also reported a significant increase following the simulation (mean 1.37, SD 0.62; t_{46}=15.12; P<.001; d=2.20).

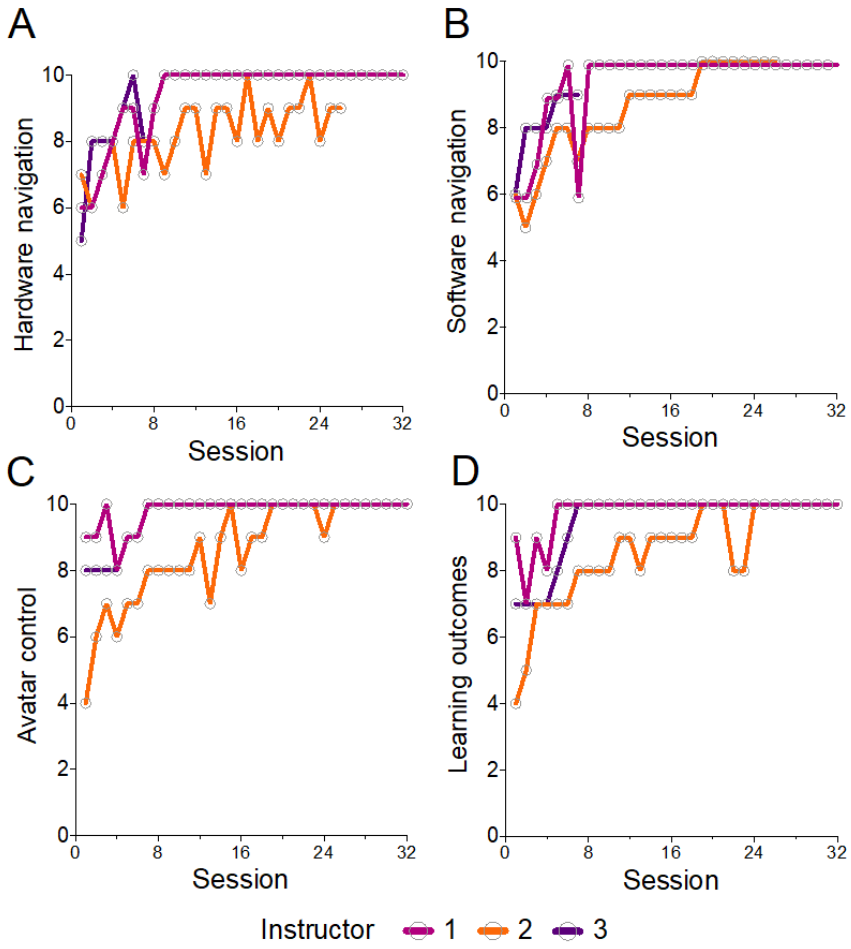
Career Considerations

At baseline, 49% of mental health nursing students stated that they were motivated to pursue a career in perinatal mental health, while 30% agreed that they felt prepared to pursue a career in perinatal mental health and 24% felt supported to pursue a career in perinatal mental health. Only 25% of psychology students were considering a career in perinatal mental health. Following the simulation, mental health nursing students felt significantly more motivated (mean 0.73, SD 0.65; t_{29}=6.15; P<.001; d=1.12), prepared (mean 1.10, SD 0.52; t_{29}=11.61; P<.001; d=2.12), and supported (mean 0.74, SD 0.74; t_{29}=5.79; P<.001; d=1.06) to pursue a career in perinatal mental health. Similarly, psychology students also reported a significantly greater likelihood of considering a career in perinatal mental health following the simulation (t_{46}=7.04; P<.001; d=1.03).

Instructor Training

In addition to assessing the benefits for participants, to better understand how much time it would take to train staff without previous XR experience to become comfortable with navigating through this training platform, we asked our instructors to document their degree of confidence on a scale from 0 to 10 regarding four key dimensions: (1) hardware navigation, (2) software navigation, (3) avatar control, and (4) delivery of session learning outcomes. Following each session, instructors assigned ratings to these constructs, thereby creating a subjective trajectory of their session delivery proficiency (Figure 5). Notably, these ratings rose rapidly and plateaued after approximately 6 to 8 sessions across all key constructs, suggesting that it will take multiple training sessions before instructors feel that they can deliver reliably consistent training sessions. We also observed some variation from session to session, which may be accounted for by a combination of measurement errors and technical and logistical factors. While not amenable to formal statistical analysis, instructors reported lower scores when they experienced Wi-Fi dropouts or software crashes.

Figure 5. Instructor development over session delivery. Following each session, instructors self-reported the following on a scale of 1 to 10: (A) ease of hardware handling; (B) ease of software navigation; (C) confidence in controlling the avatar; and (D) comfort in achieving learning outcomes.



Discussion

Principal Findings

We explored the idea that XR technologies could support the delivery of mental health training through a simulated mental health consultation, in which a trainee interacts with a human-controlled virtual avatar. An initial feasibility pilot with subject-matter experts and students demonstrated potential efficacy worthy of further investigation. We subsequently followed this up with a comprehensive evaluation of its impact on trainees from across mental health nursing, medical doctors training to be GPs, and undergraduate psychology and medicine students. Our findings demonstrate the significant potential of XR as a pedagogical tool in supporting the development of mental consultation delivery skills.

We observed notable enhancements in cognitive and affective learning across all health care trainee groups. Instructors reported high rates of successful delivery of learning objectives, while participant groups reported increased knowledge in diverse perinatal domains, including the recognition of conditions, such as depression and anxiety, during pregnancy and in the postpartum period. Trainees demonstrated proficiency in systematic evaluation using diagnostic tools to assess severity. We also observed improvements in knowledge and confidence, specific to perinatal mental issues and broader issues of working with complex mental health challenges.

The integration of XR into mental health training represents a significant advancement, offering immersive, interactive, and repeatable learning environments that traditional methods often fail to replicate effectively. Conventional training typically relies on static case studies, peer-based role play, or interactions with real patients, each of which presents limitations. XR, however, combines high-quality instructional content with advanced technological features, including real-time feedback, iterative “fail and retry” opportunities, and high-fidelity simulations. This integration is not merely a shift in delivery medium but a holistic synthesis of content and technology, fostering experiential and contextually relevant learning.

The educational content needed to address complex and sensitive scenarios, such as perinatal mental health, is notably limited within mainstream mental health nursing curricula and GP training. Traditional training often emphasizes general psychiatric principles or common conditions, leaving significant gaps in specialized instructions for nuanced cases like acute postpartum psychosis and perinatal depression. This lack of exposure to high-risk sensitive clinical contexts underscores the need for innovative training solutions that can bridge this gap. XR-based simulations offer a tailored and immersive approach, allowing learners to engage with realistic perinatal

mental health cases and gain practical experience-driven insights beyond what conventional programs typically provide.

Although this study did not conduct a direct comparison with conventional approaches, XR's ability to standardize and replicate complex scenarios addresses many logistical and ethical challenges associated with actor- or patient-based training. By facilitating autonomous practice, enhancing critical competencies, and building learner confidence in a psychologically safe environment, XR provides a valuable environment for high-stake contexts such as mental health consultations. Effective training in this domain is essential, as errors can negatively impact both therapeutic relationships and patient outcomes [36]. XR's capacity to support the development of these therapeutic relationships is key to achieving improved health outcomes for individuals with mental illness [37]. This work also suggests that immersive educational technologies might be able to influence career planning and specialization. Our study found an increase in the reported interest among trainees considering a career in perinatal mental health. This positive shift in attitude toward perinatal mental health careers is particularly significant given the documented shortage in this specialty [9]. Such tools may extend beyond traditional educational outcomes to influence career aspirations and potentially bridge the gap between abstract career concepts and tangible professional identity formation.

Immersive educational technologies, exemplified by XR simulations, possess the potential to not only shape career preferences but also address significant concerns regarding the cultivation of empathetic connections and the practical application of theoretical knowledge during training. In mental health training, a crucial aspect involves nurturing the user's ability to establish therapeutic relationships. This necessitates engaging in specific scenarios and subsequent reflection to ensure nurses can comprehensively apply theoretical knowledge effectively [38]. We were concerned that the interaction with a virtual avatar may be a poor substitute for the development of this relationship and that it may be difficult to empathize with. However, our investigation into users' social and emotional interactions within the simulation revealed positive indicators, including general and spatial presence and improvements across cognitive and affective domains. These promising outcomes suggest that immersive technologies may not act as barriers but instead as facilitators in establishing effective therapeutic relationships.

Further grounds for our concerns about the feasibility of this tool in this context came from the "Uncanny Valley" [39] phenomenon, which describes the sense of unease or discomfort experienced when an artificial representation closely resembles a human but is not quite convincingly lifelike. Stacey had indeed been designed to be as realistic as possible (working within the graphical constraints of today's technology). Our outcomes indicate that the design quality and the method for interacting with the avatar were sufficient to circumvent this effect, allowing users to transcend potential unease and engage meaningfully with the simulation. Nevertheless, somewhat paradoxically, as the graphical capabilities of XR technology increase, this area will become increasingly more important to monitor in the design and implementation of patient avatars until they become indistinguishable from real humans. This necessitates a careful iterative approach in the design and implementation of patient avatars, one that is cognizant of these psychological effects. Future iterations of XR simulations must be not only technically advanced but also underpinned by a deep understanding of user psychology to ensure that they support rather than detract from the learning objectives [40].

In looking to the future, the rapid advances being made in generative AI provide an avenue for such training tools to become increasingly autonomous, which could significantly alleviate the workload of instructors while simultaneously enhancing the dynamic interactivity of training sessions through the development of bespoke patient avatars tailored to the needs of learners. AI analysis of utterance-response pairs could predict context-specific reactions, enabling intelligent and adaptive XR training tools. XR training tools could leverage this "generative" AI to create dynamic and realistic scenarios for training health care professionals in mental health consultations, thereby enhancing their ability to understand and respond to a wide range of patient interactions. The use of generative AI could also democratize access to high-quality training resources, making them available across different geographies and socioeconomic contexts, thereby potentially reducing disparities in mental health training quality globally. Instructors could personalize scenarios, offer real-time feedback, and adapt to unique learner needs. Such potential advances do, however, raise ethical concerns [41], including the risk of bias that would need to be tackled for effective, efficient, and inclusive training.

Limitations

It is important to note that this study does not suggest that XR learning can replace traditional placements or direct learning opportunities and experiences or that simulation avatars can fully replicate real patients. What it does show is that XR could be a valuable tool for providing standardized training experiences to mental health trainees across different institutions and professional domains. The simulation employed in this study serves as a potential solution for exposing trainees to complex and nonroutine patient presentations. Going a step further, we suggest that the tool could also offer an opportunity to explore underrepresented scenarios, including those involving minoritized populations, and could be a useful vehicle for promoting cultural competence and enhancing the overall diversity of training scenarios. We propose that by using XR technology, mental health training programs may be able to bridge gaps in exposure to various clinical scenarios and populations, contributing to a more comprehensive and inclusive approach to mental health training.

While this study demonstrated significant improvements in various aspects of trainee confidence and perceived competence, it is important to clarify that the study's primary aim was not to evaluate current educational provisions or compare XR training directly to traditional methods. Instead, the focus was on assessing the feasibility and potential benefits of an XR-based tool as a supplementary learning aid within existing training frameworks. The intention was to explore how XR could augment current educational experiences rather than to position it as a replacement for established training methods. Future

research should consider comparative studies that directly assess the effectiveness of XR against traditional pedagogical approaches to determine the conditions under which XR-based learning is most beneficial. Incorporating controlled trials and longitudinal assessments would further strengthen the understanding of XR's role in skill retention and clinical application. It is also important to note that our evaluation only involved a single session and an examination of changes immediately after the session. This has shown substantial promise and must be followed up with an examination of any longer-term changes, capturing skill retention and whether this knowledge and confidence can be translated to clinical practice. Equally, the implementation of this technology into the curriculum should not be a "one-shot" standalone affair. Instead, we propose that it should be integrated systematically across multiple sessions to reinforce and build upon the acquired knowledge and skills. Long-term evaluations, including follow-up assessments at intervals beyond the immediate postsession period, are imperative to gauge the durability and sustainability of the observed impacts. Additionally, future research endeavors should explore the application of XR technology in diverse clinical scenarios to assess its versatility and effectiveness across various health care contexts. The iterative and continuous integration of XR simulations into the curriculum, coupled with ongoing assessments, will contribute to a more comprehensive understanding of its benefits and practical applicability in real-world health care settings.

While we focused on evaluating one-to-one sessions, the platform also affords the delivery of one-to-many training sessions and the opportunity for group-led discussion. One-to-one sessions in XR offer personalized interactions where trainees can practice engaging with virtual patients in a safe controlled environment, receiving tailored feedback from instructors. This approach allows for intensive skill development, particularly in handling complex or sensitive mental health scenarios. On the other hand, one-to-many sessions leverage XR's multi-user capabilities to enable group training, where multiple participants can observe and interact within the same virtual environment. By leveraging its multi-user capabilities, XR training tools could be used to create an environment conducive to collaboration, group discussion, and the promotion of intra- and interprofessional discussions.

Furthermore, in a world where hybrid (or blended) learning has started to become a norm, XR provides a practical solution for overcoming resource and time constraints faced by training programs. The ability to access training sessions and share the same learning space from anywhere in the world could provide a practical solution to the resource and time constraints faced by training programs, promoting both inclusivity and efficiency in health care education. This flexibility ensures that trainees across diverse locations and professional domains can participate in standardized training experiences, contributing to equitable and scalable mental health education.

While immersive technologies present transformative opportunities as learning tools, accessibility for individuals with visual and auditory impairments remains a critical concern. XR environments heavily rely on visual and auditory inputs, which can exclude users with disabilities if not adequately addressed. For visual impairments, accessibility may involve features, such as screen reader compatibility, audio descriptions, and haptic feedback, to convey spatial or contextual information. For auditory impairments, captions, subtitles, and integration with assistive hearing devices, such as cochlear implants, are essential. To address these challenges, the software in this study integrates specific accessibility features. For users with hearing impairments, the JoinXR platform includes automatic captioning, enabling subtitles to appear beneath a user's avatar during interactions. For users with visual impairments, the design process emphasized hardware compatibility, recommending the HTC Vive Focus 3 for VR due to its adjustable lenses and focal settings and the Microsoft HoloLens 2 for AR, which allows users to keep their glasses on. These measures reflect a commitment to inclusivity, though further advancements are needed to fully overcome accessibility barriers in XR technologies.

Finally, important considerations for the implementation of XR training tools are the economic cost and the return on investment. There are significant start-up expenditures, including the procurement of XR hardware and software licenses. In addition, adopting XR technology requires appropriate technical infrastructure, such as accessible, reliable, and reasonably fast internet connectivity, along with a long-term strategy for sustainable implementation. The rapid pace of technological advancement poses the risk of hardware and software becoming quickly obsolete, compelling organizations to contemplate strategies for regular updates and maintenance to keep pace with technological innovations. On the other hand, XR technology affords numerous opportunities to enhance educational experiences, reducing training time and improving learning efficacy [42]. Additionally, the potential of XR to facilitate remote learning could reduce the necessity for travel and accommodation expenses, which are traditionally associated with centralized training programs [43]. A critical next step for advancing this field is the development of a return-on-investment framework. This framework should account for the wide spectrum of benefits as well as the initial and ongoing expenses. In this way, organizations will have clear insights into the viability and value of adopting tools, such as the one introduced here, as they address the escalating demands of health care workforce training.

Conclusions

The use of an XR-based simulated mental health consultation scenario, where trainees interacted with a human-controlled virtual avatar, showed promise in an initial feasibility pilot and was further substantiated by a comprehensive evaluation across various health care trainee groups. Our findings indicate significant enhancements in cognitive and affective learning, with high rates of successful delivery of learning objectives. These findings show, for the first time, that XR can be used to provide an effective, standardized, and reproducible tool for trainees to develop their mental health consultation skills. We suggest that XR could provide a solution to overcome the current resource challenges associated with equipping current and future health care professionals, which are likely to be exacerbated by workforce expansion plans.

Acknowledgments

This project was funded by Health Education England, which is now part of National Health Service (NHS) England. Authors RM and FM are supported in part by the National Institute for Health and Care Research (NIHR) Leeds Biomedical Research Centre (NIHR203331). Abstract

Background: The shift to online education due to the COVID-19 pandemic posed significant challenges and opportunities for students, affecting their academic performance, mental well-being, and engagement.

Objective: This study aimed to explore the overall learning experience among health informatics master's students at Karolinska Institutet, Sweden, and the strategies they used to overcome learning challenges posed by the COVID-19 pandemic.

Methods: Through 3 structured focus groups, this study explored health informatics master's students' experiences of shifting learning environments for classes that started in 2019, 2020, and 2021. All focus group sessions were recorded and transcribed verbatim. Inductive content analysis was used to analyze the data.

Results: The results highlight the benefits of increased autonomy and flexibility and identify challenges such as technical difficulties, diminished social interactions, and psychological impacts. This study underscores the importance of effective online educational strategies, technological preparedness, and support systems to enhance student learning experiences during emergencies. The findings of this study highlight implications for educators, students, and higher education institutions to embrace adaptation and foster innovation. Implications for educators, students, and higher education institutions include the need for educators to stay current with the latest educational technologies and design teaching strategies and pedagogical approaches suited to both online and in-person settings to effectively foster student engagement. Students must be informed about the technological requirements for online learning and adequately prepared to meet them. Institutions play a critical role in ensuring equitable access to technology, guiding and supporting educators in adopting innovative tools and methods, and offering mental health resources to assist students in overcoming the challenges of evolving educational environments.

Conclusions: This research contributes to understanding the complexities of transitioning to online learning in urgent circumstances and offers insights for better preparing educational institutions for future pandemics.

Introduction

Background

The COVID-19 pandemic disrupted education worldwide, and many universities were required to shift to online education despite most being unprepared for such a shift [1]. The education response during the early phase of the COVID-19 pandemic focused on implementing remote learning modalities as an emergency response and mostly on the online delivery of educational material. The result of these efforts was a substantive rise in e-learning, whereby teaching and learning

activities took place remotely via digital platforms. After the pandemic, the use of e-learning was expected to grow [1].

e-Learning is the use of internet technologies to enhance knowledge and performance. e-Learning technologies offer learners control over the content, learning sequence, pace of learning, time, and often media, allowing them to tailor their experiences to meet their learning objectives [2]. Within the context of the COVID-19 pandemic, e-learning and online learning refer to remote teaching strategies and methods that universities used to urgently respond to the requirements of health protocols and restrictions in mobility [3].

While e-learning holds significant potential, the rapid deployment of strategies during the pandemic showed mixed results. Most of the swift adoption focused on reaching all students and enhancing accessibility, but educators lacked the time to develop and implement pedagogical strategies that could enhance the learning experience [3]. Strategies used for short-term online education may not have been suitable for the prolonged disruption caused by the pandemic.

Student experiences with e-learning during the pandemic were mixed. Some studies reported a "new normal" that students viewed positively, citing benefits such as education continuity, increased accessibility, stronger learner-lecturer interactions, and greater confidence in expressing themselves in an online learning environment [1,4-7].

Within the field of medical education, one study reported that students responded positively to the transition to online learning methods, with a notable improvement in student satisfaction related to course structure [8]. Another study highlighted medical students' generally positive attitudes toward e-learning during the pandemic. However, while e-learning was seen as a necessary and beneficial alternative, challenges were recognized, such as increased stress and anxiety, limited internet access, technical difficulties, and reduced hands-on clinical training [9]. Health profession education programs have reported issues in transitioning to online learning and maintaining continuity in education [10]. There have been difficulties related to adapting traditional teaching methods to online formats and the stress this placed on both students and educators [11]. Stress, unfamiliarity with online classrooms, uncertainty about academic futures, and the rapid shift to e-learning contributed to negative experiences for many students [12,13]. In addition, insufficient training, inadequate internet infrastructure in some countries, and lack of preparation led to poor student experiences, undermining the sustainability of e-learning [14].

The contradictory evidence on diverse experiences of e-learning during the pandemic underscores the need for further investigation within this area. To better prepare for future crises, higher education institutions need to understand the experiences of both educators and students and develop educational strategies for online learning during emergencies. Although many studies have investigated students' learning experiences during the pandemic, there are limited insights into the specific challenges and strategies used to overcome them. Contextual factors such as internet access, cultural differences, and subject of study likely influenced the experiences and perceptions of both students and educators. Therefore, there is a need to further explore e-learning experiences and strategies across different contexts and subjects of study. Health informatics education uniquely integrates theoretical knowledge with applied technical and health care–related skills, which may have been significantly affected by the shift to online learning.

Study Aim and Research Question

This study aimed to explore the overall learning experience of health informatics master's students at Karolinska Institutet (KI), Sweden, and the strategies they used to overcome the learning challenges posed by the COVID-19 pandemic. This study addressed the following research question: How did health informatics master's students at KI experience learning during the COVID-19 pandemic, and what strategies did they use to overcome related challenges?

Methods

Study Design

In this study, we conducted 3 semistructured focus group interviews comprising a total of 16 registered students and alumni of the Master's Programme in Health Informatics. The COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines [15] were used for reporting the results. The process was piloted, and questions for the participants were determined in advance by authors ND, SB, and NS adapted from previous studies on the impact of the COVID-19 pandemic on medical education [9] and on teaching and learning in health professional education [11].

In this explorative study, focus group interviews were chosen as a data collection technique as they allow for the generation of rich qualitative data through group interactions and dynamics, which is beneficial when addressing an exploratory question. Participants can build on each other's ideas, leading to more nuanced insights [16,17]. During these focus groups, the students could share their experiences and perspectives as part of an open-ended discussion, leading to a deeper understanding of their learning experiences and the strategies used to overcome challenges during the COVID-19 pandemic.

Given the exploratory study design, focus groups are ideal as a data collection method as they facilitate open-ended discussion and are effective in collecting rich data that might not have been possible to collect through more structured data collection methods. The focus groups were held remotely using the Zoom platform (Zoom Video Communications) with CS in the role of interviewer.

Study Setting and Participants

The context of the study was the Master's Programme in Health Informatics provided by the Department of Learning, Informatics, Management, and Ethics at KI. It is a 2-year global program run jointly with Stockholm University. The program is designed for students with an interest in IT and how it can be applied to the fields of medicine and health care. As such, the students may have either a technical or health care background.

Convenience sampling was used to recruit participants. Individuals who had participated in the master's program during the COVID-19 pandemic were invited to contribute. Therefore,

all participants were alumni or active registered students split into 3 cohorts: students who had registered in 2019 and graduated in 2021 (cohort 1), students who started in 2020 and graduated in 2022 (cohort 2), and students who started in 2021 and graduated in 2023 (cohort 3). Table 1 provides some characteristics of the participants. Most participants (13/16, 81%) were living in Sweden; however, as some of the students had relocated to their native countries or were working overseas, this informed the decision to conduct online focus groups.

Figure 1 shows the timeline of how the Master's Programme in Health Informatics from the academic year 2019-2020 to 2022-2023 was conducted. On-campus teaching and online teaching due to the COVID-19 pandemic are indicated using distinct colors. Students that started the program in September 2020 mostly received online teaching.

Table 1. Participant characteristics.

	Background	Experience with online learning
2019_Participant 1	Health care	No
2019_Participant 2	Health care	Yes
2019_Participant 3	Health care	No
2020_Participant 1	IT or technical	No
2020_Participant 2	Health care	Yes

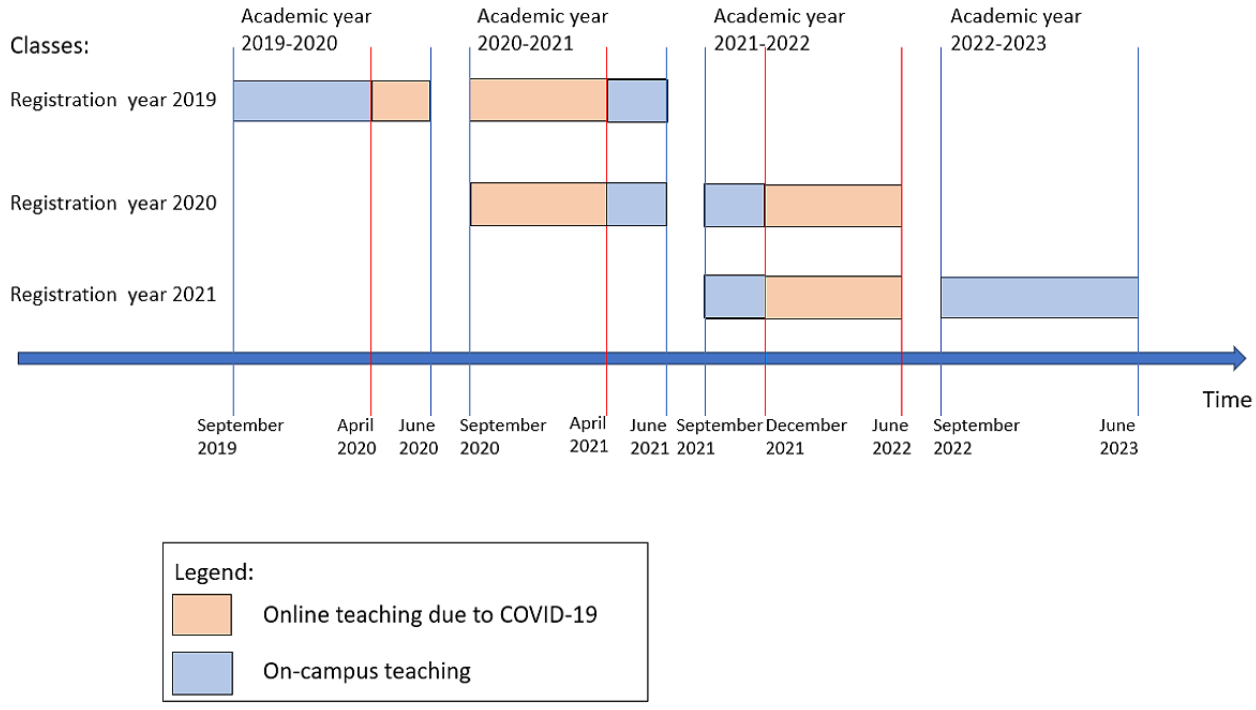
2021_Participant 2	IT or technical	Yes
2021_Participant 3	Health care	Yes
2021_Participant 4	Health care	Yes
2021_Participant 5	Health care	Yes

Figure 1. On-campus and online teaching during the COVID-19 pandemic.



Data Collection and Analysis

A total of 3 online focus group interviews were conducted during 2023 using the Zoom platform; the interviews were recorded and transcribed verbatim. To reduce familiarity bias in the study, CS, who had not been involved in teaching within the health informatics program, conducted the focus groups. The first focus group included 3 students from cohort 1, the second focus group included 8 students from cohort 2, and the third and final focus group included 5 students from cohort 3. The first focus group had a duration of 45 minutes, with the other 2 focus groups lasting approximately 1 hour and 30 minutes. The piloting process did not generate any data and was not included in the analysis.

Generated data were analyzed using inductive content analysis [18]. The inductive content analysis allowed for themes and patterns to be constructed directly from the data that were grounded in the students' actual experiences rather than imposing preconceived categories. A combination of coding methods was used: descriptive coding summarizes the main topics of the text, and pattern coding was used to condense meaning units into broader patterns to group the initial codes into broader themes. Pattern coding helps identify and understand the broader patterns and relationships within the data [19]. ND, NS, and SB conducted the initial coding. Each coder was instructed to familiarize themselves with the data, read through the entire dataset to gain an overall understanding before starting the coding process, identify meaning units, condense them, and assign codes that captured the essence of each unit. They independently reviewed all transcribed interviews, dividing the responsibilities for identifying relevant meaning units and conducting the initial coding. CS joined the analytical process once initial coding and subcategories had been generated. Upon identifying subcategories, a comparative analysis was conducted to reveal similarities and differences among student groups. Comparative analysis was conducted through peer debriefing sessions in which ND, NS, and SB compared their assigned codes and discussed differences in interpretations. All authors reviewed discrepancies collaboratively until a consensus was reached. Discrepancies were resolved by re-examining the raw data for the meaning unit in question, discussing interpretations considering the research aim, and refining the coding if needed. At this point, it was decided to collaboratively proceed with the categorization and identification of subthemes for all 3 student groups. This not only minimized the recurrence of redundant findings resulting from similarities among groups but also empowered us to emphasize the subcategories in which different student groups expressed distinct experiences or opinions.

Ethical Considerations

This research was carried out in Sweden. According to the Swedish Ethical Review Act, the research presented in our submitted manuscript did not require ethics approval as it did not handle sensitive personal information (as understood by the European General Data Protection Regulation). However, ethical requirements still apply, and written informed consent to take part in the study was obtained from all participants. The consent form outlined the study's purpose, potential risks and discomforts, the voluntary nature of participation, and the right to withdraw at any time. It also stated that no compensation would be provided for participation. Participants were assured that their confidentiality and privacy would be preserved.

Results

Overview of Data Collection and Data Analysis

Our analysis of the generated focus group data identified 1 main theme—*adapting to hybrid learning*—and three subthemes: (1) students' considerations of learning during the pandemic, (2) moving between learning environments, and (3) students' well-being and engagement in learning. Each subtheme included several categories relevant to all student groups, summarized in Table 2.

The overarching theme of *adapting to hybrid learning* highlights the challenges and experiences faced by participants navigating the transition from traditional on-campus education to online learning and vice versa. It includes the autonomy that students seek in shaping their learning experiences, the integration of learning into their daily lives, and the varying perceptions of online education as an obligation rather than a choice during the COVID-19 pandemic. It further explores the changed aspects of social interaction, the struggle with engagement in online learning, the technical challenges faced, and the diverse technological readiness levels for different learning environments. In addition, this theme addresses the psychological impact of remote learning and the need for adequate support, the varied levels of student motivation, the influence of family and pet support, and the observed lack of networking opportunities and social interaction in online educational settings.

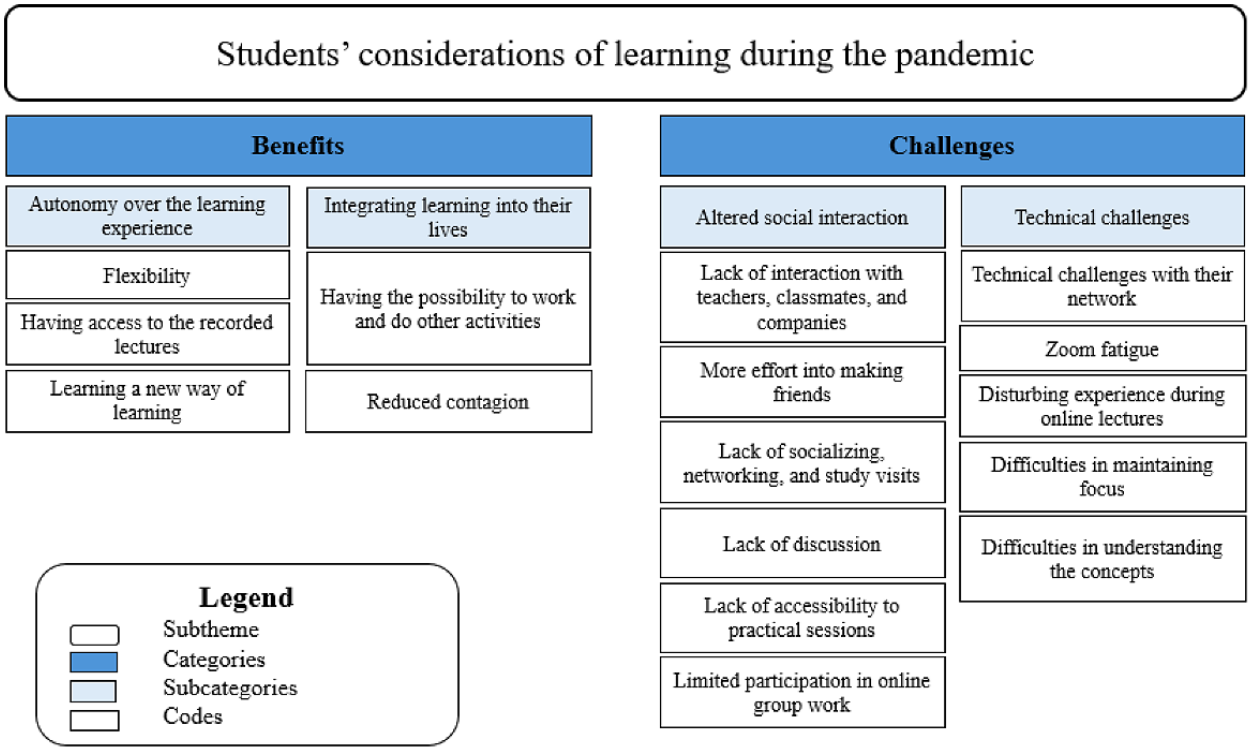
Table 2. An overview of the subcategories, categories, subthemes, and themes.

Theme, subtheme, and category	Subcategories
Adapting to hybrid learning	
Students' considerations of learning during the pandemic	
• Benefits	• Autonomy over the learning experience • Integrating learning into their lives
• Challenges	• Altered social interaction • Technical challenges
Moving between learning environments	
• Transition—campus to online education	• Online education as an obligation, not an option • Technological readiness for different learning environments • Psychological impact and support
• Transition—online to campus education	• Technological readiness for different learning environments • Lack of engagement in online learning • Different experiences in interaction with classmates and teachers between online and campus education
Students' well-being and engagement in learning	
• Motivation level • Strategies to stay motivated	• Varied levels of motivation • Group work as a connecting element • Family and pet support
• The impact of online learning on academic performance	• Autonomy • Lack of networking (social interaction)
• Overall experience and recommendations	• Improving online sessions • Improving educational support and delivery

Students' Considerations of Learning During the Pandemic

The students recognized that the changes and requirements necessitated by the COVID-19 pandemic brought both benefits and challenges. Figure 2 illustrates the relationship among the codes, subcategories, and categories for the subtheme *students' consideration of learning during the pandemic*.

Figure 2. A hierarchical structure displaying the subtheme and codes for theme 1—students' considerations related to learning during the pandemic.



Benefits

Benefits were characterized by increased *autonomy over their learning experience* and an ability to *integrate learning more readily into their lives*. Most of the participants mentioned that *flexibility* was one of the biggest benefits during the COVID-19 pandemic. Some mentioned that they could work from home or, in the case of many international students attending the Master's Programme in Health Informatics at KI, even work in their home country:

> *[The] main benefit is that it was less time-consuming. I was living at that time in [area_1] and I would have to travel to [area_2], that time was saved for me.* [2019_Participant 3]

> *I can start with one of the big benefits I had, especially in the beginning was that I was able to start the master's program from Germany where I am originally coming from. So, I moved I think 2 weeks in the program to Sweden. So, that was a big benefit to be more flexible in terms of the location for sure.* [2020_Participant 1]

Having access to the recorded lectures was appreciated as it made it possible for the students to go through the material whenever it was suitable for them. In addition, some of the students believed that they had *learned a new way of learning* and could now learn anything online. Online learning was believed to be more *efficient* as they could save time without the requirement to commute to campus:

> *...For me, it helped me to have the independence to learn as [participant] said. And yeah, and like now I can I have the feeling that I can learn anything online, I can just sign up for a course and in some videos and do it. And yeah, and in my current job, I did this a lot during the last six months. New technologies, new programming languages, everything...* [2020_Participant 7]

> *...I do watch tutorials on YouTube right now, but you get used to it. To manage to solve problems alone actually, which is really interesting because it's something that I do in my current job. If I don't know how to do something, I watch YouTube. I'm not going to ask anybody, and I think that's something with the pandemic as well...I managed to solve the problems myself.* [2020_Participant 4]

Having the possibility to work and do other activities in parallel with their studies was also appreciated by some of the participants:

> *In terms of benefits, it was very beneficial to save the commute time to the university by at least two hours a day. I was able to work in parallel with my studies. That wasn't a big deal. The third benefit, I would say [was] the flexibility to schedule meetings with colleagues in Group work. It's much easier than scheduling a physical meeting...* [2020_Participant 7]

As the risk of being infected and getting sick was high during the COVID-19 pandemic, the *reduced contagion* was also perceived as a benefit by many students as they lived with their families and wished to protect or shield them or, at least, lower the transmission risk:

> *Yes, of course. But before that, I would like to add one thing that I think it hasn't been mentioned by my fellow friend is that the advantages of online class or*

> *online learning during the pandemic is that we were able to refrain from the infection for COVID cases, of course, and I do believe that in Sweden it's well managed about the cases or the infection rate is remain low, but you know the preventive measures that we stay in our home and limiting interaction that's is also one.* [2021_Participant 5]

Challenges

The challenges that students experienced were divided into 2 distinct categories: *altered social interaction* and *technical challenges*. Most of the participants perceived the *lack of interaction with teachers, classmates, and companies* as a significant challenge of online learning. They experienced that the *group feeling* and the feeling of belonging to a bigger group was missing. Some students mentioned that they needed to put *more effort into making friends* and developing collegial relationships with their classmates. Several participants mentioned the challenges with the lack of *socializing, networking, and study visits* through online learning. This was noted through the *lack of discussion* due to people being shy and not turning on their cameras and by students leaving the online lectures directly after they finished:

> *...In this case, it's an international program. And I was not living there, so I moved to this country to learn. But also like to meet new people, make friends, to expand my network. The interaction with the teachers. And as yeah, [participant] said to others you just attend the meeting, and then you close it, and you don't have this interaction discussion afterward or during the class. So that was also a point, and I also like making friends. Of course, I made a lot of friends in this program. But you like the effort was bigger, you know? So, you have to be proactive to let's meet. But in an in-person or personal program, you have more facilities...* [2020_Participant 5]

> *...another aspect that at least made me feel a bit I shouldn't say depressed, but not as happy as I was not meeting all the people in the class. Partly built on that, you should form a team over two years, and that was for me very, very obvious that I almost missed that team spirit or the team.* [2021_Participant 1]

Lack of accessibility to practical sessions on campus and *limited participation in online group work* that might have resulted in the low quality of group work were other challenges mentioned by the students:

> *...I don't have technical problems with attending online lectures...the only thing, as I mentioned before, is we had no opportunity to have someone...to have an instructor while we were doing these programming things...having online lectures is fine but having a technical lab doesn't always work online.* [2019_Participant 2]

> *...regarding the challenge of collaboration...we had like several group assignments where we needed to have a lot of discussions...that was fairly difficult because we tend to have passive collaboration, I mean like normally one or two people lead while the others just agree it's totally different from what we have in the class where everyone can jump in and share their talks during the group work.* [2021_Participant 1]

Technical challenges associated with online learning were discussed by students of all cohorts. Some students mentioned that they were worried about the reliability of their network along with some *technical challenges with their network*. For some students, it was difficult to work with Zoom in the beginning. There was also an adjustment period required to use online platforms for longer periods, such as experiencing *Zoom fatigue* from having several hours of online classes. There were additional technical problems with hybrid sessions, and some of the participants mentioned the *disturbing experience* that they had during online learning as some people spoke at the same time, which disrupted the flow of the conversation. During hybrid learning sessions, there was a lack of interaction between those online and those present in the room on campus:

> *So, in the beginning, I mean [during] the lectures sometimes there were some network issues, and then when you are the first time sitting on Zoom, and everybody has their cameras turned off.* [2019_Participant 2]

> *...Zoom fatigue because I think during that period of time, we had two or three classes in one day. Even with a normal session like from 9:00 to 3:00, we felt really exhausted and it was worsened when we had the online classes, and I was thinking that perhaps some sessions could be minimized. I mean like normally we will like 90 minutes for a single theoretical class. But if online sessions can be reduced to about 30 or 40 minutes and the rest of the time, we could do our self-learning. I think that would have been more beneficial.* [2021_Participant 1]

> *...One negative aspect I noticed was that I didn't feel comfortable interrupting to ask a question. I know I would get distracted because it's an online setting, and sometimes when two people speak at the same time, it can be very disruptive...also there are always some technical difficulties.* [2021_Participant 2]

While some students found online learning beneficial as it allowed them to concentrate better during lectures by multitasking and engaging in other activities simultaneously, others reported *difficulties in maintaining focus*. These students struggled with reduced attention spans, often due to the distractions of being at home with their families or lack of camera use during online lectures, which contributed to a sense of disengagement:

> *...Then the other thing is that I cannot focus properly because my kids are small. When I was at home, it was distracting many, many times and difficult...* [2019_Participant 3]

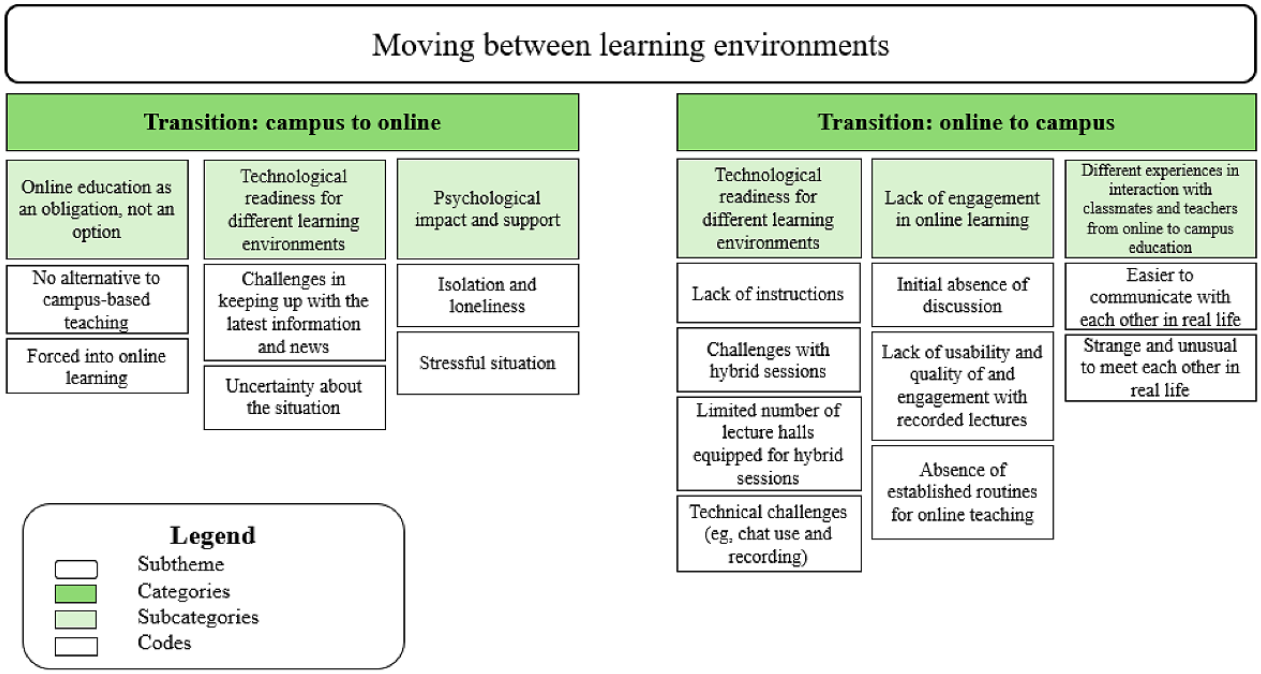
As a result, some students experienced *difficulties in understanding the concepts* and needed some assistance:

> *...Well, I think the plus point was that my husband works in technology, so I could take his help to understand the concepts and I think that was the main part that kept me going because if I don't understand things, I just...I can't focus and I can't move forward...* [2019_Participant 2]

Moving Between Learning Environments

Figure 3 illustrates the relationship among the codes, subcategories, and categories for the subtheme *moving between learning environments*.

Figure 3. A hierarchical structure displaying the subtheme and codes for theme 2—moving between learning environments.



Transition: Campus to Online Education

The COVID-19 restrictions prompted universities to shift from on-campus to online teaching. The disease spread rapidly, rendering on-campus lectures unfeasible. Numerous international students faced *challenges in keeping up with the latest information and news*. Despite the continuous updates available on the university's website, many international students experienced *uncertainty about the situation* and when everything would go back to normal:

> *...and I think that the transition between these different ways of working, I think that was hard for all of us because, well, especially for me, since I was studying before. So, I got used to online learning and then I went back to traditional learning and was very excited about that. But then it went back to online learning again and I was like, huh, OK...* [2021_Participant 2]

Working *online was an obligation rather than an option* for students, which may have made it easier to accept and manage, at least in the early stages of the pandemic. Having *no alternative to campus-based teaching* and *being forced into it* made online learning an obligation rather than a choice:

> *Well, I mean, I think there was no other choice. Everything was shut down, and there was no question of going back to campus. Nobody knew when things would reopen again, so in the beginning, we were forced into it, left with no other option. But then, I think the transition was OK.* [2019_Participant 1]

However, the psychological impact and requirement of support were important when considering the transition from on-campus to online environments. *Isolation and loneliness* and *a stressful situation* were common themes among students who did not have significant social support, such as family members living in Sweden. Most of the international students leaving their home countries to study the program in Sweden experienced that they were isolated and felt lonely during the COVID-19 pandemic:

> *...Then we changed our routines, but always we had some fear because of the unknown and what would happen next. It was always stressful, and we didn't meet our friends and teachers because from my side I don't have any relatives here, just only people from the university then I felt isolation and loneliness, and something, something alwayswas in the back of my mind and a little difficult to focus on my studies...* [2019_Participant 3]

Transition: Online to Campus Education

Technological readiness for different learning environments was a subcategory of transitioning from on-campus to an online environment and on the return to on-campus learning. At the onset of the pandemic, some students encountered challenges with Zoom due to a *lack of instructions*, particularly affecting those without a technical background. Numerous students encountered issues with audio quality during lectures and faced

challenges with hybrid sessions. The university was not fully prepared for online or hybrid formats due to the *limited number of lecture halls equipped for hybrid sessions*:

> *...I was a nurse, so I wasn't used to using it [Zoom]...No, it was difficult in the beginning to get used to using Zoom and the online campus. Nobody was explaining to you how to use it in person, so you have to do tutorials online for everything you do...* [2020_Participant 4]

> *We would have that many problems in the classroom technology-wise, like not being able to record the meetings, for instance. That was a big loss. Not being able to join functionally from home because it was not great for you. You didn't actually know what was happening in the classroom, so it was. I just wasn't expecting that. The classrooms weren't equipped to handle hybrid learning. If that was presented as an option, so.* [2020_Participant 8]

Some participants noted the *initial absence of discussion* on enhancing online learning at the onset of the COVID-19 pandemic. Nevertheless, they observed an increase in discussions on how online learning worked and how it could be improved as the pandemic progressed. In addition, at the beginning of the pandemic, technical challenges (eg, Zoom difficulties, uncertainties about chat use, and initial problems with recordings) were encountered. As the pandemic continued, these issues were addressed, leading to a gradual improvement in the online learning experience over time:

> *So, I think by the time we started [the online lectures] everything got improved especially when they started to record the lectures. Because I remember at the beginning the lecture was not recorded. But later lectures were recorded, and this was good.* [2019_Participant 2]

> *I mean for the teachers also, in the beginning, it was difficult...now if you see Zoom meetings are usually facilitated by one person who keeps an eye on the chat while the teacher is teaching. And then in between they ask questions. I mean it took a few months...and during the third semester, it became better towards the end of it. So, I think yes, I mean everybody adapted to it because that was the only way left.* [2019_Participant 1]

Other *technical challenges* included the requirement for extra tools such as headsets and screens, issues with hybrid teaching, and inadequate online content delivery, marked by a *lack of usability and quality of and engagement with recorded lectures* and an *absence of established routines for online teaching*:

> *...but that isn't very equitable for those who might not have had headphones or something like that, or maybe lived in a very small apartment, even though I live in a small apartment. Well, then maybe have a family and other people at home, maybe they didn't have any headphones, so maybe that's an aspect of the required equipment for the most optimal way of learning remotely...* [2021_Participant 2]

> *...if you maybe go and look at a lecture or recorded video on YouTube. They are very different, and they are a lot more engaged. Even though they're not live, so I do think that there should be some sort of, yeah, look over, like how you're supposed to have an online lecture to maximize learning. Because, yeah, I've, I found it quite strange that the prerecorded ones were better than the live ones.* [2021_Participant 4]

Some students encountered challenges with active participation in online and hybrid sessions, which they experienced as a lack of engagement in online learning from learners and, at times, educators. They emphasized the need for implementing strategies to enhance engagement during online sessions:

> *It lies on the lecturers. I mean, they're supposed to engage the students, and I understand from their perspective that it's so hard to engage people on a computer, because the students usually don't have their cameras on, usually, maybe even sit in their beds, listening to the lecture. And there are some lecturers who really, really try to be like: please turn on your cameras...I think that it requires maybe some standard routine for how we're supposed to do remote learning, and I mean, just like any technical product that goes into implementation, we need to have change management afterward. We need to maybe have some implementation consultants. So, both students and teachers or professors need to learn how they are supposed to teach, or for students how we are supposed to learn.* [2021_Participant 2]

Students had *different experiences in interaction with classmates and teachers between online and campus education*. Several of them noted that *it was easier to communicate with each other* during the transition from online to on-campus learning given their previous digital interaction through lectures and the WhatsApp group, although some students found it *strange and unusual to meet their classmates* in person for the first time. However, the students experienced limited interaction with teachers within the program. They found it more challenging to engage with teachers compared to their classmates:

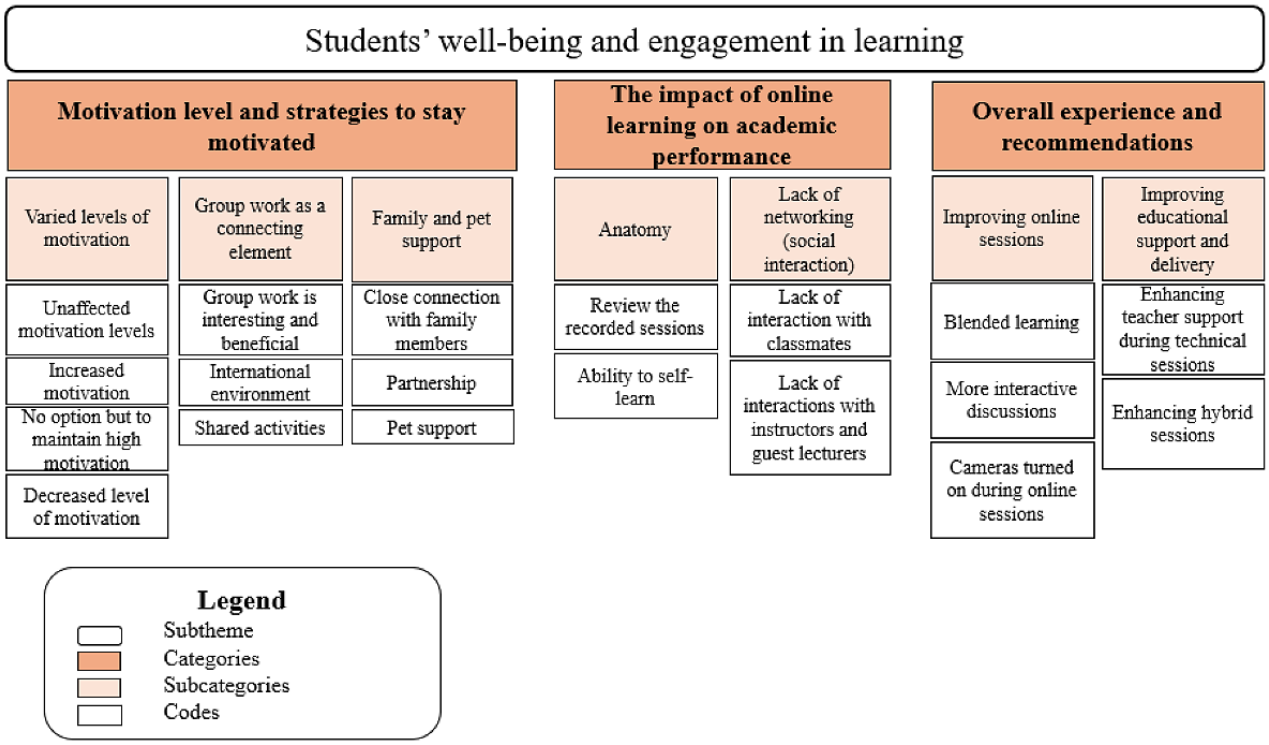
> *I think for me I can kind of remember that. Since we first started digitally and then we changed to the campus, we knew each other's faces and how we interacted. So, in a way, it was kind of easier to change...After you've trained a little bit in the digital parts, then it gives you more confidence to talk in person. On the other side maybe, I was more shy to talk to the teachers...it was harder. I felt more the distance in a way, so it's kind of the different sides, but maybe I felt nearer to my colleagues...* [2020_Participant 2]

> *I would say I mean. The first day when we met. It was, it was very weird to meet our colleagues. I mean, I'm not used to seeing them in real life. Some were shorter, some were taller, and you know it was a weird experience for the first day, I would say...* [2020_Participant 7]

Students' Well-Being and Engagement in Learning

Figure 4 illustrates the relationship among the codes, subcategories, and categories for the subtheme *students' well-being and engagement in learning.*

Figure 4. A hierarchical structure displaying the subtheme and codes for theme 3—students' well-being and engagement in learning.



Motivation Level and Strategies to Stay Motivated

The *motivationlevels* of students varied depending on their individual circumstances and also throughout the pandemic. Some students noted that their *motivation levels remained unaffected*, maintaining the same commitment to learning despite the pandemic. However, they expressed an *increased motivation* to meet people in person. Several students found that their motivation improved during the pandemic as they had more free time to plan upcoming courses, learn new skills, and engage in activities beyond their studies. Other students expressed that they had *no option but to maintain high motivation* due to visa requirements, family responsibilities, and future career plans. They highlighted that their relocation to Sweden was driven by the pursuit of a better future:

> *I would definitely say that when we moved to the campus, I felt more motivated not because of the learning, maybe because the motivation might be exactly the same, but also more, more motivated to meet people, to actually have an opportunity to meet different people because some of you have lived in Sweden and it's hard most of the time because of the difference in the cultural aspects. So, I think that's something that I remember being nice that I was happy to go to the campus and see these people and talk and learn with them.* [2020_Participant 2]

> *I think we as international students are here because you have your student visa, you have to study, and you have to pass to have your visa renewed. So, we don't have this luxury...you know, I'm bored...I don't want to study; I will skip it. No. We have to do this...We came here to study this program, and you have your plans, and you need to work to achieve your plans.* [2019_Participant 2]

> *...It's the same motivation because I brought my kids [to Sweden] and I have to make the future. That is the motivation.* [2019_Participant 3]

Nevertheless, some students reported a *decreased level of motivation*. Some related this loss of motivation to their backgrounds, particularly feeling uncomfortable with certain courses such as programming and machine learning. Others mentioned that the darkness negatively affected their mood, although it did not impact their motivation to study:

> *If I talk about the motivation, yes it was reduced because I come from a medical background, and the technical things, especially the courses like programming and machine learning...There were so many new things that sometimes I felt I was lost...Within different things, all alone, and I don't know if I'm the only one feeling like this or [if] there's somebody else, or I mean, what else do I need to make it work better? But then I didn't want to stop doing this...Because my main motivation was to learn technology and I wanted to complete it so that I know...* [2019_Participant 1]

> *I think the majority of the time that we had online lectures was during the darkest period in Sweden. And I think that affected the mood also because you then sat in front of your computer and it was dark, and then you sat inside the whole day pretty much.*

> *And then it was dark again. And so obviously that has an impact too, that it just happened to be during the most like the darkest period.* [2021_Participant 4]

Some students preferred online lectures due to the time and energy saved from morning routines such as waking up early, having breakfast, and preparing lunch. However, other students believed that lectures and interactions in person gave them more energy:

> *I really like remote learning and additionally, I'd like to add as I was saying in the beginning, I was able to be in another country because at that time my parents were living in another country and then me and [participant] actually could collaborate because we were at the same time zone.* [2021_Participant 2]

> *I will actually agree here with [participant] that also the lectures in person and interactions in person actually gave me more energy than they took, due to the fact that I was way more active. For example, I cycled to university. Then uh each morning and after class. Which always gives me an energy boost when I move more than also like just walking together on the campus, going for lunch, or getting a coffee or whatsoever. That also gave me I would stay way more energy than it took from me compared to when I would just be in my apartment. Pick up a coffee and then sit back again at the table...* [2020_Participant 1]

Group work was identified as a key factor for gaining and maintaining motivation during the pandemic. Many students believed that *engaging in group work was interesting and beneficial* throughout the program. The *international environment* played a crucial role in keeping students motivated. In addition, maintaining positive relationships with classmates and enjoying *shared activities* helped students stay motivated during the COVID-19 pandemic:

> *I would say that the group work made me more motivated. If I felt down. Honestly, we had very nice groups that we worked with. I enjoyed working with them and I learned a lot from them. But yeah, when you feel down and then we get a challenge to work on some project or some research or yeah, it was studying having some fun, and some jokes here and there. So, it wasn't 100% serious mode. So yeah, group work affected...* [2020_Participant 7]

> *If it was just entirely remote, and I never had the opportunity to meet my classmates one-on-one, I don't think I would be this motivated. Meeting them for the first time, seeing their various background, a lot of experience, and being able to tap into their own personal experiences and professional experiences gave me at least a lot of motivation, and a lot of interest in how better I can be...Or if it was just purely digital, or that involved me not traveling, I don't think I would have been this motivated.* [2021_Participant 3]

Several students noted that having close connections with their *family, a partner, or a pet* played a significant role in keeping them motivated during the pandemic:

> *Yeah, I agree. Actually, that happened to me too with my husband. He was more of a body shadowing. Like, if someone else is working on your side like you, I don't know. You get more folks. Somehow with cats, it's different though. It may not be a routine or like force it to go out. To walk the cat...So, it would actually force me to get up, play a little bit with the cat, and then come back and it was really good.* [2020_Participant 8]

The Impact of Online Learning on Academic Performance

While some students reported no change in their academic performance, others observed an improvement in their overall achievement, among other reasons due to having the opportunity to *review the recorded sessions*. The students expressed a sense of adaptability to online learning, emphasizing their *ability to self-learn*. However, the students found it challenging to grasp technical aspects solely through online learning:

> *For me, I think that the pandemic situation increased my performance. Because lectures were recorded and then I used them again and again until I understood them. And then especially for the technical part...because we are not familiar with technology, then I used again and again for all those recorded things to understand...that was very effective for me.* [2019_Participant 3]

Students experienced a *lack of interaction with classmates, instructors, and guest lecturers*, hindering the exchange of ideas and discussion of questions. This lack of networking could potentially lead to delayed job opportunities:

> *...But yes, I agree with my colleagues that some from the social side there was a lack. Having a bigger network of friends or socializing with your friends and visiting companies in person, those who were giving us lectures like different healthcare companies were giving us guest lectures, but we couldn't go in person to the companies to visit them...Because it was a pandemic, there were no, not many opportunities for summer jobs and internships, but not much open during that time. So, it was kind of that gap, which was present during [the pandemic]...* [2020_Participant 6]

Overall Experience and Recommendations

The students noted that the program altered their approach to problem-solving. However, they expressed a preference for *blended learning* over online learning alone as the latter had a negative impact on some, leading to feelings of isolation. In addition, the students provided suggestions for improvement in both online and campus-based sessions. They desired *more interactive discussions*, especially for technical sessions, to strengthen their knowledge after online lectures. Students also

believed that having *cameras turned on during online sessions* would enhance the learning experience:

> *...So overall, it was a positive experience, in my opinion. I would say I learned a new way of learning I wasn't used to, but sort of adaptability I would say. In terms of challenges, I would say I would agree with my colleagues about the social part. We were not able to socialize as compared to the normal or the offline study. It was very important. As well as building relationships with the instructors, teachers, and companies. And we were not able to do that. One other disadvantage was the interactive discussion with colleagues...* [2020_Participant 7]

> *...I can mention that not having the cameras on for example is another aspect that didn't help in concentration, also being able to socialize with people because this is a very international program, and would be amazing just to be able to have been in the classroom from the beginning to the end...* [2020_Participant 2]

> *We got to see our peers in person and kind of create a connection and sit and eat lunch with each other and talk about things to get to know each other more, which actually can not only motivate us but also affect us in our ways of learning because we can get another perspective on a certain topic or something that we wouldn't have gotten without talking to them during an informal event such as lunch, for instance...Again, I think a mix, a mix of online and on-site learning has made me at least reach my performance goals.* [2021_Participant 2]

The importance of having *teacher support* during the practical sessions in technical courses in the master's program during the pandemic highlights a key factor in improving educational support in online learning:

> *Also, we have some practical sessions for our program, so we must have someone with us in the room to ask because there are technical things in programming. I don't know where the error is in what I am doing, so I need a next eye to see what I'm doing.* [2019_Participant 2]

Enhancing hybrid sessions was mentioned as an area for improvement as students encountered numerous challenges during these sessions throughout the pandemic:

> *Yeah, I missed something. I just remembered that when we switched to in-person, there were some meetings hybrids. So people joined online while we were in the class and this was not really well organized or I don't know if it was our problem or if it could be better, but I think it's something that can be improved or just not having hybrid meetings, but I mean, I think we're not prepared and we just had like 1 computer with the meeting, so only the teacher could hear the student who was at home.* [2020_Participant 5]

Discussion

Principal Findings

This paper reports the experience of master's program students at a higher education institution due to the COVID-19 pandemic requiring adaptation to hybrid learning. Students experienced both benefits and challenges in relation to this. The transition between on-campus and online learning resulted in a hybrid learning era, which is likely here to stay. The students in this study appreciated the flexibility and autonomy provided by online learning, enabling them to integrate their studies into their daily lives. However, the rapid shift to online learning caused significant challenges, such as changes in social interactions, technical difficulties, and feelings of obligation rather than choice in adopting e-learning. The transition from on-campus to online learning caused a psychological impact on students and highlighted the need for better support and technological readiness to adapt to different learning environments. Returning to campus presented mixed experiences, with some students struggling to re-engage in face-to-face learning, whereas others faced challenges in adjusting to renewed forms of social and academic interactions. Students' motivation varied during the pandemic. Group work, family support, and having pets played crucial roles in maintaining students' moods. Despite the challenges, students were positive about hybrid learning to enhance future experiences, emphasizing the need for better networking opportunities and innovative strategies.

The findings of this study highlight implications for educators, students, and higher education institutions to embrace adaptation and foster innovation. These implications include the need for educators to stay current with the latest educational technologies and design teaching strategies and pedagogical approaches suited to both online and in-person settings to effectively foster student engagement. Students must be informed about the technological requirements for online learning and adequately prepared to meet them. Institutions play a critical role in ensuring equitable access to technology, guiding and supporting educators in adopting innovative tools and methods, and offering mental health resources to assist students in overcoming the challenges of evolving educational environments.

Comparison to the Literature

Studies have previously reported both positive and negative consequences of the shift in learning environments. Naciri et al [10] have suggested that students generally responded positively to the rapid shift to online health science education during this crisis, expressing views on aspects such as acceptance, motivation, and engagement. Despite varying socioeconomic conditions across countries, certain key factors such as access to technology, basic computer literacy, well-designed online course pedagogy, and flexibility in learning consistently supported online education. However, students encountered challenges such as inconsistent internet access, difficulties with educational platforms, and hurdles in acquiring clinical skills online. These insights are crucial for enhancing the integration of these technologies into educational frameworks [10]. This is congruent with our results, where

overall the students responded well to the rapid shift to online learning but reported both positive and negative outcomes, with challenges especially in computer laboratory sessions. Our findings also confirm the results of other studies [9,11] on the difficulties regarding limited internet access, technical problems, challenges related to adjustments from traditional to online formats, and impact on students' well-being.

Students in our study were not entirely satisfied with the practical sessions in technical courses, highlighting the need for access to teacher assistance during these sessions. This contrasts with a study that reported satisfaction with clinical teaching and practical sessions remaining adequately high during the shift to e-learning. They also reported notable improvement in student satisfaction concerning course structure, instructor expertise, learning materials, and overall contentment with the courses, as well as a tendency for student grades to improve in the online format [8].

A review study [20] revealed that motivation and self-regulated learning were significant challenges, impacting students' ability to engage critically with the material. It also showed varied attitudes toward online learning, with decreased satisfaction and emotional well-being in many students due to feelings of isolation and increased stress. These findings align with our results as students in this study also experienced loneliness and isolation, which led to a lack of focus on the studies.

Findings regarding the use of technology show that competence, perceived usefulness, ease of use, and facilitated implementation are predictors of learners' attitudes toward and intentions to use technology [18,21,22]. Technologically capable students are likely to associate poor digital implementation by educators with lower satisfaction and self-efficacy. Integration of technology with a student-centered focus is likely to influence the development of autonomy and self-regulated learning [23,24]. For students enrolled in a health informatics program, where technology is a significant aspect of the learning curriculum, it could be extrapolated that they would likely be comfortable and be able to adapt to the use of technologies for learning. Therefore, the reported themes associated with technology use may be more significant for other groups of learners in different educational fields.

In addition to these findings, there has been a significant association reported between instructors' use of effective teaching practices and student motivation. Alongside the quality of teaching and challenges associated with technology, prepandemic studies have indicated that motivation in online learning can be affected by demographic characteristics such as age, gender, employment status, income, and family obligations [22]. However, most studies were conducted at higher education institutions where students had a choice to enroll in online learning; learning in a hybrid environment may be different.

Online laboratory sessions in technical courses have shown some drawbacks in managing requests for help from student groups. During in-person sessions, teaching assistants can manage the requests of a group but, at the same time, give feedback to others (spontaneous interactions or questions that require a short answer). Using online learning tools with students divided into rooms, requests are managed only sequentially without allowing for spontaneous interactions. In addition, managing the request queue was more challenging for teaching assistants due to the unavailability of a specific function in the online learning tools. This seems to be in accordance with previous research on the topic [25-27].

Implications for the Educators, Students, and Higher Education Institutions

The transition to online learning during the COVID-19 pandemic had significant implications for educators, students, and universities. Both educators and students had to make substantial adjustments in their teaching methods and learning styles, respectively. This study highlighted a greater emphasis on active learning strategies, self-discipline and time management, active participation in discussions and group work, and the development of flexibility and resilience.

Although our study focused on the experiences of students, the importance of educators in both the design and delivery of hybrid learning must be recognized. An online replication of a physical classroom can result in bored students and exhausted teachers, with both experiencing *Zoom fatigue*. A change in pedagogy is required to teach in the hybrid learning environment. Hybrid pedagogy is a development from blended learning using elements of both online and face-to-face learning, resulting in no separation between learners in the physical or digital space [13].

A significant issue related to hybrid learning is the required use of technologies. The health informatics students recognized both individual and organizational gaps in infrastructure and a lack of technological preparedness, which was experienced by many institutions. After the pandemic, it is critical that higher education institutions ensure that technology is leveraged to provide students with a good online, physical, or hybrid experience. The pandemic has highlighted the importance of preparedness and resilience in higher education for future crises. To support online and hybrid education, institutions need to invest in robust technological infrastructure and prioritize continuous professional development and training for educators. As highlighted in our study and similar research [9,10,28,29], there is a significant need to equip educators with the skills to adapt to the evolving educational landscape, particularly in the use of digital technologies. Educators need to develop skills to effectively use online platforms and tools to create engaging and interactive learning experiences. Common themes when designing quality online instruction that engages and motivates students are those of interaction, collaboration, communication, and discussion [21,30]. Online and hybrid learning require a greater focus on interactivity; this helps break the monotony and allows for student socialization. Therefore, engaging in ongoing professional development to stay updated with the latest educational technologies is a necessity for educators. Those students who had previously had the opportunity to meet in person on campus before transitioning to online learning may have had a closer sense of community than those whose educational experience transitioned in the opposite direction. Therefore, it is vital for instructors to build and foster a sense of community to keep students motivated. Overall, the onus is

on educators to design and deliver quality teaching appropriate to the environment (web based or in person) to promote student engagement and encourage motivation to learn. To support these efforts, it is equally important that students are informed in advance of the requirements to attend classes online and be advised on the necessary technology (such as headphones, microphone, and camera). Furthermore, institutions should ensure access to technology by providing it on a short-term loan basis or guiding students in applying for grant funding, thereby ensuring equitable access to learning resources. Institutions should also guide and support educators to learn about and incorporate new technologies into their teaching practices [31-33]. In addition, providing extra resources and support to help students navigate the challenges of online learning is crucial. Given the impact that the shift had on students' mental health, higher education institutions should provide mental health resources and support systems to assist students in managing these challenges. Students, educators, and institutions play a crucial role in informing policy makers regarding challenges and implications of future crises by sharing best practices for managing education emergencies. Providing feedback, sharing research findings, and offering concrete examples are essential for ensuring that policy makers are well informed and able to respond to the evolving needs of the educational community.

Strengths and Limitations of This Study

This study is limited by its context-specific nature, focusing on a particular group of students within a specific educational environment (health informatics master's students at KI), which may not fully capture the diverse experiences of learners in other regions, disciplines, or institutional settings. This may limit the generalizability of the results. However, the recommendations in the results can apply to other programs and institutions with similar educational systems and resources. The sample size in this study could be considered a limitation. However, saturation was achieved across the entire sample as no additional new themes emerged during the data analysis process. Although the number of participants from the 2019 cohort was low, the insights gathered from this group were consistent with those gathered from students from the other cohorts.

Conclusions

The shift to hybrid learning in response to the COVID-19 pandemic presented both benefits and challenges for postgraduate students in higher education institutions. Technological preparedness, equitable access to technology, and educator training are crucial factors that institutions must address to support students' learning experiences. In addition, fostering interaction, collaboration, communication, and discussion in online and hybrid learning environments is essential for engaging and motivating students. Ultimately, educators play a key role in designing and delivering quality teaching that promotes student engagement and encourages motivation to learn regardless of the learning environment.

Future studies should aim to explore the impact of the COVID-19 pandemic on students' learning experiences across varied contexts, incorporating cross-institutional comparisons to develop a more comprehensive understanding of how different factors influence learning experiences and outcomes in hybrid and online education. In addition, it is of great importance that future studies examine new teaching methods and pedagogical approaches that can enhance students' engagement and increase communication and interaction between students in hybrid education. Finally, it is crucial to develop strategies and policies that prepare higher education institutions for crises, ensuring that they can effectively transition between educational environments—whether shifting from in-person to online or hybrid modes—while maintaining educational continuity and quality. Future research could use case studies to investigate institutional responses and apply principles of action research to collaboratively develop and refine teaching strategies and crisis management policies.

Acknowledgments

The authors would like to thank all master's students and alumni who participated in this study for their time and valuable insights. The authors received no specific funding for this work. Artificial intelligence technology such as Grammarly (Grammarly Inc) and ChatGPT-3.5 (OpenAI) was used in the preparation of this manuscript to harmonize the text. After using these tools, the authors reviewed and edited the content as needed, and they take full responsibility for the content of the publication.

Authors' Contributions

ND, SB, and NS were involved in the design of the study. These authors prepared the interview guide and piloted it. The focus groups were held online with CS in the role of interviewer. ND, NS, and SB conducted the initial coding. CS joined the analytical process once the initial coding and subcategories had been generated. After identifying subcategories, a comparative analysis was conducted to highlight similarities and differences among the student groups. We then collaboratively categorized and identified subthemes for all 3 groups. All authors contributed to the subsequent writing and review of the manuscript.

Conflicts of Interest

None declared.

Abstract

Future health professionals, including dentists, must critically engage with digital health technologies to enhance patient care. While digital health is increasingly being integrated into the curricula of health professions, its interpretation varies widely depending on the discipline, health care setting, and local factors. This viewpoint proposes a structured set of domains to guide the designing of a digital health curriculum tailored to the unique needs of dentistry in Australia. The paper aims to share a premise for curriculum development that aligns with the current evidence and the national digital health strategy, serving as a foundation for further discussion and implementation in dental programs.

(JMIR Med Educ 2025;11:e54153) doi:10.2196/54153

KEYWORDS

digital health; digital transformation; informatics; ehealth; dentistry; dental informatics; curriculum; competence; capability; dental education

Introduction

As the world continues to be digitally transformed, there are increasing expectations for health care providers to use technology and handle health information safely and ethically [1]. It is likely that future health professionals will also need to think critically about how digital health technologies can be used to transform models of care [2].

Digital health and informatics remain relatively new curriculum topics for many health professions, including dentistry. Defining the relevant curricular objectives in entry-to-practice degrees can be particularly challenging for several reasons. First, there are several definitions and conceptualizations of the term “digital health” [1,3-6]. Second, the implementation of digital health education in health profession degrees has largely been ad hoc, with different schools adopting varied approaches [7]. This has resulted in inconsistent learning outcomes and a fragmented understanding of digital health competencies for health profession graduates. Third, although a multitude of digital health competency frameworks exist [8-11], there is a notable absence of shared curriculum models specific to dentistry. Therefore, dentistry educators are not aware of or struggle to adopt best practices in the teaching of digital health.

In this viewpoint, we argue that there is a need to integrate digital health education into dentistry curricula to prepare future practitioners for the increasingly digitized health care environment. Specifically, we propose a distinct point of view for defining "digital health" in dental education, a structured set of domains to guide the design of digital health curriculum, and a framework for curriculum development that aligns with current evidence.

Beginning With the End in Mind

In Australia, a country that ranks consistently high for digital health maturity [12], clear digital health objectives are set out through national strategies such as the Australian Digital Health Agency (ADHA) Capability Action Plan (2023) and the National Healthcare Interoperability Plan (2023 - 2028) [1,13]. The government body for digital health (ie, the ADHA), peak bodies such as the Australasian Institute of Digital Health (AIDH), and digital health innovation centers all identify building workforce capability as a critical part of achieving digital transformation of health care [1,13-15]. These organizations envision a future where health professionals will work in integrated and multidisciplinary environments. Digital health education in entry-to-practice degrees is thus a core element of advancing workforce capability; however, the specific content, including priority areas of knowledge and skills, must be tailored to the unique demands of each discipline and local context. For dentistry in Australia, this means aligning the curriculum with the national digital health strategy while addressing the current maturity level and future needs of the dental profession.

Reframing "Digital Health" for the Next Generation of Australian Dental Practitioners

A lack of standardized digital health education in entry-to-practice degrees in Australia has been recognized for decades [16-18] and has been demonstrated by gaps in workforce competency [19]. Global interest in the digital transformation of health care is accelerating, catalyzed by the COVID-19 pandemic and advances in artificial intelligence (AI). However, not all health professions have advanced equally considering their digital transformation. In Australia, as in many countries, the dental sector remains traditionally siloed from the rest of the health care system and faces fragmentation in its information systems [20]. In the dental sector, the most progress in digital health has been observed in restorative and surgical procedures, where technology is directly integrated into clinical workflows [21]. For example, conventional manual techniques and laboratory workflows for the design and fabrication of dental restorations have evolved into in-house, fully digitized workflows with the application of intraoral scanners and chairside milling machines [22]. In contrast, dentistry has a relatively nascent data culture [23], with less focus on the broader scope of digital health, which we define in this viewpoint to encompass virtual care, remote monitoring, mobile health (mHealth), wearables, big data analytics, platforms, and "the exchange of data and sharing of relevant information across the health ecosystem creating a continuum of care" [4].

Developing digital health–capable dentists thus involves more than simply teaching the technical aspects of digital tools used in service delivery; it requires a shift towards understanding how digital data can inform clinical decisions, enhance patient care, and contribute to system-wide improvements. This conceptual change is crucial for moving from a service-focused practice to one that leverages digital health as an integral part of modern dental care. The Learning Health Systems (LHS) framework [24] is one example of how to help dental professionals characterize digital health. LHS are health care environments where science, informatics, incentives, and culture align to promote continuous improvement and innovation. In these systems, best practices are embedded in care, patients actively participate, and new knowledge is generated from every care experience [25]. Building on this vision, dental education should emphasize models where digital health is central to both practice and continuous improvement. This approach will foster digital health capability by cultivating a deeper understanding of how and why digital health technologies enable the delivery of high-quality, safe, and sustainable care.

Textbox 1 outlines the questions that can guide the development of a digital health curriculum for entry-to-practice dental education. These questions are intended to help educators and curriculum developers define clear goals aligned with the specific needs of the discipline and the local health care context.

Textbox 1. Defining the goals of digital health curriculum for entry-to-practice degrees.

- What is outlined in national and local digital health strategies for the next 5-10 years? What does the political and funding environment look like?
- What are the digital health-related accreditation standards of the profession?
- What does the current and future digital health maturity of the primary work environments of your graduates look like?
  - Consider the difference in goals for:
    - A rural school where graduates may work in areas with limited digital maturity
    - A health discipline or specialty where graduates will typically work in tertiary care rather than primary care

Considerations for Curriculum Development

The Australian Dental Council (ADC) recently revised its competencies for newly qualified dental practitioners; they updated the requirement to include "using digital technologies and informatics to manage health information and inform person-centred care" [26]. This prompted the authors to develop a digital health curriculum to be implemented in a higher education institution that has graduating dental professionals in Australia. As per the best practice in curriculum development [27], we considered the existing digital health competency and capability frameworks as part of our curricular needs assessment. An environmental literature scan found that only a few frameworks had been created specifically for dentistry or involved dental experts in their consultations, reflecting a lag in dentistry's digital health participation (Multimedia Appendix 1). As a result, not all topics in these existing frameworks were relevant or current to the reality of training dental professionals in Australia, who will predominantly work in small clinics in primary care, in practices with varying digital health maturity [28,29]. An exception was the digital dentistry curriculum proposed by the American College of Prosthodontists [30], which is well-researched but focused solely on digital skills for prosthodontics. This highlighted a gap in resources to support the broader skill set of graduating dentists in Australia, as outlined by the ADC.

The process of designing higher education courses aims to align industry standards with a scaffolded approach for developing effective learning outcomes that produce work-ready graduates. While the ADC's revised competency served as a catalyst for curriculum development, our efforts extended beyond the ADC's scope to meet standards such as those overseen by the Tertiary Education Quality and Standards Agency (TEQSA), which

performs the quality assurance checks for all participants, delivered as part of higher education in Australia. TEQSA's emphasis on authenticity in curricula design, as well as contemporary leading practice [31,32], influenced our approach towards designing a curriculum that not only meets regulatory competencies but also prepares students for practical, professional challenges in the evolving digital health landscape.

Finally, a critical component of our approach was to tailor the curriculum to the local context. While internationally recognized informatics competencies [33] often underpin digital health capability frameworks, they do not alone fully capture the breadth and nuances of digital health proficiency. Digital health encompasses a range of skills, including digitally enabled clinical processes, care pathways, and behavior change management, all of which are shaped by local variations in digital health maturity and sociocultural contexts. Furthermore, curriculum development often occurs under significant time and resource constraints, requiring an approach that is rigorous but targeted. For example, rural schools may not yet prioritize AI competencies if electronic health records are not yet in use locally.

Key Domains

Two frameworks were selected to inform the development of the dental digital health curriculum, both of which are government-sponsored, peer-reviewed, and directly relevant to the Australian setting [Textbox 2]. The domains in Table 1 are an abridged synthesis created by the authors, drawing on elements from the two selected frameworks. This reimagined structure is intended to facilitate the development of a digital health curriculum for dentistry, aligning learning objectives, instruction, and assessment with the national strategy in Australia.

Textbox 2. Frameworks selected to inform development of the dental digital health curriculum.

1. Framework 1 (2018): eHealth Capabilities Framework for Graduates and Health Professionals [34]. This framework was developed by the University of Sydney and eHealth New South Wales, consisting of a tri-phase literature review, focus groups with faculty and government representatives (n=23), and a Delphi method refinement with 4 iterations. The framework is structured in 4 domains and describes recommended knowledge and skills for health professions graduates in digital health.
2. Framework 2 (2021): Digital Health Capability Framework for Allied Health Professionals [35]. This framework was developed by the Department of Health, Victoria, and consisted of a 3-part development program including a competency framework review, expert discussion panel interviews (n=28), and an online survey of Victorian allied health professionals (n=164). This document draws from Framework 1 and is similarly structured into 4 domains of 3-6 subdomains, with the addition of levels of digital health proficiency ranging from Foundation, Consolidation, Expert, and Leadership.

Table . Domains and goals for digital health curriculum for an entry-to-practice dental degree.

Domain	Learning goal	Suggested learning topics
1. Digital transformation of health	Newly graduated dental practitioners will actively lead the digital transformation of dentistry by using technology to deliver patient-centred care and by recognizing the role of data and analytics in improving it.	Electronic health records, digital dentistry (radiography, intraoral scanning, CAD/CAM[a], and other digital workflows) data, interoperability and learning health systems, artificial intelligence
1. Legislation, policy, and governance	Newly graduated dental practitioners will drive improvements in the privacy and security of patient data, and model the safe, ethical, and responsible use of digital health technologies in the dental practice.	Data privacy and cybersecurity
1. Digital health for patients	Newly graduated dental practitioners will promote patient engagement in health care, prescribe appropriate digital resources, and support digital health literacy.	Digital health literacy, patient engagement in health care, and digital health equity
1. Digital professionalism	Newly graduated dental practitioners will model a professional and appropriate digital identity.	Social media and digital professionalism

[a]CAD/CAM: computer-aided design/computer-aided manufacturing.

The first domain recognizes that along with technical proficiency in digital clinical workflows, dental practitioners must be able to think in multidisciplinary terms of the flow of data and information across health care [13]. Dental practitioners must understand the importance of informatics, interoperability, and a quality improvement mindset to be the building blocks for creating LHS [24,25].

The second domain recognizes the role of the dental practitioner in safe and ethical governance of patient data across digital workflows, noting that health care is the consistently top-reporting sector for data breaches in Australia [36].

The third domain recognizes the shift from the paternalistic model of health care towards a person-centered one where the person receiving care plays an active role in shared health care decision-making. The OpenNotes mandate in the US is a good

example of this [37]. This domain is also particularly relevant to the rapid pace of AI development and the accessibility of generative AI models that patients may use to access health (mis)information. Dental practitioners must understand digital health literacy; how patients may engage with digital health technologies and services; and the uses, ethics, benefits, and risks of AI in health care.

The fourth domain recognizes that dental practitioners must develop a professional identity, which is multidimensional across social media and the internet. The obligation for a dental practitioner to uphold their professional code of conduct is binding for both their in-person and digital profiles [38].

This holistic overview of digital health in dentistry is a step towards addressing the observation that digital health education tends to be focused on medical degrees—mostly in electives or single-unit areas such as telehealth—and in utilizing diverse approaches for delivery, development, and assessment [39]. A similar observation was found during our curricular needs assessment, revealing a strong focus in single content areas such as telehealth and digital dentistry, but confirming opportunities to facilitate a more coordinated and comprehensive learning pathway to support full digital health competency.

Final Thoughts

Viewing dentistry through a "digital health" lens may seem like a small matter. However, the change in perspective for dental educators is important. Dentistry has traditionally focused on individual patient care and procedural intervention, but contemporary health care is increasingly shaped by system-level forces. AI, interoperability, value-based care, and increasing consumer participation are now current realities [40-43]. The potential for digital health to drive meaningful systemic improvements in oral health and health care cannot be truly realized without first building the necessary capability at the graduate level. Consequently, these topics can and should be taught in a structured manner in entry-to-practice dental education.

Critically, although newer generations are often seen as digitally adept, they do not automatically master the necessary digital skills simply from being exposed to technology [44]. This gap in digital competency underscores the importance of intentional curriculum design. Universities are increasingly using the approach of constructive alignment to enhance outcome-based education [45], and this approach should be used to design a longitudinal digital health curriculum that can align with the intended graduate attributes.

This viewpoint has outlined the premise for designing a digital health curriculum in dentistry, using a structured set of domains based on current evidence and adapted to the Australian context. The proposed domains provide a foundation for educators to build a curriculum that aligns with the unique needs of dental professionals and the national strategy for digital health. This approach is intended for integration into the University of Melbourne's dentistry program and aims to encourage the further development and discussion of digital health education within dental programs, both nationally and globally.

Conclusion

It can be difficult for educators to define digital health curriculum that is both evidence-based and relevant to their discipline and local context; to design it is to predict the future. However, keeping pace involves changing our view of digital health in dentistry. A common understanding about the language of digital health is important for developing health professionals who will be able to navigate the environment of the modern health care system. We found that existing digital health capability frameworks were useful to define a view of digital health across an entry-to-practice dental degree, and high level roadmaps and frameworks are valuable to envision a future-ready dental graduate who can embrace the next wave of digital transformation. This perspective will be useful for developing the curriculum aligned with the national vision of building workforce capability and realizing the aim of safe, connected care.

Acknowledgments

Our sincere thanks to Alastair Sloan, Melbourne Dental School's Head of School, and the Centre for Digital Transformation of Health for supporting this educational initiative.

Abstract

Background: Student feedback is crucial for evaluating the effectiveness of institutions. However, implementing feedback can be challenging due to practical difficulties. While student feedback on courses can improve teaching, there is a debate about its effectiveness if not well-written to provide helpful information to the receiver.

Objective: This study aimed to evaluate the impact of coaching on proper feedback given by dental students in Saudi Arabia.

Methods: A total of 47 first-year dental students from a public dental school in Riyadh, Saudi Arabia, completed 3 surveys throughout the academic year. The surveys assessed their feedback on a Dental Anatomy and Operative Dentistry course, including their feedback on the lectures, practical sessions, examinations, and overall experience. The surveys focused on assessing student feedback on the knowledge, understanding, and practical skills achieved during the course, as aligned with the defined course learning outcomes. The surveys were distributed without coaching, after handout coaching and after workshop coaching on how to provide feedback, designated as survey #1, survey #2, and survey #3, respectively. The same group of students received all 3 surveys consecutively (repeated measures design). The responses were then rated as neutral, positive, negative, or constructive by 2 raters. The feedback was analyzed using McNemar test to compare the effectiveness of the different coaching approaches.

Results: While no significant changes were found between the first 2 surveys, a significant increase in constructive feedback was observed in survey #3 after workshop coaching compared with both other surveys (P<.001). The results also showed a higher proportion of desired changes in feedback, defined as any change from positive, negative, or neutral to constructive, after survey #3 (P<.001). Overall, 20.2% reported desired changes at survey #2% and 41.5% at survey #3 compared with survey #1.

Conclusions: This study suggests that workshops on feedback coaching can effectively improve the quality of feedback provided by dental students. Incorporating feedback coaching into dental school curricula could help students communicate their concerns more effectively, ultimately enhancing the learning experience.

KEYWORDS

student feedback; coaching; dental education; student evaluation; teaching methods; educational intervention

Introduction

Feedback, a cornerstone of effective performance improvement, plays a crucial role in various domains, including education. Understanding how feedback is delivered and received is essential to maximize its impact. Several models provide frameworks for analyzing feedback processes, such as Hattie and Timperley's [1] model, which categorizes feedback based on its focus (task, process, and self-regulation), and Kluger and DeNisi's [2] Feedback Intervention Theory, which explores the instructional, motivational, emotional, and learning effects of feedback. These models highlight the complexities of feedback delivery and the importance of considering the recipient's needs and the specific context. These models go beyond simple evaluation and rather focus on providing actionable information that supports student learning and development.

Feedback is a critical method of measuring the effectiveness of performance and outcome of any institution. More importantly, if these institutions play an important role in education, health, or essential services, it is crucial to use student feedback to ensure the successful performance of these institutions. Feedback is often challenging to execute due to interaction issues or practical applicability [3,4]. Challenges arise from a complex interaction between the providers and recipients'

performance [4]. An example of these challenges could be the fear of recognizing unsatisfactory performance, discouragements, and liability. However, feedback's primary purpose is to improve the outcome. Delivering productive feedback to assess teaching procedures and students' experience is critical for effective learning and developing a solid connection between feedback providers and recipients [5-7]. In addition, it serves to evaluate teaching strategies. By aligning with the principles of key feedback models, the overall learning experience can be enhanced for both students and faculty.

Giving feedback to recipients can be complex; however, various techniques have been reported in the literature; 1 of the popular techniques is the "compliment sandwich," in which the recipient receives 1 criticism between 2 positive comments [8]. In contrast, another effective technique is to eliminate the negative connotation of feedback, in which the feedback provider mentions the mistakes and provides some solutions [9]. In any case, it is important to note that effective feedback comprises structure, content, and time [10]. When this feedback is expected from students to instructors, another level of challenge can be anticipated [11]; certain boundaries between the students and their instructors may restrict students' ability to express themselves freely. Students may also perceive end-of-course feedback as a mere administrative requirement fulfilling curricular mandates, potentially diminishing their perceived value and engagement in the process. Hence, to give constructive feedback, it is essential to guide students to the fact that the goal is not to deliver the feedback by criticizing but to enhance the feedback process to be more effective and constructive [12,13].

Many educational institutions imply student and professor feedback concerning courses in which they are both involved [14]. The feedback from the students usually involves a set of surveys to rate a course and the instructor giving that course. This process could assist the instructors in better recognizing areas of strengths and weaknesses, ultimately improving the educational experience [15-17]. Debate emerges that questions the effectiveness of such feedback [15,18-20]. A recent study found that implementing feedback could be beneficial if incorporated into the curriculum while also providing instructors with how to receive such feedback and how to adapt to these comments [17,21,22]. Furthermore, another author highlighted the importance of student evaluation and excelling in education, which could provide the instructor with minor adjustments to reform the course [21-23]. In contrast, some instructors note that this feedback will not encourage them to modify their courses [23]. Furthermore, some instructors might find it difficult to solely base altering decisions on input provided by students, arguing that some aspects will affect the student's ability to provide trustworthy information based on factors such as the ability to construct critical feedback or complex circumstances, including age, gender, or educational background [18,24].

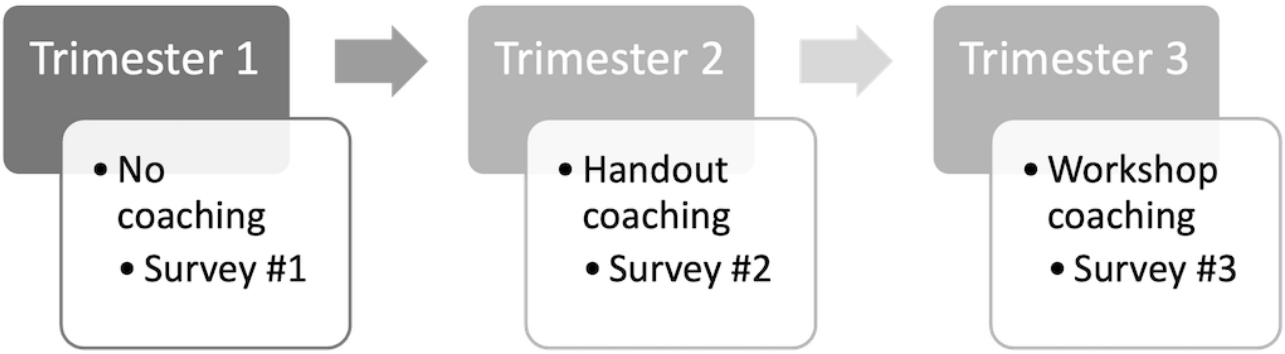
Although previous studies assessed the effect of feedback given by students on teaching quality and the improvement of feedback over a certain period [14,18], the relations between coaching to give and receive feedback and the feedback received from students after coaching have not been investigated among dental students in Saudi Arabia. Teaching students how to provide reflective, constructive feedback to elicit better outcomes for course, curriculum, and general educational development would be significant. Thus, the primary objective of this study was to evaluate the feedback given by students in the College of Dentistry, King Saud bin Abdulaziz University for Health Sciences (KSAU-HS), after using 2 different coaching approaches on how to provide feedback. The secondary objective was to improve the effectiveness of the feedback given by dental students after exposing them to 2 different coaching approaches on how to provide feedback. The null hypothesis of the current study is twofold as there is no difference in the nature of the feedback given by the students using 1 coaching methods, and both the coaching methods increase the proportion of constructive student feedback equally.

Methods

Overview

In total, 50 students were invited to participate in the study. Students were asked to complete 3 surveys in open-ended question format at the end of each trimester (repeated measures design, Figure 1). These surveys asked the same questions but were specific to each trimester. Invited students were asked to provide feedback on the RSTO 311 course. This study focused on first-year dental students enrolled in their introductory dental course, which serves as their initial exposure to fundamental dental concepts, including tooth anatomical landmarks, cavity preparation techniques, and restorative procedures in both theoretical and simulated clinical environments. Each survey consisted of 5 questions, adopted by Hajhamid and Somogyi - Ganss [16]. The first question was to indicate the 2-digit number assigned to each student by a research assistant who never interacted with the students to ensure anonymity. The second question was about the lectures given during the trimester. The third question was about the practical sessions taken during the trimester. The fourth question was about the quizzes, written and practical exams taken during the trimester. The fifth and last question was about the overall course (Multimedia Appendix 1). Based on the course learning outcomes, the students are expected to meet minimum criteria of knowledge and understanding as well as practical skills; thus, the survey focused on these aspects of the course.

Figure 1. Study design showing coaching methods for feedback given in surveys #1, #2, and #3.



At the beginning of the course, an invitation was sent to all students taking the RSTO 311 course. The students were offered a bonus (2 grades) if they participated in the study. If they wished not to participate, they could write an essay about a topic related to their course and get the same bonus grades. The survey was designed using Google Forms and was sent by email to all participating students; the survey link was sent by the same research assistant who assigned the 2-digit numbers to participating students. Consent was obtained from all participating students at the beginning of each survey. Before completing the first survey at the end of the first trimester, no coaching or instructions were given to the students on how to receive and provide feedback. Before completing the second survey at the end of the second trimester, students were coached by reading a 2-page handout on how to receive and provide feedback, which can be covered in approximately 10 minutes (Multimedia Appendix 2). The handout explains the different types of feedback, as well as steps and examples for giving constructive feedback. Before completing the third and last survey at the end of the third trimester, students were coached by attending a 1-hour workshop on how to receive and provide constructive feedback. The workshop was given by a faculty member who was not involved in the course or the research study. The workshop similarly explained different theories on giving and receiving feedback and demonstrated to the students how to improve feedback with examples. Both the handout and the workshop were based on a previously published paper [16].

All 3 surveys' answers were evaluated independently by 2 raters, the course director and the co-course director of the course. The answers were rated as either neutral, positive, negative, or constructive feedback. Any disagreement between the 2 evaluators' ratings of the survey answers was discussed and agreed upon before the analysis. Answers were considered neutral feedback if there were no positive, negative, or constructive comments. Answers were deemed positive if general praise was included. Answers were considered negative if the provided nonconstructive criticism. Finally, answers were considered constructive if there were any suggestions to improve the course in any aspect, even if they contained any positive or negative comments. When rater disagreement was noted in cases where responses were not clearly considered as positive or negative feedback and did not include any constructive comment or intent for improvement, responses were rated as neutral. Data were collected and analyzed based on the ratings given by the 2 evaluators and then compared between surveys.

Student feedback was collected in textual form and subsequently coded into 4 categories: positive, negative, neutral, and constructive. The reliability of this coding process was ensured through independent assessments by 2 raters. Kappa statistics was used to assess inter-rater reliability between the 2 raters. The ratings followed a nominal scale (1=neutral, 2=positive, 3=negative, and 4=constructive); hence, frequency and proportions were reported for the ratings as descriptive statistics. Inferential statistical analysis was used to test rating changes over time (McNemar test). The level of significance of .05 was used for inferential analysis with P values <.05 reported as statistically significant. Analysis was performed combined for 4 questions as well as separately for each question. IBM SPSS Statistics software (version 29) was used for descriptive and inferential analysis.

Ethical Considerations

An institutional review board ethical approval was obtained from King Abdullah International Medical Research Center for this cross-sectional study (IRB/3004/23). This study was conducted during the academic year 2023 - 2024 among first-year dental students who took the Dental Anatomy and Operative Dentistry course (RSTO 311) at the College of Dentistry, KSAU-HS, a public dental school in Riyadh, Saudi Arabia. The RSTO 311 is a yearly course divided over 3 trimesters. The course has theoretical and practical components: 30 lectures and 40 practical sessions. The students were assessed based on weekly continuous assessment, 3 quizzes, 3 written exams, and 3 practical exams.

Results

Of the 50 students in the class, 47 participants (25 male and 22 female participants) were included who completed all 3 surveys at 3 different time points, giving a participation rate of 94%. Out of 50, 1 student dropped the course, 1 refused to participate, and 1 failed to complete the third survey.

The 2 raters provided a total of 564 ratings each. Overall, 541 out of 564 ratings matched, suggesting a 95.9% level of agreement. The κ value was 0.941, which, being above 0.9, indicates an almost perfect level of agreement between the raters, demonstrating a high degree of reliability in the classification of responses. Discrepancy in data was discussed, re-evaluated, and a final agreement was reached and recorded. The following are randomly selected examples presented from students' feedback:

Neutral feedback: "No complaints about it"

Positive feedback: "The course provided a solid foundation in the subject matter, it was a valuable learning opportunity"

Negative feedback: "The work was hard and tiring and the time was not enough"

Constructive feedback: "In some anatomy lectures, clearer explanations were needed. Providing a short video would offer better visualization for students"

Within-subject analysis was conducted separately for each of the 4 questions in the 3 surveys. No significant changes were observed between survey #1 and #2 in any of the 4 questions, separately or combined. However, there were statistically significant changes between survey #1 and #3 with regards to increase in proportion of constructive ratings for questions 2 - 4 as well as for the 4 questions combined. Significant change in ratings was also found in survey #3 relative to survey #2 for questions 1 - 3 as well as for the 4 questions combined (Table 1).

Table . Ratings for each of the 4 questions at each of the 3 surveys.

Question and rating		Survey #1, n (%)	Survey #2, n (%)	Survey #3, n (%)
#1[a]				
	Neutral	10 (21.3)	9 (19.1)	13 (27.7)
	Positive	4 (8.5)	2 (4.3)	0 (0)
	Negative	15 (31.9)	25 (53.2)	9 (19.1)

[a] nonconstructive ratings include positive, negative and neutral.

[b] MN_1(b)=McNemartest using binomial distribution to examine change from survey #1.

[c] MN_2(b)=McNemartest using binomial distribution to examine change from survey #2.

For each question, the change from survey #1 was coded as desired versus not desired. Desired change was defined as any change from positive, negative, or neutral to constructive. All other changes were coded as not desired. The proportion of desired changes is summarized in Table 3. Survey #3 showed a higher proportion of desired changes compared with survey #2. For the 4 questions combined, 20.2% had desired changes at survey #2% and 41.5% at survey #3 compared with survey #1. In survey #3, the most frequent changes reported overall for the 4 questions combined were: neutral to constructive (17.6%), negative to constructive (16.5%) and constructive to constructive (16.5%).

Table . The proportion of desired changes in surveys #2 and #3 compared with survey #1.

Proportion of desired changes	Survey (#2 versus #1), n (%)	Survey (#3 versus #1), n (%)
Question 1	7 (14.9%)	16 (34%)
Question 2	10 (21.3%)	23 (48.9%)
Question 3	9 (19.1%)	19 (40.4%)
Question 4	12 (25.5%)	20 (42.6%)
Four questions combined	38 (20.2%)	78 (41.5%)

Discussion

Principal Findings

This study compared student responses without coaching, coaching using a feedback handout, or coaching using a feedback workshop before completing the surveys. Results demonstrate that handout coaching showed no significant difference compared with no coaching with respect to the number of neutral, positive, negative, or constructive ratings. However, workshop coaching significantly increased the number of constructive ratings compared with both no coaching and handout coaching ($P<.001$, Table 1). Therefore, the null hypothesis was rejected. The reason for these results could be due to the fact that handouts were distributed to the students, and they were asked to read the 2-page document independently. This method does not involve student and instructor interaction and is hence, less engaging. There was also no measure of whether the students in fact read the handout and grasped the information. Thus, no significant changes were noted between survey #1 and survey #2. Workshop coaching, on the other hand, was done in a classroom setting with 1 faculty member present, ensuring a 100% attendance rate of all participating students. Furthermore, the students were able to ask questions regarding the information presented in the workshop and were asked to fill out survey #3 immediately after the workshop, before leaving the classroom.

The proportion of constructive feedback, compared to nonconstructive feedback, significantly increased after workshop coaching (Table 2). The workshop-based format provided multiple examples in a story format from past student feedback, whereas the handout only stated the description of proper feedback writing without detailed examples compared with the examples presented in the workshop. The educational value of workshop coaching has been previously established, wherein the students are “active learners” and can engage in asking questions during the learning process [25,26]. Information presented in video format can also enhance information retention, owing to reduced student cognitive loading and optimized use of visual learner memory [27]. Furthermore, the key learning points are emphasized during the workshop, and audio-visual learning is more likely to keep the students more attentive and engaged in the content being delivered [28]. This is also demonstrated in Table 3, where the most frequently reported changes in feedback from survey #1 (no coaching) to survey #3 (workshop coaching) were from neutral and negative to constructive, reported in this study as “desired changes”.

The effectiveness of workshop coaching can also be understood through several educational and psychological frameworks. For example, the constructivist learning theory emphasizes the importance of social interaction and guided learning in developing cognitive skills [29]. The workshop format, which encourages active participation and immediate feedback from the instructor, aligns with this theory by fostering an environment where students engage with and construct their knowledge of feedback writing through scaffolding, wherein support is provided by a more knowledgeable person. This approach helps students internalize new feedback techniques through direct interaction and reflection on real examples. Furthermore, the importance of emotional intelligence in feedback delivery cannot be overlooked. According to Goleman [30], empathy and self-regulation are key components of emotional intelligence that influence how feedback is communicated. In the workshop setting, students are not only taught the mechanics of constructive feedback but also how to consider the emotional impact of their words, enhancing their ability to offer feedback that is both critical and supportive. This connection to emotional intelligence helps explain why the workshop coaching produced a higher proportion of constructive feedback compared with the handout coaching.

Comparison With Previous Work

In any educational environment, student satisfaction is an essential criterion for quality assessment [31]. Student evaluations of teaching are surveys typically used to collect, analyze, and interpret teaching quality [32]. Hence, every year, students are asked to evaluate the course material and provide feedback. In this study, the survey questions provided to the students concerned the lectures, practical sessions, and examinations at KSAU-HS. They were distributed immediately after the end of each trimester to ensure the feedback was relevant and firsthand. The purpose of these distributed surveys was to gather information on the course teaching, practical sessions, and facilities so that an action plan may be set to ensure improvement. However, most student feedback tends to be general or rely on their personal experience rather than providing helpful information related to the learning experience [33]. As this study is based on open-ended questions, analyzing responses can be quite intricate unless the process is made more structured. Hence, this study evaluated student responses after a handout and workshop coaching.

Written comments add value to both students and educators when compared with scale-type questions [34]. The students are given the possibility to explain their perspective beyond Likert-type scales and raise further topics that may not have

been covered in closed-ended questions [35]. Written comments are more informative for educators, and suggestions are beneficial when compared with receiving a statistical summary of quantitative results [36]. “Student evaluations of teaching” instruments can be a source of valuable thoughts from students and can help educators gain insight into how students perceive their learning experience and how different students learn best in a given setting [37]. However, these benefits can only be reliable after bringing a little order to the chaos of written responses.

The main purpose of the study was to improve the quality of feedback provided by the students. To the best of our knowledge, this is the first study introducing interactive workshop coaching for proper feedback among teaching institutes in Saudi Arabia. The workshop was able to improve the constructive criticism given by the students compared with self-learning using the handout. It is likely that the lower performance with handout coaching reflected less motivation, responsibility, or independence of the students [38]. These results are contrary to a previous similar study, in which both the handout and workshop coaching similarly improved student feedback [16]. The difference in results could be attributed to the nature of the dental school between both studies. This study was performed in a governmental dental school where students are not obliged to pay tuition fees. On the contrary, since their education is financed largely by loans, students from the Canadian private dental school may be more encouraged to commit to assigned tasks [39,40]. It is also worth noting that dental students at our institution are more familiar with lecture- and workshop-based learning as opposed to self-directed learning; as most dental schools in Saudi Arabia have not completely shifted from teacher-centered learning to a more interactive or evidence-based style [41]. Furthermore, culturally, expressing opinions, especially those with negative connotations or suggestive tones, may not necessarily be favored [42]. However, the results of this study clearly show the benefits of workshop coaching in directing students to provide their perception towards the course. This emphasizes the importance of including such a coaching approach for first-year students as part of the academic curriculum at the beginning of their studies.

Limitations

One of the limitations of this study was the inclusion of only first year students, as students in older years may have responded differently to the handout coaching, likely being more familiar with independent self-learning. Students in older years may also be more exposed to course-based surveys compared with first-year students. This also reduced the sample size of the participants. Furthermore, the difference between the topics covered over the 3 trimesters of the course may have influenced the feedback given by the students. In addition, when the students were given the third survey, they had already been exposed to both handout and workshop coaching on proper feedback, and this emphasis on appropriate feedback writing may have led to the higher number of constructive comments in survey #3. Furthermore, self-reported student feedback is subject to various biases, such as recall bias, acquiescence bias, social desirability bias, and cultural influences, which could impact the accuracy of the responses. Finally, the incentive of the bonus grades may have introduced self-selection bias; however, as the incentive was offered to all students equally, whether they participated in the survey or chose to submit an essay assignment, this may have mitigated the bias.

Conclusions

This study compared the effectiveness of 3 approaches, no coaching, handout coaching, and workshop coaching, on improving the quality of feedback provided by dental students. The results show that workshop coaching significantly increased the number of constructive feedback ratings, compared with both no coaching and handout coaching. This study encourages a more expressive feedback culture that facilitates student or instructor interaction in a constructive manner, wherein instructors can receive and implement feedback to improve the educational process. This suggests that interactive, instructor-led workshops foster a more engaged learning environment, encouraging students to provide higher-quality feedback. Given these findings, educators can implement interactive workshops focused on teaching students how to provide constructive feedback. These workshops should encourage active engagement through real-life examples and peer discussions. Given that the study shows significant benefits in first-year students, feedback coaching can be introduced early in the academic program. Building on the concept of scaffolding, educators could start with guided feedback exercises during the workshop, gradually increasing the level of independence as students become more proficient. Educators can also integrate emotional intelligence training into feedback workshops by helping students understand how to express feedback empathetically and how to regulate their emotions while providing feedback. Further studies evaluating different coaching methods to enhance student feedback are needed, with consideration to assign different methods to each study group. Future research should also investigate the impact of standardized coaching protocols on the quality of student feedback and use the data to improve assessment and learning outcomes.

Abstract

Background: This cross-sectional study assessed the perceived alignment between preclinical education and clinical practice in root canal treatment (RCT) among dental practitioners in China, aiming to identify systemic gaps in dental curricula and their clinical implications.

Objective: Dental professionals in Eastern Coastal China. This study distributed questionnaires through hospital dental specialties and medical forums, covering the Southeastern Region of China.

Methods: A validated, web-based survey was distributed to 90 dental professionals in Eastern Coastal China, focusing on 9 key stages of RCT, preoperative preparation, intraoperative procedures, postoperative care, and clinician-patient communication. Responses were measured using a 7-point Likert scale to evaluate perceived discrepancies between education and clinical practice.

Results: A total of 83 valid questionnaires were recovered, which revealed significant disparities between academic training and clinical demands. The survey showed that the specialized practitioners identified pronounced mismatches in RCT operative techniques and doctor-patient communication (P<.05). Participants aged ≤29 years demonstrated heightened awareness of discrepancies in disinfection protocols and temporary filling procedures (P<.05). Shanghai-trained practitioners reported fewer educational-clinical gaps across multiple procedural stages (P<.05). Notably, 82% of respondents rated comprehensive RCT implementation as more challenging than individual procedural components. Curriculum deficiencies were identified in treatment indication diagnostics (56.6% agreement) and communication training (43.4% agreement). Emerging technologies like virtual reality and augmented reality (VR and AR) showed minimal educational penetration (3.7% exposure rate). In the free-response section, qualitative feedback highlighted equipment accessibility issues (eg, thermal gutta-percha tools) and instructor-dependent learning outcomes.

Conclusions: Structural discrepancies exist in Chinese preclinical RCT education, influenced by factors such as experience level, age, and region. These findings underscore the need for curriculum reforms, emphasizing competency-based training, enhanced simulation technologies, and standardized clinical protocols, particularly in areas like periodontal pathology and communication skills.

KEYWORDS

root canal treatment; endodontic education; dental education; clinical practice; dental medical workers

Introduction

Periapical lesions and endodontic diseases are highly prevalent among the global adult population [1], with root canal treatment (RCT) being one of the most common interventions provided by general dentists in clinical practice and the preferred treatment method for treating endodontic diseases.

Studies have shown that RCT is a challenging clinical intervention in dentistry, leading to varying degrees of practical difficulty for dental practitioners. Over 70% of dental practitioners express a desire for more clinical training [2]. Unlike most surgical dental procedures, RCT involves multiple steps, and any errors can result in unsatisfactory outcomes. RCT is performed in a concealed space, with limited space for operation and without visual control. It involves a variety of equipment, requires fine competence of the dentist, and involves complex operational procedures. According to dental practitioners, they often perform RCT procedures feeling a lack of control. In an emotional survey report related to RCT, nearly

all dentists expressed feelings such as anxiety, frustration, stress, or exhaustion [3].

Compared with other dental disciplines, endodontic therapy demands higher levels of manual dexterity and independent operational skills. Educational institutions play a crucial role in nurturing individuals to meet societal needs [4]. Optimal dental education should produce competent general practitioners in dentistry to ensure patient safety [5,6]. However, the difference in education among dental schools is considered a major obstacle to standardizing and ensuring the quality of dental education [5]. Early research on endodontic education focused on improving teaching methods, while later studies began to focus on different learning periods and the introduction of new technologies [7]. Authoritative organizations such as the European Society of Endodontology (ESE) have established guidelines to ensure educational standards. Furthermore, most dental schools in China offer a 5-year dental training program leading to a Bachelor of Dental Surgery degree, with the emphasis on clinical practice training in the final year of the dental education plan (following the "Clinical Practice for Chinese Undergraduate Students Majoring in Stomatology" standards established by Chinese Stomatological Association) [8]. Due to differences in economic and cultural backgrounds between Western countries and China, disparities exist in dental education programs, licenses, curricula, and facilities [9].

Regarding the allocation of teaching time in endodontic education, significant differences exist among countries. Previous studies show substantial variations in preclinical endodontic education at dental schools. In Germany, the average time spent on theoretical courses is 13.3 hours, practical courses require an average of 45.4 hours, and the total time for the endodontics course averages 56 hours [10,11]. In Spain, 95% of schools allocate over 20 hours for preclinical training, with 60% of schools dedicating over 50 hours [12]. However, in a study in China, 71.99% of Chinese schools spend less than 4 hours per week on endodontics education, totaling no more than 80 hours per semester, with the lowest training time allocated to periodontics and significant shortages in facilities for dental surgery courses [13]. This indicates that education emphasis and methods vary greatly across regions.

In terms of educational systems, comparing China and the United States illustrates 2 distinct teaching models. In the United States, after completing 4 years of general education, students are required to independently prepare some practice equipment, have relatively ample time to focus on coursework and preclinical training at schools, and enhance their skills through dental practice [9]. In China, dental schools are divided into three categories: 8-year program, 5-year program, and 3-year program. The 8-year program is only held in a few renowned dental schools in China, while the majority of dental students pursue the 5-year Bachelor program [14]. Although the order and proportion of courses may differ across schools in China, the undergraduate curriculum generally includes basic courses and dental courses. The undergraduates take public courses and basic courses of medicine in the first 2 years, focusing on clinical medical courses in the junior and senior years, with the opportunity to do a rotation in several departments such as Otolaryngology and Endocrinology. In the final year, there is no theoretical research, and all the time belongs to clinical practice. In America, clinical practice typically takes 2 years. In addition, China has 93 dental institutions offering a shorter 3-year training program for dental assistants [15]. Upon completion of the 3-year program and assessments, students are awarded the junior college in China, comparable to Bachelor of Science in Dental Hygiene in the United States (70% superposable curriculum). Differences in the dental degree concepts between China and the United States might lead to inequity situations [16]. Dental education in China is mainly government-supported, with schools providing equipment for students. Some dental schools cannot afford to provide advanced materials for all students [9].

Due to the aforementioned reasons, China exhibits certain differences from other countries, both in the content and discipline orientation of endodontic education. Past research on endodontic teaching primarily focused on undergraduate and postgraduate students, leading to the limitations of research not addressing specialized students and lacking feedback from clinical practitioners. This study is designed as a random sampling survey targeting clinical health care professionals to gather evaluation data on clinical RCT and corresponding teaching practices. This aims to identify issues related to the differences between clinical practices and classroom education, the effectiveness of teaching content, difficulties in practical components, and the bias in educational training.

Methods

Questionnaire Design

The design of the questionnaire referred to the fuzzy Delphi method and formed an expert group consisting of experienced oral physician (1), university professor (1), and dental nurses (2). The questionnaire validity was verified through 2 rounds of structured opinion solicitation. Expert discussions focused on the professionalism of the questions (accuracy of instrument references and rationality of operational sequences), representativeness (coverage of essential procedures of standard root canal treatment), and breadth (including preoperative preparation, intraoperative emergencies, and postoperative evaluations). At the same time, the wording of the questions was screened for semantic ambiguity and reading complexity calibration (Flesch-Kincaid level≤8). After 3 iterative modifications, a final consensus rate of 86.4% at the item level was achieved. To prevent respondent misunderstandings, nonconsensual operational terms were annotated in the questionnaire in Multimedia Appendix 1. Participants were required to read the survey instructions before participating in the survey, which outlined the basic process and main content of the questionnaire, as well as clarified the voluntary nature of participation and the noncommercial research purposes of the data.

The questionnaire consists of 30 questions in 4 categories. The basic questions follow a 7-point Likert scale to categorize the sensitivity of the responses. Some questions are designed as multiple-choice and free-response options. The main content focuses on the differences between in-school learning content and clinical practice, the practical difficulty of clinical RCT,

and issues related to educational methods and approaches in RCT. The questionnaire refers to the uniformly used endodontic teaching textbooks in the China region, dividing the entire process of clinical root canal treatment into 9 stages: determining indications, x-ray photography and observation, equipment adjustments, local anesthesia, root canal preparation, root canal disinfection and temporary sealing, root canal filling, posttreatment supplies organization, and clinical doctor-patient communication and doctor-nurse cooperation. To prevent any cognitive misinterpretation, we provided annotations for nonconsensus operations (Multimedia Appendix 1). Before participating in the questionnaire survey, participants are required to read the survey notice, which outlines the basic processes and main content of the survey and clarifies the voluntary nature of participation and the noncommercial research purpose of the data.

Data Source

This study distributed questionnaires through hospital dental specialties and medical forums, covering the Southeastern Region of China.

Statistical Analysis

Data collection was managed using internet-based survey software. Descriptive statistics were applied to each question to obtain basic distribution characteristics, and data were cross-compared for different grouping situations. The statistical analysis in the study was carried out using SPSS 26 (IBM), with 1-way analysis of variance used for certain differential issues and the K-W independent sample test and nonparametric test methods used for questions related to the difficulty of RCT operations. The level of statistical significance was set at $P<.05$.

Ethical Considerations

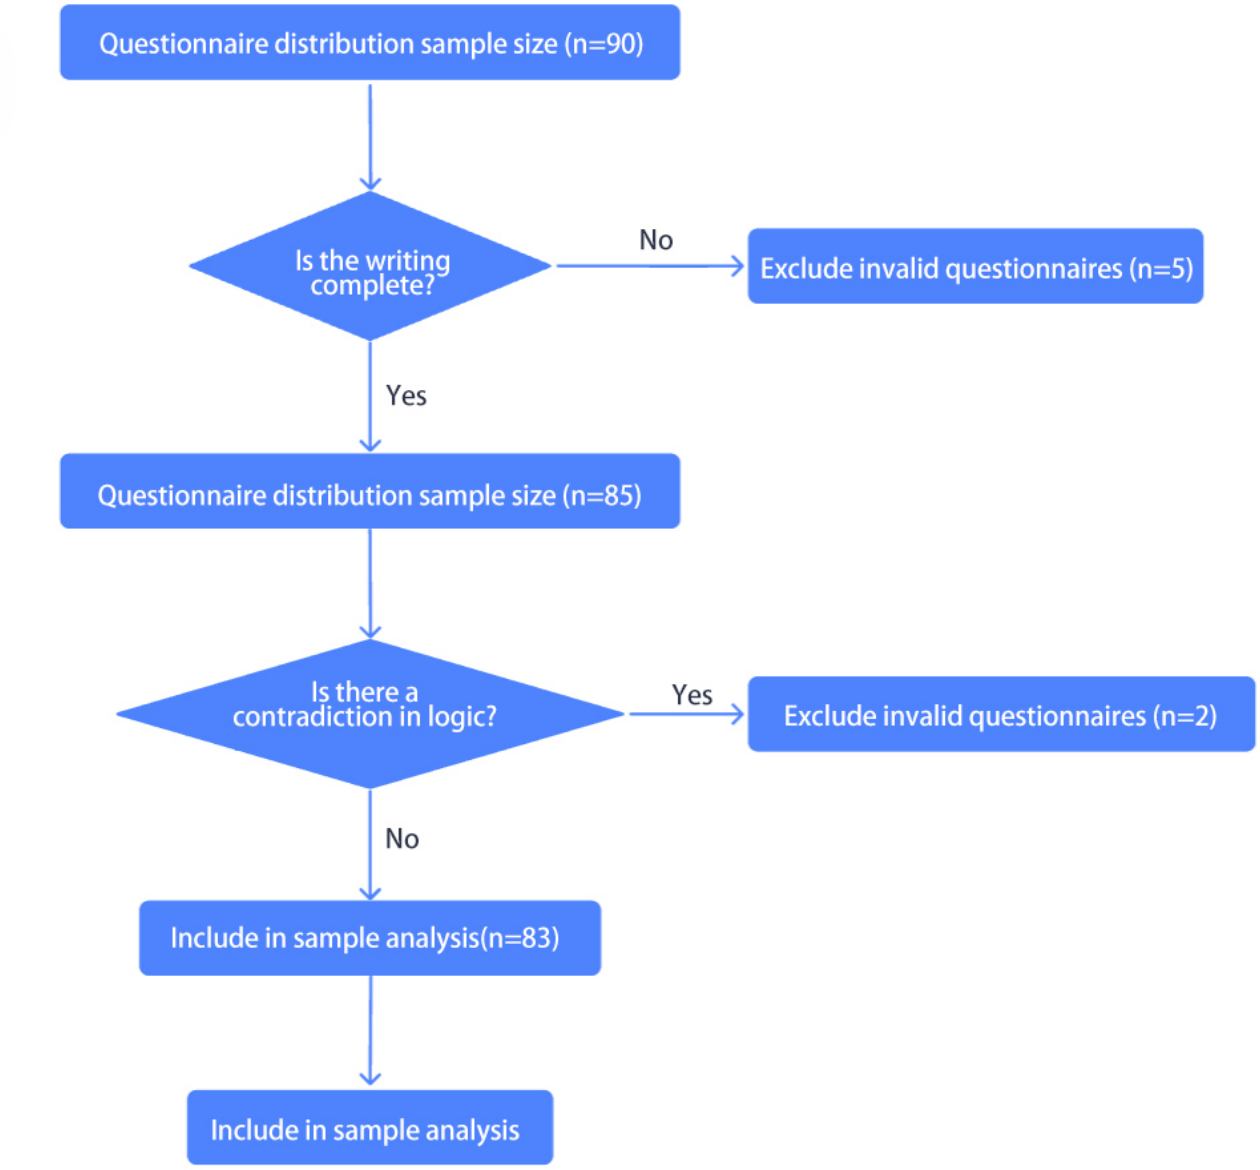
The questionnaire was distributed and collected in May 2024, over a period of 30 days. A total of 90 questionnaires were distributed, yielding 83 valid responses. A total of 7 incomplete or unsuccessfully retrieved questionnaires were excluded from the data analysis, resulting in a response rate of 92.22%. The questionnaire was filled out anonymously, with no personal names or specific hospital names disclosed. This study was conducted in the form of a questionnaire and was approved by the Ethics Committee of Shanghai University of Engineering Science (Approval No. EST-2024‐027). Written informed consent of the participants was obtained prior to enrolment in the study.

Results

Overview

The questionnaires were distributed and collected from May 1 to May 30, 2024, lasting for 30 days. A total of 90 questionnaires were collected, of which 7 were determined to be invalid due to missing key variables (such as education and age) or logical contradictions. Ultimately, 83 complete data sets were included (missing rate of 7.8%), with an effective recovery rate of 92.22%, as shown in Figure 1. The questionnaires were filled out anonymously without involving personal names or specific hospital names.

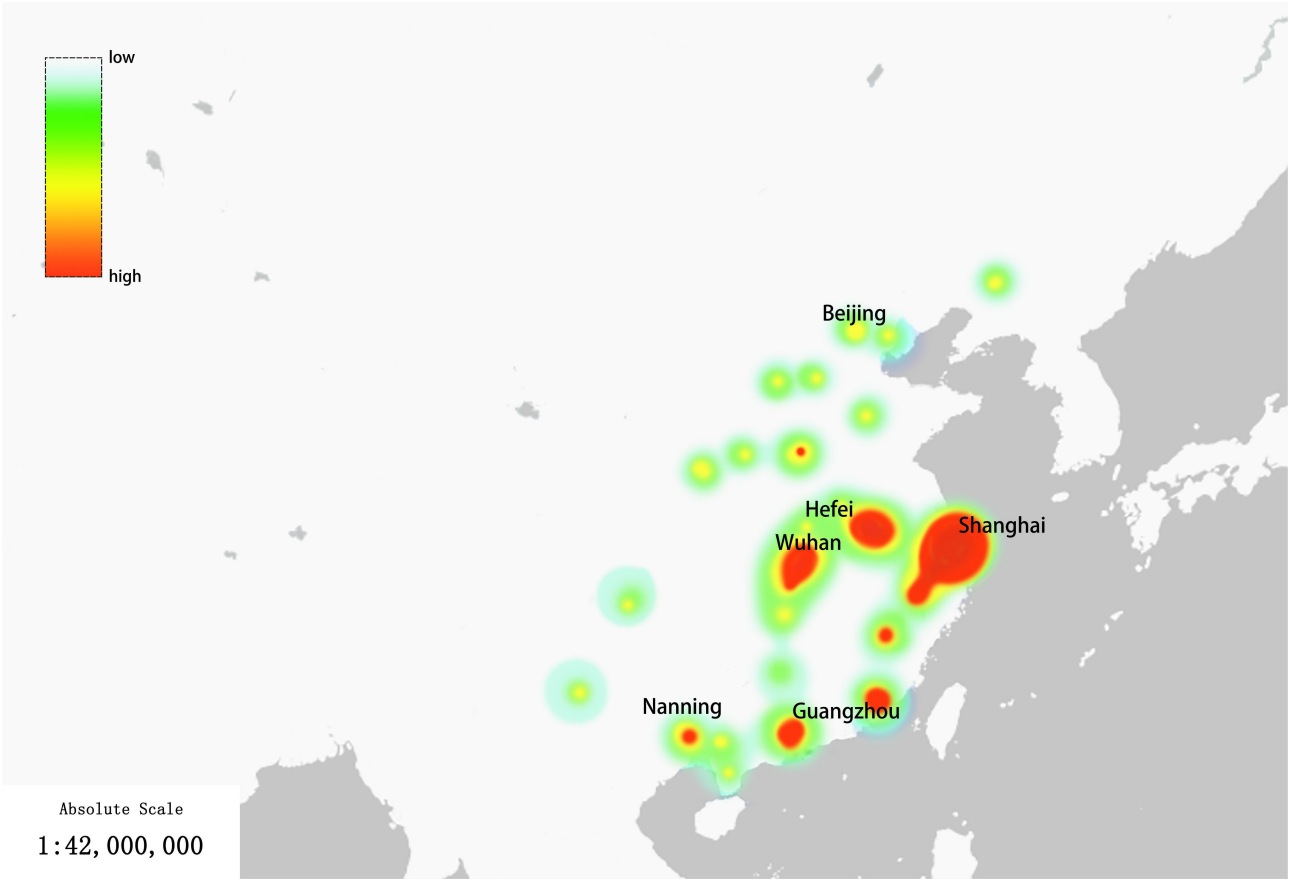
Figure 1. Data screening flowchart.



Through reliability and validity tests, the standardized reliability coefficient of the questionnaire items was 0.845, and the KMO test coefficient result was 0.87, indicating that the reliability and validity of this questionnaire were good. To evaluate the robustness of the results, the following sensitivity analyses were conducted, using parametric tests (ANOVA) and nonparametric tests (Mann-Whitney U) to analyze the intergroup differences. The results were highly consistent (the direction of *P* values was consistent, and the level of significance did not change). After excluding samples with >10 years of work experience (n=12) and reanalyzing, the impact of education and region on teaching satisfaction remained significant ($P<.05$), indicating that the results were not sensitive to outliers. Therefore, the collected data is meaningful for reference.

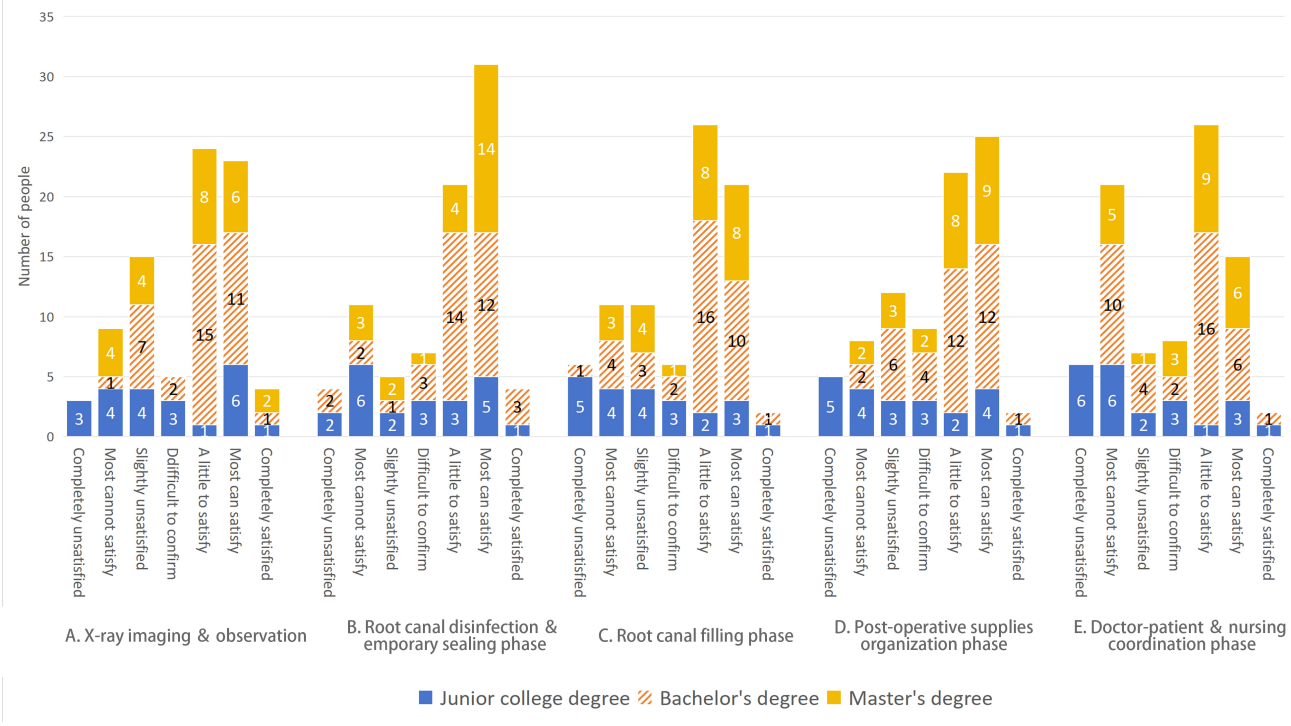
The participants in the study were exclusively practicing dental professionals, with 45.78% hailing from the Shanghai region, as depicted in the density distribution map (Figure 2). These survey participants all have undergone university-level education in the field of dentistry, possess a minimum of 1 year of clinical dental work experience, and have engaged in the performance of RCT during their professional tenure. The age demographic of participants ranged from 21 to 60 years, comprising 36.1% males and 63.9% females. In terms of their educational attainment, 26.5% held junior college degrees, 44.6% possessed bachelor's degrees, and 28.9% had obtained master's degrees. The spectrum of clinical dental work experience extended from a minimum of 1 year to a maximum of 36 years.

Figure 2. Density visualization of the regional distribution of participants: color indicates the number of participants from less (green) to more (red).



Regarding the congruence between specific aspects of school instruction and clinical practices, respondents' answers exhibited notable disparities. This investigation revealed that in the x-ray imaging and observation stage, the congruence between bachelor's and master's degree holders was notably superior to that of junior college graduates (P<.05). Participants with junior college degrees account for 50% (11/22) of the total who expressed negative evaluations of school teaching (selecting "completely unsatisfied," "most cannot satisfy," and "slightly unsatisfied" options). In contrast, those with bachelor's and master's degrees reported negative evaluations at rates of 22.9% (8/35) and 33.3% (8/24) of their respective totals. Bachelor's and master's degree holders significantly surpass junior college degree holders in their positive assessments of school teaching and clinical practices; the proportion of junior college degree holders who gave positive evaluations (choosing "completely satisfied," "a little to satisfy," and "slightly satisfied" options) is 36.4% (8/22) of their total, while bachelor's and master's degree holders selected positive evaluation options at rates of 77.1% (27/35) and 66.7% (16/24), respectively. Thus, bachelor's and master's degree holders evidently hold more favorable views of school teaching and clinical operations compared with those with junior college degrees. For further details, refer to Figure 3. Similarly, discrepancies based on educational backgrounds were also apparent in other phases, such as root canal disinfection and temporary sealing, root canal filling, postoperative supplies organization, doctor-patient and nursing coordination, as depicted in Figure 3.

Figure 3. The perceptions of respondents with different educational backgrounds regarding the integration of school teaching and clinical practices across 5 stages of the randomized controlled trial (RCT).



In Figure 3, junior college degree holders who selected negative evaluation options such as "completely unsatisfied," "most cannot satisfy," and "slightly unsatisfied" constituted 50% (11/22), 45.5% (10/22), 59.1% (13/22), 54.6% (12/22), and 63.6% (14/22) of their demographic, respectively. In contrast, those who opted for positive evaluations like "completely satisfied," "a little to satisfy," and "slightly satisfied" represented 36.4% (8/22), 40.9% (9/22), 27.3% (6/22), 31.8% (7/22), and 22.7% (5/22) of the same group. On the other hand, bachelor's and master's degree students who chose negative evaluation options made up 26.2% (16/61), 16.4% (10/61), 24.6% (15/61), 21.3% (13/61), and 32.8% (20/61) of their respective totals, while those who selected positive evaluation options accounted for 70.5% (43/61), 77.0% (47/61), 70.5% (43/61), 68.9% (42/61), and 62.3% (38/61) of their groups.

In the phases of root canal disinfection and temporary sealing operations, it is apparent that the "40~" age group perceives a significantly higher alignment between school teaching and clinical practices compared with the "21-29" age group (P<.05). Among participants aged 40 and above, 50% (5/10) selected "slightly satisfied," followed by 30% (3/10) who chose "a little to satisfy" and 20% (2/10) who opted for "completely satisfied." Conversely, within the 21–29 age group, 23.5% (12/51) of participants indicated "slightly unsatisfied", which trailed only behind the 25.4% (13/51) who chose the "a little to satisfied" option. For further details, refer to Figure 4. The 40+ age group (yellow) exclusively opted for positive attitudes (choosing "completely satisfied," "a little to satisfy," and "slightly satisfied" options), whereas 41.2% (21/51) of the 21 - 29 age group (blue) selected negative attitudes (selecting "completely unsatisfied," "most cannot satisfy," and "slightly unsatisfied" options).

On the issue of the practical difficulty of clinical treatment, respondents' evaluations were homogeneous, revealing no significant categorical disparities. With respect to the overall difficulty of clinical treatment, 82% of respondents (68/83) selected the options of "slightly difficult" and "normal," exhibiting a skewness value of 0.701. In the assessment of the difficulty of each phase of RCT, respondents generally perceived the difficulty of each stage to lie between "normal" and "slightly easy," with skewness values lower than the overall difficulty skewness value. Detailed findings are illustrated in Figure 5.

Regarding perception issues in certain phases, the responses of the participants have exhibited significant variances. For instance, in the equipment adjustment phase, the congruence of the participants from the Shanghai area is generally higher than that of the participants from other regions, and they also perceive the clinical practice difficulty of this phase to be relatively low (P<.05). For the composition of the difference in the equipment adjustment phase, refer to Figure 5A: the graph of the sample of the Shanghai area shows a positively skewed distribution, with a skewness value of 0.385; the graph of the sample from other areas exhibits a negatively skewed distribution, with a skewness value of −1.013. In other phases such as indications judgment, equipment adjustment, root canal preparation, root canal disinfection and temporary sealing, root canal filling, postoperative supplies organization, and the phase of doctor-patient and nursing coordination in the clinic, the graphical representation of the sample from the Shanghai area also reveals a significantly positive bias compared with those from other areas, as detailed in Figure 6.

In the survey assessing the disparities between clinical work and on-campus learning, 69.9%(58/83) of the respondents opined that the scenario of judging the indications for RCT in the clinic is more intricate, 68.7% (57/83) of the respondents

held the view that there is a marked divergence in the modes and methods of doctor-patient communication in the clinic vis-a-vis the related instruction in the academic setting, and with regard to the configuration and application of equipment, 51.8% (43/83) of the respondents contended that there is a significant variance between the clinical RCT work and the on-campus pedagogy. See for details.

When asked about the teaching methods encountered in the school, 78% (64/83) of the respondents received cavity preparation and filling training in the school, 75.6% (62/83) of the respondents reported that video demonstration was a prevalent teaching method, and 61% (50/83) of the respondents were exposed to the practice of taking x-ray imaging in the school. However, 25.6% (21/83) of the respondents were exposed to dental modeling software practice and digital assessment and review, and only 3.7% (3/83) of the respondents were exposed to VR or AR in the school learning process.

56.6% (47/83) of the respondents believed that there is too much didactic teaching in the school teaching process, while the proportion of practical practice is insufficient. 48.2% (40/83) of the respondents advocated for an enhancement in the identification and treatment teaching of different pulp conditions. 45.8% (38/83) of the respondents expressed the desire for an augmentation in the identification and treatment instruction of various periodontal conditions. In addition, respondents who believed that the school should focus on the content of patient psychological care/doctor-patient communication and appointment schedules in the clinic also reached 43.4% (36/83). See Figure 7 for details.

Finally, this study collated and categorized the self-statements of the participants in the “other” option. In the clinical practice of RCT, there is a noted difficulty in identifying or using/disbursing tools or medications: 20% (3/15) of the respondents think it is difficult to use the Gutta Percha Obturation Guns in the root canal filling phase. 33.33% (5/15) of the dental practitioners believed residual pulpitis is a common complication of RCT. In addition, 20% (3/15) of the respondents emphasized that in the on-campus instruction, the importance of the practice instructors cannot be understated, of which 66.67% (2/3) are college degree holders.

Figure 4. In the context of root canal disinfection and temporary sealing phase, respondents of different age groups expressed their views on the integration of school teaching and clinical operations.

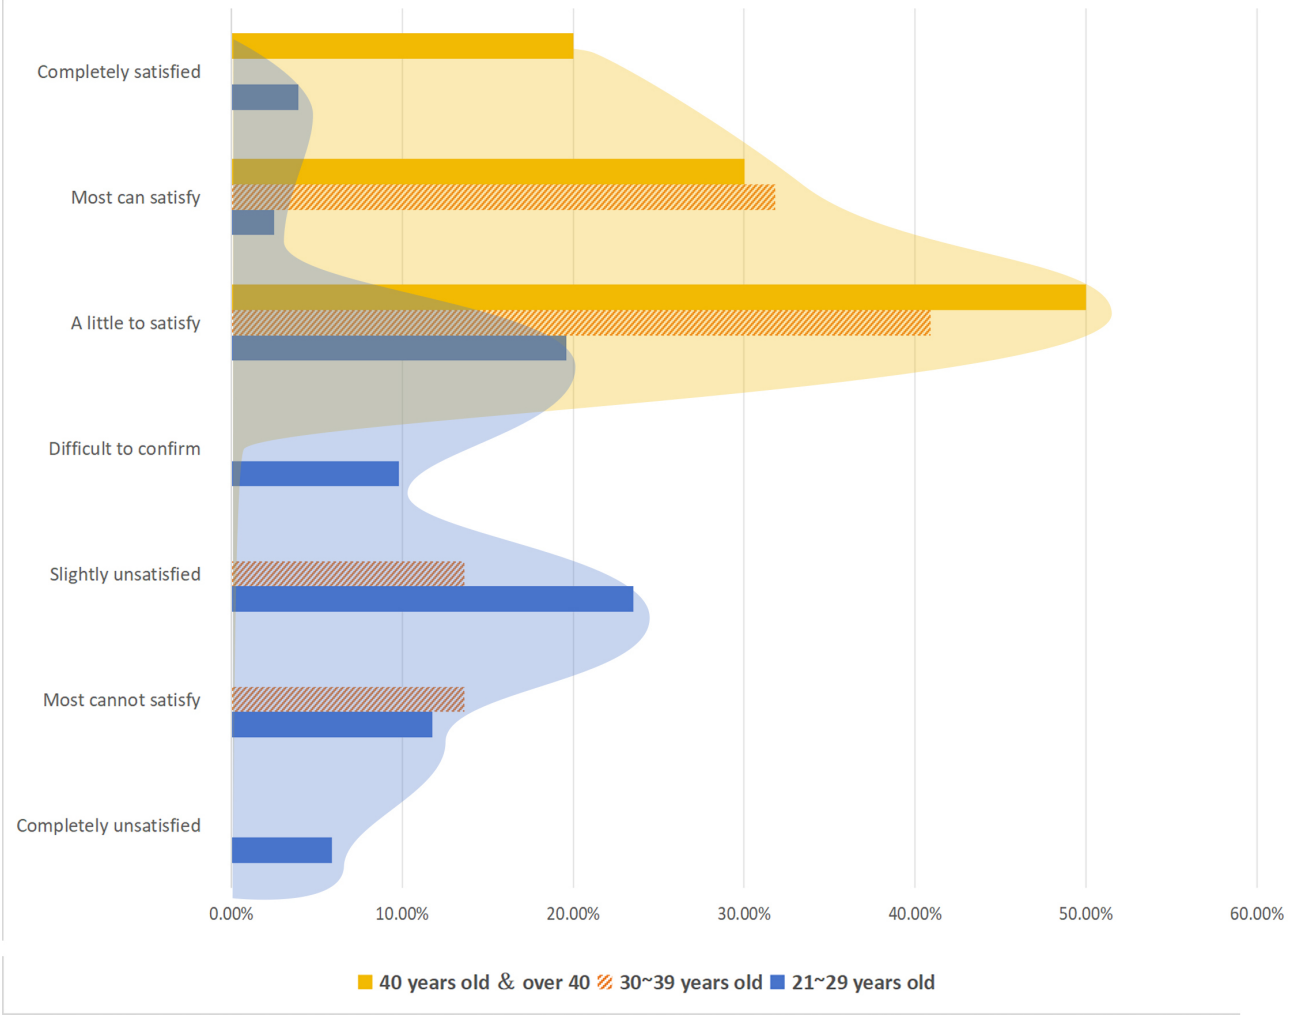


Figure 5. The trend in respondents' answers to the overall difficulty of root canal treatment and the difficulty of each stage is depicted as follows: the solid line (representing the overall difficulty of a randomized controlled trial [RCT]) has a skewness value of 0.701, which is larger than the skewness values of the dashed lines (representing the difficulty of each individual stage).

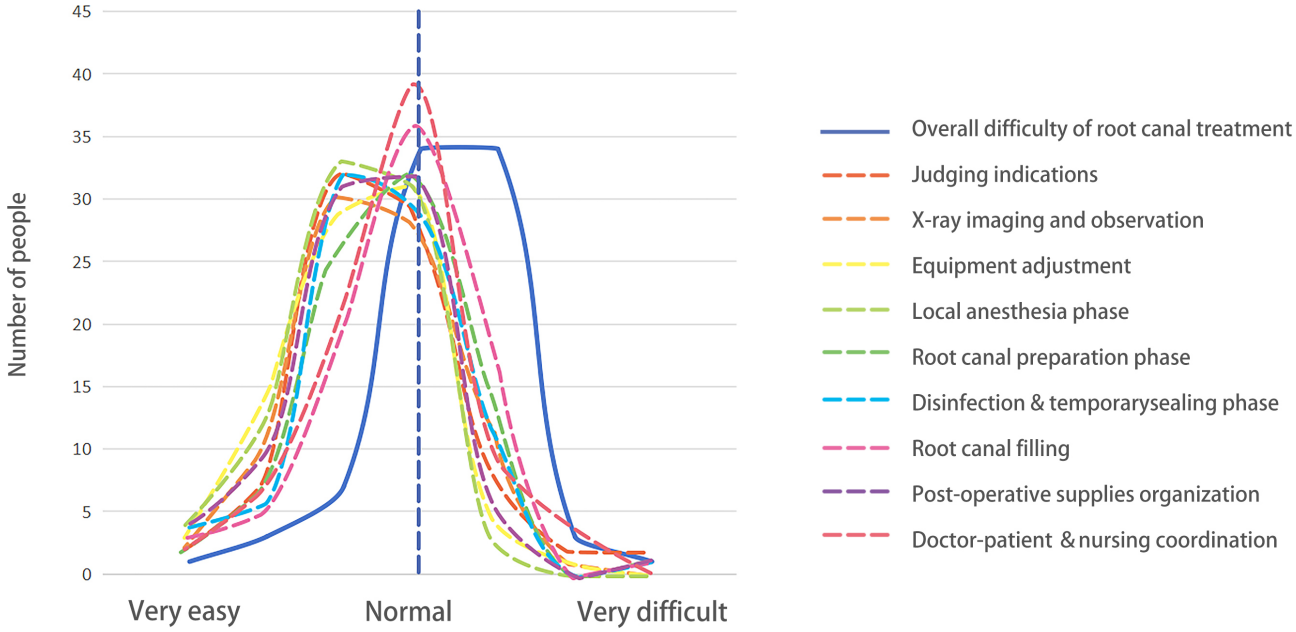

Figure 6. The trend in responses to questions about the variability in certain phases of root canal treatment shows that the skewness values for the Shanghai population samples, from left to right across the 7 graphs (A-G), are 0.385, 0.105, 0.567, 0.323, 0.499, 0.578, and 0.758, respectively. In contrast, the corresponding skewness values for the population samples from other regions are −1.013, −0.339, −0.306, −0.942, −0.383, −0.211, and −0.215.

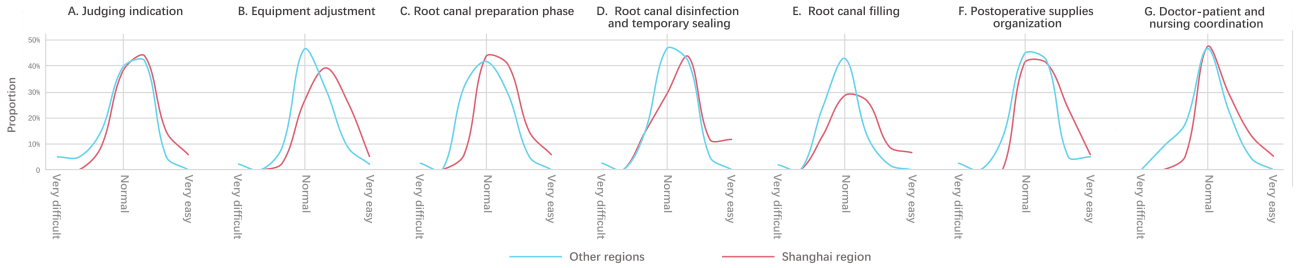

Figure 7. Respondents considered an improved aspect of the school: the red box denotes the 4 aspects of root canal treatment teaching that a significant number of participants suggest should be improved.

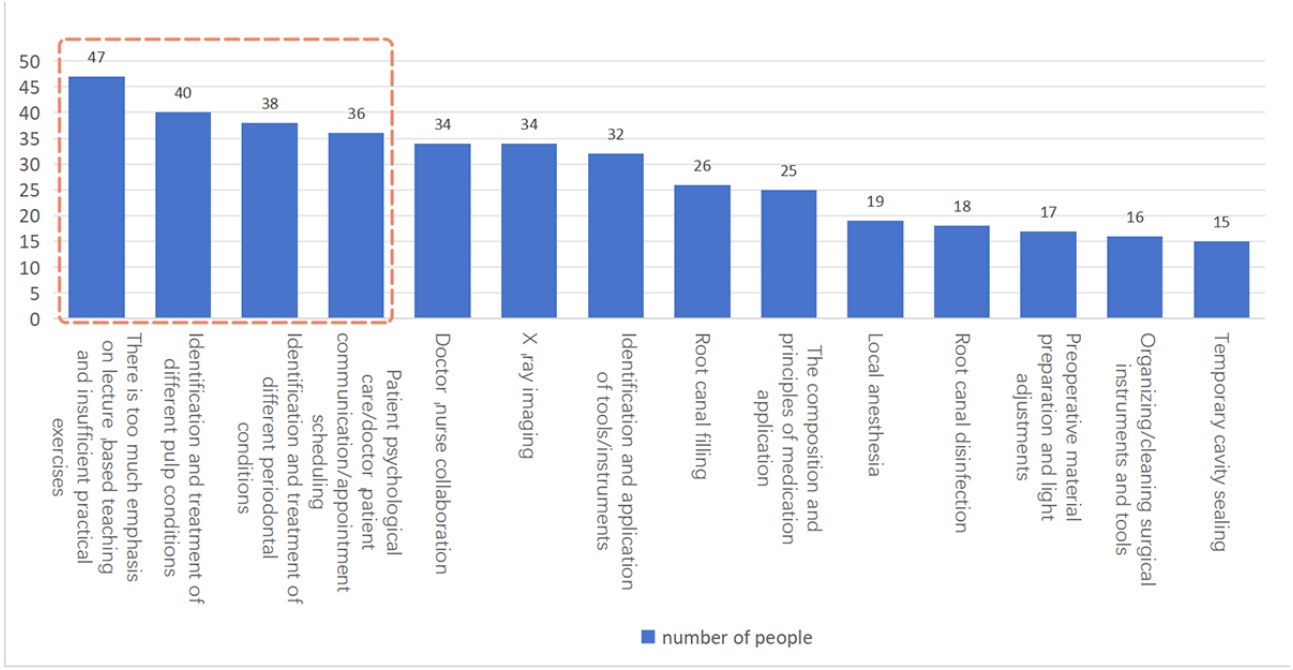

Discussion

Principal Findings

The results of this study revealed multiple factors affecting the satisfaction of root canal therapy teaching in the Southeastern Region of China, including educational background, regional differences, age stratification, and insufficient periodontal disease teaching content. These findings not only reflect the intuitive feedback of clinical medical staff on teaching effectiveness but also provide important references for optimizing dental education.

Education Stratification and Uneven Distribution of Teaching Resources

This study shows that medical staff with a specialized degree evaluate the integration of teaching and clinical practice significantly lower than those with undergraduate and master's degrees. This difference may be closely related to the uneven distribution of teaching resources. In China, most specialized colleges focus their dental courses on basic operation training, while systematic teaching of complex techniques such as root canal therapy is mostly concentrated at the undergraduate level and above. Similar phenomena were also mentioned in the studies of Hua [16] and Jiang et al [17], which pointed out that the number of endodontic class hours in Chinese specialized colleges is only 50% - 60% that of undergraduate colleges, and there is a lack of standardized textbook support. It can be seen that China's specialized education urgently needs to increase the depth of teaching in root canal therapy to narrow the capability gap between different educational groups.

Further analysis showed that the teaching content of specialized education is insufficient for determining the indications of root canal therapy and dealing with complex root canal anatomical shapes, leading to a lack of systematic thinking when graduates face complex clinical cases [16]. It is worth noting that nearly half of China's oral medical practitioners have a specialized background [18,19], and their professional abilities directly affect the quality of primary medical care. However, there is very limited research on specialized dental teaching and professional skills. We searched Google Scholar with "pulpology," "root canal treatment," "teaching," and "students" as core keywords. In the related Chinese literature in the past 6 years (2017 - 2024), only Hua [16] and Jiang et al [17] mentioned the problem of oral education for people with a specialized degree, while 92.3% (24/26) of the studies focused on people with undergraduate degrees and above. This reflects a serious imbalance between educational research and practical needs.

Regional Differences Reflect Inequality in Educational Resources

Respondents in the Shanghai area had a significantly higher level of satisfaction with teaching quality compared with other regions, a result highly correlated with regional disparities in the distribution of oral medical resources. A study on national oral health resource surveys also showed issues of inequality in the distribution of the national oral labor force and institutions [19]. Beijing has the highest proportion of dentists, while Tibet has the lowest [15]. In addition to the differences caused by economics between provinces and cities, there are also differences within cities. For example, although the total number of dental care personnel in Shanghai is relatively adequate, its distribution is unfair, with fewer dental care personnel employed in suburban areas [18]. Furthermore, clinical internship bases in the Shanghai area are mostly top-level hospitals, offering students more opportunities to engage with cutting-edge technologies compared with intern hospitals in other regions.

This disparity essentially reflects the synergistic effect of "education-healthcare" resources. In economically developed regions, clinical needs drive the update of teaching content, forming a virtuous cycle. The application of advanced technology in clinical settings leads to the transformation of teaching cases, which in turn enhances student capabilities. While in less developed areas, limited by equipment and teachers, the teaching content lags behind clinical practice [20], resulting in students facing the dilemma of "not taught in school, but needed in clinical practice."

Age Factor's Influence on the Satisfaction of Root Canal Teaching

This study also found significant differences in the perception of certain skills based on age, such as the discrepancy in the root canal disinfection and temporary sealing operation. As shown in Figure 3, the perception of the difficulty of clinical root canal treatment varies with age. The "40 years old and above" group had a significantly higher level of satisfaction with the integration of teaching and clinical practice than the "21–29 years old" group. The "40 years old and above" group generally had a more positive perception of school teaching, while nearly half of the "21–29 years old" group was not very satisfied with school teaching. The reasons for this diversity could be multifaceted. On one hand, over the past 20 years, there may have been changes in the teaching content and methods related to clinical root canal treatment in China's dental specialty programs. On the other hand, older respondents, due to their longer work experience, may have memory biases about their school teaching and, because of their extensive work experience, may be less sensitive to the perceived difficulty of root canal procedures. In addition, there may be a disconnect between teaching content and clinical practice. Some teaching may not keep pace with clinical changes or emphasize certain operational aspects in school teaching, causing some students to struggle with the clinical practice's complexity. Further investigation is needed to clarify these situations.

Interdisciplinary Impact of the Periodontal Disease Teaching Gap

Nearly half of the respondents called for an increase in teaching on differential diagnosis between periodontal and pulp diseases, exposing the current lack of interdisciplinary integration in the curriculum. In other countries, the issue of periodontal disease teaching is also prominent. In the United States and Europe, there is a problem of poor consistency in periodontal disease teaching [21,22]. The conclusions of these previous surveys align with the conclusions of this study, indicating that periodontal disease teaching is a challenge in both oral education and practice. Periodontal disease courses in Chinese schools

receive the least amount of time [13]. Due to insufficient class hours, students lack proficiency in key skills related to periodontal diseases, leading to a tendency to overlook periodontal factors in clinical operations and increasing treatment risks.

New Media Technology

Despite the widely recognized potential of VR or AR technology in dental education [22], only 3.7% of respondents in this study had exposure to such technology. This situation reveals the slow digital transformation in China's oral education. The reasons for this are two-fold: first, most institutions lack the financial support to purchase VR equipment on a large scale; second, teachers receive inadequate training on the pedagogical suitability of new technologies.

Other Considerations

In terms of difficulty perception, the results of this study reflected an interesting phenomenon, respondents generally believed that the overall difficulty of root canal treatment was higher than the difficulty of each individual step. As shown in Figure 4, this indicates a lack of "holistic thinking" training in teaching. Currently, most institutions adopt a step-by-step teaching approach (such as practicing root canal preparation and obturation separately), but clinical operations require integrated capabilities across multiple dimensions, such as "case assessment, treatment plan design, instrument selection, and emergency management." Students lack awareness of the "cascade effects of operational errors" during their school years (such as strategies for managing perforations caused by excessive root canal preparation). Drawing on experiences from other disciplines, Jiangxi University of Traditional Chinese Medicine has adopted "full-process situational simulation" as a teaching method, effectively improving the effectiveness of clinical skills training. It is recommended that China's dental specialty teaching include "clinical scenario comprehensive training" to train students' decision-making abilities through high-fidelity models and case libraries, narrowing the gap between "item-by-item proficiency" and "overall competence."

Due to the wide age range of the samples in this study, there may be differences in teaching methods across different periods. However, after excluding the older sample population, we found that age does not interfere with the impact of other factors (such as education level, region, etc.) on the satisfaction of root canal treatment teaching. Therefore, it suggests that age is not the primary factor, and the disconnection between root canal treatment teaching and clinical practice still exists to some extent.

Strengths and Limitations

This study adopts the perspective of in-service oral health care workers to retrospectively examine issues in root canal treatment teaching, providing a better understanding of whether school teachings can be effectively applied in clinical practice. The random sampling in this study, without limiting educational background, well reflects the situation and needs of clinical oral health care workers. Moreover, this study uses a Likert 7-point scale, which provides more accurate sensitivity assessments compared with the commonly used 5-point scale.

The main limitation of this study is that the data was primarily collected from the Shanghai area and surrounding cities in the Southeastern part of China, without distinguishing between urban and rural areas, thus preventing further analysis on urban-rural disparities. In addition, due to the limitation of the sample size, the generalizability of the findings from this survey needs to be further improved, necessitating further research to evaluate the effectiveness of school teaching and the details of clinical operations and the difficulty of RCTs.

Conclusions

This cross-sectional investigation systematically identifies structural discrepancies between preclinical RCT education and clinical workflows in China, with experiential, demographic (eg, training backgrounds), and geographic factors significantly modulating educational-clinical alignment. The findings reveal structural disparities in factors such as clinical experience, educational qualifications, and hospital location. These disparities influence clinical treatment plan decisions, potentially leading to overtreatment or inappropriate management, thus exacerbating patient discomfort, extending treatment duration, and increasing treatment burden. Optimizing classroom content (VR or AR, thermal obturation systems, etc) can expedite students' transition to clinical practice and bolster their confidence in the diagnostic and therapeutic process. By correlating clinicians' educational satisfaction metrics with workplace competency demands, this study establishes a novel evaluative framework for dental pedagogy reform, emphasizing competency-based curricula, standardized clinical protocols, and technology-enhanced immersive learning. Subsequent studies can further expand the sample sizes through multicenter sampling across diverse regions to evaluate the changes in academic–clinical consistency.

Acknowledgments

The authors sincerely thank Prof. Zhou Jin and Dr. Hibrising for their unparalleled care and support during the surveys and all dental practitioners who helped us to finish the data collection.

Data Availability

The datasheets of the study are available after communication with the corresponding author.

Authors' Contributions

Abstract

Background: The integration of digital technology in dental education has been recognized for its potential to address the challenges in training removable partial denture (RPD) design. RPD framework design is crucial to long-term success in the treatment of dentition defects, but traditional training methods often fall short of adequately preparing students for real-world applications.

Objective: This study aimed to evaluate the efficacy of a 3D simulation–based preclinical training software for RPDs in enhancing learning outcomes among first-year stomatology master's students, while also assessing user perceptions among students and faculty.

Methods: RTS (Yikchi Siu) is a preclinical training software that simulates the clinical process of treating patients with partial edentulism. In this study, 26 newly enrolled master's degree students in stomatology who volunteered to participate were randomly divided into a control group (n=13) and a training group (n=13). The training group used the RTS for 2 credit hours (90 min) of self-study, while the control group received theoretical lessons and case practice from an instructor. After 2 hours, both groups completed the theoretical knowledge and drawing tests for RPD simultaneously. Test results were evaluated and graded by 2 experts in prosthodontics. Both users and teachers filled out a questionnaire afterward about their training experience.

Results: Participants in the training group obtained better final grades compared to controls (theoretical test: 88.8, SD 2.3; 85.7, SD 3.3, respectively; P=.01; drawing test: 89.8, SD 4.5; 85.1, SD 4.3, respectively; P=.01). The training group had a shorter completion time in the drawing test (12.6, SD 19 min; 17.7, SD 3 min, respectively; P<.001) but there were no significant differences in the completion times in the theoretical test (23.2, SD 2.2 min; 24.9, SD 2.8 min, respectively; P=.14). Students and faculty generally had a favorable opinion of the RTS.

Conclusions: The effectiveness of the RTS for newly enrolled master's degree students in stomatology to understand and apply their knowledge of RPD framework design was validated; the system was well received by both students and faculty members, who reported that it improved the effectiveness and convenience of teaching.

removable partial dentures; preclinical training; simulation; 3D; participatory

Introduction

As life expectancy and the size of the aging population continue to increase, so does the prevalence of patients with partial edentulism [1]. Removable partial dentures (RPDs) are versatile and cost-effective alternatives to fixed and implant restorations, and thus an increasing number of patients are choosing them to restore their dentition [2-4].

In the conventional training paradigm, students predominantly use 2D graphic representations and textual exercises to design RPD frameworks [5]. However, this is very different from how it is done in actual clinical practice [6,7]. In fact, RPD framework design is an ongoing challenge within the context

of prosthodontics training [8]. This is largely attributable to the intricate nature of RPD components and the considerable diversity of design proposals [9,10]. The design process requires the synthesis of theoretical knowledge and clinical practice; that is, a high degree of clinical decision-making ability is necessary [7,11].

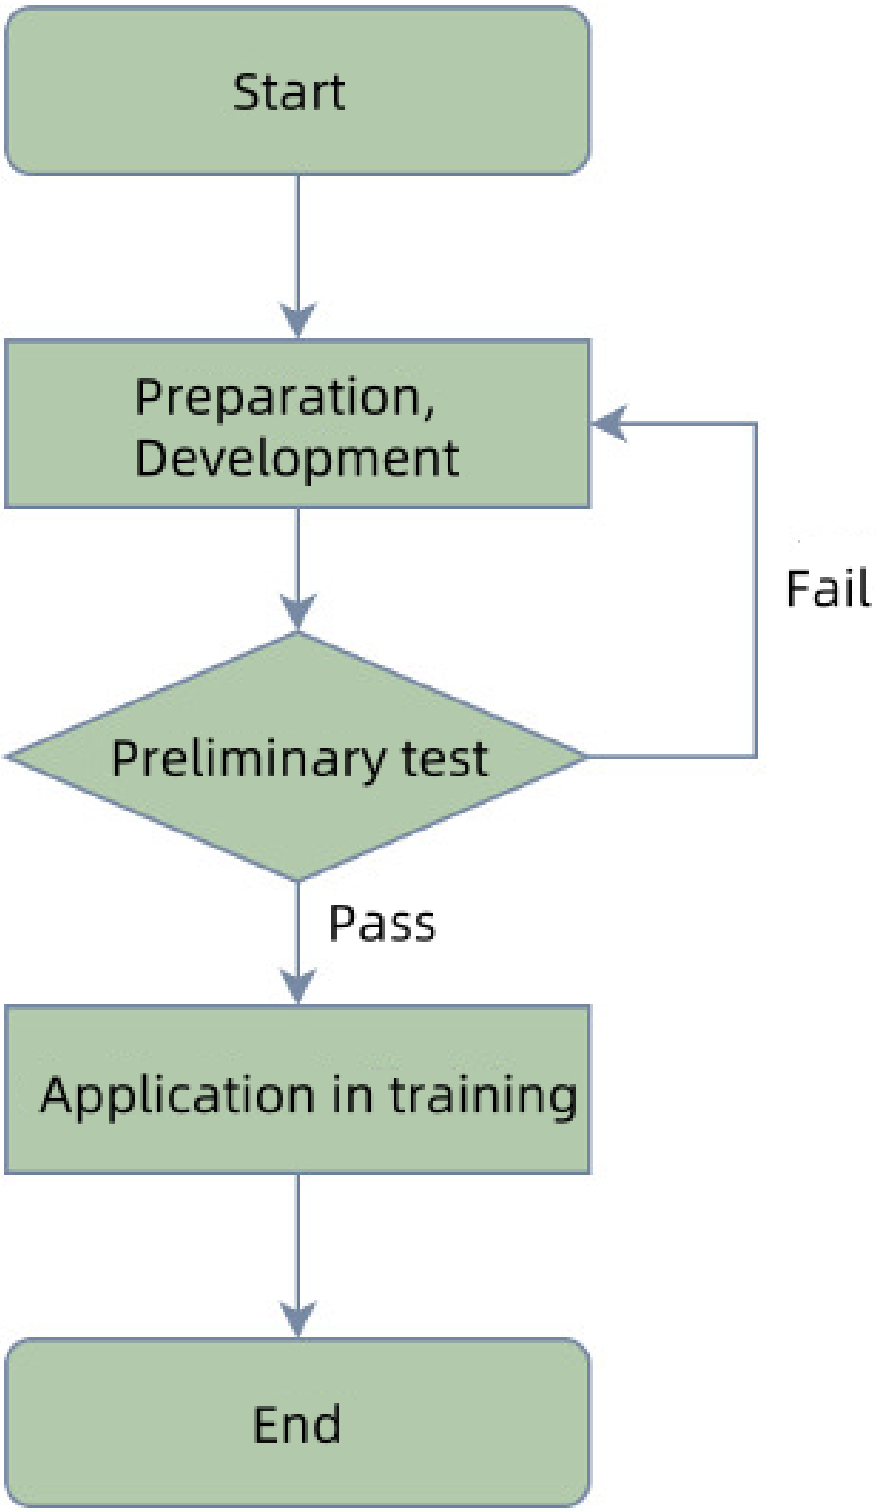
The advent of simulation technology in dentistry has led to immersive training systems including some based on force feedback and mixed reality [12]. However, there is a lack of studies on nonimmersive simulation approaches. In this context, to enhance the efficiency of training in the design of RPD frameworks, the use of training systems that incorporate 3D casts has increasingly been recognized as an innovative and reliable approach [13]. One reason for this is the popularity of digital RPD design software, which enables users to export 3D casts in standard tessellation language format for use in training. The use of such casts facilitates a more comprehensive understanding of the design principles and components of the RPD framework [14-16]. A substantial body of evidence indicates that integrating such systems into teaching curricula can significantly enhance student interest and learning outcomes as well as the efficacy of teaching [5,16,17]. This study describes novel 3D RPD simulation software designed for preclinical training in RPD framework design and provides a preliminary evaluation of its efficacy. We hypothesized that RTS (Yikchi Siu) would improve the test scores of RPD design and reduce completion time compared to traditional training methods.

Methods

RPD Training System

RTS is a participatory training program developed to enhance the RPD design skills of users without preclinical training. We designed and tested it in 3 phases: software preparation and development, preliminary tests, and application in training (Figure 1). During the development phase (August 2023 to July 2024), a prototype was prepared, designed, and developed. In the test phase (August 2024), 5 students (3 master's students and 1 doctoral student) enrolled at the Peking University School of Stomatology were recruited to test the system, and based on the outcomes, a panel of experts was asked to suggest modifications to the RTS; the system was modified accordingly. Finally, in the training phase (September 2024 to October 2024), the RTS was introduced to 26 newly enrolled postgraduate students who had not received preclinical training, and the system was quantitatively and qualitatively assessed by analyzing their test scores and feelings about its use. The study design followed the recommended framework for software development [18] and the criteria for the validation process [19].

Figure 1. Flowchart of RTS development.

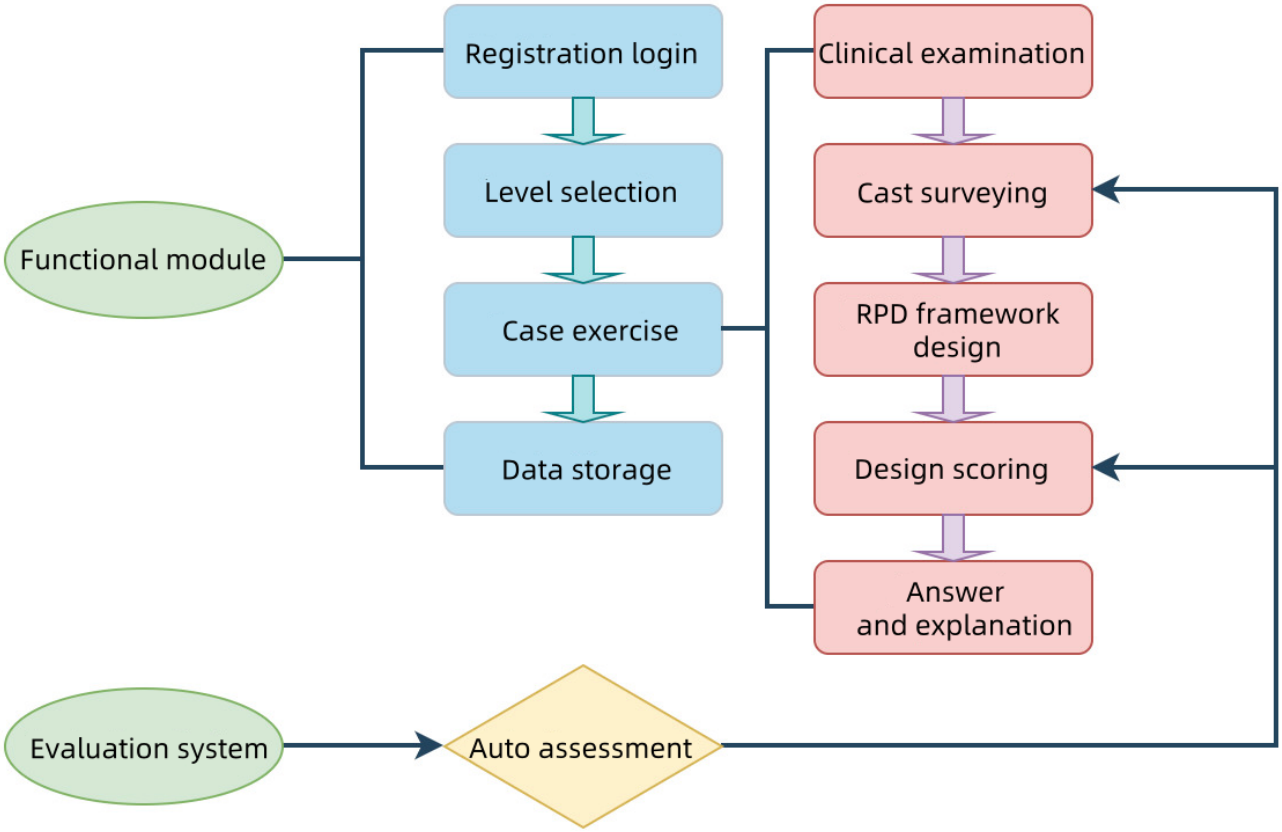


RTS was developed using Visual Studio Code and is a standalone program for Windows 10 (Microsoft Corporation). The software includes 3D digital casts created from clinical plaster casts from 19 dental patients. These cases were carefully selected and prepared by the software developers and then reviewed and approved for relevance and accuracy by 2 prosthodontics experts. The digital casts were created using the 3Shape cast scanner, replicating real-world clinical conditions.

The training content is divided into 5 topics: clinical examination, cast surveying, RPD framework design, design scoring, and answer and explanation (Figure 2). The RTS includes a functional module and an evaluation system. The former facilitates user engagement, and the latter involves assessment, design, and evaluation of user outcomes. The auto assessment component quantitatively assesses user performance, providing a comprehensive educational tool for preclinical dental training. Users view the 3D cast and perform digital surveying with mouse clicks. If the surveying perspective is

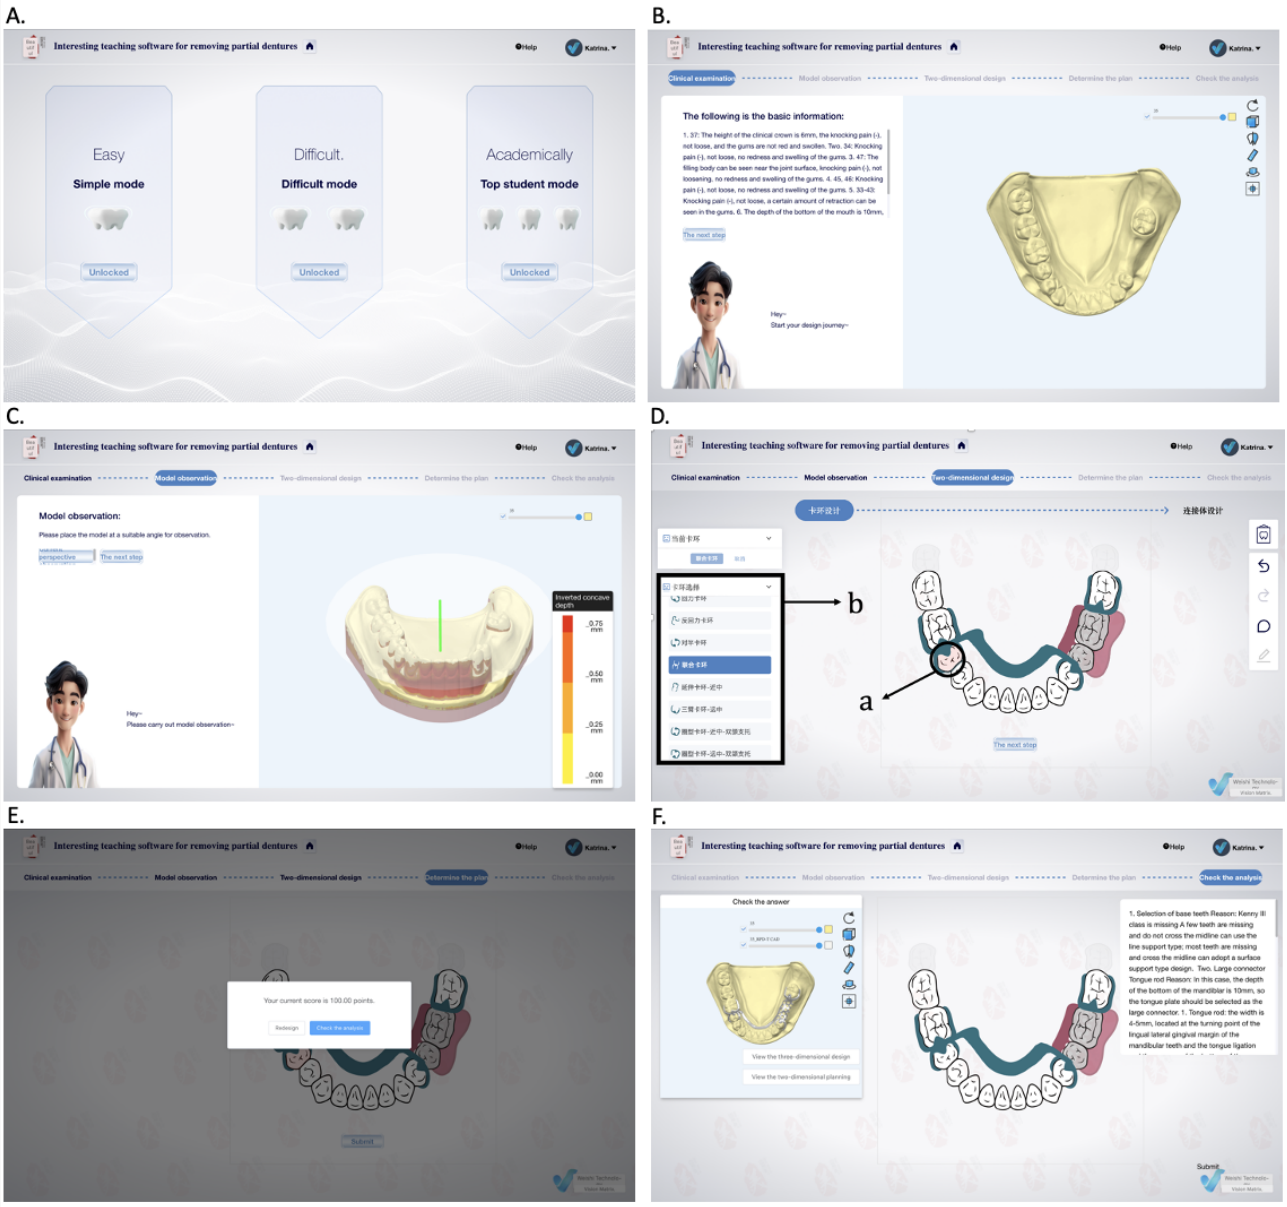
incorrect, an error message appears, and the user cannot proceed with the RPD framework design until the cast is oriented correctly. Once the surveying angle is correct, a confirmation message is displayed. Users then design an RPD framework blueprint based on the clinical examination and cast survey data.

Figure 2. Framework of RTS. RPD: removable partial denture.



After completing the design, users submit it for automatic scoring by the RTS evaluation system, which provides immediate feedback, including a standardized design for comparison. Faculty members can also review and manually grade the designs in the background (Figure 3). Figure 3 shows an example of a Kennedy classification III case exercise. The user logs on to the webpage and selects an available training mode (Figure 3A). Each mode contains 6 to 7 practice cases, all of which must be successfully completed before the next mode will be unlocked. The user clicks and rotates the 3D cast of a dental defect to view it, determine the Kennedy type, and obtain information about the intraoral clinical examination (Figure 3B). Then the user adjusts the appropriate viewing angle to survey the inverted concave area (Figure 3C). Next, the user designs the framework for RPD (a: red indicates the selected tooth as an abutment; b: selection of an appropriate clasp design), including features such as abutment teeth, clasps, rests, and major and minor connectors, to complete the design for the case (Figure 3D). The design is submitted and the system automatically scores it (Figure 3E). A system score of 60 and above will display the standardized design plan and an explanation; otherwise, the case must be designed again (Figure 3F). To start the RPD case practice, users must open the provided URL [20], register, and log in. Then the system automatically saves their practice records.

Figure 3. Screenshots from the RTS.



Application

Sample Size Calculation

A pilot study will be conducted with 5 newly admitted graduate students per group. Sample sizes will be calculated independently for both primary end points (drawing test scores and test time), with the larger of the 2 values being adopted to guarantee adequate power for all outcome assessments. Using pilot data of drawing test time (control group: 17.7, SD 2.7 min; training group: 12.6, SD 1.8 min) with α=.05 (2-tailed) and 80% power, the minimum sample size was 7 per group (total 14). Considering educational intervention complexity, we enrolled 13 per group (total 26).

Quantitative Assessment

For quantitative assessment, 26 newly enrolled graduate students who had not received RPD preclinical training volunteered to assess the system. In addition, the students were recruited and randomly allocated via sealed envelope drawing into 2 groups, the control group (n=13) and the training group (n=13).

Both groups first underwent a preclinical training course for RPDs. The instructor provided an explanation of the functionality of the software to ensure that each participant had the requisite knowledge and proficiency to use it. Then the training group was instructed to use the RTS to learn and practice the RPD framework design independently. By contrast, the graduate students in the control group were required to learn the theoretical aspects of RPD and complete the associated classroom exercises under the guidance of an instructor. During the period, the control group was not permitted to use RTS for learning purposes. At the conclusion of the experiment, both groups were administered a quiz assessing their theoretical knowledge of the RPD framework design and their design ability. The test included 10 clinical cases of dentition defects which were developed by 2 experts in prosthodontics, including 3 cases each of Kennedy Class I and II, and 2 cases each of

Class III and IV. The assessment was conducted by 2 prosthodontic experts using a 100-point grading scale established based on RPD design principles and requirements from textbooks [21,22] and the National Dental Practitioner Training Manual (Table 1). The final scores were calculated as the mean values of the ratings given by 2 independent experts for each student group's assessments.

Table . Removable partial denture design drawing evaluation rubric.

Category (subcriteria)	Maximum score	Remarks
I. Basic design principle (20)		
Fulcrum line design	6	• Consistency with task description
Force distribution	6	• Balanced occlusal loading
Antirotation or sinking measures	4	• Indirect retainers or rests
Lever arm	2	• Minimize cantilever
Stress breaker	2	• If applicable
II. Component design (20)		
Direct retainers	10	• Clasp type selection
Indirect retainers	5	• Position rationality
Major connectors	5	• Type selection
III. Clinical applicability (10)		
Kennedy classification	5	• Correct I-IV
Esthetic considerations	2.5	• Consistency with case description
Functional considerations	2.5	• Consistency with case description
IV. Drawing (50)		
Missing tooth position	20	• Accurate identification and correct marking
Color	10	• Blue metal components and red resin bases
Neatness	10	• Neat and accurate
Component drawing	20	• Component positioning and drawing • Minor connector spacing and drawing • Finish line

Qualitative Assessment

To evaluate the subjective efficacy of the RTS, a questionnaire was administered to students and staff to assess user experiences as well as instructor and student satisfaction with the system (Multimedia Appendix 1). The questionnaire included 10 questions, with respondents indicating their level of satisfaction or agreement with statements ranked on a 5-point Likert item (1=strongly dissatisfied or strongly disagree to 5=strongly satisfied or strongly agree) [12]. The questionnaire includes 6 student-specific questions and 4 teacher-specific questions. An open-ended question was also included to elicit feedback on potential shortcomings.

Statistical Analysis

This study used a combination of descriptive and inferential statistics to evaluate the scores and time spent on theoretical and drawing tests. First, all data were summarized descriptively using means and SD to illustrate the central tendency and dispersion of each group. Normality was assessed using the Shapiro-Wilk test, which was prioritized for its robustness with small sample sizes (n<50). Homogeneity of variance was evaluated via *F* tests to validate the assumptions for subsequent parametric tests. Results confirmed that all 4 datasets met both normality and homoscedasticity assumptions. Independent samples *t* tests were used for 2-group analyses, reporting *t* values, degrees of freedom (*df*), and *P* values. Mann-Whitney *U* tests were concurrently performed to ensure robustness, reporting *U*, *z*, and *P* values. Effect sizes were quantified using Cohen *d* to complement statistical significance. To examine linear agreement between 2 experts' scores, interrater reliability was assessed through Pearson correlation coefficient and intraclass correlation coefficient (ICC) under a 2-way

random-effects absolute agreement model, accounting for both systematic differences and random error between raters. Statistical evaluation was performed using the SPSS analysis program (IBM SPSS Statistics 26.0, IBM Corp). GraphPad PRISM 10.0 software (GraphPad Software) was used to create graphs.

Ethical Considerations

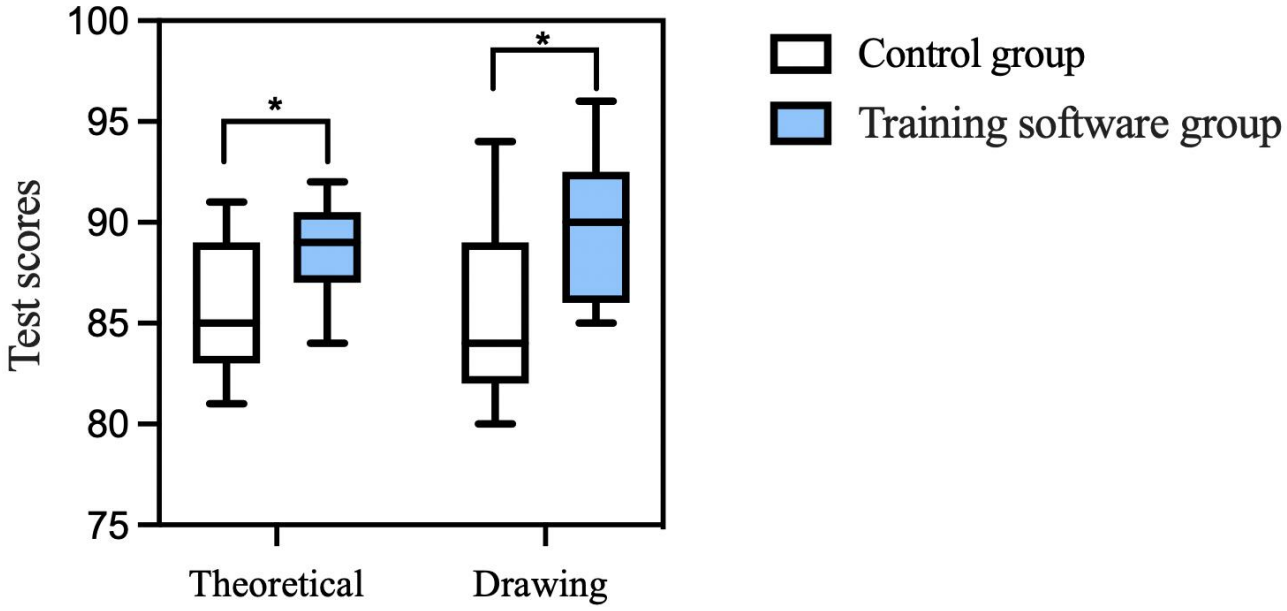
This study was approved by the ethics committee of Peking University School and Hospital of Stomatology (PKUSSIRB-202273003-免). Participants understood the study details and their rights, including their right to withdraw at any point without consequences. Participants' privacy is secured in all written and published data arising from this study. Names of participants or other identifying information are not and will not be used in reports or published papers.

Results

Quantitative Assessment: Test Scores

As shown in Figure 4, the theoretical test score in the training group was 88.8 (SD 2.3), while the drawing test score was 89.8 (SD 4.5). These values were 85.7 (SD 3.3) and 85.1 (SD 4.3), respectively, in the control group. Thus, the training group had significantly better scores for both tests (P=.01). Moreover, the Mann-Whitney U test was further applied for evaluation, and the P value remained less than .05, both groups with a large effect size (Cohen d = 1.1). The nonparametric test confirmed this result on the theoretical test (U=33.0, z=–2.5, P=.01) and the drawing test (U=33.0, z=–2.5, P=.01) (Figure 4). A strong positive correlation was observed between the raters' evaluations (Pearson r=0.70, P<.001; ICC=0.84, 95% CI 0.7-0.9).

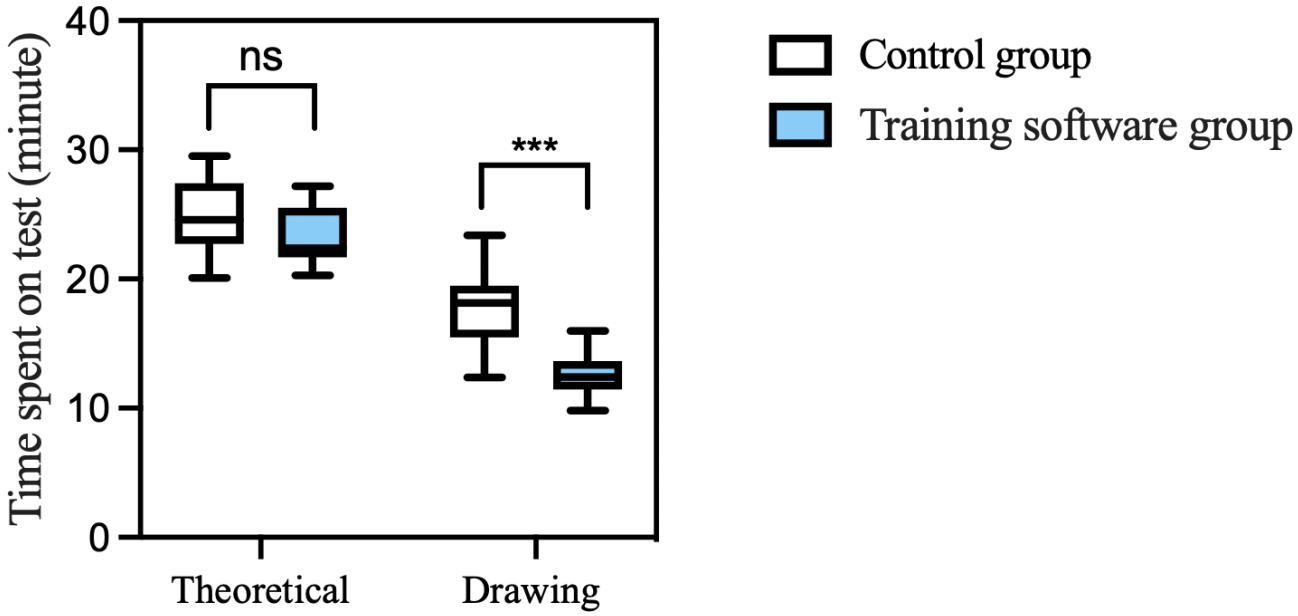
Figure 4. Comparison of test scores between the control and training groups. *P<.05.



Quantitative Assessment: Test Time

As shown in Figure 5, the mean completion times were 23.2 (SD 2.2) minutes in the training group and 24.9 (SD 2.8) minutes in the control group for the theoretical test; they were 12.6 (SD 1.9) minutes and 17.7 (SD 3) minutes for the drawing test, respectively, with a significant difference in the latter test only (P<.001).

Figure 5. Time spent on tests. ***P<.001, ns: not significant.



Response to Questionnaire

As shown in Table 2, users found the RPD framework design to be easier and more accessible when using the RTS. In addition, all users indicated that the program was convenient and straightforward to use. Users indicated a greater preference for the RTS over traditional training methods and expressed great satisfaction with the responsive features. Faculty members also had positive views, reporting that the system significantly reduced preparation time for teaching and improved teaching effectiveness.

Table . Responses of the training group (n=13) to the questionnaire.

Questionnaire item	Very dissatisfied or strongly disagree, n (%), 1 Point	Dissatisfied or disagree, n (%), 2 Points	Neutral, n (%), 3 Points	Satisfied or agree, n (%), 4 Points	Very satisfied or strongly agree, n (%), 5 Points	Mean (SD)
The software program encourages users to practice in designing RPD[a] frameworks.	0 (0)	0 (0)	0 (0)	1 (8)	12 (92)	4.9 (0.3)
The software program is highly responsive and allows for real-time feedback.	0 (0)	0 (0)	0 (0)	2 (15)	11 (85)	4.8 (0.4)
The software program is easy to use.	0 (0)	0 (0)	0 (0)	0 (0)	13 (100)	5 (0)
The software program effectively helps users to learn and practice RPD design, enhancing decision-making and critical skills.	0 (0)	0 (0)	1 (8)	1 (8)	11 (85)	4.8 (0.6)
The software program allows users to learn more about surveying 3D casts and digitally drawing designs.	0 (0)	0 (0)	0 (0)	0 (0)	13 (100)	5 (0)
I would like to use the RTS for skills training in the future.	0 (0)	0 (0)	1 (8)	3 (23)	9 (69)	4.6 (0.6)

[a]RPD: removable partial denture.

Discussion

Principal Findings

Based on the above experiments, it can be concluded that the RTS significantly improved both theoretical and drawing test scores related to RPD design among newly enrolled graduate students. Moreover, the system substantially reduced the time required for students to complete RPD design drawings. The positive feedback from both students and faculty members further suggests that RTS shows great promise as a preclinical training software for RPD design.

With the accelerated development of digital technology and the emergence of new educational models, online responsive training methods are playing an increasingly pivotal role in the field of medical education [23-25]. Such methods have notable benefits in terms of reduced teaching costs, providing an immersive experience, enabling resource sharing, and offering personalized learning and feedback, to name a few [26,27]. In the field of dental education, RPD design is a key ongoing challenge and area of focus. Students frequently have difficulty grasping the concepts related to RPD components and lack access to case-based instruction [5,28]. This is due to the inherent limitations of traditional teaching methods, which often lack the necessary casts and RPD frameworks needed for effective preclinical training, as well as the inability to practice on clinical cases [16,29,30]. The AiDental system was previously designed to teach RPD design, and has demonstrated effective teaching outcomes for RPD design instruction in dental education. However, Mahrous et al [31] have revealed 2 persistent limitations in the study: a suboptimal user interface design that may reduce learner engagement and insufficient analytical feedback on student performance. The design of Musawi et al [32] contains a specific clinical RPD process but uses 2D graphics, which lack a sense of immersion and interactivity. The RTS overcomes these limitations.

Using RTS, students can treat dentition defects and design RPD frameworks in a simulated clinical setting. The absence of a surveyor or plaster casts during the surveying and design processes ensures that the training content is more closely aligned with the clinical environment, thereby creating a more realistic training experience. This approach allows the trainer to integrate theoretical knowledge with clinical practice effectively, facilitating a smoother transition from theory to practice.

Regarding its efficacy, the training group achieved better results than did controls in both the theory and drawing tests. This means that the program helped users to understand and master RPD design theory better, increasing the design speed. This

may be because the program allows users to create personalized study plans based on their individual learning abilities and mastery levels, which significantly improves learning efficiency.

There were no statistically significant differences in the times taken by the 2 groups to perform the theory test, while the training group spent significantly less time completing the drawing test. This indicates that the program facilitated a more comprehensive understanding, making students more proficient in RPD design. The immediate feedback on, and comprehensive analysis of, incorrect responses provides a rapid-response mechanism for challenging content, enabling users to identify knowledge gaps accurately in a time-efficient manner. Moreover, the case practice and personalized guidance module of the program facilitates one-on-one training for students, in contrast with the traditional classroom setting.

Finally, both students and teachers viewed the software program positively. Students gave high ratings for user-friendliness, indicating that it allowed them to grasp essential functions quickly. They expressed a high level of interest in the RTS and perceived it to be more engaging and participatory than conventional paper-based RPD design. In addition, users were more inclined to dedicate time to the RTS to gain insight into RPD design. In fact, all of the users (n=13) indicated that the program allowed them to learn how to survey casts digitally, which is particularly beneficial in the context of the increasing use of CAD (Computer-Aided Design) software and 3D casting. Furthermore, users indicated a desire to do more digital training over traditional training in the future.

Teachers reported that the system notably reduced the time required for lesson planning. Instructor preparation time decreased from 90 minutes (traditional methods) to 45 minutes using RTS. They also felt that it made teaching easier and resulted in improved outcomes. Finally, they indicated a willingness to integrate such systems into future lesson plans as a potential option for self-study and after-school practice with students.

While the current system demonstrates promising educational outcomes, several refinements could further enhance its efficacy. Incorporating advanced haptic feedback technology could improve students' understanding of RPD biomechanics by simulating real-world force distribution during clasp design and framework adaptation. Recent studies have shown that force-feedback systems significantly enhance skill acquisition in preclinical dental training, particularly in prosthodontic procedures requiring precise tactile sensitivity [33,34]. In addition, integrating augmented reality for surveying and undercut analysis could bridge the gap between simulation and clinical application, as augmented reality has proven effective in improving spatial awareness in dental education [35]. To maximize impact, future iterations should explore embedding this tool into official dental curricula as a standardized preclinical training module. Structured integration, as seen with successful simulation platforms in medical education [23], would facilitate widespread adoption. Multi-institutional collaborations could also validate their scalability, similar to the collaborative frameworks used in the Association for Dental Education in Europe guidelines for simulation-based training [36]. By addressing these refinements and curricular integration pathways, the system has the potential to become a benchmark for RPD education.

Limitations and Future Work

The limitations of this study include the relatively small sample size, the recruitment of participants from a single school, and the absence of a randomization process. In addition, there may have been unidentified differences in the intrinsic and current learning abilities of the students. To enhance the rigor and reliability of the study, a randomization process could be used to balance the groups and mitigate the impact of confounding variables, thereby yielding higher-quality evidence. There is a paucity of data on the efficacy of such training modules for dental students. Consequently, future studies should collect more data to validate the long-term effectiveness and clinical transferability of these methods in real-world preclinical training settings, thereby facilitating their broader adoption [37,38]. Due to the inability to perform real-time adjustments for nonstandard anatomical structures, the model surveying function in RTS demonstrates poorer adaptability for complex cases. Manual operation with traditional surveyors enhances spatial awareness and biomechanical understanding, which digital tools may not fully replicate. So, it is important to note that the surveying function in the RTS cannot replace the use of an actual physical surveyor for preclinical training. This feature is designed solely to provide students with preliminary practice in understanding model survey angles. Comprehensive mastery of model surveying techniques still requires training with a physical surveyor.

Simulation can be an indispensable tool for training students so that they develop the necessary skills for authentic real-world scenarios. Our results show that the RTS effectively enhances the efficacy of RPD design instruction. It offers a flexible training module that can be adapted to evolving trends in dental education.

Conclusions

The novel RTS effectively improves the teaching and practice of RPD design. This study has described the system and offered a preliminary validation of its effectiveness. The system was viewed positively by both students and teaching staff. It enhanced the design competence of students not previously exposed to standardized preservice training in prosthodontics. It also made teaching easier and led to better teaching and learning outcomes. Thus, it can be considered an effective tool for teaching and learning RPD design.

Abstract

Background: Traditional laboratory teaching of pathogenic cocci faces challenges in biosafety and standardization across medical specialties. While virtual simulation shows promise, evidence from large-scale, multidisciplinary studies remains limited.

Objective: The study aims to evaluate the effectiveness of integrating virtual simulation with traditional laboratory practice in enhancing medical microbiology education, focusing on the identification of biosafety level 2 pathogenic cocci. The study assessed improvements in student performance, theoretical understanding, laboratory safety, and overall satisfaction, while achieving standardization and cost reduction across multiple medical specialties.

Methods: This randomized controlled trial involved 1282 medical students from 9 specialties. The experimental group (n=653) received virtual simulation training—featuring interactivity and intelligent feedback—prior to traditional laboratory practice, while the control group (n=629) did not receive such training. Our virtual system focused on biosafety level 2 pathogenic cocci identification with dynamic specimen generation.

Results: The experimental group showed significantly improved performance across specialties (P<.05 for each specialty), particularly in clinical medicine, in which the experimental group score was 89.88 (SD 13.09) and the control group score was 68.34 (SD 17.23; P<.001). The students reported that virtual simulation enhanced their theoretical understanding (1268/1282, 98.9%) and laboratory safety (1164/1282, 90.8%) while helping them achieve standardization (790/1282, 61.6%,) and cost reduction (957/1282, 74.6%). Overall student satisfaction reached 97.2% (1246/1282), with distinct learning patterns observed across specialties. The test scores were significantly higher in the experimental group, with a mean of 80.82 (SD 17.10), compared to the control group, with a mean of 67.45 (SD 16.81).

Conclusions: This large-scale study demonstrates that integrating virtual simulation with traditional methods effectively enhances medical microbiology education, providing a standardized, safe, and cost-effective approach for teaching high-risk pathogenic experiments.

KEYWORDS

medical education; virtual simulation; pathogenic cocci; blended learning; multispecialty evaluation; laboratory safety; cost-effectiveness

Introduction

Pathogenic cocci remain significant pathogens in clinical practice, and experiments that include these microorganisms are crucial for medical education [1-3]. The increasing prevalence of antibiotic resistance and the inherent biosafety risks associated with handling pathogenic microorganisms present substantial challenges in educational settings [4-6]. Traditional laboratory teaching, while essential, faces limitations in ensuring consistent safety standards and providing standardized learning experiences across diverse medical specialties. Virtual simulation technology has emerged as a transformative tool in medical education [7-10]. In microbiology

education specifically, this technology offers unique advantages in visualizing microscopic processes and safely simulating high-risk procedures [11,12]. Recent studies have demonstrated its potential in enhancing spatial understanding and mastery of physiological concepts [13-15]. However, most existing research has focused on single-specialty applications or small-scale implementations, leaving a significant knowledge gap regarding the effectiveness of virtual simulations across multiple medical disciplines [16-18]. To address these challenges, our teaching team developed a comprehensive system called Virtual Simulation Experiment for Pathogenic Cocci in Pus Specimens. This innovative system aims to revolutionize teaching on the subject of pathogenic cocci through 3 key features: dynamic specimen generation, integrated biosafety level 2 (BSL-2) safety protocols, and real-time performance tracking.

This study addresses critical questions in medical laboratory education. Specifically, this study aims to evaluate the effectiveness of virtual simulation across 9 medical specialties, representing one of the largest multidisciplinary investigations in this field. We seek to assess the impact on learning outcomes, safety enhancement, and cost-effectiveness in teaching related to pathogenic cocci experiments, while analyzing specialty-specific learning patterns and their implications for customizing virtual simulation approaches. By addressing these objectives, this research provides comprehensive insights into the integration of virtual simulation in medical microbiology education.

Methods

Virtual Simulation System

Experimental Content

Based on Kern's 6-step curriculum development model [19], for the pathogenic cocci virtual simulation teaching system constructed for this study, we first identified core issues through teaching evaluation. We specifically identified a lack of standardization in BSL-2 pathogen handling and inadequacies in cocci identification skills (ie, problem identification). By analyzing biosafety standards and the needs of the teaching faculty, we established a hierarchical competency framework covering Gram staining, culture isolation, biochemical testing, and integrated diagnosis (ie, needs assessment). The system content strictly aligned with 3 key teaching objectives: the basic modules included standardized operating procedures compliant with aseptic techniques (objective formulation); the intermediate modules integrated a dynamic specimen generation system to enable diversified training (educational strategies); and the advanced modules incorporated an embedded assessment system to monitor diagnostic decision-making capabilities in real time (implementation and evaluation). All experimental procedures are embedded with BSL-2 protection protocols, and the precision of the virtual simulation meets the operational standards of BSL-2 laboratories (quality control during implementation).

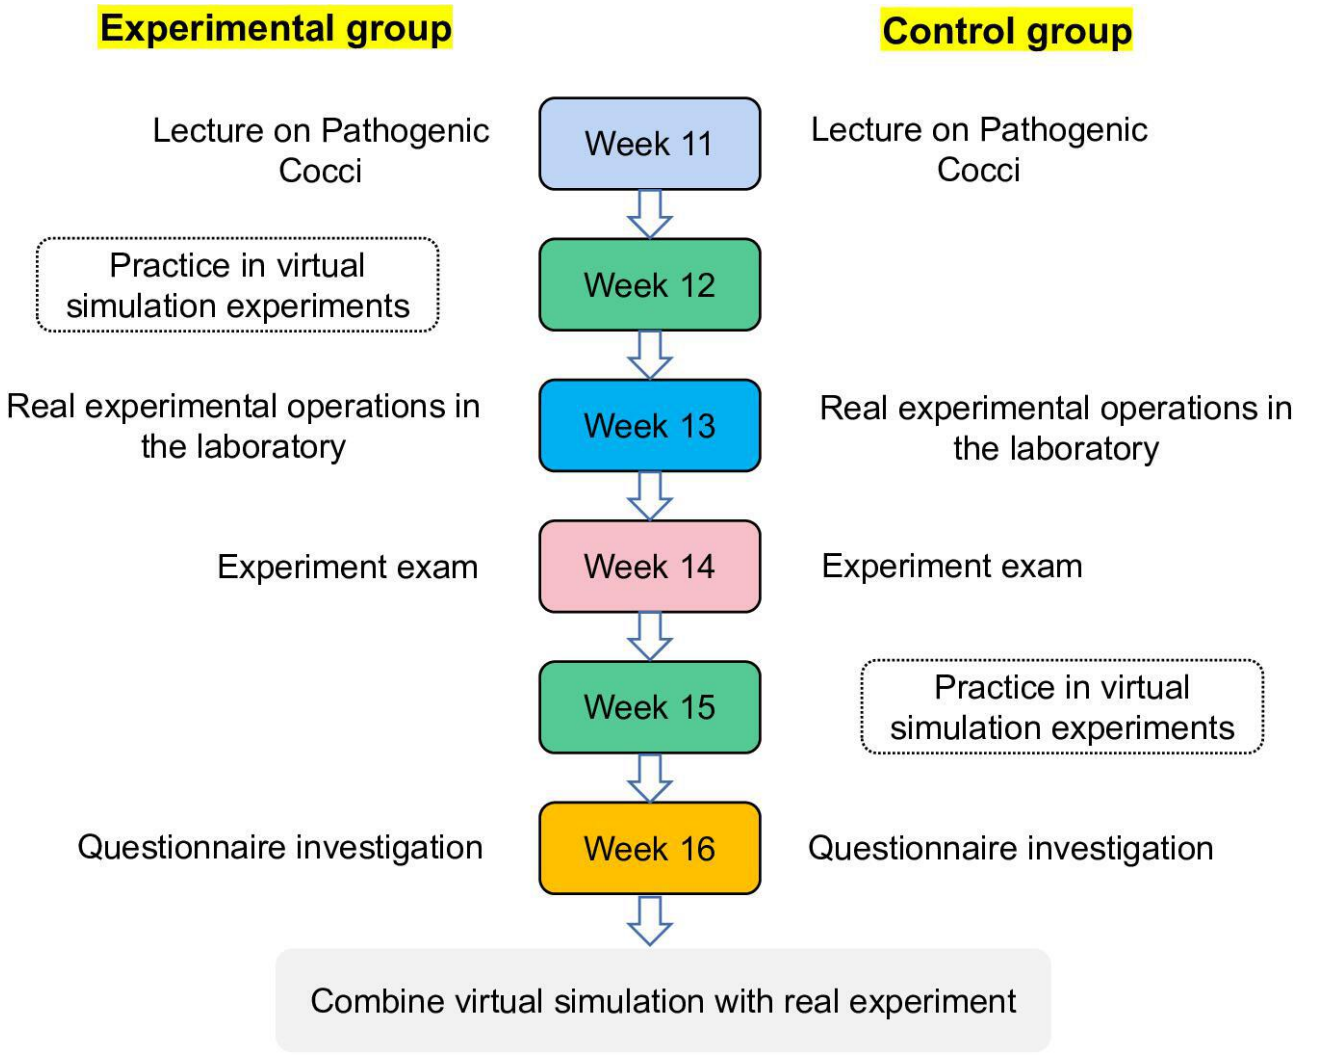
System Features

The design of this virtual simulation platform fully embodies the closed-loop concept of the Kern model: interactive virtual microscopy technology addresses the pain point of limited specimen types in traditional teaching (problem orientation); the real-time operation feedback system corresponds to the error-correction needs in the hierarchical teaching objectives (objective alignment); and the automated assessment module not only enables immediate evaluation of operational accuracy (formative assessment) but also generates personalized learning curves, providing data support for continuous curriculum improvement (summative assessment). Compared with traditional experimental methods, the platform, through intelligent error-correction guidance and a virtual consumables system (optimization of educational strategies), ensures full coverage of operational standards (needs response) while reducing teaching costs (verification of implementation effectiveness), thus completely realizing a closed-loop curriculum development process from problem identification to effect evaluation.

Study Design and Implementation

This study used a randomized controlled trial design with a mixed methods evaluation spanning from September 2023 to January 2024. A total of 1282 medical students from 9 specialties (clinical medicine, traditional Chinese medicine, pediatrics, nursing, medical imaging, preventive medicine, clinical pharmacy, acupuncture, moxibustion, and traditional Chinese pharmacy) participated in the study, with equal, random assignment to experimental (n=653) and control (n=629) groups. The teaching implementation followed a systematic schedule across 6 weeks (detailed in Figure 1), integrating theoretical lectures, virtual simulation exercises, practical laboratory sessions, and comprehensive assessments of both groups. This design enabled direct comparison of learning effectiveness between traditional and virtual simulation–enhanced teaching approaches.

Figure 1. Course schedule.



Teaching Process

The implementation of this teaching system integrated both virtual simulation and traditional laboratory approaches. The teaching process followed a systematic structure comprising preclass preparation, in-class activities, and postclass assessment. All participating students received standardized learning materials and safety protocols, with the experimental group using the virtual simulation platform under instructor guidance while the control group followed traditional laboratory teaching methods. Both groups engaged in comprehensive learning activities designed to achieve the specified learning objectives, with emphasis on laboratory safety awareness and standardized experimental procedures.

Data Collection

A comprehensive evaluation framework was established to assess the effectiveness of the teaching system. The assessment strategy incorporated 3 primary components: performance assessment through standardized practical tests, learning experience evaluation via structured questionnaires, and comparative cost analysis of resource use. Key evaluation indicators encompassed experimental operation proficiency, theoretical knowledge mastery, student satisfaction levels, teaching resource efficiency, and safety protocol compliance. This multidimensional assessment approach enabled thorough evaluation of both learning outcomes and teaching effectiveness.

Statistical Analysis

The collected data underwent rigorous statistical analysis using SPSS (version 25.0; SPSS Inc). Statistical methods included independent 2-tailed *t* tests for comparing group differences in continuous variables and χ^2 tests for analyzing categorical data. All statistical analyses were conducted with a significance level set at $P<.05$. This analytical approach ensured robust evaluation of the teaching system's effectiveness while maintaining scientific rigor in data interpretation.

Ethical Considerations

This study was approved by the ethics committee of Chongqing Medical University (approval number 2023027). The study was conducted in accordance with local legislation and institutional requirements. We obtained informed consent from participants through an online questionnaire system. Participants were provided with a research information statement detailing the study's purpose, participation requirements, potential risks and benefits, data protection measures, and a declaration that participation was voluntary. Participants were required to confirm they had read and understood this information and agreed to participate before being included in the study. No

financial or material compensation was provided to participants. All data were fully anonymized prior to analysis.

Results

Virtual Laboratory System Development

The developed virtual laboratory system (Multimedia Appendix 1) successfully integrated 3 core modules: knowledge review, a learning module, and an assessment module. The experimental procedure flow (Multimedia Appendix 2) was effectively translated into the virtual environment. The 3-module design received high approval from 1214 of 1282 (94.7%) participants across all medical specialties (Multimedia Appendix 3). Figure 2 shows the CONSORT (Consolidated Standards of Reporting Trials) diagram of participation flow.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flow chart of participation.

Learning Performance Analysis

Comparative analysis revealed significant differences in test scores between the experimental and control groups (Table 1). The experimental group demonstrated higher performance across multiple medical fields, with particularly notable improvements in clinical medicine, nursing, traditional Chinese pharmacology, and the science of acupuncture and moxibustion (overall $P<.001$).

Table . Experiment test scores of students from different majors.

Subject	Control group score, mean (SD)	Experiment group score, mean (SD)	*P* value
Clinical medicine	68.34 (17.23)	89.88 (13.09)	<.001
Traditional Chinese medicine	60.54 (17.01)	67.97 (13.14)	.02
Pediatrics	76.29 (18.83)	84.84 (15.26)	.003
Nursing	64.25 (12.56)	73.11 (16.82)	<.001
Medical imaging	70.39 (19.39)	79.94 (18.50)	.01
Preventive medicine	68.83 (15.13)	78.56 (17.72)	.01
Clinical pharmacy	69.41 (21.12)	86.53 (16.05)	.003
Science of acupuncture and moxibustion	60.11 (11.32)	71.47 (15.66)	<.001
Traditional Chinese pharmacology	65.33 (11.28)	82.96 (14.16)	<.001
Overall	67.45 (16.81)	80.82 (17.10)	<.001

System Advantages Analysis

Student perception analysis (Table 2) highlighted key advantages of the virtual system: 90.8% of students reported enhanced safety, 79.6% appreciated the unlimited repetition capability, and 74.6% mentioned cost reduction. The standardized experimental conditions (61.6%) and personalized teaching features (50.6%) also received positive recognition.

Table . Distribution of responses among medical students (n=1282) on key advantages of virtual simulation experiments.

Option	Responses, n (%)
Enhanced safety	1164 (90.8)
Standardized experimental conditions	790 (61.6)
Lower costs	957 (74.6)
Unlimited repetition	1020 (79.6)
Simulating abnormal situations	701 (54.7)
Personalized teaching	649 (50.6)
Intelligent assessment system	607 (47.3)

Interface Design and Implementation

The interface design evaluation (Multimedia Appendix 4) showed that 658 of 1282 (51.3%) students found it well designed and clear. Regarding difficulty levels (Multimedia Appendix 5), 1168 (91.1%) students found the experiment appropriately challenging, and 1156 (90.2%) students reported that the first-person perspective enhanced their learning experience (Table 3), with the 3-module design receiving high approval (Multimedia Appendix 3).

Table . First-person perspective: impact on biosafety level 2 lab experience and understanding of microbial techniques among medical students (n=1282).

Medical specialty	Significantly enhanced, n (%)	Little impact, n (%)	Uncertain, n (%)
Total	1156 (90.2)	62 (4.8)	64 (5.0)
Clinical medicine	340 (87.9)	21 (5.4)	26 (6.7)
Traditional Chinese medicine	89 (88.1)	8 (7.9)	4 (4.0)
Pediatrics	136 (90.1)	7 (4.6)	8 (5.3)
Nursing	243 (93.1)	10 (3.8)	8 (3.1)
Medical imaging	98 (89.9)	5 (4.6)	6 (5.5)
Preventive medicine	70 (93.3)	3 (4.0)	2 (2.7)
Clinical pharmacy	47 (88.7)	2 (3.8)	4 (7.5)
Science of acupuncture and moxibustion	92 (92.9)	2 (2.0)	5 (5.1)
Traditional Chinese pharmacology	41 (89.1)	4 (8.7)	1 (2.2)

Learning Outcomes and Satisfaction

The results showed that 1268 of 1282 (98.9%) students reported improved comprehension (Table 4). Student acceptance data (Table 5) indicated that 1145 (89.3%) were willing to adopt virtual simulation as a supplementary learning tool. Overall satisfaction (Table 6) reached 97.2%, with 39.6% being “very satisfied” and 57.6% “generally satisfied.”

Table . Enhancement of knowledge and understanding through virtual simulation experiments among medical students (n=1282).

Medical specialty	Significantly deepened understanding, n (%)	Somewhat helpful, n (%)	Little to no help, n (%)
Total	383 (29.9)	885 (69.0)	14 (1.1)
Clinical medicine	109 (28.2)	269 (69.5)	9 (2.3)
Traditional Chinese medicine	26 (25.7)	75 (74.3)	0 (0.0)
Pediatrics	47 (31.1)	103 (68.2)	1 (0.7)
Nursing	78 (29.9)	183 (70.1)	0 (0.0)
Medical imaging	32 (29.4)	77 (70.6)	0 (0.0)
Preventive medicine	21 (28.0)	54 (72.0)	0 (0.0)
Clinical pharmacy	21 (39.6)	30 (56.6)	2 (3.8)
Science of acupuncture and moxibustion	37 (37.4)	60 (60.6)	2 (2.0)
Traditional Chinese pharmacology	12 (26.1)	34 (73.9)	0 (0.0)

Table . Survey on willingness to use virtual simulation experiments as a supplement to pathogenic biology experiments among medical students (n=1282).

Medical specialty	Willing, n (%)	Unwilling, n (%)	Indifferent, n (%)
Total	1145 (89.3)	73 (5.7)	64 (5.0)
Clinical medicine	341 (88.1)	26 (6.7)	20 (5.2)
Traditional Chinese medicine	87 (86.1)	10 (9.9)	4 (4.0)

Discussion

Principal Findings

Virtual simulation technology offers innovative and effective solutions for teaching related to laboratory experiments [20-23]. Our program was developed to address a critical training gap identified in institutional needs assessments: over 80% of students sought enhanced training in pathogenic bacteria, yet 90% of faculty opposed live cocci experiments due to biosafety concerns.

The 3-module design (the knowledge review, learning module, and assessment module) successfully reconciled this “must-learn vs cannot-do” paradox, achieving 94.7% student approval. This structure aligns with cognitive learning theory [20] while specifically addressing the staged requirements of microbiology experiments [21]. Quantitative assessments confirmed significant improvements across specialties (P<.05), including a 98.9% enhancement in theoretical understanding and 90.8% increase in safety awareness—effectively overcoming key limitations of traditional teaching through (1) standardized experimental procedures, (2) 60% cost reduction over 5 years, and (3) integrated BSL-2 safety training.

These findings are corroborated by prior research [11,24-26], particularly regarding virtual laboratories’ advantages in safety and accessibility. The program’s cost-effectiveness and scalability (serving large student populations with easy updates) will allow the further optimization of teaching models [7-9] and expansion of remote education possibilities.

Nevertheless, real experiments retain irreplaceable advantages in cultivating practical operational skills and sensory experiences [27]. Feedback from 1.1% of students indicating limited assistance from virtual experiments highlights the persistent limitations in substituting for hands-on operations in real environments [4-6]. Consequently, virtual simulation experiments and real experiments each possess distinct advantages [13-15,28]. The optimal teaching strategy should therefore involve an organic integration of both approaches [16-18,29].

Based on tracking student feedback, we identified the main issues with the virtual experiment system as lag, lack of speed adjustment options, poor learning module integration, incomplete results analysis, and inadequate error simulation compared to real experiments. To address these problems, we developed a series of optimization strategies. First, server performance should be enhanced and the program’s code should be optimized to resolve lag issues. Second, the introduction of an intelligent time management system would allow students to adjust the experiment’s progress. In terms of instructional design, the learning modules could be improved by increasing interactive guidance and feedback. Simultaneously, incorporating data visualization tools would strengthen results analysis, and refining the simulation fidelity would allow it to better reflect real experimental conditions. Additionally, we designed a multidimensional evaluation system to continuously collect and analyze student feedback for iterative system optimization. Lastly, it is important to strengthen teacher training, which is crucial for guiding student learning through virtual experiments. Through comprehensive implementation of these strategies [30], we expect to significantly enhance the technical implementation, instructional design, and learning experience of virtual experiments, thereby substantially improving their educational effectiveness.

To ensure analytical rigor, this study used a complete case analysis method, including only data from students who completed both tests and questionnaires. While this approach enhanced data quality and analytical consistency, it also reduced the effective sample size, potentially limiting the generalizability of the results. Future research might consider advanced techniques such as multiple imputation to handle missing data and extending the scope of the study to different educational levels to enhance its representativeness. Subsequent studies should adopt a mixed methods approach, integrating quantitative analysis with qualitative research, and use a longitudinal design to assess the long-term educational effectiveness of virtual experiments. These research directions would deepen understanding of virtual experiments’ educational effectiveness, promote teaching innovation, and provide crucial guidance for future education practices.

Conclusion

The virtual simulation experiment system described here serves as an effective complement to real experiments, offering significant advantages in terms of safety, repeatability, and standardization. Our study demonstrates its effectiveness through improved student performance and a high satisfaction rate (97.2%). The 3-module design effectively enhanced students' understanding (98.9% reporting improvement) and engagement with the experimental procedures. While virtual experiments show distinct advantages in visualization and allow repeated practice, they work best when integrated with traditional hands-on experiments to provide a comprehensive learning experience. This combination leverages the strengths of both approaches—the safety and flexibility of virtual simulation with the irreplaceable tactile experience of real laboratory practice. Future development should focus on technical optimization and enhanced integration with traditional teaching methods to further improve educational outcomes.

Abstract

Background: Medical education continues to favor didactic lectures as the predominant method of instruction. However, in recent years, there has been a shift toward active learning methodologies such as gamification.

Objective: This study aimed to describe the implementation of 3 open-access, web-based pharmacology games tailored for medical students: *Cross DRUGs*, *Find the DRUG*, and *DRUGs Escape Room*. The study also evaluated the impact of gamification on knowledge retention, student engagement, and learning experience in pharmacology education.

Methods: We used a quasi-experimental design to examine the effects of gamification on knowledge retention by comparing pretest and posttest scores between the gamer and control groups. Each week, students self-selected into either the gamer group or the control group based on personal preference. All students were provided with online access to the same lecture slides. Students in the control group completed both the pretest and posttest but did not play any of the games. A survey was administered to assess students' perceptions of gamification as a learning tool.

Results: Of the 72 students enrolled in the course, 49 (68%) agreed to participate, with 40 (56%) students completing both the pretest and posttest and being included in our analysis. As participation could vary weekly, an individual student might have appeared in both groups across different weeks, resulting in 59 gamer sessions and 20 control sessions. The mean pretest scores were 6.05 (SD 2.31) for the control group and 6.20 (SD 2.13) for the gamer group. The mean posttest scores were 6.90 (SD 2.02) for the control group and 8.47 (SD 1.30) for the gamer group. The gamer group exhibited significantly improved posttest scores (P=.006), while the control group did not (P=.21). Most respondents (25/30, 83%) found the games enjoyable and agreed that the games effectively helped them understand pharmacological concepts (24/30, 80%). Additionally, 70% (21/30) of students believed they learned better from the gaming format than from didactic lectures. Most favored a blended approach that combines lectures with games or case studies.

Conclusions: Gamification can serve as an effective complementary teaching tool for helping medical students learn pharmacological concepts.

pharmacology; gamification; open access; medical education; medical students

Introduction

Medical education continues to favor didactic lectures as the predominant method of instruction [1,2], even though this traditional approach fosters passive learning, reinforces teacher-centeredness [3], and yields lower rates of knowledge retention compared to other approaches [4]. In recent years, there has been a growing shift toward innovative and active learning methodologies, among which gamification has emerged as a promising strategy [5].

In its simplest terms, gamification involves integrating game elements into nongame contexts [6,7]. Gamification in education is grounded in several learning theories, including humanistic learning and adult learning theories [8,9]. It incorporates features such as goal setting, incremental challenges, immediate feedback, progression systems, and rewards to foster deeper

involvement in learning tasks [10,11]. Gamification has been shown to enhance motivation, improve academic achievement, and foster social interaction, thereby supporting its use as an effective teaching tool [11-13].

For Generation Z learners, considered to be "digital natives," gamification may be the most appropriate pedagogical method as it meets Generation Z's familiarity and immersion in digital platforms [14-17]. Furthermore, their extensive exposure to technology may have resulted in the development of constrained attention spans, a preference for visual and kinesthetic learning activities, and a need for immediate feedback [14]. This trend in learning preferences requires educators to transition from content providers to facilitators of learning who can skillfully leverage technology, including gamification, to boost student engagement and motivation [14,18,19].

Although many studies have demonstrated that gamification enhances the learning experience and increases knowledge retention [20-24], they have been criticized for publication bias and for consistently reporting positive outcomes in health professions education programs [25]. Methodological concerns have also been raised, with most studies lacking proper control groups, raising doubts about the reliability of the evidence supporting the impact of gamification on learning outcomes. A systematic review on gamification underscored the need for more rigorous research designs with defined control groups to accurately assess the benefits of gamification in health professions education [25]. This study aimed to describe the implementation of 3 open-access, web-based pharmacology games for medical students and to explore the impact of these games on knowledge retention and student experience.

Methods

Setting and Study Design

Khalifa University College of Medicine and Health Sciences is a 4-year postgraduate entry medical school in the United Arab Emirates. Many of the students do not follow the traditional premedical route and instead have engineering backgrounds. The pharmacology course is a mandatory 4-week course for all first-year medical students. It typically requires memorization of large amounts of information, which presents an academic challenge for students. Recognizing that a lecture-based delivery of the pharmacology course might not benefit students who may struggle with rote memorization of a long list of facts, we sought innovative teaching methods to enhance the learning experience.

We conducted a quasi-experimental study to examine the effects of gamification on student experience and knowledge retention during the first 3 weeks of a 4-week pharmacology course; the final exam week was excluded. Quasi-experimental designs are commonly used in medical education when randomization is not feasible due to the practical and ethical constraints of real-world educational settings [26]. We used a pretest-posttest, nonrandomized control group design. This approach is consistent with the framework of nonequivalent group designs where participants are not randomly assigned but are compared based on pretest and postintervention outcomes to infer the impact of the intervention [27,28].

Ethical Considerations

The CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist was used to guide our reporting [29]. The study was approved by the Institutional Review Board of Khalifa University of Science and Technology (H20-036). At the start of the course, each student received an email invitation to participate in the study along with an informed consent form, and all participants provided informed consent. The email described the study's purpose and explained that it was anonymous and confidential. Participation was voluntary, and no incentives were offered. Students were informed that they could withdraw from the study at any time without any consequences. Student participation and data deidentification were handled by a study coordinator who was not involved in student teaching or grading.

Participants and Group Allocation

Students were allowed to self-select into either the gamified (gamer) or nongamer (control) group each week based on their personal preference. While this self-selection limited random assignment, it is a pragmatic approach for studying educational interventions that mirror real-world classroom decision-making [30]. Given the weekly self-selection process, a single student could participate in both types of sessions across different weeks, resulting in 59 gamer sessions and 20 control sessions, reflecting learning sessions rather than unique participants.

Game Design

We chose 3 open-access, web-based game formats—crossword puzzle, word search, and escape room—because they align with adult learning theories by incorporating clear goals, incremental challenges, and immediate feedback [7]; require minimal technological infrastructure; and support asynchronous, self-directed learning suited to Generation Z's digital preferences. *Cross DRUGs* (Multimedia Appendix 1), based on a crossword game, was generated via an online crossword puzzle generator available on the Education website [31]. *Find the DRUG* (Multimedia Appendix 1) was based on the Hunting Words game and was produced using an online word search puzzle generator available on the Educolorir website [32]. *DRUGs Escape room* (Multimedia Appendix 1), created via Google Forms using the EduGame template, required students to solve a series of sequential, drug-related clues to progress through the game.

Each game tested students on the drugs covered during the preceding week of the pharmacology course, including the mechanisms of action, primary indications, and clinically relevant side effects. Two authors, who were faculty members in the pharmacology course, independently drafted each game's questions based on weekly learning outcomes. A third author, also a course instructor, reviewed the games for accuracy and curricular alignment. Games were single-player and time-limited, but students were allowed unlimited attempts. Students were given 48 hours to participate in the game, and only 1 attempt was required for inclusion. Upon completion, correct answers and brief explanations were provided via the learning management system.

Assessment

All students received the same curriculum. At the end of each week and before game access, all students completed a 9-item multiple-choice pretest. The pretest was conducted to assess the pharmacological knowledge of students regarding the content covered that week and to ensure the homogeneity of the knowledge acquired by both the control and gamer groups. Instructions on how to access the games were provided via email, along with a reminder encouraging students to play the game. At the end of the 48-hour period for game completion, a matched 9-item posttest was released to both groups. Students in both the gamer and control groups accessed the posttest at the same time. The pretest and posttest contained identical items to leverage spaced repetition principles and measure knowledge gains attributable to gameplay. Spaced repetition involves revisiting material at intervals to reinforce understanding over time [33]. The tests were formative and did not influence course grades. Students in the control group had online access to the lecture slides that were also available to the gamer group, while the latter engaged in gameplay.

Survey Instrument

At the end of the course, all students who participated as gamers were asked to complete an online questionnaire assessing enjoyment, perceived learning benefits, and preferences for gamification versus lectures using a 5-point Likert scale (1=strongly agree to 5=strongly disagree). The survey also evaluated the importance of incorporating a reward system into gamification and compared gamification to other teaching methodologies. The postgame survey was administered only to students in the gamer group, as it focused on perceptions of the gamified activities. Because the control group did not receive any additional instructional method beyond lecture slides, the questionnaire was not applicable. We calculated Cronbach α for internal consistency (overall α=0.88; reward-related items α=0.65) [34]. Deleting any question caused the α coefficient to decrease, suggesting that each question contributed to the overall reliability, as shown in Multimedia Appendix 2.

Data Analysis

We performed analyses in R (version 4.2.3; R Foundation for Statistical Computing). In line with prior studies on the impact of games on learning outcomes, score differences (posttest minus pretest) between control and gamers were used to assess the effectiveness of the games [35]. The Shapiro-Wilk test and Mann-Whitney test were performed using the built-in stats package, and Cronbach α was calculated using the psych package. To assess the normality of the pretest and posttest scores, the Shapiro-Wilk test and histogram inspection were conducted. Because the scores were not normally distributed, we compared groups with the Mann-Whitney test (Wilcoxon rank-sum test with continuity correction) and set statistical significance at $P<.05$.

Results

Of the 72 students enrolled in the course, 49 (68%) agreed to participate, with 40 (56%) students completing both the pretest and posttest and being included in our analysis (Figure 1). As students self-selected into the gamer or control group each week, there were 59 gamer sessions and 20 control sessions. The average number of attempts per gamer was 3.4 (SD 0.85). Participant demographics are presented in Multimedia Appendix 3. The self-identified mean age was 23.9 (SD 2.69) years for the control group and 24.0 (SD 1.79) years for the gamer group. Students had educational backgrounds in engineering or scientific disciplines (*others*), typically holding bachelor's degrees in chemistry, biology, biochemistry, or psychology. None of the students reported prior educational experience in pharmacy or pharmacology.

Figure 1 displays the average pretest and posttest scores for both groups. The mean pretest scores were 6.05 (SD 2.31) for the control group and 6.20 (SD 2.13) for the gamer group. The mean posttest scores were 6.90 (SD 2.02) for the control group and 8.47 (SD 1.30) for the gamer group. The gamer group demonstrated a significant improvement in posttest scores ($P=.006$), whereas the control group did not show a statistically significant change ($P=.21$).

Survey results demonstrated positive perceptions of gamification as a learning tool. Of the 30 students surveyed, 24 (80%) agreed that the games were an efficient way to understand pharmacological concepts, and 25 (83%) reported that the games were enjoyable. Most students (21/30, 70%) believed that they learned better from the gaming format than from didactic lectures, and 67% (20/30) agreed that awarding points, such as extra credits, for game-related activities would be beneficial. Less than half of the respondents (12/30, 40%) agreed with allocating prizes to game winners, while the remaining students were evenly divided between neutral and disagreement (Table 1). Surveyed students favored a teaching methodology that combines lectures with games or case studies, with the highest percentage of students (9/30, 30%) preferring lectures as their third preference (Figure 2).

Figure 1. Mean (SD) number of correct responses on the pretest and posttest for students who did not play the game (control group; n=20 sessions) and those who played the game (the gamer group; n=59 sessions). Each data point represents a learning session rather than a unique participant. The highest attainable score was 9. *P=.006.

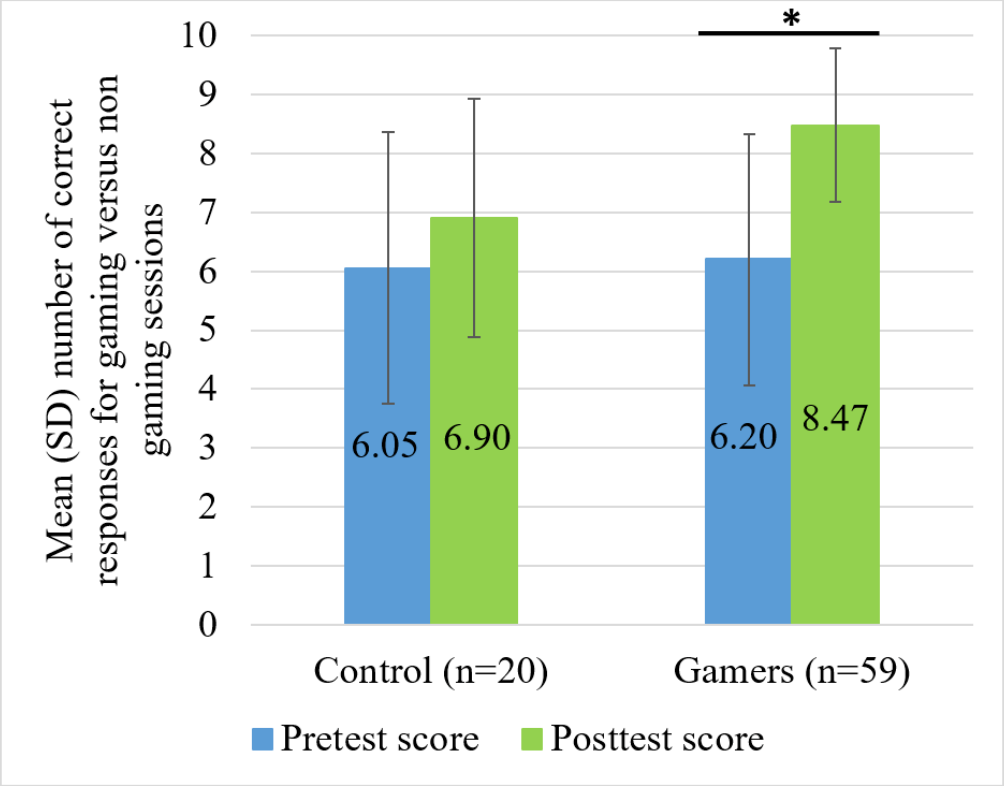

Table . Students' responses to 5 evaluation statements on gamified pharmacology learning activities (n=30). The statements assessed perceived effectiveness, enjoyment, learning preferences, and attitudes toward rewards.

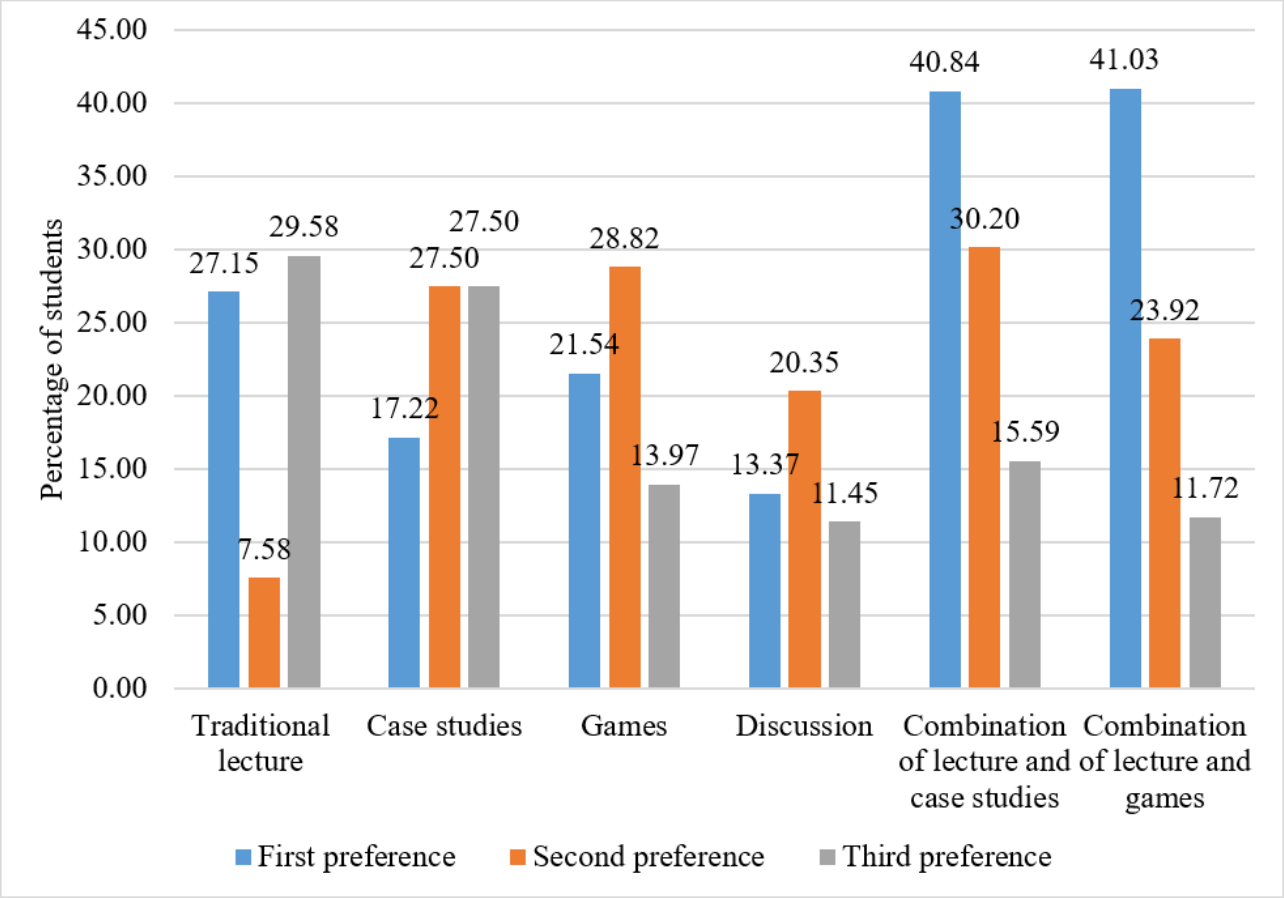
Statements	Strongly agree or agree, n (%)	Neutral, n (%)	Strongly disagree or disagree, n (%)
The game was an effective way to learn pharmacological concepts	24 (80)	3 (10)	3 (10)
I enjoyed the game	25 (83)	3 (10)	2 (7)
I learn better in a game format than in a didactic lecture	21 (70)	3 (10)	6 (20)
I feel that prizes should be awarded to the winners of the games	12 (40)	9 (30)	9 (30)
Points (either as extra credit or incorporated into the overall grading scheme) should be associated with game activities	20 (67)	4 (13)	6 (20)

Figure 2. Students' preferences for different instructional formats in pharmacology education, presented as percentages for first, second, and third choices (n=30).



Discussion

We integrated 3 low-cost, easily implemented, open-access pharmacology games into a pharmacology course for medical students. Students who engaged in the game-based learning approach demonstrated better knowledge retention with a significant improvement in test scores compared to the control group. Most students also perceived the games as effective, enjoyable, and preferable compared to traditional lectures. Many students suggested that a blended instructional model combining didactic sessions with interactive games would optimize learning by balancing content delivery with engaging reinforcement.

Our decision to implement gamification in pharmacology education was partly driven by the academic profile of our students, many of whom came from engineering backgrounds. These students often prefer spontaneous, pragmatic, and concrete learning styles with hands-on, goal-oriented, and sequential tasks. Research has shown that engineering students tend to favor trial-and-error learning; practical application; and structured, step-by-step problem-solving approaches [36]. These characteristics made them well suited for gamified learning environments that emphasize active participation and immediate feedback. In line with this, we selected crossword puzzles, word search activities, and web-based escape rooms, as they require minimal setup and support self-directed, asynchronous learning [37,38]. By breaking up complex pharmacology concepts into brief game sessions with immediate feedback, students experienced incremental successes that built self-efficacy and intrinsic motivation [25,39]. Furthermore, the variety of game formats helped sustain attention and catered to diverse learning preferences within the student cohort.

Two recent systematic reviews in pharmacy education and higher education reported that the most common type of research methodology was pretest and posttest evaluation [35,40]. Among the 3 games we implemented, the crossword and word search games lack supporting evidence in the literature that uses pretest and posttest scores [24,38,41]. In contrast, escape room–based strategies have been more rigorously evaluated, frequently using pretest and posttest to quantify knowledge gains. Consistent with our findings, several studies reported substantial improvements in posttest scores among pharmacy and medical students following escape room activities, although many lacked control groups [20,42-44]. While different in design, other gamified learning tools have also demonstrated improved knowledge retention. For instance, second-year medical students who played "Who Wants to be a Physician"—a game inspired by the TV show "Who Wants to be a Millionaire"—achieved higher posttest scores compared to peers who attended traditional tutorial sessions [45]. Similarly, both preclinical and final-year medical students and residents who engaged in board or card games showed posttest score improvements [46-48]. Additionally, the "Pharmacotrophy" tournament, which incorporated Kahoot-based quizzes and in-person matches, significantly enhanced PharmD students' knowledge acquisition, likely due to its incorporation of fun elements and a relaxed, competitive environment [49]. These findings suggest that

gamified approaches can be effectively integrated across various stages of medical education, from preclinical training to residency.

A common methodological limitation across many gamification studies is the lack of a control group, which limits the ability to draw causal inferences [20,24,38,41-44,46-48,50]. Notably, a systematic review of pharmacy education found that just 2% of studies included a control arm [40]. Our study addressed this gap by incorporating a clearly defined control group each week, enabling us to objectively demonstrate that game-based learners achieved significantly greater knowledge gains than their nongamer peers.

Consistent with previous research, most students perceived the games as efficient, enjoyable, and of more educational value than conventional didactic lectures. Students in previous studies found gamified learning methods, such as the diabetes board game, virtual escape room, crossword puzzles, and "Who Wants to be a Physician," to be enjoyable ways to learn pharmacology, often citing increased engagement and confidence in the subject matter [20,24,38,41,45,46]. Similarly, use of the Kahoot platform increased medical student motivation and participation [51]. In our study, more than 80% of gamers agreed that the puzzles and escape room enhanced their understanding of pharmacological concepts and enjoyment of the subject. These findings underscore that well-designed gamification can meaningfully enrich medical education by providing opportunities for interactive learning.

Although students enjoyed the games, many favored a blended approach that combines interactive activities with conventional lectures. This preference suggests that while gamification can foster engagement, learners may not yet be ready to replace lectures entirely, especially within a traditionally structured curriculum. Our voluntary, supplemental design likely contributed to the positive findings by allowing motivated students to opt in without penalizing others. One study found that the impact of gamification depended on participant personality traits, suggesting that it was not beneficial for all learners [52], with some students considering games inefficient or tedious [53]. The moderate-enjoyment hypothesis further cautions that excessive game elements can overload cognitive resources, reducing learning gains beyond an optimal point [54]. Accordingly, we aimed to balance play and learning—using play to complement and reinforce complex information to increase learning efficiency, rather than as a stand-alone replacement for didactic teaching. This strategy aligns with recent recommendations to incorporate game-based learning as an optional strategy and only for tedious or difficult concepts [53]. A recent review supported the use of game-based learning as complementary tools, as it noted that the long-term applicability of these methods requires further exploration [5].

It is notable that the 3 games used in this study deliberately centered on a single game element—"rules and goals"—to provide clear objectives for each activity without introducing confounding game elements such as competition, narratives, or collaboration [55]. By focusing solely on structured challenges with immediate feedback, we could more confidently attribute the observed gains in retention and engagement to goal-oriented game elements [25]. We intentionally omitted competition, a common gamification feature [13,56-58], because it shifts the focus from learning to winning and has been associated with increased anxiety [58,59]. A recent randomized crossover study warned against using competitive gamification in medical education, finding no evidence of benefits on students' competence or internal motivation [60].

Our use of free, open-access platforms addressed barriers in resource-limited settings, where 50% of gamified training platforms for preclinical medical education required paid access [61]. This aligns with the United Nations Educational, Scientific and Cultural Organization "Education for All" initiative by promoting equitable educational resources worldwide [62]. Moreover, while most research on gamification as an educational tool in health professions has been conducted in the United States or Canada [25], by conducting this study in the Middle East—an underrepresented region in gamification research—we contributed valuable data to global medical education literature and demonstrated the approach's feasibility beyond North American contexts.

Further research is essential to build on our findings and to fully understand the potential of gamification in pharmacology education. Investigating the broader impact of open-access, web-based gamification will help validate and generalize these results, paving the way for more engaging and effective learning experiences for medical students. In future research, we would like to explore additional parameters such as academic achievement, long-term memory retention, and practical applicability. As a next step, we also propose developing a free mobile app. This tool has significant potential for learning due to its easy accessibility and affordability, especially because mobile apps are rarely used in pharmacology education [63].

Our study has several limitations. As a single-site, quasi-experimental study with a modest sample size, its generalizability may be limited. As students self-selected as gamers, it is possible that those who were more academically motivated chose the games as an additional study tool. There were also substantially more gamer instances than controls. To mitigate potential bias from unequal group sizes, we analyzed learning sessions rather than unique students, treating each week's participation as an independent observation reflecting exposure to the intervention. We used nonparametric statistics (Mann-Whitney U test), which do not assume equal variances or normally distributed data, thereby making our comparisons robust to group-size differences. Future studies should use randomized allocation or stratified sampling to ensure balanced groups.

In conclusion, integrating simple, low-cost web-based games into a pharmacology curriculum can enhance knowledge retention and learner engagement. As a complementary, optional strategy, gamification offers a feasible strategy to enrich traditional didactics and meets the needs of diverse medical student populations.

KEYWORDS

ChatGPT; artificial intelligence; language; translation; health care disparity; natural language model; survey; patient education; accessibility; preference; human language; communication; language-concordant care

We appreciate the thoughtful insights shared by Quon and Zhou [1] regarding our study on the application of ChatGPT in translating patient education materials [2]. We wholly agree that the linguistically distinct languages, such as Mandarin, can present challenges in capturing all the nuances and achieving precise translations.

In response to the comment regarding the use of multiple prompts, we acknowledge the complexity and variability in artificial intelligence (AI)-generated translations. However, it is important to consider the practical limitations within a clinical setting. Asking providers to use various prompts in real time may not be feasible due to time constraints and the need for efficiency in patient care. We believe that focusing on a single, effective prompt can streamline the translation process while we explore avenues for improvement in the AI's capabilities. This could be a productive avenue for future research.

Addressing the concern regarding the reliance on board-certified dermatologists for post-translation review, we want to clarify that, in addition to being board-certified dermatologists, all reviewers were native speakers in the language they reviewed, including fluency in Mandarin at a college level. This proficiency allows for a confluence of both clinical and linguistic insights when evaluating translations, reinforcing the validity of our findings. We appreciate the importance of rigor in translation review and remain committed to enhancing the integrity of our translated materials.

Overall, while we recognize the areas where ChatGPT can improve, we also see its current utility as a valuable tool for expanding access to language-concordant care in clinical settings. Our study serves as a helpful step toward identifying and addressing the limitations of AI translations, and we welcome continued dialogue to refine these practices.

Abstract

(JMIR Med Educ 2025;11:e72336) doi:10.2196/72336

KEYWORDS

artificial intelligence; cinematic clinical narrative; cinemeducation; medical education; narrative learning; pharmacology; AI; medical students; preclinical education; long-term retention; AI tools; GPT-4; image; applicability; CCN

I extend my sincere appreciation for the thoughtful critique [1] of my study, "Enhancing Medical Student Engagement Through Cinematic Clinical Narratives: Multimodal Generative AI–Based Mixed Methods Study" [2]. The author's insights regarding engagement mechanisms, theoretical expansion, and methodological refinements offer valuable perspectives that contribute to the broader discourse on the pedagogical applications of generative artificial intelligence in medical education.

While the Cognitive Affective Model of Immersive Learning framework originated to explain learning with immersive virtual reality technologies [3], I concur that its underlying principles are applicable to my study. The debate over the role of media versus instructional methods in learning has been longstanding. While some argue that the medium itself shapes cognition, social structures, and cultural norms [4], others reject this notion, asserting that media are merely delivery mechanisms and that instructional methods alone drive learning outcomes [5]. The Cognitive Affective Model of Immersive Learning reframes this debate by emphasizing that it is not the medium (eg, immersive virtual reality) that inherently enhances learning, but rather how instructional methods leverage the unique affordances of that medium. In the context of cinematic clinical narratives (CCNs), the structured narrative and multimodal design capitalize on engagement mechanisms similar to those observed in immersive learning. Future research could further examine how instructional design within CCNs optimally harnesses these principles to promote knowledge retention and clinical application.

The author's recommendation of the integration of pretest and posttest methodologies is well-founded. While the published study employed posttest assessments to measure comprehension, incorporating pretest measures would facilitate a more granular evaluation of baseline knowledge and attitudinal shifts attributable to CCNs. Furthermore, longitudinal assessments could provide critical insights into the durability of knowledge retention and the sustained impact of CCNs over extended timeframes. I aim to incorporate these into future studies.

The author's call for broader contextual applications of CCNs beyond traditional classroom settings is well-taken. While the study examined CCN implementation within a structured learning environment, I am currently working on converting CCNs into self-contained short films that can be viewed online for self-directed learning. This adaptation aims to provide learners with greater flexibility while maintaining the engagement and narrative-driven structure of CCNs. Investigating how these self-contained films perform across varied instructional modalities could yield valuable insights into their scalability and applicability within diverse educational contexts.

Finally, I concur with the author's observation that medical students are increasingly turning to digital platforms such as social media for information and engagement. Medical educators should take note and examine the factors that make these

platforms so compelling. By understanding the draw of these digital environments, educators can incorporate similar characteristics into medical school learning materials to meet students where they are. Expanding CCN research to explore how elements such as interactivity, brevity, and personalization influence learner engagement could provide valuable insights into modernizing medical education. I am grateful for the astute observations and constructive recommendations by the author. These perspectives will undoubtedly inform my future research directions and further the integration of artificial intelligence–driven methodologies in my studies on medical education.

KEYWORDS

artificial intelligence; cinematic clinical narrative; cinemeducation; medical education; narrative learning; AI; medical students; preclinical education; long-term retention; pharmacology; AI tools; GPT-4; image; applicability; CCN

I read with great interest the recent study by Bland [1], "Enhancing Medical Student Engagement Through Cinematic Clinical Narratives: Multimodal Generative AI–Based Mixed Methods Study," which explored the use of cinematic clinical narratives (CCNs) in medical education. The findings highlighted the potential of multimodal generative artificial intelligence (AI) to enhance engagement and knowledge retention among medical students. While the study effectively demonstrated novel use of AI to modernize case learning, further exploration of engagement mechanisms and broader learning theories may deepen our understanding of how these approaches can be optimized for educational impact.

Engagement in learning is multifaceted and can be linked to immersion [2] and intrinsic motivation [3]. As Bland observed, students exhibited heightened situational interest in CCNs, reinforcing the idea that immersive learning environments can enhance attention and recall. However, beyond the constructivist learning theory discussed in the study, additional models could be considered to expand the theoretical framework for understanding these results. One such model is the Cognitive Affective Model of Immersive Learning framework [4], which emphasizes the interplay between representational fidelity, cognitive load, and technological mediation in shaping learner experiences. Exploring the Cognitive Affective Model of Immersive Learning and similar frameworks could provide a more nuanced perspective on how technology interacts with learner motivation and engagement.

Another area for further inquiry is the role of pretest and posttest methodologies in evaluating learning outcomes. As the study rightly acknowledges, medical education research is often limited to single posttest designs [5], which may not capture students' initial levels of engagement or attitudes toward learning. Additionally, fidelity of experience is important for recall, as realistic and contextually accurate learning environments can enhance memory retention and application. Implementing pretest assessments could help quantify shifts in engagement, allowing researchers to distinguish between students who are inherently motivated and those whose interest is primarily triggered by the intervention itself. Such an approach could offer valuable insights into how CCNs influence different learner profiles.

Moreover, the conditions under which learning occurs significantly affect student engagement. The study employed a classroom-based intervention, which effectively bridged the gap between controlled laboratory settings and real-world educational environments. Future research might explore how CCNs perform across varied instructional contexts, including self-paced online learning and clinical simulation settings, to assess their adaptability and impact on different learning situations and scenarios.

Bland provides good evidence that multimodal AI resources hold promise in medical education, underscoring the need to adapt to the evolving preferences of modern medical students who increasingly turn to social media for information and engagement. Expanding this research to integrate additional learning theories and measures, with varied instructional settings will help establish best practices for how to use these innovative tools. I appreciate the author's novel approach and am eager to see how future developments in this field will shape medical education.

letter to the editor; ChatGPT; AI; artificial intelligence; language; translation; health care disparity; natural language model; survey; patient education; accessibility; preference; human language; communication; language-concordant care

We commend the recent publication by Dzuali et al [1], which explored the application of ChatGPT for translating patient education materials into multiple languages. This important study highlights a critical area where artificial intelligence (AI) can potentially bridge gaps in language-concordant care. To further this research, we would like to raise several points to enrich the discussion and understanding of the findings.

The study demonstrates that while ChatGPT provides clinically usable translations for Spanish and Russian, its performance with Mandarin is suboptimal. This inconsistency raises important questions regarding the linguistic complexities and structural differences between English and Mandarin, which may hinder the accuracy and appropriateness of translations. Previous research has shown that the nuanced sentence structures and specialized terminology in Mandarin pose challenges for AI models such as ChatGPT, suggesting the need for more refined approaches when using AI for translation in linguistically distinct languages [2].

Being familiar with the Mandarin language, we have firsthand experience with the challenges that come with translating between languages with distinct linguistic structures. Mandarin, with its nuanced sentence structures and specialized terminology, presents difficulties for large language models such as ChatGPT. These challenges are compounded by differences in grammar, idiomatic expressions, and cultural contexts, which may lead to inaccuracies and misunderstandings in translations. Therefore, this study could provide additional insight into how cultural context influences translation quality. Mandarin, for example, involves not only linguistic precision but also an understanding of cultural nuances that could affect comprehension [3]. Future studies could explore how AI models such as ChatGPT are trained to account for these contextual factors to ensure culturally appropriate translations.

Another area for potential exploration in this study is the testing of alternative prompts and the impact they may have on translation quality. While the study focuses on a single translation prompt—“Translate this into <target language>”—the variability of AI-generated translations could be better evaluated through a variety of prompts. Utilizing multiple prompts could reveal a broader range of performance outcomes, especially for linguistically complex languages such as Mandarin and Russian. Other studies have shown that different AI prompts can produce vastly different results [4].

Lastly, the study heavily relies on the involvement of board-certified dermatologists for posttranslation review, which is applicable to the context of dermatology-related information, but may not fully address the extent of errors and misinformation. While human oversight is essential, the study could benefit from a more robust evaluation of how different levels of human intervention—such as linguistic experts or specialists in medical translation—might improve translation accuracy [5]. Future research should explore how different combinations of AI-generated translations and human review from varied sources could optimize clinical usability.

Overall, while ChatGPT shows promise for improving access to language-concordant patient education, further refinement and validation are required. This study is an important milestone in starting this discussion surrounding AI-translation in medical contexts, and we commend the authors for their valuable contribution to advancing the field. They clearly demonstrate a meticulous approach, thoughtful analysis, and commitment to improving patient care through innovative solutions.

KEYWORDS

chatGPT; medical education; Saudi Arabia; perceptions; knowledge; medical students; faculty; chatbot; qualitative study; artificial intelligence; AI; AI-based tools; universities; thematic analysis; learning; satisfaction; LLM; large language model

Large language models (LLMs) such as DeepSeek, ChatGPT, and ChatGLM have significant limitations in generating citations, raising concerns about the quality and reliability of academic research. These models tend to produce citations that are correctly formatted but fictional in content, misleading users and undermining academic rigor. In the recent study titled "Perceptions and earliest experiences of medical students and faculty with ChatGPT in medical education: qualitative study," the section addressing concerns about ChatGPT deserves a deeper discussion [1].

There are several reasons for the citation issues in LLMs, which can be analyzed as follows. First, most LLMs cannot access paid subscription databases and therefore solely rely on open-access resources [2]. This limits the citations generated by LLMs to open-access journals, potentially omitting more significant research published in subscription-based journals. Second, LLMs are trained on vast amounts of text data and generate content by analyzing patterns and structures in text. However, they lack the ability to understand the content of the text or think critically, implying that they cannot judge the accuracy and reliability of information. Third, the algorithms underlying LLMs are often opaque, leaving users unable to understand the specific processes of information handling. This makes it difficult for users to determine the reliability of citations generated by LLMs and to effectively evaluate their results. Recent research also stated that half of generated search results lack citations, and only 75% of those with citations support the claims, posing trust concerns as user reliance grows[3].

Recently, an experiment conducted by the Journal of Clinical Anesthesia involved publishing a fictional article titled "Spinal Cord Ischemia After ESP Block" to test the spread and citation of a fabricated academic content. Surprisingly, the fictional article was widely cited, over 400 times, including in some journals with high impact factors[4], revealing a lack of rigor in academic citation practices, where many authors may not check the original literature and instead copy references directly. This incident sparked widespread discussion about academic citation practices, emphasizing the importance of critical thinking by scholars while citing materials.

The use of fictional citations by LLMs poses a multifaceted problem: it misleads users into drawing incorrect conclusions and making inappropriate decisions, undermines the rigor and credibility of academic research, and hinders the dissemination of knowledge by limiting access to accurate scientific information [5]. The issue of LLMs generating fictional citations is complex and requires the combined efforts of multiple stakeholders for resolution. Developers must continuously improve the LLM technology and algorithms, users must increase their awareness and critical evaluation skills while using LLMs, and academic institutions must strengthen the management and education in academic practices. Only through these efforts can we ensure that LLMs play a positive role in academic research and promote the dissemination and progress of knowledge.

ChatGPT; Gemini; DeepSeek; medical education; AI; artificial intelligence; Saudi Arabia; perceptions; medical students; faculty; LLM; chatbot; qualitative study; thematic analysis; satisfaction; RAG retrieval-augmented generation

We appreciate the thoughtful critique of our manuscript "Perceptions and earliest experiences of medical students and faculty with ChatGPT in medical education: qualitative study" [1] by Zhao and Zhang [2]. Concerns over the generation of hallucinated citations by large language models (LLMs), such as OpenAI's ChatGPT, Google's Gemini, and Hangzhou's DeepSeek, warrant exploring advanced and novel methodologies to ensure citation accuracy and overall output integrity [3].

The LLMs have demonstrated a propensity to generate well‐formatted yet fictitious references—a limitation largely attributed to restricted access to subscription-based databases and their reliance on probabilistic text generation [4]. As LLMs evolve, future iterations may integrate more reliable retrieval-based architectures, enhancing their capacity to cite legitimate sources while reducing fabricated references [4,5]. However, until such improvements are systematically validated, scholars must remain cautious.

One suggested enhancement is using retrieval-augmented generation (RAG) [6]. This approach integrates up-to-date external information, substantially improving real-world applicability. However, even RAG-based systems can misinterpret or distort source content under high-trust conditions. To address this, the authors developed Hallucination-Aware Tuning (HAT) [6]. HAT trains dedicated detection models to generate labels and detailed descriptions of identified hallucinations. These descriptions are then used by GPT-4 to correct discrepancies. The combination of corrected and original outputs forms a preference dataset that, when used for Direct Preference Optimization training, yields LLMs with reduced hallucination rates and improved answer quality [6].

We also propose another solution aimed at fundamentally reducing citation errors: the development of "Reference-Accurate" academic LLM by major global publishers. Leading journals could develop their own specialized LLM, trained exclusively on rigorously verified academic literature from robust databases. This targeted training would ensure that every generated reference is accurate and directly traceable to published work. Ideally, these publisher-backed LLMs would be made freely available to promote open science.

Therefore, we recommend a dual approach that combines advanced RAG methodologies with publisher-developed academic LLMs. Comparative studies should be conducted to evaluate the citation accuracy, factual consistency, and overall performance of RAG-HAT-tuned models against these publisher-specific models. Collaborative efforts among academic institutions, publishers, and AI developers are essential to establish standardized protocols and reliable training datasets. Such partnerships would not only enhance the reliability of LLM-generated outputs but also foster greater trust in AI-assisted scholarly communication.

Moreover, the broader academic community bears responsibility for critically appraising AI-generated content. While LLMs can streamline information retrieval and synthesis, human oversight remains indispensable for safeguarding academic integrity. Rather than dismissing AI-driven tools due to their current flaws, we advocate for further research to ensure greater alignment

with evidence-based scholarship and authentic publications. Future LLM iterations may rapidly overcome these limitations, but until then, transparency, responsible usage, and ongoing improvements in AI training remain imperative.

In conclusion, while RAG augmented by HAT represents a potential advancement in reducing hallucinations, the development of specialized, reference-accurate academic LLMs by publishers may offer a promising pathway. By integrating both strategies and ensuring human oversight, the academic community can ensure that AI-driven tools reliably support the rigor and transparency essential to scholarly research.

Abstract

Background: Telehealth training is increasingly incorporated into educational programs for health professions students and practicing clinicians. However, existing competencies and standards primarily address videoconferencing visit logistics, diagnostic modifications, and etiquette, often lacking comprehensive guidance on adapting interpersonal skills to convey empathy, cultural humility, and trust in web-based settings.

Objective: This study aimed to establish consensus on the knowledge, skills, and attitudes required for health professions students and clinicians to build rapport with patients in telehealth videoconferencing visits and to identify teaching strategies that best support these educational goals.

Methods: An e-Delphi study was conducted using a panel of 12 interprofessional experts in telehealth and telehealth education. Round 1 involved interviews, followed by anonymous surveys in rounds 2 - 4 to build consensus.

Results: All 12 experts participated in rounds 1 - 3. In total, 19 themes related to rapport-building and 77 specific curriculum items were identified, all achieving the established level of consensus.

Conclusions: Using a competency-based education framework, this study provides guidance for health professions educators, teaching clinicians, and students on how to adapt interpersonal skills for telehealth including detailed content related to knowledge, skills, attitudes, and teaching strategies. Future research is needed to test the feasibility, acceptability, and effectiveness of curricula based on these competencies and teaching strategies.

KEYWORDS

health professions education; health care professional development; clinician-patient relationship; interpersonal skills; health care communication; empathy; web-based care

Introduction

Background

Telehealth, including the use of videoconferencing visits (VV), is quickly becoming an important and common vehicle for delivering health care [1,2]. Growth in the use of VV is anticipated, given that clients or patients (hereafter referred to collectively as patients) and clinicians are increasingly receptive to VV as a supplement to in-person care [2].

Although telehealth competencies and training are being incorporated into some health professions educational programs [3-7], a recent scoping review found that 53% of sources emphasized a need for additional education and practice in telehealth etiquette and interpersonal aspects of care [8]. Many health care professionals remain uncertain of ways to establish rapport during VV [9-11]. A mixed methods study by Elsevier Health that included 3000 nurses and doctors found that over half believed telehealth would negatively impact their ability to demonstrate empathy and requested further guidance on

interpersonal skills in VV [12]. Studies show that not all interpersonal skills are interchangeable between in-person and VV [2,13] and that adapting skills for VV often does not come naturally but can be learned [14,15].

Definition of Rapport and Importance

Rapport, a term often used colloquially, has been defined within the health sciences and psychology as a desirable state of interpersonal connection that requires positivity, mutual responsiveness, and behavioral coordination [16,17] as well as respect, acceptance, empathy, and a mutual commitment to engage [18]. When intentionally fostered, rapport facilitates the development of a therapeutic relationship with outcomes that include trust, improved care outcomes, and satisfaction for both the patient and clinician [10, 13, 19-23]. Connection or rapport within a web-based care environment has only begun to be explored. These studies suggest that many in-person relationship-based skills are effective, but adaptations are necessary and must be used intentionally by clinicians and patients [9,10,20,24].

Knowledge Gap and Need for Research

Recent evidence-based telehealth etiquette and interpersonal checklists [25,26], along with educational interventions for health care students [14] and professional development workshops for clinicians [15,27], show promise in preparing current and future clinicians to adapt their interpersonal skills. However, telehealth etiquette often emphasizes practical and professional behaviors for efficient VV (eg, technical preparedness, ensuring a professional environment, and communication techniques to ensure diagnostic and treatment accuracy) rather than adapting interpersonal skills to convey empathy, cultural humility, and trust or to build personal connection in a web-based environment. Additionally, evidence-based resources are needed for interprofessional educators to support curriculum development across health care disciplines [7].

Building rapport in VV requires specific knowledge, skills, and attitudes as well as teaching strategies designed to facilitate relationship-based care competencies. Building upon previous descriptive studies [9,10,13,20,28-31], this project aimed to use an e-Delphi study to explore what relationship-based care elements are important to include in a telehealth curriculum. This will provide a strong foundation for the future curricula development of interprofessional students and clinicians across disciplines while closing a crucial gap in our practice and pedagogical knowledge.

Research Aim and Questions

This study aimed to establish expert consensus on training health professions students and clinicians in rapport-building during VV. Two research questions guided the study: (1) what knowledge, skills, and attitudes are essential for health professions students and clinicians to build rapport with patients in telehealth VV? (2) What teaching strategies best facilitate the development of this knowledge and these skills and attitudes?

Methods

Study Design

An e-Delphi methodology was used to build consensus by collecting, analyzing, and sharing data results with an interprofessional panel of experts in telehealth and telehealth education. The Delphi technique, widely used in nursing and health care research, assumes that group opinion is more valid and reliable than individual opinion, making it effective for achieving consensus on topics with limited evidence or uncertain practice standards [32]. This iterative, structured method uses interviews and surveys to gather expert input over multiple rounds until consensus is reached. Experts remain anonymous to one another to prevent any individual from dominating the process. After each survey round, data are summarized and shared with experts, reflecting both their individual responses and the group's collective responses. This feedback allows experts to revise their input based on group insights. Rounds typically continue, often between 2 and 4 times, until an acceptable level of consensus is achieved [32]. The web-based Delphi technique (e-Delphi), increasingly adopted for its cost-effectiveness, facilitates efficient participation from geographically diverse experts [33].

Recruitment and Selection of Participants

An interprofessional panel of national and international experts was recruited to participate in this e-Delphi study. The panel included licensed nursing and medical professionals (registered nurses, medical doctors, and advanced practice providers), as well as speech and occupational therapists, all proficient in reading, writing, and conversing in English. Participants were required to have experience in at least 1 of the following activities: (1) conducted research on VV, (2) participated in telehealth advisory panels, (3) developed telehealth curricula, or (4) provided extensive instruction in telehealth, with a significant focus on adapting relational and communication skills for telehealth care.

Our interprofessional research team initially identified 21 experts meeting these criteria. These experts were invited to recommend additional participants, resulting in 7 further suggestions. Recruitment occurred over 3 rounds of targeted emails to assemble a diverse panel of telehealth experts with broad perspectives and experiences. To encourage participation across all rounds of the study, participants received a small financial incentive for their time upon completion.

Ethical Considerations

This educational research was deemed to pose minimal risk to the expert participants, as defined under the Common Rule; therefore, written consent was not conducted. A statement in the initial questionnaire clarified that participants' willingness to complete the interview and surveys constituted their verbal consent. The study received an exempt determination from the health system's institutional review board for clinical investigations (protocol ID: Pro00117125) prior to beginning the study. To maintain participant privacy, data were deidentified, and all study communications, interviews, and study data were conducted and stored on a secure

password-protected server with firewall protection and multifactor authentication. Additionally, the study was registered in the Open Science Framework on January 22, 2025 [34].

Data Collection Procedures

Four rounds of data collection were planned to build adequate consensus among the experts. In round 1, interviews were conducted with experts individually on a university-approved secure Microsoft Teams videoconferencing platform using an interview guide with semistructured open-ended questions developed by the research team. This guide, informed by the 2 original research questions, focused on the knowledge, skills, attitudes, and teaching strategies essential for building rapport in VV. Interviews were chosen as a method for the initial round to gather qualitative descriptive data based on the experts' experiences, given the limited published research on rapport-building in VV.

The specific knowledge, skills, attitudes, and teaching strategies identified using qualitative content analysis of the interview data in round 1 were compiled into a Qualtrics survey for round 2. The round 2 survey asked experts to prioritize the knowledge, skills, attitudes, and teaching strategies using a 4-point Likert scale by asking the extent of importance (4=very important, 3=important, 2=of some importance, and 1=not important). A 4-point scale was selected to enhance survey completion and encourage participants to choose between an item being important or unimportant [35]. Contextually, this aligns with an educator's need to decide whether to include or exclude content from their curriculum. Open-ended questions allowed the participants to provide comments related to their decisions and describe any need to revise or expand the content.

The round 3 survey included the same questions as round 2 and was designed to show experts their ratings compared to those of the other experts in the study. The experts were given an opportunity to rerate each of their original responses or keep them the same. Revision of round 2 items or recommendations for new items from open-ended questions in round 2 were also incorporated into the round 3 survey. Member checking using a final questionnaire was planned in round 4 to evaluate if the panel felt the results reflected their expertise and recommendations. All Qualtrics surveys were sent to participants via the institution's secure Microsoft Teams platform.

Expert participants received emails with survey links for all rounds of the study, including a questionnaire to collect their relevant professional background details prior to the first-round interview. Surveys were developed and administered using Qualtrics, a secure university-approved web-based survey platform.

Data Analysis and Statistical Considerations

Descriptive statistics were selected to report panel responses for each survey item (mean, SD, IQR, and consensus level) and attrition rates over the course of rounds. Since building a curriculum necessitates making a dichotomous decision to include or exclude topics or teaching strategies, for the purposes of calculating consensus, responses were collapsed into 2 categories: important (items rated very important or important) and unimportant (items rated less important or unimportant). The percentage of agreement between the experts was used to measure the level of consensus. Although curricula to teach rapport-building in VV may not require complete agreement, rapport is an important indicator of quality care; therefore, consensus was considered sufficient when an item was rated important or very important by at least 70% of the experts on the panel [32,36]. Statistical analysis was supported by using Microsoft Copilot within Microsoft Excel, leveraging its artificial intelligence (AI)–driven capabilities to generate insights and summaries.

A 5-member coding team conducted qualitative content analysis of the narrative interview data from round 1 and the open-ended responses for all later survey rounds. Codes were derived directly from the transcribed text data and kept close to the participants' descriptions [37], and the analysis was guided by a process outlined by Elo and Kyngäs [38]. NVivo software (version 14.0; QSR International Pty Ltd) was used to facilitate the qualitative analysis, including coding and development of a codebook. At least 20% of the data were reviewed by 2 or more team members, with conflicts resolved through discussion. After initial manual coding, the team used Copilot to generate preliminary summaries and thematic overviews of the interview data. Testing and refining prompts ensured that results aligned with the manually generated NVivo codebook. The study's rigor was enhanced by (1) team-based analysis by researchers with extensive qualitative experience; (2) judicious use of AI tools to validate findings [39]; (3) regular coding meetings to refine codes, categories, themes, and survey items [40]; (4) concurrent data collection and analysis [41]; (5) detailed memos to maintain an audit trail of analytical decisions [39]; and (6) member checking by asking participants to clarify interview responses, evaluate survey items, and reflect on the final analysis [42]. The ACCORD (Accurate Consensus Reporting Document) guided the reporting of results [43].

Results

Overview

In total, 12 of the 16 interprofessional telehealth experts emailed an invitation consented to participate in the study, representing a 75% response rate. Interviews were conducted with the panel of experts in January 2025. This was followed by 3 survey rounds from February to April 2025. All 12 experts completed the round 1 interview and the round 2 and round 3 surveys, representing a 100% participation rate. A total of 11 of the 12 (92%) experts participated in round 4 member checking.

Panel Characteristics and Expertise

Most participants had doctoral degrees (8/12, 67%) and more than 20 years of professional experience (8/12, 67%). A third of the experts had 11 or more years of experience using telehealth with a deep range of involvement in practice, education, research, and advisory capacities (see Table 1 for further characteristics). Of the 12 experts, 2 (17%) were international experts, with the balance residing in the United States. The panel's expertise included using telehealth in a variety of contexts, including adult and pediatric care, rural settings, palliative and hospice care, and mental health. Members of the expert panel have contributed to the development of

practice standards and educational curricula, established telehealth clinics, taught educational courses, conducted research, and published journal papers and books on telehealth. In addition, several experts in the study have developed conceptual models and conducted research specifically on relational aspects of telehealth. All participants were actively involved in teaching professional and interprofessional educational programs with a focus on telehealth.

Table . Expert participant characteristics (N=12).

Characteristic		Values, n (%)
Education level		
	Master's degree	2 (17)
	Doctoral degree	8 (67)
	Professional degree (MD)	2 (17)
Licensure		
	Nursing or midwifery	7 (58)
	Medicine	2 (17)
	Speech-language pathology	1 (8)
	Physician assistant	2 (17)
Length of professional experience (years)		
	11 - 12	4 (33)
	21 - 30	3 (25)
	31 - 40	4 (33)
	>40	1 (8)
Professional experiences with telehealth		
	Conducted visits or consultations	9 (75)
	Conducted research	10 (83)
	Participated on advisory panels	8 (67)
	Developed curriculum	8 (67)
	Provided instruction focused on rapport	11 (92)
Length of telehealth experience (years)		
	2 - 4	4 (33)
	5 - 10	4 (33)
	11 - 20	4 (33)

First Round Results

Overview

Data collected and coded from the 12 expert interviews were organized into educational areas of knowledge, skills, attitudes, and teaching strategies as directed by the research question. Within each of these areas, themes emerged that helped organize more specific items that the experts recommended for a curriculum focused on building rapport in VV. The themes and specific items related to each topic are described below. Since these educational areas, themes, and specific items were incorporated into the round 2 survey, they can also be reviewed in their entirety in Tables 2-5, along with their descriptive statistics and consensus ratings.

Table . Education areas within the knowledge domain (N=12).

Theme and item		Consensus[a], n (%)	Mean (SD)[b]	Median (IQR)
Basic knowledge of telehealth and its applications				
	Telehealth taxonomy	9 (75)	2.83 (0.835)	3 (2.25-3)
	Evidence-based uses of video visits	12 (100)	3.83 (0.389)	4 (4-4)
	Types of video visits (eg, urgent care, follow-up care, and medical management)	12 (100)	3.50 (0.522)	3.5 (3-4)
	Types of clinician roles and responsibilities (eg, clinical evaluation, preoperative education, and facilitating support group)	11 (92)	3.33 (0.651)	3 (3-4)
	Situations not appropriate for video visits	12 (100)	3.75 (0.452)	4 (3.25-4)
	Common challenges in video visits	12 (100)	3.92 (0.289)	4 (4-4)
	General adaptations necessary	12 (100)	3.58 (0.515)	4 (3-4)
How to create a web-based environment that supports rapport				
	Ground rules for video visits (eg, what to expect, what to do if internet connection lost, and ways to enhance the quality of the visit)	12 (100)	3.83 (0.389)	4 (4-4)
	Awareness of how generational, cultural, educational, geographic, and socioeconomic factors influence a patient's participation in video visits	12 (100)	3.75 (0.452)	4 (3.25-4)
	Importance of privacy (auditory or visual) and confidentiality in the patient's and clinician's spaces (eg, private spaces and data protection)	12 (100)	3.92 (0.289)	4 (4-4)
	Choice of video visit setting or background (eg, quiet and nondistracting)	12 (100)	3.50 (0.522)	3.5 (3-4)
	Adaptations related to patient population or type of visit (eg, children, non-English speakers, team-based consultation, mental health evaluation, and group-based care)	12 (100)	3.75 (0.452)	4 (3.25-4)
Functional use of videoconferencing technology platforms				
	Understanding of videoconferencing platform functions and set-up	12 (100)	3.33 (0.492)	3 (3-4)
	Problem-solving of most common technical problems	12 (100)	3.25 (0.452)	3 (3-3.75)
Rapport basics				

Theme and item		Consensus[a], n (%)	Mean (SD)[b]	Median (IQR)
	Awareness of attributes of rapport (eg, shared experience of comfort and engagement and being "in sync")	12 (100)	3.83 (0.389)	4 (4-4)
	Awareness of the outcomes of rapport for patients and clinicians (eg, trust and collaboration)	12 (100)	3.83 (0.389)	4 (4-4)
	Basic rapport-building strategies (eg, active listening and showing genuine interest, respect, and empathy)	12 (100)	4.00 (0.000)	4 (4-4)
	Importance of patients feeling heard and understood	12 (100)	4.00 (0.000)	4 (4-4)
	Increased importance of facial expression and body mannerisms in video visits	12 (100)	3.67 (0.492)	4 (3-4)
	Indicators that rapport has been established (eg, shared smiles, laughter, warmth, and sense of connection)	12 (100)	3.83 (0.389)	4 (4-4)
	Unique opportunities to cultivate rapport in video visits	12 (100)	3.67 (0.492)	4 (3-4)
	Unique rapport challenges in video visits (eg, internet lag interfering with the ability to feel "in sync" and visits becoming brief and transactional)	12 (100)	3.83 (0.389)	4 (4-4)

[a]This describes the percentage of experts who scored the item as either "important" or "very important."

[b]Group mean Likert score. Note that each specific item within the survey was rated as 4=very important, 3=important, 2=of less importance, or 1=unimportant.

Table . Education areas within the skills domain (N=12).

Theme and item	Consensus[a], n (%)	Mean (SD)[b]	Median (IQR)
Creating a safe and comfortable web-based environment			
Supporting patient's comfort with technology	11 (92)	3.58 (0.669)	4 (3-4)
Managing technical challenges	11 (92)	3.33 (0.651)	3 (3-4)
Ensuring patient's desired level of privacy during the video visit	12 (100)	3.83 (0.389)	4 (4-4)
Navigating technological and other video visit distractions to maintain rapport	12 (100)	3.67 (0.482)	4 (3-4)
Taking time to build rapport at the beginning of the video visit	12 (100)	3.92 (0.289)	4 (4-4)
Monitoring level of rapport throughout the video visit	12 (100)	3.50 (0.522)	3.5 (3-4)
Navigating the patient's wants and needs within video visit parameters with mutually agreeable care goals	12 (100)	3.83 (0.389)	4 (4-4)
Demonstrate knowing the patient with recall of important information (eg, medical and social)	12 (100)	3.58 (0.515)	4 (3-4)
Demonstrating cultural humility (eg, respecting differences and practicing self-awareness)	12 (100)	3.67 (0.492)	4 (3-4)
Managing time and flow so patients do not feel rushed	12 (100)	3.50 (0.522)	3.5 (3-4)
Avoiding abruptly ending visits, ensuring that patients' questions and needs are addressed	12 (100)	3.92 (0.289)	4 (4-4)
Navigating moments of disconnection (eg, anger, disagreement, and disengagement)	12 (100)	3.75 (0.452)	4 (3.25-4)
Adapting verbal communication techniques to facilitate rapport in video visits			
Keeping communication clear and simple	12 (100)	3.67 (0.492)	4 (3-4)
Managing conversation flow and pacing to reduce interruptions and "talk overs"	12 (100)	3.75 (0.452)	4 (3.25-4)
Using words as a replacement for physical touch to acknowledge emotions and demonstrate support (eg, "I wish I could give you a hug")	11 (92)	3.58 (0.669)	4 (3-4)

Theme and item		Consensus[a], n (%)	Mean (SD)[b]	Median (IQR)
	Increasing use of reflective practices (eg, restating what the patient has said, asking more questions, and using teach-backs) to validate or confirm accurate understanding	12 (100)	3.83 (0.389)	4 (4-4)
	"Narrating the visit" to describe what you are doing that might be difficult for the patient to interpret (eg, looking at your laboratory work and writing orders for medication)	12 (100)	3.75 (0.452)	4 (3.25-4)
Enhancing nonverbal communication techniques to facilitate rapport in video visits				
	Using body language (eg, facial expressions, hand gestures, and body posturing) to express feelings, emphasize suggestions, or show intentions (eg, eye contact, nodding, and leaning in to show attentiveness, smiling, and hand over heart to show empathy)	12 (100)	4.00 (0.000)	4 (4-4)
	Using platform technology to keep the patient engaged and enhance learning or understanding (eg, screen sharing images, placing links to information in chat, and "show and then tell")	11 (92)	3.50 (0.674)	4 (3-4)
Maintaining attentiveness and presence				
	Pausing or breaking between video visits to reset and cultivate presence	10 (83)	3.17 (0.718)	3 (3-4)
	Managing personal distractions (eg, phone and computer alerts)	12 (100)	3.58 (0.515)	4 (3-4)
	Setting up technology and lighting to ensure that both the clinician and the patient can view the other's body language (eg, "passport view")	12 (100)	3.58 (0.515)	4 (3-4)
	Setting up technology to enhance eye contact with the patient during documentation and medical record review (eg, close to the computer camera)	12 (100)	3.75 (0.452)	4 (3.25-4)
	Heightening attentiveness to visual and auditory signals that might reflect patient emotion	12 (100)	3.58 (0.516)	4 (3-4)
Using a web-based environment to humanize the care experience				
	Seeking cues in the patient's environment to know them as a person	10 (83)	3.25 (0.754)	3 (3-4)

Theme and item		Consensus[a], n (%)	Mean (SD)[b]	Median (IQR)
	Using cues in the patient's environment to build connection	10 (83)	3.25 (0.754)	3 (3-4)
	Using self-disclosure based on cues in the patient's environment to build connection	9 (75)	2.92 (0.900)	3 (2.25-3.75)
	Personalizing your professional web-based environment to facilitate connection	9 (75)	3.00 (0.739)	3 (2.25-3.75)
	Using idiosyncratic aspects of video visits as opportunities to build connection (eg, unexpected pet encounters or technology issues)	12 (100)	3.25 (0.452)	3 (3-3.75)
Other				
	Magnifying use of active listening techniques	12 (100)	3.83 (0.389)	4 (4-4)
	Heightening self-awareness to ensure that your verbal and nonverbal behaviors reflect empathy and caring	12 (100)	3.92 (0.289)	4 (4-4)

[a]This describes the percentage of experts who scored the item as either "important" or "very important."

[b]Group mean Likert score. Note that each specific item within the survey was rated as 4=very important, 3=important, 2=of less importance, or 1=unimportant.

Table . Education areas within the attitudes domain (N=12).

Theme and item		Consensus n (%)[a]	Mean (SD)[b]	Median (IQR)
Willingness to adapt to changing situations with ease				
	Willingness to make extra effort to connect in video visits	12 (100)	3.67 (0.492)	4 (3-4)
	Patience with unexpected situations and technological challenges	12 (100)	3.67 (0.492)	4 (3-4)
Respect for patient challenges associated with video visits				
	Respect associated with being in someone's home digitally	12 (100)	3.83 (0.389)	4 (4-4)
	Respecting patient's perception of whether video visits can meet their needs and goals	12 (100)	3.67 (0.492)	4 (3-4)
Other				
	Valuing video visits as a viable care delivery model	12 (100)	3.75 (0.452)	4 (3.25-4)
	Receptivity to learning new skills for video visits	12 (100)	3.67 (0.492)	4 (3-4)
	Valuing relational aspects of care with a desire to adapt interpersonal skills for video visits	12 (100)	3.75 (0.452)	4 (3.25-4)

[a]This describes the percentage of experts who scored the item as either "important" or "very important."

	Peer learning (eg, observing, interacting with preceptors, mentors, and role models)	12 (100)	3.58 (0.515)	4 (3-4)
	Integration of telehealth adaptations into standard curricula (ie, when learning about developing in-person rapport, students would also learn about appropriate adaptations for telehealth)	12 (100)	3.92 (0.289)	4 (4-4)

[a]This describes the percentage of experts who scored the item as either “important” or “very important.”

[b] Group mean Likert score. Note each specific item within the survey was rated as 4=very important, 3=important, 2=of less importance, or 1=unimportant.

Knowledge

Expert participants described the importance of ensuring that students and clinicians had basic knowledge of telehealth. This included the evidence-based uses of VV, types of VV, roles and responsibilities of clinicians, situations not appropriate for VV, common challenges, and required adaptations. Providing information to ensure a functional understanding of videoconferencing technology and how to address common technical problems was also identified as basic telehealth

knowledge, as was instruction on specific ways to create a web-based environment supporting rapport. This included creating ground rules for VV and understanding how generational, cultural, educational, geographic, and socioeconomic factors influence a patient's participation in VV. The importance of ensuring privacy in not only the patient's but also the clinician's environment was emphasized as essential to developing rapport and trust. Finally, the experts recommended that basic knowledge of the antecedents (eg, feeling safe and comfortable, privacy, and attentiveness), attributes (eg, shared positive experiences, shared smiles, engagement, and sense of connection), and outcomes (eg, trust, confidence, and collaboration) of rapport were important to teach, along with the unique opportunities and challenges associated with rapport-building in VV.

Skills

The data highlighted essential skills for students and clinicians, including creating a safe and comfortable environment, adapting verbal and nonverbal communication techniques for VV, maintaining attentiveness and presence, and using the web-based environment to humanize the care experience. Experts provided detailed recommendations for each category that helped enrich the survey items developed in round 2. For example, they emphasized the importance of establishing rapport at the beginning of a video visit and monitoring it throughout. Managing the time and flow of the VV to avoid rushing patients and preventing abrupt endings were identified as critical skills. Demonstrating cultural humility and navigating moments of interpersonal disconnection were also identified as crucial for maintaining rapport.

Experts highlighted the need to pace verbal communication to reduce interruptions or "talk overs" and to "narrate the visit" by explaining the clinician's actions that might be unclear or not visible to patients. Using words to replace physical touch to acknowledge emotions and demonstrate care was emphasized. Enhancing active listening techniques, including body language, to reflect empathy and caring was described as particularly important. Examples included placing a hand over the heart to show empathy or leaning into the camera to demonstrate attentiveness.

Participants also stressed the importance of encouraging attentiveness by setting up technology to improve eye contact, sense of presence, and visualization of emotions. Finally, experts noted opportunities within a VV to humanize the experience and build rapport by seeking cues in the patient's environment to know them as a person and identify common interests. Using unique aspects of a VV, such as unexpected pet encounters or technology issues (eg, sharing a laugh about challenges of technology rather than focusing on frustration), to build interpersonal connection was also described as useful.

Attitudes

The importance of cultivating affirming attitudes was mentioned throughout the interview data. This included a willingness to adapt to changing situations with ease, such as making extra efforts to connect in VV and having patience with unexpected situations and technological challenges. Respect associated with entering a patient's home environment digitally was highlighted, as well as respecting the patient's perception of whether a VV could meet their needs. Other attitudes that the experts felt needed to be nurtured included valuing VV as a viable care model and adapting relational aspects of care for VV. Being receptive and excited to learn new skills for VV was also emphasized as an important attitude for educators to foster.

Teaching Strategies

The importance of integrating telehealth adaptations into the standard educational curriculum was frequently discussed in the interviews, and a variety of teaching strategies were recommended. Methods supporting experiential and affective learning, such as simulation with standardized patients and opportunities for self-reflection, were identified. Self-paced modules, videos demonstrating effective and ineffective rapport-building skills, and small group methods like case studies and discussion groups were identified as useful strategies. The opportunity to receive real-time feedback and learn by observing and interacting with preceptors, mentors, and role models was emphasized.

Second Round Results

All 75 items that emerged from the qualitative content analysis in round 1 were presented to the experts in a survey format. Participants rated each item's level of importance from a Likert scale score of 4=very important to 1=not important. The percentage of agreement, the group's mean Likert score, SD, and IQR for each item follow and are organized by the educational areas: knowledge (Table 2), skills (Table 3), attitudes (Table 4), and teaching strategies (Table 5). All 75 items presented to the experts for rating reached the a priori level of at least 70% consensus in round 2. In total, 71% (53/75) of the items achieved 100% consensus, indicating that all 12 experts felt that these items should be included in a curriculum focused on teaching rapport-building in VV. There were very high levels of consensus among the items related to knowledge and attitude. A total of 20 of 22 (91%) of the items in the knowledge domain had 100% consensus, and all 7 items related to attitudes had 100% consensus. In total, 4 of 15 teaching strategy items reached 100% consensus. Table 6 illustrates the strong levels of consensus achieved in round 2.

Table . Level of consensus by educational area and teaching strategy.

Educational areas (total items)	Items with 100% consensus, n (%)	Items with 92% consensus, n (%)	Items with 83% consensus, n (%)	Items with 75% consensus, n (%)
Knowledge (n=22)	20 (91)	1 (5)	0 (0)	1 (5)
Skills (n=31)	22 (71)	4 (13)	3 (10)	2 (7)
Attitudes (n=7)	7 (100)	0 (0)	0 (0)	0 (0)
Teaching strategies (n=15)	4 (27)	4 (27)	5 (33)	2 (13)

The group's mean Likert scores ranged from 2.83 to 4.00 (SD 0-0.985) for each item. The high mean of most of the items also reflects strong agreement on the items evaluated in round 2. Although there were no disputed items, 5 items only reached a 75% consensus level (Table 6). The high levels of consensus resulted in most items having relatively low SD and IQR ratings.

Three items (taxonomy, asynchronous learning, and discussion groups) in particular had lower means, with higher SDs. The median of these items was 3 (IQR 2.25-3), 3 (IQR 3-3), and 3 (IQR 3-3.75), respectively. This suggests that a core group of the experts closely agreed, but a few participants felt differently about these 3 items. The median for real-time feedback with AI was 3 (IQR 2.25-4), and the median for modular learning was 3 (IQR 2.25-4). Both also had high SDs (Table 5). This suggests that these items were more complex or controversial with a broader range of opinions, even though they still met the consensus threshold.

Open-ended responses from several of the experts in this round suggested the need for 2 additional items. This included the importance of incorporating information on ways a clinician could adapt teaching methods in VV and providing opportunities for practicing VV that involved an interprofessional team.

Third Round Results

Since all 75 items in round 2 reached the established consensus threshold, round 3 focused on gathering feedback from the expert panel on the 2 new items developed from the open-ended survey responses in round 2. Consistent with round 2, these items were presented in a Qualtrics survey, with experts asked to rate their importance on a 4-point Likert scale. Both items met the consensus threshold. The first item, "importance of adapting teaching methods to patient learning preferences and experience with videoconferencing," had 100% (12/12) consensus, a mean Likert score of 3.58 (SD 0.52), and a median of 4 (IQR 3-4). The second item evaluated in round 3, "opportunities to practice VV involving an interprofessional team," achieved 92% (11/12) consensus, a mean Likert score of 3.17 (SD 0.58), and a median of 3 (IQR 3-3.75). Open-ended feedback in round 3 suggested distinguishing educational content on patient learning preferences from content on the patient experience with VV, as these are distinct topics. Experts also noted that some patient learning preferences may not be viable options in VV.

Fourth Round Results

The focus of round 4 was to share the study's overall results and provide the experts an opportunity to indicate if these accurately reflected their experiences and perspectives. The participants' responses affirmed the results, and as one expert shared, "Building rapport through video-mediated communication can be challenging, and the items highlighted tangible and effective steps to mitigate this." Some of the experts' responses helped explain areas where there was less than 100% consensus. One expert indicated that in the populations they worked with, patients may not be comfortable with clinicians stating, "I wish I could offer you a hug" or having clinicians humanize a VV by looking for things in their environment. These comments reflected the importance of cultural humility, understanding the context of the VV, and individual patient preferences and perspectives. One expert expressed surprise that having students role-play being a patient did not receive a higher level of consensus sharing, "Empathy is a muscle. If you don't consistently remind yourself what it feels like to be the patient, you are more likely to forget and deliver more callous, depersonalized care."

All the participants indicated that they felt the results could inform interprofessional practice and teaching. As one expert stated,

> *These results can be a great jumping-off point for developing more focused training and education around telehealth communication. Since there seems to be a general awareness of the importance of rapport, but a lack of clarity on the specific skills needed, there's an opportunity to design tools, workshops, or even curricula that help providers build those skills more intentionally.*

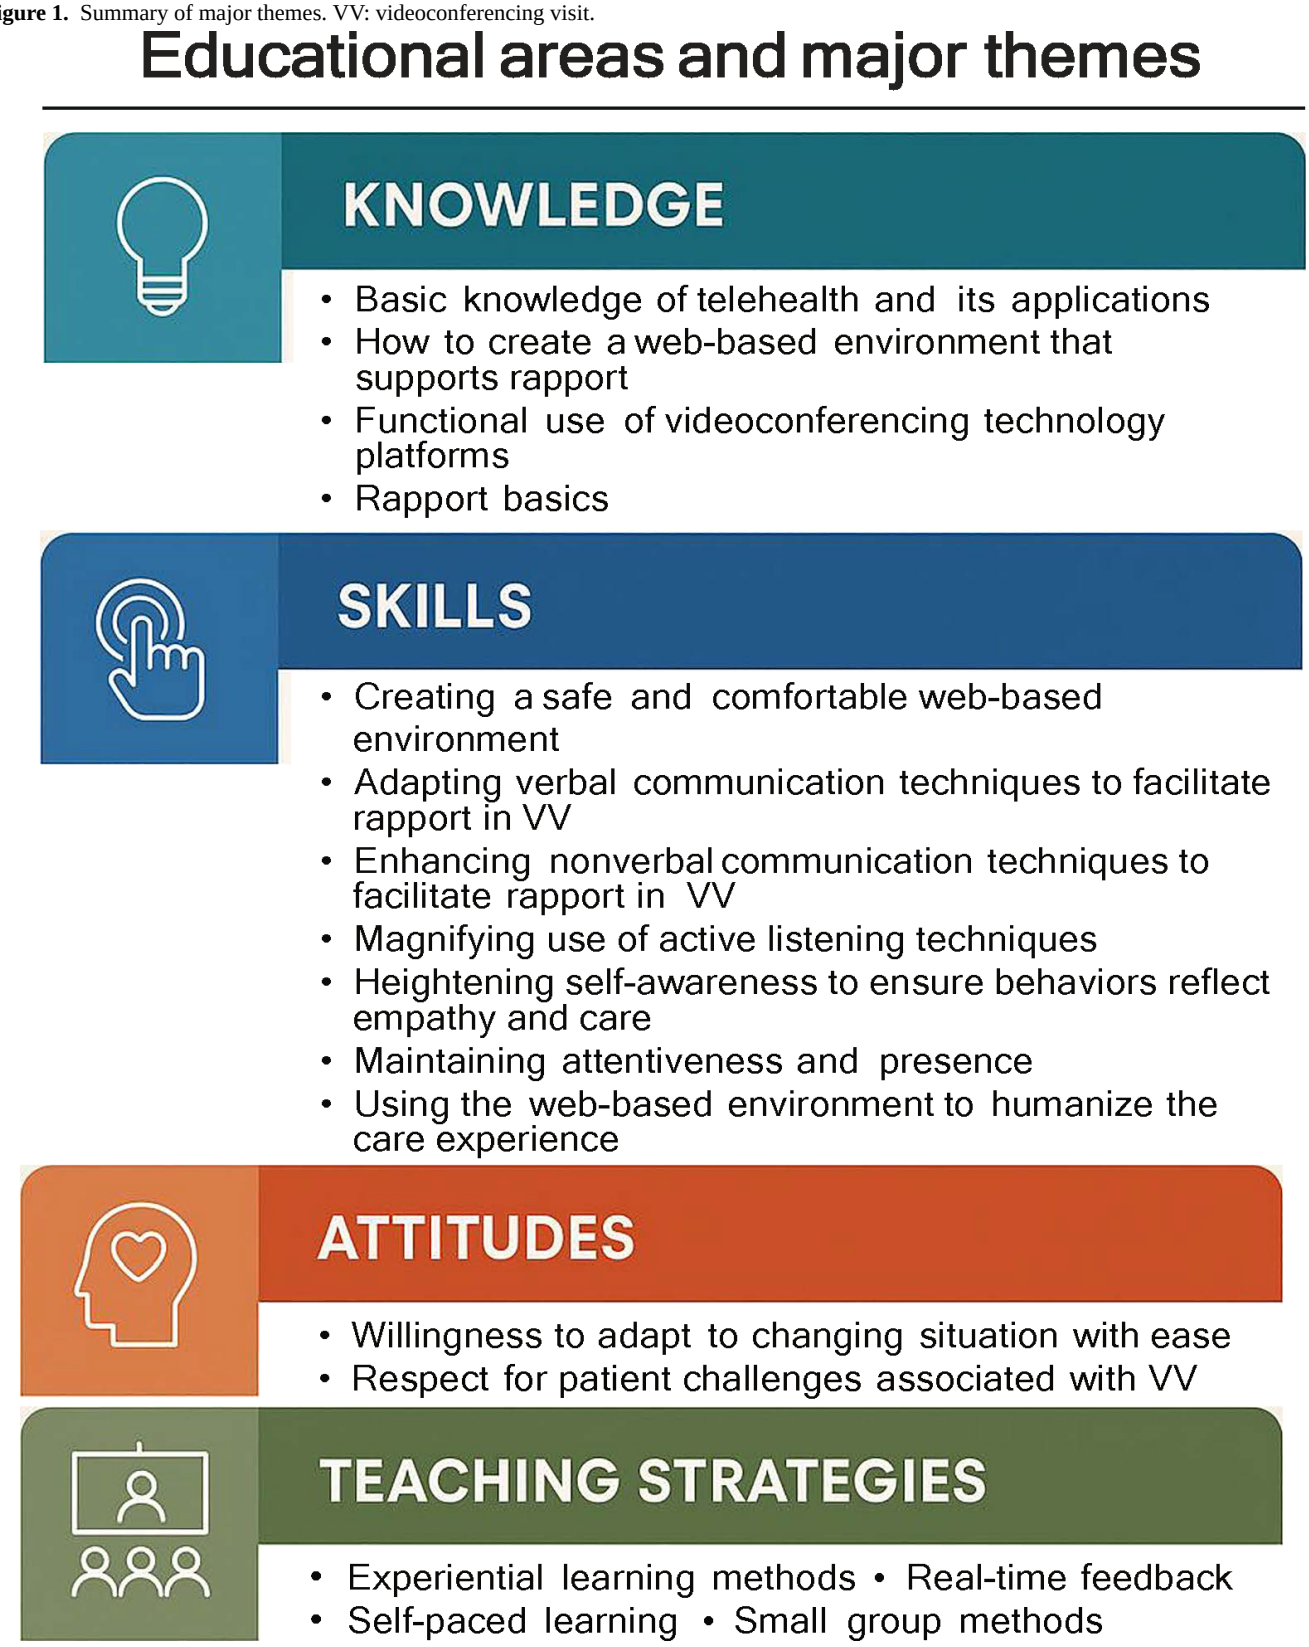
Another shared, "This could really push institutions to start thinking beyond the technology and more about the patient experience."

Discussion

Principal Findings

Teaching and learning how to establish and maintain rapport in VV were identified as important educational gaps. The aim of this study was to build consensus around the knowledge, skills, and attitudes required for health professions students and clinicians to build rapport with patients in VV as well as to identify what teaching strategies best support these educational objectives. This e-Delphi approach was an effective and efficient method for consolidating the expertise of 12 interprofessional telehealth clinicians and educational experts (Figure 1). The high retention rate throughout the study may indicate the importance and relevance of this specific topic to telehealth experts.

Figure 1. Summary of major themes. VV: videoconferencing visit.



The experts quickly agreed on the importance of 19 themes and 77 items to guide curriculum development. The depth and breadth of these themes and items demonstrate the importance of enhancing relationship skills beyond those described in etiquette guidelines or competencies. Although the number of themes and items could be perceived as excessive or impractical to incorporate into telehealth education, evidence that clinicians lack confidence in their relationship-based skills demonstrates the need for a more robust curriculum. The study results provide a comprehensive and useful reference for building a curriculum based on developing knowledge, skills, and attitudes. Like other complex competencies, these may need to be integrated throughout a health profession curriculum or offered in self-paced modules for professional development.

The number of themes and items related to adapting relationship-based care and communication skills for VV demonstrates the importance of this element in the curriculum and aligns with existing research [13,14,20,29]. The expert panel also emphasized the importance of learning to create interpersonal connections at the beginning of a VV and monitor the level of rapport throughout the visit. Additionally, not rushing or ending the VV abruptly and taking time to clearly understand the patient's wants and needs with mutually agreeable care goals were highlighted as important to building rapport. These suggestions align with telehealth best practices reported in oncology and palliative care [29,31,44], as well as practices identified as important in ambulatory care [10,13,45,46].

Similarly, fostering a sense of presence and attentiveness during the VV was a key focus. Many of these items have been reported in other research as important, including how to set up technology to enhance telepresence and body language communication (eg, eye contact, facial expressions, and body posture) and paying close attention to visual and auditory signals that might reflect patient emotion [20,26,47]. Best practices related to camera positioning and eye gaze originally recommended by the American Telemedicine Association [48] have been shown to influence interpersonal comfort and self-disclosure in web-based interactions and may facilitate trust and collaboration [49].

The curricular themes and items also addressed navigating barriers that impact building rapport in VV. Rettinger and Kuhn [50] described internet connectivity issues and a lack of skills in navigating or problem-solving technological challenges in VV as the barriers most frequently described in the 56 studies included in their scoping review. What was highlighted by the experts in this e-Delphi study is the importance of managing these challenges to maximize clinician-patient rapport. In addition to problem-solving skills, the overall attitude of the clinician in managing these challenges was highlighted. The experts felt that patience and light-heartedness were essential attitudes, even suggesting that technological challenges could present opportunities to build rapport around a shared experience. The high level of importance expressed by the expert panel for teaching rapport basics and managing VV challenges affirms the need for clinicians to be proficient and comfortable in both interpersonal and technological skills.

A recent scoping review on rapport in oncology ambulatory care found that more studies focused on nurses' attitudes than knowledge and skills [51]. Attitudes were also identified as critical by the experts in this study, who indicated that without positive attitudes, motivating adult learners to acquire new knowledge and skills becomes challenging. They articulated the need to cultivate positive attitudes toward telehealth and a willingness to adapt interpersonal skills accordingly. This was also identified as an important barrier in the scoping review of Rettinger and Kuhn [50].

Affective competency is reflected in students' ability to conceptualize and internalize subject matter related to attitudes, emotions, or biases in ways that influence their values, decisions, and behaviors [52,53]. Teaching in this domain of learning requires that educators place a greater emphasis on their students becoming caring, emotionally and culturally intelligent, and ethical professionals rather than on their acquisition of factual knowledge [20,53,54]. Achieving this goal necessitates creating a safe learning environment and using teaching strategies that enhance student self-awareness and encourage exploration of diverse perspectives and needs [53,55]. This highlights the importance of building a curriculum and using teaching strategies that address the affective domain of learning and aligns with the importance the experts placed on attitudes and reflective teaching strategies.

Research suggests that opportunities to practice conducting VV with standardized patients and in simulation laboratories have promoted positive learning outcomes [56]. This aligns with the results of this study, where real-time feedback and experiential learning methods reached higher levels of consensus. While module-based learning is evidence-based and necessary, given that this is how many health educational and professional programs are currently delivered [57], the experts in this study emphasized the importance of a learning environment that enabled hands-on practice.

Our results are relevant to various health professions that engage in telehealth. The Interprofessional Education Collaborative (IPEC) Core Competencies for Interprofessional Collaborative Practice [58] provide a framework for interprofessional collaborative practice centered upon 4 competency domains: communication, teams and teamwork, roles and responsibilities, and values and ethics. Each of the 4 competency domains is well-aligned with our panel's insights into effective education for telehealth rapport-building. Specifically, the IPEC competencies in communication and teams and teamwork resonate with our expert panel's emphasis on clear, culturally humble, and empathic communication adapted to the web-based setting. IPEC competency statements regarding communication that is responsive, respectful, and compassionate, as well as practicing active listening, directly relate to skills our expert panel prioritized, such as narrating visits, managing disruptions, and adapting both verbal and nonverbal cues to build rapport. The roles and responsibilities IPEC competency domain align with the panel's suggestion to teach interprofessional learners how to understand one another's scopes of practice and leverage each team member's unique contributions to enhance web-based care experiences. Finally, the values emphasized throughout the IPEC values and ethics domain, which include respect, cultural humility, and patient-centeredness, mirror the attitudinal attributes our experts identified as critical to building trust and interpersonal connection in video visits. The high level of consensus across the Delphi rounds and the incorporation of strategies like team-based practice opportunities, patient privacy, and rapport measurement underscore the practical application of IPEC competencies when designing meaningful telehealth education for various health professions.

Implications and Future Research

The research questions and analysis used a competency-based educational framework often applied by educators when developing competency-based education [59]. Organizing the findings by cognitive or mental skills (knowledge), manual

psychomotor skills (skills), and affective skills (attitudes) was done intentionally to make it relevant and easy for health profession educators to incorporate the results into their existing competency-based telehealth programs. When paired with existing checklists [25,26,46] and professional competency guidelines [3,4,58], these results can support the creation of stand-alone programs on relationship-based care in telehealth or module-based programs that can be integrated into broader telehealth curricula.

Future research is needed to test the feasibility, acceptability, and effectiveness of building curricula based on these competencies. Pilot testing of the proposed curriculum model would be an important next step in evaluating learning outcomes. This could be followed by a controlled study to examine whether these outcomes translate into measurable improvements in perceived rapport scores. In addition, gaining a better understanding of the patient perspective on rapport-building strategies is an important area for further study, along with exploring how these strategies may vary based on the VV context, purpose, and the type of professional conducting the VV.

Strengths and Limitations

The strengths of this study include the collection of data from interprofessional health care clinicians and educators. The use of the ACCORD [43] and multiple strategies to enhance the trustworthiness bolstered methodological rigor. The analysis incorporated a broad range of participants' responses to ensure credibility. Offering participants opportunities in rounds 2 - 4 to review the findings and provide feedback or suggestions also enhanced the study's dependability. The context of the participants was also thoroughly described to allow readers to determine how the findings can be applied in other programs and settings. Although the goal of a Delphi study is to build consensus, there is a risk of forcing conformity [32]. By interviewing participants individually in the first round, this study provided each expert an opportunity to fully share their views and ensured the participants remained anonymous to one another. The rapid and high levels of consensus for most of the items suggest that the analysis of the interview data and subsequent development of survey items were dependable, largely representing the experts' opinions.

This study has several limitations. Given the limited existing research on building rapport in VV, the reliance on expert interviews in round 1 constrained the participant pool. Although purposive criteria guided recruitment, the panel did not encompass all professions engaged in the use and instruction of VV. As such, the panel's composition may not fully reflect the broader population of telehealth clinicians and educators, particularly those in early-career stages. In addition, most participants were based in the United States, which may limit the applicability of findings in international or cross-cultural contexts. This may stem from social and cultural differences in communication norms. In addition, variations in health care systems, technological proficiency, device access, and internet availability across countries may further limit the generalizability of the findings. Finally, although there are no strict guidelines for Delphi panel size, the relatively small sample may not have captured the full range of perspectives. These factors may have increased the risk of selection bias and could affect the validity and generalizability of the study findings [32].

Conclusions

It is widely recognized that a strong rapport between patients and clinicians is essential in VV. Yet, despite this understanding, evidence-based practical guidance on adapting interpersonal skills for web-based care remains limited. This study offers a tangible first step toward addressing this gap. Its results provide detailed guidance on the knowledge, skills, and attitudes necessary for health professions students and clinicians to build rapport in VV settings. In addition to outlining these competencies, the study presents a clear structure, actionable content, and recommended teaching strategies to support curriculum development in health professions education. While web-based care brings numerous benefits, failing to deliberately adapt relationship-based skills for VV risks reducing patient interactions to impersonal, task-focused exchanges. To fully realize the potential of telehealth, it is critical to invest in evidence-based approaches that preserve and promote meaningful interpersonal connections in the web-based environment—for the benefit of both patients and clinicians.

Acknowledgments

This project was supported by small grants, including an award from Duke Academy for Health Professions Education and Academic Development and an Emerging Pedagogies Seed Grant from the Center for Applied Research and Design in Transformative Education, part of Duke University Learning Innovation & Lifetime Education.

Authors' Contributions

PDK, JCDG, and MW designed the study protocol. PDK interviewed all study participants. PDK, DMN, AE, JCDG, and MW coded and analyzed the data. PDK drafted the initial manuscript, and all other authors contributed to critical reviews and revisions of the manuscript. All authors have approved the final manuscript and agreed to publication.

Abstract

Background: Modern health care systems worldwide are facing challenges, and digitalization is viewed as a way to strengthen health care globally. As health care systems become more digital, it is essential to assess health care professionals' competencies and skills to ensure they can adapt to new practices, policies, and workflows effectively.

Objective: The aim of this study was to analyze how the attitudes, skills, and knowledge of medical students concerning digital health have shifted from 2016 to 2022 in connection with the development of the national health care information system architecture using the clinical adoption meta-model framework.

Methods: The study population consisted of 5th-year medical students from the University of Oulu in Finland during 2016, 2021, and 2022. A survey questionnaire was administered comprising 7 background questions and 16 statements rated on a 5-point Likert scale assessing students' attitudes toward digital health and their self-perceived digital capabilities. The results were recategorized into a dichotomous scale. The statistical analysis used Pearson χ^2 test. The Benjamini-Hochberg procedure was used for multiple variable correction.

Results: The study included 215 medical students (n=45 in 2016, n=106 in 2021, and n=64 in 2022) with an overall response rate of 53% (43% in 2016, 74% in 2021, and 42% in 2022). Throughout 2016, 2021, and 2022, medical students maintained positive attitudes toward using patient-generated information and digital applications in patient care. Their self-perceived knowledge of the national patient portal significantly improved, with agreement increasing by 35 percentage points from 2016 to 2021 (P<.001) and this trend continued in 2022 (P<.001). However, their perceived skills in using electronic medical records did not show significant changes. Additionally, students' perceptions of the impact of digitalization on health promotion improved markedly from 2016 to 2021 (with agreement rising from 53% to 78%, P=.002) but declined notably again by 2022.

Conclusions: Medical students' attitudes and self-perceived competencies have shifted over the years, potentially influenced by the national health information system architecture developments. However, these positive changes have not followed a completely linear trajectory. To address these gaps, educational institutions and policy makers should integrate more digital health topics into medical curricula and provide practical experience with digital technologies to keep professionals up-to-date with the evolving health care environment.

Introduction

Modern health care systems around the world are facing challenges due to the aging population, increasing prevalence of chronic diseases, and other lifestyle-associated conditions [1,2]. At the same time, countries are grappling with shortages of the health care workforce, especially in remote and rural areas [3]. Different exposures to health risks create health inequalities between individuals with higher and lower education and income levels [4,5]. These factors put pressure on health care systems to shift their focus toward promoting health and preventing diseases through patient engagement and self-management.

According to the World Health Organization (WHO), the term "eHealth" focuses on using information and communication technologies in health care, while "digital health" serves as a broader umbrella term that also encompasses advanced computer sciences such as artificial intelligence. Furthermore, the term "mHealth," a subset of eHealth, is defined as "the use of mobile wireless technologies for health" [2]. Regardless, digital transformation is seen as an essential component and enabler to enhance the quality, accessibility, and affordability of health services [2,6]. In 2021, the WHO published the Global Strategy on Digital Health 2020 - 2025, seeking to assist nations in strengthening their health care systems through digitalization [7]. The European Union (EU) has named digital solutions as one of the key enablers to deliver health and care services more effectively to patients [8,9]. The COVID-19 pandemic, starting in 2020, and the resulting lockdowns accelerated the technological leap by forcing health care institutions worldwide to swiftly develop and implement digital strategies [10-13].

In 2022, Finland was ranked as the top country in the annual Digital Economy and Society Index report, which monitors the digital progress of the European Union Member States [14]. Accordingly, Finland has a long history of enforcing digitalization in health care [15,16]. One example of this development is the introduction and implementation of the Finnish nationwide, centralized shared electronic data system service, called the Kanta Services, which comprises several service entities such as an electronic patient portal, prescription database, and patient data repository. The implementation of these services has taken place in several stages throughout the 2010s [17-19].

In Finland, the key competence requirements for a graduating doctor have been established at a national level [20]. These requirements are based on international literature, including the UK's Generic Professional Capabilities framework and the International Association for Medical Education guidelines [21-23]. The basic education for medical professionals in Finland consists of 2 years of pre-clinical studies followed by 4 years of clinical training. In the EU, the profession of medical doctor is recognized as a qualification in all member states on the basis of harmonized minimum training requirements [24].

As health care systems become more digital, it's essential to assess health care professionals' competencies and skills to ensure they can adapt to new practices, policies, and workflows effectively [25]. According to current literature, medical students globally have positive attitudes toward learning about digital health and consider the introduction of digital health topics into the medical curricula to be important [26-34]. However, more reserved perceptions toward digital health have also been reported among students [35].

Many nations have made efforts to develop and implement national digital health strategies, including initiatives to incorporate digital health education at local and national levels [36-40]. Furthermore, the European Medical Students' Association has implemented policies emphasizing the inclusion of digital health in medical education curriculum to ensure future doctors in Europe possess crucial digital skills [41], and the recent Digital Health Competencies in Medical Education framework outlines the essential digital competencies for medical education on a global level [42]. Efforts have been made to modernize basic medical education in Finland as well; an example of this is the national MEDigi project (2018 - 2021) funded by the Finnish Ministry of Education and Culture [43]. In addition to digitizing the teaching of medicine and dentistry, the project aimed to ensure a high level of competence in the use of digital health care tools among medical students and to establish national eHealth competence themes [44].

In our previous study, we aimed to compare the attitudes of medical and nursing students toward digital health. Based on the study results, the differences between the 2 student groups were small, and overall, the students' attitudes toward digital health were positive [33]. Now, we seek to deepen our understanding of the changes in medical students' attitudes, skills, and knowledge regarding digital health in relation to the underlying development of the national health care information system architecture. For this purpose, we used the clinical adoption meta-model (CAMM) framework. This framework is developed to describe the health information system adoption over time, and it incorporates 4 dimensions: availability, use, behavior changes, and outcome changes [45]. In this study, the aim is to focus on the third dimension of the model, namely, to describe the behavior changes (attitudes and competencies) of medical students in connection with the development of the national health care information system architecture over time.

Methods

Ethical Considerations

The research was conducted in accordance with the instructions of the Finnish Advisory Board on Research Integrity [46], and in compliance with EU data protection regulations [47] as well

as the established research practices of the University of Oulu and the Faculty of Medicine. Therefore, no approval from the ethics committee was required. Full consideration was given to matters related to data protection in accordance with the ethical principles applicable to research subjects. Participation in the study was voluntary, and students were asked for their consent to collect and use data for the purpose of the study. The students were informed of the purpose of the study and their right to withdraw and prohibit the use of their data at any time. No incentives were offered for participation.

Study Design

The study population for this comparative cross-sectional study consisted of 5th-year medical students at the University of Oulu who participated in a compulsory 1-day digital health course held in spring 2016, 2021, and 2022. The aim of this 1-day course was to provide essential knowledge on digital health and its applications from the perspective of health care professionals. There were 105, 144, and 154 medical students who enrolled in the courses in 2016, 2021, and 2022, respectively. The students were invited to participate in the study via email in 2016, as well as through the course's Moodle environment in 2021 and 2022.

This study adheres to the EQUATOR CROSS (A Consensus-Based Checklist for Reporting of Survey Studies) guidelines for survey research [48]. The checklist was used to ensure comprehensive reporting of study design, data collection, analysis, and interpretation.

Study Questionnaire

After completing the digital health course, a web-based survey was conducted on the students' perceptions of digital health using a Webropol survey tool. The survey was compiled in 2016, and it was developed based on literature and expert reviews [49]. The survey was piloted prior to its use. The pilot group consisted of 2 fifth-year medical students and 2 medical teachers, both of whom had backgrounds in teaching digital health.

The Finnish-language survey questionnaire consisted of 16 statements (Q1-Q16) measured on a 5-point Likert scale ("Fully disagree" to "Fully agree"), surveying students' attitudes to digital health and their self-perceived digital competencies. The survey used in 2021 and 2022 was adapted from the 2016 survey by changing the term "medical doctor" to "health care professional," as nursing students also participated in the 1-day course in 2021 and 2022. An English translation of the latter questionnaire is presented in Multimedia Appendix 1. The statements were related to 5 themes concerning digital health: (1) the usage of patient-generated information and the role of digital applications in patient care; (2) health information systems; (3) digitalization of the working environment; (4) the changing role of patients and professionals; and (5) the culture of experimentation and readiness to participate in innovation activities.

Data Analysis

The 5-point Likert-scale responses "Fully agree" and "Somewhat agree" were combined to form the category "Agree." Similarly, the responses "Fully disagree," "Somewhat disagree," and "Neither agree or disagree" were combined to form the category "Disagree" using Excel (Microsoft Corp.).

The data analysis was conducted using a Pearson χ^2 test to examine relationships between the medical student's digital health attitudes and competencies in 2016, 2021, and 2022. We used χ^2 Calculator by Social Science Statistics to perform the statistical analysis and Effect Size Calculator (effect type: phi) by Statistics Kingdom to calculate effect sizes [50,51]. A *P* value less than .05 was considered statistically significant [52]. Cohen interpretation of the ϕ is as follows: small effect ϕ=0.1, medium effect ϕ=0.3, and large effect ϕ=0.5 [53]. Based on consultation with a statistician, significance values were corrected for multiple comparisons using the Benjamini-Hochberg procedure to control the false discovery rate (FDR =0.25) [54]. According to the Benjamini-Hochberg procedure, *P* values ≤.03 were found to be statistically significant. The results of data analysis, including the χ^2 statistics (χ^2), degrees of freedom (*df*), *P* values, phi coefficients (ϕ), and Q-values, are reported in Multimedia Appendix 2.

Results

Demographic Characteristics of the Study Sample

The sample size of the study included a total of 215 medical students (n=45 in 2016, n=106 in 2021, and n=64 in 2022), with an overall response rate of 53% (43% in 2016, 74% in 2021, and 42% in 2022). No participants were excluded due to incomplete or invalid responses. There were no missing values or other deviations in the questionnaire results. Details regarding gender distribution and age distribution are presented in Table 1.

Table . Demographic characteristics of the study sample (N=215), including gender distribution and age distribution by decade of birth.

Characteristics	Medical students in 2016 (n=45), n (%)	Medical students in 2021 (n=106), n (%)	Medical students in 2022 (n=64), n (%)
Gender distribution			
Women	27 (60)	56 (53)	34 (53)
Men	18 (40)	50 (47)	27 (42)
Other	—[a]	—	3 (5)
Age distribution (birth decade)			
1960	3 (7)	—	—
1970	3 (7)	—	1 (1.5)
1980	20 (44)	13 (12)	7 (11)
1990	19 (42)	93 (88)	55 (86)
2000	—	—	1 (1.5)

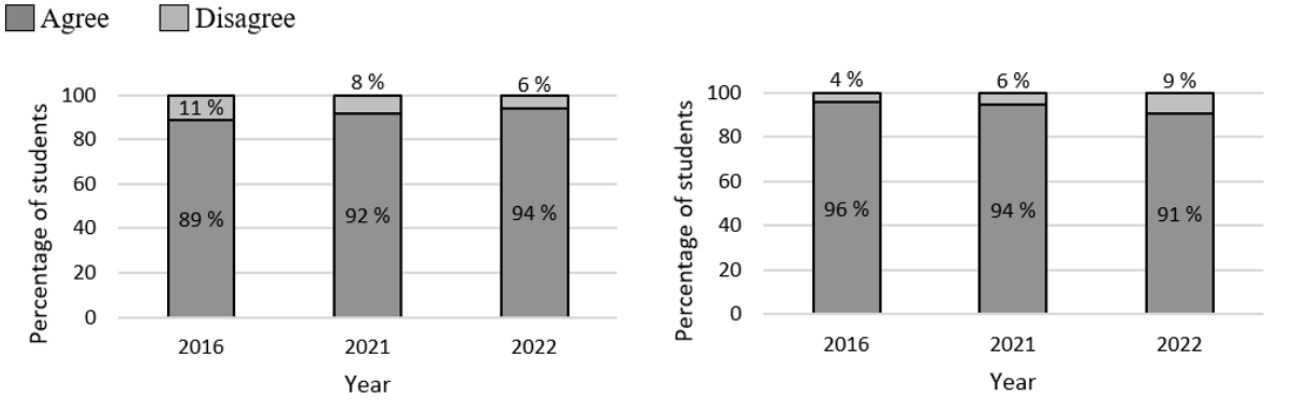
[a]Not applicable

The average working experience in health care sector was 1.1 (SD 1.3) years in 2021 and 0.9 (SD 1.1) years in 2022. In the 2016 survey, 96% of the students had worked as assistants to medical doctors. The work experience of the students in a field corresponding to their prior education was on average 1.1 (SD 2.5) years in 2021 and 0.9 (SD 2.1) years in 2022. While the 2016 dataset likely includes career changers (persons born in 1960 and 1970) [55], we lack sufficient information about their backgrounds to draw definitive conclusions about this.

The Usage of Patient-Generated Information and the Role of Applications in Patient Care

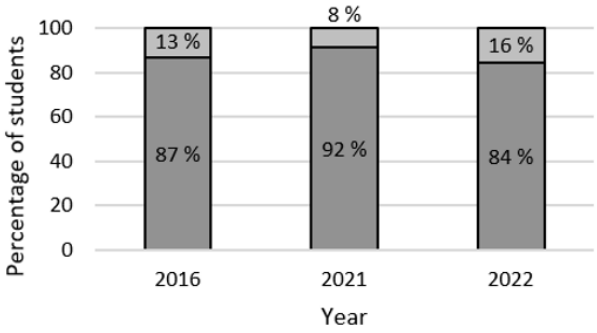
Overall, there were no major changes in medical students' attitudes toward using patient-generated information and the role of digital applications in patient care between 2016, 2021, and 2022 (Figure 1). Students consistently held positive views, asserting that digital applications benefit patients' health and motivation. They also emphasized the importance of health care professionals being proficient in using these applications.

Figure 1. Percentages of students agreeing and disagreeing with each statement related to the theme "The usage of patient-generated information and the role of applications in patient care." A statistical analysis was performed using a χ^2 test.

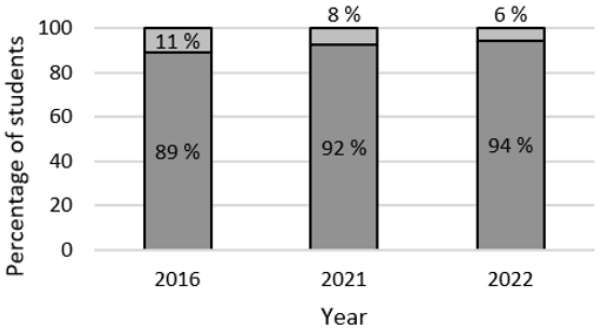


Q1) The usage of health applications by patients contributes positively to their healthcare.

Q2) It is important for healthcare professionals to be able to utilise digital applications in patient care.



Q3) It is important for healthcare professionals to be able to utilise patient-generated health data in patient care.

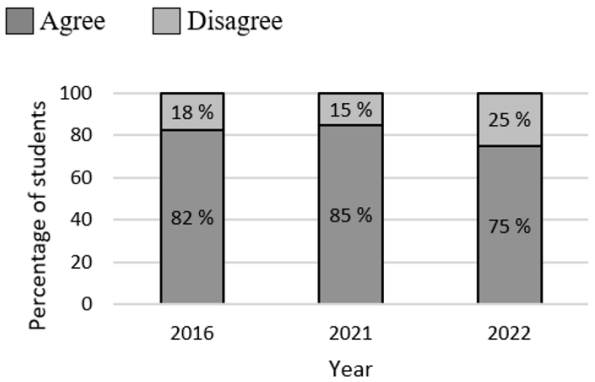


Q4) The engagement of the patient in their treatment and care (e.g., by using electronic self-monitoring and self-care systems) leads to better patient motivation and improved health outcomes.

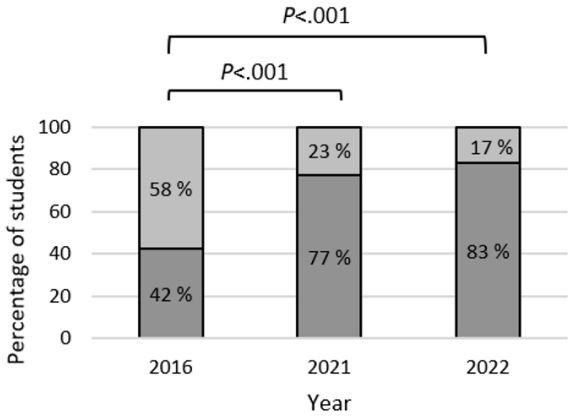
Health Information Systems

There was a significant improvement in the students' self-perceived knowledge of the information contained in the national patient portal (My Kanta Pages), with agreement increasing by 35 percentage points from 2016 to 2021, and this trend continued in 2022 (Figure 2).

Figure 2. Percentages of students agreeing and disagreeing with each statement related to the theme "Health information systems." A statistical analysis was performed using a χ^2 test.



Q5) I know how to use the tools within electronic medical record systems to facilitate my daily work as a healthcare professional.



Q6) I know what kind of information the national patient portal (My Kanta Pages) incorporates and what features it offers to the patient and the healthcare professional.

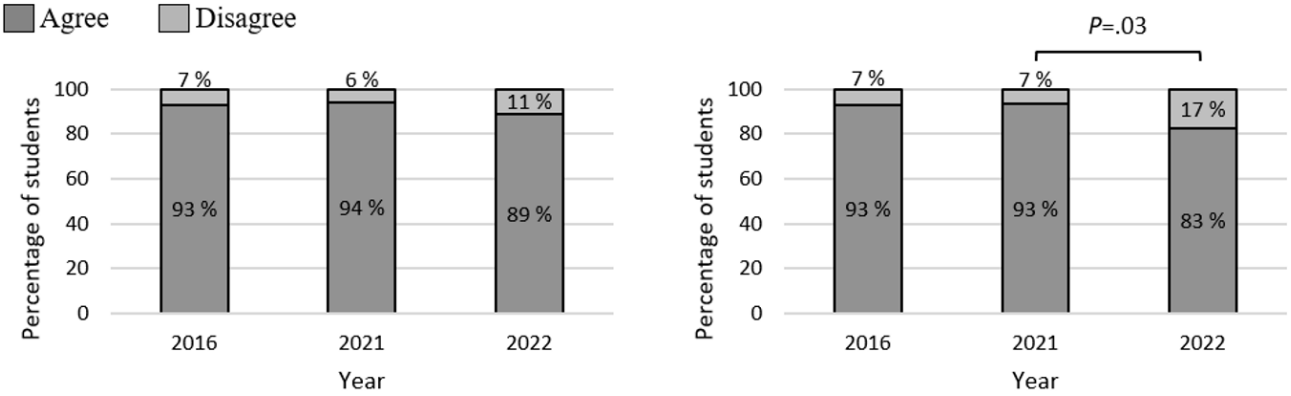
However, there was no significant change in students' self-perceived skills in using electronic medical records over

this period. If anything, the students perceived their skill set to be weaker in 2022 compared to 2016 and 2021, though this difference was not statistically significant.

Digitalization of the Working Environment

The survey data indicates that medical students consistently recognize the importance of digitalization in enhancing health care professionals' working methods (Figure 3). From 2021 to 2022, there was a significant shift in students' perceptions of how digitalization would affect their working lives in the coming years. In 2021, only 7% of the students disagreed that digitalization significantly changes health care professionals' practical work, consistent with 2016. By 2022, this disagreement rose to 17%, demonstrating greater uncertainty.

Figure 3. Percentages of students agreeing and disagreeing with each statement related to the theme "Digitalization of the working environment." A statistical analysis was performed using a χ^2 test.



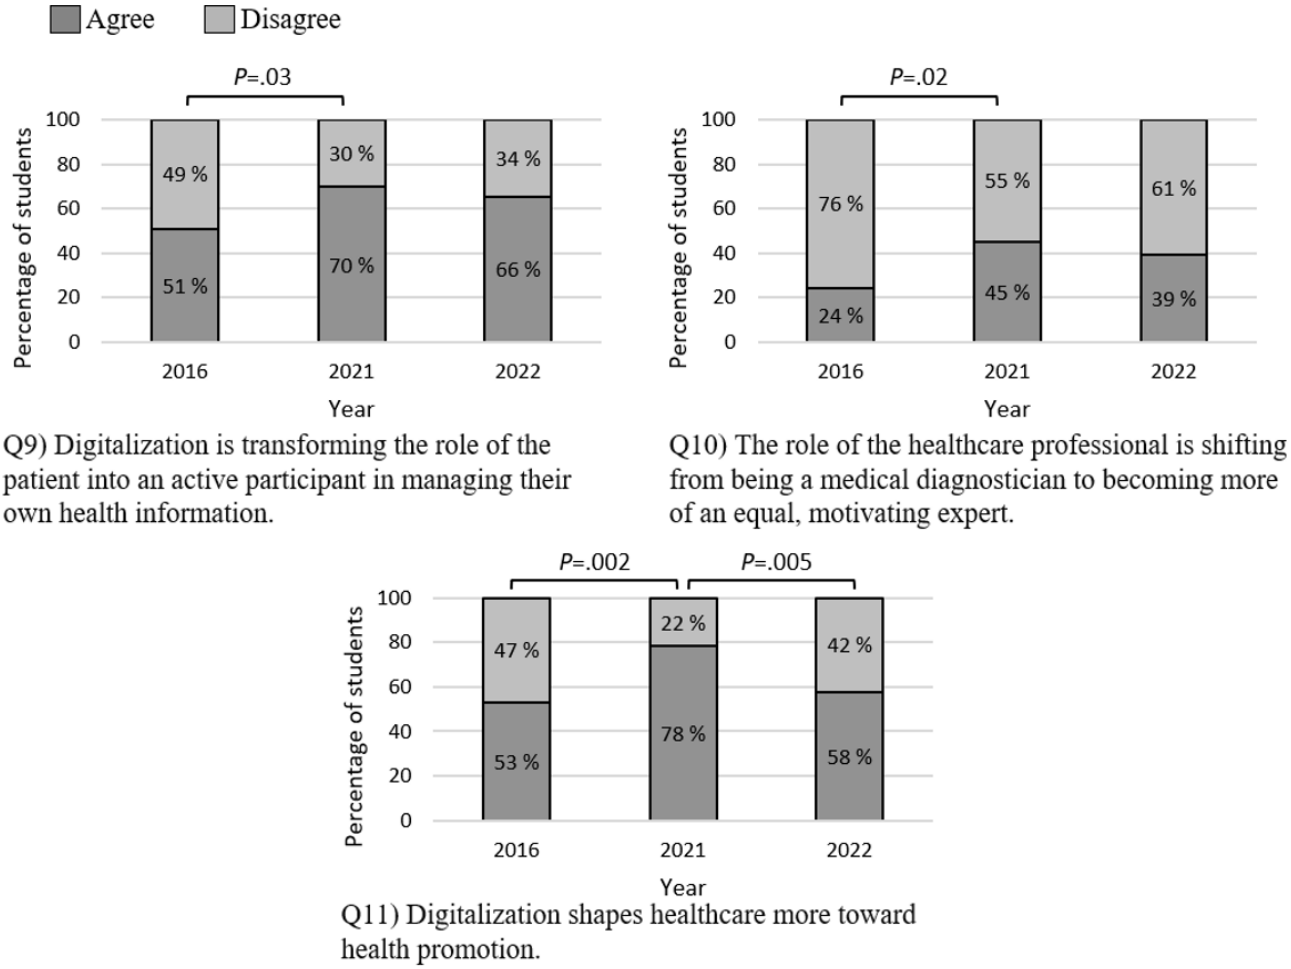
Q7) It is important for healthcare professionals to be able to improve their working methods and/or practices within their work community through digitalization.

Q8) The digitalization of healthcare is expected to significantly affect the practical work of healthcare professionals in the coming years.

The Changing Role of Patients and Professionals

Between 2016 and 2021, medical students' attitudes about the roles of patients and professionals evolved, reflecting increased patient involvement in managing their health information and more equitable relationship between patients and professionals (Figure 4). Additionally, the students' perceptions of the impact of digitalization on health promotion improved significantly from 2016 to 2021 (with agreement rising from 53% to 78%) but declined notably again by 2022.

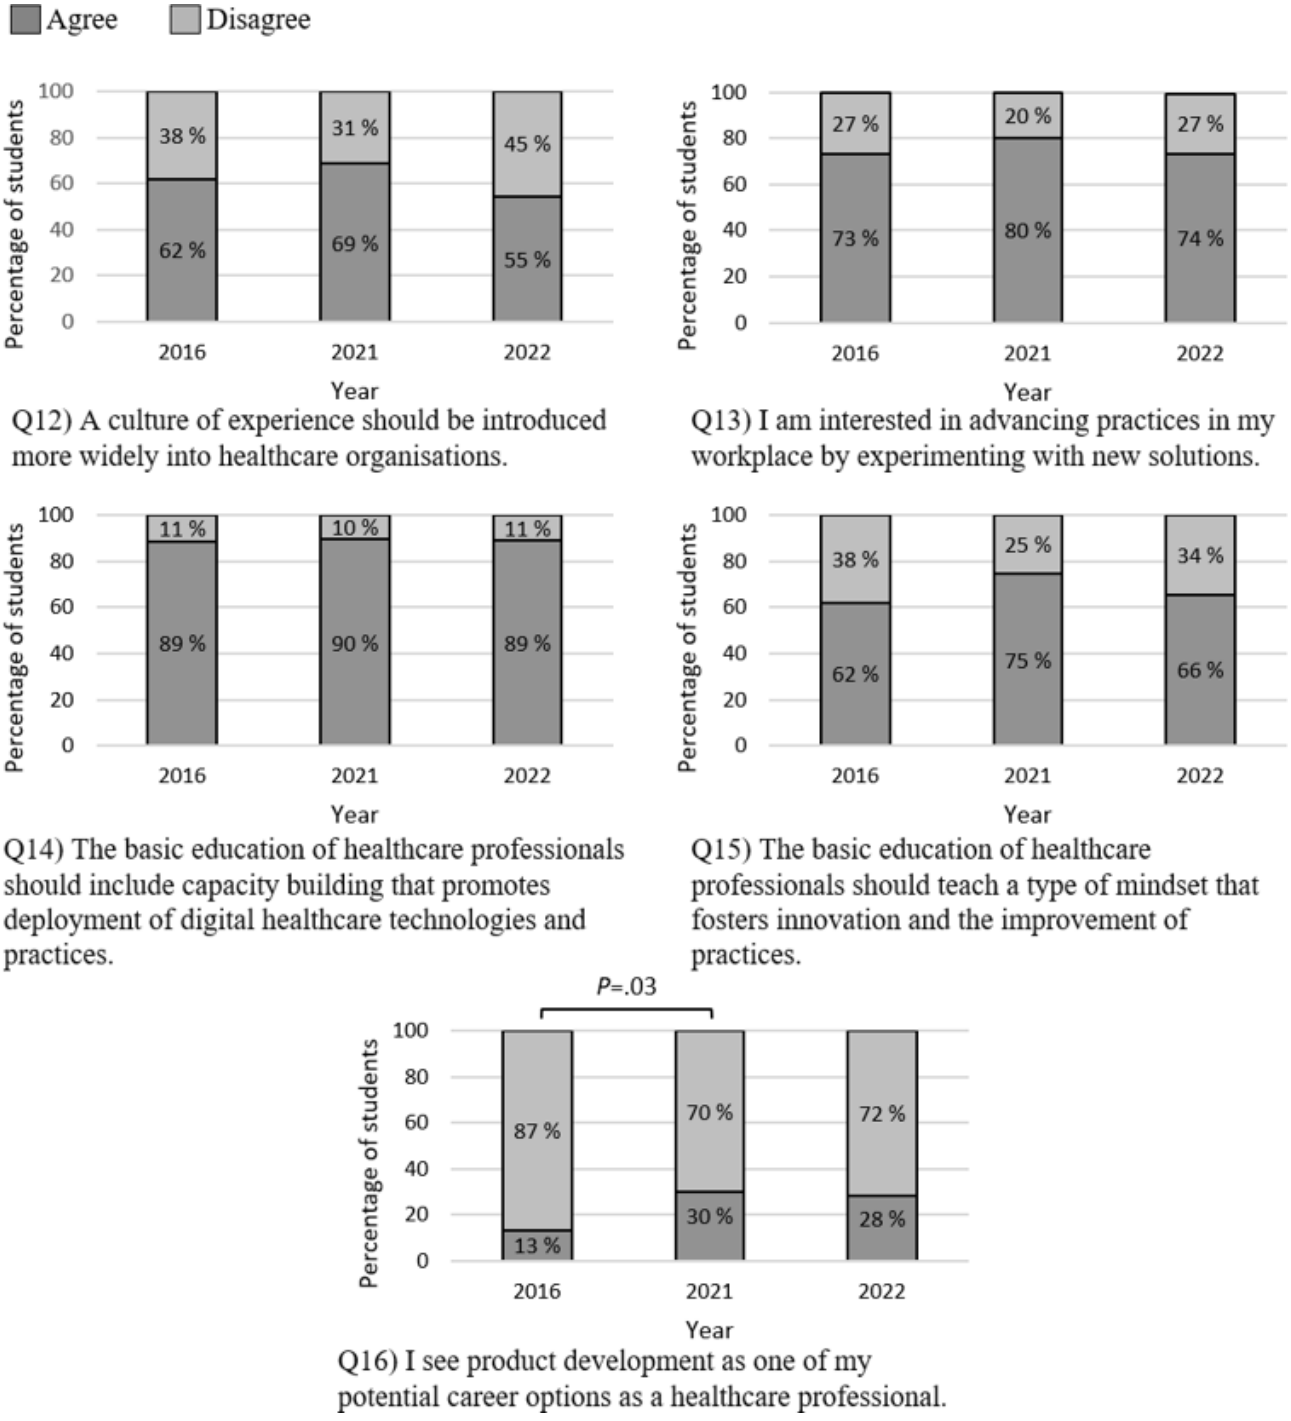
Figure 4. Percentages of students agreeing and disagreeing with each statement related to the theme "The changing role of patients and professionals." A statistical analysis was performed using a χ^2 test.



The Culture of Experimentation and Readiness to Participate in Innovation Activities

The participating students consistently valued the inclusion of digital health topics in basic medical education across 2016, 2021, and 2022, with no significant changes in attitudes (Figure 5). In addition, alternative career options, such as product development, became increasingly appealing, with the percentage of students considering this path more than doubling from 2016 to 2021 and remaining relatively stable in 2022.

Figure 5. Percentages of students agreeing and disagreeing with each statement related to the theme "The culture of experimentation and readiness to participate in innovation activities." A statistical analysis was performed using a χ^2 test.



Discussion

Principal Findings

Overall, we observed a positive shift in the participating medical students' attitudes and an improvement in their self-perceived digital competencies between 2016 and 2022. This coincides with advancements in the national health information system, providing an excellent opportunity to assess the outcomes from the CAMM framework viewpoint. Interestingly, we observed that the changes in attitudes were not consistently linear; while there was a positive trend overall, the 2022 results showed signs of stagnation or decline, with the exception of the students' increasing knowledge of the national patient portal.

To our knowledge, there has been only 1 umbrella review describing health care providers' attitudes to patient portals using CAMM [56]. This study primarily focused on the adoption of patient portals, revealing predominantly reserved attitudes and concerns among professionals, such as increased workload, insufficient training and resources, accuracy of information, and issues related to patient privacy. Our study contributes to this by extensively mapping the attitudes and digital competencies of future health care professionals, reflecting potential changes connected to the advancements in the national

health information system architecture across three different time points. In our work, students' self-perception of knowledge of the national patient portal had significantly improved. Our data also indicated that, as early as 2016, medical students valued the importance of using patient-generated information and patient engagement via self-care systems relatively high, with 87% and 89% of the students, respectively. This might indicate that while there have been initial concerns among professionals, future professionals are increasingly recognizing the value of digital tools and patient engagement.

In our study, medical students perceived the use of digital applications and patient-generated data in patient care as a positive factor: there were no statistically significant differences in the participating students' attitudes between 2016, 2021, and 2022 (see Figure 1). From a system adoption point of view, this finding suggests that the widespread use of digital applications had already prompted students to recognize their importance as early as 2016. EU legislation has emphasized the role of medical and health digital applications as a part of patient empowerment and has also recognized potential risk aspects [1,57]. Both the WHO and the European Commission have participated in establishing the European mHealth Knowledge and Innovation Hub as part of the Horizon 2020 project [58]. The initiative aims to support the integration of mHealth services into the national health systems of European countries.

Our results indicate a significant improvement in medical students' knowledge of the national patient portal since 2016 (see Figure 2, Q6). We believe that this development may be linked to the introduction and implementation of new national health information exchange services in the 2010s and beyond. For example, the implementation of the national patient data repository in public health care in Finland was only completed in late 2015, less than a year before our first data checkpoint [15,19]. Similar nationwide systems for the exchange of health information between patients and professionals can be found in several countries [59], but studies on students' competencies in the use of these systems are scarce in the literature. Additionally, we discovered that students in 2022 rated their ability to use electronic patient record systems slightly lower than students in both 2021 and 2016. Although this finding was not statistically significant, we know that requirements for recording patient data have become more demanding, and the functionalities of the systems have increased [60]. These trends may have influenced the students' perceptions in 2022.

Prior research indicates that medical students have concerns regarding the impact of digitalization on the patient-doctor relationship [28,35]. Our study reveals a shift in attitudes related to the roles of patients and professionals. We discovered a statistically significant difference between 2016 and 2021 in the attitudes of participating students toward patients' roles in managing their health information and collaborating with professionals. Additionally, students in 2021 recognized the role of digitalization in shaping health care toward health promotion. These findings align with both national and EU health strategies, which emphasize electronic services to support the active role of citizens in maintaining their own well-being [1,61]. In Finland, the national health exchange services were complemented by a personal health record repository service (Kanta Personal Health Record or Kanta PHR), which entered its first-phase production in 2018 [19]. The service allows citizens to input, store, and share their well-being data with professionals. At the EU level, the EU is establishing a European Health Data Space ecosystem aiming to empower individuals of member states with control over their health data [9].

Overall, we saw slightly more reserved attitudes toward digital health in 2022 compared to 2021. The assertion to presentation 'The digitalization of healthcare is expected to significantly affect the practical work of healthcare professionals in the coming years' was notably less supported in 2022 compared to 2021 (see Figure 3, Q8). This trend suggests that electronic health services and tools have become fully integrated into the health care system. It may even indicate that, from the students' perspective, digitalization has reached its apex in health care. This shift could be linked to the advancements in digital health education in the basic medical training in Finland, such as the completion of the national MEDigi project in 2021 and the introduction of its eHealth competence areas in 2020 [43,44].

Another noteworthy discovery was the significant increase in the number of students who agreed that "Digitalization shapes health care more toward health promotion" between 2021 and 2022, followed by a notable decrease in agreement between 2021 and 2022 (see Figure 4, Q11). This change in attitudes could be partly linked to the "care debt" and prolonged waiting times for treatment that emerged during the global health emergency caused by the COVID-19 pandemic in 2020 - 2023 [62,63]. It is also possible that after over 2 years of remote and blended education, students in 2022 may be exhibiting signs of digital fatigue [64,65]. As a result, the enthusiasm for digitalization driven by the COVID-19 pandemic may have started to decline by 2022. Nevertheless, these trends require further research to fully comprehend the underlying causes behind the phenomenon. The more reserved attitudes of the participating students and their somewhat lower self-assessed skills suggest the necessity for an increased focus on digital training for future health care professionals. This is crucial to ensure their competencies align with the broad health strategies in Europe and on a global scale.

The medical students who participated in this study in 2016, 2021, and 2022 were aligned in their belief that the basic education of health care professionals should include capacity building promoting the deployment of digital health solutions (see Figure 5, Q14). This consensus resonates with findings from previous studies [26-34]. The students' attitudes shifted positively toward alternative career paths such as product development (see Figure 5, Q16). This change was statistically significant between 2016 and 2021: in 2016, only 13% of students agreed with this claim, whereas almost a third of the students agreed with it in 2021. Although the difference between 2016 and 2022 was not statistically significant, the trend was consistent with percentages of 13% and 28%, respectively. This is an important finding, as end-user involvement is considered a critical success factor in information technology projects [66-69]. A Finnish study revealed that younger physicians were more eager to participate in health information system development compared to their older counterparts [70]. Additionally, research indicates that interdisciplinary

collaborations between health care and engineering professionals can foster innovation and new practices, underscoring the importance of interprofessional education [71,72]. However, introducing digital health topics and innovation activities into medical curricula has proven to be challenging in practice due to crowded curricula designs and competing interests [29,73-75].

Strengths and Limitations

Our overall response rate was 53%. Our study sample was collected from one of the 5 Finnish medical universities at 3 different time points. The results are likely to be applicable to other Finnish medical faculties given the similar surrounding health care system and relatively homogeneous education system [20,43]. Furthermore, these findings may also have relevance to other countries, particularly those with similar health care systems, health care information system architecture, and medical curriculum design. However, confirming this would necessitate further research.

There are also several limitations to this study. Firstly, we had a relatively restricted sample size from 1 education institution, which may affect the generalizability of the findings. While cross-sectional studies are useful for examining associations, causal relationships cannot be established, which should be considered when interpreting the findings. We relied on self-assessment to evaluate competencies in this study, which means we were unable to measure absolute changes in skills and knowledge. Because of minor variations in the collection of demographic characteristics among the study sample, a statistical comparison of the students' demographic characteristics could not be conducted. Furthermore, the dichotomization of variables may potentially hinder the reflection of results in real-world situations.

Future research should aim to include larger and more diverse samples from multiple institutions and possibly from other health care professions to enhance the generalizability of the findings. Additionally, longitudinal studies could provide more insight into causal relationships and how the attitudes and capabilities of the students may shift after entering working life. More information on the best teaching strategies for digital health topics is needed to facilitate optimal learning outcomes for health care professionals.

Conclusions

There has been a shift in self-perceived digital competence and attitudes of medical students over the years, potentially influenced by the development of national health information system architecture. However, this change has not followed a completely linear trajectory, and students' attitudes toward digital health have become somewhat more reserved in certain areas over time, particularly regarding the extent to which digitalization alters health care processes and its role in health promotion.

To address these gaps, medical educational institutions and policy makers should consider integrating more digital health topics into curricula, offer practical experience with digital health technologies, and implement effective teaching strategies for digital health. Given the rapid evolutions of the health care field, it is crucial to ensure the professionals keep up with the changes of this dynamic working environment. The integration of digital health education should be carefully considered and evaluated to ensure it meets the needs of both students and health care systems.

Acknowledgments

We would like to thank all the students who participated in this study as well as well as Lingsoft Language Services (Ltd) for English language editing of the manuscript.

Authors' Contributions

PV, TT, PK, EJ, JJ, AT, MM, TP, and JR were responsible for the conception and design of the study as well as the acquisition and interpretation of the data. PV conducted the statistical analyses and drafted the tables and figures. PV wrote the original draft conceptualization. TT, PK, EJ, JJ, AT, MM, TP, and JR reviewed and edited the manuscript. TP was responsible for the conception and design of the survey questions and the study as well as commenting on the manuscript. The final version of the manuscript was approved by all contributing authors.

Conflicts of Interest

The employer of PV, PK, TT, and JR received support for salaries from the MEDigi project funded by Finnish Ministry of Education and Culture (MEDigi OKM/270/523/2017). Otherwise, the authors declare no other known competing financial interests or personal relationships that may have influenced the work reported in this paper.

Abstract

Background: The increased use of digital data in health research demands interdisciplinary collaborations to address its methodological complexities and challenges. This often entails merging the linear deductive approach of health research with the explorative iterative approach of data science. However, there is a lack of structured teaching courses and guidance on how to effectively and constructively bridge different disciplines and research approaches.

Objective: This study aimed to provide a set of tools and recommendations designed to facilitate interdisciplinary education and collaboration. Target groups are lecturers who can use these tools to design interdisciplinary courses, supervisors who guide PhD and master's students in their interdisciplinary projects, and principal investigators who design and organize workshops to initiate and guide interdisciplinary projects.

Methods: Our study was conducted in 3 steps: (1) developing a common terminology, (2) identifying established workflows for research question formulation, and (3) examining adaptations of existing study workflows combining methods from health research and data science. We also formulated recommendations for a pragmatic implementation of our findings. We conducted

a literature search and organized 3 interdisciplinary expert workshops with researchers at the University of Zurich. For the workshops and the subsequent manuscript writing process, we adopted a consensus study methodology.

Results: We developed a set of tools to facilitate interdisciplinary education and collaboration. These tools focused on 2 key dimensions— content and curriculum and methods and teaching style—and can be applied in various educational and research settings. We developed a glossary to establish a shared understanding of common terminologies and concepts. We delineated the established study workflow for research question formulation, emphasizing the "what" and the "how," while summarizing the necessary tools to facilitate the process. We propose 3 clusters of contextual and methodological adaptations to this workflow to better integrate data science practices: (1) acknowledging real-life constraints and limitations in research scope; (2) allowing more iterative, data-driven approaches to research question formulation; and (3) strengthening research quality through reproducibility principles and adherence to the findable, accessible, interoperable, and reusable (FAIR) data principles.

Conclusions: Research question formulation remains a relevant and useful research step in projects using digital data. We recommend initiating new interdisciplinary collaborations by establishing terminologies as well as using the concepts of research tasks to foster a shared understanding. Our tools and recommendations can support academic educators in training health professionals and researchers for interdisciplinary digital health projects.

research question; digitalization; digital data; data science; health research; interdisciplinary

Introduction

Background

Health research increasingly leverages the abundance of data from our "digital lives," including mobility data, social media data, or data from wearables [1,2]. Such digital data are commonly "unstructured" because it may not conform to a tabular format (eg, images, videos, sound, and free text) and often require specific expertise for harvesting; transforming; preprocessing; and creating meaningful insights into health, disease, and treatment [1,3-5]. Moreover, such digital data are often originally generated for nonresearch purposes and without addressing a specific research question [6]. In turn, they may lack standard quality attributes found in digital data collected for specific research purposes, such as depth, completeness, or consistency, which present methodological complexities to meaningfully use these data [1]. Therefore, reusing these digital unstructured data for health research requires diverse expertise, skills, and interdisciplinary collaboration between health domain experts (eg, clinicians and health scientists) and data scientists as method experts (eg, from data science, computer science, or statistics) [5,7,8].

Such interdisciplinary collaborations are often faced with challenges due to the seemingly conflicting research approaches between the disciplines. In addition to differences in terminologies and concept definitions, the prevailing emphasis of linear deductive approaches in health research contrasts with the often more explorative and iterative approaches used in data science [7]. In health research, it is customary to predefine key elements of the scientific process, including a research question and related hypothesis, in a protocol and scientific report (eg, STROBE [Strengthening the Reporting of Observational Studies in Epidemiology] or PRISMA [Preferred Reporting Items for Systematic Reviews and Meta-Analyses] guidelines) [9-12]. These standard practices are deeply influenced by the tradition of clinical trials and treatment development, which place a strong emphasis on measurement validity, robustness, scientific rigor, and safety [13], as errors in study conduct or treatment could place study participants at risk. By contrast, data science generally tends to emphasize exploration, pattern discovery, or hypothesis generation as well as more iterative and inductive analysis approaches [1,14]. Some health researchers may perceive this greater emphasis on iterative approaches as lacking scientific rigor or focus on specific research questions.

For young researchers, interdisciplinary digital health collaborations might be particularly challenging because they need to balance traditional scientific methods with more iterative data-driven techniques. This dual demand highlights the importance of fostering interdisciplinary skills in education, enabling students to balance the rigorous demands of hypothesis-driven research with the iterative and inductive approaches of data science. Addressing these complexities represents an educational challenge for both established and young researchers.

Despite broad recognition of their importance, both practical and teaching or educational guidance on how to manage and overcome the challenges of interdisciplinary digital health collaborations are scarce. Such guidance is also important for educational purposes to foster skills for interdisciplinary collaboration among both young and established researchers as well as health professionals. Continuous education for experienced researchers is equally important to keep them updated with evolving methods and foster effective collaboration across disciplines.

This Study

To address this need, our study focuses on skill development to successfully navigate interdisciplinary collaborations and education in health-related research fields. We reviewed established workflows for research question formulation and investigated whether and how established workflows in health research may require adaptations to accommodate inductive and exploratory data science practices and novel analysis techniques. The study findings were translated into a set of tools and recommendations designed to facilitate interdisciplinary education and collaboration. These tools focus on 2 key

dimensions—*content and curriculum* and *methods and teaching style*—and can be applied in various educational and research settings. Lecturers can use them to design interdisciplinary courses, supervisors can guide PhD and master's students in their interdisciplinary projects, and principal investigators can design and organize workshops to initiate and guide interdisciplinary projects. By implementing these tools, educators and researchers can create more cohesive and productive educational resources for interdisciplinary collaborations. In the following sections, we offer our insights and a more detailed outline of how our study findings can inform both the *content* and *methods* dimensions, using an existing interdisciplinary course as an example.

The aims and findings of our study are intended to be globally relevant and applicable to all researchers using digital data in the context of health research and health care. Importantly, they also provide academic educators with a clear workflow and practical recommendations for discussing and addressing the challenges of interdisciplinary collaboration. As the focus is on research question formulation, a fundamental aspect of the research process, these recommendations are especially valuable for educational purposes, helping educators guide researchers and students through this essential phase of research projects.

To achieve our aims, we chose a consensus study approach that is appropriate to harmonize and bridge insights from experts from diverse research disciplines. Moreover, we focused our effort on the different approaches of research question formulation as the guiding example for this study because it represents a central step in guiding the research process and subsequent study design decisions. This process also served as an illustrative example to highlight the differences in research approaches between health research and data science.

Methods

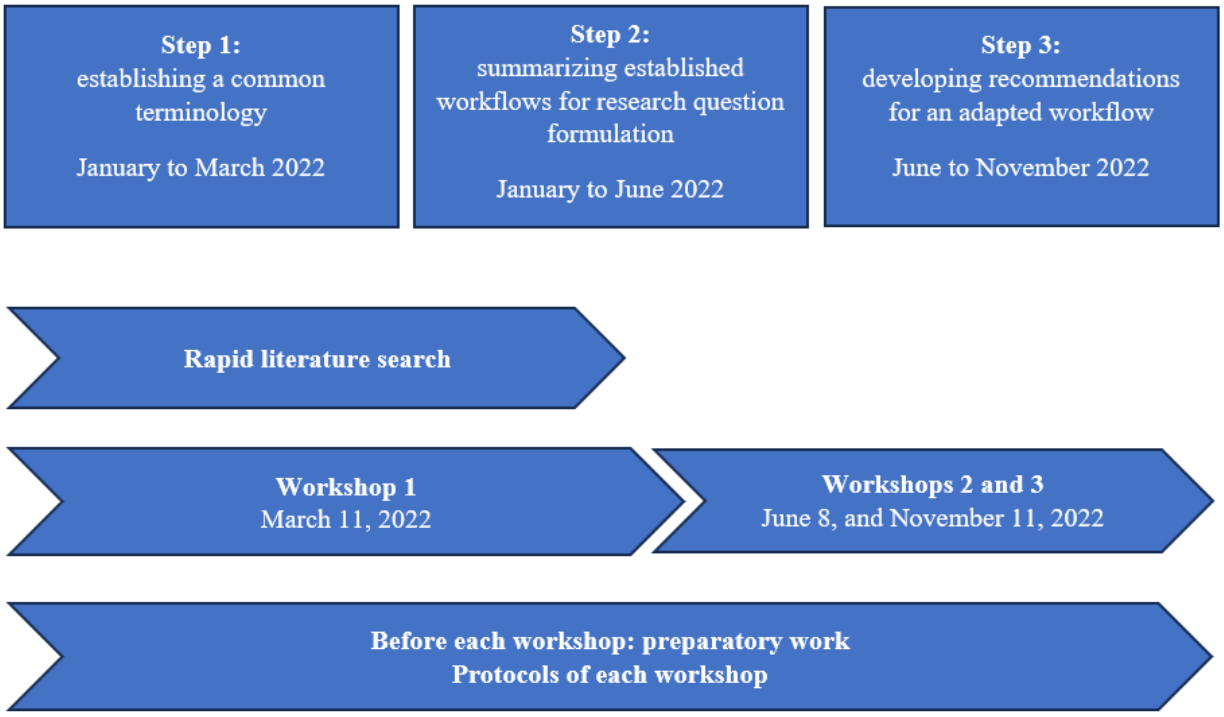
Consensus Methods

We used the nominal group technique with expert groups to gather insights from a diverse range of experts. This approach aimed to foster interdisciplinary skills and knowledge and achieve consensus on adapting research question development.

This study was structured by the following three high-level steps (Figure 1):

1. To create a common terminology to facilitate interdisciplinary and transdisciplinary collaborations that are required for research projects reusing digital data (ie, repurposing data originally generated for nonresearch purposes)
2. To describe the "established workflow" for research question formulation in health research on the basis of existing literature
3. To formulate suggestions and recommendations for adapting the "established workflow"

Figure 1. Study flow.



To inform steps 1 and 2, a rapid literature review was performed to identify established concepts for defining a research question in health research and data science as well as in other fields (refer to the Preparatory Research: Literature Search for the "Established Workflow" and an Example Scenario section). Expert inputs were gathered in a series of three 1.5-hour expert workshops. To foster a focused discussion in the workshops, participants were asked to complete preworkshop tasks. These inputs were summarized by JS and VvW and presented at the beginning of each workshop to discuss potential disagreements and allow participants to explain or comment on their and others' inputs. The consensus and agreement of each objective

were reached by an iterative, deliberative process. This included expert inputs before workshops, discussions during the workshop, and finally, expert feedback on and approval of the consolidated findings. These findings were synthesized, formulated, and shared by JS and VvW after each workshop. Furthermore, each participant was actively involved in the manuscript writing. These methods facilitated the systematic collection of input from participants in group and individual settings, enabling a comprehensive understanding of experts' knowledge and consolidating diverse perspectives. Workshops were recorded after receiving consent from the team. Workshop minutes, including the results of the preworkshop tasks, were sent for approval to the expert group. When necessary, individual researchers were contacted after workshops for clarification on specific issues raised during the workshops. The documentation and reporting of the workshop and the Accurate Consensus Reporting Document (ACCORD) checklist [15] for the consensus methodology are available in Multimedia Appendices 1 and 2.

The first 2 steps were accomplished in workshops 1 and 2. Building on these results, a third workshop was dedicated to identifying the need for the adaptation of established research practices in the health field to streamline collaboration with data scientists and to better integrate and communicate the need for research principles and standards, including open science and reproducibility.

Participants

The consensus meetings in the form of expert groups were led by JS and VvW, who led a previous project focusing on challenges and best practices of digital data, which inspired this study. Furthermore, JS is a scientific manager of the scientific community whose members were recruited for the consensus exercise. VvW's expertise lies in epidemiology and digital health research, and JS's expertise is mainly in digital ethics considering health research and health care. The workshop participants were recruited by JS and VvW among the diverse members of the Digital Society Initiative (DSI) Health Community at the University of Zurich. The members from the DSI were selected because it is a competence center for digital transformation that fosters interdisciplinary collaborations and projects studying the interplay and implications of digital transformations in society. Participants were included if they had experience with projects using digital data or planned to be involved in such projects. The workshop was promoted on the DSI website, through newsletters, and via word-of-mouth within the community. A total of 21 researchers from different disciplines and from all career stages participated in the workshops. This number of participants enabled to have an expert group with sufficient diversity to foster discussions and include insights from diverse disciplines. Of the 21 researchers, 13 (62%) represented health research, 3 (14%) represented data science, and 7 (33%) represented the social sciences and humanities.

Preparatory Research: Literature Search for the "Established Workflow" and an Example Scenario

A rapid literature search was conducted to inform the planning of the workshops and to develop a project roadmap (by JS and VvW). To gather information on the established workflow for research question formulation (steps 1 and 2), we searched the literature for publications, reviews, and course guidelines written either in English or German in PubMed and Google Scholar databases (search terms are provided in Multimedia Appendix 1). The search was further complemented by retrieval of guidelines from universities in Switzerland, Germany, the United States, and the United Kingdom, for which we searched on selected university websites. In addition, coauthors contributed materials they were familiar with or had previously used for teaching or research purposes. On the basis of this literature, we proposed the initial model for the "established workflow" that combines existing well-established frameworks and practices. To guide the discussions of our workshops, we developed an example scenario of digital data reuse for health research, which was communicated to participants before the workshops (Multimedia Appendix 3).

Ethical Considerations

The study followed the recommended procedures of the ethics committee of the Medical Faculty of the University of Zurich by completing the Data Protection/Ethics Self-Assessment Tool and received an exempt status. Participants were informed about the study's scope and goals as well as the nature of their involvement. They provided consent before the workshop and were informed that they could withdraw from the study at any time without providing a reason. The participants did not receive any compensation for their participation. The only personal information collected for the study was sociodemographic data, which were anonymized.

Results

Establishing a Common Terminology

Anticipating that a lack of harmonization concerning terminologies and concepts may hinder an effective interdisciplinary workshop collaboration, we aimed to establish a shared understanding of common terminologies. To this end, the workshop leaders (JS and VvW) developed a glossary before the first workshop, which was discussed and further refined by collecting written feedback from the participants after workshop 1 (Table 1).

The workshop discussions concerning the glossary centered around discipline-specific interpretations of concepts such as "research task," "research objectives," "research aims," and "research goals," whose interpretations were dependent on the embedding in different research methodologies, such as qualitative or quantitative research approaches. A central discussion centered around the recognition of different "research tasks," that is, high-level research aims from a methodological viewpoint, including, for example, exploration, confirmation, prediction, methods development, or theory development. For prediction and classification tasks, participants mentioned 2 subcategories of analyses, which are supervised learning methods that rely on labeled data and outcomes and include the broad class of (multivariable) regression models. By contrast, unsupervised methods (eg, neural networks) aim to find new data structures and features without the need for prior labeling and are often developed in a less linear, inductive manner.

Table 1. Common terminology for interdisciplinary research projects using digital data.

Terms	Definitions
Confirmatory research	• Hypothesis-driven research, experimental research, or research aiming at testing and confirming a hypothesis in a broader context of a theory. This research is also referred to as hypothetico-deductive research in some disciplines.
Exploratory research	• Data-driven research that aims at exploring new patterns and associations to formulate hypotheses.
Hypothesis	• A tentative, hypothetical prediction of the nature and direction of relationships between sets of data, phrased as a declarative statement. It is an assumption about scientific laws, causation, or empirical regularities. A hypothesis should be testable or falsifiable. This refers to quantitative evidence-based health research.
Unstructured data	• Raw data that are not in a predefined structure (eg, tables) or data that may be structured but still require substantial preprocessing or feature extraction (eg, continuous sensor data).
Principles and criteria of good research and research practice	• A set of values and norms for good conduct of research, including validity, scientific integrity, objectivity, and ethical study conduct.
Research aim	• The research aim is the overall, general, and long-term intention of a research project. The research aim describes the "what" of the research—where we aspire to be at the end.
Research design	• Research design describes the general outline of data collection (eg, cross-sectional and longitudinal studies) and analytical methods (eg, randomization, observational, and with or without control group) to answer the RQ[a]. It describes the "how" of research.
Research objective	• The specific goal linked to a RQ [16].
Research problem	• The research problem describes the rationale for a study, for example, by highlighting the societal or medical needs. It describes the "why"—the specific needs a study wants to address.
RQ	• A clear and concise question determining the research aim, objective, design, methodology, data collection, and analysis. The RQ narrows the aim and objective of the research. The process of defining a good RQ is dynamic and iterative. The RQ is refined through the different steps of the research cycle. We define the RQ in the context of quantitative evidence-based health research.
Research task	• A research task describes a high-level classification of aims or tasks in research, including descriptive research, exploratory research, confirmatory research, prediction and classification, theory development, or methods development.
Reuse of digital data	• The process of harvesting, transforming, and using structured or unstructured digital information that was initially generated for purposes other than research.
Theory or model	• A systematic, structured explanation or representation of facts, phenomena, or processes that sets the ground for research design, formulation of hypotheses, and predictions.
Tools to specify RQ	• Frameworks and tools that facilitate the development of specific aspects of defining the RQ or study design.
Types of RQ	• The type of RQ determines the main approach for achieving the research aim. Usually, there is a difference between quantitative and qualitative RQs that reflect quantitative and qualitative approaches. • Quantitative approaches use statistical and mathematical methods to address precise questions, typically using a deductive approach with a strong emphasis on the framework and structure. • By contrast, qualitative approaches use, for example, open-ended responses, focus groups, and interview-based techniques and focus on individual experiences and singularities. It seeks to determine or discover a process or define experiences. RQs tend to be inductive, flexible, adaptable, and nondirectional [17].

[a]RQ: research question.

The group further discussed the central role of hypotheses and linear, highly structured research approaches in health research, for example, in confirmatory research tasks (confirming a hypothesis, eg, by use of randomized controlled experiments or trials) and, to some extent, research focusing on predictions tasks (developing prediction models or classifiers to predict future events or out-of-sample attributes). In health research, it is generally recommended that the development of prediction methods follows a protocol that includes careful selection of predictors and (external) validation of the final model [18]. At the same time, it was also pointed out that some quantitative research tasks, such as methods development (ie, the development and validation of data analysis methods) or exploratory research (ie, detection of patterns and associations

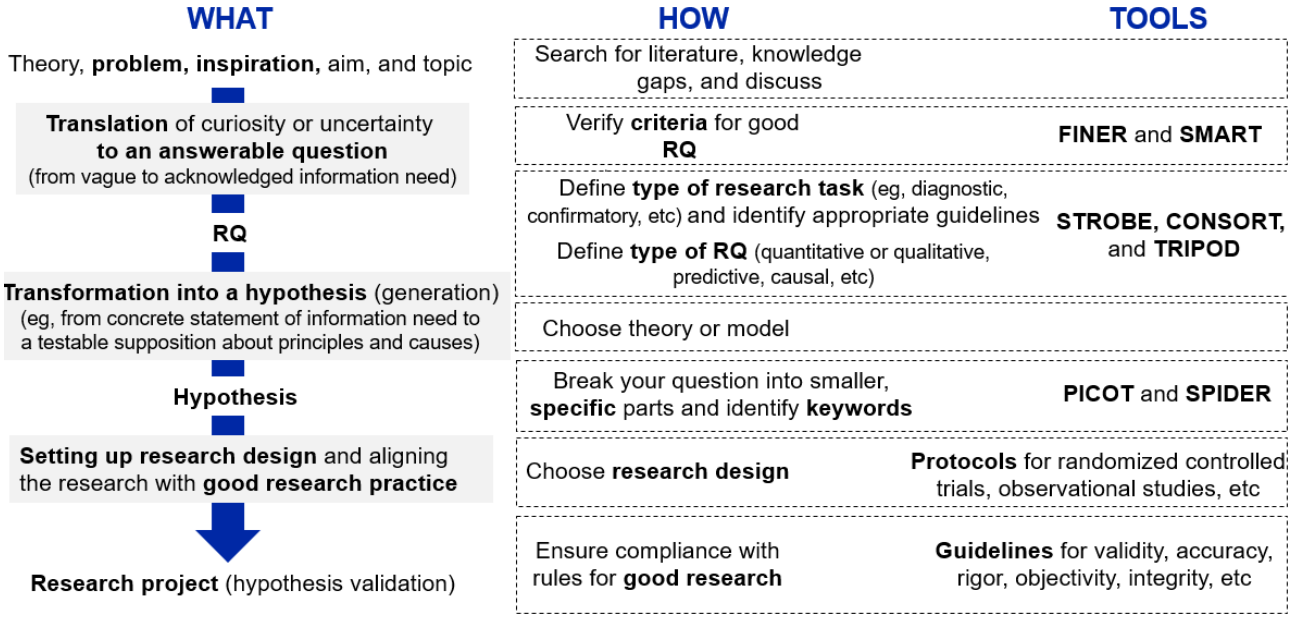
to generate new hypotheses), as well as qualitative research, generally depend much less on the specification of hypotheses. Workshop participants with a qualitative background argued that hypotheses can be implicitly involved in the research project. In qualitative research, it is common for the research question to evolve due to the necessity to critically reflect and adjust the study focus in each research step. As a result, the overall research process in qualitative research and some quantitative tasks, such as methods development, can be more iterative and dialectical when compared to deductive or confirmatory health research.

These discussions led to a key insight that interdisciplinary collaborations may be streamlined through the identification and discussion of the most appropriate "research task" early on, which can help guide subsequent discussions about the research question and the role of hypotheses in a common direction.

Summarizing Established Workflows for Research Question Formulation

The first 2 workshops were dedicated to better understanding how different disciplines approach the initial steps of a research project, including research question definition and study design choices. Informed by our rapid literature review, Figure 2 illustrates a summary workflow for established research design practices in health research. The vertical axis of Figure 2 illustrates the recommended steps for defining a research question (the "what"), starting from finding inspiration to developing a hypothesis, designing an appropriate study, and validating the hypothesis. Aligned with these definition steps, Figure 2 displays established practices (the "how") to execute the recommended steps. The third column references various frameworks and checklists aiding the implementation of each recommended step (the "tools").

Figure 2. Workflow of the recommended practices for defining a good research question. CONSORT: Consolidated Standards of Reporting Trials; FINER: Feasible, Interesting, Novel, Ethical, and Relevant; PICOT: Population, Intervention, Comparison, Outcome, and Time; RQ: research question; SMART: Specific, Measurable, Achievable, Realistic, and Timely; SPIDER: Sample, Phenomenon of Interest, Design, Evaluation, Research Type; STROBE: Strengthening the Reporting of Observational Studies in Epidemiology; TRIPOD: Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis.



The workflow of established practices generally starts with identifying a meaningful problem or question to be addressed in a study. The inspiration often emerges from a real-world challenge or knowledge gaps, but it can also be derived from existing theories or be triggered by discussions among colleagues. Workshop members also mentioned the influential role of funding criteria (ie, to increase chances for funding success) or topic-specific funding calls. This inspiration, curiosity, or uncertainty then needs to be translated into an answerable question [19-21]. Although we found little guidance in the literature on how to operationalize this step, it is often recommended to check the research question against the FINER (feasible, interesting, novel, ethical, and relevant) and SMART (specific, measurable, achievable, realistic, and timely) quality attributes to ensure its suitability for testing in a research study [16,20,22,23].

The wording of the research question itself may already imply a specific research task (eg, exploratory, confirmatory, or qualitative research) [21]. We differentiate between research aim and research objective. Research aim is the overall goal of the research, whereas research objective is the specific goal linked to a research question [16]. Having clarity on the research task will also facilitate the identification of appropriate reporting guidelines, such as STROBE (for observational studies), CONSORT (Consolidated Standards of Reporting Trials; for randomized controlled studies), or TRIPOD (Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis; for the development of prediction models). These reporting guidelines primarily intend to guide the communication of study results but can also be useful in converting the research question into a study design.

Ultimately, decisions regarding the study design should be guided by the research question, while also considering practical

limitations and available means and resources [23]. Frameworks such as PICOT (population, intervention, comparison, outcome, and time) and similar tools (eg, SPIDER [sample, phenomenon of interest, design, evaluation, research type] for qualitative research) [9,20,24] provide useful starting points for defining the study design. We include both the FINER and PICOT tools and their equivalents to ensure the best possible quality of the research question. Some research studies have shown that using only PICOT might be suboptimal [23]. The PICOT framework is frequently applied in health research, as PICOT is already defined above [21]. Further high-level study design decisions concern the study duration and measurement frequency (longitudinal vs cross-sectional studies), the allocation of study participants into comparator groups (randomization vs "as is" in observational research), as well as numerous practical aspects concerning study execution (eg, sample size and methods of data collection and analysis) [21,24]. Study design and study execution also need to adhere to the principles and criteria of good research and research practice to achieve valid, reliable, and accurate results [25]. Moreover, the research must comply with the standards of objectivity, reproducibility, and research integrity [26,27].

Overall, the workshop discussions confirmed that the workflow summary (Figure 2) represents a useful starting point for interdisciplinary collaborations to illustrate the established practices and to explore conceptual differences between health research, data science, and other scientific disciplines.

Developing Recommendations for an Adapted Workflow

Building on the proposed example scenario for using digital data in health research (Multimedia Appendix 3) and the established workflow description from step 1, the participants then discussed 2 types of workflow adaptations to better reflect practices and approaches from data science (Figure 2). These included the following: (1) structural modifications by changing the sequence of workflow steps (ie, introducing additional steps that should become standard in a novel workflow—the "what") and (2) the need for introducing additional contextual constraints or novel quality criteria (ie, modifications that do not change the workflow but may impact their execution—the "how").

Modifications to the "What": The Steps in Research Questions Workflow

Overall, the workshop participants perceived that the general sequence of the established workflow (the "what") still applies to studies using (structured and unstructured) digital data. Complementary steps with their potential pitfalls were proposed to better reflect the additional challenges of working with digital unstructured data (Multimedia Appendix 4.

First, for unstructured data, preprocessing and feature extraction should be allocated a distinct workflow step to emphasize the need for thorough consideration during study planning and execution, to ensure that the data are usable, credible, and useful for the research question at hand [28-31]. On one hand, the assessment of data quality and validity is more challenging. On the other hand, preprocessing and feature extraction through machine learning require additional assumptions and may lead to predictions and derived parameters with uncertain distributional characteristics (eg, normal ranges) or propagation of algorithmic errors and biases.

Second, the selection of appropriate analysis methods to address the research question as a new workflow step would underscore the importance of scientific rigor [1,31-38]. For example, deciding between pretrained deep learning models requires preliminary investigations about the model features and the training database, which goes beyond the choice of more standard statistical techniques (eg, regression models) [39,40].

Finally, the general importance of efforts to render science reproducible and transparent was identified as a new step in the workflow.

Modifications of the "How" of the Research Question Workflow

The workshop group identified potential contextual and methodological changes to research practices (the "how"; Table 2). These proposed changes can be grouped into 3 clusters.

Table 2. Proposed changes to the "how" parts of the research question formulation workflow.

Change number	Contextual constraints and quality criteria	Description	Steps this is applicable to
I	Consider real-life incentives and constraints in defining research problems	• The decision about RQ[a] can be strongly influenced by other nonacademic factors such as the availability of funding or data.	RQ
II	Acknowledge feasibility and resource constraints	• The choice of research design and data analysis tools involves costs that must be considered, particularly to ensure compliance with scientific integrity.	Research design
III	Declare limitations in RQ scope	• Each RQ has limitations; it is important to define what RQ can and cannot answer.	RQ
IV	Allow for and document iterations in RQ development and analysis	• Proper documentation is important for ensuring transparency and helps with evaluating and tracking the decisions regarding the iterations in RQ.	RQ
V	Acknowledge and respond to the increasing need for interdisciplinary expertise	• For the feasibility of the RQ, it is important to consider the needed expertise and skills. This becomes particularly important in research involving digital unstructured data as it requires an interdisciplinary set of skills.	All steps
VI	Enhance reproducibility	• Reproducibility in data science means obtaining consistent results using the same input data and methods. On a higher level, reproducibility in science also refers to the ability to duplicate findings if the same methods are used [41]. • Reproducibility in science also refers to the concept of making data; computational steps, methods, and codes; and conditions of analysis transparent and available, so that others can verify the findings.	All steps
VII	Enhance replicability	• Replicability refers to applying the same methods from a different study on different data. Observed differences in findings should be explicable by data-specific differences between studies.	All steps
VIII	Enhance robustness	• Robustness refers to analyses that apply the same database but use different methods. Observed differences in findings should be explicable by method-specific differences between studies. Within the same study, robustness is often evaluated by sensitivity analyses that use the same data but vary methods (eg, by applying different model parameters).	All steps
IX	Critically assess generalizability	• Generalizability means that the study results or outcomes are also applicable in other study settings and samples.	All steps

[a]RQ: research question.

The first cluster includes the acknowledgment of what we have labeled as real-life constraints (change numbers I and II) and limitations in the scope of research questions (change number III). Appropriately addressing such real-life constraints can be fostered by greater transparency and experience exchange.

The second cluster of proposed contextual changes pertains to enabling more interdisciplinary and iterative workflows (change numbers IV and V). Reasons for iterative approaches include more complex choices of analysis methods, the need for verifying the validity and robustness of model results, or the need to manually search for the best model parametrization. These challenges also require a greater emphasis on interdisciplinary collaborations that combine subject-domain knowledge and data science expertise.

The final cluster reflects the need for strengthening research quality criteria to foster open science, better reproducibility, and greater transparency (change numbers VI-IX). As analytical methods and databases become more complex, there is also an increasing need for transparency; adequate documentation; as well as publicly available analysis protocols, software codes, data, and analysis files. Studies should critically examine their findings under changing data or method combinations, thus exploring reproducibility, robustness, replicability, or generalizability (the 3RG criteria) and enhancing the overall quality of research. An important means to achieve these goals are open science and Findable, Accessible, Interoperable, and Reusable (FAIR) data principles [42].

Recommendations Toward a Pragmatic Approach of Teaching and Conducting Research Question Formulation

The workshop discussions produced a set of specific recommendations to promote approaches for defining good

research questions for reusing digital data. These recommendations are also well suited for educational use, helping to navigate the challenges of interdisciplinary collaboration and to foster interdisciplinary skills.

Iterative Research Question Formulation

As a principle, data collection, preprocessing, and analysis methods should follow the research question; researchers should not lose sight of the research aim, objective, and question. Defining a good research question is a fundamental and universal first step of science, which ideally should not be preceded by the choice of data or methods. However, the linear process of defining a research question common to health research may need several iterations to ensure that the complexity and feasibility of reusing and integrating digital data are accounted for.

The lecture instructors, supervisors, and principal investigators of interdisciplinary projects can apply this recommendation by emphasizing the importance of research question formulation in interdisciplinary projects. Furthermore, they can facilitate a discussion or create exercises for students to practice how the linear process of research question definition changes into a more iterative process when collaborating with other disciplines.

Reconciling Linear And Iterative Approaches: Continuum of Research Tasks

To reconcile the apparent conceptual differences between health research and data science approach research projects, we propose to reframe the scientific process as a continuum of knowledge accumulation over the course of multiple studies. Such a continuum can consist of several different research tasks (projects) combining deductive and inductive research approaches. Not all research tasks will involve explicit research questions or hypotheses. However, systematic reflections on how study results can inform new hypotheses and research questions and how they could be tested in future studies could become an integral part of a study, for example, as a last step in exploratory analyses.

Lecture instructors, supervisors, and principal investigators of interdisciplinary projects can use this recommendation to emphasize the continuum of research tasks. They can create exercises consisting of different research tasks where students practice combining deductive and inductive approaches in research design. These exercises can guide students to recognize that research is not always a straightforward process of hypothesis testing but may involve exploratory tasks that inform future studies. Instructors can also encourage students to reflect systematically on their research results, guiding them to think about how current findings can shape future hypotheses and research directions. This reflection can be incorporated into project work, where students work on iterative research tasks, examining how knowledge accumulates across studies and how inductive and deductive methods interact throughout this process. This practice prepares students to handle the nonlinear nature of interdisciplinary research, especially when bridging health research and data science.

Research Quality Criteria

The complexities involved in digital data preprocessing and analysis require careful design decisions and thorough reporting to ensure adherence to research quality standards. The reuse of existing, digital unstructured data and the need for extensive preprocessing may obfuscate or compound issues of external and internal validity [14]. Moreover, the use of machine learning techniques such as deep neural networks may generate "unexplainable" predictions or classifications that challenge the transparency and open science paradigms. The verification of "whether the data measure what they are supposed to measure (in the context of the research question)" [14] remains crucial and deserves appropriate attention, but it may become more difficult to achieve. We recommend that researchers systematically scrutinize interim results to ensure that they are "on the good track." Such checks can, for example, include the replication of results from different studies. Furthermore, transparency in reporting and reproducibility are key to scientific rigor.

Lecture instructors and supervisors can emphasize the importance of maintaining research quality in interdisciplinary projects. They can design exercises where students practice making careful design decisions in their research projects, ensuring that issues of validity, transparency, and reproducibility are addressed throughout the process. One approach could be to guide students in developing protocols for systematic checks of their interim results. Instructors can also promote transparency by teaching students how to document their research processes thoroughly, facilitating reproducibility and open science principles. By applying these exercises, students learn to critically evaluate the quality of their research.

Take Active Measures to Foster Interdisciplinarity

We recommend reflecting these aspects appropriately in teaching and training of next-generation researchers as well as in establishing new interdisciplinary research groups or collaborations. Therefore, in teaching, it is important to also convey a realistic view of how research works in practice. Students should be sensitized to real-world challenges and the need for pragmatic decision-making, while still striving for the basic principles of "good research practices." The literature review and our own experiences suggest that students are mostly taught the "ideal model," and thus, they are often not well prepared for the realities of research. It seems preferable to discuss challenges openly and to expose students to ethical and practical dilemmas early on.

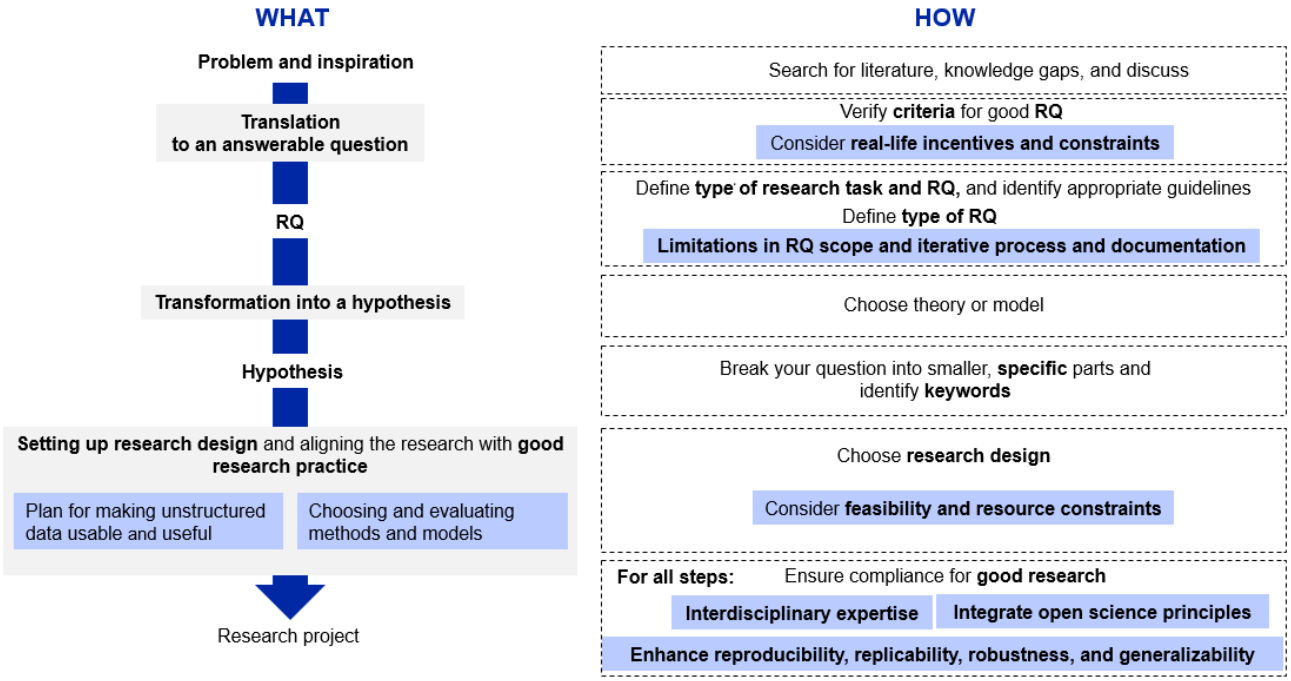
Lecture instructors and supervisors can sensitize students toward real-world challenges. They can prepare specific exercises where students can reflect on the problems that might arise from real-life constraints.

The added complexity and additional financial needs for education for interdisciplinary collaboration and open science should be acknowledged by funding agencies.

Specific Tools to Inform the Teaching of Interdisciplinary Courses on Real-World Data Analyses

Our study provides practical tools to guide the content and curricula of courses focused on interdisciplinary projects and collaborations. A more detailed description of the application of the study results to teaching is provided in Multimedia Appendix 5. The structure of our workshops (Figure 1) and the results of each workshop can be directly translated into the tools focusing on both dimensions of *content and curriculum* as well as *methods and teaching styles*. In terms of *content and curriculum*, the glossary with key concepts and terminology can be used to introduce students to interdisciplinary work. The workflow (Figure 2) combined with the glossary can serve as an interdiction to research practices for students with a different background, for example, humanities. Finally, our adapted workflow (Figure 3) sensitizes students for additional topics of transparency, FAIR data, reproducibility, and open science. Regarding *methods and teaching styles*, the sequence of workshops (Figure 1) and their results as outlined in the *content and curriculum section* can be directly translated into teaching phases, which build on top of each other. As illustrated by the example described in Multimedia Appendix 5, the structure of 3 teaching phases is useful and effective for teaching interdisciplinary research collaborations. A key insight from our workshop (modifications to the "how"—cluster 1) consisted of the need to acknowledge and address real-world challenges in study planning and execution. In our experience, case studies and illustrations of the scientific process of real-world examples are greatly appreciated by students.

Figure 3. Adapted workflow. The blue-colored boxes contain the added aspects in the "what" and "how" categories.



Discussion

Principal Findings

This study examined how interdisciplinary research collaborations between health research and data science can be streamlined by creating a shared conceptual understanding of terminologies and best practice workflows and by acknowledging or merging approaches from other disciplines. In a series of interactive workshops, our interdisciplinary group of coauthors concluded that the workflow of established practices for formulating a research question, generating hypotheses, and defining research designs remain valid. We argue that the reuse of digital data does not substantially change scientific activity, particularly the fundamental step of defining a good research question [1,43]. Achieving clarity on the research question benefits data analysis and interpretation by providing structure and informing the study design workflow. Moreover, a shared understanding of the research question and study workflow facilitates the inclusion of diverse domain knowledge to ensure research quality and result quality [6,14,44]. In line with this, the group noted general tendencies in research toward more open, transparent, and reproducible research, which are influenced by recommended data science practices. Along those lines, health research should increasingly foster good scientific practices that help to align the reuse of digital data with principles of reproducibility, robustness, generalizability, validity [1,32], transparency, and open science.

Our set of tools and recommendations can also be integrated into medical education by providing academic educators with a structured approach to teaching research question formulation in the context of using digital data in health research. By emphasizing the importance of both hypothesis-driven and data-driven research methods, educators can guide researchers in navigating the interdisciplinary challenges of health research and data science. The importance of creating a common terminology and discussion about scientific principles can further increase awareness about the challenges of interdisciplinary collaboration between health researchers and

data scientists. The proposed workflow and recommendations equip researchers with the tools to address the challenges of research question definition for interdisciplinary projects. The clear and practical steps provided by the workflow ensure that students not only grasp theoretical concepts but also apply them effectively in real-world scenarios, preparing them for collaborative, data-driven environments in health care and research.

For implementation, the set of tools and recommendations could be integrated into medical curricula and PhD programs through dedicated courses, workshops, or modules focusing on research methods and interdisciplinary collaboration for young researchers. Medical educators can adopt these recommendations to structure class discussions, assignments, and group projects, ensuring that students are exposed to both research approaches. In Multimedia Appendix 5, we provide an example of an interdisciplinary course implementing this set of tools. To evaluate the effectiveness of this implementation, a combination of qualitative and quantitative assessments can be used. Surveys and feedback from both students and educators can measure how well the workflow improves understanding and application of interdisciplinary research question formulation.

Our interdisciplinary effort recognized and discussed several potential obstacles toward bridging the approaches of established health research and data science. In the following sections, we repeat 4 key insights from our workshop interactions on how such obstacles can be overcome. First, we noted substantial differences in the use of terminologies across disciplines. For interdisciplinary collaborations, it is important to clarify key terms and concepts early on and to develop a shared understanding of the research aim and research question.

Second, in the early stages of the project, workshop participants expressed confusion about different types of analysis methods and their relationship with specific research tasks and high-level aims, such as prediction and classification, confirmatory research, or exploratory research. Agreeing on the high-level conceptual framework of “research tasks” helped structure the workshop discussions effectively. The discussion around the concepts of “research task” also fostered insights about commonalities and overlaps between concepts of data and health research. For example, many data science tasks can be classified as exploratory or prediction or classification tasks, which have conceptual counterparts in health research methodologies, each with corresponding reporting quality guidelines. Referring to specific research tasks rather than making global statements about data science or health research resonated well with the workshop participants and facilitated the discussions considerably.

Third, by introducing the concept of a “research task,” the group was also better able to examine the relationships among research aims, objectives, and tasks and how they are reflected in the workflow of established practices. Participants believed that exploratory or prediction or classification tasks, in particular, did not fit well into the workflow because such work is often not strictly hypothesis driven. However, 2 insights helped to align the workflow framework with the task concept: answering a research question may involve multiple research tasks in the same analysis, such as using prediction and classification tasks for data preprocessing, and later using these predictions in a confirmatory analysis, for example, as an exposure variable. Moreover, the scientific process can be viewed as a continuum of studies. From this perspective, the workflow of established practices can also be seen as a higher-level discovery cycle that spans across multiple studies. For example, an initial study may explore initial exploratory hypotheses or generate a first iteration of a prediction model, thus leading to new hypotheses. Indeed, exploratory and inductive methods can be useful to keep an open mind and become inspired by empirical data. In this way, the research tasks can be seen as a continuum—where data-driven research ends, hypothesis-driven research can start. Follow-up studies could then explore the hypotheses or validate the prediction model (whose structure can also be considered a hypothesis) in new data or in a confirmatory analysis. In combination, these multiple research tasks or study sequences are still likely to conform to the proposed workflow of recommended practices.

Finally, reusing unstructured and structured digital data brings new ethical challenges, such as privacy and consent issues, and problems with (public) trust and data diversity [45-49]. Traditional ethical assessments for data use in research and ethics review committees might not be well suited to address the challenges of digital data and might need adaptations [45,50]. Weighing the potential benefits and risks of using digital data becomes more complex. This problem is accentuated because the availability and production of digital data are often not based on a scientific decision, and rather, other factors such as political or social phenomena play a role [1]. While the need for novel ethical mechanisms to guide researchers is to be found in recently developed self-assessment tools for ethical data use [51,52], these new ethical mechanisms need further refinement to be widely adopted.

Strengths and Limitations

The strength of the expert groups was that participants represented a diverse group in terms of disciplines and career stages. However, it is possible that not all potentially relevant viewpoints were represented. A further strength was that the inputs from experts were collected systematically via different channels (eg, discussions, preworkshop tasks, and commenting on documents) throughout the consensus process. This allowed to harmonize and synthesize knowledge and insights from diverse disciplines. Experts also had several opportunities to review discussion outcomes and final summaries through workshop protocol and involvement in manuscript writing.

There are limitations regarding our proposed workflow. First, it represents an idealized process for defining a good research question, which is often challenged by funding and resource constraints or established norms. Some parts of the workflow might not be explicitly applicable to all types of research. The example scenario used to develop the workflow was based on hypothesis-driven deductive research, which often uses relational and causal research questions. We did not explicitly include inductive, qualitative approaches in health research, but we see the deductive and inductive research on a spectrum [53]. This limitation does not prevent the overall concept of the workflow

from being applied to other types of research, such as inductive, data-driven, or exploratory research.

Finally, although the literature review was conducted with great care and the expert group included several experienced researchers and faculty from different scientific disciplines, it was not possible to conduct a fully systematic search across all research disciplines due to resource constraints. Therefore, it is possible that some potentially relevant concepts and guidelines were not included.

Conclusions

In an age of digital transformation, established scientific practices with a strong focus on formulating research question design remain relevant and useful for gaining clarity about research aims. We recommend initiating new collaborations in the health domain with a review of terminologies and concepts to avoid misconceptions and problems further downstream in the research process. Our terminology and workflow may serve as tools to be used in medical education to support young and established researchers in interdisciplinary health research projects. To this end, we found the concept of "research tasks" particularly useful to foster a shared understanding among our collaborators. In addition, we recommend adapting the way the established workflow is taught to prospective researchers in health research and other disciplines, incorporating concepts from open science, the 3RG criteria, and the "science as a continuum" paradigm. We also call for funding agencies and publishers to incentivize and acknowledge investments in defining good research questions for complex novel data and analysis methods.

Data Availability

All data are available in the manuscript and multimedia appendices.

Authors' Contributions

JS contributed to conceptualization, data curation, investigation, methodology, project administration, resources, visualization, and writing the original draft. Abstract

Background: ChatGPT is a large language model-based chatbot developed by OpenAI. ChatGPT has many potential applications to health care, including enhanced diagnostic accuracy and efficiency, improved treatment planning, and better patient outcomes. However, health care professionals' perceptions of ChatGPT and similar artificial intelligence tools are not well known. Understanding these attitudes is important to inform the best approaches to exploring their use in medicine.

Objective: Our aim was to evaluate the health care professionals' awareness and perceptions regarding potential applications of ChatGPT in the medical field, including potential benefits and challenges of adoption.

Methods: We designed a 33-question online survey that was distributed among health care professionals via targeted emails and professional Twitter and LinkedIn accounts. The survey included a range of questions to define respondents' demographic characteristics, familiarity with ChatGPT, perceptions of this tool's usefulness and reliability, and opinions on its potential to improve patient care, research, and education efforts.

Results: One hundred and fifteen health care professionals from 21 countries responded to the survey, including physicians, nurses, researchers, and educators. Of these, 101 (87.8%) had heard of ChatGPT, mainly from peers, social media, and news, and 77 (76.2%) had used ChatGPT at least once. Participants found ChatGPT to be helpful for writing manuscripts (n=31, 45.6%), emails (n=25, 36.8%), and grants (n=12, 17.6%); accessing the latest research and evidence-based guidelines (n=21, 30.9%); providing suggestions on diagnosis or treatment (n=15, 22.1%); and improving patient communication (n=12, 17.6%). Respondents also felt that the ability of ChatGPT to access and summarize research articles (n=22, 46.8%), provide quick answers to clinical questions (n=15, 31.9%), and generate patient education materials (n=10, 21.3%) was helpful. However, there are concerns regarding the use of ChatGPT, for example, the accuracy of responses (n=14, 29.8%), limited applicability in specific practices (n=18, 38.3%), and legal and ethical considerations (n=6, 12.8%), mainly related to plagiarism or copyright violations. Participants stated that safety protocols such as data encryption (n=63, 62.4%) and access control (n=52, 51.5%) could assist in ensuring patient privacy and data security.

Conclusions: Our findings show that ChatGPT use is widespread among health care professionals in daily clinical, research, and educational activities. The majority of our participants found ChatGPT to be useful; however, there are concerns about patient privacy, data security, and its legal and ethical issues as well as the accuracy of its information. Further studies are required to understand the impact of ChatGPT and other large language models on clinical, educational, and research outcomes, and the concerns regarding its use must be addressed systematically and through appropriate methods.

ChatGPT; LLM; global; health care professionals; large language model; language model; chatbot; AI; diagnostic accuracy; efficiency; treatment planning; patient outcome; patient care; survey; physicians; nurses; educators; patient communication; clinical; educational; utilization; artificial intelligence

Introduction

Large language model (LLM) refers to advanced artificial intelligence (AI) models designed for natural language processing tasks. LLMs are trained on vast amounts of text data and use deep learning techniques to understand and generate human-like language. They helped transform various fields, including medicine [1]. Some examples of most popular LLMs are LlaMA by Meta, Orca and Phi-1 by Microsoft, BLOOM, PaLM2 by Google, and GPT by OpenAI. ChatGPT, a chatbot powered by GPT-3/4 was released by OpenAI in November 2022, incorporating billions of parameters that enable it to comprehend and generate human-like text with the capability of context creation. Its intuitive interface and capacity for prompt engineering have enabled diverse applications across domains [2].

In medicine, recent studies have demonstrated ChatGPT's potential to support clinical decision-making, summarize complex medical data, and streamline documentation processes. For instance, ChatGPT has been evaluated for its ability to generate discharge summaries, assist in developing differential diagnoses, and simplify patient communication [3-5]. Its role in medical education has also been explored, demonstrating its utility in preparing students for licensing exams like the United States Medical Licensing Examination (USMLE) and enhancing self-directed learning through case-based scenarios [5-7]. ChatGPT was also shown to be capable of defining and answering clinical vignettes and achieved >60% of the threshold on the USMLE, which is the passing score for all three exams [8,9]. Additionally, its ability to provide personalized health education and assist in chronic disease management has been highlighted as a promising avenue for improving patient outcomes [4,10].

The integration of ChatGPT into health care settings is accelerating, with a growing body of literature examining its applications. Despite these advancements, significant challenges remain. Concerns about data privacy, ethical implications, and the accuracy of AI-generated content persist as barriers to widespread adoption [4,5,10]. Additionally, little is known regarding global health care professionals' perspectives and the extent and impact of ChatGPT's integration in health care settings [11,12]. Most studies to date, have been limited to localized settings or specific subgroups. Yet, successful and ethical integration of ChatGPT into health care workflows depends heavily on end-user acceptance, awareness of limitations, and perceptions regarding safety, usability, and value [5-7].

This study aimed to evaluate health care professionals' awareness and perceptions of ChatGPT, with a focus on its applications, challenges, and utility across clinical, educational, and research settings. We surveyed a diverse group of health care professionals—including physicians, nurses, researchers, and educators—from multiple countries and practice settings. Using a cross-sectional survey design, we collected data on their familiarity with ChatGPT, how and why they used it, and their concerns about its integration. Our a priori hypothesis was that while many health care professionals would recognize ChatGPT's potential benefits, such as improving efficiency, communication, and access to knowledge, they would also express concerns regarding ethical, legal, and accuracy-related issues.

This study offers timely insights for health care leaders, educators, and policymakers considering the responsible adoption of generative AI tools. By reflecting on global perspectives from frontline users, our findings may help shape discussions on how to balance innovation with safety and trust in clinical AI applications.

Methods

This study was conducted as a cross-sectional survey between April 20 and July 3, 2023 (Multimedia Appendix 1).

Survey Instrument Development and Validation

The questionnaire used in this study was developed de novo by the research team. The design process was informed by the research team's multidisciplinary experience in medicine, education, and digital health, as well as the evolving discourse around AI in health care. To assist with rapid prototyping, the research team used ChatGPT (OpenAI) to generate the first draft of the questionnaire. This initial draft provided a foundation for question phrasing and thematic organization. The final survey was iteratively refined by the study investigators to ensure clinical and contextual relevance.

To enhance clarity and assess feasibility, the questionnaire was piloted informally among five health care researchers affiliated with our institution. Their feedback informed improvements in question wording, branching logic, and estimated completion time (approximately 5 minutes). No formal psychometric validation was conducted.

The final survey included 33 questions and was distributed electronically using Research Electronic Data Capture (REDCap) (version 13.1.30; Vanderbilt University) [13]. The questionnaire was structured around six thematic domains: (1) respondent demographics and work environment, (2) awareness and familiarity with ChatGPT, (3) frequency and purpose of use, (4) perceived benefits and challenges of ChatGPT in daily practice, (5) views on ethical, legal, and data security concerns, and (6) future expectations and training needs. The questionnaire incorporated branching logic to adapt follow-up questions based on initial responses—for example, only respondents who reported using ChatGPT were asked about specific applications or frequency of use. A visual summary of the questionnaire flow and branching logic is provided in Multimedia Appendix 2. The final instrument has been reported in Multimedia Appendix 1.

Participants and Sampling Strategy

We used a convenience sampling approach. The questionnaire was distributed to health care professionals via targeted emails, and professional Twitter, LinkedIn, and Instagram accounts using a snowball technique [14]. No predefined inclusion or exclusion criteria were applied beyond the requirement of being a health care professional (eg, physician, nurse, educator, researcher). There were no regional or institutional restrictions.

As the survey was open and anonymous, we did not estimate a denominator or calculate a response rate. For the purposes of this study, we defined the application of ChatGPT in the medical field broadly to include its use in clinical care, research, medical education, and health care–related administrative tasks. This inclusive definition reflects the multifaceted roles that health care professionals fulfill and acknowledges that tools such as ChatGPT may support a wide range of activities beyond direct patient care, such as writing grants, academic correspondence, and synthesizing medical literature. Survey items were designed to capture this broad spectrum of use across domains relevant to daily professional practice.

Demographic information of participants was summarized. Among those familiar with ChatGPT, opinions on the tool and potential dissemination resources were assessed. For those who had not used it, barriers to usage were examined (Multimedia Appendix 2). Participants with experience using the ChatGPT were also asked about perceived challenges and approaches for enhancing usability. Summary statistics were provided as numbers and frequencies. Comparative analyses were conducted using the χ^2 test, with a two-sided P value <.05 considered statistically significant. JMP Pro (version 14.1.0 software; SAS Institute Inc.) was used for the analyses.

Ethical Considerations

The study protocol was evaluated by the Mayo Clinic institutional review board and it was determined that it was exempted under 45 CFR 46.102 of the Code of Federal Regulations (2/28/2023). No personally identifying information was collected, and all data were fully anonymous. Study participation was voluntary and survey completion was considered as consent. All survey responses were stored on secure, access-restricted servers in compliance with institutional data protection policies.

Results

Main Findings

A total of 115 health care professionals from 21 countries responded to the survey. Table 1 displays a summary of their demographic information (Figures 1–2).

Table . Baseline characteristics.

Variables	Participants (N=115), n (%)
Age (years)	
20 - 29	30 (26.1)
30 - 39	27 (23.5)
40 - 49	26 (22.6)
50 - 59	10 (8.7)
>60	22 (19.1)
Sex[a]	
Female	45 (39.5)
Male	68 (59.6)

Others[e]	6 (5.3)
Frequency of ChatGPT usage (n=68)	
Multiple times per day	14 (20.6)
Once per day	3 (4.4)
Three to five times per week	14 (20.6)
Less than three times a week	13 (19.1)
Only tried it few times	24 (35.3)

[a]Due to lack of responses, missing data are not included in the reported totals; as a result, some category counts may not sum to the overall sample size.
[b]NP/PA: nurse practitioner/physician assistant.
[c]RN: registered nurse.
[d]ICU: intensive care unit.
[e]For Others see Multimedia Appendix 3.
[f]The subcategories are not mutually exclusive.

Figure 1. ChatGPT usage based on participants' age, gender, and country of work.

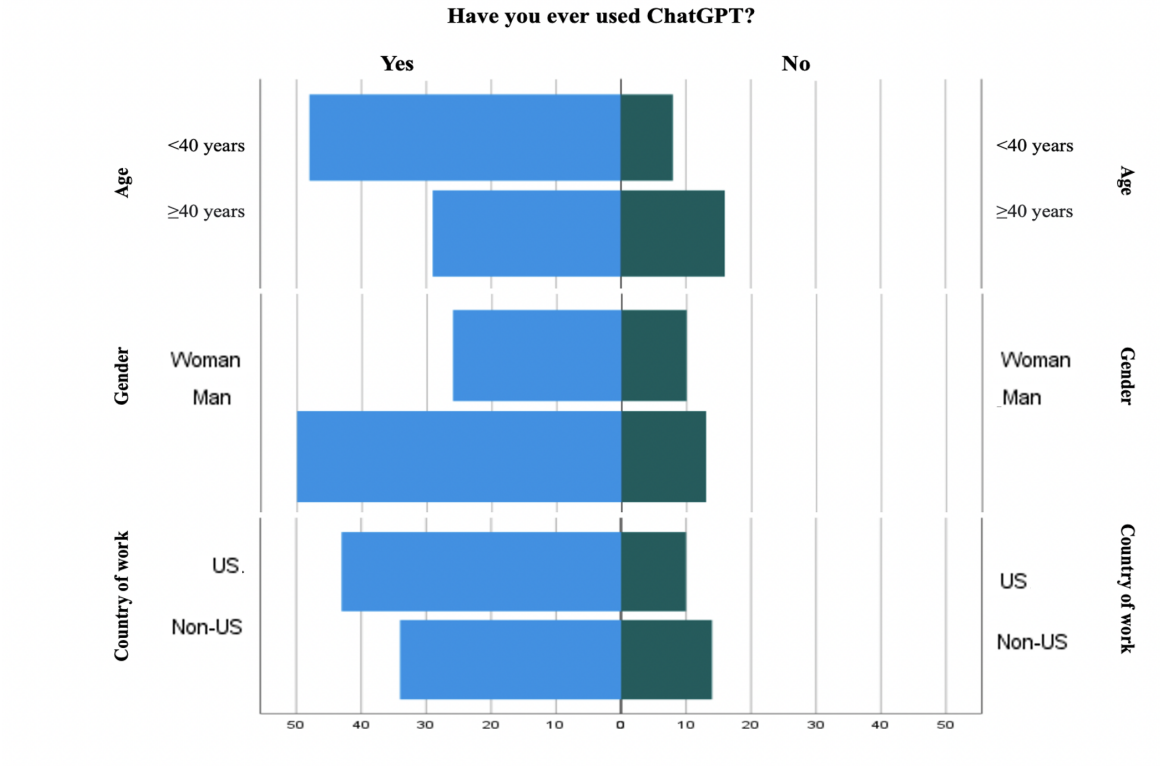

Figure 2. ChatGPT usage based on participants' years since graduation, length of work in the current unit, and profession.

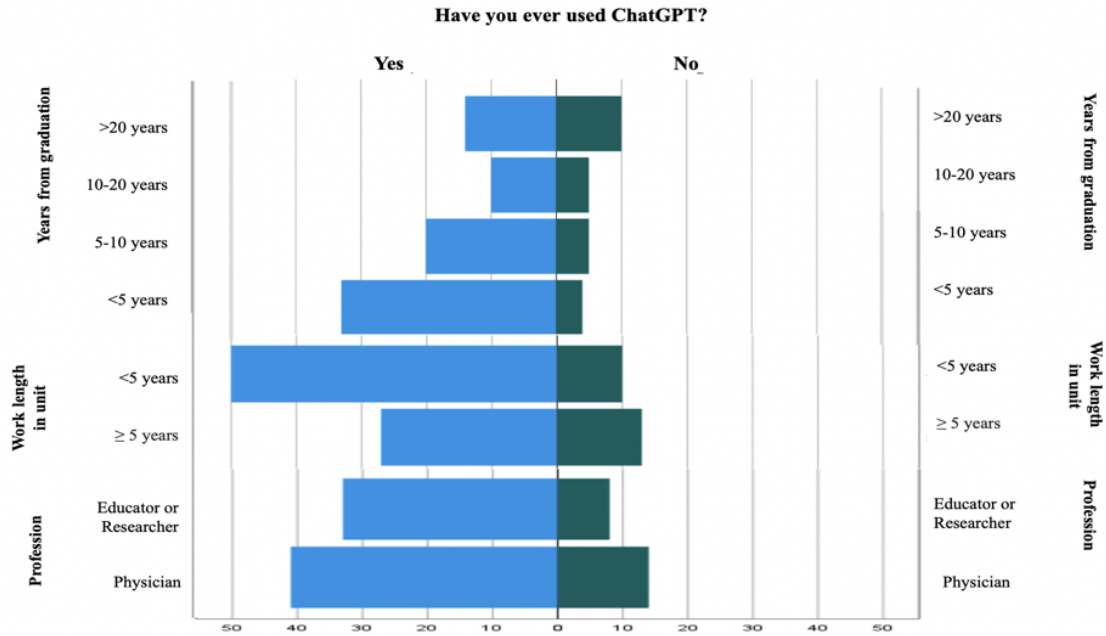

Of the 115 participants, 101 (87.8%) had heard of ChatGPT, mainly from social media (n=33, 32.7%) and peers or colleagues (n=43, 42.6%). Of those, 77 (76.2%) had used ChatGPT before, with 18 (23.4%) using it multiple times per day and 23 (29.9%) having tried it only a few times. Moreover, 71 out of 77 (92.2%) participants used it in English. Among these, 50 were not native English speakers, and only 16/50 (32%) speakers used it both in English and their native language (Figure 3). Furthermore, variations in ChatGPT usage in daily practice were observed between participants using ChatGPT in English versus those who used it in their native language (Figure 4).

Figure 3. Ratio of native language use versus English use among participants while using ChatGPT.

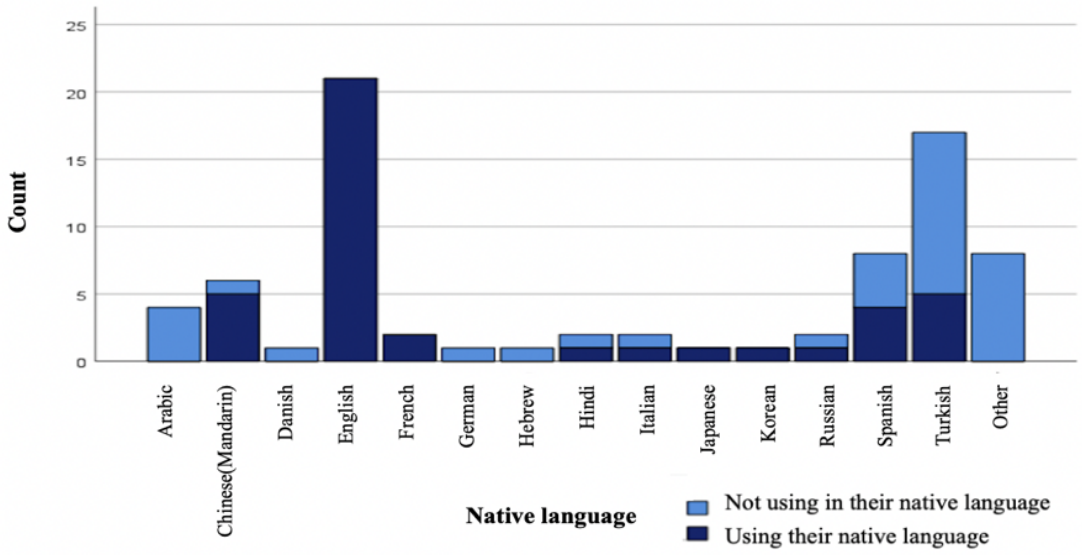

Figure 4. Main reasons for using ChatGPT in daily practice based on the language used by the participants.

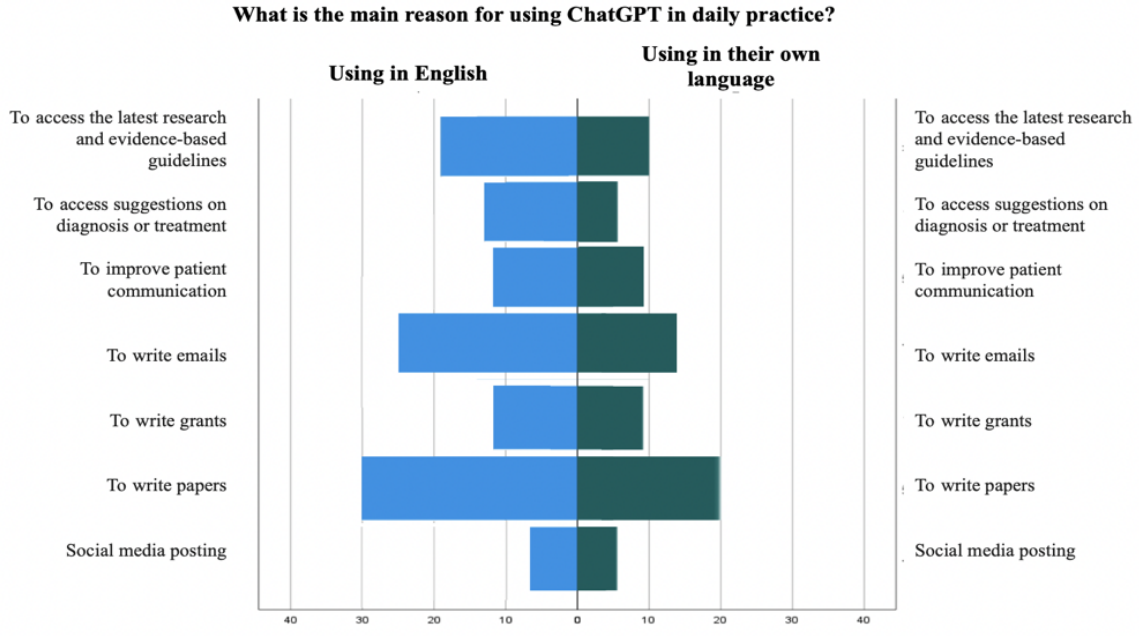


The most common reasons to use ChatGPT included writing papers (n=29, 44.6%) and emails (n=25, 38.5%), and obtaining suggestions on diagnosis or treatment (n=14, 21.5%) (Table 2). Additional reasons for ChatGPT usage by health care professionals in daily practice are shared in Table 3.

Table . ChatGPT usefulness based on used features in daily practice.

ChatGPT features	Participants (n=68), n (%)
Usefulness in daily practice	
Not important	14 (20.6)
Slightly important	21 (30.9)
Moderately important	13 (19.1)
Important	13 (19.1)
Very important	7 (10.3)
ChatGPT's usefulness, 0 (most negative experience) to 10 (most positive experience)	
≥7	42 (61.8)
4-5-6	19 (27.9)
≤3	7 (10.3)
Most useful features	
To access and summarize research articles efficiently	22 (46.8)
To provide quick answers to clinical questions	15 (31.9)
To provide patient education materials	10 21.3
To write emails, grants, and papers	25 53.2

Table . Percentage of participants' main reasons for using ChatGPT in daily practice (multiple choice questions).

Main reason for using ChatGPT in daily practice	Participants (n=68), n (%)
Writing papers	31 (45.6)
Writing emails	25 (36.8)
To access the latest research and evidence-based guidelines	21 (30.9)
To access suggestions on diagnosis or treatment	15 (22.1)
To improve patient communication	12 (17.6)
To write grants	12 (17.6)

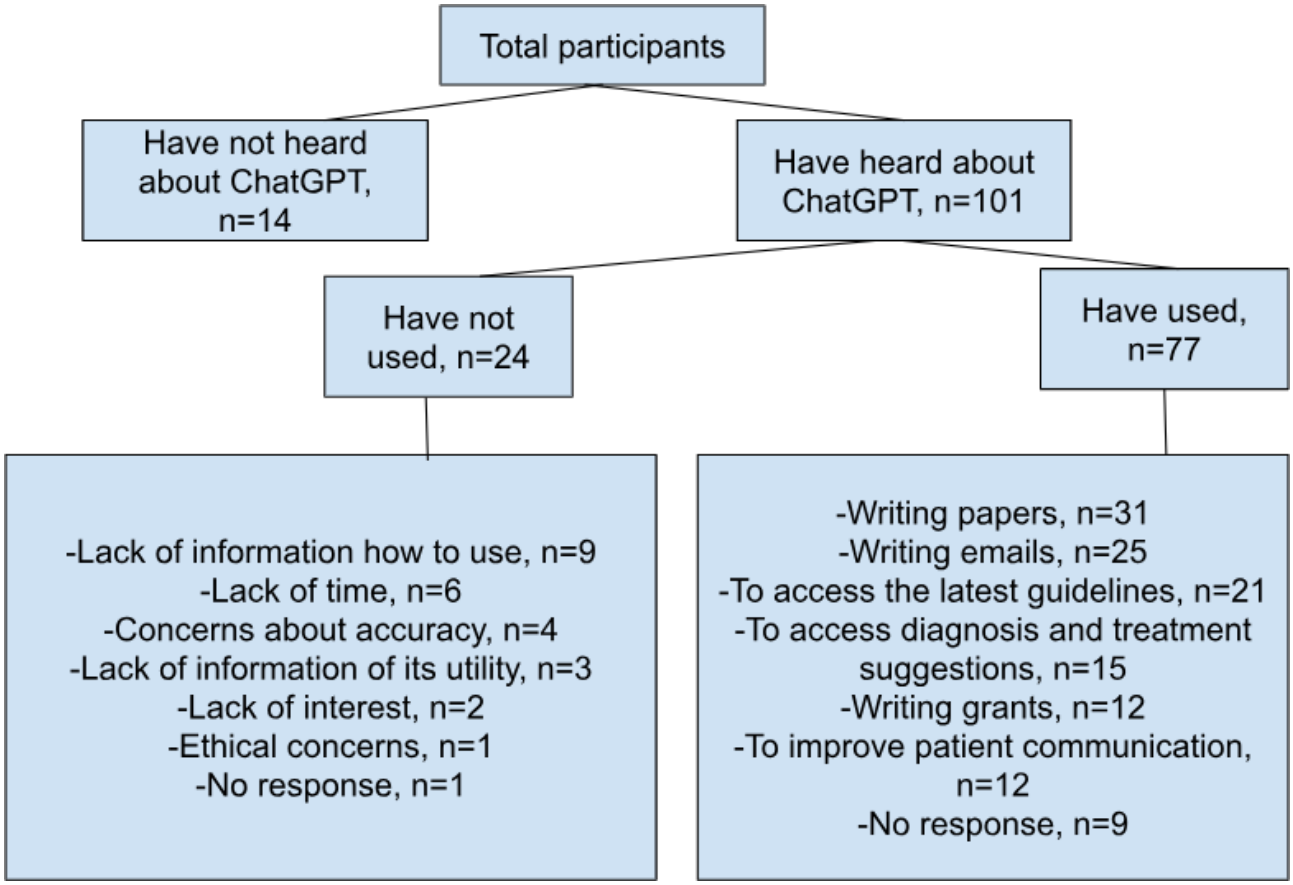
Incorporation of ChatGPT Into Daily Practice

Of the 77 participants who used ChatGPT, 36 (46.8%) used ChatGPT in their clinical practice, 58 (75.3%) used it for research, and 56 out of 77 (72.7%) used it for educational activities (Figure 5).

Among all respondents, 42/101 (43.6%) participants agreed that they would not be concerned if their clinician used ChatGPT while providing care to them if they were the patient, whereas 32 (32.7%) disagreed and preferred that their clinician not use ChatGPT during care.

The majority (n=79, 78.2%) of participants agreed that ChatGPT could be useful for medical or health care professional education. In nonclinical settings, participants stated that ChatGPT could help to reduce workload (n=57, 73.1%), improve efficiency by automating certain tasks (n=51, 65.4%), offer greater access and efficiently summarize research articles (n=52, 66.7%), create patient educational materials (n=49, 62.8%), provide quick answers to questions (n=48, 61.5%), and enhance the ability to write papers (n=37, 47.4%).

Figure 5. Factors contributing to use and nonuse of ChatGPT. The activities are not mutually exclusive and therefore, the total number of participants may exceed 115.



Challenges for Integrating ChatGPT Into Daily Practice

The main reasons for respondents not using ChatGPT included concerns about the accuracy of ChatGPT responses (n=14, 29.8%), limited applicability to their practice (n=18, 38.3%), legal and ethical considerations (n=6, 12.8%), limited diagnostic capabilities (n=4, 8.5%), lack of time (n=3, 6.4%), and lack of interest (n=2, 4.3%).

As one of the significant barriers is legal and ethical considerations, participants were asked to define plagiarism or copyright violations. Participants defined it as copying text or ideas from ChatGPT and using it for another source without citation (n=64, 63.4%), paraphrasing or summarizing content from ChatGPT and using it for another source without citation (n=41, 40.6%), using images from ChatGPT without permission (n=36, 35.6%), reusing or repurposing content from ChatGPT that was previously created for another purpose without permission (n=44, 43.6%).

In response to the legal and ethical challenges, participants proposed several solutions for integrating ChatGPT into daily practice. Participants stated that data encryption (n=63, 62.4%), access control (n=52, 51.5%), user authentication such as two-factor authentication (n=48, 47.5%), compliance with regulations such as Health Insurance Portability and Accountability Act or General Data Protection Regulation (n=62, 61.4%), transparency and informed consent (n=53, 52.5%), and regular training and awareness for health care professionals (n=58, 57.4%) are necessary to ensure patient privacy and data security.

Views on ChatGPT's success and other possible uses

When asked whether the participants knew ChatGPT had performed with ≥60% accuracy on the USMLE, 52 (51.5%) participants indicated they had heard this before. Additionally, 76 (68.5%) participants reported that they had not used any other AI platform.

Participants stated that ChatGPT can improve patient outcomes through personalized health education by providing tailored information and support (n=76, 75.2%); assisting with medication management through reminders and refill prescriptions, and provide information on side effects and interactions (n=55, 54.5%); telemedicine support for health care professionals to conduct virtual consultations, collect patient data, and provide decision support (n=48, 50%); aiding in symptom triage for patients (n=49, 48.5%); and offering mental health support by providing guidance on self-management techniques and coping strategies (n=49, 48.5%).

The distribution of responses based on different levels of postgraduate experience is reported in Multimedia Appendix 4. This distribution was largely balanced between the participants with fewer than 10 years and those with 10 or more years of experience.

Discussion

Principal Findings

This study offers a global perspective on how health care professional perceive and use ChatGPT in clinical, research, and educational context. Our findings demonstrate that awareness and adoption of ChatGPT are already widespread, with 76.2% of respondents having used the tool at least once. Participants primarily reported using ChatGPT for manuscript and email writing, grant application preparation, accessing research articles, clinical guideline support, diagnostic suggestions, and improving patient communication. Notably, more than three-quarters of participants agreed that ChatGPT holds potential utility in medical education, highlighting its ability to enhance learning experiences and facilitate task automation. Moreover, our study indicates that health care professionals endorse its use among colleagues. However, concerns about data privacy, ethical risks such as plagiarism, and the accuracy of AI-generated content remained as significant barriers to broader adoption. Proposed solutions included implementing safety protocols such as data encryption, access control, and regulatory compliance. In exploratory analyses comparing ChatGPT use, we did not identify significant differences across professional experience levels, which might be due to the limited sample size. Due to the wide range and uneven distribution of medical subspecialties represented, we were not able to conduct a formal comparison across specialties.

Implications of Findings

Our findings highlight the broad and flexible potential of ChatGPT in health care workflows. In clinical practice, ChatGPT is perceived as a tool that can enhance efficiency by automating routine documentation tasks, such as generating draft discharge summaries and patient letters. It also supports decision-making by offering fast access to evidence summaries and aids communication through the creation of patient-friendly materials [5,15]. In medical education, participants identified ChatGPT as a valuable educational supplement—one that could be incorporated into curricula to simulate real-world clinical scenarios and assist in preparing students for standardized exams like the USMLE [5,16]. It can also support personalized learning experiences tailored to individual needs and self-directed learning pathways. In research, ChatGPT was valued for its ability in grant writing, literature synthesis, and ideation, especially in the early stages of manuscript development or protocol design [5].

These findings underscore the need for structured training programs and ethical guidelines to support responsible integration of AI tools. Implementing human-in-the-loop systems, in which clinicians oversee and validate AI outputs, may enhance safety, and build user confidence while mitigating risks associated with biases or inaccuracies in AI-generated content [17].

Comparison to the Literature

Our findings align with prior studies that underscore ChatGPT's potential in health care. Cascella et al [2] described ChatGPT's potential to reduce administrative burden and assist with clinical reasoning, which mirrors participants' reported use of ChatGPT for documentation and clinical queries. In medical education, Gilson et al [8] showed that ChatGPT achieved passing scores on all three components of the USMLE, highlighting its utility in medical education. Similarly, Kung et al [9] emphasized its role in creating standardized templates for patient education materials. These findings also align with our participants' views on its usefulness for both learners and patients alike. Sallam [18] highlighted ChatGPT's capacity to process and summarize complex medical data efficiently, which our participants also leveraged for research and evidence access.

However, our study adds unique insights by capturing global perspectives from diverse practice settings. Unlike prior reports focused on specific institutions or national populations, our results reflect a cross-disciplinary, international sample, offering a broader view of how generative AI is being perceived across diverse practice settings.

The main reasons behind the lack of use of ChatGPT in daily practice were mainly due to the nonapplicability to their practice, lack of information regarding its use, and concerns about the accuracy of ChatGPT's responses, and legal and ethical considerations. The reason behind not using ChatGPT due to lack of information may be partially attributed to insufficient training opportunities for health care professionals in the use of generative AI. Previous studies have also indicated similar concerns regarding its implementation [19]. For instance, the concern for the spread of wrong information is a major obstacle, and different languages may have inconsistent results [20,21]. Many studies have shown that up to 96.7% of users are concerned about ethical and legal obstacles [3,18], particularly plagiarism [21-23], and copyright issues [3,18]. In a study conducted by a university at Sweden, 62% of students considered the use of chatbots for assignments and exams as cheating [24]. Our study showed that 86 out of 101 participants defined copying from ChatGPT as plagiarism. These concerns show that the implementation of ChatGPT into clinical settings will require a transition period supported by extensive safety measures. Health care professional leaders need to work with technology experts to develop learning objectives, curricula, assessments and evaluations, and safety protocols for this emerging technology.

Regarding the accuracy of ChatGPT's responses, our study shows that health care professionals identified this as having a paramount importance. Similar studies have shown that ChatGPT should be used with caution due to potential biases of AI, which may lead to the generation of inaccurate information. When used in the health care system, this could potentially lead to harmful consequences [25].

Educational Implications

The educational relevance of our findings is especially important. Our study suggests several opportunities:

- Curriculum design: Educators can incorporate ChatGPT into simulation- and case-based learning modules to foster clinical reasoning and application of evidence-based medicine.

- Needs Assessment: Educators may use baseline familiarity and usage patterns to tailor AI training initiatives and address gaps in knowledge or ethical understanding.
- Institutional Strategies: ChatGPT may serve as a tool in flipped classrooms, interactive tutorials, and self-directed learning, offering real-time feedback and access to guideline-driven responses.
- Learner Outcomes: By providing immediate feedback and access to evidence-based guidelines, ChatGPT has the potential to improve learner performance on standardized assessments [16].

Additionally, ChatGPT's ability to generate accessible explanations for patients could enhance health literacy and improve communication between physicians and patients.

Strengths and Limitations

This study has several strengths. We examined ChatGPT adoption from a global perspective. By including participants from 21 countries and various clinical and academic backgrounds, the study provides a valuable overview of current usage patterns and attitudes toward generative AI tools in health care. The survey instrument was comprehensive, capturing a wide range of use cases and concerns across clinical, research, and educational domains.

However, several limitations must be acknowledged. Although participants were from diverse countries, they are unlikely to represent the full range of health care professionals within their regions. The sample was likely skewed toward individuals with greater access to technology and academic networks, especially in countries where access to ChatGPT or certain social media platforms may be restricted or limited. Therefore, findings should be interpreted with caution and may not be generalized to all health care professionals in low-resource or digitally restricted settings. The use of convenience and snowball sampling likely introduced self-selection bias, attracting participants with preexisting interest in technology or AI. Because of this sampling method, we could not calculate a response rate. Most respondents were from academic hospital settings in the United States, which may limit applicability to other regions or practice environments. Conducting the survey in English may have limited the global inclusivity. Given the swift pace of technological advancements, particularly in generative AI applications such as ChatGPT and the continuous process of learning and integration by health care professionals, the present survey may not accurately capture the current perceptions and attitudes of doctors and nurses toward these technologies [26], limiting the temporal relevance of our findings . Lastly, although our survey included open-ended questions, multiple-choice questions may have led participants to an available answer.

Future Directions

Further research is needed to address unanswered questions:

1. Long-term impact: Studies should evaluate how ChatGPT influences clinical outcomes, patient satisfaction, and educational performance over time.
2. Ethical frameworks: There is a pressing need for the development of institutional and regulatory guidelines governing AI use in health care [17].
3. Cross-language applications: Investigating how ChatGPT performs across different languages could help improve accessibility for non-English-speaking populations.
4. Training programs: Evidence-based strategies are needed to guide health care professionals in the ethical and effective use of generative AI technologies.

Conclusion

ChatGPT usage is expanding within health care settings due to its variety of capabilities, and the majority of health care professionals are likely aware of its availability. It can improve the caliber of writing papers, grants, and emails; help health care professionals in accessing the latest guidelines, diagnosis, and treatment suggestions; and possibly improve patient communication. There are several concerns related to the implementation of LLMs in clinical practice, including legal, ethical, and operational issues. Further research is necessary to clarify the role of ChatGPT and LLM-based generative AI tools in health care education, research, and clinical practice.

Abstract

Background: The optimal duration of emergency medicine (EM) residency training remains a subject of national debate, with the Accreditation Council for Graduate Medical Education considering standardizing all programs to 4 years. However, empirical data on how residents accumulate clinical exposure over time are limited. Traditional measures, such as case logs and diagnostic codes, often fail to capture the breadth and depth of diagnostic reasoning. Natural language processing (NLP) of clinical documentation offers a novel approach to quantifying clinical experiences more comprehensively.

Objective: This study aimed to (1) quantify how EM residents acquire clinical topic exposure over the course of training, (2) evaluate variation in exposure patterns across residents and classes, and (3) assess changes in workload and case complexity over time to inform the discussion on optimal program length.

Methods: We conducted a retrospective cohort study of EM residents at Stanford Hospital, analyzing 244,255 emergency department encounters from July 1, 2016, to November 30, 2023. The sample included 62 residents across 4 graduating classes (2020‐2023), representing all primary training site encounters where residents served as primary or supervisory providers. Using a retrieval-augmented generation NLP pipeline, we mapped resident clinical documentation to the 895 subcategories of the 2022 Model for Clinical Practice of Emergency Medicine (MCPEM) via intermediate mapping to the Systematized Nomenclature of Medicine, Clinical Terms, Clinical Observations, Recordings, and Encoding problem list subset. We generated cumulative topic exposure curves, quantified the diversity of topic coverage, assessed variability between residents, and analyzed the progression in clinical complexity using Emergency Severity Index (ESI) scores and admission rates.

Results: Residents encountered the largest increase in new topics during postgraduate year 1 (PGY1), averaging 376.7 (42.1%) unique topics among a total of 895 MCPEM subcategories. By PGY4, they averaged 565.9 (63.2%) topics, representing a 9.9% (51/515) increase over PGY3. Exposure plateaus generally occurred at 39 to 41 months, although substantial individual variation was observed, with some residents continuing to acquire new topics until graduation. Annual case volume more than tripled from PGY1 (mean 445.7, SD 112.7 encounters) to PGY4 (mean 1528.4, SD 112.7 encounters). Case complexity increased, as evidenced by a decrease in mean ESI score from 2.94 to 2.79, and a rise in high-acuity (ESI 1‐2) cases from 16% (4374/27,340) to 30.9% (9418/30,466).

Conclusions: NLP analysis of clinical documentation provides a scalable, detailed method for tracking EM residents' clinical exposure and progression. Many residents continue to gain new experiences into their fourth year, particularly in higher-acuity cases. These findings suggest that a 4-year training model may offer meaningful additional educational value, while also highlighting the importance of individualized assessment given the variability in learning trajectories.

Introduction

The Challenge of Measuring Clinical Experience

The optimal duration of emergency medicine (EM) residency training remains a critical unresolved question in graduate medical education. As the Accreditation Council for Graduate Medical Education considers standardizing all programs to a 4-year model, this debate has highlighted a fundamental gap in our understanding. We lack reliable methods to measure how residents accumulate and master clinical experience across a vast spectrum of EM presentations [1]. While these clinical

encounters form the foundation of physician development and shape future practice patterns, programs have struggled to systematically track and optimize them, even within competency-based educational frameworks [2-5].

Current methods for measuring clinical exposure in EM suffer from both practical and conceptual limitations. Self-reported case logs, the traditional standard, demonstrate significant error rates due to recall bias [6,7]. Approaches using diagnostic coding systems such as the International Classification of Diseases, 10th revision, fundamentally misalign with EM's paradigm [8-11]. The core work of emergency physicians, evaluating and ruling out life-threatening conditions, often results in nonspecific final diagnoses (eg, "abdominal pain") that mask the complexity of care delivered [12]. Furthermore, we know that evaluating for life-threatening illnesses within the context of abdominal pain can be confounded by mimics such as acute coronary syndrome, which are nonspecific, have a high overlap with other conditions, and while they are considered, may not appear in the final diagnosis but nonetheless expose the resident to evaluating for that condition.

A Novel Natural Language Processing–Based Approach

Natural language processing (NLP) of clinical documentation offers a potential breakthrough. By analyzing the comprehensive narrative content of clinical notes that capture the diagnostic reasoning process, NLP can measure case exposure with greater granularity. When combined with the Systematized Nomenclature of Medicine–Clinical Terms, a clinical terminology system designed to represent complex medical concepts, this approach can systematically document both the breadth of conditions evaluated and the depth of clinical reasoning used. This methodological advance aligns with emerging calls for "precision education" in medical training, where the analysis of clinical data drives personalized learning optimization [5,13].

Study Objectives

In this study, we used NLP to provide a comprehensive, data-driven analysis of EM resident development. Using electronic health record data from a single academic medical center spanning multiple resident cohorts, we pursued three objectives: (1) quantify topic exposure curves and clinical progression, mapping how residents accumulate diagnostic topic exposure over time; (2) examine variation in clinical exposure patterns between individual residents and graduating classes; and (3) analyze the distribution of clinical experiences across presentation types and complexity levels to provide empirical evidence relevant to the debate on optimal training duration.

Methods

Study Design and Population

We conducted a retrospective analysis of emergency department (ED) encounters at Stanford Hospital between July 1, 2016, and November 30, 2023. Stanford Hospital serves as the primary training site for our residency and is a high-volume academic ED and level 1 trauma center. This period captured the primary training site experiences of 4 resident classes (2020 - 2023). The study included all EM residents who completed their full 4-year training during this period (n=62). The resident cohort had a mean age of 29.0 (SD 3.6) years, and 40 (64.5%) residents were male. The cohort was predominantly White (n=49, 79%) and non-Hispanic (n=60, 96.8%), with other racial identities including Asian (n=11, 17.7%), Black (n=1, 1.6%), and other (n=1, 1.6%). Encounters in which residents served as either the primary or supervisory resident were included. Resident-patient encounters were identified using the electronic health record's treatment team data. A rule-based algorithm was developed to attribute each encounter to the appropriate residents. Primary attribution was assigned to the first resident to document their involvement with a patient, and this was cross-referenced with shift schedule data to ensure that the encounter occurred during the resident's clinical duties. To account for both primary and supervisory roles, encounters were also coattributed to a senior resident if they were documented on the treatment team in close temporal proximity to a junior resident, reflecting an active supervisory role. When both junior and senior residents were assigned to an encounter, we credited topic exposure to both residents for resident-level analysis but counted each encounter once for patient and encounter-level summaries; per–postgraduate year (PGY) proportions used denominators based on unique, non-double-counted encounters. Encounters from nonclinical or administrative shifts were excluded. Our program is a 4-year PGY1 to 4 program where the PGY4 year includes 40 weeks of ED time with a specific emphasis on developing supervisory skills and practicing with graduated responsibility.

Residents also gain clinical experience at 2 high-volume, high-acuity affiliated sites (Kaiser Santa Clara and Santa Clara Valley Medical Center) that use a different electronic health record. These data were not included in our analysis. Depending on the PGY level, these external sites constitute approximately 30% to 35% of a resident's total ED training time. Encounters from off-service rotations (eg, intensive care unit, anesthesia, and obstetrics) were also excluded. Residents who did not complete the program were excluded from this analysis to ensure the integrity of longitudinal exposure curve construction.

Ethical Considerations

This study was approved as minimal-risk research by the Stanford University Institutional Review Board (IRB 69107). A waiver of informed consent was granted because the study involved secondary analysis of existing clinical documentation. Data access was authorized through the Stanford Research Repository. All data were deidentified and analyzed within a secure, Health Insurance Portability and Accountability Act–compliant environment, and no identifiable information left the repository. The study complied with institutional and national regulations for human participants research.

Data Sources and Variables

We extracted deidentified structured data, including patient demographics, Emergency Severity Index (ESI), and disposition status, as well as unstructured data in the form of clinical documentation from the Stanford Research Repository [14]. We focused on note sections capturing resident diagnostic

reasoning—history of present illness, medical decision-making, and ED course narratives.

NLP Overview

We developed a multistage NLP pipeline to map the narrative content of resident clinical documentation to the 895 clinical subcategories of the 2022 Model for Clinical Practice of Emergency Medicine (MCPEM) [15]. Our approach used a retrieval-augmented generation framework with a Health Insurance Portability and Accountability Act–compliant instance of Google's Gemini 1.5 Flash large language model, which was selected for its balance of cost-effectiveness and high performance within our institution's available tools [16-18]. This involved extracting key clinical concepts from resident notes and mapping them, as an intermediate step, to the Systematized Nomenclature of Medicine–Clinical Terms, Clinical Observations, Recordings, and Encoding subset before final classification into MCPEM topics [19]. This 2-stage process was chosen to preserve granular clinical detail while using a standardized clinical terminology.

Our retrieval-augmented pipeline can be conceptualized using standard NLP terminology as a 3-stage information retrieval (IR) to information extraction (IE) to classification process. The IR component selects relevant note sections and retrieves candidate concept matches from the Systematized Nomenclature of Medicine–Clinical Terms. The IE component, implemented implicitly through the language model, identifies and normalizes key medical entities and filters them for contextual relevance (eg, negated, historical, or uncertain findings). The classification stage maps these normalized concepts to the MCPEM topics.

Validation Methodology

We validated this pipeline through a manual review of 500 randomly selected encounters by 4 board-certified emergency physicians (CP, WD, JH, and RK). This process confirmed the high accuracy of our automated approach, with the model's classifications agreeing with the expert consensus 89.76% (377/420) of the time. The interrater reliability among the physician reviewers was substantial (κ=0.71). A comprehensive description of the NLP architecture, model configuration, and validation methodology is provided in Multimedia Appendix 1.

Analysis

Our analysis focused on 3 key aspects of resident development. To appropriately account for the resident as the primary unit of analysis and the clustered nature of the data (ie, multiple encounters nested within each resident), all encounter-level data were first aggregated to the individual resident level. Statistical comparisons were performed on this resident-level dataset (N=62).

First, we constructed topic exposure curves by tracking cumulative unique topics over time. Topic exposure rates were calculated using 30-day sliding windows. We defined exposure plateaus as periods where residents encountered fewer than 1 new topic per 100 patients over 3 consecutive measurement windows. Second, we examined variation in exposure by analyzing differences in case volumes, topic coverage, and patient acuity. To quantify the equity of exposure distribution among residents within the same PGY level, we calculated the Gini coefficients. Originally developed to measure income inequality, the Gini coefficient quantifies the inequality of a frequency distribution, with values ranging from 0 (representing perfect equality) to 1 (representing perfect inequality) [20]. In this context, a Gini coefficient of 0 would indicate that all residents in a cohort had the exact same volume of exposure to a given measure (eg, high-acuity cases), while a value of 1 would indicate that a single resident received all of the exposure and all others received none. This metric provides a standardized way to compare the degree of interresident variability across different clinical domains and training years. Third, we tracked clinical complexity progression using ESI scores and admission rates as proxies.

Analyses were performed using R (version 4.3.1; R Foundation for Statistical Computing) and Python (version 3.11). Statistical comparisons between classes were performed using Kruskal-Wallis tests with eta-squared effect sizes. A *P* value of <.05 was considered to indicate statistical significance.

Results

Resident Cohort

Our analysis included the primary-site training experiences of 62 EM residents from 4 graduating classes (2020 - 2023). Over the course of their training, this cohort managed 244,255 patient encounters, representing 133,748 (54.8%) unique patients. Detailed demographic and clinical characteristics of the patient encounters are provided in Table 1.

Table . Demographic and clinical characteristics of emergency department patient encounters managed by emergency medicine residents at Stanford Hospital, 2016 to 2023 (N=133,748).

Characteristic	Values
Patient demographics	
Age (y), mean (SD)	47.2 (25.7)

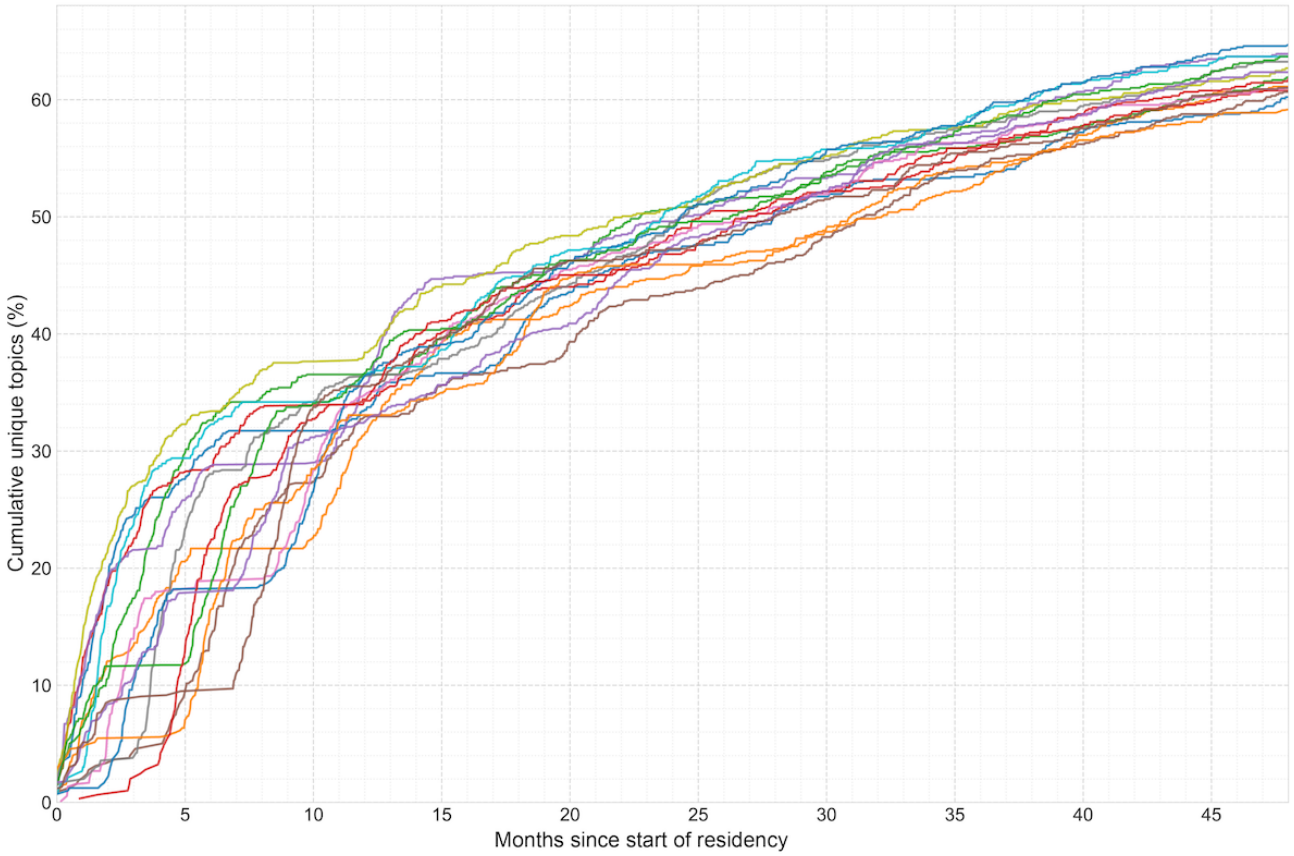
5	1894 (0.8)
Missing	4410 (1.8)

Topic Exposure Progression and Interresident Variation

EM residents demonstrated a clear, progressive acquisition of clinical topic exposure throughout training (Figures 1-4). The most rapid new topic exposure occurred during postgraduate year 1 (PGY1), with residents encountering a mean of 376.7 (42.1%) unique topics of the 895 MCPEM subcategories. However, PGY1 was also the year with the greatest interresident variability in topic coverage (coefficient of variation [CV]=9.1%). As residents progressed through training, the variation in total topic exposure decreased (PGY4 CV=2.8%).

Figure 1. Cumulative clinical topic exposure curve for the emergency medicine graduating class of 2020 at Stanford Hospital, 2016 - 2020 (n=15). The x-axis represents months of training, and the y-axis represents the mean cumulative number of unique clinical topics from the Model for Clinical Practice of Emergency Medicine encountered by residents. The curve does not reach the total of 895 Model for Clinical Practice of Emergency Medicine topics, indicating that no resident achieved 100% topic exposure during their training at the primary academic site.



Exposure coverage continued to increase in subsequent years, reaching a mean of 447.6 (50%) of MCPEM topics in PGY2, 515.0 (57.5%) in PGY3, and 565.9 (63.2%) in PGY4. Exposure plateaus, defined as periods with minimal new topic exposure, typically occurred in the fourth year of training; for example, the Class of 2023 reached plateaus at a mean of 39.8 (SD 3.0) months (mean 3268 encounters). However, individual variation was substantial: some residents plateaued as early as 38.2 months (2742 encounters), while others continued to encounter new topics through their final month, with final topic coverage ranging from 59.44% (532/895) to 67.26% (602/895) of all possible topics among PGY4 residents.

Figure 2. Cumulative clinical topic exposure curve for the emergency medicine graduating class of 2021 at Stanford Hospital, 2017 - 2021 (n=16). The x-axis represents months of training, and the y-axis represents the mean cumulative number of unique clinical topics from the Model for Clinical Practice of Emergency Medicine encountered by residents. The curve does not reach the total of 895 Model for Clinical Practice of Emergency Medicine topics, indicating that no resident achieved 100% topic exposure during their training at the primary academic site.

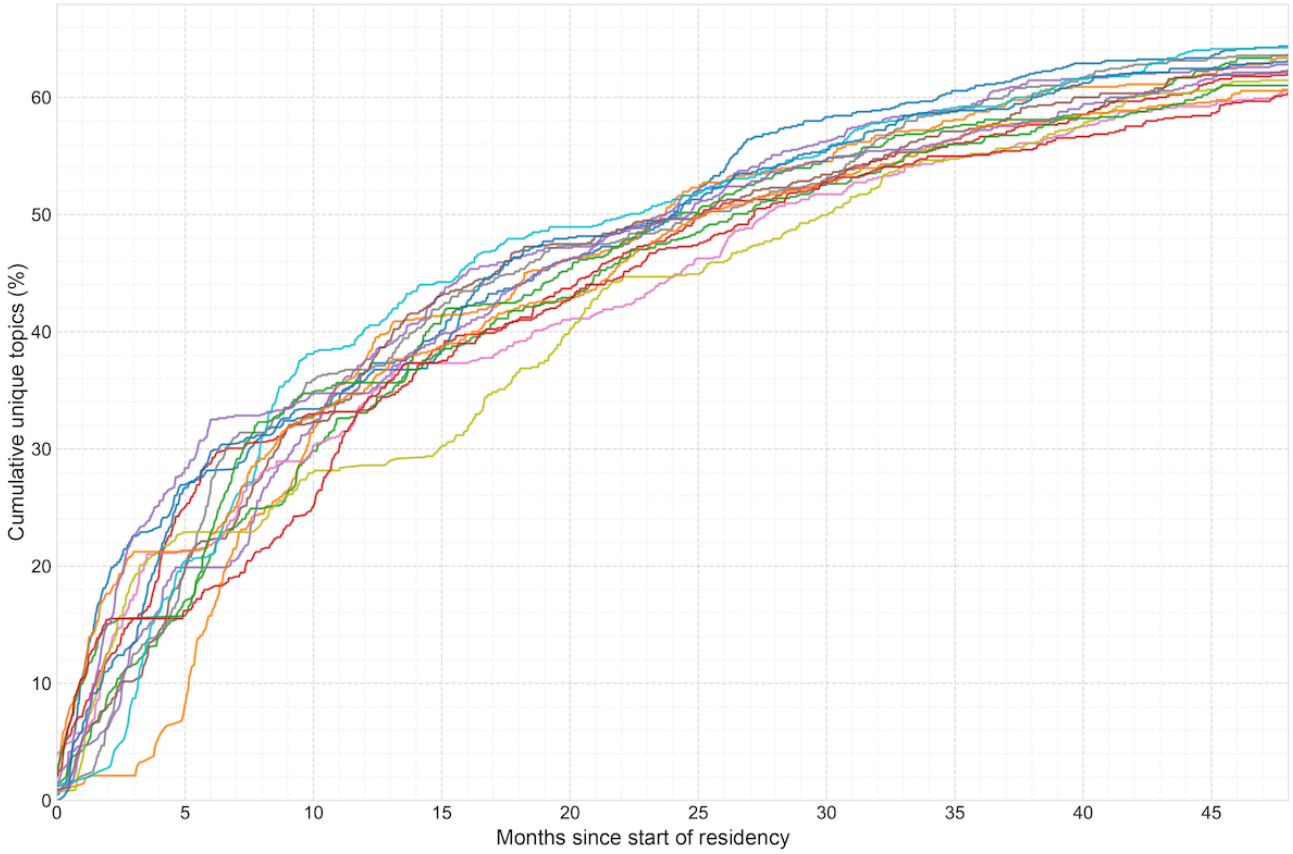


Figure 3. Cumulative clinical topic exposure curve for the emergency medicine graduating class of 2022 at Stanford Hospital, 2018 - 2022 (n=15). The x-axis represents months of training, and the y-axis represents the mean cumulative number of unique clinical topics from the Model for Clinical Practice of Emergency Medicine encountered by residents. The curve does not reach the total of 895 Model for Clinical Practice of Emergency Medicine topics, indicating that no resident achieved 100% topic exposure during their training at the primary academic site.

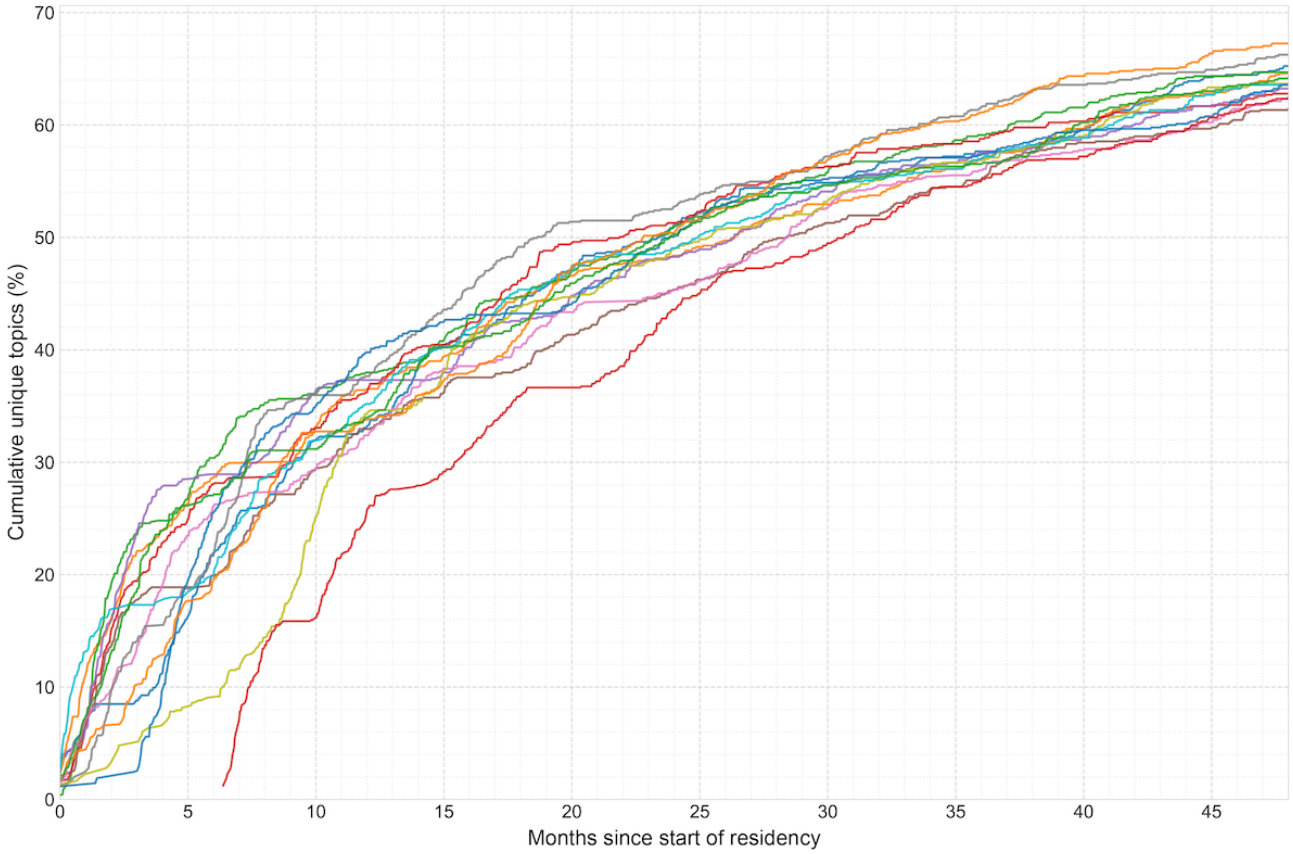

Figure 4. Cumulative clinical topic exposure curve for the emergency medicine graduating class of 2023 at Stanford Hospital, 2019 - 2023 (n=16). The x-axis represents months of training, and the y-axis represents the mean cumulative number of unique clinical topics from the Model for Clinical Practice of Emergency Medicine encountered by residents. The curve does not reach the total of 895 Model for Clinical Practice of Emergency Medicine topics, indicating that no resident achieved 100% topic exposure during their training at the primary academic site.

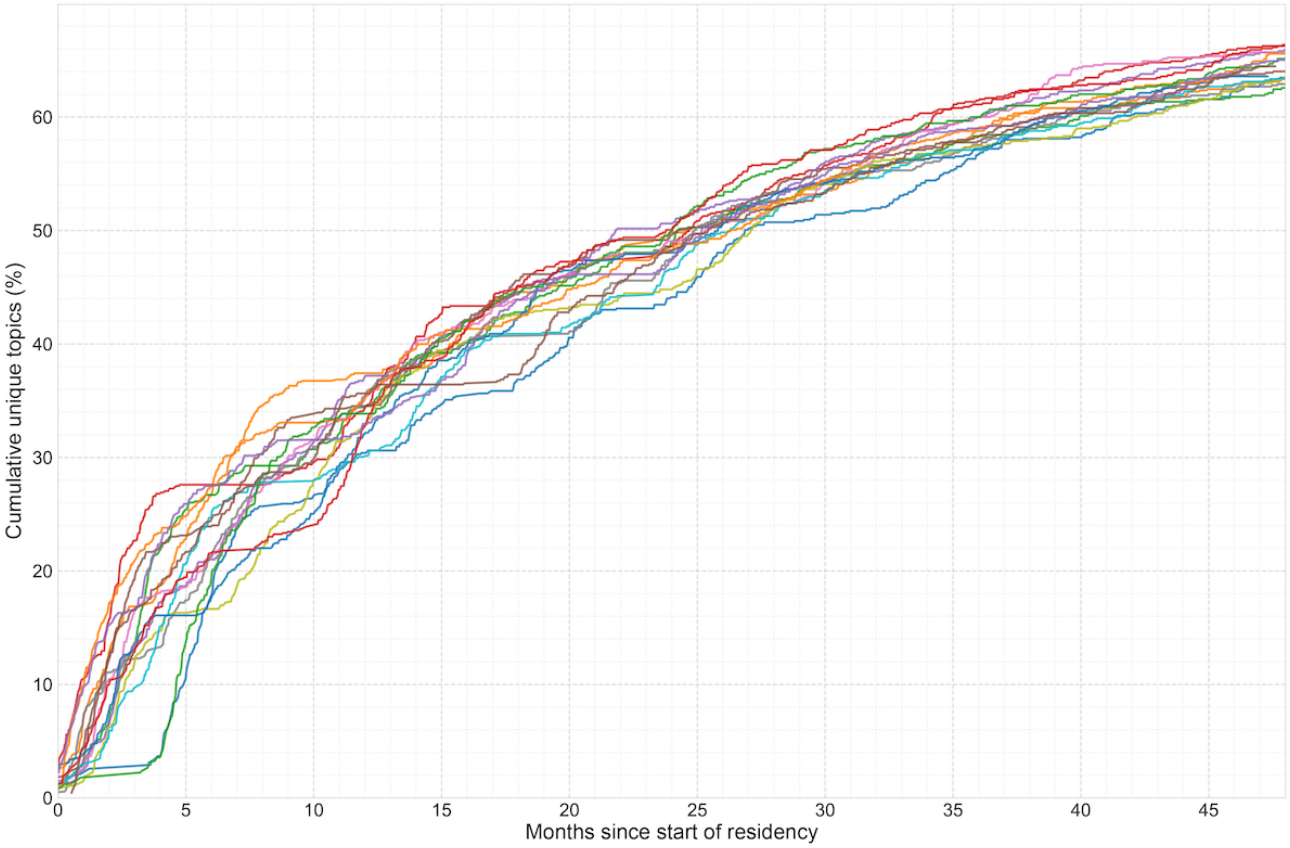

Progression of Clinical Workload and Complexity

In parallel with increasing topic exposure, residents demonstrated a progressive increase in their clinical workload and the complexity of cases managed (Table 2). Annual case volumes more than tripled from PGY1 (mean 445.7 encounters) to PGY4 (mean 1528.4 encounters). This growth in volume was accompanied by increasing case acuity, as mean ESI scores progressively decreased from 2.94 in PGY1 to 2.79 in PGY4. Correspondingly, the proportion of high-acuity patients (ESI 1 - 2) managed by residents increased from 16% (4374/27,340) in PGY1 to 30.91% (9418/30,466) in PGY4, and admission rates rose from 31% (8475/27,340) to 37.50% (11425/30,466) over the same period. Notably, the CV for both clinical volume and admission rates followed a U-shaped pattern, decreasing from PGY1 to PGY3 before increasing again in PGY4.

Table . Progression of clinical experience by postgraduate year (PGY) for emergency medicine residents (N=62), Stanford Hospital, 2016 to 2023.

	PGY1	PGY2	PGY3	PGY4
Annual clinical volume and complexity				
Number of encounters, mean (95% CI)	445.7 (417.6 - 473.7)	772.1 (738.5 - 805.8)	1193.4 (1138.5 - 1248.2)	1528.4 (1429.1 - 1627.8)
ESI[a] score, mean (95% CI)	2.94 (2.93 - 2.96)	2.87 (2.85 - 2.88)	2.85 (2.84 - 2.87)	2.79 (2.76 - 2.81)
High-acuity cases (ESI 1 - 2), n/N (%)	4374/27,340 (16)	5575/27,479 (20.2)	7398/30,101 (24.5)	9418/30,466 (30.9)
Admission rate, % (95% CI)	31.0 (29.7 - 32.4)	38.3 (37.3 - 39.4)	35.5 (34.6 - 36.3)	37.5 (36.3 - 38.8)
Cumulative topic exposure				
Cumulative unique MCPEM[b] topics covered, mean (95% CI)	376.7 (367.9 - 385.5)	447.6 (442.2 - 453.0)	515.0 (510.9 - 519.0)	565.9 (561.9 - 569.9)
Cumulative total percentage of MCPEM covered, %	41.1	50	57.5	63.2
New topics encountered each year, mean (SD)	376.7 (28.4)	71.0 (18.1)	67.3 (14.1)	50.9 (13.3)
Interresident variability (CV[c]), %				
CV for clinical volume	24.6	17	18	25.4
CV for admission rate	16.4	11.1	9.5	13.4
CV for topic coverage	9.1	4.7	3.1	2.8

[a]ESI: Emergency Severity Index.

[b]MCPEM: Model for Clinical Practice of Emergency Medicine.

[c]CV: coefficient of variation.

Distribution of Clinical Experiences

Residents' exposure to the 895 distinct clinical topics followed a consistent pattern—they encountered a small core of presentations (n=49, 5.5%) more than 100 times each, a larger set (n=284, 31.7%) between 10 and 100 times, and the majority (n=562, 62.9%) fewer than 10 times. Topic distribution showed moderate inequality (mean Gini coefficient=0.611), with consistency between the graduating classes (P=.61). High-acuity case exposure was more unequally distributed (Gini=0.292) than the overall case volumes (Gini=0.117).

Discussion

Principal Findings

Our analysis of 62 EM residents across 4 years of training revealed distinct and progressive patterns in the arc of their clinical experience. Using a novel NLP methodology on over 244,000 clinical encounters, we found that residents demonstrated a rapid acquisition of topic exposure in their first year, which continued, albeit at a slower rate, deep into their fourth year. Importantly, this continued exposure occurs in the context of increasing clinical complexity and, based on our program's structure, escalating supervisory responsibility. These findings provide empirical evidence that can inform the national debate on the optimal length of EM training and highlight the potential for data-driven, precision education.

Implications for Competency-Based Medical Education

The observed pattern of topic exposure, rapid initial acquisition followed by a plateau, aligns with the power-law "experience curves" documented in medical education by Pusic et al [21] However, it is critical to note that case exposures are merely the substrate for learning and are not all equal in value toward developing competence. The conversion of these experiences into durable competence is a complex process mediated by the *deliberate* components of the theory of deliberate practice by Ericsson [22], such as feedback, reflection, and coaching [22-24]. Indeed, recent research has shown that even established competency measures, such as milestones, may not directly correlate with early-career patient outcomes, cautioning against a simple equation of more exposure with more competence [25]. Therefore, the primary value of the exposure data we present lies in its ability to serve as a powerful objective input for these established educational frameworks. At our institution, for example, these components are formalized through a resident coaching program and a quarterly Clinical Competency Committee, systems for which this objective exposure data can provide a more precise foundation for assessment and goal-setting, and tracking progress toward the Accreditation Council for Graduate Medical Education milestones [2,26].

Informing the Debate on Training Duration

A central question for the EM as a specialty is whether a 3- or 4-year training model is optimal. Our data provide empirical

evidence relevant to this debate. The finding that residents continue to acquire a mean of 50.9 new core topics in their PGY4 year, representing a 9.9% (51/515) increase over PGY3, suggests that the fourth year offers more than just redundant experience. This quantitative increase is accompanied by a significant qualitative shift—PGY4 residents manage a higher proportion of high-acuity patients (ESI 1 - 2) and cases requiring hospitalization. This exposure to a more complex and challenging case mix, as supported by work from Lam et al [10] and Zhou et al [27], is critical for developing the advanced diagnostic reasoning necessary for independent practice.

Understanding Interresident Variation

Our analysis also revealed significant interresident variation, particularly in the timing of exposure plateaus and in the experience with high-acuity cases. This aligns with findings from other specialties and supports a more personalized view of competency development [28]. This variability is likely to be driven by a combination of systemic factors and resident choices. We propose framing this variability within the concept of "warranted versus unwarranted variation" as described by Holmboe and Kogan [29]. While some variation is an expected and even desirable feature of individualized learning, our NLP-based tool provides a mechanism for programs to identify potentially unwarranted gaps in exposure to core experiences. Notably, the decreasing CV in total topic coverage from PGY1 (9.1%) to PGY4 (2.8%) suggests that a longer training duration may lead to a more standardized and equitable clinical experience among graduates.

The U-shaped pattern observed in the variability of clinical volume and admission rates is an intriguing finding. We hypothesize that this reflects the evolving roles within our program—PGY1 residents have variable schedules due to numerous off-service rotations; PGY2 and PGY3 residents assume more structured supervisory roles within a pod system, which may standardize their workflow and decrease variability; finally, in PGY4, residents are granted greater autonomy to run a pod independently while also supervising junior residents, potentially allowing individual practice styles to reemerge at increasing variability.

Bridging the Curriculum-Practice Gap and Methodological Advantages

A key finding of this study is that even after 4 years, residents were not exposed to over a third of the topics listed in the MCPEM (329/895, 36.76%). This highlights the fundamental tension between the prescribed curriculum and the reality of clinical practice. Achieving 100% topic coverage is likely an unachievable goal for any single residency program. The true aim of training is not encyclopedic exposure but rather developing the core competencies and adaptive expertise required for safe, independent practice and effective lifelong learning. Our NLP-based methodology offers a powerful, dual-pronged approach to address this gap. At the local program level, it serves as a diagnostic tool, enabling educators to identify and amend exposure gaps through targeted interventions, such as simulation. More broadly, the scalability of this approach presents an opportunity to transform the specialty's understanding of its own work. If applied across multiple institutions, this method could create a dynamic, data-driven map of the actual clinical practice of EM, providing an evidence base for future revisions of the MCPEM. This would allow the model to better reflect the true prevalence and complexity of conditions encountered in contemporary practice, ensuring a more authentic alignment between what is taught, what is tested, and what is practiced. Nonetheless, there will likely always remain a set of high-acuity, low-frequency conditions for which training programs must prescribe exposure through didactics, as real-world encounters will be too rare to ensure universal competence.

A key advantage of this methodology is its practical implementation. Traditional NLP pipelines often require a substantial upfront investment in manual data annotation for model training and specialized expertise. In contrast, our retrieval-augmented generation approach takes advantage of a pretrained large language model that requires no model-specific training, dramatically reducing the implementation complexity. To offer a concrete sense of financial feasibility, the total cost for the application programming interface calls to process all 244,255 clinical encounters for this study was approximately US $180, demonstrating the financial accessibility of this approach for programs seeking to adopt data-driven educational strategies. Framing our pipeline in IR and IE terms also clarifies where most misclassifications arise—either from retrieval scope or from information-extraction phenomena such as negation or temporality—providing a useful structure for future error analysis and comparison to traditional rule-based clinical NLP systems.

Limitations

This study has several limitations. As a single-institution study, our findings may not be generalizable to programs with a 3-year training format, or to institutions operating in different clinical settings. A primary limitation is that our analysis excludes data from additional training sites, which constitute a significant proportion of resident training (approximately 30% - 35% of ED time, depending on the PGY level), and from off-service rotation where key procedural and critical care exposures occur (eg, anesthesia, intensive care unit, etc). The training period for our cohorts also overlapped with the COVID-19 pandemic, which may have influenced case volumes and mix, although the remarkable consistency of exposure patterns we observed across the 4 classes mitigates this concern. Finally, although our NLP approach achieved high accuracy in classifying clinical encounters (89.7% agreement with physician review), this methodology relies on the comprehensiveness of resident documentation, which may vary between individuals and over time.

In conclusion, our analysis reveals both consistent patterns in resident clinical exposure and substantial individual variation in topic exposure trajectories. The finding that many residents continue to encounter new clinical topics into their fourth year provides empirical evidence for the potential educational value of a 4-year training model. NLP of clinical documentation offers EM programs a powerful and accessible tool to objectively measure and optimize resident clinical experiences based on actual exposure patterns, moving beyond traditional metrics to

foster a more precise, data-informed, and equitable approach to graduate medical education.

Abstract

Background: Video-sharing sites such as YouTube (Google) and TikTok (ByteDance) have become indispensable resources for learners and educators. The recent growth in generative artificial intelligence (AI) tools, however, has resulted in low-quality, AI-generated material (commonly called "slop") cluttering these platforms and competing with authoritative educational materials. The extent to which slop has polluted science education video content is unknown, as are the specific hazards to learning from purportedly educational videos made by AI without the use of human discretion.

Objective: This study aimed to advance a formal definition of slop (based on the recent theoretical construct of "careless speech"), to identify its qualitative characteristics that may be problematic for learners, and to gauge its prevalence among preclinical biomedical science (medical biochemistry and cell biology) videos on YouTube and TikTok. We also examined whether any quantitative features of video metadata correlate with the presence of slop.

Methods: An automated search of publicly available YouTube and TikTok videos related to 10 search terms was conducted in February and March 2025. After exclusion of duplicates, off-topic, and non-English results, videos were screened, and those suggestive of AI were flagged. The flagged videos were subject to a 2-stage qualitative content analysis to identify and code problematic features before an assignment of "slop" was made. Quantitative viewership data on all videos in the study were scraped using automated tools and compared between slop videos and the overall population.

Results: We define "slop" according to the degree of human care in production. Of 1082 videos screened (814 YouTube, 268 TikTok), 57 (5.3%) were deemed probably AI-generated and low-quality. From qualitative analysis of these and 6 additional AI-generated videos, we identified 16 codes for problematic aspects of the videos as related to their format or contents. These codes were then mapped to the 7 characteristics of careless speech identified earlier. Analysis of view, like, and comment rates revealed no significant difference between slop videos and the overall population.

Conclusions: We find slop to be not especially prevalent on YouTube and TikTok at this time. These videos have comparable viewership statistics to the overall population, although the small dataset suggests this finding should be interpreted with caution. From the slop videos that were identified, several features inconsistent with best practices in multimedia instruction were defined. Our findings should inform learners seeking to avoid low-quality material on video-sharing sites and suggest pitfalls for instructors to avoid when making high-quality educational materials with generative AI.

Introduction

Background

Video-sharing platforms such as YouTube (Google) and TikTok (ByteDance) have become entrenched features of the educational landscape. Both instructors and students rely on these resources for a variety of purposes relating to teaching and learning [1-3], and the inherent benefits of video instruction in science education, specifically, have been well-documented [4-6]. Nonetheless, these video-sharing platforms' greatest advantages—accessibility and low barriers to creating and sharing—are also arguably their greatest weaknesses, as the lack of barriers leads naturally to large amounts of low-quality material appearing alongside authoritative, high-value material. Because these platforms rely mostly on advertising for revenue, algorithms that recommend videos based on past views [7] and prioritize engaging over reliable videos [8] make it difficult to find the most credible and useful videos, not simply those most likely to maximize time on the site [8]. Furthermore, not all audiences may have the motivation or ability to assess the reliability of online videos [9,10], and in the absence of a shared standard of quality, one audience might find a video informative while another finds it inappropriate. Frameworks for assessing the quality of multimedia instruction have been advanced over the past few decades [6,11-13], but these are directed toward educators and instructional designers. How learners judge the quality of educational content remains poorly studied, and in the absence of guidance, students may simply defer to intuition [14].

The accessibility of social media platforms, and the lack of any uniform standard for judging quality, inherently present a challenge to any learner searching for educational content. The recent explosion in generative artificial intelligence (genAI) technologies, including large language models (LLMs) like ChatGPT (OpenAI) and Claude (Anthropic), and image generators like Stable Diffusion (Stable Diffusion AI) and Midjourney [15], has added further complication to this situation. To genAI users, time and effort are no longer barriers to generating shareable content. As a result, writing websites [16], social networks [17,18], and online markets [19] are increasingly cluttered with fake artificial intelligence (AI)–generated essays, posts, artwork, and merchandise. More troublingly, the scientific literature is now polluted with false machine-generated studies and data [20,21], often to push contrarian agendas [22]. The low-quality, high-volume, AI-generated content behind these examples has been called "slop" [19]; its proliferation led *MIT Technology Review* to deem slop the "biggest AI flop" of 2024 [23]. Slop lacks a single widely accepted definition, but journalists and industry commentators generally agree that slop is of low quality, ubiquitous, lacking in artistic or scientific value, and generated to maximize exposure or engagement, or simply to fill space on sharing platforms [16,19,24]. At best, slop is a distraction requiring time and effort to sift through in search of good material; at worst, it presents specific dangers to learners, educators, creative professions, and the overall atmosphere of public information [24].

The degree to which slop has crept into educational materials is largely unknown. Exploratory studies in medical and undergraduate science education suggest that carelessly produced genAI content can pose a significant risk of misunderstanding, spread outright misinformation [25,26], or promote deskilling or "metacognitive laziness" [25,27] in learners. Learners turn to AI content when they are most easily influenced—while uncertain or confused—and thus are most likely to be persuaded by errors or biases in the genAI output [28]. Yet errors abound in such content; in medical teaching, genAI output has been found to misrepresent rare diseases or those with variable presentations [29,30], and AI-generated anatomical diagrams often contain gross inaccuracies [31,32]. In other fields, genAI has been shown to create garbled chemical models and biased depictions of researchers [33,34], inaccurate but plausible-sounding descriptions of metabolic processes [35], and realistic images of nonexistent animal species, leading to confusion in biodiversity conservation efforts [36].

As for video, it is possible to create entirely AI-generated video clips using tools such as Synthesia and Sora (OpenAI); however, at the time of writing, these tools (unlike those above) are not yet available for free use, or free users are limited to very short clips. Consequently, fully AI-generated videos are not yet as widespread as images and text. This does not, however, mean video-sharing sites are free of slop. Free users can, for example, use AI tools to animate a photo of a "narrator," or stitch together stock or AI-generated images to create a longer video. Tutorials on making videos in this fashion are widely available [19,37].

The purpose of this study is to examine the reach and characteristics of lazily-made genAI content in online videos on preclinical biomedical sciences (medical biochemistry and cell biology; eg, Biochemistry & Nutrition and Cell Biology & Histology topics in the USMLE Foundational Sciences area, as these are the authors' disciplines of expertise). Although slop has been widely discussed in popular media, it has not yet received much scholarly attention, so our first priority is to establish a useful definition of slop in educational media. To this end, we use the theoretical framework of "careless speech" recently advanced [38] to propose legal-ethical responsibilities of genAI.

Theoretical Framework

The characteristics of slop are ultimately a consequence of genAI's intrinsic structure. All present genAI tools work by predicting associations between linguistic elements, based on human-reinforced training with real (human-generated) data. They cannot directly access external reality. They may therefore state falsehoods as fact or realistically depict impossible scenes (so-called hallucinations or confabulations), so long as the output correlates with training data [38]. GenAI is also prone to subtle errors or omissions in addition to outright falsehoods; it has difficulty grasping humor, nuance, or insinuation [26]; it does not exhibit a clear concept of uncertainty and tends to make confident assertions even where there is no clear answer [38,39]. Most genAI tools are programmed to sound authoritative and to give responses deferentially and in accord with a user's desires (sycophancy) [40]. For any AI-generated task, biased or incomplete information in the training data (eg, absence of

an important but uncommon viewpoint) will result in biased output [41,42]. The "speech" generated by AI (which we mean here to encompass not only language but also images, video, sounds, and other output), therefore, appears authoritative and competent but is unmoored from physical reality, lacks any motivations or principles, and carries whatever biases are present in the training data.

Can AI-generated speech be trusted, then? A recent paper by Wachter and colleagues [38] suggests the answer is no, unless there is cross-validation with the outside world, for example, using "human in the loop" [43,44] or "zero-shot translation" [45] approaches to verify accuracy, forestall errors, and account for uncertainty or caveats in the output. Wachter and colleagues use the term "careless speech" to describe the type of output that unsupervised AI produces. Careless speech is quasi-factual output that correlates with what humans say is reality (the training data), but without direct access to that reality; it is a coherent statement approximating a factual statement. Careless speech is not necessarily misinformation, as it is not always false. Rather, it is independent of reality; it may resemble truth, but exists separately.

We believe careless speech is a useful framework for establishing a definition of slop relevant to educational material. From this point onward, we use the term "material" to refer to a specific created object (eg, a video), and reserve the word "content" for the subject matter (contents) of these materials.

We define slop as follows: slop is any material, created mostly or entirely by generative AI, with little or no apparent human care toward the accuracy, fluency, or helpfulness of the material or of its most likely use or interpretation.

The operative word in this definition is *care*, to which we assign two meanings [46]: (1) deliberate attention and effort (eg, prompt design, editing, and fact-checking) toward ensuring the material has desirable characteristics, that is, to "care for" (taking on "responsibility to meet a need that has been identified" [46]); and (2) some professional or personal stake in the outcome, implying an ownership of and accountability for the product and its likely uses, that is, to "care about." AI-generated material that does not discernibly exhibit care in *both* senses of the term is slop, regardless of its accuracy. Our definition implies that any material made entirely by genAI is slop; material made by genAI with human intervention may or may not be slop, depending on the degree of care in the intervention.

Our definition makes no direct reference to the quality of the material. This is intentional. If one defines "quality" in terms of accuracy and realism, genAI is making tremendous strides in improving its quality. Yet just as the content (meaning here the messaging and subject matter) of AI output is, at best, incidentally accurate—in Wachter's words, "True responses are an accident of probability and reinforcement via human feedback, not agency or a conception of truth or intent to tell the truth" [38]—the quality of AI output is, at best, incidentally good. Without a caring human in the loop, AI output can only approximate, by correlation, characteristics associated with quality. Thus, slop is independent of quality in the same way that careless speech is independent of reality.

Likewise, our definition is agnostic regarding the purpose for which the AI-generated material is made. Slop is often made and disseminated to game engagement metrics (eg, clickthroughs, likes, and views), ultimately for the creator's financial or political gain [19,24]. However, it is possible that some slop is made with the genuine intent of informing or entertaining—only without adequate care to ensure this intent is fulfilled. We therefore believe intent and purpose are irrelevant to the definition of slop, particularly since the intentions of those generating the slop are generally unknown.

Educational Implications of Slop and Careless Speech

Careless speech was proposed as a framework for understanding the dangers of genAI output in legal settings. In educational settings, genAI is likely to present a distinct set of risks. Much of the research on educational hazards of genAI focuses narrowly on non-factual or hallucinated output [30-32,35,36] or on bias and ethical risks [34,47-50]. A more holistic understanding of the impact of careless speech on learning requires a broad framework for what makes educational materials effective at all.

With respect to video, the theory of multimedia learning [51] is one such framework and is supported by considerable empirical evidence [4]. Drawing from cognitive load theory, this model considers structural and design features that influence the effectiveness of multimedia materials. Complementary to this theory, other models emphasize the content of multimedia materials, specifically themes of active learning and features that promote engagement with the video [6,12,13]. Thus, the effectiveness of multimedia educational tools may be seen as having both design or structural components and content components that support learning.

Because the concern of this study is the educational effectiveness of video, some might question our choice to focus on AI slop rather than low-quality video more generally. There are at least 2 reasons why slop deserves particular attention. First, the sheer volume of slop is already overwhelming online platforms [16,18,19]. Students are thus extremely likely to encounter slop, which may soon comprise the majority of low-quality video. Second, instructors wishing to use genAI responsibly need to know the likely failure modes of the technology, so that proper attention can be paid to avoiding these pitfalls, maximizing educational impact, and reinforcing the necessity of human judgment in human-centered professions [52].

This study examines the current prevalence and problematic characteristics of slop educational videos on popular platforms, according to the following three research questions (RQs):

- RQ1: What are the qualitative characteristics of slop videos that might imperil learning or trust in educational systems?
- RQ2: What is the prevalence and reach of slop, according to our definition, in medical biochemistry or cell biology material on YouTube and TikTok, as discerned from viewership data?
- RQ3: Are there any quantitative metrics, such as view or like rates, that can reliably identify slop videos?

To address RQ1, we rely on a 2-stage qualitative content analysis in which we identify the educationally hazardous traits

of likely slop videos and map them to the 7 characteristics of careless speech identified by Wachter et al [38]. We approach RQ2 and RQ3 using basic data mining methods. We hypothesize that slop videos display features contravening both the structural and content-thematic elements of effective multimedia instruction and present a significant (and growing) share of the educational space on these platforms.

Methods

Study Design and Approach

A complete description of the search and screening procedure is given in Multimedia Appendix 1. The overall strategy was to search YouTube and TikTok for videos on biochemical topics that first-year medical students often find challenging, to examine these videos for signs of careless AI use, and to compile a list of problematic features of the suspected genAI videos (RQ1). Data on viewership, video age, and duration were also collected to infer the reach and popularity of these videos, compared with the entire dataset (RQ2), and to see if these correlated with slop (RQ3).

Searching and Screening of Videos

YouTube and TikTok were searched using third-party application programming interfaces (APIs; SerpAPI YouTube Search Engine and Apify TikTok Search API) over a 2-week period in late February and early March 2025. In total, 10 queries were used for each platform (Table 1), incorporating both single-word and sentence-like queries to obtain a variety of results.

Table . Summary of search results for each of the 10 queries. Unique URLs include off-topic and non-English videos that were excluded at later stages of screening.

Search query	YouTube URLs (raw), n	YouTube URLs (unique), n	TikTok URLs (raw), n	TikTok URLs (unique), n
How do enzymes work	209	114	60	—[a]
Protein secondary versus tertiary structure	210	96	60	—
Ion channel function	154	66	89	—
Cell cycle regulation	198	105	60	—
Carbohydrate metabolism	59	51	60	—
Electron transport chain	208	101	84	—
Urea cycle	68	67	42	—
Pentose phosphate pathway	195	109	60	—
Cytoskeleton	185	114	60	—
What are eicosanoids	110	85	88	—
Total	1596	908	663	617

[a]Not available, as the TikTok URLs were deduplicated as a single group.

Residential proxy servers were used, and stored browser data were cleared before each search. The search results were exported in JSON format, from which bare URLs were extracted and deduplicated, resulting in 908 and 617 unique video links for YouTube and TikTok, respectively. These videos were viewed for a few seconds each to identify off-topic and non-English videos, which were excluded. The 1082 on-topic videos remaining (814 YouTube and 268 TikTok) were then screened briefly for common "tells" of AI-generated material (refer to Multimedia Appendix 1 for rubric); 1 screener (EMJ) viewed each video for a minimum of 30 seconds (or the whole video, if less than 30 s) and flagged any showing signs suggestive of genAI. A list of these videos was then distributed among 3 reviewers, who viewed them in their entirety to verify that the "tells" were present and to provide a score (0=not AI-generated, 1=partially AI-generated, and 2=mostly AI-generated), and to note any factual errors. These videos were labeled as "likely AI-generated" (but not necessarily slop) if the average score was 1.0 or higher (only 1 video did not meet this criterion). AI detection tools were not used, due to their known unreliability [53].

To determine viewership, video metadata (including days online, duration, number of views, likes, and comments) was scraped for the entire 1082-video dataset using commercial data-scraping agents (Apify YouTube and TikTok Scrapers). Metrics were compared between the AI-generated and overall population datasets using a permutation test [54], a nonparametric test deemed appropriate because of the highly nonnormal distributions of data and the fact that the AI dataset was contained within the overall dataset.

Qualitative Analysis

A detailed description of the qualitative analysis method is given in the Multimedia Appendix 1. A 2-stage procedure was used. The first stage consisted of an inductive content analysis [55] to categorize features that we deemed educationally problematic. We define "educationally problematic" as violating one or more tenets of effective multimedia instruction according to Mayer's [51] cognitive theory of multimedia instruction, or principles of quality explanatory video design, including precise and descriptive language, clear learning objectives, and opportunities for engagement and reflection, as outlined by Brame [6], Kulgemeyer [12], and Ring and Brahm [13]. The objects of

analysis were decided to be any audiovisual feature (such as graphics, narration, linguistic features, sounds, or combinations of these) that were potentially inaccurate, misleading, distracting, irrelevant, or clearly biased. The videos deemed "likely AI-generated" (plus 6 additional videos found independently; not included in above statistics) were viewed separately, in their entirety, by 2 faculty (EMJ and JDN), one of whom was not involved in the screening steps (the additional videos were found in a YouTube video search for an unrelated project, using queries "enzyme catalysis," "metabolic pathways," "what is an enzyme mechanism," or "lipid bilayer structure"). Each viewer independently compiled a list of such features in all videos and then compared observations. Features tended to relate to either the arrangement and layout of audiovisual and linguistic elements (structural or design features) or the informational content of the videos (content features). An effort was thus made to divide all problematic features between these categories. This was deemed insufficient because certain features involved an inappropriate pairing of structural with content elements. A third category of "content – structure/language" features was thus created for audiovisual features that were "conditionally" problematic based on content, or vice-versa. These categories formed the core of the coding frame. The viewers independently assigned preliminary codes to features in each category, rewatched videos, and modified as appropriate. The viewers then met again to compare codes, re-view videos, and revise until agreement was reached on all codes.

Following the inductive content analysis, a deductive coding stage was performed [56], in which the viewers separately mapped the consensus codes onto the 7 characteristics of careless speech [38]. Reviewers independently assigned codes from the first stage to these 7 characteristics (except "lack of references to source material," as references are not typically provided in teaching videos), then met and discussed to obtain internal consistency. Some of the codes could not be mapped to the characteristics of careless speech, so 2 new characteristics of slop were proposed, and the reviewers again separately assigned codes to these characteristics, met, and revised until agreement was reached.

After completion of the qualitative analysis, an assessment of each video in the AI dataset as "slop" or "not slop" was made. We considered a video "slop" if it contained at least 2 of our codes of problematic content and exhibited at least 1 of the 7 characteristics of careless speech, except "lack of references to source material." Agreement by both reviewers was required for a "slop" assignment. All videos in the likely-AI dataset were judged to be slop by these criteria.

Ethical Considerations

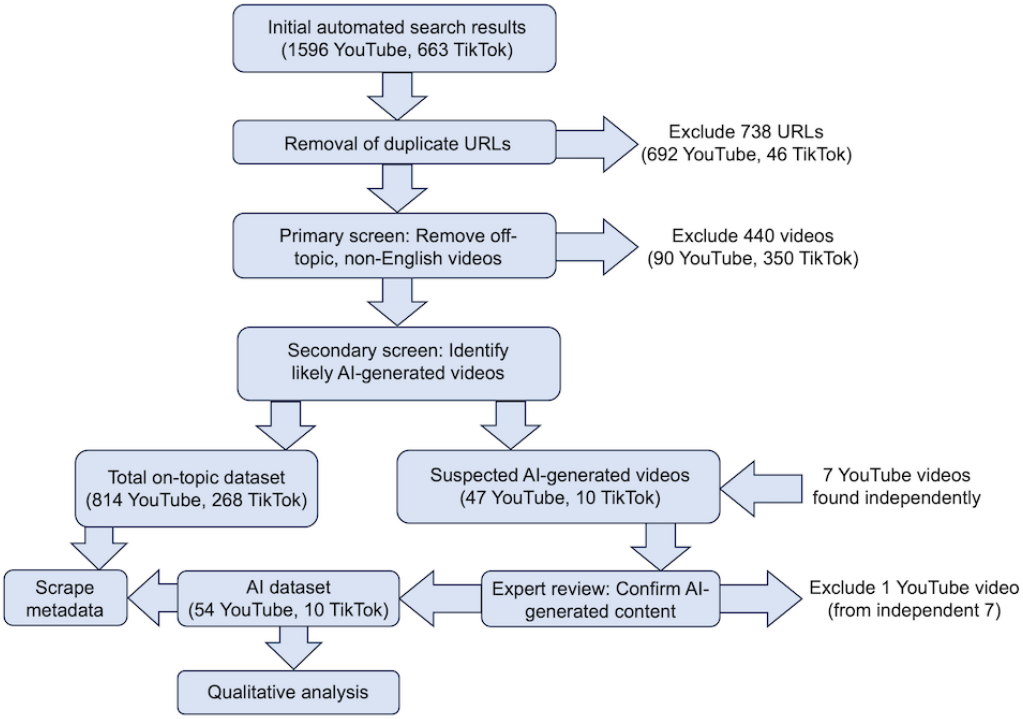
Because this study uses only publicly available data and videos shared with the public are accessible via general search, it is not a research involving human participants, and no ethical review was sought.

Results

Summary of Dataset and Prevalence of Slop

The study design is summarized in Figure 1. Summary statistics for the 814 YouTube and 268 TikTok videos examined, and a complete numbered listing of all videos, are available in the Multimedia Appendix 2. Regarding RQ2, 47 of 814 YouTube videos (5.8%) were judged to be slop according to our definition. We found that slop on YouTube was concentrated among YouTube Shorts, short-format videos that play in a loop: although only 279 of the YouTube videos examined (34.3%) were Shorts, 37 of 47 videos identified as slop (78.7%) were Shorts, with only 10 standard YouTube videos being slop. This finding is unsurprising, given YouTube's recent integration of genAI tools with Shorts [57], although most of the videos on the list predate this development. On TikTok, 10 of 268 on-topic videos (3.7%) were judged to be slop; across both platforms, the proportion was 57 of 1082 videos (5.3%) slop. We caution that these numbers likely underestimate the true prevalence of slop, as our method was designed to only identify obvious, low-quality AI-generated videos, and many better-quality videos may have been missed. Furthermore, since the platforms were searched using an automated tool, links to suggested videos, possibly containing more slop, were not retrieved.

Figure 1. Study design. The final AI dataset for qualitative analysis is a subset of the total on-topic dataset, plus 6 additional YouTube videos found after the initial search (these 6 not included in summary statistics). AI: artificial intelligence.

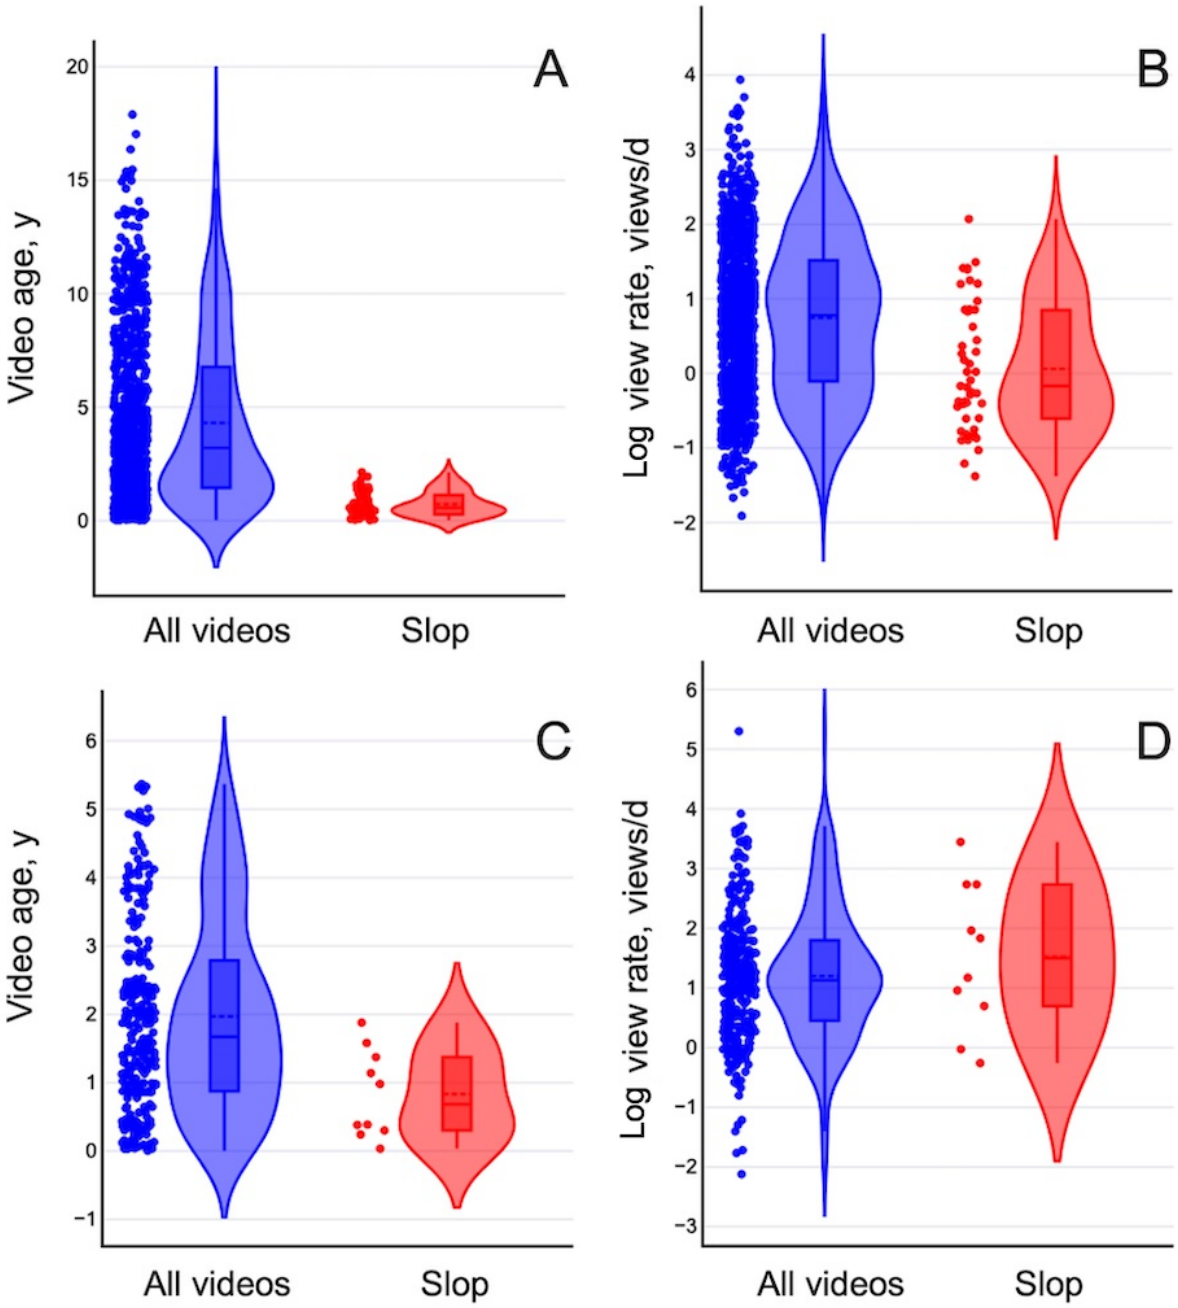


Regarding RQ3, video metadata revealed the videos varied widely in terms of age (number of days online at time of data collection), duration, number of views ("plays" on TikTok), and number of likes and comments (Tables S1 and S2 in Multimedia Appendix 1). Slop video durations on YouTube were, on average, shorter than the population at large, due to the overrepresentation of YouTube Shorts. On TikTok, the opposite was true; however, the TikTok average is skewed by 1 very long (24 min) video. View and like rates were calculated by dividing the total number of likes, views, and so on for each video by the age of the video in days to obtain average views, likes, and so on per day. This step was essential due to the widely varying ages of the videos, making raw counts of these figures misleading. The distributions of video age and view rate (log scale) are presented graphically in Figure 2; rates of likes and comments are not shown because many videos had no likes or comments and would thus not appear on a log-scale plot.

On both platforms, slop videos tended to have lower rates of engagement (views, likes, shares, and comments) than the population at large, although the difference was not statistically significant (eg, P=.87 for TikTok collect rate) according to permutation tests. The difference in engagement was more pronounced on YouTube. YouTube slop videos were engaged with about an order of magnitude less frequently, on average, than the population (Table S1 in Multimedia Appendix 1, last 3 columns), although the extremely broad and asymmetric distributions made the difference insignificant (P=.11 for view rate; data not shown). Notably, 21.3% (10/47) of the slop YouTube videos had no likes, and 78.7% (37/47) had no comments at the time of scraping.

Engagement with TikTok videos was generally higher than with YouTube videos (last 4 columns of Table S2 in Multimedia Appendix 1). Rates of views (plays), collects (which we regard as analogous to YouTube likes), and comments are all higher than the corresponding YouTube metrics, which may reflect broader differences in the manner of use of the 2 platforms, or simply a greater number of videos to choose from on the much larger YouTube. TikTok also has a "share" feature, which lacks a direct YouTube analog. All of these metrics were lower in the slop group than in the population (Figure 2D and Table S2 in Multimedia Appendix 1), although the differences were less pronounced than on YouTube (and, again, statistically insignificant; eg, P=.38 for view rate; data not shown). All numbers should be taken with caution due to the small sample size (n=10) of slop TikTok videos. Slop thus appears less popular than general materials on TikTok, although proportionately more so than on YouTube. The reason for the difference in relative visibility or popularity of slop between the 2 platforms is not clear from our data. Specifically addressing RQ3, it appears none of the metrics we collected correlates significantly with the presence of slop.

Figure 2. Distributions of the age of videos at time of collection (A and C) and log of view rate in views/day (B and D) for YouTube (A and B) and TikTok (C and D). Dashed and solid lines are mean and median, respectively. Violin plots generated using StatsKingdom Violin Plot Maker.



Qualitative Characteristics of Slop

Overview

The qualitative analysis resulted in 16 codes for problematic features. Code categories encompassed features of either the video content, the video structure or format, or features with both structural and content components (ie, structural features not suited to the content). We assigned these categories as groups A, B, and C, respectively, organized hierarchically in Table 2 (the distributions of these codes among our video dataset are given in Multimedia Appendix 2, along with a precise definition of each code, including inclusion and exclusion criteria). Following is a brief description of each code, with examples where appropriate.

Table . Codes for problematic features of AI-generated videos in our dataset. The “common variants” list is not exhaustive.

Category and codes	Common variants
Content codes	
A1. Factual inaccuracies	• Hallucinations or inventions presented as truthful
A2. Omissions of facts or context	• Missing details or definitions • Missing facts • Lack of examples • Lack of adherence to best practices of discipline
A3. Overgeneralization or oversimplification	• Superficiality • Lack of qualifications or contexts for facts • Inappropriate conflation of distinct items
A4. Inappropriate or inconsistent level of depth or inattention to audience needs	• Uncertain target audience or purpose • Missing, unmet, or unclear learning objectives • Mixing of beginning and advanced topics
A5. Sloppy analogies	• Meaningless analogies (lack of correspondence) • Misleading or misemphasized analogies (distracting correspondence) • Overextended analogies
Structure and language codes	
B1. Poor graphic or animation quality	• Poor clarity, resolution, or size • Animation artifacts
B2. Poor audio quality	• Inappropriate volume or speed • Compression or conversion artifacts
B3. Poor grammar and vocabulary	• Nongrammatical speech or text • Limited or repetitive vocabulary
B4. Speech or narration irregularities	• Inconsistent or unnatural tone, pitch, or emphasis • Unnatural pace, cadence, or stress • Mispronunciations • “Script read aloud” narration
B5. Poor editing or sequencing	• Excessive transitions • Video and audio transition asynchronously • Abrupt beginnings or ends • Inappropriate speed
Content – structure and language codes	
C1: Problematic descriptiveness	• Overuse of descriptive words and clichés • Verbose scripts • Indirect, repetitive language • Needless or inappropriate emotion • Vague, empty descriptions
C2: Mismatching audio-visual elements	• On-topic but irrelevant graphic elements • Graphics and narration covering different aspects of subject • Narrator – narration mismatch • Text unrelated to content or speech
C3: Distracting or off-topic material	• Music • Distracting visual items (eg, watermarks) • Needless text overlays
C4: Meaningless graphics	• Nonsense graphics or diagrams • Nonphysical depictions of physical objects
C5: Text irregularities	• Garbled text • Illegible text

Category and codes	Common variants
C6: Disorganization	• Illogical sequence of material • Poor flow or fluency • Lack of linkages between topics or sections

A1: Factual Inaccuracies

This code refers to direct errors of fact, that is, hallucinations of the genAI. Factual errors were fairly common in the slop dataset. Some are glaring (eg, Video 1088 claims that biochemistry "allows the sun to rise and set"), but most are subtle and plausible-sounding. For example, Video 546 (nominally about protein structure) discussed "primary," "secondary," "tertiary," and "quaternary proteins," as if these labels refer to types of protein rather than organizational levels of protein conformation. Video 1083 states that the rate of an enzyme-catalyzed reaction increases, but only up to a limiting value, as the enzyme concentration increases (this is only true if the enzyme concentration exceeds the substrate concentration, which is almost never the case; typically, the rate increases up to a limiting value as the substrate concentration increases, ie, the Michaelis-Menten model). As this latter example illustrates, errors of fact often coincided with misframing of facts (next code).

A2: Omissions of Facts or Context

This code reflects content that is narrowly or technically correct, but which does not present needed additional information, that is, misleadingly framed content. This may take the form of missing facts, details, or categorizations, a lack of examples, a lack of nuance or uncertainty, bias, or a lack of adherence to best practices in presenting the subject matter. For example, Video 15 discusses the cytoskeleton keeping cells from collapsing without mentioning that this only applies to eukaryotes, as prokaryotes use the cell wall for this purpose; Video 510 states enzyme active sites fit substrates "perfectly," which is true only for a small subset of enzymes.

A3: Overgeneralization or Oversimplification

Several videos made generalizations about phenomena with important exceptions or simplified topics to a misleading degree. A tendency to generate oversimplified summaries is a known feature of LLMs [58]. Accordingly, videos made oversimplified claims such as quaternary structure being defined as "how multiple protein molecules interact" (Video 691), or treated multiple related topics as a single subject (Video 493, which referred to "urea cycle disorder" as a single disease).

A4: Inconsistent Level of Depth or Inattention to Audience Needs

The videos in the AI-generated dataset were extremely diverse in terms of detail, professionalism, and style, and it was often not clear who the intended audience was. Some videos were simply inexplicable, for example, Video 643, a description of the electron transport chain (ETC) atop a clip from the children's television series "Barney & Friends," set to a synthesized version of "Yankee Doodle." Video 875 was apparently intended as a meme. Even the most professional videos, however, often had no apparent audience in mind and covered material to inconsistent levels of detail and depth. Some gave entry-level overviews of a topic, but in a manner that assumed knowledge of more advanced topics (eg, Video 866 ostensibly gives an introduction to the cell cycle, but mentions the functions of maturation-promoting factor and platelet-derived growth factor). Learners would likely find these videos confusing in terms of how much content they should know, or what aspects of the content were most important.

A5: Sloppy Analogies

One of the most insidious features of AI-generated videos is the frequency of almost-accurate, yet misleading analogies, which we have termed "sloppy analogies." In an effective analogy, the items being compared have similar meanings (semantic correspondence) and similar positions or relationships toward other items (structural correspondence), and ideally do not have coincidental, misleading similarities (for detailed discussion, refer to the study by Thagard [59] and references therein). Sloppy analogies violate one of these correspondences (typically the structural correspondence), or make use of distracting, irrelevant similarities between analogs, or extend the analogy to situations where it is not helpful. A learner may thus gain a misrepresentation of the subject, or an improper sense of importance of an irrelevant feature of the subject.

Some sloppy analogies were particularly terrible. For example, Video 679 compares nicotinic acetylcholine receptors to a gateway leading into a beehive, with acetylcholine molecules as "worker bees" that open the gate to allow the "queen bee" (a Na^+ cation) into the hive (the cell). While the semantic correspondence (the ion channel and the gate) is sound, the structural correspondence is nonexistent: beehives do not have gates, a queen bee does not need to be "let in" to the hive (a queen seldom leaves the hive), and worker bees, unlike acetylcholine, have numerous roles both inside and outside the hive (cell), which they can enter and leave freely. This analogy is baffling, not illuminating.

However, not all sloppy analogies are this obviously bad. Video 1085, for instance, compares metabolic regulation to the coordination of an orchestra by a conductor ("just as a conductor ensures each instrument plays in harmony, enzymes coordinate the complex symphony of biochemical reactions in our bodies"). Both structural and semantic correspondences exist between a conductor and a regulatory enzyme, but the analogy suggests enzymes somehow "choose" which pathways to accelerate or inhibit. It ignores the distributed nature of most metabolic regulation and implies a single, central locus of metabolic control. This analogy captures only one similarity between analogs, ignoring several major dissimilarities, and thus creates a misleading view of how metabolic regulation works in reality.

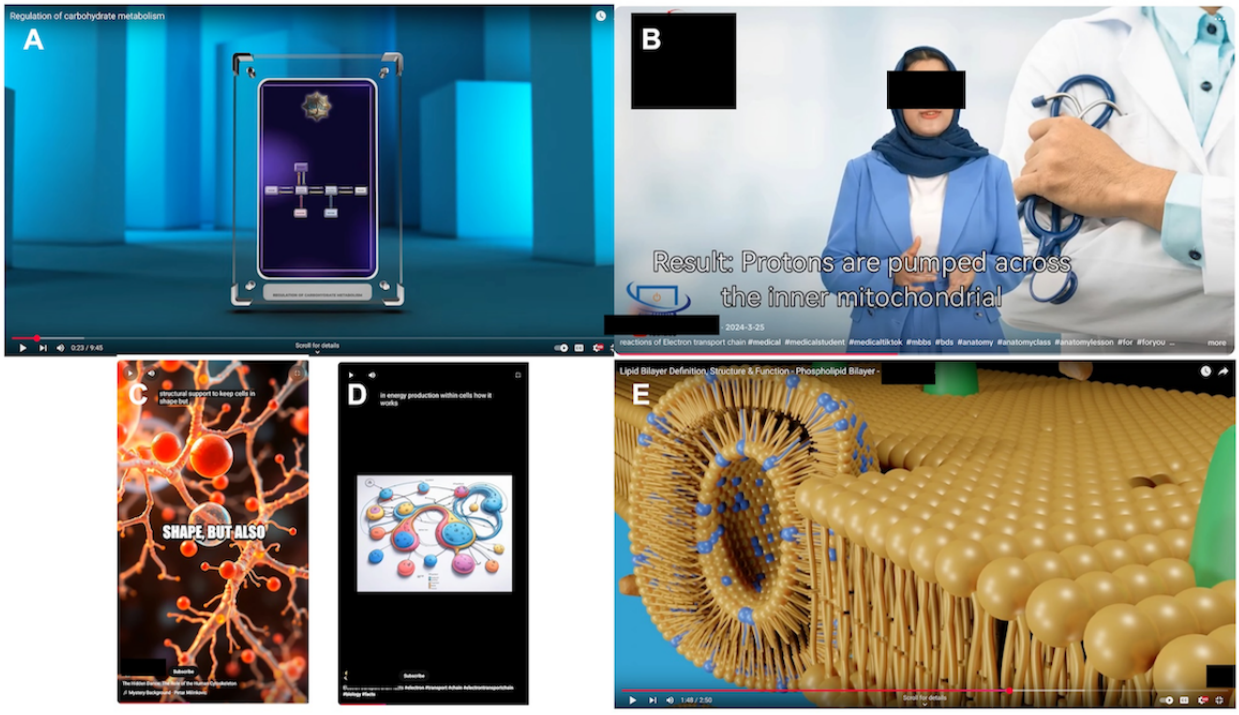
Other sloppy analogies in the dataset included the ETC being likened to a "relay race" (several videos), protein quaternary

structure as a “protein party” (Video 864), and enzymes being akin to a “set of instructions” for making molecules (Video 752).

B1: Poor Graphic or Animation Quality

Most videos in the dataset made use of cartoon graphics or animations, or joined still images with transitions. In making the videos, insufficient attention to detail or editing led to poor-quality graphics, such as low-resolution, pixelated, or blurry images, pictures too small to be clearly seen, and jerky or flickering movement (Figure 3).

Figure 3. Gallery of video stills illustrating problematic video features. (A) Video 388, diagram too small to be read, unrelated graphic background (codes B1, C2). (B) Video 1045: Monotonous narration, unrelated graphic background, narrator moves and gestures unnaturally (codes B4, C2). (C) Video 559: Distracting text overlay, nonphysical depiction of cytoskeletal fibers (codes C3, C4). (D) Video 712: Meaningless metabolic pathway diagram with garbled text (codes C4, C5). (E) Video 1086: Nonphysical depiction of physical objects (vesicle embedded in bilayer; code C4). Names and logos of content creators have been redacted.



B2: Poor Audio Quality

Similarly, inattention to editing caused many videos to have audio that was too fast or slow, varied wildly in volume, or contained sudden cuts. This code applies to general audio; spoken language is accounted for by codes B3 and B4.

B3: Poor Grammar and Vocabulary

Several videos contain grammatical errors in either spoken words or on-screen text (eg, “Do you know what is cytoskeleton?” [Video 222]) or use inappropriate vocabulary. Most of these errors are minor and unlikely to affect understanding of the subject, but are distracting to native English speakers and may be confusing to learners whose native language is not English.

B4: Speech or Narration Irregularities

Many videos with spoken narration exhibit the flaws commonly seen in text-to-voice translation: Unnatural tone or stress, mispronunciations of certain words, awkward pace or cadence, emotionless (or overly emotional) tone, and narration that sounds like text being read aloud. Abbreviations are often read out like words, for example, K_A, association constant, was pronounced “ka” in Video 864; in Video 712, ETC (electron transport chain) was read as “et cetera.” These flaws are generally not sufficient to affect understanding of the material, but they are distracting and require extraneous processing to ignore [6].

B5: Poor Editing or Sequencing

Videos in the list often exhibited excessive or poorly executed transitions between images or sections, started or stopped abruptly (often mid-sentence), shifted rapidly between different topics, or featured visual and auditory elements that did not transition together, leading to an audio-visual mismatch (also refer to code C2). In most cases, this lack of attention to fluent editing created only a distraction; poor sequencing impacting understanding of the content is captured by code C6.

C1: Problematic Descriptiveness

Several studies have found LLM-generated writing tends to overuse adjectives [60] or create prose with an effusive, grandiose style [61,62]. We observed this tendency in nearly all of the videos in our AI-generated dataset, most of which were apparently based on LLM-written scripts. Words frequently overused by AI (“amazing,” “crucial,” and “delve”) were superabundant. In addition to descriptive words, the videos in our list frequently overused certain cliches [63]: “deep dive,” “break it down,” “unsung hero” (Video 1085 used this term

four times in nine minutes), and constructions like "from … to …" (or "whether it's … or …") all appeared far more frequently than would be expected in ordinary narration. More generally, the scripts of our videos tended toward repetitive and indirect language, often incorporating needless emotion or forced casualness ("pretty cool, huh?"). In extreme cases (Video 1088), the scripts gave elaborate, emphatic declarations of a topic's importance without ever incorporating actual facts. Several videos also made analogies for simple concepts not needing an analogy, such as the cytoplasm filling the inside of a cell "like the water in a water balloon" (Video 638; also refer to code A5).

C2: Mismatch of Audio and Visual Elements

In multimedia educational materials, visual elements should be paired with relevant auditory elements so that inputs to the 2 cognitive channels can reinforce one another; off-topic and unnecessary visuals should be minimized [6]. This principle was frequently violated in the AI-generated videos in our dataset. Off-topic graphic backdrops were present in many videos (Figure 3A–B), and in others, the graphics and narration described different aspects of the subject, or text not matching or reinforcing the narration was displayed. Video 1087, for example, showed a model of DNA while discussing proteins. Some videos (eg, Videos 940 and 1087) displayed animated or avatar narrators whose hand gestures did not match the points of emphasis in the script (Figure 3B), a common artifact of photo-animation software like HeyGen. These distracting visual elements require cognitive processing to ignore, diluting the educational effectiveness of the videos. They may also, without careful structuring, suggest misleading connections between audio and visual content, resulting in a misconception of the topic being presented [64].

C3: Distracting or Off-Topic Material

Beyond mismatched visuals and sound, many videos displayed miscellaneous off-topic and distracting features, such as music, watermarks, animations, or unnecessary text overlays (which often obscured relevant imagery). Some videos included unrelated or loosely related stock footage (eg, Video 541, about fatty acids, showed supplement pills on a tray). These so-called "seductive details" contribute to cognitive load without imparting real information [65].

C4: Meaningless Graphics

Some of the visual elements in the videos were nonphysical representations of real objects, or completely meaningless diagrams (Figure 3C–E). Many of these graphics could be scientifically misleading, such as an inaccurate rendering of a protein structure (Video 691) or a phospholipid vesicle embedded in a bilayer membrane (Video 1086, Figure 3E).

C5: Text Irregularities

AI image generators struggle to create realistic text, and accordingly, several of the videos featured nonsense words resembling real words, such as "eectron." Properly rendered text was also often illegible, either due to poor resolution, inadequate size, or cropping.

C6: Disorganization

Videos in the dataset frequently suffered from general disorganization. Topics were presented in a nonintuitive sequence, concepts did not flow naturally from one to the next, and linkages between subjects were often not explained or insinuated. Disorganization occurred at the level of structure and editing (eg, a rapid series of images being flashed in the background while a single topic was explained, as in Video 638) or content (eg, Video 1083 described the effects of enzyme inhibitors on an enzyme's kinetic parameters before discussing enzyme kinetics). Disorganization contributes to cognitive load by requiring the learner to "hold" relevant information in working memory while waiting for complementary information [65].

Many of the 16 codes of problematic slop content could be directly matched with the seven characteristics of careless speech: (1) factual inaccuracies or inventions (hallucinations or obsolete ideas); (2) nonrepresentativeness of sources (bias; statements not proportionally representing the totality of views); (3) incompleteness (statements that are narrowly correct but omit needed context); (4) lacking signifiers of uncertainty (unwarranted confidence or failure to account for variability in responses); (5) lacking references to source material (failure to cite relevant sources, where appropriate); (6) references not based on referred text (hallucinated or off-topic references); and (7) inaccurate summaries of referenced text (incorrect or incomplete summary of a real reference) [38]. These mappings of codes are presented in Table 3.

Table . Alignment of qualitative codes from Table 2 with characteristics of careless speech. Two additional code groupings, which we designate "communicative nonfluency" and "message – delivery incoherence," were identified in addition to the 7 features of careless speech published previously.

Careless speech characteristic	Codes from Table 2
Factual inaccuracies	A1, A2, C4, C5
Nonrepresentativeness of sources	A2, A3
Incompleteness	A2, A3, A4, A5
Lacking signifiers of uncertainty	A3, A5
Lacking references to sources	A2
References not based on referred text	A1, A2
Inaccurate summaries of referred text	A1, A2, A3, C1, C4
Additional characteristics of slop	
Communicative nonfluency	B1, B2, B3, B4, B5, C6
Message – delivery incoherence	A4, C2, C3, C6

Because the features of careless speech describe content, they align most closely with groups A and C of our codes for characteristics of slop. For instance, A1 is virtually identical to "factual inaccuracies or inventions." We note that the careless speech codes involving references are less relevant to the case of educational videos or lessons, which often do not cite references (references are presumed to be the latest discipline-standard textbooks or review articles). Only 2 of the videos in our slop dataset (681 and 697) cited a reference.

The group B codes, and codes C2, C3, and C6, did not specifically align with any of the characteristics of careless speech, as these codes are primarily concerned with the form and structure of the speech. We consider these codes to embody 2 additional common characteristics of slop (if not of careless speech more generally): "communicative nonfluency" (C6 and all group B) and "incoherence of message and delivery" (A4, C2, C3, and C6). Communicative nonfluency often makes low-end genAI materials recognizable (telltale linguistic features, robotic narration, unnatural animations, and so forth), while the incoherence of message and delivery (features such as excessive or unnecessary transitions, mismatching visual and auditory output, confusing or inappropriate diagrams, and illogical sequencing) limits its usefulness as a teaching tool, even when factually accurate. Since many videos incorporated content or styles that were incompatible with a particular audience or set of learning goals, we included code A4 in this group as well.

Discussion

Prevalence and Reach of Slop

Our results show that slop accounts for a small but nonnegligible portion of medical biochemistry and cell biology videos, seems to be comparably popular to nonslop videos, and cannot be reliably distinguished from nonslop on the basis of that quantitative features. These findings accord with previous studies of educational YouTube videos, which found quantitative metrics do not correlate with video quality [11,66]. Some studies have suggested that the number or text of comments may correlate with quality [11], but we did not observe any strong correlation of comment rates with slop (Tables S1 and S2 in Multimedia Appendix 1). The text content of comments was not examined in this study. We may thus conclude that slop cannot easily be identified without viewing the video. We also emphasize that our method is only able to detect obvious and low-quality genAI output, so the true prevalence of slop is certainly higher than our numbers suggest, and as the apparent quality of genAI content improves, even viewing a video may soon be insufficient to identify it as slop.

In the course of this research, we observed that many of the slop videos were posted by channels that consisted mostly or entirely of slop material, suggesting that characteristics of the channel or creator, and not the individual video, may provide evidence that a video is slop or otherwise questionable. Studies of channel characteristics, rather than video characteristics, should thus be a productive line of future slop research.

Problematic Features of Slop

At present, research on the educational effects of genAI video is scant. At least 3 recent small-scale studies have examined the effectiveness of AI-constructed video on learning, and all found little difference in learning outcomes between genAI and traditional materials [67-69]. Critically, however, all of these studies used extensively edited and fact-checked videos, designed by disciplinary experts. In other words, the videos in these studies were not slop. A full understanding of the hazards of slop must be drawn not from well-designed genAI materials but from slop typical of online video platforms.

When addressing RQ1, we identified 16 problematic features of slop videos that may impact educational value (Table 2). These features encompass both subject matter and structure-based aspects, and thus imperfectly align with the features of careless speech (Table 3), which is a subject matter–based construct. We feel it is relevant to include structure-based features in consideration of slop, since proper formatting and editing of multimedia educational materials contribute to educational effectiveness [6,12,65,66]. Thus, some consideration of video format and structure is appropriate in assessing the impact of slop.

While all 16 features can dilute the educational effectiveness of videos, we think 2 deserve additional discussion. The first

of these is sloppy analogies (code A5). The educational perils of imperfect analogies and metaphors have been described for disciplines including the biological sciences [70,71], chemistry [72,73], and physics [74,75]; genAI does not add any new hazards. Rather, genAI removes the effort barrier to creating a weak analogy, and along with it, the mental check of whether the analogy makes sense (unless further prompting or editing, ie, care, is performed by the content creator). What is particularly damaging about sloppy analogies is the illusion of understanding [76] generated by an intuitive but inaccurate or unnuanced analogy. Previous studies have shown that analogies can have negative effects on metacomprehension if not reinforced by experiential inputs, such as experimentation [77]. Video, being an inherently passive medium, is thus especially inclined to mislead by analogies presented without real-world reinforcement, and experimental data confirm that video instruction is prone to an illusion of understanding effect when misconceptions are present [76,78]. While this is equally true of all videos (not just slop), the ease with which genAI conjures plausible-sounding analogies makes slop videos especially likely to contain poor analogies and metaphors, as seen in our dataset. Incidentally, at least 1 popular book on genAI in teaching [79] specifically recommends asking an LLM to create analogies for unfamiliar topics. Based on our results, we strongly feel unsupervised beginning learners should not follow this suggestion (to be fair, this book emphasizes the importance of careful prompting when asking an LLM for an analogy, but since beginners are typically not capable of evaluating the analogy, there would be no way for a beginner to know if a prompt was effective). However, experienced instructors might find this suggestion useful as part of a carefully curated activity, for example, asking students to identify problems with the analogy.

The second educational hazard worth further discussion is problematic descriptiveness, code C1. Numerous studies have commented on the tendency of LLMs to overdescribe [60,62] as in our slop videos. For example, the passage “a toolbox of folds and domains that evolution has mixed and matched over billions of years to create the incredible diversity of proteins we see today” (Video 864) has to be read or heard several times to extract the main point: that proteins contain modular folds and domains that perform discrete functions. Apart from being distracting (and annoying), this overly descriptive style creates a problem of misplaced emphasis in many of the videos. Unable to know which terms or ideas are really important and which are incidental, the LLM attaches descriptive words or phrases to everything it can. A human teacher, however, would preferentially reserve description for the most salient words and topics, thus cueing the learner toward the important material. Goodwin [80] described this practice as “highlighting,” and identified it as one component of the so-called professional vision that frames expertise in any discipline. An LLM lacks the professional vision of an educator (or any other profession) and thus cannot model a professional’s practice of sense-making, except insofar as a human professional shapes the genAI output. Instead, all aspects are treated as potentially equal by the LLM, resulting in an unfocused, directionless treatment of the subject.

Other features of slop identified in our qualitative analysis generally align with the 7 features of careless speech [38] or violate good practices of multimedia teaching [6,51]. We identify 2 clusters of features that do not neatly map onto the careless speech framework, “communicative nonfluency” and “message – delivery incoherence” (Table 3). Communicative nonfluency may be loosely defined as the property of requiring undue cognitive effort to understand; it aligns closely with so-called perceptual fluency, or the ease of making sense of inputs based on sensory features [81]. Perceptual fluency is strongly associated with metacognition, specifically judgment-of-learning [82] and perceived accuracy or truth [83,84]. Accordingly, students have perceived fluent delivery (in video or live lecture) as more instructive even though fluency did not affect learning gains [85,86]. These findings suggest students prefer fluent over nonfluent learning materials, and thus would be less likely to perceive slop videos as reliable, even if the slop video lacked any factual errors. However, as the realism and fluency of genAI output increase, this effect would be expected to diminish as technology improves, and thus communicative nonfluency may not be a characteristic marker of slop in the future.

Message – delivery incoherence refers to a mismatch between the concept being communicated (the message) and the object or language ostensibly used to communicate it (the delivery). In our video dataset, this most frequently took the form of mismatching audio and visual elements (code C2) or superfluous content (code C3). Either of these will increase the amount of cognitive processing needed to encode the underlying message, and thus hinder learning [65]. For instance, extraneous visual content (such as watermarks and text overlays duplicating the narration) conveys no relevant information and competes for working memory with the educational content [6]. Likewise, mismatched content between channels (such as a description of cell cycle regulation over a schematic of ligand-receptor binding; Video 1051) requires processing to identify which channel contains the relevant information, so-called extraneous overload [65], or may create a misimpression that the two channels are, in fact, related. It is thus considered best practice in video instruction to remove superfluous material (“weeding”) and to ensure information in audio and visual channels complement each other [6,65]. Message – delivery incoherence also sometimes took the form of presentations that were inappropriate for the apparent learning goal of the video, or were so muddled that the learning goal was indiscernible (codes A4 and C6). Relevance to learners and links to previous knowledge are considered important elements of effective instructional video design [13], and were conspicuously weak in most of the slop videos. These deficiencies could impact engagement with the videos [6], even if factual accuracy were not a concern.

Of course, none of our problematic features of slop is entirely unique to AI-generated material, and most are not unique to video. Classroom lectures may use flat, repetitive language or incorporate unnecessary content; human teachers may make bad analogies or fail to highlight key points. Living instructors, however, generally bear some risk of consequence for ineffective teaching (care in the second sense of the term), such as poor evaluations, career stagnation, or a personal sense of failure.

GenAI is totally unencumbered by such consequences, and the human who uses genAI to make educational slop for free public platforms (particularly when posting anonymously) is, to some extent, insulated from these consequences—although not from gain in the form of monetization or self-satisfaction. Additionally, living instructors often have the chance to immediately correct student misconceptions that may result from a bad analogy or other errors through just-in-time teaching techniques; for asynchronous video, this is not a possibility, requiring videos to be high-quality from the beginning. Slop is likely to remain a significant problem on video-sharing platforms as long as there is an asymmetry between the risks and rewards of sharing it. Students lacking the expertise to evaluate content on unfamiliar subjects will be especially vulnerable.

Implications for Content Creators and Learners

Fortunately, our inventory of slop characteristics provides a ready checklist of pitfalls that caring creators of genAI material can work to avoid. The central pillar of making good genAI material is maintaining a human-in-the-loop [44] at every point in the creation and dissemination process. Prompting (and reprompting or iterative prompting) needs to be done in a planned and deliberate fashion; tools such as prompt-design frameworks [87] are helpful at this stage. The output must then be evaluated not only for accuracy and appropriate context, but also for alignment with intended learning goals and audience characteristics, which should be explicitly stated. GenAI descriptions, explanations, and metaphors should never be accepted at face value, but rather examined closely (and amended, if necessary) to avoid misleading, oversimplified, or misemphasized statements. If possible, the output should align with the viewer's experience of reality and use meaningful mental models (eg, the human experience, expertise, accuracy, trust, or HEAT heuristic [44]) and be coherent with respect to subject matter and presentation. The output should give a balanced overview of the field without unduly favoring a particular viewpoint [41]. Attention should be paid to the fluency of the output (video quality and realism, natural-sounding speech and audio, and appropriate transitions). Once posted to an online forum, material should be monitored for signs of misinterpretation (eg, comments reflecting confusion or dislike) and edited or removed as necessary. Finally, clear disclosure of the use of genAI will help establish trust with the audience. While this will not impact the quality or effectiveness of the material, these efforts toward building trust may be seen as a sign of care. Slop-free genAI material requires more than just good prompting; human involvement throughout the lifecycle of the material is essential to make sure good AI creations continue to fulfill their intended functions. We are currently in the process of developing lifecycle guidelines for genAI educational materials.

For learners, the presence of slop on video-sharing sites presents a challenge. The videos encountered in the course of this study are at the lowest end of quality and usefulness; future slop may be far more realistic and seemingly helpful than today's slop, but as long as genAI works in an associative fashion, it will always be careless speech (and thus unreliable). Learners should thus focus not on detecting and excluding suspected genAI material, but on cross-checking claims made in online videos with other sources, verifying the credentials of the creators, and discussing points of concern with subject matter experts. Sadly, vetting and comparing sources of information is a skill that takes time and effort to develop. Furthermore, genAI is often presented to learners as a shortcut to learning (eg, as a way to quickly digest and summarize dense information), or as a source of information [39] while its ability to introduce misconceptions and misframings of reality [28,38] is far less recognized. We therefore recommend that learners approach known genAI output with great caution, always validate sources, and consult with experts when possible, and generally exercise judgment when using video-sharing platforms for educational purposes.

Limitations

Our definition of slop is intended only for educational materials and may not be appropriate in other contexts, such as art, advertising, or political speech. Since we restricted our attention to videos, not all characteristics of slop may be relevant to other output types (such as still images or text). Our numerical data should be considered semiquantitative at best, since we believe our methods underestimate the prevalence of slop for reasons given above. Our estimates of slop's prevalence for RQ2 may not apply to other major platforms where slop is endemic (eg, Facebook [Meta] or Instagram [Meta]) due to the different user bases and content moderation practices on these platforms. We should also emphasize that our aim in RQ1 was only to identify problematic features of genAI material—any potential educational benefits of AI-generated learning materials were not considered for the purposes of this study.

A well-known problem with genAI output is bias, which in this study was encompassed by code A2, incompleteness. We did not examine bias in our dataset in any further detail (eg, biased overviews of a discipline and bias in examples), but this aspect of slop clearly needs deeper attention in future work. We also note, as mentioned previously, that our own dataset is biased toward obviously bad genAI content, due to our screening method, so some of our findings may not be fully generalizable to higher-quality slop.

Our methodology made no effort to identify the purposes for which the slop videos were made. It is likely that most of the AI videos in our dataset were made not to educate, but to accumulate views and other markers of engagement. While irrelevant to the educational impacts of slop, further study of the motivating factors behind slop's rapid proliferation on the internet may help to curb its influence.

Perhaps most significantly, this study does not address the enormous ethical concerns raised by slop, such as unmitigated biases, the unpaid and uncredited use of intellectual property for training, and the environmental impacts of needless AI use [41,50]. Slop disregards ethical considerations, as care forms a basis for ethics [46], and a definition of slop that is based in an ethics framework (rather than on features of its content, as in this study) would be needed for a proper accounting of the ethical dimension of slop. Regardless, ethical matters feature prominently in UNESCO's (United Nations Educational, Scientific and Cultural Organization) recent statement of guidelines for responsible AI use in education [88], and while

ethics is only one of many risks of improper educational use of genAI [50], it deserves attention in future research on slop.

Conclusions

We have suggested a definition of slop that, to our knowledge, is the first in the scholarly literature. We define slop as AI-generated material that is produced with little or no care toward its educational usefulness or quality, situated in the broader conceptualization of careless speech [38]. Using this definition, we find that slop composes a small percentage of preclinical biochemistry and cell biology videos on YouTube and TikTok, but these videos could be found without considerable effort and present specific educational risks to learners. Among these risks are misleading content (eg, inaccuracies and improper comparisons), nonfluency endangering effective cognitive processing, and incoherent presentation (eg, problematic descriptiveness and disorganization). Our findings can hopefully inform better practices among responsible creators of genAI material for education. We also hope our findings will be informative to other disciplines, such as journalism, in which vetting of information sources is critical and under threat by genAI materials.

Some commentators [16,24] have suggested that slop is a temporary problem that will be solved by technological means, much as spam email has been curtailed by email filtering. Even if this proves to be true, existing slop videos will persist on the internet for some time, potentially training future genAI applications, and thus propagating subtle misconceptions or misemphases throughout future, higher-quality genAI output. As genAI becomes more central to education and training, these propagated errors may be used to train human beings, leading to a generational erosion of understanding and expertise [38]. Slop is therefore a problem that needs to be recognized and fought right now, and we hope this study provides a useful starting point for this fight.

Acknowledgments

We thank Prof Deidre Hurse for assistance with preparing the Qualitative Analysis section of the Methods and for identifying helpful sources; Profs Dwayne Baxa and Serena Kuang for helpful discussions on organization of the manuscript; and Profs Tammy Campbell and Anya Goodman for assistance with video screening and suggestions on study design (respectively). The work in this paper was self-funded by the lead author.

Disclaimer

No generative artificial intelligence tools were used at any point during the collection and analysis of data for this project, or in the preparation of the manuscript.

Abstract

Background: Effective communication is fundamental to high-quality health care delivery, influencing patient satisfaction, adherence to treatment plans, and clinical outcomes. However, communication skills training for medical undergraduates often faces challenges in scalability, resource allocation, and personalization. Traditional methods, such as role-playing with standardized patients, are resource intensive and may not provide consistent feedback tailored to individual learners' needs. Artificial intelligence (AI) offers realistic patient interactions for education.

Objective: This study aims to investigate the application of AI communication training tools in medical undergraduate education within a primary care context. The study evaluates the effectiveness, usability, and impact of AI virtual patients (VPs) on medical students' experience in communication skills practice.

Methods: The study used a mixed methods sequential explanatory design, comprising a quantitative survey followed by qualitative focus group discussions. Eighteen participants, including 15 medical students and 3 practicing doctors, engaged with an AI VP simulating a primary care consultation for prostate cancer risk assessment. The AI VP was designed using a large language model and natural voice synthesis to create realistic patient interactions. The survey assessed 5 domains: fidelity, immersion, intrinsic motivation, debriefing, and system usability. Focus groups were used to explore participants' experiences, challenges, and perceived educational value of the AI tool.

Results: Significant positive responses emerged against a neutral baseline, with the following median scores: intrinsic motivation 16.5 of 20.0 (IQR 15.0 - 18.0; d=2.09, P<.001), system usability 12.0 of 15.0 (IQR 11.5 - 12.5; d=2.18, P<.001), and psychological safety 5.0 of 5.0 (IQR 5.0 - 5.0; d=4.78, P<.001). Fidelity (median score 6.0/10.0, IQR 5.2 - 7.0; d=–0.08, P=.02) and immersion (median score 8.5/15.0, IQR 7.0 - 9.8; d=0.25 P=.08) were moderately rated. The overall Immersive Technology Evaluation Measure scores showed a high positive learning experience: median 47.5 of 65.0 (IQR 43.0 - 51.2; d=2.00, P<.001). Qualitative analysis identified 3 major themes across 11 subthemes, with participants highlighting both technical limitations and educational value. Participants valued the safe practice environment and the ability to receive immediate feedback.

Conclusions: AI VP technology shows promising potential for communication skills training despite the current realism limitations. While it does not yet match human standardized patient authenticity, the technology has achieved sufficient fidelity to support meaningful educational interactions, and this study identified clear areas for improvement. The integration of AI into medical curricula represents a promising avenue for innovation in medical education, with the potential to improve the quality and effectiveness of training programs.

artificial intelligence; technology-enhanced learning; virtual patient; communication skills; simulation

Introduction

Effective communication is fundamental to high-quality health care delivery, influencing patient satisfaction, adherence to treatment plans, and clinical outcomes [1]. Despite its significance, communication skills training for medical undergraduates often faces challenges in scalability, resource allocation, and personalization. Although traditional methods such as role-playing with standardized patients or observational feedback sessions are effective, they are resource intensive and

may not provide consistent feedback tailored to individual learners' needs in all circumstances [2,3].

Artificial intelligence (AI) offers an innovative solution to address these challenges by simulating realistic patient-provider interactions in controlled, scalable environments. Given their ability to show proficiency in medical knowledge, large language models (LLMs) have been used by medical students in the preclinical phase, as the models aid them in differential diagnosis and provide interactive practice cases to support learning [4]. Recent applications of LLMs in medical education demonstrate expanding capabilities across diverse educational contexts. Advanced LLMs (ChatGPT, Copilot, PaLM, Bard, and Gemini) show comparable performance to students in gross anatomy assessments, indicating potential for educational support in foundational medical sciences [5]. Furthermore, LLMs have shown competitive performance against medical students in specialized topic areas, suggesting potential for supplementing traditional learning approaches [6].

A narrative review of AI in health care communication indicated that these systems have the potential to replicate the complexities of clinical encounters, including interpreting verbal and nonverbal cues, ensuring empathy in responses, and managing dynamic conversational scenarios [7]. Furthermore, communication, as an emotional exchange of information, can be considered a complex system characterized by diversity, nonlinearity of response, interconnectedness of individuals (akin to a neural network), dynamism, feedback orientation, and constant information flow. AI encompasses these facets and can help predict emergent behaviors with machine learning.

AI tools, such as conversational agents and LLMs, can provide health care learners with opportunities to practice communication skills repeatedly and independently while receiving immediate and detailed feedback on performance [8,9]. Simulated virtual patients (VPs) have shown promise in prenatal counseling education, where ChatGPT-generated dialogues increased the realism and variety of patient interactions while maintaining clinical accuracy [10]. In emergency medical services, generative pretrained transformer–based VPs integrated with mixed reality simulation improved the effectiveness of communication training for medical first responders, although technical delays remained a limiting factor [9]. Large-scale implementations have achieved substantial reach, with platforms such as the Geeky Medics Virtual Patient Simulator conducting over 45,000 AI-powered clinical consultations using GPT-3.5 and GPT-4 technologies [11]. However, training needs are substantial yet largely unmet: a previous study reported that 74.8% of medical students wanted structured AI training in medical curricula, but only 26.8% felt competent to inform patients about AI applications [12].

Primary care settings are ideal for communication skills training [13], given the frequent need for effective patient-provider communication to address complex, multidisciplinary health issues. Training future medical professionals in this context requires tools that mirror the intricacies of real-world interactions, including handling diverse patient populations, managing sensitive topics, and navigating the nuances of shared decision-making. AI platforms offer an opportunity to simulate such scenarios with high fidelity while ensuring accessibility and scalability, thus addressing key gaps in current educational approaches [14-16]. Previous studies have used AI in primary care education [17,18]; however, publications using advanced language models to simulate VP encounters remain limited, as the vast majority are discussion papers and viewpoints [19].

To systematically evaluate the educational effectiveness of AI-powered learning tools in health care education, robust measurement frameworks are essential. The rapid proliferation of immersive technologies in medical training, from virtual reality simulations to AI VPs, has created a need for validated assessment instruments that can capture the multidimensional nature of technology-enhanced learning experiences. Recent frameworks, such as the Immersive Technology Evaluation Measure (ITEM) developed by Jacobs et al [20], provide a structured approach to evaluating the educational efficacy of technology-enhanced learning tools and have demonstrated use in conversational AI in medical student evaluation [21]. The ITEM assesses the following domains: engagement, intrinsic motivation, cognitive load, system usability, and postexperience debriefing. These domains are particularly relevant in simulation training with technology, where the fidelity of the simulated interaction as well as the learners' motivation to engage and ability to reflect on performance are pivotal to achieving meaningful educational outcomes [22]. Applying such frameworks, this study aims to investigate the use of AI technologies in communication training within the primary care context for medical undergraduates.

This study aims to evaluate AI VP technology as a tool to support communication-based learning and to compare this technology with standardized patients used in primary care educational sessions, using quantitative and qualitative analysis. Through quantitative inquiry, the study seeks to evaluate how medical undergraduates perceive the effectiveness and usability of conversational AI, as well as its impact on their confidence and self-reported competence in communication skills. Complementing this, a qualitative analysis explores the experiences of learners using these AI-powered tools, focusing on the challenges and benefits they encounter while practicing communication skills in simulated primary care scenarios. Together, the purpose of these analyses is to provide a comprehensive understanding of the tool's utility and effectiveness and areas for potential improvement in enhancing communication training for future health care professionals.

Methods

Ethical Considerations

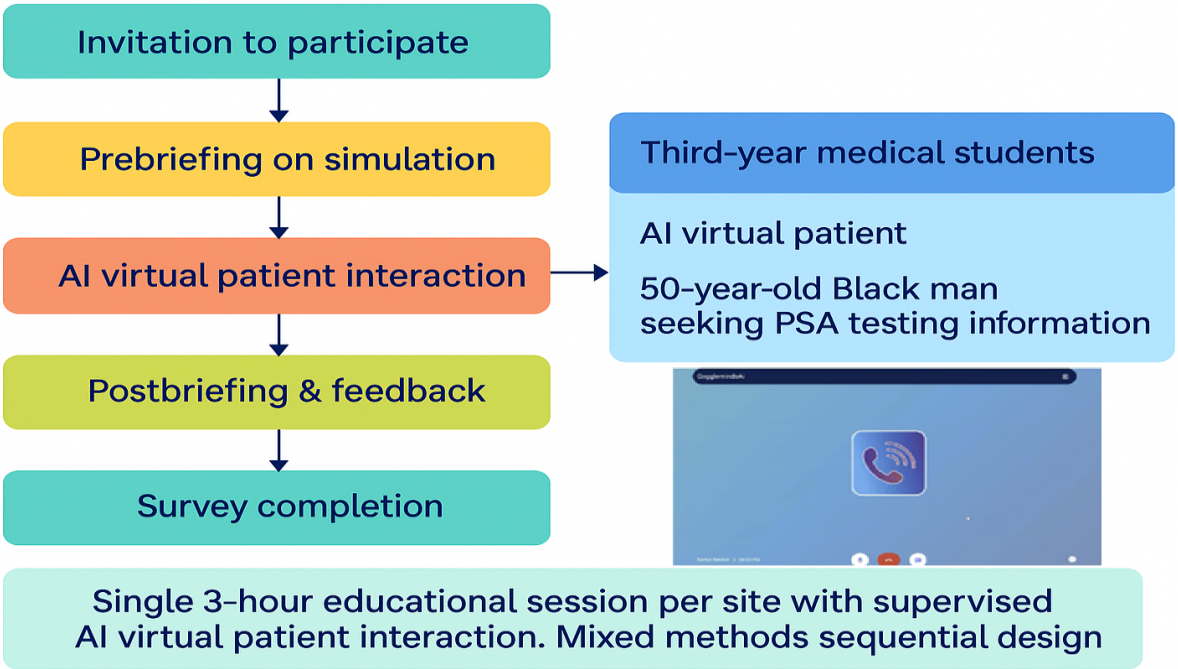
Ethical approval was obtained from a regional Independent Research Board, Swindon, United Kingdom (CJ062023). Furthermore, the senior academic staff at the University of Bristol approved the study. Informed consent was obtained from all participants, who were free to opt out at any time. All data were anonymized prior to analysis to ensure privacy and confidentiality. No financial or other compensation was provided for participation.

Study Design

The study used a mixed methods sequential explanatory design comprising 2 distinct phases: a quantitative phase followed by a qualitative phase. The mixed methods design strengthens the research findings and provides a holistic approach to answer the research aims [23]. The qualitative focus group phase enables a more detailed understanding of the quantitative phase.

The study sought to provide a nuanced understanding of how AI can enhance communication skills training for medical undergraduates. Primary care training sites were invited to participate via email. Three sites were randomly selected from email responses, with the number limited to 3 for technology oversight purposes. Third-year medical students completing primary care clerkships and general practitioner (GP) facilitators were recruited from 3 selected sites, with 5 students and 1 GP facilitator per site. All approached participants consented to participate (18/18, 100% response rate). The participating students (n=15) represented 6% of the total third-year medical student population (N=240), with GP facilitators totaling 3 participants. Students in their third year of study were selected, as the third-year curriculum focuses on primary care communication skills. Practicing doctors were included because they represent the educator demographic who would implement AI VP technology in clinical teaching. Their participation provided stakeholder perspectives on feasibility, usability, and educational value from the instructor viewpoint. Educational sessions at the primary care sites lasted 3 hours and were conducted as single-exposure experiences at each site. The theme of the day was evaluating urological cancer, and students interacted with the AI VP (20 min per consultation) only during these supervised sessions, with no access provided outside the research period. Standardized materials were provided to the facilitators to conduct a prebriefing on simulation and important aspects of communication. Learning objectives included developing shared decision-making communication skills for prostate cancer screening discussions; explaining the benefits and limitations of prostate-specific antigen (PSA) testing, including the concepts of specificity and sensitivity; exploring patient concerns and health anxieties; applying evidence-based counseling techniques for screening decisions; and addressing patient questions about ethnicity-related cancer risks. Furthermore, the facilitator at each site conducted a postbriefing on student performance on consultations. The students and facilitators were invited to attend 3 focus group discussions following their participation in AI simulation and completion of the initial survey. Figure 1 outlines the procedure and shows a screenshot of the display seen by participants. Survey methods are reported using the Consensus-Based Checklist for Reporting of Survey Studies (CROSS; Checklist 1).

Figure 1. Participant recruitment and study protocol. AI: artificial intelligence; PSA: prostate-specific antigen.



Technical Implementation

The VP was constructed using OpenAI's GPT-3.5-turbo LLM accessed via RESTful application programming interface (API) end points. The system was hosted on the Firebase cloud infrastructure (Google LLC), using Firebase Authentication for secure user access, Firestore database for session management, and Firebase Hosting for web application deployment. All communications with the OpenAI API were encrypted using HTTPS protocols. The language model was configured with specific parameters to optimize conversational flow and educational authenticity. API requests used a temperature setting of 0.7 to balance response creativity with consistency.

The AI VP was programmed with a comprehensive system prompt defining the patient persona as a 50-year-old Black man seeking information about PSA testing. The prompt included specific instructions to maintain character consistency, use an appropriate level of medical knowledge for a lay person, express realistic health concerns and anxieties, and avoid breaking the illusion of being a real patient (see Multimedia Appendix 1 for more information on the prompt). Conversational context was

maintained through session-based memory management. Students accessed the AI VP through a secure web-based interface featuring a conversational chat window with dual input modalities. The interface supported both typed text responses and voice input captured via Web Speech API (Google LLC) for speech-to-text transcription. User authentication was implemented through Firebase Authentication to ensure secure access and session isolation between participants. Student speech was captured using browser-based microphone interfaces and converted to text using the Web Speech API configured for British English language recognition. AI responses were converted to natural speech using the ElevenLabs text-to-speech synthesis service, configured with a professional male voice model emulating a London accent. Prior to deployment, the research team extensively tested the AI VP by interacting with the VP as a doctor to ensure consistent character portrayal, appropriate medical knowledge representation, and reliable technical performance. Content validity was achieved by testing, and ecological validity was sought by real-world deployment in primary care settings. A video example of this system is available in Multimedia Appendix 2.

Survey Instrument and Focus Group Development

The survey used an abridged version of the ITEM, which assesses 5 domains of experience in a health care education context using technology-enhanced learning in simulation [24,25]. The engagement subdomain included 2 questions related to the realism (fidelity) of the experience. The measure was developed on the basis of the Model for Immersive Technology in Healthcare Education (MITHE), which proposes that the learners' perception of the usability of technology is integral to experiential learning [20]. System usability was measured as learners' perceptions of technology ease of use (using adapted System Usability Scale items), recognizing that these perceptions are influenced by individual learners' characteristics such as prior technology experience and adaptability to novel interfaces. The study team reviewed the full ITEM questionnaire (40 questions) and reduced the number of questions to 12, which is supported by Jacobs and Rigby's [24] work on measure development, minimizing the effect on internal consistency and maintaining construct validity. Domain scores were calculated by summing the individual item responses within each ITEM domain: fidelity (2 items, range 2 - 10), immersion (3 items, range 3 - 15), intrinsic motivation (4 items, range 4 - 20), debriefing psychological safety (1 item, range 1 - 5), and system usability (3 items, range 3 - 15). All items were rated on a 5-point Likert scale with a consistent scoring direction. The Intrinsic Motivation Inventory was used to assess the perceived interest, learning value, and user competence, as proposed by the self-determination theory [26]. The survey was designed by medical tutors, and the construct was derived from the work of a consortium of simulation specialists on using simulation educational technology using the Delphi methodology [25].

In the subsequent focus group sessions (n=3), the interview data were enhanced by 4 open-ended questions in the initial survey to explore the authenticity, realism, and potential learning value of the interaction and to compare AI to human patients. Each focus group was facilitated and led by a medical tutor (KB), and 5 areas of questioning were developed by the study team. An interview guide with topics on educational value, realism, technical aspects, further development, and future applications was created, allowing for deeper probing through conversation (see Multimedia Appendix 3 for topic guide). Focus group interviews were conducted after the AI interaction, and the end data produced were obtained from participants from AI VP groups. Additionally, each focus group included a medical tutor to enrich the perspectives, with a facilitator encouraging student input to minimize the power differential this created.

Data Analysis

Quantitative Component

Quantitative data obtained through the survey instrument ITEM were analyzed using both descriptive and inferential statistical methodologies, using nonparametric methods suitable for Likert scale data. Statistical analysis was performed using R software (version 4.3.2; R Foundation for Statistical Computing) [27]. The primary metrics used to summarize the responses for each domain (fidelity, immersion, intrinsic motivation, debriefing, and usability scores) were the median and IQR, as these are the most appropriate measures of central tendency and variability for ordinal data. This inference provides an accurate representation of participants' response without assuming a normal distribution. The median rating for each domain was standardized as a percentage of the maximum possible score to allow for fair comparisons of ratings. Given the small sample size, inferential statistical analysis was limited to exploratory purposes. Single group nonparametric statistical analysis was conducted using 1-sample Wilcoxon signed rank tests comparing participant domain scores against neutral response values (domain midpoints) [28]. Neutral values represent a theoretical reference point where there is a lack of prior experience and represent a conceptual no-effect condition [29]. This approach was selected due to the ordinal nature of Likert scale data and small sample size precluding parametric assumptions. Effect sizes were calculated using Cohen *d* conventions (0.2=small, 0.5=medium, 0.8=large effect) to assess practical significance alongside statistical significance. Statistical significance was set at $P<.05$ for this exploratory analysis, with no corrections applied for multiple comparisons given the pilot study design.

Qualitative Component

Open-ended survey responses were uploaded to NVivo software (version 12; QSR International Pty Ltd) for an initial content analysis. A thematic content analysis was performed to investigate the participants' experience of using an AI VP to simulate a primary care consultation. The thematic analysis was performed using a hybrid inductive-deductive approach guided by the MITHE framework and ITEM domains while remaining open to emergent themes. The focus group data were analyzed by 1 author (KB), and the open-ended response codes and themes were explored by 2 other authors (CJ and HJ). The thematic analysis was conducted following the 6-step framework outlined by Braun and Clarke [30], encompassing getting familiarized with the data, generating initial codes, searching for themes, reviewing themes, defining and naming themes, and producing the final report. A provisional codebook was developed from theoretical constructs and then iteratively refined through independent dual coding by 2 authors (CJ and HJ).

Codebook development used a collaborative shared document approach with interrater agreement, and discrepancies were resolved through a subsequent consensus discussion. Finally, 2 authors (CJ and HJ) refined and revised the datasets to capture the overall narrative and major themes. Furthermore, the open-ended question dataset was analyzed on the basis of a study by Braun et al [31], who suggest that a reduced transcript length can be both concise and informative, retaining the unguarded perspectives of participants.

Results

Demographics

The survey respondents included third-year clinical medicine undergraduate students from a UK medical school. Of the 18 participants, 15 were medical students (83%), and 3 (17%) were practicing doctors in primary care and group tutors. No participants had prior experience interacting with an AI-simulated patient.

Quantitative Results

There were no missing data from the 18 participants.

A quantitative survey assessed the perceived effectiveness and usability of the AI tool and the medical undergraduates' engagement with the tool. Results are summarized in Table 1, and the results of the 5 domains are standardized in Figure 2.

Table . Summary of the AI[a] educational domain ratings.

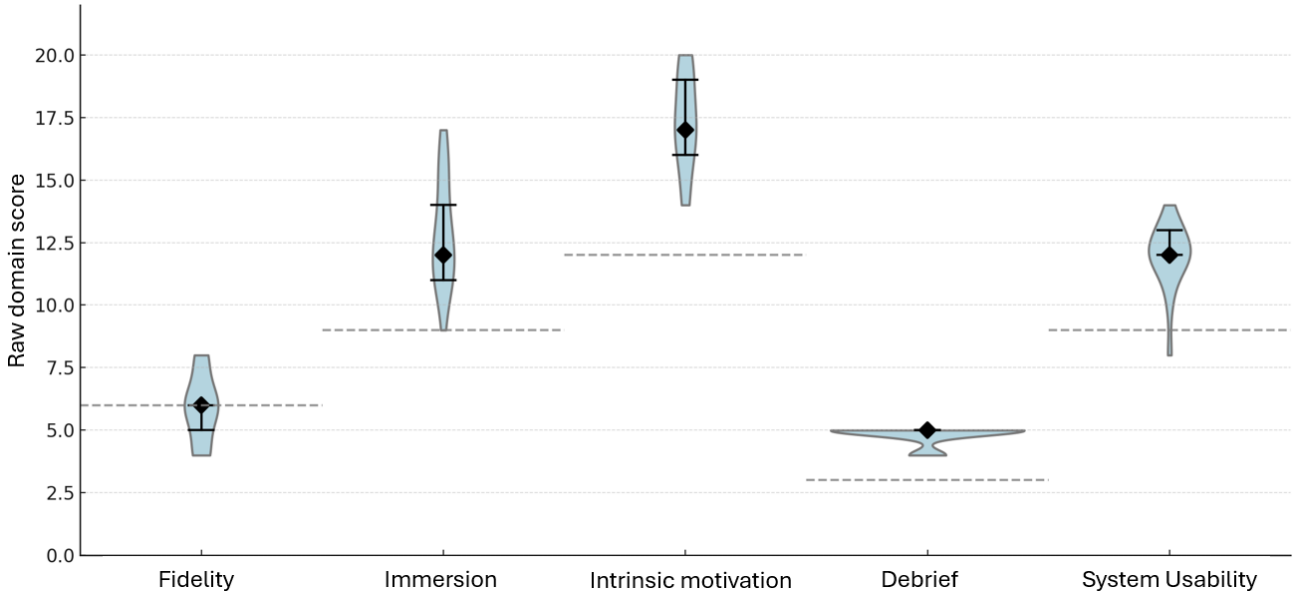
Domain	Raw median score/maximum possible score (IQR)	Difference between the median and neutral scores	Standardized median score/5.0 (IQR)	Median score as percentage of maximum possible score (%)	Effect size (*d*)	*P* value[b]	Context[c]
Fidelity	6.0/10.0 (5.2-7.0)	0.0	3.0 (2.6-3.5)	60.0	–0.08	.02	Realism of AI virtual patient communication
Immersion	8.5/15.0 (7.0-9.8)	0.5	2.8 (2.3-3.3)	56.7	0.25	.08	Participant engagement and immersion
Intrinsic motivation	15.5/20.0 (15.0-18.0)	4.5	4.1 (3.8-4.5)	82.5	2.09	<.001	Internal motivation and learning potential
Debriefing	5.0/5.0 (5.0-5.0)	2.0	5.0 (5.0-5.0)	100.0	4.78	<.001	Quality and safety of reflective discussion
System usability	12.0/15.0 (11.5-12.5)	3.0	4.0 (3.8-4.2)	80.0	2.18	<.001	Ease of use and accessibility of the platform
Total	47.5/65.0 (43.0-51.2)	9.5	3.6 (3.3-3.9)	73.1	2.00	<.001	Combined score across all domains

[a]AI: artificial intelligence.

[b]*P* values derived from the Wilcoxon signed rank test comparing each domain's score to a neutral reference point.

[c]Context summarizes what each domain aims to measure in relation to the AI-enhanced learning activity.

Figure 2. Violin plot of raw domain scores versus a neutral benchmark.



The fidelity or realism of the AI communication had a moderate median score of 6.0 (IQR 5.2 - 7.0), of a maximum possible score of 10.0. Furthermore, the median score for immersion was 8.5 (IQR 7.0 - 9.8), with a maximum possible score of 15.0. The difference between the median score and a neutral response comparator (ie, median difference) was equivalent in both domains (fidelity: median difference=0.0; *P*=.02; immersion: median difference=0.5; *P*=.08).

Intrinsic motivation had a high median score of 15.5 (IQR 15.0 - 18.0), with a maximum possible score of 20.0. There was a significant difference compared to the neutral response, with a large effect size (median difference=4.5; *d*=2.09, *P*<.001).

A universally high score was reported for the psychological safety of interacting with an AI VP during simulation debriefing (median 5.0, IQR 5.0 - 5.0). There was a significant difference compared to the neutral response, with a large effect size (median difference=2.0; *d*=4.78, *P*<.001).

System usability was highly rated, with a median score of 12.0 (IQR 11.5 - 12.5) on a maximum possible score of 15.0, which showed a significant positive difference from the neutral response, with a large effect size (median difference=3.0; *d*=2.18, *P*<.001).

The total measure score was high, with a median of 47.5 (IQR 43.0 - 51.2), and showed a significant positive median difference compared to the neutral response, with a large effect size (*d*=2.00, *P*<.001).

Qualitative Results

Following a collective review of the responses of 18 participants to the focus group questions and open-ended questions, 3 overarching themes were identified, supported by 11 subthemes (Table 2 and Figure 3). Convergence of these themes and integration with quantitative results are described later under Key Findings and Implications in the Discussion section.

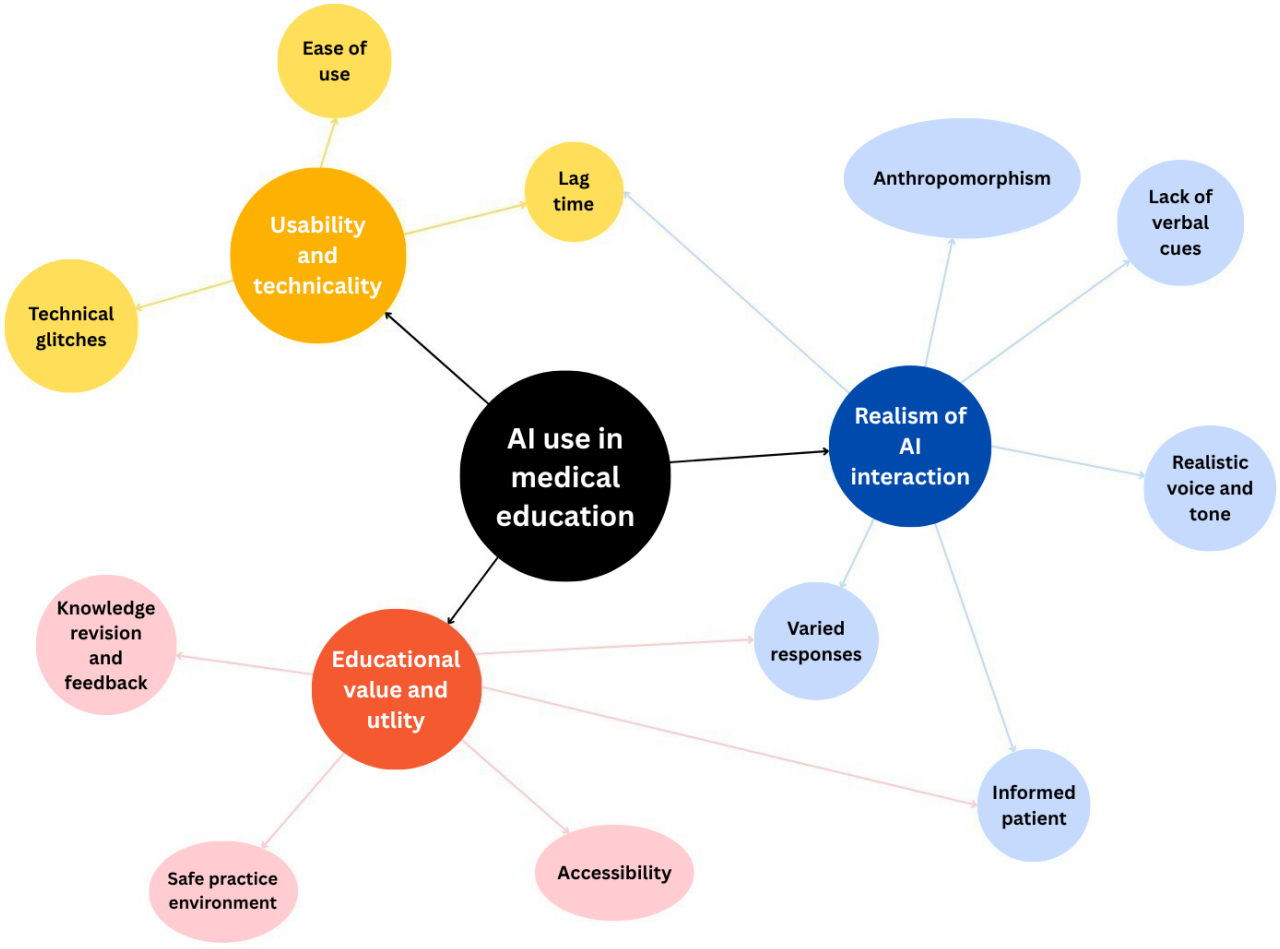
Table . Qualitative summary of the major themes and subthemes identified from responses to open-ended survey questions and focus group interviews.

Theme and subtheme	Description	Illustrative quote (participant number; quote ID)
Usability and practicality		
Time lag	Significant pauses disrupted the natural flow of conversation and reduced realism.	"Long pauses between questions. Hard [*sic*] felt like emotionless answers." (P3; Q1)
		"The pause between question and answering made it difficult for the consultation to flow and didn't feel it replicated a 'real' consultation." (P6; Q2)
Technical glitches	System crashes or repeated questions caused frustration and disrupted learning.	"There were a lot of faults and hiccups as we did it but wasn't too bad overall." (P12; Q3)
		"There was also some glitches that required questions to be asked multiple times or for the consulting student to begin again." (P17; Q4)
Ease of use	The technology was generally easy to access and use.	"The technology [is] straightforward to access and use." (Focus group 1; Q5)
Realism of AI[a] interaction		
Anthropomorphism	Some interactions felt mechanical, with reduced empathy and natural conversational flow.	"It felt very robotic with a lot of miscommunication." (P12; Q6)
		"Robotic answers and there was a delay in responding." (P16; Q7)
		"It felt like a realistic conversation." (Focus group 2; Q8)
Informed patient	AI responses were either too short or overwhelming with unnecessary details.	"The AI gave more information unprovoked/not asked for than a patient normally would." (P17; Q9)
		"The patient was very well informed." (P13; Q10)
		"Gave very scientific responses." (P10; Q11)
	AI used technical language inappropriate for a simulated patient role.	"The AI was using medical jargon that you wouldn't normally expect a patient to use." (P17; Q12)
Lack of nonverbal cues	The absence of body language and facial expressions limited realism and engagement.	"Also not being able to see the AI's body language." (P16; Q13)
Educational value and utility		
Realistic voice and tone	AI's voice and tone were seen as realistic and contributed to a sense of authenticity.	"AI voice was human-like, but the answers were a bit too succinct." (P5; Q14)
		"Realistic voice." (P13; Q15)
		"I think the voice was very realistic, the time delay wasn't too much of an issue." (P18; Q16)
Varied responses	AI responses were sometimes unexpected, adding a layer of realism.	"The AI patient gives unpredictable answers and asks questions like a patient would." (P16; Q17)
		"Was really impressed by how the AI bot could interpret conversational language and respond appropriately." (P9; Q18)
	AI responses were repetitive, leading to a lack of conversational depth.	"There were limited responses however and we got a sense of déjà vu with some of the responses." (P9; Q19)
		"It answered some questions that we didn't ask." (P17; Q20)
Knowledge revision and feedback	AI reinforced clinical knowledge effectively and provided a platform for self-assessment.	"Very useful knowledge checking in a clinical setting." (P1; Q21)
		"The AI can ask questions which helps with the learning." (P7; Q22)
		"Good to learn clinical knowledge." (P4; Q23)

Theme and subtheme	Description	Illustrative quote (participant number; quote ID)
Safe practice environment	AI provided a low-risk space for students to practice and make mistakes without judgment.	"It would be very useful as a revision tool to check how we as students present knowledge/consult with patients." (P5; Q24) "This was a good tool for practicing giving patients information in a safe space." (P9; Q25)
Accessibility	The ability to use AI for practice outside formal clinical settings was highly valued.	"Allows us to practice at home." (P10; Q26) "It would be really useful to have access to it at home to practice with." (P17; Q27)

[a]AI: artificial intelligence.

Figure 3. Thematic map displaying the interlinking themes and subthemes. AI: artificial intelligence.



Theme 1: Usability and Practicality

The AI VP interface demonstrated mixed usability outcomes across 3 key domains. Response delays of approximately 2 - 3 seconds consistently disrupted the natural flow of conversation and reduced perceived realism (Q1 and Q2), impacting participants' ability to maintain authentic consultation dynamics. System instability presented additional challenges, with technical faults requiring question repetition or consultation restarts (Q3 and Q4), interfering with the intended focus on communication skills development. Despite these technical limitations, participants found the interface straightforward to access and operate without requiring technical support or extensive instruction (Q5), facilitating smooth adoption across focus groups.

Theme 2: Realism of AI Interaction

Realism emerged as the most debated aspect among participants, with varied perceptions across multiple dimensions of the VP experience. Participant perspectives on the AI's humanlike qualities were mixed: while some participants found the interactions mechanical and emotionless (Q6 and Q7), focus groups generally perceived the overall experience as reasonably authentic (Q8). The AI's knowledge level created divergent opinions, with some viewing the detailed, scientific responses as unrealistic for typical patients (Q9, Q10, and Q11), particularly when medical jargon was inappropriately used (Q12). The audio-only format limited realism owing to the absence of visual and nonverbal communication cues (Q13), reducing engagement and authenticity compared to face-to-face consultations. However, participants praised the AI's voice

quality and tone as contributing to authenticity (Q14, Q15, and Q16), supporting the simulation's credibility as a telephone consultation format. The AI's ability to provide unpredictable responses and interpret conversational language enhanced perceived authenticity (Q17 and Q18), although repetitive responses occasionally created a sense of déjà vu, diminishing the conversational depth (Q19 and Q20).

Theme 3: Educational Value and Utility

Participants recognized significant educational potential across 3 key areas that could enhance medical training. The AI effectively reinforced clinical knowledge and provided opportunities for self-assessment (Q21, Q22, and Q23), with participants valuing the AI's ability to prompt a discussion of clinical concepts they might not have considered. The virtual environment offered a psychologically safe practice space without the risk of patient harm or judgment (Q24 and Q25), enabling students to experiment with consultation approaches and make mistakes without consequences. Participants particularly valued the potential for accessible, asynchronous learning outside formal clinical settings (Q26 and Q27), representing aspirational use for home-based practice and revision, although access was limited to supervised study sessions during the research period.

Discussion

This mixed methods study explored the application of AI communication training tools in medical undergraduate education within a primary care context. The findings indicate that AI VP encounters can enhance communication skills training by providing a scalable, accessible, and realistic simulation environment.

Key Findings and Implications

Participants reported moderate levels of perceived realism (fidelity score 6/10), with the voice quality achieving authenticity but technical limitations, such as response delays and overly clinical language, reducing overall fidelity. Despite these limitations, the AI VP demonstrated sufficient realism for educational engagement, as evidenced by the high intrinsic motivation score (16.5/20.0) and positive learning value feedback.

In particular, the results demonstrated high levels of perceived effectiveness, usability, and psychological safety among participants. High median scores for intrinsic motivation and system usability were particularly notable, indicating strong engagement and ease of use. These findings align with previous research suggesting that AI tools can effectively support medical education by providing immediate feedback and opportunities for repeated practice [32,33]. The high intrinsic motivation score suggests that students found the AI tool engaging and beneficial for their learning, which is crucial for the adoption of new educational technologies [34]. Learning motivation can be seen as a mediator between technological acceptance and self-efficacy on the task [35,36]. Importantly, AI technologies create a dynamic and adaptive learning ecosystem that tailors educational experiences to individual preferences, enhancing engagement and effectiveness.

Immersion scores (median 8.5/15) aligned with prior ITEM validation research demonstrating that computer screen–based educational experiences typically achieve moderate immersion levels [37]. These scores may reflect the inherent limitations of a 2D interface rather than deficiencies of AI VPs. Importantly, prior studies have found equivalent learning outcomes between high-immersion virtual reality and 2D screens, suggesting moderate immersion may be optimal because it avoids excessive cognitive load while maintaining educational presence.

Technological acceptance on the basis of reasoned action was first proposed as the technology acceptance model [38], which is used to explain the association between acceptance of a computer system and the behavioral intention thereof. System usability within human-computer interaction is critical in the use of technology [39]. The MITHE framework provided an appropriate theoretical basis for our AI VP evaluation, as conversational AI creates immersive learning experiences through cognitive and social engagement rather than visuospatial immersion. System usability within MITHE encompasses both learner perceptions of technology ease of use and individual learner characteristics that influence technology adoption, both of which were evident in our participants' varied responses to the AI VP interface. Furthermore, in the context of technological learning, this means that students who find technology-based learning activities inherently interesting are more likely to engage deeply and persistently. Thus, there is a paradigm of interrelating concepts between engagement and usability. The AI tool enabled both to be established and demonstrated an educational value to students.

Realism in simulation refers to the degree to which a simulation accurately represents real-life scenarios. It involves creating an environment that closely mimics actual clinical situations, allowing learners to engage in tasks and decision-making processes as they would in real clinical settings. Realism is necessary for ensuring that the skills and knowledge acquired during simulation training are transferable to real-world practice [14,40]. Fidelity in simulation is the extent to which the simulation replicates the real-world environment and experiences. It encompasses various dimensions, such as physical, conceptual, and psychological dimensions [41]. The degree of fidelity in this pilot study was reported as moderate by participants. Participants highlighted issues such as time lag, technical glitches, and the lack of nonverbal cues, which impacted the perceived fidelity of the AI interactions. The AI VP provided a naturalistic voice, which was the foundation for a humanlike experience. However, the psychological fidelity was impacted by the extent to which learners could emotionally and cognitively engage with the AI as if they were in a real situation. High psychological fidelity scenarios have the potential for students to develop not only their communication skills but also their empathy and bedside manner.

While AI VPs may not have a physical presence, their interactions can be designed to closely replicate real patient encounters. This includes realistic voice modulation, appropriate use of medical terminology, and the ability to simulate complex medical scenarios. In this study, the scenario required the AI VP to simulate a patient asking a doctor questions, leading to a balanced discussion on PSA testing. Participants appreciated

the AI's ability to simulate informed patient interactions, which enhanced their clinical knowledge and decision-making skills. However, some noted that the AI's responses could sometimes be overly detailed or robotic, detracting from the realism of the simulation. This feedback suggests that future iterations of AI VP should aim to balance informativeness with a natural conversational flow. The ability of the AI to provide detailed responses was seen as both a strength and a limitation, indicating the need for a more nuanced approach to AI response generation.

AI models, especially advanced ones such as LLMs, can understand the context of a prompt. This means they can interpret the nuances of a question or statement and generate responses that are contextually appropriate. For example, if a medical student asks about symptoms of a specific condition, the AI model can provide detailed information relevant to that condition [42]. This is somewhat incompatible with the patient perspective of lacking the understanding of a problem because of which they consult with a physician. A dynamic interaction improves realism, and the varied responses by the AI VP provided users with adaptive and personalized responses. Advanced AI models can simulate emotions and empathy in their responses [7,43]. For example, if a student is practicing delivering bad news to a patient, the AI can respond with appropriate emotional cues, such as expressing concern or asking for clarification, to mimic a real patient's reaction. A narrative synthesis of learning empathy through simulation suggests that simulation is an appropriate method to teach empathy to preservice health professional students [44].

In a pilot study among medical students, earlier LLM models, for example, GPT-3.5, that generated text-only responses were reported to create a plausible experience for students. The analysis revealed that most answers provided by the LLM were medically plausible and in line with the illness script [45]. Vaughan et al [46] recently reported that LLMs can create realistic simulation examples following text-based review. Furthermore, the accuracy, relevance, and structure of the AI programs benefit review prior to adoption in medical education settings [47].

The thematic analysis also revealed that participants valued the safe practice environment provided by the AI VPs. The ability to practice communication skills without the risk of harm to real patients was seen as a significant advantage, supporting the use of AI in medical training [48]. Additionally, the accessibility of the AI tool, allowing for asynchronous learning, was highlighted as a key benefit, particularly for students needing flexible study options [49]. Cognitive presence and social presence are essential for a comprehensive learning experience. While asynchronous learning environments offer flexibility to accommodate individual schedules, they also present challenges in enhancing cognitive and social presence. Despite an informative and realistic interaction, this aspect of learning may have been impacted, as participants assigned immersion a moderate median score. Social presence is the ability of learners to project themselves socially and emotionally in a learning environment. It involves the sense of being "there" and being able to interact meaningfully with others. The illusion of presence—that is, a student wholly experiencing the interaction as if they are a doctor talking to a real patient—may be broken by a simple time lag in response [50].

Educational Value and Future Applications

The study's findings suggest that AI-powered VPs have substantial educational value, particularly in enhancing communication skills in primary care settings. The positive feedback on knowledge reinforcement and the potential for personalized feedback indicates that AI tools can complement traditional training methods, providing a more comprehensive learning experience. The ability to receive immediate, detailed feedback from the AI was particularly valued by participants, highlighting the potential of AI to support continuous improvement in communication skills, contributing to the broader argument of adoption of AI in medical education curricula. Further advances in AI computational complexity with a reduced time lag in response and authenticity of character will further improve learner experience. There are numerous use cases beyond this pilot study, including patient standardization for objective structured clinical examinations, simulated consulting, advanced manikin simulation with realistic patient response, and procedural skills communication feedback. Integrating machine learning into the review of a participant's behavior and response to AI VP could add a degree of automation to medical and allied medical licensing examinations. Model variations allow for changes in VP characteristics; however, model stability and sensitivity need further investigation. Future development should prioritize technical infrastructure to minimize response delays using API optimization, advanced prompt engineering to achieve more natural conversational patterns, and adaptive information delivery systems that balance patient authenticity with educational value. Conversational analysis would be an important step to evaluate the clinical narrative and naturalness. Eventual integration of visual avatars and enhanced voice prosody could address nonverbal communication limitations while maintaining the accessibility advantages of current screen-based implementation.

Strengths and Limitations

To our knowledge, this is the first study to use an advanced, realistic voice on a recent LLM model, with the aim to assess simulation realism for students for use in practicing consultation skills. The context of primary care consulting that focused on discussing a case of PSA testing additionally tested the AI in a conversation that helped students develop their cognitive reasoning skills. The use case provides evidence for future work in assessing the accuracy of responses and AI feedback on the consultation via transcript analysis.

Being a pilot study, this study was underpowered, and the results demonstrating statistical significance ($P<.05$) with large effect sizes need to be interpreted with caution. This study was conducted at 3 randomly selected sites with a small sample of students (n=15) representing 6% of the third-year cohort (N=240), which may limit the generalizability of findings to the broader medical student population despite the random site selection. Furthermore, the measures were abridged versions of validated questionnaires. This study did not aim to analyze the content validity; however, construct validity was assumed

from prior work in this field. Additionally, this was an observational study, and a comparison of human consultation was not conducted, which is important for future work. The assumption of high intrinsic motivation and other domains requires further comparison to standard learning methods such as using actors.

Learning objectives focused on shared decision-making communication skills for prostate cancer screening discussions. This feasibility study assessed the perceived educational value of an AI VP through ITEM scores and qualitative feedback rather than a formal pre- and postcompetency assessment, representing a limitation. Future research should incorporate validated communication skills assessments to quantify learning outcomes objectively.

Focus groups enable the inclusion of a social element into the development of ideas on a topic; however, the presence of a tutor during the data collection may have influenced the responses by students, even when the facilitator is attuned to this and adapts questions to promote collective contribution.

Conclusion

The research aimed to explore the practical application of an AI VP tool in preparing future health care professionals for real-world patient interactions. AI VP technology shows promising potential for communication skills training despite the current limitations in realism. While it does not yet match human standardized patient authenticity, the technology achieved sufficient fidelity to support meaningful educational interactions. Furthermore, the study identified clear areas for improvement. The integration of AI into medical curricula represents a promising avenue for innovation in medical education, with the potential to improve the quality and effectiveness of training programs. Future research focusing on comparison with medical actors in assessment and AI-generated participant score will assist in strengthening the argument for AI integration into health care education.

Abstract

Background: Mock examinations are widely used in health professional education to assess learning and prepare candidates for national licensure. However, instructor-written multiple-choice items can vary in difficulty, coverage, and clarity. Recently, large language models (LLMs) have achieved high accuracy in medical examinations, highlighting their potential for assisting item-bank development; however, their educational quality remains insufficiently characterized.

Objective: This study aimed to (1) identify the most accurate LLM for the Japanese National Examination for Radiological Technologists and (2) use the top model to generate blueprint-aligned multiple-choice questions and evaluate their educational quality.

Methods: Four LLMs—OpenAI o3, o4-mini, o4-mini-high (OpenAI), and Gemini 2.5 Flash (Google)—were evaluated on all 200 items of the 77th Japanese National Examination for Radiological Technologists in 2025. Accuracy was analyzed for overall items and for 173 nonimage items. The best-performing model (o3) then generated 192 original items across 14 subjects by matching the official blueprint (image-based items were excluded). Subject-matter experts (≥5 y as coordinators and routine mock examination authors) independently rated each generated item on five criteria using a 5-point scale (1=unacceptable, 5=adoptable): item difficulty, factual accuracy, accuracy of content coverage, appropriateness of wording, and instructional usefulness. Cochran Q with Bonferroni-adjusted McNemar tests compared model accuracies, and one-sided Wilcoxon signed-rank tests assessed whether the median ratings exceeded 4.

Results: OpenAI o3 achieved the highest accuracy overall (90.0%; 95% CI 85.1% - 93.4%) and on nonimage items (92.5%; 95% CI 87.6% - 95.6%), significantly outperforming o4-mini on the full set (P=.02). Across models, accuracy differences on the non-image subset were not significant (Cochran Q, P=.10). Using o3, the 192 generated items received high expert ratings for item difficulty (mean, 4.29; 95% CI 4.11 - 4.46), factual accuracy (4.18; 95% CI 3.98 - 4.38), and content coverage (4.73; 95% CI 4.60 - 4.86). Ratings were comparatively lower for appropriateness of wording (3.92; 95% CI 3.73 - 4.11) and instructional usefulness (3.60; 95% CI 3.41 - 3.80). For these two criteria, the tests did not support a median rating >4 (one-sided Wilcoxon, P=.45 and P≥.99, respectively). Representative low-rated examples (ratings 1 - 2) and the rationale for those scores—such as ambiguous phrasing or generic explanations without linkage to stem cues—are provided in the supplementary materials.

Conclusions: OpenAI o3 can generate radiological licensure items that align with national standards in terms of difficulty, factual correctness, and blueprint coverage. However, wording clarity and the pedagogical specificity of explanations were weaker and did not meet an adoptable threshold without further editorial refinement. These findings support a practical workflow in which LLMs draft syllabus-aligned items at scale, while faculty perform targeted edits to ensure clarity and formative feedback. Future studies should evaluate image-inclusive generation, use Application Programming Interface (API)-pinned model snapshots to increase reproducibility, and develop guidance to improve explanation quality for learner remediation.

KEYWORDS

large language models; licensing exam; radiology, educational evaluation; medical education; item generation

Introduction

Mock examinations are a key pedagogical tool in training programs for health professionals. These are designed to consolidate the knowledge required for national licensure and to gauge students' achievement [1-3]. In particular, multiple-choice formats are valuable because they enable the systematic, efficient appraisal of the broad foundational knowledge expected in clinical practice, making them integral to the quality of the curriculum. However, most items are written by individual instructors that draw on past examinations or personal clinical experience, and their difficulty and content validity are rarely subjected to systematic review [4,5]. These can result in biases in content coverage, inconsistencies in wording, and variable educational usefulness, which undermine the stability of learning outcome assessments.

Several studies have reported the high accuracy of large language models (LLMs) in health professional licensure examinations, owing to their rapid advancements [6-9]. In text-based multiple-choice questions, models have begun to match or surpass human test-takers while generating rationales and keyword-level explanations that can serve as formative feedback [10-13]. These suggest the potential utility of LLM-assisted item writing during the construction of high-quality question banks. However, most research has centered on the accuracy of LLMs in answering existing licensure items [14-16], while empirical evidence regarding the educational quality of questions authored by LLMs remains scarce [13,17]. A comprehensive appraisal that includes (1) appropriate difficulty, (2) completeness and accuracy of content coverage, (3) clarity of option wording, and (4) usefulness of accompanying explanations is necessary to address this knowledge gap and clarify the practical value of artificial intelligence (AI)-supported mock examinations, as well as its limitations.

This study evaluated the quality of AI-generated multiple-choice questions based on the Japanese National Examination for Radiological Technologists. Several LLMs were used to answer the exam, then the highest-performing model was used to generate a set of mock items. These AI-generated questions were then evaluated across several aspects (ie, item-level difficulty, item-level factual accuracy, accuracy of content coverage, appropriateness of wording, and instructional usefulness) through blinded expert review and statistical analysis. By doing so, this study aims to provide empirical data on the educational soundness of AI-generated items, as well as highlight any emerging challenges.

Methods

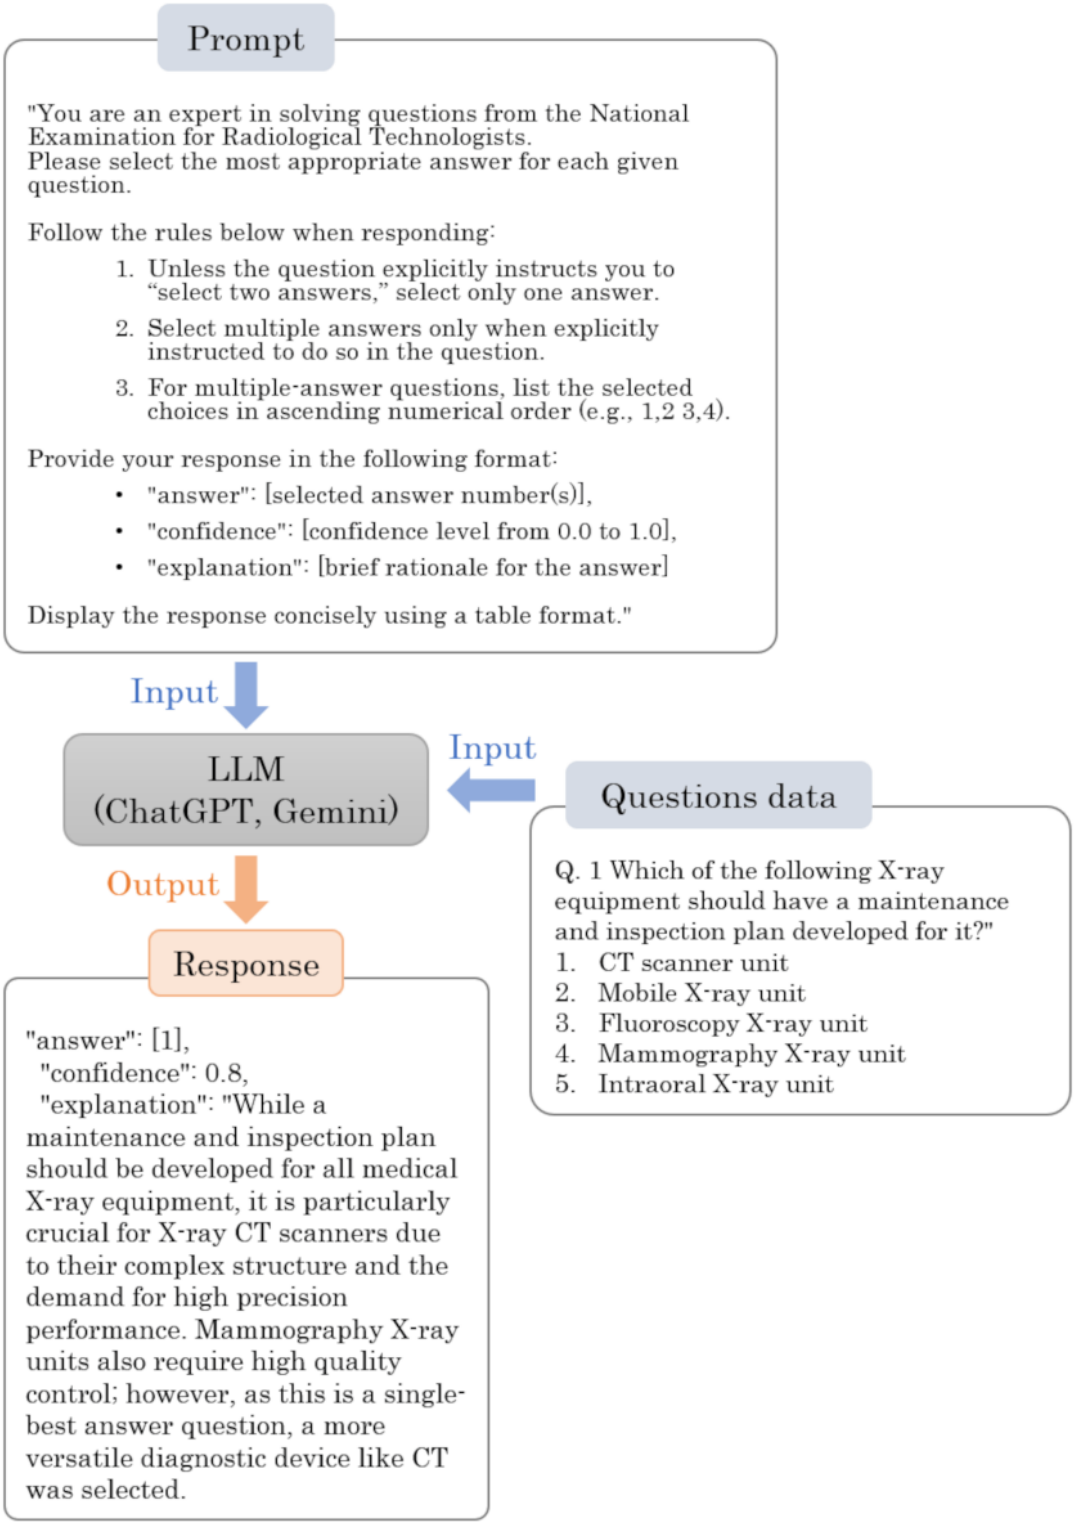
Models and Study Period

Four LLMs released in February 2025 were evaluated: OpenAI o3, OpenAI o4-mini, OpenAI o4-mini-high (all OpenAI), and Gemini 2.5 Flash (Google). The evaluations were conducted from March 14 to May 8, 2025, using the publicly accessible browser interfaces, with the desired engine explicitly selected in each platform's menu. The browser access was chosen to mirror typical educational use and to simplify image I/O (upload, preview, and per-item attachment). The item-generation study was conducted from May 15 to June 28, 2025, using OpenAI o3, the model with the highest answer accuracy. To ensure consistency, we used an identical Japanese prompt template across models. To avoid carryover effects, we started a new session for each 50-item batch with the OpenAI models and used per-item input with Gemini; image files (PNG) were attached when required by an item. As browsing and memory features were disabled, outputs relied solely on pretrained parameters and the provided materials.

Answer Accuracy

Answer accuracy was assessed based on all 200 items of the 77th National Examination for Radiological Technologists, administered on February 20, 2025. All items were multiple-choice, and question stems containing images were presented unchanged. Each model was given the question stem and options in Japanese, then instructed to select the correct answers in single-best or multiple-select format. Multimedia Appendix 1 lists the subjects and the number of items per subject. Due to the differences in each model, the input procedures were adapted accordingly. For OpenAI models, stems and options were pasted from four text files (items 1 - 50, 51 - 100, 101 - 150, and 151 - 200) into separate sessions. PNG files were attached for each image item, with the filenames labeled to match the corresponding item numbers. However, since Gemini permits only one file upload, the stems and options were pasted directly into the prompt while attaching an image file as needed. All inputs were entered manually. A concrete workflow is shown in Figure 1.

Figure 1. Representative interaction with a large language model (LLM). This diagram illustrates the workflow used to evaluate the answer accuracy of large language models. The LLMs were given prompts to answer each question (including text and images when applicable) in Japanese, with specific instructions for answer selection and formatting. The output included the selected answer, a confidence score, and a brief explanation. All actual prompts and inputs were entered in Japanese, but this example is shown in English for illustration purposes. CT: computed tomography.



The outputs of the model were compared to the official answer key issued by the Ministry of Health, Labor and Welfare. The correct and incorrect responses were counted overall for 200 items and separately for the 173 items that did not require image interpretation (ie, nonimage items). Statistical significance was tested across models.

Item Generation

Generation Procedure

The mock items were generated using OpenAI o3, since it had the highest accuracy among all four models. Image-based stems were excluded since all models performed poorly on these. Using the same examination as a blueprint, OpenAI o3 was

used to produce 192 questions across 14 subjects (Table 1), matching the same distribution of items. The model was supplied with text files containing the past 5 years of examination items and the official test specifications, ensuring its alignment with test objectives. Browsing remained disabled. Since Healthcare Safety Management is a new domain introduced in 2025, thereby lacking any historical reference items, it was excluded from the mock item generation. Items were generated separately for each subject in Japanese, and each output included the stem, five options, the key, and a brief rationale.

Table . Distribution of artificial intelligence (AI)-Generated Mock Items.

Subject	Blueprint target (n=200)	Generated (n=192)
Diagnostic Imaging Techniques	20	20
Nuclear Medicine Technology	20	20
Radiation Therapy Technology	20	20
Medical Imaging Informatics	10	10
Basic Medical Sciences	30	30
Radiation Science & Engineering	36	36
X-ray Imaging Equipment	20	20
X-ray Imaging Techniques	20	20
Image Engineering	6	6
Radiation Safety Management	10	10
Healthcare Safety Management[a]	8	0

[a]Since Healthcare Safety Management was only recently introduced as a new subject in the 2025 blueprint, it was excluded from the mock item generation.

Evaluation of Generated Items

All 192 generated questions were reviewed by experts of the subject matter; these were faculty members with at least 5 years of experience as subject coordinators in radiological technology programs and who routinely author mock examinations. Items were assigned to reviewers by discipline, and each question was evaluated by one expert. The reviewers rated each item on a five-point scale: (1) unacceptable; (2) major revision needed; (3) revisable; (4) minor revision; and (5) adoptable across five criteria including, item difficulty, factual accuracy, accuracy of content coverage, appropriateness of wording, and instructional usefulness.

For each criterion, we calculated the median score and tested the statistical significance of the proportion of high ratings (≥4). The evaluation framework, which is based on faculty experience with national examination item writing, is presented in Table 2.

Table . Evaluation of generated items.

Evaluation criterion	Rating scale[a]
Item difficulty	1 - 5
Factual accuracy	1 - 5
Accuracy of content coverage	1 - 5
Appropriateness of wording	1 - 5
Instructional usefulness	1 - 5

[a]Rating scale definition: 1=Unacceptable; 2=Major revision needed; 3=Revisable; 4=Minor revision; 5=Adoptable.

Statistical Analysis

Statistical analysis was performed using JMP (version 18; JMP Statistical Discovery LLC). Cochran Q test was initially used to examine overall differences in answer accuracy; when significant, pairwise differences were probed with McNemar test using Bonferroni correction. The item generation study used a one-sided Wilcoxon signed-rank test (H : median ≤4). Statistical significance was set at $P<.05$ for all analyses.

Ethical Considerations

This study did not involve human participants or patient-identifiable data. The Ethics Committee of Teikyo University reviewed the project and determined that formal ethical approval was not required because the work evaluated the quality of test items and did not constitute human medical research. Accordingly, informed consent was not applicable.

Results

Answer Accuracy

The accuracy of the LLMs on the full 200-item set and the nonimage 173-item set is shown in Table 3. All models consistently scored lower in the full set versus the nonimage set, with OpenAI o3 achieving the best results at 90% and 92.5%, respectively. A significant difference was seen between OpenAI o3 and OpenAI o4-mini on the full set, whereas no significant differences were seen among models on the nonimage set.

Table . Model accuracies and statistical comparisons on 200 benchmark questions and 173 nonimage questions.

Variables	200 questions[a]	173 nonimage questions[a]
Model accuracy		
OpenAI-o4-mini-high, %	86.0 (80.5, 90.1)	88.4 (82.8, 92.4)
OpenAI-o4-mini, %	82.5 (76.6, 87.1)	86.7 (80.8, 91.0)
OpenAI-o3, %	90.0 (85.1, 93.4)	92.5 (87.6, 95.6)
Gemini 2.5 Flash, %	83.0 (77.2, 87.6)	89.6 (84.1, 93.3)
Cochran Q test (*P* value)	.01	.10
Pairwise McNemar test (Bonferroni-adjusted *P* value)		
OpenAI-o4-mini-high versus OpenAI-o4-mini	≥.99	N/A[b]

[a] Accuracy shown with 95% CIs in parentheses (Wilson score, two-sided, without continuity correction).

[b]Not applicable.

Item Generation

Table 4 presents the scores and statistics for all 192 questions, while Figure 2 illustrates the prompt template and sample outputs. Among item difficulty, factual accuracy, and accuracy of content coverage, the medians and the proportions of scores ≥4 did not differ significantly, although accuracy of content coverage had the highest score. Meanwhile, instructional usefulness had a significantly lower score than appropriateness of wording. The evaluation criteria and evaluation examples of items that scored 1‐2 for the lower-scoring criteria—appropriateness of wording and instructional usefulness—are detailed in Multimedia Appendix 2.

Table . Reviewer ratings by evaluation criterion for the AI-generated items (n=192).

Evaluation criterion[a]	Mean score (95% CI)	*P* value[b]
Item difficulty	4.29 (4.11, 4.46)	<.001
Factual accuracy	4.18 (3.98, 4.38)	.001
Accuracy of content coverage	4.73 (4.60, 4.86)	<.001
Appropriateness of wording	3.92 (3.73, 4.11)	.44
Instructional usefulness	3.60 (3.41, 3.80)	≥.99

[a] “Evaluation criterion” refers to the five evaluation criteria defined in Table 2.

[b]One-sided Wilcoxon signed-rank test against the null hypothesis such that the median score is ≤4.

Figure 2. Prompt summary and representative example of item generation. (A) Summary of the prompts used to instruct the language model to generate original mock questions aligned with the National Examination for Radiological Technologists. The summary outlines the role of the model, input references, specifications of generation, item-creation rules, and output format. (B) The actual prompt and representative response generated by the model. The prompt included specific formatting and content-generation instructions written in Japanese. The response shows the generated item, correct answers, and explanation in Japanese.

A

Role & General Instruction:
Generate practice questions for the National Examination for Radiological Technologists that reflect the official exam's tone, difficulty, and content focus.
Reference materials:
Use items 1–144 from the past five years of the National Examination (72nd to 76th, 2020–2024) as reference material to guide question generation in terms of content and format.
Specifications for Item Generation:
Create the specified number of questions for the designated subject, ensuring coverage of the subtopics and keywords provided in the reference materials.
Instructions for Item Creation:
Generate original five-choice questions that follow the style and level of past exams. Use both single-answer and two-answer formats, marking correct answers and including brief explanations for each.
Output Format :
Present each item in a standardized format with a numbered question, five answer choices, clearly indicated correct answer(s), and a brief explanation for all options.

B

Prompt (Original Japanese)

「あなたは診療放射線技師国家試験の問題作成の専門家です。以下の参考資料を基に、国家試験本番と同等の文体・難易度・出題傾向を持つ練習問題を作成してください。

参考資料：過去5年分（第72回(2020年)～第76回(2024)の診療放射線技師国家試験問題集（問1から問144）

問1　性ホルモンが腫瘍の増殖に関わるのはどれか。2つ選べ。
1. 腟癌
2. 陰茎癌
3. 尿道癌
4. 子宮体癌
5. 前立腺癌
：
：
：
問144　受精が起こるのはどこか。
1. 腟
2. 卵管
3. 卵巣
4. 子宮頸部
5. 子宮内膜

出題内容の指定
- 科目：**[放射線物理学]**
- 問題数：**[10問]**
- 範囲・キーワード：**[出題範囲(PDF_2_放射線物理学)]**

科目 の小項目のみを抽出し表示する。

出題にあたっての条件
- 国試本番と同等の口調・専門性・難易度を再現すること。過去問の典型的な表現（「～はどれか。」など）や形式にならう。
- 問題は**完全新規**に作成すること（参考資料と**同一の問題文にならない**ように留意すること）。過去問をヒントにテーマや表現を変えて出題してよいが解答そのものは新しく考案する。
- 出題形式：**5肢択一形式**（正答1つ）と**5肢複択形式**（正答2つ）を組み合わせること。全体の約**70%**を正答1つの問題、約**30%**を正答2つの問題とする。
- **選択肢**は問題ごとに**1～5の5つ**を用意すること（内容は出題範囲に必ず沿ったもの）。
- 正答が2つある問題では、問題文の末尾に「**2つ選べ。**」と明記し、受験者が2つ選ぶ形式であることを示す。
- **解答表示:** 各問題の選択肢の直後に「正答：○」と正解選択肢を記号で示す（正解が複数ある場合は「正答：2と4」のように列記）。
- **解説:** 各問題に対して、正解の根拠および各選択肢の解説を添えること。他の選択肢が誤りである理由や関連知識も含め、受験者の理解が深まる説明を書く。

出力フォーマット: 以下の形式で問題文、選択肢、正答、解説を記載すること（各問題を通し番号で番号付けする）。

問題1．～（問題文）～はどれか。 ※複数正解の場合、文末に「2つ選べ。」
1. 選択肢1
2. 選択肢2
3. 選択肢3
4. 選択肢4
5. 選択肢5

正答：2 ※複数正解の場合「正答：2と4」

解説：問題文や選択肢に関する解説。正解が正しい理由と他の選択肢が誤りである理由をそれぞれ説明する。」

Response (Generated in Japanese)

練習問題（全10問）
問題1.
水中において 1.25 MeV の光子が物質と相互作用する際、最も卓越する現象はどれか。
光電吸収
コンプトン散乱
電子対生成
レイリー散乱
光核反応
正答: 2
解説: 光電吸収は E^(−3)、電子対生成は E^(+) に支配されるが、低原子番号物質で 1 MeV 付近ではコンプトン散乱が最大となる。レイリー散乱は無電離散乱で寄与が小さく、光核反応は高エネルギー域（数10 MeV 以上）で顕在化する。

問題2.
線エネルギー付与 (LET) が最大となるのはどれか。
5 MeV α粒子
25 MeV 陽子
6 MeV 電子
1 MeV γ線
120 keV X 線
正答: 1
解説: LET は電荷の 2 乗に比例し速度の 2 乗に反比例する。重くて遅いα粒子 (He^(2+)) は密度エネルギー付与が大きく、他の放射線より高LET となる。

問題3.
光電吸収係数を増大させる要因はどれか。2 つ選べ。
低原子番号物質
低エネルギー光子
材料密度の低下
高原子番号物質
高エネルギー光子
正答: 2 と 4
解説: 光電吸収係数は概ね $\propto Z^3 \cdot 4E^{-3}$ に比例する。よって低エネルギー(2)・高 Z (4) が係数を大きくする。密度は質量減弱係数を変えず、(1)(3)(5)はむしろ係数を小さくする。

問題4.
X 線管で発生する制動X 線の最短波長を 1/2 に短縮するには管電圧 (kV) をどのように変化させればよいか。
2 倍にする
√2 倍にする
1/2 にする
1/√2 にする
変化させない
正答: 1
解説: 最短波長 $\lambda_{min} = hc/eV$ であり $\lambda_{min} \propto 1/V$。半減させるには電圧を 2 倍にする必要がある。

問題5.
熱中性子の速度に影響する物理量はどれか。2 つ選べ。
温度
中性子の質量
原子核の原子番号
中性子のスピン
電離密度
正答: 1 と 2
解説: Maxwell-Boltzmann 分布より $v_{rms} = \sqrt{3kT/m}$。速度は温度 (1) と質量 (2) に依存し、核種の Z やスピン、媒質の電離密度とは直接関係しない。

Discussion

Principal Findings

This study compared four LLMs in terms of answer accuracy on the Japanese National Examination for Radiological Technologists. The top performer, OpenAI o3, was used to generate the mock test, which was then evaluated by experts in terms of educational quality. As shown in Table 3, on the full set of items, only the comparison between the OpenAI o3 and OpenAI-o4-mini variant reached statistical significance; when image-based items were excluded, no model differences were observed.

To contextualize the observed accuracy differences, we briefly summarize the multimodal architectures and vision–language pipelines of the evaluated models as they pertain to radiologic image questions. Built on a GPT-4 lineage, OpenAI o3 integrates a high-resolution visual encoder with unified attention over linguistic and visual tokens [18,19], likely enhancing sensitivity to low-contrast findings and subtle anatomical cues typical of radiography and CT. In contrast, OpenAI o4-mini is a lightweight variant with reduced-resolution patch embeddings [20,21], which can yield coarser visual representations and miss subtle image cues. OpenAI o4-mini-high supplements the mini architecture with targeted medical-image fine-tuning and partial recovery of high-resolution inputs [22,23], consistent with improved mapping of relevant visual patterns. Lastly, Gemini 2.5 Flash uses a two-tower design in which an external vision encoder converts images to tags prior to language processing [24,25]; such pipelines may incur information loss for domain-specific anatomical details. In line with these architectural differences, performance gaps emerged on image-based questions but not on text-only items.

The pronounced performance spread on image-based questions could be mainly attributed to the aggressive parameter reduction in OpenAI o4-mini and the information loss inherent in the image-to-tag pipeline in Gemini, both of which weaken visual feature representation. Thus, current systems may not fully capture clinically grounded context and the knowledge required for radiologic image interpretation. This finding is consistent with the results of previous studies reporting similar limitations in specialty radiology examinations [26,27]. However, OpenAI o3 and o4-mini-high have higher resolution encoders and benefit from medical-specific fine-tuning. However, due to the limited sample sizes and proprietary nature of the detailed model architectures, these explanations remain partly hypothetical. Nevertheless, these findings highlight the importance of the visual module scale and the presence of medical-domain training when selecting an LLM for the development of -generated questions in this field.

Building on these findings, the 192 items generated by the top model were reviewed across five educational criteria. Item difficulty, factual accuracy, and content coverage were rated favorably, indicating alignment with national expectations and the official blueprint [26]. By contrast, appropriateness of wording and instructional usefulness were comparatively weaker, with reviewers noting ambiguous phrasing and explanations that did not consistently link stem cues to the correct answer or to distractor misconceptions. These strengths and weaknesses are consistent with observations from related medical-education settings [28-30] and underscore the need for editorial refinement prior to instructional deployment.

This study has several limitations. First, the image-based items were excluded from expert review, thus precluding the assessment of visual tasks. Second, each question was evaluated by a single expert, and thus inter-rater reliability could not be assessed. Third, reproducibility is limited by the use of publicly accessible browser interfaces. All evaluations were conducted through browser UIs with visible labels: OpenAI o3, OpenAI o4-mini, OpenAI o4-mini-high, and Gemini 2.5 Flash. Although this choice mirrors typical educational use and simplifies image I/O, it limits control over versioning and decoding parameters. Prompt delivery also varied across platforms due to UI constraints: OpenAI models received items in 50-question batches per session, whereas Gemini required per-item input, with a single image upload when applicable. Such differences in prompt granularity, context priming, and file-attachment workflows may have influenced outputs and should be considered when interpreting the comparable performance of Gemini Flash and o3. To mitigate these effects, we used an identical Japanese prompt template, disabled memory features, initiated new sessions for each batch, preserved the original exam order, and performed a single pass per item without retries. Input handling is detailed in the Methods section. These input structures reflected platform UI constraints (OpenAI allowed 50-question batches per session, whereas Gemini required per-item prompts and a single image attachment when applicable); although memory features were disabled and each batch began in a new session, processing the OpenAI items in batches could still introduce minor within-session priming; therefore, residual order effects cannot be fully excluded. Application-level temperature settings were not user-configurable. Moreover, because decoding remained stochastic and we performed a single pass per item without retries, run-to-run response variability cannot be fully excluded even with identical prompts. Given that browser-based services can update without notice, outputs may drift over time even when identical prompts and labels are used [31-33]. Thus, to strengthen version control and reproducibility, future studies should standardize prompt injection through Application Programming Interface endpoints with pinned model snapshots, identical per-item wrappers, and fully logged metadata (prompt templates, model identifiers, timestamps, and decoding parameters). In the future, visual encoders are expected to operate at a higher resolution and undergo additional tuning for medical domains. This could enable LLMs to automatically generate image-based items across modalities (eg, computed tomography, magnetic resonance imaging, and ultrasound), thus bringing mock exams closer to clinical reality. Further improvements in the feedback system could also be seen. By delivering adaptive feedback that varies in depth according to each learner's proficiency, students can be provided with on-demand, targeted remediation material. LLMs could also be used to map items to the national blueprint in real time, enabling the detection and correction of domain imbalances while reducing faculty workload. Lastly, aligning these models with overseas licensure frameworks could expand their use to

ultimately support a multilingual, multi-profession, international mock-exam bank.

Conclusions

This study demonstrated that an LLM (OpenAI o3) can attain high accuracy on national radiological technology examination, as well as generate new multiple-choice items with appropriate difficulty, factual correctness, and syllabus coverage, as evaluated by experts. Although the AI-generated questions fell short in terms of wording clarity and pedagogical feedback, these can be mitigated through targeted editorial review. Practically speaking, LLMs can be used to draft content that is eventually refined by the faculty. This workflow could enable the more efficient development of mock examinations and reinforce curriculum alignment without imposing additional burden on instructors. However, performance gaps on image-based items, the absence of inter-rater reliability data, and the inherent volatility of cloud-hosted models underscore the need for cautious implementation and transparent reporting of model metadata. Nevertheless, future advancements in high-resolution visual encoders and medical-specific tuning can close this multimodal gap, while adaptive feedback functions and automated blueprint mapping can further extend the educational value of AI-generated assessments. After overcoming these barriers in terms of technical improvements and reproducibility safeguards, LLMs can be a strong asset in radiological technology education, which can even extend to the licensure preparations of other allied health professionals worldwide.

Acknowledgments

The authors thank Hiroki Ohtani, Hiroki Saito, Tatsuru Ota, Kiyoshi Hishiki, and Masao Fujihara of Teikyo University for their careful evaluation of the problem statements and for the constructive feedback that strengthened this study. Disclosure of generative AI use (language editing only). We used OpenAI o3 solely to assist with language editing (readability, clarity, and minor stylistic consistency). No AI tools were used to generate scientific content, analyze or interpret data, or determine conclusions. All statements and references were verified by the authors, who take full responsibility for the final manuscript. Editing with OpenAI o3 was performed interactively; the manuscript wording was subsequently finalized by Enago Co., Ltd.

Funding

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors. The article processing charge for open access publication was supported by Teikyo University's Open Access Publication Support Program. The funder had no role in the study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Abstract

Background: Artificial intelligence (AI) systems are becoming increasingly relevant in everyday clinical practice, with Food and Drug Administration–approved AI solutions now available in many specialties. This development has far-reaching implications for doctors and the future medical profession, highlighting the need for both practicing physicians and medical students to acquire the knowledge, skills, and attitudes necessary to effectively use and evaluate these technologies. Currently, however, there is limited experience with AI-focused curricular training and continuing education.

Objective: This paper first introduces a novel blended learning curriculum including one module on AI for medical students in Germany. Second, this paper presents findings from a qualitative postcourse evaluation of students' knowledge and attitudes toward AI and their overall perception of the course.

Methods: Clinical-year medical students can attend a 5-day elective course called "Medicine in the Digital Age," which includes one dedicated AI module alongside 4 others on digital doctor-patient communication; digital health applications and smart devices; telemedicine; and virtual/augmented reality and robotics. After course completion, participants were interviewed in semistructured small group interviews. The interview guide was developed deductively from existing evidence and research questions compiled by our group. A subset of interview questions focused on students' knowledge, skills, and attitudes regarding medical AI, and their overall course assessment. Responses were analyzed using Mayring's qualitative content analysis. This paper reports on the subset of students' statements about their perception and attitudes toward AI and the elective's general evaluation.

Results: We conducted a total of 18 group interviews, in which all 35 (100%) participants (female=11, male=24) from 3 consecutive course runs participated. This produced a total of 214 statements on AI, which were assigned to the 3 main categories "Areas of Application," "Future Work," and "Critical Reflection." The findings indicate that students have a nuanced and differentiated understanding of AI. Additionally, 610 statements concerned the elective's overall assessment, demonstrating great learning benefits and high levels of acceptance of the teaching concept. All 35 students would recommend the elective to peers.

Conclusions: The evaluation demonstrated that the AI module effectively generates competences regarding AI technology, fosters a critical perspective, and prepares medical students to engage with the technology in a differentiated manner. The curriculum is feasible, beneficial, and highly accepted among students, suggesting it could serve as a teaching model for other medical institutions. Given the growing number and impact of medical AI applications, there is a pressing need for more AI-focused curricula and further research on their educational impact.

Introduction

Background

The digital transformation in the health care system represents a fundamental process of change and innovation that is altering the roles, competencies, and cooperation of doctors to a large extent [1]. Eric Topol [2] describes an increasing "super-convergence" of technologies that is transforming the existing health care system into a digital health care system. The key characteristics of this new system are individualization, precision, and prevention. It is expected that this will result in data-based health care that will be characterized by a pronounced intensification of interdisciplinary cooperation and a stronger participatory role for patients. Every patient is increasingly becoming a "big data" challenge, with huge amounts of information about previous illnesses and conditions. At the same time, existing medical knowledge is growing exponentially. These two facts cumulate in increasingly complex decision-making processes in patient care. One recent digital transformative technology that can help bridge this complexity gap by preparing, analyzing, and organizing large amounts of data is artificial intelligence (AI). In health care, AI is becoming increasingly important for extracting and interpreting clinically useful information from large volumes of digital data and information sources and, in some cases, deriving recommendations for therapeutic action.

In the following section, the term "AI applications in medicine" refers to medical software, devices, and technologies such as apps whose analytical processes are AI-based and which are used in the health care sector by patients and/or practitioners.

AI Applications in Medicine

Integrating AI applications into medical processes can automate repetitive tasks currently handled by humans. This hybrid working model improves human performance through technology. In 2012, the US Food and Drug Administration (FDA) certified a medical AI application for the first time [3]. Currently, the FDA database comprises 950 applications (as of the last FDA update on August 7, 2024), predominantly in radiology and the cardiovascular field [4]. Clinical AI systems have already demonstrated expert-level performance in radiology [5-7] and equaled the diagnostic performance of health care professionals in medical imaging [6]. Beyond radiology, there are numerous publications on the clinical application of AI [8-16] and large language models such as ChatGPT [17-19]. A scoping review by Han et al [20] generated an overview of all published randomized controlled trials on clinical AI as of November 2023 and found 84 studies. Their review underpins the growing evidence for the use of AI-supported tools in health care. However, from a populational and thus patient perspective, attitudes toward AI in health care are still fluid and demonstrate varying levels of knowledge, acceptance, and skepticism across different countries and demographic groups [21-24].

The Need for Curricular Training About AI in Medicine

This development has far-reaching implications for doctors and requires a fundamental examination of AI systems [25,26]. At present, neither medical professionals already practicing nor the generation currently studying is adequately prepared for the integration of AI in medicine. At the same time, both groups will—or are already—encountering actionable AI in their day-to-day work that is or will be able to predict, diagnose and, if necessary, treat diseases [2]. At a clinical level, doctors require the competencies to critically assess AI applications to use only those tools that have an evidence-based effect on improving clinical workflows or patient outcomes. At the development level, it is also important to ensure that doctors are actively involved in the development and scientific testing of new AI applications. This raises the question of the extent to which these systems can be effectively integrated into the diagnosis and treatment process, as well as how limitations of the systems can be recognized by medical users and how a fallback level can be ensured. In rapidly changing health care systems, it is therefore essential to ensure that doctors have the knowledge, skills, and attitudes to both master current challenges and be prepared for future challenges [1].

The basic competencies required for this must be learned by medical students during studies and continuously developed throughout their careers [27]. There are already various international ideas for this qualification mandate. For example, the Standing Committee of European Physicians addresses this goal in its Policy on Digital Competencies for Doctors and defines digital core competencies [28]. The EU Health Policy Platform has formulated specific instructions for achieving these core competencies [29]. According to these policymakers, educators should consider including content about the following skill sets into their curricula: (1) general digital skills (data and software security, ethical and legal implications), (2) technical digital skills (telemedicine, AI, health apps, smart devices, robotics, virtual reality/augmented reality, data literacy), and (3) the patient-doctor relationship (digital communication and collaboration, digital health literacy). Seth et al [30] created a theoretical framework of topics related to AI that need to be taught to train medical students in this technology. Laupichler et al [31] emphasize the need to assess medical students' AI literacy and attitudes in order to hone medical curricula to the AI educational needs of the next generation.

According to a recent review by Gordon et al [32], a growing number of medical schools are addressing AI throughout medical studies, but this is limited by the fact that only 2 of the 278 included studies focused on educational competencies in AI. For the German landscape, a study on national course programs found that the majority (72%) of surveyed medical schools stated that they offer AI-related learning opportunities [33]. In contrast to this, 70% of German medical students indicated in a survey conducted at the same time that they had never received any education in digital topics [34]. This surprising discrepancy can be explained by the fact that, although most German medical schools report offering such opportunities, they are mostly part of elective or extracurricular courses, with only 2 institutions including a separate subject specifically on AI in the core curriculum. As a result, existing AI curricula are currently only available to a very limited number of students, and large-scale AI education is still lacking. Recent studies consistently highlight knowledge gaps in AI

education from the perspectives of both international medical students [31,35-37] and German medical students [31,34,38-41]. Students displayed low familiarity with AI and limited awareness of its potential applications in health care; they also reported limited or uncertain access to AI education in medical training. However, they believed AI training would be beneficial and showed great interest in working with it. Results differed regarding attitudes. Although Alkhaaldi et al [36], Moldt et al [42], and Laupichler et al [31] found students to be more optimistic and accepting about AI applications, in Boillat et al's [37] survey there was more skepticism among students regarding the potential harm of AI for patients and job safety within the medical profession.

Despite the increasing number of medical schools that include AI-related teaching according to recent literature, current medical curricula struggle to meet the demands of students to equip them with a strong competency base to interact with, integrate, and critically evaluate AI tools in their clinical practice. Integrating education on core AI competencies into the general curriculum on a broader scale could significantly improve students' experience levels with AI, enhance their attitudes toward the technology, and better prepare them to navigate medical AI effectively in clinical practice.

The objective of this paper is twofold. The first part introduces the concept of a novel, multisession elective course, "Medicine in the Digital Age," which integrates AI teaching in the context of digital transformation into the medical curriculum at a German university. The second part presents findings from a qualitative interview evaluation of participants' feedback on the AI module as well as their overall experience of the elective. Our aim was to conduct an explorative prospective study using a semistructured qualitative interview approach to generate a multidimensional insight into students' knowledge, skills, and attitudes in dealing with AI in medical practice and their overall learning experience. For this, we asked students to comment on the following a priori deductive dimensions of interest: "Areas of AI Application," "Future Work," and "Critical Reflection." The interview findings supported the iterative refinement of our teaching concept, as well as the ongoing educational reform processes.

Methods

Ethical Considerations

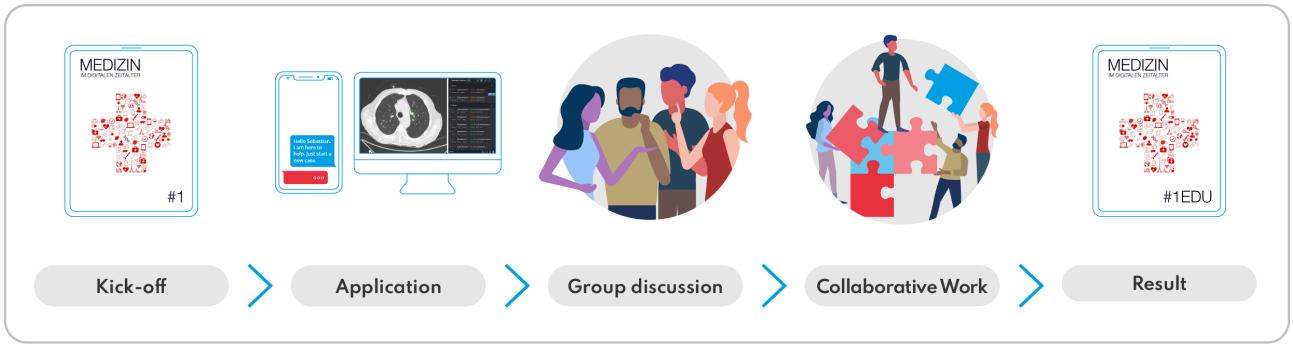
The local ethics committee was consulted during the development of the teaching evaluation for the curriculum presented. Following the consultation, the committee confirmed that the teaching evaluation constituted an additional quality assurance measure for teaching and curriculum development. This evaluation complements the existing concept for quality assurance at the Mainz University Medical Centre [43]. In accordance with the committee's recommendations, it was determined that an ethics vote was not considered necessary. However, participation in the evaluation required informed written consent from all students involved and was strictly voluntary. No compensation was provided to participants. To ensure confidentiality, all responses were pseudonymized prior to analysis.

Structure and Rationale Behind the Module on AI

The teaching module "Artificial Intelligence" is part of the competency-based multisession elective course entitled "Medicine in the Digital Age." The overall course aim is to equip students with digital skills that can be applied in a medically sound, technically feasible, legally compliant, data protection–compliant and ethically responsible manner and thus prepare them for the working environments of the future [2]. It was the first curriculum of its kind in Germany [1].

The "Medicine in the Digital Age" course consists of 5 modules: AI; digital doctor-patient communication; digital health applications and smart devices; telemedicine; and virtual/augmented reality and robotics. The course is offered to medical students in their clinical years as a 5-day elective, with each module comprising an 8-hour face-to-face course day. The didactic concept follows a flipped classroom and blended learning format by combining e-learning (e-book), face-to-face teaching (hands-on workshops, practical exercises, discussion and reflection formats), coproduction, and transfer projects (Figure 1). The different formats alternate over the course and build on each other.

Figure 1. Didactic concept consisting of e-learning, workshops, discussion/reflection formats, and transfer. The results of the learning process are incorporated into the e-learning e-book.



Using an interactive e-book, the participants deal with topics of digital transformation in the preliminary stages of the course. The e-book was created by our working group consisting of experts from medicine, medical education, ethics, media education, data science, and data protection, and also included patient perspectives. Its content mirrors the program of the elective course and contains a dedicated chapter for each module, combining theoretical background, reflective articles,

and stakeholder or patient interviews. Students are expected to read the corresponding chapter in preparation for each course day to independently develop the basics of digital medicine. The entire e-book follows the collaborative concept of "Do it by the book, but be the author" [44]. By incorporating all student transfer projects into an iterative version of the e-book, students are encouraged to actively interact with the course and become the "authors" of their elective course's e-book after completion of the elective.

The thematic breadth and interconnectedness of medical specialties necessitates an interdisciplinary team of lecturers. Therefore, onsite teaching is carried out by various medical disciplines (anesthetists, surgeons, medical informaticians, psychologists, pediatricians, psychosomatics, radiologists, orthopedic and trauma surgeons). In addition, computer scientists, representatives of federal state data protection and medical ethics, and patients complement the team of lecturers in the spirit of a transdisciplinary approach.

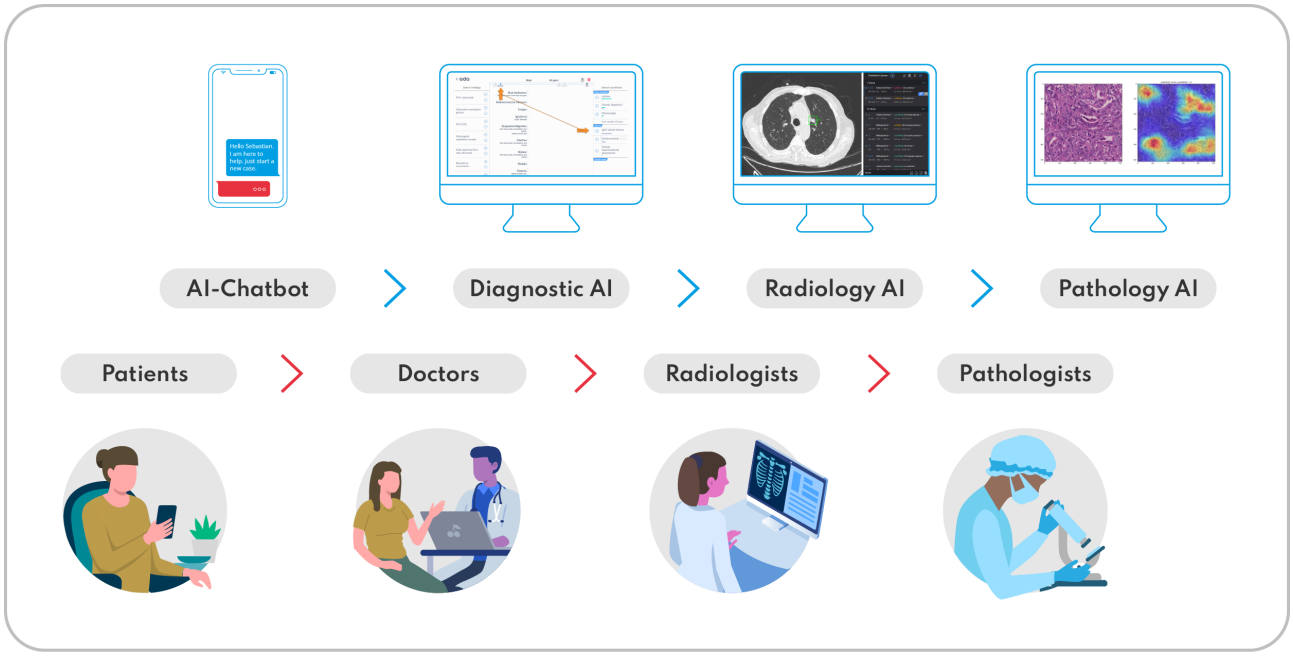
For the AI module, e-learning combined with face-to-face teaching and transfer tasks results in a total of 20 hours of teaching on AI. In accordance with the KSAVE model (Knowledge, Skills, Attitudes, Values, and Ethics) [45,46], the AI module aims at teaching the following overarching competences:

1. The student can describe various areas of application and programs that work with AI and is able to categorize clinical AI assistance systems in medical treatment in an evidence-based manner.
2. The student is able to explain examples of AI-assisted anamnesis, clinical examination, diagnosis, and therapy.
3. The student is able to name limitations of AI applications in current clinical practice and to evaluate the use and benefits of AI within the complex interplay of technical, legal, and ethical principles as well as under sociopolitical framework conditions and to place them in a medical context.
4. The student is able to reflect on how roles in the medical profession will change or evolve in the light of integrated AI assistance systems.

To give an example: a student demonstrates competence mastery by reflecting on the integration of AI-based systems into clinical workflows in oncological imaging in radiology, emphasizing their role in improving early identification of curative versus palliative needs and complementing clinical decision-making. They critically evaluate practical applications across anamnesis, diagnosis, and therapy, addressing limitations such as data quality, clinician acceptance, and ethical concerns. Through this analysis, the student links theoretical knowledge to real-world challenges, demonstrating readiness to apply AI to improve patient care and health care processes.

In the onsite teaching of the AI module, the focus is on practical workshops (Figure 2). These are designed to illustrate the integration of AI into medical treatment processes, followed by discussion and reflection sessions to promote the transfer to the students' own actions.

Figure 2. Workshops within the AI curriculum demonstrate hybrid workflows between humans and AI. The human workflow (lower section) is enhanced by the integration of AI-based narrow intelligence (upper section) along the patient care continuum by various medical specialists. AI: artificial intelligence.



Workshop on Medical History/AI Chatbot

To address the relevant technologies (ie, natural language processing, large language models, and chatbots), students are introduced to an AI-based smartphone app (Ada Health), which acts as a chatbot to take a symptom-based clinical history and make a suspected diagnosis [47-49]. Students then take a clinical history in groups of two from one of the lecturers, who takes on the role of a patient based on a predefined case vignette. First, one of the students takes a classic medical history and

formulates a suspected diagnosis. Thereafter, the second student obtains a medical history of the same patient case by reading out the chatbot's questions. Subsequently, the independently formulated suspected diagnoses are compared with the suspected diagnoses of the chatbot in the entire group. The students discuss which anamnesis questions and diagnoses they did not consider, and which questions and diagnoses the chatbot did not list. The usefulness of the different suspected diagnoses is then discussed and differences in the clinical histories are explored to determine the advantages and disadvantages of each method.

Workshop on Radiology/AI-Supported Radiology

Together with a radiologist, students learn how digitalization is changing the way radiologists work (eg, Picture Archiving and Communication System, radiology information system, speech recognition). Radiological AI applications are demonstrated as examples. Specifically, an AI for the automatic detection of tumor-specific lung foci is demonstrated. The software (InferVision, InferRead CT Lung) provides the user with the size and localization of the lesion as well as an estimate of the malignancy as a percentage. Additionally, an AI application for the automatic diagnosis of conventional X-ray examinations of the thorax is presented (Oxipit, ChestEye). The students learn that a number of published papers have already shown that various AI applications are equivalent to radiologists in individual subtasks [6].

Workshop on Pathology/AI-Supported Pathology

Students are introduced to the influence of digitalization on the field of pathology. For this purpose, a pathologist demonstrates the use of AI as a supporting tool in the diagnosis and detection of malignant changes in histopathological tissue sections [16]. Both the technical and informative background, as well as the process of developing and scientifically evaluating an AI application (AI development life cycle) and its practical application (integration into patient care), are illustrated. Students learn more about the future potential of AI in pathology and can ask questions and contribute their own thoughts.

Discussion and Reflection Formats

For reflection, students and lecturers discuss the following questions together in fishbowl discussions:

- What are the opportunities and risks of using AI in the context of patient treatment?
- How do we deal with probabilities calculated by an AI?
- What will your day-to-day work look like in 2025?
- What new skills will you need in the future?

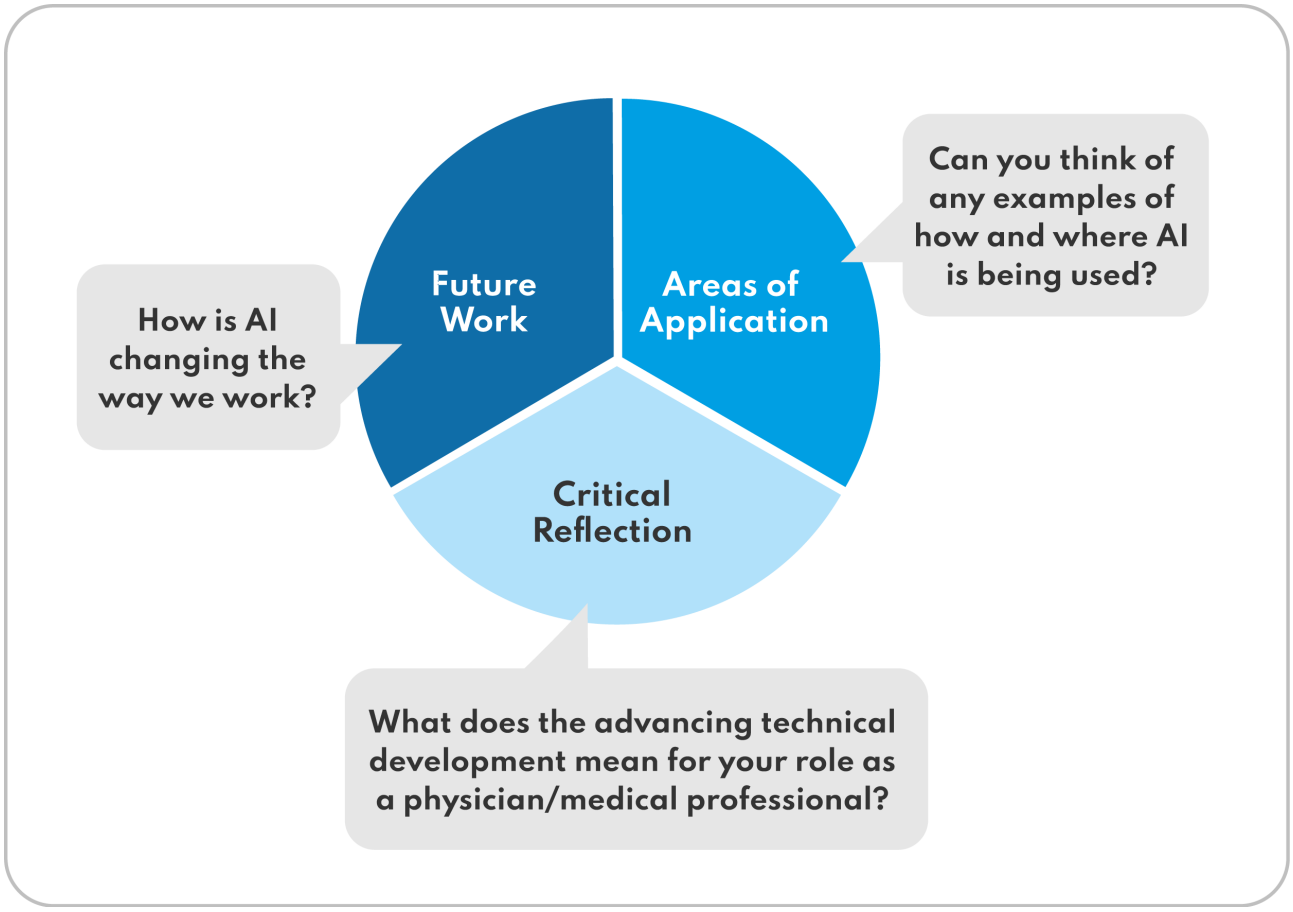
Transfer Projects

Throughout the course, students work in self-selected small groups (groups of 4) on the overarching task of researching a useful medical AI application and presenting it in plenary on the last day of the course. The group presentations are followed by 15-minute discussion rounds with the plenum. The transfer projects students chose reflect the wide range of AI in terms of technology (language, imaging, data procession), medical use cases (conservative medicine, surgical medicine), and different age groups (from AI solutions for pediatrics to palliative care). In addition to their research, part of students' transfer performances also lies in critically analyzing and presenting their various solutions. Among others, students addressed topics such as an AI-supported ultrasound image navigation for regional anesthesia [50], an AI algorithm supporting clinicians in sepsis management [13], or an AI algorithm predicting the end of life developed by Stanford University [51].

Evaluation

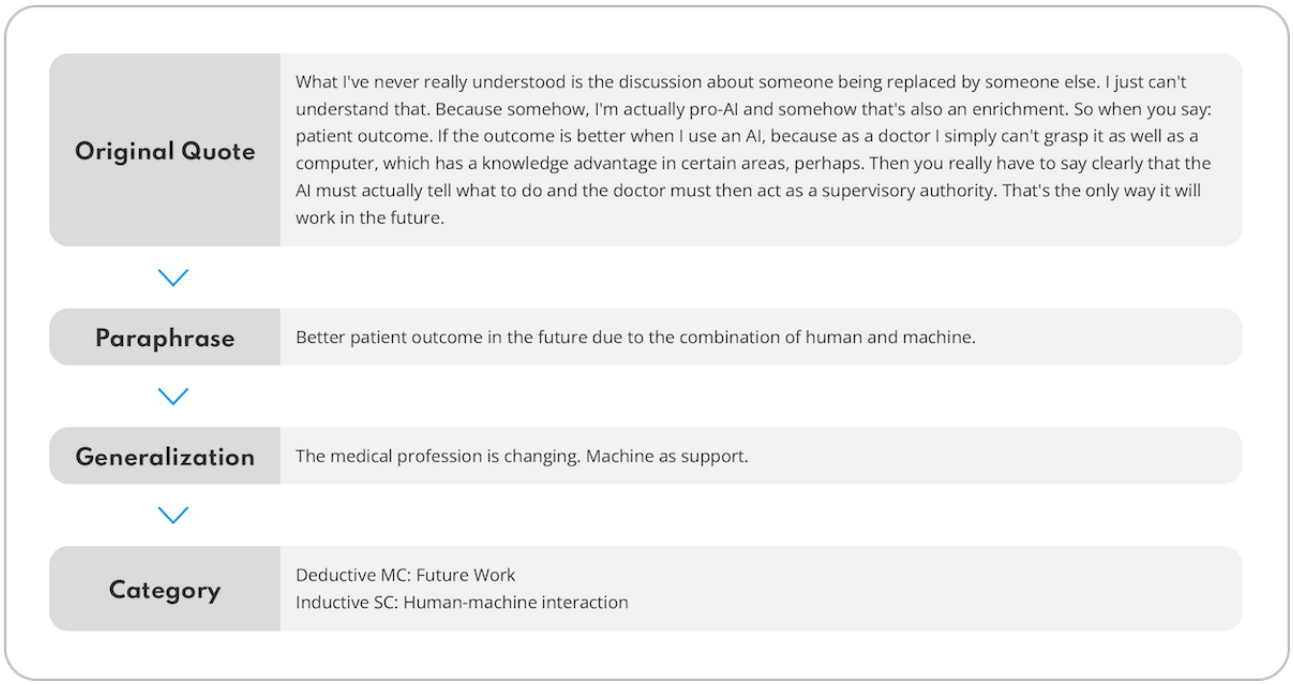
The elective course on Medicine in the Digital Age including the presented AI module was introduced to the medical curriculum at the University Medical Centre of the Johannes Gutenberg-University Mainz. The evaluation of the 3 groups consisting of medical students in their second and third clinical year (ie, years 4 and 5 of the 6-year medical program) was carried out using semistructured, focused, guided group interviews consisting of open and targeted questions based on Merton, Fiske, and Kendall [52,53]. The interview questions were formulated based on the KSAVE model. The interview guide aimed to ascertain the participants' existing competencies in the areas of knowledge, skills, and attitudes in dealing with AI in physicians' practice. This theoretical background resulted in 3 main interview topics: "Areas of Application," "Future Work," and "Critical Reflection" (Figure 3). Additionally, the last section of the interview addressed students' overall assessment of the course. The interview guide was used to evaluate the entire course and is provided in the appendix (Multimedia Appendix 1).

Figure 3. Outline of the main points of the interview guide questions on AI (circle) including guide questions (boxes outside). AI: artificial intelligence.



The focus group interviews took place within 2 weeks of the comprehensive course. Participants were informed about recording, transcription, data usage, storage, and privacy, and consent was obtained beforehand. The interviews were conducted and recorded by a researcher with expertise in qualitative research. The audio files were then transcribed for further analysis by 3 student research assistants (KD, LU, and EK). The interview transcripts were subsequently analyzed using content-structuring qualitative content analysis according to Mayring [54]. This is a text analysis method that follows a logical, systematic pattern and aims at transferring raw text data into structured categories (Figure 4). Categories can be formed deductively based on previous knowledge or hypotheses, or inductively based on new, text-immanent findings. For a structured evaluation of the results, the categories formed in the category system were organized hierarchically into main categories (MCs) and subcategories (SCs). The MCs were deductively derived from the research questions prior to the survey phase. During the analysis process, additional inductive SCs were formed from the interview statements. Inductive coding was used and codings were discussed and agreed upon by the coding research assistants. Saturation was achieved by interviewing all participants and subsequently coding all interview material.

Figure 4. Process of category development through the continuous comparison of the content of the deductive categories with the compiled material. Through the steps of paraphrasing, generalization, and reduction of the content-structuring content analysis, additional inductive categories can be developed, and the statements can then be assigned to an explicit category. MC: main category; SC: subcategory.



The Results section presents the parts of the overall evaluation results that explicitly relate to the AI module and the overall course assessment.

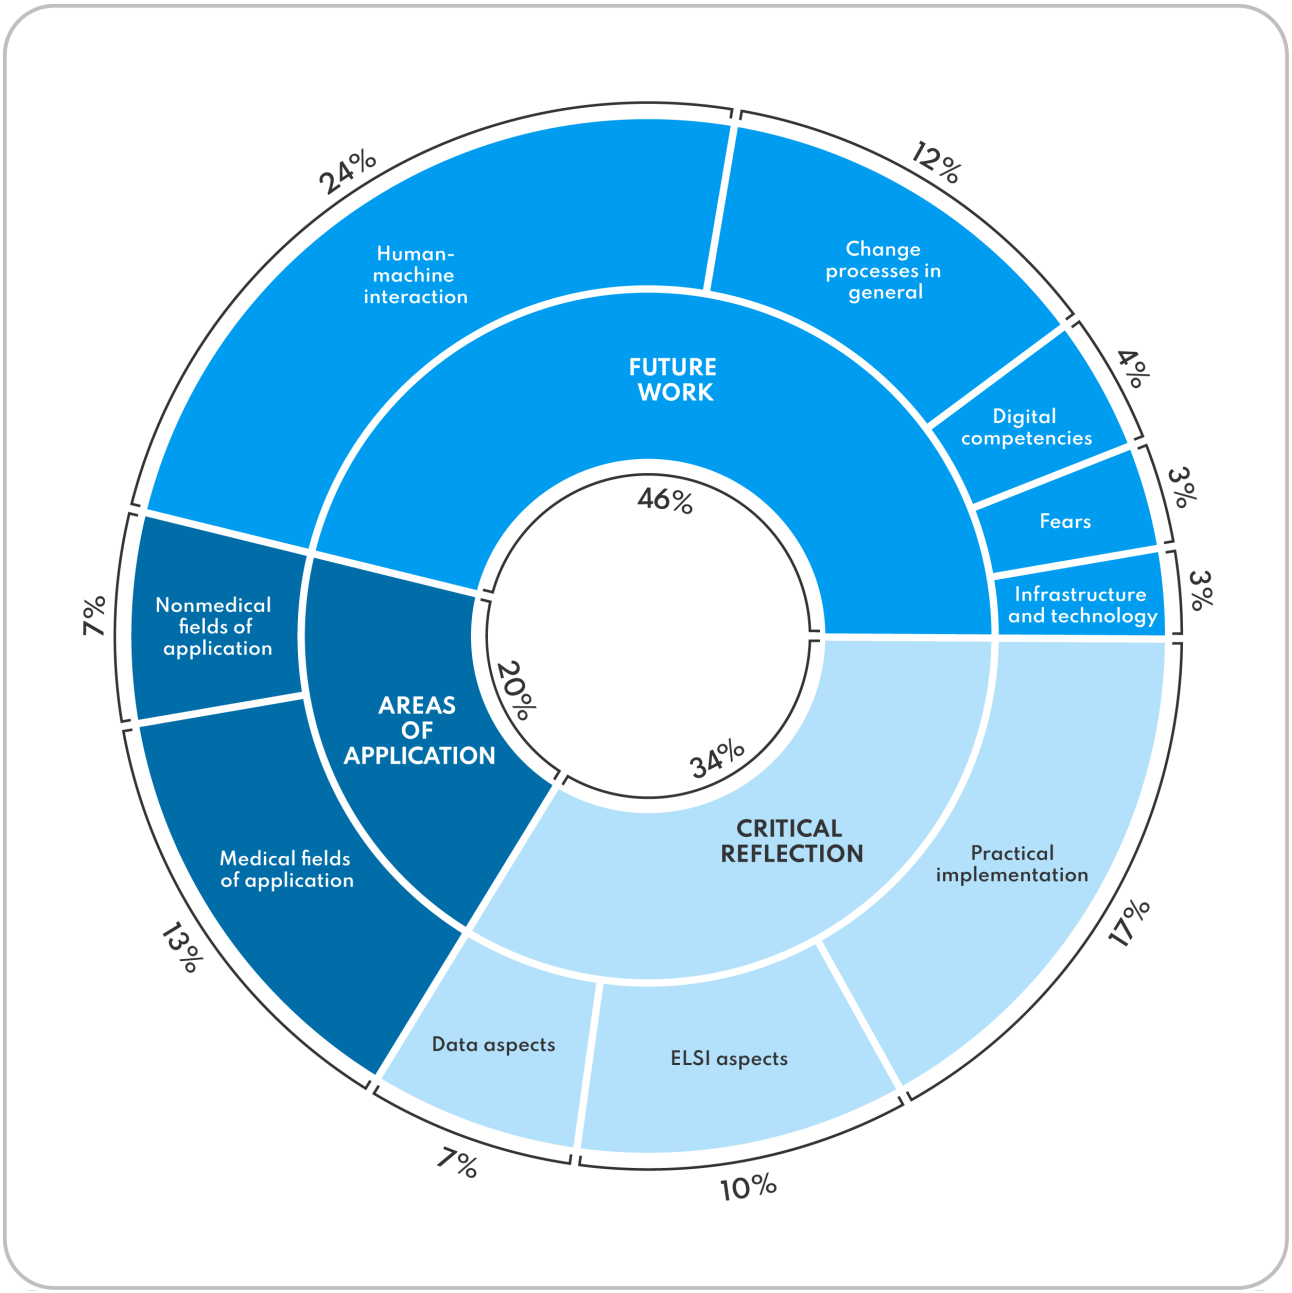
Results

Evaluation Outcomes

From 3 group cycles, 18 semistructured, focused, guided interviews were conducted with all 35 participants (female=11, male=24) from the 3 consecutive courses, which formed the basis for the qualitative evaluation of the course concept. The interviews lasted 24:36 minutes on average. In all interviews, a total of 214 statements were made that could be assigned to the area of “Artificial Intelligence” and 610 statements related to “Overall Course Assessment.”

Following the analysis steps outlined above, the 3 deductive MCs related to AI—“Areas of Application,” “Future Work,” and “Critical Reflection”—were assigned further concrete inductive SCs derived from the content of the text during the evaluation process (Figure 5). Statements in the MC “Overall Course Assessment” were divided into the 6 SCs “Learning Experience,” “Learning Success,” “Structure,” “Content,” “Methods,” and “Conclusion.” For quality assurance purposes, the results report was written in accordance with the Consolidated Criteria for Reporting Qualitative Research (COREQ) checklist [55]. The following section details the qualitative results for each main category. Anchor quotes support the result report for each category. For this, quotes were translated into English by the authors and minor changes were made to improve readability. An extensive overview of anchor quotes for all SCs is provided in the appendix (Multimedia Appendix 2). Identification codes in parentheses accompany each quote to allow allocation to individual participants (the ID code reads as follows: course run:interview number:speaker ID).

Figure 5. Graphical depiction of the qualitative research results on the AI teaching module broken down into main and subcategories, based on 214 coding units (student statements). Percentages are relative to the overall sample of 214 statements on AI. All percentages are rounded. AI: artificial intelligence; ELSI: Ethical, Legal, and Social Implications.



Main Category "Areas of Application"

This category investigated students' knowledge about the existence of different AI applications in health care and beyond and their attitudes toward them after completing the elective course. A total of 20% (43/214) of all statements on AI fall into the category "Areas of Application." Of these, 29 fall into the SC "Medical fields of application" and 14 into the SC "Nonmedical fields of application."

For the SC "Medical fields of application," students listed a variety of medical use cases. The topics that were covered in the course dominated, namely diagnosis in general as well as image diagnosis in radiology, pathology, and dermatology.

> *During the week, for example, I learnt that the radiologists can have the lung round foci assessed by AI during the CT scan. With different probabilities. […] Then we learned in the pathology department that in the future AI will also calculate […] how high the probability is whether it is a tumor or not. Or […] this dermatology AI, which can show whether it's a melanoma or a benign mole. […] So I've definitely learnt a lot, I could go on listing all the examples.* [3:6:F]

In terms of diagnosis, participants rated the use of AI in triage and preliminary anamnesis in the outpatient sector as useful. This could reduce waiting times and counteract missing information. Regarding image diagnosis, the students refer to AI as a "safety net" backing up their own findings with a digital second opinion.

Interviewees expressed disbelief about the status quo on several levels. They discussed the limited usage of AI applications in everyday clinical practice and their own lack of knowledge before attending the course. They identified a general absence of curriculum focused on AI in medicine within their own course of study. Overall, students were surprised by the variety of possible applications, as well as by the rapidly increasing number of market-ready AI medical products. They expressed great interest in the use of AI in their medical practice and see the meaningful and context-specific application of AI as an urgent task of the present.

For the SC "Nonmedical fields of application," at the nonmedical level, students mentioned various possible or already existing application scenarios for AI, some of which have been adopted into everyday life without reflection (eg, voice assistants, navigation, purchase recommendations). The most attention was paid to autonomous driving and transportation.

Main Category "Future Work"

A total of 46% (99/214) of all statements on AI fall into the category "Future Work." Of these, 51 fall into the SC "Human-machine interaction," 26 into the SC "Change process in general," 9 into the SC "Digital competencies," 7 into the SC "Fears" and 6 into the SC "Infrastructure and technology."

For the SC "Human-machine interaction," students focus on the question of how AI can contribute to becoming a better doctor. The students state that they thought intensively about the combination of humans and machines during the course week and consider this combination to be the optimum for the future practice of medicine.

> *Just like the chess player and the computer together (Centaur Chess computer), they are unbeatable. […] and hopefully it will be the same with the doctor [and AI].* [2:1:3]

"Shared decision making" and digital second opinions can counteract incorrect treatment or improve treatment outcomes in the sense of assistive systems and thus increase patient safety. The students describe their experiences with the anamnesis chatbot and characterize the comparison of the two forms of anamnesis as very informative. The differences between the chatbot anamnesis and their own anamnesis practice were thus revealed. Emphasis was placed on the aspect of social anamnesis, which the students carried out more intensively than the chatbot. However, the students rated the chatbot's anamnesis procedure as more structured and systematic than their own. Students predominantly regard AI as an opportunity.

For the SC "Change processes in general," students did not consider the medical profession to be threatened by the use of AI, but the practice of the profession and the subdivision of specialties may change. Students stated that the rapid increase in knowledge means that doctors are even more obliged than before to undergo continuous further training. The preinformed patient will become more of a discussion partner at eye level. The interviewees see this as a great opportunity to improve the doctor-patient relationship, as the inclusion of AI in routine medical procedures could lead to an increase in personnel and time resources, allowing doctors to focus on the traditional core medical activities of consultation, treatment, and care.

For the SC "Digital competencies," the competency profile and requirements for the medical profession are also changing as a result of the transformation. Here, the interviewees speak of a lack of or inadequately trained digital skills, which are also not considered in the standard curriculum. Students would like a safe framework for trying out new technology. Furthermore, the use of AI in everyday medical work requires clear quality criteria that are similar to a review process for evaluating technologies. The ability to correctly classify AI-generated information and to critically question the statements made by the AI is regarded as particularly relevant. According to the students, it is and remains the task of the doctor to assess which application is appropriate for the individual patient and when treating physicians need to actively decide against its use.

> *Where does the AI get the data from? How is it analyzed? And above all, how is it checked to make sure it really is a sensible AI? You need to know that. In a way just like we learn how to read scientific publications. And decide whether they are good or bad.* [2:1:3]

For the SC "Fears," the biggest problem addressed is general ignorance and the resulting fear of, for example, the threat of job losses. Students suspected that this fear is the reason why AI applications are often not developed by health care experts, but by fast-moving commercial companies. Students also considered the combination of human and machine to be problematic if it is not possible for the doctor to understand how the AI operates and reaches decisions.

For the SC "Infrastructure and technology," the students note that the technical change in everyday working life is particularly noticeable through deficits in (technical) equipment.

Main Category "Critical Reflection"

A total of 34% (72/214) of all statements on AI fall into the category "Critical Reflection." Of those, 36 fall into the SC "Practical implementation," 22 into the SC "ELSI aspects" (Ethical, Legal, Social Implications), and 14 into the SC "Data aspects."

For the SC "Practical implementation," students see opportunities for larger-scale, international cooperation. This requires openness and investment in progress and research. They take their practical experience from the "clinical anamnesis" workshop as an example of low-threshold contact, which they want to take out of the course to raise awareness. The limitations of the chatbot, for example, making a misdiagnosis, are critically questioned. In such cases, the intended time saving backfires and becomes extra work.

> *That would unsettle me […] if something completely different comes out as a treatment suggestion or what I see in an MRI image or something like that, then it would make me very insecure and then I would want to make sure. Be it through the senior physician or that I can just have a look: How does this AI come up with this? And if that doesn't work, then it's*

> *unfavorable for the procedure. Then you have to rely on the senior consultant again and maybe the head physician […] and then I'm back where I was before without AI.* [2:1:3]

One problem discussed is that current AIs can only act as "narrow intelligence" in very specific settings, meaning that anomalies that do not correspond to the AI's specific field of action remain undetected. This results in the risk of unconsidered use. In general, all interviewees share the opinion that not everything that is technically possible should also be used in practice and that each use case must be considered individually.

For the SC "ELSI aspects," the question of whether increasing digitalization will reduce or intensify doctor-patient contact is viewed critically. On the one hand, digitalization represents an opportunity to relieve doctors and invest the freed-up capacities in the doctor-patient relationship. On the other hand, there is a risk that AI will impact the interpersonal interaction and thus the patient's individuality.

The possibility of consciously influencing AI is the subject of intense ethical debate. Specifically, it is questioned at what point it is unethical not to use the advancing technology, as this would deliberately deny the patient the best possible treatment.

> *At some point it becomes unethical not to use such things. […] That's actually the point. Why are we always so afraid that we're not important enough? At some point, the doctor is no longer the all-knowing person.* [2:3:1]

The interviewees see a further ethical dilemma in the case of a discrepancy between the diagnosis provided by the doctor and the AI. The right not to know and the handling of probabilities play a decisive role in sensitive areas, such as prenatal or genetic diagnostics and palliative medicine. Students also discussed the unclear legal situation regarding liability issues as a possible cause of rejection of AI applications.

For the SC "Data aspects," regarding data protection, too little regulation violates personal rights. Too much regulation makes it difficult or, in the worst case, prevents access to data for clinical research. In general, students also question the lack of traceability of AI results. They critically note that convenience or lack of time can lead to the results not being checked over time.

Main Category "Overall Course Assessment"

Of all 610 "Overall Course Assessment" statements, 134 fell into the SC "Learning Experience" and 108 into the SC "Learning Success." The remaining statements were categorized into the SCs "Structure" (n=61), "Content" (n=126), "Methods" (n=142), and "Conclusion" (n=39).

For the SCs "Learning Experience" and "Learning Success," students highlighted engaging with AI and digitalization as a significant learning success, given the absence of such topics in the standard curriculum.

> *I'm just glad that I had this week, because it really showed me what we don't learn at university. And how big the topic actually is for us.* [2:2:2]

They described the hands-on interaction with various technologies as "eye-opening" (2:2:4) and the group work on human-AI comparisons as "impressive" (2:1:4). Many students, initially skeptical or ambivalent about AI, reported increased knowledge and awareness of AI technologies and a deeper understanding of their impact as a result of the elective. They felt better prepared for their future careers regarding questioning and categorizing digital tools such as apps or AI, and underlined the gain in competences:

> *I think everyone left with a gain in expertise. Be it in the form of medical expertise, technical expertise, or simply that you've thought about things like data protection and apps and so you've also gained absolute everyday expertise.* [1:3:B1]

For the SCs "Structure," "Content," and "Methods," students appreciated the involvement of diverse experts, valuing the variety of perspectives on the technology.

> *What was outstanding […] was that the input came from the legal side, from the ethical side, from the technical side somehow every time.* [3:8:A]

They praised the active and innovative learning format of the elective, noting that it encouraged reflection and engagement rather than the rote learning typical of other subjects.

> *It's often the case that you're told things and then you have to memorize them. And here it was more the case that you were given information but then had to think about it yourself, for example to discuss it or draw a picture or whatever. And that's a completely different kind of learning, which unfortunately we don't usually do that much of in our degree programs. So I thought it was really good. Because these are actually skills that you should have and not that you can somehow memorize a book.* [2:1:3]

The discussion formats were highlighted as a distinctive feature in comparison with previous teaching experiences, with critical reflection helping students develop a more nuanced understanding of the topic.

> *I think you learnt an incredible amount, especially in the discussions, and you were actually forced to really think about certain theses. I also found this kind of discussion extremely productive.* [2:2:4]

For the SC "Conclusion," students almost unanimously agreed that the elective had broadened their horizons and appreciated the opportunity to participate. They wished that the course would be expanded so that more students could participate. Some expressed a wish for more breaks or even longer discussion sessions. Although students felt that the scope and time commitment of the elective was appropriate, many would have liked it to last longer:

> *"I think the biggest minus is actually the time. It's rare that you leave a course saying: 'Hey, I wish I'd stayed longer.' But […] Tuesday and Wednesday were actually days when I thought: 'Okay. I could have stayed two hours longer'.* [2:2:5]

In summary, the qualitative evaluation showed a high level of acceptance of the course concept and differentiated attitude toward AI among students. The course participants emphasized the increase in their knowledge and competences about the technology as well as the appreciation they felt as a result of the intensive and varied collaboration with each other and with the lecturers. The opportunity for critical discussion, practical interaction, and application was rated particularly positively. All 35 students stated that they would recommend the elective course to peers.

Discussion

Principal Findings

The digitalization of medicine and the use of AI applications is a fundamental process of change that will have a major impact on the future job profile of doctors to an extent that cannot yet be foreseen. What is certain, however, is that we are transitioning from the "information age" to the "age of artificial intelligence" [26] and that the integration of AI into medical treatment processes will redefine human-machine interaction. It is therefore essential to prepare future doctors to use AI in daily practice [27]. At present, although curricula are beginning to change, structured teaching concepts are lacking in terms of curricular mapping, although educators and practitioners emphasize the need to impart such competencies both nationally and internationally. Most students also advocate for AI education in their studies and report limited or no exposure to AI technologies and learning resources [35-37,41]. This does not mean that students must be able to program themselves but they must learn the practical application of AI in line with ELSI principles, data science, biostatistics, and evidence-based medicine during their studies [30,56].

The qualitative results of the AI module show that the embedding of curricular teaching about AI is generally feasible and sensible, that the added value of such a teaching module is recognized by students and acknowledged with great interest and acceptance, and that it leads to an increase in competence among students and promotes a critical and reflective attitude toward new technologies. Regarding the core aspects reflected in the main categories of the analysis (Areas of Application, Future Work, Critical Reflection), several key points can be learned, as detailed in the following sections.

Areas of Application

At present, it is not sufficiently clear how and when AI should be used in clinical diagnostics and therapy. Regarding the "how," students demonstrate a forward-thinking and nuanced examination to potential AI applications in clinical settings.

With regard to the "when," clarification is needed on the specific areas and questions where AI can assist in the clinical workflow [30,57]. Here, students express ambivalence about its integration, acknowledging both benefits and risks.

Future Work

Regarding patient care, students highlighted AI's potential to enhance care through personalized application and resource optimization, aligning with its reported ability to save time and personnel resources amid health care resource scarcity [58]. Students expressed some apprehension about the future impact of AI on the medical profession, though concerns about career choices were less prominent. This aligns with a survey in which 83% of medical students disagreed that AI would render radiologists obsolete [41]. Nonetheless, a minority of participants expressed fears about career prospects. Although AI's full impact remains unpredictable, it is undeniable that medical professions will change. Wartmann and Combs [26] speak of a "reboot" of the health care system and postulate the need to skillfully manage the interface between medicine and machines, as AI will surpass human capabilities in certain tasks [26]. Reflecting this, students stressed the importance of human-machine interaction and corresponding digital skills.

Critical Reflection

Most students underlined the potential of AI for their future career while maintaining a critical perspective, avoiding blind enthusiasm. They emphasized the risk of AI manipulation and its consequences for patient care, underscoring the need for doctors to retain ultimate decision-making authority over AI recommendations. The evaluation presented here thus indicates students' development of a critical attitude due to the module. These findings underscore the importance of future medical curricula teaching students to integrate AI assistance into their decision-making processes [2].

At the industry and developer level, students also acknowledged the need to design AI applications with ELSI aspects in mind. Such recommendations already exist. For example, the multisociety statement on the ethics of AI in radiology [59] and a white paper from the European Society of Radiology outline key ethical and practical considerations for the responsible use of AI in clinical practice [60].

In summary, students acknowledged the evolving nature of AI in health care as well as the necessity for skillful management of the interface between medicine and AI. They emphasized the importance of human-machine interaction as well as the need to develop digital skills while maintaining a reflective mindset toward technology.

Implications

Current literature on medical students' evaluation of their AI competencies demonstrates a relevant knowledge gap and the need for rapid-employment curricula solutions to change this. Overall, both the Medicine in the Digital Age elective as well as its AI teaching module were demonstrated to be feasible and reasonable teaching concepts, which supported maintaining the blended learning approach and the basic content of the modules. Nevertheless, valuable insights for iteration were drawn from the evaluation. First, the course has been updated to reflect technological and regulatory developments, such as the AI Act. Second, insights from students' transfer projects and reflective discussions informed an "agility by design" [61] approach, incorporating noteworthy projects or themes identified through students' input into the subsequent course iterations.

With the didactic framework, course design, and content outlined, this teaching concept can serve as a transferable model for implementation and adaptation in other universities or

training settings. Adjustments may be required to address specific target groups or local circumstances.

Evaluating the AI module's learning objectives—knowledge, skills, and reflection—is critical in both simulated (eg, Observed Structured Clinical Examination exams) and real-world settings. Complex educative interventions like this require robust assessment of efficacy and sustainability. Future research should explore whether a single elective suffices, if refresher courses are needed, or if phased AI education is beneficial. To validate this teaching course, prospective longitudinal trials comparing students who attended the AI module and untrained students are essential.

Methodological Strengths

The "Medicine in the Digital Age" curriculum described here addresses the digital transformation of medicine in an interdisciplinary and interactive way for medical students. AI is one of the 5 teaching modules and the rapid development and adoption of AI technologies in health care requires students and professionals to familiarize themselves with it and develop an attitude toward it. Standard quantitative methods can only inadequately depict the development of a professional attitude. The potential of the qualitative methodology used in teaching research should therefore be emphasized. Qualitative approaches provide insights into the learners' assessment of individual learning success, including gains in the areas of knowledge, skills, and attitude, as well as the content design and methodological structure. They are therefore ideal for the iterative further development of teaching concepts and the evaluation of attitude-oriented teaching content. The application of qualitative methodology represents a distinctive strength and unique contribution of this study. Although most research on medical students' perceptions relies on quantitative questionnaire surveys, this study uses qualitative survey instruments. The 2 existing qualitative studies in Germany are limited by their focus on analyzing free-text survey responses [34] and by their narrow scope, specifically examining students' attitudes toward mental health chatbots [42]. To the best of our knowledge, this study is the first to offer comprehensive, in-depth qualitative insights into German medical students' perceptions and attitudes toward AI.

Limitations

A common limiting factor in qualitative research is the small sample size. Helfferich [62] cites a sample size of between 6 and 120 respondents as appropriate. This means that our sample of 35 students can be assumed to have sufficient result validity. A second limitation could be that the results present a retrospective evaluation. Incorporating a qualitative pre-post analysis might have drawn a more concise picture of students' changes in knowledge, attitudes, and reflection on AI as a result of the course. Third, the findings might not be generalizable to other medical training programs, student attitudes, countries, or demographics. Lastly, group dynamics in the focus groups might have influenced the outcome by introducing social desirability bias.

Conclusions

Digitalization will continue to fundamentally change medicine. Therefore, in line with international appeals, today's education and training curricula must teach students and practicing physicians the basic competencies for using digital tools such as AI applications. It is not enough to simply integrate context-specific AI solutions as teaching examples into existing curricula. The aim of future curricula must be to equip students with the key competencies for their future day-to-day work in the age of AI and enable them to internalize knowledge, skills, and attitudes toward these tools from the beginning of their training. As an outlook for the AI curriculum presented here, it can be said that it addresses this need in a unique way. The qualitative teaching evaluation showed that students were able to deal with the topic in a very differentiated way after the AI teaching unit. The transferability of the curriculum to other university locations can be assumed in principle. The curriculum could therefore serve as an exemplary teaching concept for other universities and contribute to training medical students in two future-oriented skills: AI literacy and its transfer to medical human-machine interaction.

Acknowledgments

Above all, the authors would like to thank all participants of this study for their valuable insights. Furthermore, they would like to thank Björn Hirte for his great support in designing the illustrations in this paper. Open Access funding was provided by the Open Access Publishing Fund of Philipps-Universität Marburg.

Authors' Contributions

All authors were responsible for drafting, conceptualization, methodology, validation, and visualization. KD was responsible for interview curation and analysis. SK was responsible for funding acquisition, project administration, resources, software, and supervision. SK, FJ, KD, and ZSO were responsible for curricular development. DT supported the methodology portion through his expertise as a medical educator. KD, ZSO, and SK wrote the original draft. ZSO edited and finalized the initial draft. All authors reviewed and edited the manuscript.

Conflicts of Interest

SK is the founder and a shareholder of MED.digital. All other authors declare no conflicts of interest.

Abstract

Background: Programmatic assessment supports flexible learning and individual progression but challenges educators to develop frequent assessments reflecting different competencies. The continuous creation of large volumes of assessment items, in a consistent format and comparatively restricted time, is laborious. The application of technological innovations, including artificial intelligence (AI), has been tried to address this challenge. A major concern raised is the validity of the information produced by AI tools, and if not properly verified, it can produce inaccurate and therefore inappropriate assessments.

Objective: This study was designed to examine the content validity and consistency of different AI chatbots in creating single best answer (SBA) questions, a refined format of multiple choice questions better suited to assess higher levels of knowledge, for undergraduate medical students.

Methods: This study followed 3 steps. First, 3 researchers used a unified prompt script to generate 10 SBA questions across 4 chatbot platforms. Second, assessors evaluated the chatbot outputs for consistency by identifying similarities and differences between users and across chatbots. With 3 assessors and 10 learning objectives, the maximum possible score for any individual chatbot was 30. Third, 7 assessors internally moderated the questions using a rating scale developed by the research team to evaluate scientific accuracy and educational quality.

Results: In response to the prompts, all chatbots generated 10 questions each, except Bing, which failed to respond to 1 prompt. ChatGPT-4 exhibited the highest variation in question generation but did not fully satisfy the "cover test." Gemini performed well across most evaluation criteria, except for item balance, and relied heavily on the vignette for answers but showed a preference for one answer option. Bing scored low in most evaluation areas but generated appropriately structured lead-in questions. SBA questions from GPT-3.5, Gemini, and ChatGPT-4 had similar Item Content Validity Index and Scale Level Content Validity Index values, while the Krippendorff alpha coefficient was low (0.016). Bing performed poorly in content clarity, overall validity, and item construction accuracy. A 2-way ANOVA without replication revealed statistically significant differences among chatbots and domains (P<.05). However, the Tukey-Kramer HSD (honestly significant difference) post hoc test showed no significant pairwise differences between individual chatbots, as all comparisons had P values >.05 and overlapping CIs.

Conclusions: AI chatbots can aid the production of questions aligned with learning objectives, and individual chatbots have their own strengths and weaknesses. Nevertheless, all require expert evaluation to ensure their suitability for use. Using AI to generate SBA prompts us to reconsider Bloom's taxonomy of the cognitive domain, which traditionally positions creation as the highest level of cognition.

KEYWORDS

artificial intelligence; assessment; Bing; ChatGPT; Gemini; medical education; single best answer

Introduction

Across disciplines of education, including medical education, programmatic assessment offers flexible learning modalities that pave the road for individual progression. However, it represents a challenge to educators, as they are required to develop frequent assessments that reflect different competencies, thus necessitating the continuous creation of examination content in a comparatively restricted time [1]. For many years, multiple choice questions (MCQs) have been adopted in medical education for assessing knowledge and clinical reasoning skills

in high-stakes undergraduate and postgraduate medical exams. MCQs are reliable, objective, standardized, equitable, and efficient formats for testing large volumes of content in a limited time. A main problem with MCQs is that producing high-quality questions is time-consuming, from drafting the question that includes a clinical vignette or stem, a lead-in question, a correct answer, and distractors to validation of content and detection of potential flaws [1,2]. To tackle this dilemma, the application of many technological innovations, including artificial intelligence (AI), has been tried [3].

AI refers to machines mimicking the human brain in performing intellectual tasks. This originates from the imitation game developed by the British mathematician Alan Turing, who posed the universally famous question "Can machines think?" [4]. Since then, many AI research laboratories have invested time, effort, and money to answer this question. One particular AI research laboratory known as OpenAI, based in California, United States, has revolutionized our world at the end of 2022 by launching an AI-based large language model (LLM) software (GPT-3.5) that uses natural language processing to engage in human-like conversations and making it freely available for the public [5]. Within a few weeks after its release, the OpenAI chatbot, known as ChatGPT, had gained much attention in many fields, including medical education. It became the fastest-growing app of all time with more than 120 million users in just a few months after its launch [6]. This led competitors to develop and launch other chatbots. Microsoft launched Bing Chat AI in February 2023, followed by Google releasing Gemini in March 2023 [7]. A newer, improved version of ChatGPT (ChatGPT Plus), which uses the GPT-4 Turbo language model, has been developed by OpenAI and launched as a paid subscription version by the end of 2023 [6]

In terms of assessment in medical education, ChatGPT has been the most extensively studied chatbot. It was found to be able to quickly and accurately apply known concepts in medicine to novel problems, including reflection prompts and examination questions, and to mimic human writing styles, introducing a potential threat to the validity of traditional forms of medical student assessment including short answer assessment [8], it even successfully passed the USMLE (United States Medical Licensing Examination) [9]. Similarly, ChatGPT-4 was able to achieve a mean of more than 75% in the newly derived undergraduate medical exit examination: UKMLA (United Kingdom Medical Licensing Assessment) [10]. Its application has been described across multiple areas of academic assessment, for example, developing innovative assessments, grading submitted work, and providing feedback [11]. Nevertheless, concerns persist around the validity of the information provided by all AI tools. Sample [12] argued that if the chatbot response is not properly verified, it can be misleading and result in "junk science."

Additionally, the broad availability of LLMs such as ChatGPT, Gemini, and Bing has facilitated extensive comparative studies across various domains. For example, 1 study evaluated these models using case vignettes in physiology and found that ChatGPT-3.5 outperformed Bing and Google Bard (an old version of Gemini), indicating its superior effectiveness in case-based learning [13]. Another study, using the clinicopathological conferences method, compared the ability of AI chatbots to infer neuropathological diagnoses from clinical summaries. The findings revealed that Google Bard and ChatGPT-3.5 correctly diagnosed 76% of cases, while ChatGPT-4 achieved a higher accuracy rate, correctly identifying 84% of cases [14]. Similarly, a comparison of ChatGPT-3.5, Google Bard, and Microsoft Bing in hematology cases highlighted significant performance differences, with ChatGPT achieving the highest accuracy [15].

Recent studies have explored the use of AI in generating MCQs and single best answer (SBA) questions for medical examinations, highlighting its potential applications and limitations. For instance, Zuckerman et al [16] examined ChatGPT's role in assessment writing, while Kıyak et al [17] and Mistry et al [18] investigated AI-generated MCQs in pharmacotherapy and radiology board exams, respectively.

Despite these contributions, the ability of AI to generate valid SBA questions, an assessment format that better evaluates higher-order cognitive skills such as data interpretation, problem-solving, and decision-making [19], remains an area requiring further exploration. Additionally, a critical consideration is the variation in AI-generated outputs and the potential for examination candidates to predict examination items based on curriculum learning objectives (LOBs). Given the significance of these issues, this study aims to examine the content validity and consistency of different chatbots in generating SBAs for undergraduate medical education.

Methods

Study Context

The Graduate Entry Medical Programme at Ulster University's School of Medicine is a 4-year program. Similar to most UK medical schools, students undergo assessment through a series of SBA papers comprising over 1500 questions across the program. Managing this extensive assessment requirement has prompted the exploration of innovative solutions to support the assessment team.

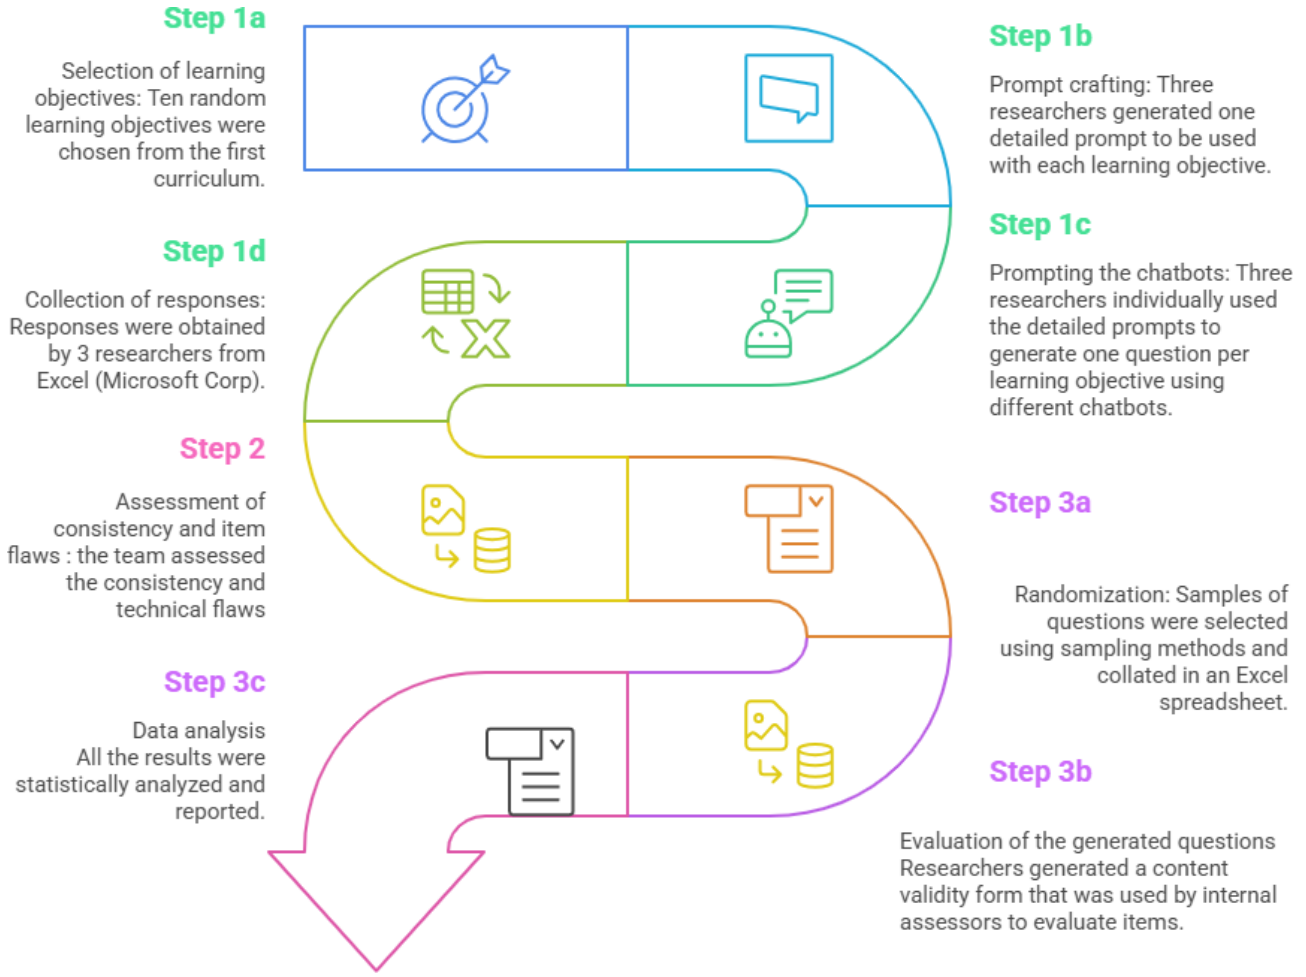
To ensure assessment standards, the school has implemented a rigorous quality assurance process. Questions are first created by designated clinical or academic authors who have been trained and provided with a "house style" to follow. Questions then undergo internal review by other clinical or academic staff before external review by external examiners to ensure they meet rigorous requirements. Post hoc psychometric analysis of question performance is also used to drive evidence-based review and enhancement. This meticulous review process aims to uphold the integrity and effectiveness of assessments used to make high-stakes progression decisions and forms part of a wider suite of quality processes to deliver against the assessment strategy.

Study Design

This exploratory comparative study was conducted between December 2023 and May 2024; we continued to follow the school's established quality assurance process, but the designated first authors of the questions were AI chatbots. This includes 3 versions of AI chatbots: ChatGPT which will be

referred to as ChatGPT-3.5 in this study, Google Gemini, and Microsoft Bing AI, in addition to the subscription-only version of OpenAI: ChatGPT-4 that provides access to GPT-4 Turbo, which is advertised as a more powerful and faster version of GPT-4. During this study, Google changed the name of its platform from Bard to Gemini. For consistency, this paper will refer to the current name: Gemini. Figure 1 depicts the full study design, which included three main phases: (1) Generation of questions using various AI chatbots, (2) Assessment of the consistency of the chatbot outputs, and (3) Evaluation of the quality of the questions generated.

Figure 1. The study design. SBA: single best answer.



Generation of Questions Using Various AI Chatbots

In phase one, the research team randomly selected year 1 curriculum LOBs (n=10) to create SBA questions for. These objectives were selected using stratified random sampling from the official list of LOBs for second-semester educational units. Three researchers were involved, and each one created a new account for each of the 4 chatbot platforms. All researchers used the same predefined prompts (see below) around the same time (end of December 2023) to request 10 questions from each chatbot, one for each LOB. The 10 prompts were entered one by one in the same conversation with each chatbot. All the questions were compiled into a shared Microsoft Excel (Microsoft Corp) spreadsheet for analysis in steps 2 and 3.

To allow a fair comparison, the same prompt was used in each chatbot, which specified SBA features:

- You are a university lecturer in a UK medical school. Generate an MCQ on “the learning objective,” with the following criteria:
  - The question is in a clinical vignette format.
  - The question is designed to assess the knowledge (±clinical judgment) of undergraduate medical students.
  - The question meets the standard for a medical graduate examination.
  - Five choices are allowed for each question.
  - Only 1 correct answer
  - Tag the correct answer.
  - Justify the correct answer.

Assessment of the Consistency and Quality (Item Flaws) of the Chatbot Outputs

In the second phase, researchers involved in the previous step assessed each chatbot’s output consistency and technical flaws. Consistency was evaluated based on the similarity between the outputs generated across the 3 researchers, including any bias in the correct answer allocation (eg, favoring option “A” as the correct answer). Similarity was evaluated based on specific elements of the output and accordingly classified into one of three categories: (1) exact questions: when the outputs contain the same wording, condition, and lead-in question; (2) similar

questions: when the outputs share common elements such as patient characteristics, age, condition, presentation, or lead-in question; (3) different questions: when the outputs do not have any content in common.

Technical item flaws assessed the overall construct and structure of the questions produced by the chatbots using 7 previously published criteria for determining the quality of SBAs [20]. The 7 criteria include judgments on whether the questions: follow the SBA structural format, satisfy the "cover test" rule where the question should be answerable solely from the vignette or stem and lead-in (with the answers "covered"), test the application of knowledge rather than recall isolated facts, have item balance (which ensures a balance in information between the stem, lead-in, and options), tests 1 idea, are dependent on the vignette to reach the correct answer, and have appropriate lead-ins length. The researchers used a defined scale to evaluate how often or to what extent each criterion was met across the 3 researchers' outputs. Each criterion was scored on a scale from 0 to 3 for each of the 10 LOB prompts. In this scale, 0 meant none, 1 meant 1 SBA, 2 meant 2 SBAs, and 3 meant all 3 SBAs, representing the number of questions produced by each chatbot that met the criterion. With 3 assessors and 10 LOBs, the maximum possible score for any individual chatbot was 30.

Assessment of the Content Validity and Accuracy of the Questions Generated

In phase 3, samples of questions generated by the chatbots were distributed to various internal assessors as per our normal quality review process. The questions were selected using stratified random sampling to select 1 of the 3 questions generated by each chatbot for each LOB, yielding a total of 39 questions. Alongside this, a content validation evaluation form, developed by the research team, was used to ensure consistent review between assessors, providing assessors with clear expectations and an understanding of the task. The assessors are faculty members with expertise in the curriculum content. Each question was evaluated by 7 assessors.

Considering published recommendations for content validation [21,22], 20 internal assessors were invited, of which 7 consented to participate. The internal assessors critically reviewed the questions based on several criteria to ensure their quality and alignment with educational objectives. This includes content clarity and validity; accuracy of information, answers, and justification; and educational accuracy. Each of these elements was scored on a Likert scale of 1 to 4 (with 1 representing the lowest level of construct and 4 the highest level of the construct; Multimedia Appendix 1).

Statistical Analysis

Quantitative data was analyzed through scores obtained from the rating scale using IBM SPSS Statistics (version 26; IBM Corp). Subsequently, 2 content validity indexes were computed: the Item Content Validity Index (I-CVI) and the Scale Level Content Validity Index (S-CVI). Percentages and frequencies were calculated for the questions' scores to provide further insights into the data. A 2-way ANOVA without replication was conducted to assess differences in chatbot performance across 6 domains. Post hoc comparisons were performed using the Tukey-Kramer HSD (honestly significant difference) test to identify specific group differences. The average ratings provided by 7 evaluators were used for each chatbot and each criterion. The Krippendorff alpha [23] was used to assess interrater reliability, using the K-Alpha Calculator [24]. A coefficient value of 0.8 is considered satisfactory [23]. However, the low Krippendorff alpha suggested a need for further refinement of the rating scheme or additional training for raters to improve reliability.

Ethical Considerations

Participants were informed that their responses would be anonymized and that they could withdraw from this study at any point without penalty. Informed consent was obtained from all participants before data collection. Only those who provided explicit consent were included in this study. This study received ethical approval from the Ulster University Centre for Higher Education Research and Practice Ethics Committee and the Learning Enhancement Directorate Ethics Filter Committee (LEDEC; formerly CHERP; LEDEC-24-004). All data were anonymized during the analysis phase to ensure confidentiality and to protect participants' identities. Staff members who chose not to participate experienced no disadvantage or impact on their professional standing. No financial or material compensation was offered to participants for their involvement in this research.

Results

Generation of Questions

In response to the predefined prompts provided to the chatbots, 3 of them (free ChatGPT, ChatGPT Plus, and Gemini) generated 10 questions each, for a total of 30 across the 3 researchers. Bing could not respond to the prompt for LOB9 and thus generated 9 questions, for a total of 27 across the 3 researchers. Thus, 117 questions were generated (Multimedia Appendix 2).

Assessment of Consistency Within Chatbots and Technical Item Flaws Among the Outputs

Consistency within chatbots was evaluated based on the similarity of outputs between the 3 researchers and any bias in the allocation of the correct answer option. Bing had the highest degree of similarity between items generated by multiple users (4 exact question matches and 20 similar ones), while ChatGPT-4 had the highest degree of variation (Table 1).

Table . Similarity between the questions generated by different chatbots.

	Gemini (N=30), n (%)	Bing (N=27), n (%)	ChatGPT-3.5 (N=30), n (%)	ChatGPT-4 (N=30), n (%)
Exact questions	0 (0)	4 (14.81)	2 (6.67)	0 (0)
Similar questions	24 (80)	20 (74.07)	22 (73.33)	22 (73.33)
Different questions	6 (20)	3 (11.11)	6 (20)	8 (26.67)

The original predefined prompt did not request answer options to be given in any particular order. Therefore, for assessing potential bias in the correct answer allocation, 3 scenarios were modeled (Table 2):

- Any bias or preference in the correct answer allocation based on the raw chatbot output.
- Any bias or preference in the correct answer allocation based on the chatbot output when the researchers manually ordered answers into alphabetical order.
- Any bias or preference in the correct answer allocation based on a new output, where each chatbot was prompted to produce 30 new SBA questions with answers alphabetically.

Table . Assessment of possible bias or preference in correct answer allocation.

Options	Gemini (N=30), n (%)	Bing (N=27), n (%)	ChatGPT-3.5 (N=30), n (%)	ChatGPT-4 (N=30), n (%)
Original chatbot output				
A	5 (16.67)	6 (22.22)	9 (30)	11 (36.67)
B	12 (40)	4 (14.81)	10 (33.33)	10 (33.33)
C	6 (20)	10 (37.04)	7 (23.33)	4 (13.33)
D	5 (16.67)	6 (22.22)	3 (10)	4 (13.33)
E	2 (6.67)	1 (3.7)	1 (3.33)	1 (3.33)
Manual reordering of chatbot output into alphabetical order				
A	4 (13.33)	8 (29.63)	8 (26.67)	6 (20)
B	10 (33.33)	3 (11.11)	3 (10)	7 (23.33)
C	3 (10)	5 (18.52)	7 (23.33)	5 (16.67)
D	9 (30)	4 (14.81)	6 (20)	5 (16.67)
E	4 (13.33)	7 (25.93)	6 (20)	7 (23.33)

Gemini, ChatGPT-3.5, and ChatGPT-4 occasionally provided answer options in alphabetical order when not specifically prompted. Gemini consistently demonstrated a preference for the correct answer to be listed as option B. The ChatGPT-3.5 and ChatGPT-4 appeared to favor options A, B, and C. Bing appeared to favor options A and E.

Regarding the technical item flaws among the outputs, the chatbots performed similarly in terms of following an SBA format (Figure 2A) and achieving the "cover test" satisfaction (Figure 2B), although ChatGPT-4 scored slightly lower on satisfying the cover test. Overall, Gemini performed well across most items, except for item balance. Notably, Gemini stood out by creating questions with a lead-in that relied heavily on the vignette for the answer (Figure 2F). Bing scored low across most evaluation items but performed well in generating a lead-in question of appropriate length (Figure 2G). ChatGPT Plus, which required a paid subscription, did not outperform the other chatbots in any item. The evaluation item "questions test the application of knowledge rather than recall of isolated facts" received the lowest scores across all the chatbots (Figure 2C), with Gemini achieving the highest score among them.

Figure 2. Shows technical item flaws among the chatbots: (**A**) single best answer format, (**B**) satisfy the "cover test" rule, (**C**) test the application of knowledge rather than recall isolated facts, (**D**) questions were balanced, (**E**) lead-in question tests one idea, (**F**) questions depend on the vignette to reach an answer, and (**G**) appropriate lead-in question length. The total number of questions generated by Bing was 27.

	(A) Using single-best answer format	(B) Satisfy the "cover test" rule	(C) Testing the application of knowledge	(D) Balanced structure	(E) Test a single concept	(F) Depend on the vignette to reach an answer	(G) Appropriate lead-in question length
Gemini	93%	60%	57%	83%	83%	97%	73%
Bing	97%	37%	100%	88%	88%	33%	85%
ChatGPT-3.5	97%	47%	100%	70%	70%	47%	40%
ChatGPT-4	80%	50%	97%	73%	73%	67%	70%

Assessment of Content Validity and Accuracy

Seven internal assessors evaluated item clarity and relevance, deriving the I-CVI for individual SBA items and the S-CVI (following the Universal Agreement method) to assess the overall content validity for questions from each chatbot (Table 3). Items with I-CVI>0.79 and scales with S-CVI/UA>0.8 can be interpreted as acceptable [20].

Assessors also evaluated items for content clarity and 4 elements of accuracy: vignette information, answers, justifications, and educational accuracy, on a scale from 1 to 4 (Tables 4 and 5). The Krippendorff alpha coefficient was low, 0.016, with a 95% bootstrap CI of −0.066 to 0.116.

As depicted in Tables 3 and 4, SBA questions from 3 chatbots (ChatGPT, Gemini, and ChatGPT Plus) had similar content clarity and S-CVI values. In comparison to the other chatbots, Bing performed worst in content clarity, overall (scale) validity, and all elements of item accuracy. ChatGPT Plus, which required a paid subscription, did not outperform the other chatbots except in the measure of educational accuracy. Further statistical analysis was performed using the 2-way ANOVA without replication, which showed statistically significant differences among chatbots and domains (P<.05). However, the Tukey-Kramer HSD post hoc test revealed no significant pairwise differences between individual chatbots, as all comparisons had P values>.05 and overlapping CIs. Thus, although the chatbots' performance varied overall, specific chatbot differences were not statistically significant.

Table . Item-content validity and scale-content validity across the chatbots.

Item number	Gemini	Bing	ChatGPT-3.5	ChatGPT-4
I-CVI[a]				
1	1	1	1	1
2	1	1	1	1
3	1	1	1	1
4	1	1	1	1
5	0.85	0.85	0.85	0.83
6	0.85	0.85	0.71	0.85
7	0.85	0.85	0.85	0.85
8	0.85	0.85	0.85	0.85
9	0.85	—[b]	0.85	0.85
10	0.85	0.85	0.85	0.85
S-CVI/UA[c]	0.91	0.83	0.9	0.91

[a]I-CVI: Item Content Validity Index.

[b]Not applicable.

[c]S-CVI/UA: Scale Level Content Validity Index.

Table . Average score for content clarity and accuracy of items across the chatbots.

	Content clarity[a]	Accuracy of information[b]	Accuracy of answers[c]	Accuracy of justification[d]	Educational accuracy[e]
Gemini	3.68	3.71	3.8	3.91	3.49
Bing	3.41	3.3	3.49	3.47	3.2
ChatGPT-3.5	3.75	3.71	3.84	3.9	3.5
ChatGPT-4	3.71	3.66	3.81	3.82	3.56

[a]Content clarity refers to the extent to which the question is clearly written, free of ambiguity, and easily understood by the intended audience.

[b]Accuracy of information verifies that the facts, concepts, and explanations presented are scientifically and contextually correct.

[c]Accuracy of answers ensures that the correct response is indeed accurate, while the distractors remain plausible yet distinguishable.

[d]Accuracy of justification evaluates whether the rationale provided for correct and incorrect answers is logically sound, evidence-based, and supports a deeper understanding of the topic.

[e]Educational accuracy assesses whether the question is appropriately challenging to the student level, measures higher cognitive levels (such as application or analysis), and adheres to best practices in assessment design.

Table . Two-way ANOVA table.

Source of variation	Sum of squares due to the source	*df*	Mean sum of squares due to the source	*F* test	*P* value
Average content clarity and accuracy scores	0.304357	2	0.152178	24.26587	<.001
Chatbots	17.9744	4	4.493601	716.5349	<.001
Error	0.05017	8	0.006271	—[a]	—
Total	18.32893	14	—	—	—

[a]Not applicable.

Discussion

Interpretation of Findings

This study was designed to examine the content validity and consistency of SBA questions generated by different chatbots in the context of undergraduate medical education. The findings revealed that no single chatbot excelled in all studied domains nor demonstrated a universal superiority over other chatbots, but rather showed unique strengths of some chatbots in specific areas and highlighted their notable limitations in other ones. This emphasizes the importance of critically assessing the output

of chatbots in a context-sensitive manner. Bing produced items that were least suitable for inclusion in medical student assessment. These findings echo previous studies, which also show Bing to generate less valid MCQs in comparison to other chatbots [25]. ChatGPT-4 showed the greatest variation in responses across users (suggesting higher protection against examination candidates predicting potential assessment items), and had strong performance in content clarity and accuracy, though it also exhibited some less effective question design practices, such as poorer performance in the "cover test" rule. These findings align with the results of Doughty et al [26], who found that GPT-4's ability to generate effective MCQs was nearly on par with human performance, in which 81.7% of the generated MCQs met all evaluation criteria, suggesting that fewer than 1 in 5 questions would need revision by instructors. However, in cases where ChatGPT-4 failed to meet a quality standard, this was typically the only issue with the question. Gemini performed well across all evaluations, matching ChatGPT Plus's strong index score for content validity, and excelled in creating questions where the lead-in tested 1 item and relied heavily on the vignette for the answer. Although slightly behind both ChatGPT versions in content clarity, Gemini scored the highest in providing accurate justifications for the correct answer.

This variation across chatbots is consistent with results from studies where chatbots were asked to answer questions. Kumari et al [15] found significant differences in solving hematology case vignettes using LLMs. ChatGPT achieved the highest score, followed by Google Gemini and then Microsoft Bing. In line with this, Dhanvijay et al [13] reported that ChatGPT-3.5 scored the highest, Bing the lowest, and Bard (Gemini) ranked in the middle when solving case vignettes in physiology. When chatbots were tested on their ability to answer SBA questions, ChatGPT-4 and Microsoft Copilot (Bing) outperformed Google Gemini [27]. Overall, these results suggest that OpenAI's ChatGPT shows strong potential in the medical education field. However, it is worth noting that none of the models were able to answer all questions correctly, and in our study, all platforms had some flaws when generating SBAs.

Additionally, this study's results reveal several key insights and revelations concerning SBA questions produced by AI chatbots. First, we observed that chatbots often exhibit a correct answer bias toward particular options. Recent studies have identified that LLMs tend to display positional bias when handling MCQs [28,29]. Radford et al [30] and Li and Gao [31] found that this susceptibility to positional bias is pronounced in the GPT-2 family however a more recent technical report for GPT-4 suggests AI's performance in MCQ remains susceptible to the position of the correct answer among the choices [32], a pattern referred to as "anchored bias." To minimize this inherent bias that appears to occur across AI platforms, when using AI to generate MCQ or SBA, we would recommend not stipulating an order for answer options in the prompt.

Furthermore, assessment literature emphasizes that high-quality SBA questions should assess the higher levels of Bloom's taxonomy to encourage students' critical thinking and complex problem-solving [33]. Our study revealed that chatbots were not always successful in crafting questions that engaged these advanced cognitive levels, and this was an area of relative weakness when evaluating items. Gemini scored highest, followed by ChatGPT Plus, ChatGPT-3.5, and then Bing. Similar findings regarding ChatGPT's limitations were reported by Herrmann-Werner et al [34]. Likewise, studies by Klang et al [35] and Liu et al [36] also emphasized GPT-4's limited ability to integrate knowledge and apply clinical reasoning, highlighting challenges in logical reasoning, which could limit AI's ability to generate questions that test this concept. However, it should be noted that while human-written questions were rated higher in direct comparisons, the score gap was narrow and largely insignificant, suggesting that AI tools still hold potential as educational aids [2].

Our analysis also revealed some technical flaws, variations, and inconsistencies in item construction within all chatbots. These flaws highlight instances of overconfidence and inadequacies in question design, suggesting an inability of the chatbots to evaluate their output's consistency, relevance, and complexity. Flawed MCQs hinder the accurate and meaningful interpretation of test scores and negatively impact student pass rates. Therefore, identifying and addressing technical flaws in MCQs can enhance their quality and reliability [37]. Similarly, Klang et al [35] reported that approximately 15% of questions generated using detailed prompts required corrections, primarily due to content inaccuracies or methodological shortcomings. These revisions often involved addressing a lack of sensitivity in certain topics, such as failing to include specific details such age, gender, or geographical context in the questions or answers.

Most of the questions tested recall and comprehension levels, but Gemini included some that assessed the application of knowledge. In contrast, Bing struggled to generate questions on specific topics. These findings can be explained as critical thinking at higher levels involves considering evidence, context, conceptualization, methods, and the criteria required for judgment [38]. AI models are trained on large datasets of text, but they may not fully understand the context or underlying concepts behind the content. Higher-order thinking skills, such as application, analysis, and synthesis, require deeper comprehension and reasoning that AI might not be able to simulate effectively.

Thus, using AI to generate SBAs encourages us to reconsider Bloom's taxonomy of the cognitive domains [39,40], which traditionally positions "creation" as the highest level of cognition. In the era of AI, evaluation might be considered the most critical level of cognition [41]. While AI chatbots can often produce well-written questions aligned with LOBs, they still require expert evaluation to ensure their suitability for use. Future research should compare AI-generated outputs with those from subject matter experts to assess accuracy and relevance. Evaluating AI's ability to test higher-order cognition in Bloom's taxonomy is also crucial. As AI evolves, ongoing validation is essential to ensure reliability and effectiveness in assessments.

Despite the methodological rigor and innovative approach of this study, some limitations need to be highlighted to improve the interpretation of the findings presented here. First, the researchers or assessors generated or evaluated only 30 questions per chatbot. Variation was observed in the content validity and

accuracy between the SBAs produced by an individual chatbot. Therefore, this sample may not sufficiently represent the wide range of possible outputs, potentially limiting the generalizability and robustness of the findings. Second, the accuracy of the chatbots' responses may have been compromised by the absence of reference materials, which could have negatively affected their performance. Finally, this study is limited by low interrater reliability and the use of measures are not specifically designed to assess MCQ quality. Future research should consider using validated tools to enhance evaluation accuracy.

Conclusions

Chatbot platforms varied in their ability to generate educational questions. ChatGPT models produced the most variable outputs, reducing predictability while maintaining strong content clarity and accuracy with minimal answer bias. Gemini performed similarly but showed a strong preference for 1 option, while Bing had the least variation and the lowest content clarity and accuracy. ChatGPT-4 did not significantly improve question quality but maximized variability. Technical flaws were present across all platforms, with many questions poorly linked to vignettes. Most tested recall and comprehension, though Gemini included some application-level items, whereas Bing struggled with specific topics.

These findings highlight AI's limitations in generating higher-order thinking questions, reinforcing the need for expert evaluation. This challenges Bloom's taxonomy's traditional cognitive hierarchy, suggesting that "evaluation" may be more critical than "creation" in AI-assisted assessments.

Acknowledgments

The authors extend their gratitude to the internal assessors from the School of Medicine, Ulster University, who dedicated their time to evaluating the questions.

Abstract

Background: Artificial intelligence and large language models (LLMs)—particularly GPT-4 and GPT-4o—have demonstrated high correct-answer rates in medical examinations. GPT-4o has enhanced diagnostic capabilities, advanced image processing, and updated knowledge. Japanese surgeons face critical challenges, including a declining workforce, regional health care disparities, and work-hour-related challenges. Nonetheless, although LLMs could be beneficial in surgical education, no studies have yet assessed GPT-4o's surgical knowledge or its performance in the field of surgery.

Objective: This study aims to evaluate the potential of GPT-4 and GPT-4o in surgical education by using them to take the Japan Surgical Board Examination (JSBE), which includes both textual questions and medical images—such as surgical and computed tomography scans—to comprehensively assess their surgical knowledge.

Methods: We used 297 multiple-choice questions from the 2021 - 2023 JSBEs. The questions were in Japanese, and 104 of them included images. First, the GPT-4 and GPT-4o responses to only the textual questions were collected via OpenAI's application programming interface to evaluate their correct-answer rate. Subsequently, the correct-answer rate of their responses to questions that included images was assessed by inputting both text and images.

Results: The overall correct-answer rates of GPT-4o and GPT-4 for the text-only questions were 78% (231/297) and 55% (163/297), respectively, with GPT-4o outperforming GPT-4 by 23% (P=<.01). By contrast, there was no significant improvement in the correct-answer rate for questions that included images compared with the results for the text-only questions.

Conclusions: GPT-4o outperformed GPT-4 on the JSBE. However, the results of the LLMs were lower than those of the examinees. Despite the capabilities of LLMs, image recognition remains a challenge for them, and their clinical application requires caution owing to the potential inaccuracy of their results.

KEYWORDS

LLM; ChatGPT; Japan Surgical Board Examination; surgical education; large language models; artificial intelligence; Medical Licensing Examination; diagnostic imaging

Introduction

Surgical training requires a considerable time commitment, as it includes various educational activities, on-the-job training, and supervised clinical experience [1]. In Japan, the surgery field is facing many challenges, such as the declining numbers of surgeons, regional health care disparities [2], and working-hour–related challenges [3]. Consequently, it is important to understand whether new technologies such as artificial intelligence (AI) and large language models (LLMs) can augment surgery education and training [4].

LLMs are AI systems trained on billions of words from papers, books, and other internet sources. ChatGPT—released by OpenAI in November 2022—is a generative AI chatbot that supports multimodal inputs and text generation, with a GPT as its backend [5]. ChatGPT has achieved conversational interactivity and human-like or better correct-answer rate across various fields—including the medical field [6]—suggesting that

LLM applications could be beneficial in clinical, educational, and research settings [7].

GPT-4—released in March 2023—achieved an excellent correct-answer rate for United States Medical Licensing Examination (USMLE)-style questions, exceeding the passing threshold of 60% [8]. Moreover, in the field of surgery, GPT-3.5 obtained a 65% correct-answer rate for the US General Surgery Specialist Examination [9], and GPT-4 achieved a 76% correct-answer rate for the Korean Surgical Specialist Examination [10]. However, GPT-4 does not include an image-recognition function; consequently, questions that included images were excluded from both of these studies. To the best of our knowledge, no previous study has yet evaluated the correct-answer rate of LLMs on the Japan Surgical Board Examination (JSBE).

GPT-4-Vision (GPT-4V)—an improved version of GPT-4 with image-processing capabilities [6]—can process and interpret images along with text data, extending its potential application to areas that require image analysis. When both text- and image-based questions from the USMLE were input into GPT-4V, its correct-answer rate improved from 83.6% to 90.7% [11]. However, there have been no reports on the functional evaluation of AI in the field of surgery that includes image evaluations.

GPT-4 Omni (GPT-4o)—released in May 2024—features a considerably faster processing speed than GPT-4 and includes many upgrades, such as its improved non-English-language processing and enhanced visual and speech understanding [12]. Additionally, the GPT-4o knowledge base has been updated with data up to October 2023, enabling it to offer more accurate answers based on recent information and accurate text generation [13]. Several reports have evaluated the performance of Chat-GPT4o using medical examinations, but only 3 reports have evaluated the effectiveness of image input in addition to text [14-16]. Moreover, no study has yet evaluated it in the field of surgery. In many cases, diagnostic imaging plays an important role in surgical treatment plans, and specific images—such as intraoperative imaging findings—are sometimes used. Consequently, evaluating how LLMs handle surgery-specific images is critical for understanding their current capabilities. If LLMs have a high level of knowledge related to surgery-specific images, they have the potential to be effective tools in real clinical practice and surgical education.

There have been few reports evaluating the extent to which LLMs, such as GPT, possess surgical knowledge, particularly in relation to interpreting surgical images—a skill essential for clinical decision-making. This study aims to assess and compare the performance of GPT-4 and GPT-4o on JSBE, focusing not only on general surgical knowledge but also on image recognition and diagnostic accuracy. We examined the models' responses to text-only and text-with-image questions using a retrospective evaluation design. We hypothesized that GPT-4o would outperform GPT-4, particularly on image-based questions. The findings of this study should be useful for medical educators and AI researchers seeking to understand the capabilities and limitations of LLMs in surgical education and training.

Methods

Question Dataset

This study used multiple-choice questions from the 2021 - 2023 JSBE published by the Japan Surgical Society. Each question had five possible choices, with some requiring a single answer and others requiring two. The responses for the two-answer questions were deemed correct only if both correct answers were selected. The number of answers required was specified in the input text. Electronic versions of previous papers that were available for sale were also used. The Japan Surgical Society granted permission to answer these questions.

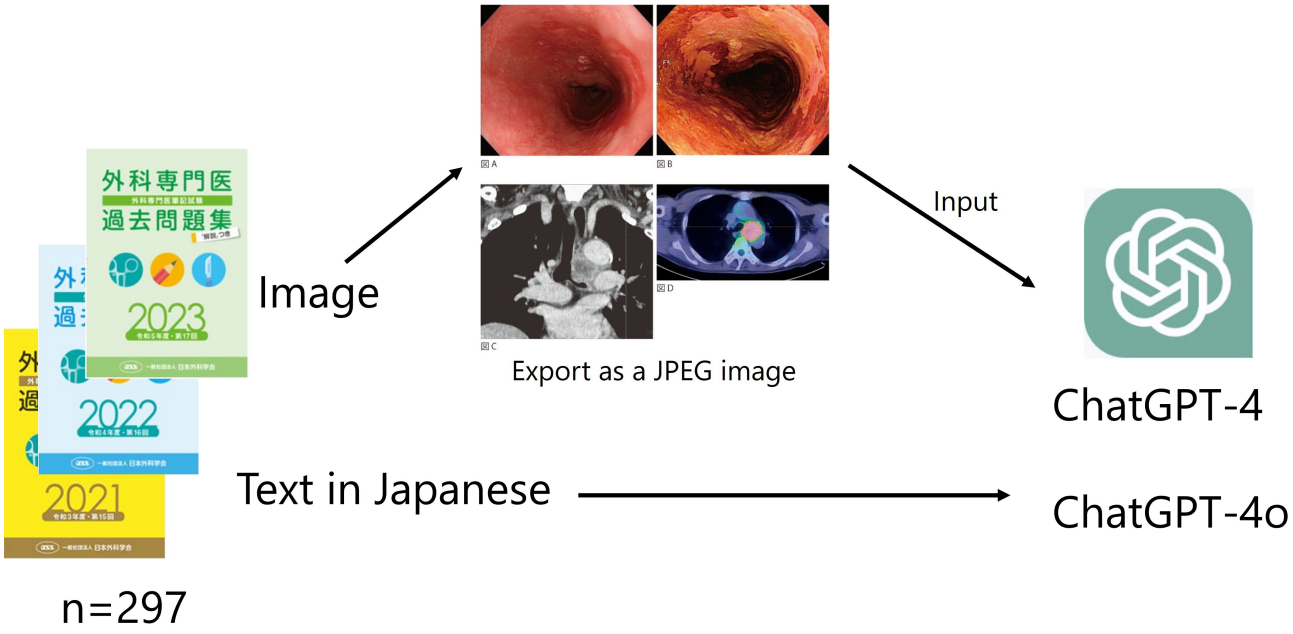
The JSBE is a multidisciplinary surgical knowledge examination designed for senior resident doctors in Japan who have completed a 3-year surgical training program. The number of examinees, successful candidates, and pass rates are listed in Table 1. There were 100 questions in each year, but 1 question in 2022 and 2 questions in 2023 were excluded as inappropriate questions, so a total of 297 questions were used in this study. The questions were presented in Japanese. To evaluate and compare responses to text-with-image questions, text-only questions were also included in the study. The text, obtained from an electronic question booklet, was entered into the models in an extensive markup language (XML) format. Moreover, screenshots of the test images were obtained from the booklet and saved in JPEG format, with their captions also being included.

Table . Annual test results of the Japan Surgical Board Examination.

Year	Examinees	Successful examinees	Pass rate (%)	Correct-answer rate (%)
2021	289	261	90.3	84.2
2022	1594	1534	96.2	92.7
2023	835	814	97.5	92.7

Questions with multiple images were exported and combined into a single image (Figure 1). The correct answers were also obtained from the electronic question booklet. The percentage of correct answers for each topic was calculated based on the number of correct answers provided by actual examinees for each question.

Figure 1. Collection of data from JSBE and input into GPT models. The questions were entered into an electronic booklet in Japanese. The images were saved as screenshots and input into ChatGPT-4o. JSBE: Japan Surgical Board Examination.



Question Classification

The questions were classified based on whether they included images. Of the 297 questions, 104 included images (text-with-image questions), and the remaining 193 were text-only questions. They were grouped into 6 categories—that is, gastrointestinal surgery (134/297, 45.1%), cardiovascular surgery (44/297, 14.8%), thoracic surgery (30/297, 10.1%), pediatric surgery (30/297, 10.1%), breast and endocrine surgery (30/297, 10.1%), and emergency anesthesiology (29/297, 9.8%). The number of image modalities and images per question was as follows: the highest number of questions included computed tomography (CT) images (44/104, 42.3%), followed by endoscopy (15/104, 14.4%), and ultrasound (13/104, 12.5%) images. Additionally, X-ray (10/104, 9.6%), radiofluoroscopy (10/104, 9.6%), magnetic resonance imaging (MRI; 8/104, 7.7%), surface of skin findings (8/104, 7.7%), positron emission tomography (6/104, 5.8%), intraoperative findings (5/104, 4.8%), pathology (5/104, 4.8%), and other modality images (5/104, 4.8%) were also included. Furthermore, 44 out of 104 questions included 1 image (42.3%), 42/104 included 2 images (40.4%), 11/104 included 3 images (10.6%), 6/104 included 4 images (5.8%), and 1/104 included 6 images (which was the maximum; 1.0%). The percentage of correct answers for each topic was calculated based on the percentage of correct answers to the individual questions and was then compared with the percentages of correct answers provided by both GPT-4 and GPT-4o.

Data Collection and Assessment

We used the GPT-4 and GPT-4o models via OpenAI's application programming interface (API) without additional fine-tuning or custom configuration. All parameters were maintained at their default setting. No pretraining or fine-tuning was conducted, and no custom persona was provided. The questions were submitted via the OpenAI API in June 2024, and the GPT-4 and GPT-4o responses were collected. The internal GPT-4o and GPT-4 versions used in this study were gpt-4o-2024-05-13 and gpt-4-turbo-2024-04-09, respectively. GPT-4o was trained on data up to October 2023, whereas GPT-4 was trained on data up to December 2023 [17].

A maximum token limit of 4096 tokens was assumed, consistent with the default for many GPT-based API end points. All other parameters—for example, the temperature, top_p, and frequency penalty—were kept at their default settings.

All test questions were presented in Japanese. To ensure consistent model behavior and clear response formatting, the following English-language prompt was placed before each question: "Please answer the following question. Indicate the symbol of the option selected by you at the end." This prompt was immediately followed by the question text in Japanese. This structure aimed to maintain response consistency across test items. The prompting strategy primarily followed a zero-shot format.

Questions with images were assessed twice—that is, once with and once without images. The answers that matched those in the question booklet were considered correct. Moreover, the percentage of correct answers was calculated for each image modality with the questions, and the percentage of correct answers was calculated based on the number of images included in the question. The percentage of correct answers for GPT-4o and GPT-4 were compared for all questions, text-only questions, and text-with-image questions, by the question category, image modality used, and number of images. For category-by-category comparisons, only the results for questions with image inputs were compared, but for the other items, the results with and without image inputs were also compared.

Statistical Analyses

McNemar test was used to compare the proportion of correct responses between the GPT-4 and GPT-4o. Fisher exact test was used for each category—that is, with or without images, lower-order thinking versus higher-order thinking, and 2 answers

versus 1 answer—to assess the GPT-4o correct-answer rate for each category. Additionally, a chi-square test was conducted to compare grades across topics. All tests were 2-tailed, and *P* values<.05 were considered significant. All *P* values were nominal and were not corrected for multiple comparisons. The statistical analyses were conducted using JMP Pro 17.0 (SAS Institute Inc).

Ethical Considerations

This study did not include human participants or patient data. All the data used in this study are publicly available. Therefore, it was excluded from review by the Institutional Review Board of Tohoku University (IRB number 11000629).

Results

Correct-Answer Rates of GPT-4 and GPT-4o

Of the 297 questions used for the text-input only test, GPT-4 answered 164 (55%) correctly and GPT-4o answered 225 (76%) correctly; thus, GPT-4o outperformed GPT-4 by 21% (*P*<.001). Additionally, when image inputs were performed for the 104 text-with-image questions out of the 297 questions, GPT-4o outperformed GPT-4 by 23% (*P*<.001), providing 231 (78%) and 163 (55%) correct answers, respectively. Comparisons of their correct-answer rates for individual groups showed that GPT-4o provided significantly more correct answers for image-based questions (GPT-4o 67% vs GPT-4 45%; *P*=<.002), text-only questions (83% vs 61%; *P*=<.001), digestive surgery (70% vs 42%; *P*=<.001), cardiovascular surgery (98% vs 68%; *P*<.00031), and breast and endocrine surgery (93% vs 67%; *P*=.0047). However, no significant differences (GPT-4o vs GPT-4) were evident between their correct-answer rates for questions related to thoracic surgery (63% vs 57%; *P*=.41), emergency surgery and anesthesia (86% vs 66%; *P*=.06), and pediatric surgery (73% vs 70%; *P*=.71). Notably, GPT-4o provided more correct responses than GPT-4 (Table 2).

Table . GPT-4 and GPT-4o correct-answer rates for the Japan Surgical Board Examination.[a]

Question type	Number of questions	Image input	Correct-answer rate		*P* value
			GPT-4, n (%)	GPT-4o, n (%)	
All questions	297	–	164 (55)	225 (76)	.001
		+	163 (55)	231 (78)	.001
Text-with-image questions	104	–	46 (44)	64 (62)	.002
		+	47 (45)	70 (67)	.<001
Text-only questions	193	–	118 (61)	161 (83)	.<001
Topic					
Digestive surgery	134	+	56 (42)	94 (70)	.<001
Cardiovascular surgery	44	+	30 (68)	43 (98)	.<001
Thoracic surgery	30	+	17 (57)	19 (63)	.41
Pediatric surgery	30	+	21 (70)	22 (73)	.71
Breast and endocrine surgery	30	+	20 (67)	28 (93)	.005
Emergency and anesthesia	29	+	19 (66)	25 (86)	.06

[a]Data are presented as the number of correct answers.

GPT-4o's Correct-Answer Rate on Text-With-Image Questions Compared With its Rate on Text-Only Questions

Even when image inputs were used for the text-with-image questions, GPT-4o provided 67% correct answers, compared to 83% for the text-only questions, indicating a statistically significant difference (*P*<.002).

Correct-Answer Rate With and Without Image Input

The percentages of correct responses provided by both models with and without image inputs were compared for 104 text-with-image questions—here, GPT-4o provided correct-answer rates of 62% and 67% with and without image inputs (*P*=.2), respectively, whereas GPT-4 provided correct-answer rates of 44% and 45% with and without image inputs (*P*=.86; Table 3).

Table . GPT-4 and GPT-4o correct-answer rates based on image-input and no image-input questions.[a]

Large language model	Input image, n (%)[b]	No input image, n (%)[b]	*P* value
GPT-4	47 (45)	46 (44)	.86
GPT-4o	70 (67)	64 (62)	.20

[a]Data are presented as the number of correct answers. Values in parentheses indicate the percentage of correct responses.

[b]The percentage indicates the percentage of correct answers to the 104 text-with-image questions.

Correct-Answer Rate Comparison of GPT-4 and GPT-4o by Category

GPT-4 provided the highest percentage of correct answers for pediatric-surgery questions (70%) and the lowest for gastrointestinal-surgery questions (19%; *P*=.0027). By contrast, GPT-4o provided the highest percentage of correct answers for cardiovascular-surgery questions (98%) and the lowest for thoracic-surgery questions (63%; *P*=.002). The correct-answer rate for the examinees referred to here is the correct-answer rate for all examinees from 2021 to 2023 (Table 4).

Table . GPT-4o, GPT-4, and examinees' correct-answer rates across various categories.

Topic	Number of questions	Text-with-image questions, n (%)	Correct-answer rate (%)		
			GPT-4	GPT-4o	Examinees
All questions	297	104 (35)	55	78	90
Digestive surgery	134	43 (32)	42	70	89
Cardiovascular surgery	44	19 (43)	68	98	91
Thoracic surgery	30	17 (57)	57	63	88
Pediatric surgery	30	11 (37)	70	73	92
Breast and endocrine surgery	30	7 (23)	67	93	90
Emergency and anesthesia	29	7 (24)	66	86	91

[a]Not applicable.

Comparison of GPT-4 and GPT-4o Responses by Image Modality and Number of Figures

Using the text-with-image questions, the correct-answer rates for GPT-4 and GPT-4o were compared using various imaging modalities and images. GPT-4 provided the highest percentage of correct answers for questions on radiofluoroscopy and inspection (70% and 75%, respectively), whereas GPT-4o provided the highest percentage of correct answers for radiofluoroscopy and ultrasound (80% and 92%, respectively). By contrast, the correct-answer rates of the models were low for questions that included intraoperative and pathological findings—that is, they were 20% and 40% for GPT-4, respectively, and 40% for GPT-4o for both intraoperative and pathological findings. Moreover, a weak negative correlation was evident between the number of images and the percentage of correct answers, but it was not statistically significant (Table 5).

Table . Correct-answer rate comparisons based on imaging modality and number of images.[a]

Variables	n	Correct-answer rate, n (%)			
		GPT-4		GPT-4o	
		Image input +	Image input −	Image input +	Image input −
Imaging modality					
Text-with-image questions	104	47 (45)	46 (44)	70 (67)	64 (62)
XP[b]	10	5 (50)	4 (40)	6 (60)	5 (50)
Radiofluoroscopy	10	7 (70)	6 (60)	8 (80)	6 (60)
Ultrasound	13	6 (46)	8 (62)	12 (92)	10 (77)
CT[c]	60	25 (42)	27 (45)	39 (65)	37 (62)
MRI[d]	8	5 (63)	2 (25)	5 (63)	4 (50)
PET[e]	6	4 (67)	2 (33)	3 (50)	2 (33)
Endoscopy	15	9 (60)	8 (53)	9 (60)	11 (73)
Surface of skin findings	8	6 (75)	4 (50)	5 (63)	6 (75)
Intraoperative findings	5	1 (20)	2 (40)	2 (40)	3 (60)
Pathology	5	2 (40)	2 (40)	2 (40)	2 (40)
Other	5	2 (40)	3 (60)	5 (100)	4 (80)
Number of figures					
1	44	19 (43)	18 (41)	28 (64)	26 (59)
2	42	18 (43)	19 (45)	32 (76)	27 (64)
3	11	7 (64)	8 (73)	10 (91)	9 (82)
4	6	3 (50)	1 (17)	1 (17)	1 (17)
6	1	0 (0)	0 (0)	0 (0)	0 (0)

[a]Data are presented as the number of correct answers. Values in parentheses indicate the percentage of correct responses.

[c]CT: computed tomography.

[d]MRI: magnetic resonance imaging.

[e]PET: positron emission tomography.

Discussion

Principal Findings

GPT-4o significantly outperformed GPT-4 across all evaluated categories. However, neither GPT-4 nor GPT-4o achieved examinee-level accuracy for any question (Table 1). The correct-answer rates for text-only questions were higher than those for text-with-image questions for both models. Moreover, the inclusion of image inputs did not lead to a significant improvement in performance on text-with-image questions (Table 3). Performance varied by image type, with particularly low correct-answer rates for questions involving intraoperative and pathological images. By contrast, the correct-answer rates were relatively higher for radiological images such as CT and MRI images.

The results showed that there was no significant difference in the percentage of correct responses between GPT-4 and GPT-4o for thoracic surgery, emergency and anesthesia, and pediatric surgery. When comparing GPT-4o to the results of examinees, both demonstrated similarly low correct-answer rates for questions related to thoracic and gastrointestinal surgery. There was no consistent pattern evident in terms of which surgical category exhibited the highest correct response rate.

Additional Analysis by Problem Type

In terms of category-specific differences, the percentage of correct responses for both GPT-4 and GPT-4o did not differ significantly for thoracic, emergency and anesthesia, and pediatric surgery. A comparison of GPT-4o and examinee correct-answer rates demonstrated similarly low correct response rates for questions related to the thoracic and gastrointestinal surgeries. However, no consistent trend was evident with the highest percentage of correct responses. The correct-answer rate was low for thoracic surgery because questions in this field comprised a high proportion of text-with-image questions. By contrast, it was high for breast and endocrine surgery and emergency and anesthesiology, which comprised fewer

text-with-image questions. However, the opposite trend was evident for cardiovascular surgery, where no consistent trend was evident in the correct-answer rates for text-with-image questions. This result could be attributed to the fact that many of the questions could be answered correctly without image recognition, or that many of the images were easy to understand even when image recognition was required.

Responses to Intraoperative Imaging Problems

An additional study on the correct-answer rate was conducted to assess the differences in the GPT model responses based on the imaging modality. This is only a hypothesis, but owing to the small sample size, as 1 question contained several types of images, the correct-answer rate was more than 20% lower than the overall GPT-4 correct-answer rates for questions involving intraoperative findings and those of GPT-4o for intraoperative and pathological images compared with those for radiological modalities such as CT and MRI (Table 4). Only questions involving intraoperative findings had a correct-answer rate after image input that was more than 20% lower than the average for both GPT-4 and GPT-4o, which could be considered to be a GPT image-recognition weakness. Additionally, the responses to intraoperative images were evaluated individually (Multimedia Appendix 1). Although liver resection was identified in intraoperative liver-resection images, the actual resection was misidentified. Moreover, in images of mediastinal tumors, the tumor and recurrent nerve were either not mentioned or could not be identified, whereas from the intraoperative inguinal-hernia images, the arteriovenous vein in the inferior abdominal wall was misidentified as the vas deferens.

Implications of Findings

From this research, it is evident that GPT-4o significantly outperformed GPT-4 across all evaluated categories, indicating that OpenAI's model development is progressing steadily. However, despite these improvements, neither GPT-4 nor GPT-4o achieved the correct-answer rates of actual examinees. This highlights that current LLMs, while advancing rapidly, still fall short of the reliability required for high-stakes clinical decision-making or licensing-level assessments. In particular, GPT-4o exhibited lower accuracy on text-with-image questions compared to text-only questions, and the inclusion of image inputs did not significantly improve its performance. This reflects an ongoing limitation in the image recognition capabilities of LLMs, especially for complex visuals such as intraoperative and pathological images, and suggests that caution is warranted when considering these models for clinical use.

However, this study was conducted without pre-tuning, and the accuracy of LLMs could be potentially improved by tuning them in a field-specific manner [7]. Pretuning them on data from medical textbooks and previous examinations could enhance the relevance and accuracy of their responses. Pretraining has the potential to improve model performance, but the process can be complicated and is not supported by some models. The results of the models that did not undergo pretraining can be said to be results that can be applied to general readers and various models.

A "Socratic tutor mode" educational application of GPT-4o has been reported, wherein the complexity of medical questions can be changed during the conversation based on the learner's understanding [7]. In this study, GPT-4o provided a high percentage of correct answers to text-only questions, which could be used for learning guideline content and obtaining general surgical knowledge, where the answers are clear to residents and majors studying surgery. Additionally, if its image-recognition capabilities improve in the future and it becomes possible to diagnose intraoperative images specific to surgery with a high degree of confidence, it could become a useful indicator when making decisions in daily clinical practice.

Comparison to the Literature

Previous studies have shown that the GPT-4 correct-answer rate could be improved for USMLE by using images to complement the text input [11]. However, similar to our study, researchers have reported that inputting image information did not increase the percentage of correct answers [16,18-22]. Additionally, a previous study has suggested that GPT-4 prioritizes verbal information over images [20].

Previous reports [23] have shown that ChatGPT is able to provide more accurate responses when given English-language input than non-English-language input, but it has also been shown that the correct-answer rate of GPT-4o has improved when given Japanese-language inputs [12]. Moreover, the results of this study reflect this fact, which is consistent with the findings of a previous study on radiology [14], highlighting GPT-4o's enhanced reasoning and better responsiveness to Japanese inputs, thereby successfully addressing the limitations of earlier variants.

Strengths and Limitations

It should be noted that, unlike previous studies which relied on recalled questions or researcher-derived answers [9,10], commercially available past examinations were used in this study to ensure a more accurate and reliable assessment, making it a strong point of our research. Nonetheless, this study had several limitations. First, the LLMs were only asked each question once; however, LLMs are generative models, often referred to as "probabilistic parroting" models [24]. This is because they generate answers based on the probability of selecting the most appropriate word from the training data. Consequently, different answers can be returned for the same question with a certain probability when asked multiple times [25]. To address this problem, it is necessary to ask the same question multiple times and assess the degree to which the answers fluctuate. Second, ChatGPT responses can be interspersed with answers based on false evidence or factual errors, commonly referred to as "hallucinations," which is the phenomenon of asserting incorrect content as if it were correct [26,27]. Even though such responses can be determined to be false by specialists, they can confuse doctors during training. This phenomenon occurs even as the correct-answer rate of the model improves—that is, the greater the confidence in responses, the more difficult it can become to identify incorrect information. Third, LLMs—including ChatGPT—are updated periodically, which could alter their correct-answer rate or incur unexpected pretraining as the questions are entered.

Consequently, the reproducibility of test results in future studies remains uncertain. Finally, we used a relatively small number of questions, which could have resulted in an inadequate analysis, particularly for the category-specific correct-answer rate. The differences in the correct-answer rate between GPT-4o and GPT-4 were substantial in the fields of cardiovascular surgery, digestive surgery, and breast and endocrine surgery; however, differences in other fields were minimal, which could be attributed to the limited sample size. If the JSBE is able to obtain more high-quality problems as it continues to hold more events, it could be possible to evaluate models with an even greater correct-answer rate.

In conclusion, GPT-4o outperformed GPT-4 for the JSBE. Although there is still room for improvement in image recognition and clinical applications, which should be approached with caution, the results suggest that improved models and pretraining could provide LLMs with more accurate medical knowledge and enhance their clinical judgment, which could be useful in enhanced learning for surgeons.

Abstract

Background: Generative artificial intelligence (AI) has shown rapid advancements and increasing applications in various domains, including health care. Previous studies have evaluated AI performance on medical license examinations, primarily focusing on ChatGPT. However, the availability of new online chat-based large language models (OC-LLMs) and their potential utility in pharmacy licensing examinations remain underexplored. Considering that pharmacists require a broad range of expertise in physics, chemistry, biology, and pharmacology, verifying the knowledge base and problem-solving abilities of these new models in Japanese pharmacy examinations is necessary.

Objective: This study aimed to assess the performance of 18 OC-LLMs released in 2024 in the 107th Japanese National License Examination for Pharmacists (JNLEP). Specifically, the study compared their accuracy and identified areas of improvement relative to earlier models.

Methods: The 107th JNLEP, comprising 345 questions in Japanese, was used as a benchmark. Each OC-LLM was prompted by the original text-based questions, and images were uploaded where permitted. No additional prompt engineering or English translation was performed. For questions that included diagrams or chemical structures, the models incapable of image input were considered incorrect. The model outputs were compared with publicly available correct answers. The overall accuracy rates were calculated based on subject area (pharmacology and chemistry) and question type (text-only, diagram-based, calculation, and chemical structure). Fleiss' κ was used to measure answer consistency among the top-performing models.

Results: Four flagship models—ChatGPT o1, Gemini 2.0 Flash, Claude 3.5 Sonnet (new), and Perplexity Pro—achieved 80% accuracy, surpassing the official passing threshold and average examinee score. A significant improvement in the overall accuracy was observed between the early and the latest 2024 models. Marked improvements were noted in text-only and diagram-based questions compared with those of earlier versions. However, the accuracy of chemistry-related and chemical structure questions remains relatively low. Fleiss' κ among the 4 flagship models was 0.334, which suggests moderate consistency but highlights variability in more complex questions.

Conclusions: OC-LLMs have substantially improved their capacity to handle Japanese pharmacists' examination content, with several newer models achieving accuracy rates of >80%. Despite these advancements, even the best-performing models exhibit an error rate exceeding 10%, underscoring the ongoing need for careful human oversight in clinical settings. Overall, the 107th JNLEP will serve as a valuable benchmark for current and future generative AI evaluations in pharmacy licensing examinations.

KEYWORDS

generative AI; artificial intelligence; ChatGPT; Gemini; pharmacist; National License Examination

Introduction

Generative artificial intelligence (AI) development has been remarkable in recent years and has been adopted in many fields, including education and health care. There have been reports that generative AI has been used to summarize clinical texts [1-4] and has been introduced into clinical practice [5,6]. Furthermore, the potential benefits of generative AI in medical education have been explored [7-10], and its usefulness has been demonstrated in the writing and publishing of medical research [11].

In the United States, generative AI has been implemented in 86% of health care organizations [12]. Moreover, approximately 40% of health care professionals use generative AI at their workplaces at least once a week [13]. Correspondingly, online chat-based large language models (OC-LLM) have attracted the attention of many users because of their ease of use. In health care, the use of OC-LLMs can have serious consequences if their performance is inadequate. Therefore, verifying the knowledge base and problem-solving capabilities of OC-LLMs in health care settings is essential.

A wealth of information is available on the web in the medical and health care domains, and OC-LLMs acquire a substantial amount of knowledge during pretraining. In addition to general medical knowledge, pharmacists must have expertise in fields, such as physics and chemistry, which differ from those required by other health care professionals. However, few studies have evaluated the performance of OC-LLMs in pharmacies. The performance of ChatGPT (GPT-3.5 and GPT-4V models) in the Japanese National License Examination for Pharmacists (JNLEP) was evaluated by Sato and Ogasawara [14]. Since then, numerous new OC-LLM services and models have been released in 2024. However, the performance of these newly released models in the field of pharmacy has not been sufficiently evaluated. Furthermore, it was hypothesized that each OC-LLM service (ie, ChatGPT, Gemini, Claude, and Perplexity) has distinct strengths and limitations.

Accordingly, the purpose of this study is to evaluate the performance of various OC-LLMs introduced in 2024 in the field of pharmacy using the JNLEP and to assess performance improvements in the latest models.

Methods

Services and Models

The following 18 OC-LLMs, all available as of 2024, were evaluated (Table 1): ChatGPT (7 models), Gemini (4 models), Claude (5 models), and Perplexity (2 models). Claude 3.5 Sonnet (new) was renamed as Claude 3.5 Sonnet in June 2024, and as of January 2025, these models are the most commonly used OC-LLMs. Microsoft Copilot, one of the most popular OC-LLMs [15], was excluded because its underlying engine, GPT-4 (released in 2023), was evaluated in a previous study as the model used in ChatGPT and is mainly used for tasks other than digital browser-based dialogues. Although Copilot has continued to improve in terms of functionality and performance, the details of its current model and update history remain undisclosed. Consequently, this was excluded from the 2024 OC-LLM performance evaluation in this study.

Table . Characteristics, release dates, and evaluation dates of the OC-LLM[a] services and models used in this study.

Service and model	Deprecated or active[b]	Uploadable image	Release date[c]	Evaluation date[d]

[d]Performance evaluation date of each model used in this study.

Japanese National License Examination for Pharmacists

This study used 345 questions from the 107th JNLEP held in February 2022. This dataset is the same as that used by Sato and Ogasawara [14]. The questions in the 107th JNLEP are organized into the following 9 subject categories: physics, chemistry, biology, hygiene, pharmacology, pharmaceuticals, pathophysiology, regulations, and practice. All questions were presented in a multiple-choice format, requiring the selection of 1 or 2 correct answers from the 5 options. The passing criteria for the 107th JNLEP included an overall accuracy of at least 62.9% along with 2 additional conditions. The details of the 107th JNLEP were extensively covered by Sato and Ogasawara [14].

Data Measurement

All OC-LLMs, except for ChatGPT GPT-4, were evaluated for their performance from May to December 2024. The data outcomes for ChatGPT GPT-4 were collected from a preliminary study conducted in November 2023 [14]. For ChatGPT GPT-3.5, a preliminary test was conducted in February 2023. However, a new evaluation was conducted in May 2024 to assess the potential performance improvements in the same model.

For all models, the complete set of questions from the 107th JNLEP was input in Japanese in order of the question numbers. Although response performance can be improved through prompt engineering [16-18], no prompts were used in this study.

For questions that included diagrams or charts, the questions and options were input as text, whereas the diagram or chart portion was input as an image. Some early models could not process the diagrams (Table 1); therefore, these questions were omitted and marked as incorrect.

Data Analysis

The output from each OC-LLM was compared with publicly available correct answers [19] to determine whether the responses were correct or incorrect. An incorrect answer (ie, hallucinations) was defined as a response in which the selected answer differed from the published correct answer, the specified number of answers was not selected, or no answer was provided.

Even when the correct option number could not be explicitly identified in the output by the OC-LLMs, the response was considered correct if the selected content matched the correct answer choice. The accuracy of each model was evaluated based on the total number of subjects and question types (text only, including diagrams, calculations, chemical structures, and graphs). Question-type classification was subjectively determined by the researcher based on the content of the questions. Questions with diagrams were also counted as those containing graphs or chemical structures. The calculated questions included text-only and diagram-based questions.

To assess improvements in model accuracy, statistical comparisons were performed between the 3 model outputs (ChatGPT GPT-4, Gemini 1.0 Pro, and Claude 3 Sonnet) released in early 2024 and those of the latest 4 flagship models (ChatGPT o1, Gemini 2.0 Flash Experimental, Claude 3.5 Sonnet [new], and Perplexity Pro).

Answer consistency was used to validate whether the tasks in which the generative AI model excelled or struggled showed similar trends across models based on the highest accuracy model of each service.

Statistical Analysis

A generalized linear mixed model (GLMM) was used to evaluate the accuracy improvements. The correctness of the responses to each question was set as the dependent variable. The model type (early or latest), question type (text-based or diagram-based), and their interactions were specified as fixed effects. Models and questions were included as random effects. Fleiss' κ [20] was used to assess the consistency of responses. All statistical analyses were performed using R (version 4.4.2; R Foundation for Statistical Computing).

Results

Performance Statistics of AI Models

The performances of 18 generative AI models from 2024 in the pharmaceutical field were evaluated (Table 2). The performance of the 4 flagship models (ChatGPT o1, Gemini 2.0 Flash Experimental, Claude 3.5 Sonnet [new], and Perplexity Pro) was over 80%, which was markedly higher than that of the passing criteria. When reassessed, ChatGPT GPT-3.5 recorded an overall accuracy of 38.8% (134/345), indicating no marked progress from its former performance of 35.4% (122/345), showing no substantial improvement.

Table . Overall accuracy of each OC-LLM[a] on the 107th JNLEP[b].

Service and model	Correct answers[c]	Overall accuracy	Passing criteria[d]
ChatGPT			
GPT-3.5	134	0.388	Failed
GPT-4o mini	215	0.623	Failed

[a]OC-LLM: online chat-based large language.

[b]JNLEP: Japanese National License Examination for Pharmacists.

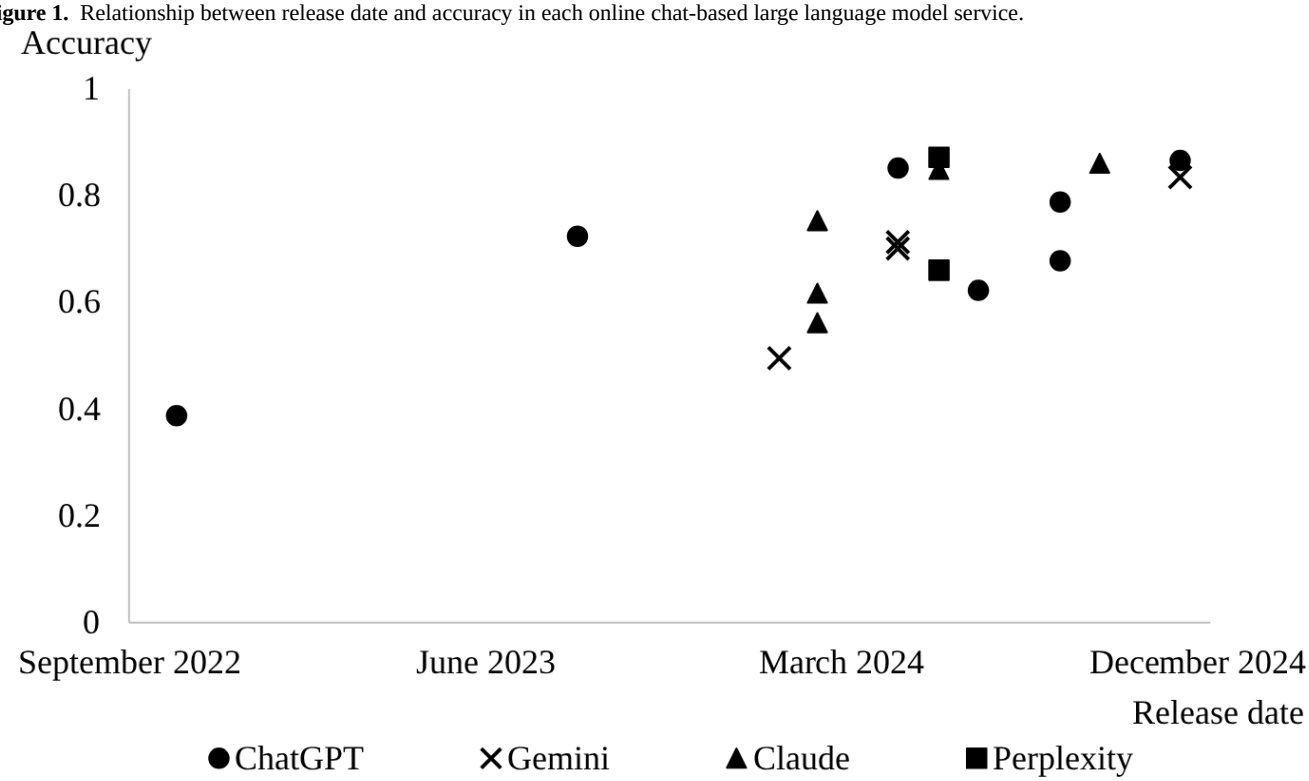
[c]Number of correct answers out of all 345 questions in the 107th JNLEP.

[d]Overall accuracy>62.9%.

[e]GPT-4 results were obtained from Sato and Ogasawara [14].

For all services, the model enhancements were confirmed to result in increased accuracy. All the models released after September 2024, regardless of whether they were light, medium, or high, met the qualification criteria (Figure 1). All GPT-4 results were obtained from Sato and Ogasawara [14]. The raw data of each model's item-by-item correctness are presented in Multimedia Appendix 1.

Figure 1. Relationship between release date and accuracy in each online chat-based large language model service.



Performance of AI Models According to Subject and Question Type

By subject, pathophysiology and pharmacology showed high accuracy for all models except for the ChatGPT GPT-3.5 model. In the most recent models, the accuracy in pharmaceuticals and biology improved substantially, whereas in physics and chemistry, only minor improvements were observed (Table 3). In the 4 flagship models, the average accuracy based on subject was lowest for chemistry (10.3/20, 51.3%), followed by physics (15.3/20, 76.3%). All the other subjects achieved an accuracy exceeding 80%.

For questions that consisted of only text, most models exhibited high accuracy, with a few exceptions. Three models (ChatGPT o1 preview, ChatGPT o1, and Perplexity Pro) showed a correct answer rate of over 90%. The accuracy decreased greatly for questions that included diagrams; the average of all 18 models was 36.7% (22.4/61) and was 50.8% (31.0/61) when models that could not input diagrams were excluded. For questions that included figures, Claude 3.5 Sonnet (new) showed the highest accuracy (47/61, 77%). For the calculation questions, the most recent model showed an improvement in accuracy but did not achieve high accuracy for questions that included chemical structures (Table 4).

[a]OC-LLM: online chat-based large language model.

[b]JNLEP: Japanese National License Examination for Pharmacists.

[c]GPT-4 results obtained from Sato and Ogasawara [14].

[d]The mean (SD) for text is 0.788 (0.131), diagram is 0.367 (0.279), calculation is 0.580 (0.219), graph is 0.333 (0.257), and chemical structure is 0.254 (0.213).

Statistical Analysis of Improved Accuracy and Response Consistency

The GLMM analysis demonstrated that the accuracy of the latest flagship models was significantly higher than that of earlier models (P<.001). In addition, questions containing diagrams had significantly lower accuracy than that of text-only questions (P<.001). The interaction term between the flagship status and question type was not significant (P=.53). Therefore, the difference in accuracy between the early and most recent models was consistently observed, regardless of whether the questions included diagrams or were text-based. Moreover, the flagship models did not show a greater improvement in the accuracy of diagram-based questions. The Fleiss' κ value was 0.334, thus verifying the consistency of each question for the 4 flagship models in the 345 questions.

Discussion

Overview

This study evaluated the performances of 18 generative AI models in the pharmacy field by applying the same prompt to an identical input task of the 107th JNLEP. Although previous studies evaluated the performance of generative AI in the health care field using several models, this study is the first to directly compare several OC-LLMs under identical conditions for the same task. Recent meta-analyses have evaluated the performance of generative AI in health care [21,22]. However, as individual

studies differ in language, prompts, and input tasks, inherent limitations exist in terms of interpreting these results.

Among these models, Perplexity Pro achieved the highest overall accuracy (301/345, 87.2%). When restricted to text-only questions, the ChatGPT o1 preview demonstrated the highest accuracy (271/284, 95.4%). For questions including diagrams, Claude 3.5 Sonnet (new) demonstrated the best performance (47/61, 77%). In early multimodal models, such as ChatGPT GPT-4 and Gemini 1.0 Pro, the accuracy for questions with diagrams was low. However, the accuracy of the latest versions of the flagship models has significantly improved. These findings indicate that the ability to recognize diagrams advanced markedly over the past year.

In terms of overall accuracy, the 4 flagship models exceeded not only the passing criteria but also the average examinee score of 68.2% [14]. This suggests that the current generative AI may possess a more extensive knowledge base than that of novice human pharmacists. However, even the best models had over 10% incorrect answers (ie, hallucinations); therefore, these models must be interpreted with caution, especially in health care.

Subject-specific analysis demonstrated accuracy improvements for all subjects when using the latest 4 flagship models. The performance for the subjects of hygiene and regulations tends to be weaker [16,23,24]. This is likely due to the influence of country-specific health care systems and social contexts, which may not be fully covered by pretraining data. In addition, the low accuracy observed in basic science subjects (physics, chemistry, and biology) is consistent with the trends reported in previous studies [25]. However, even in these subjects, improvements in accuracy were observed with the 2024 flagship models; hence, previous weaknesses may have been overcome. This improvement is likely attributable to the enhanced training data, increased model parameters, and the implementation of multimodal and reasoning capabilities. Although improvements in accuracy were observed, the flagship models still showed low accuracy in subjects, such as chemistry (10.3/20, 51.3%) and physics (15.3/20, 76.3%). This may be because these subjects included many questions that required abilities beyond factual knowledge, including calculations and image recognition. Low accuracy in chemistry has also been reported in previous studies [26].

Question type–specific analysis revealed lower accuracy for items that required image recognition or calculation, relative to text-only questions. Considering that image recognition and calculation are abilities that conventional large language models are not designed to handle and are acquired later through multimodal integration, the insufficient performance in this domain may be due to the incomplete maturation of learning.

Among the diagram-based questions, those involving chemical structures exhibited the lowest accuracy. The small mean and SD across all models for chemistry indicate that the performance of the current models did not show a considerable improvement. This may be because of two factors: (1) chemical structures are foundational scientific knowledge needed exclusively by pharmacists, leading to limited web-based availability (ie, reduced opportunities for large language model pretraining); and (2) interpreting chemical structures requires more sophisticated image recognition skills than that required for the interpretation of tables or graphs.

Claude 3.5 Sonnet (new) demonstrated the highest accuracy across all 3 types of questions—computation, graph interpretation, and chemical structure recognition. However, Claude's flagship model showed lower accuracy for text-based questions than that of the ChatGPT and Perplexity flagship models. Therefore, a novel finding of this study is that the top-performing model differed according to the question type.

The GLMM analysis demonstrated a significant increase in overall accuracy by 2024. Although improvements in the accuracy of the questions containing diagrams were observed in the individual models, these differences were not statistically significant. The tendency for lower accuracy on diagram-based questions persisted even in the flagship models.

According to Landis and Koch [27], a Fleiss' κ of 0.344 among the 4 flagship models indicates a certain degree of consistency. This result suggests that although these models handle simpler questions similarly, their incorrect answers differ across more challenging questions, thus indicating variations in their strengths and weaknesses. Initially, it was hypothesized that the types of questions with which each OC-LLM service struggles would differ. Correspondingly, the observation that even the flagship models with high overall accuracy failed to achieve substantial response agreement, as measured by the κ coefficient, supports this hypothesis. Therefore, identifying the specific domains in which each OC-LLM service underperforms remains an important subject for future research, including meta-analysis.

In this study, each model was evaluated using the same task to compare their performance directly. Some models included in this study have been deprecated and are no longer available. Although many new OC-LLMs are expected to emerge in the future, evaluating their performance using the 107th JNLEP will enable their comparison with previous models. Ultimately, the 107th JNLEP can serve as a benchmark for evaluating the performance of generative AI models in the field of pharmacy in Japan.

In this study, questions from the Japanese National Pharmacist Examination were input in Japanese in their original format. Translating non-English tasks into English should improve the accuracy of AI [28-31]. Therefore, this study evaluated the performance of AI models in the pharmaceutical field using Japanese input. However, higher accuracy may be achieved when questions are input using English translations. The accuracy of each model is based on the evaluation time, and the same model may show improved performance due to upgrades. Perplexity has been upgraded multiple times; however, the available models remain as Standard and Pro versions, and the version information is not disclosed to users.

Although the highest-performing model among the 18 OC-LLMs in this study achieved an accuracy of 87.2% (301/345), it also indicated that over 12.8% (n=44 questions) of the responses were incorrect (ie, hallucinations). With the improved performance of the OC-LLMs, it is anticipated that their use by medical and pharmacy students for inputting national

examination questions for self-study will increase. However, as the latest models generate logical and fluent answers, it has become increasingly difficult to identify hallucinations. Even when using flagship models in 2024, the following approaches to reduce the risk of hallucinations are required in medical applications: limit use to cases in which users can independently determine the correctness of the output or confirm the supporting source information through the links provided.

The performance improvements of the OC-LLMs in this study may facilitate their broader integration into routine pharmacy practice in the near future. In clinical pharmacy practice, responding to inquiries from patients and health care professionals regarding drug information is a frequent task. These inquiries include questions about adverse drug reactions, drug interactions, dosage adjustments, or contraindications. Suitably, support from high-performance OC-LLMs is expected to improve the quality of responses and reduce the time required to address such inquiries. The use of OC-LLMs in direct medical support, for example, in selecting personalized pharmacological treatments, requires careful consideration of ethical issues, such as explainability, responsibility, privacy, and patient rights.

Principal Findings

This study evaluated the performance of 18 OC-LLMs available in 2024, based on questions from the National Pharmacist's License Examination in Japan. As the models were upgraded, their accuracy improved. The performance of the flagship models exceeded both the passing criteria and the examinees' average score. In the latest versions of the OC-LLMs, enhancements in multimodal capabilities significantly improved accuracy in both interpreting charts and figures and solving calculation-based questions. Furthermore, the answer consistency of the flagship models was not robust, which suggests that each model had different strengths and weaknesses.

Limitations

In this study, only a single set of examination questions was tested, and each question was entered only once. Generative AI has a characteristic known as temperature, which refers to the inherent variability in its responses. This means that the model can generate different answers even when given the same question. Therefore, if the test is repeated, the accuracy of each OC-LLM method can vary. Several studies have evaluated OC-LLM performance by testing questions over multiple years [32-34] or conducting multiple rounds of testing [35]. However, similar to many previous studies, to evaluate the 18 models within a limited time frame, only 1 set of questions was administered per examination year to each model. Human examinees also underwent the national pharmacist's examination only once, rendering the testing conditions comparable. The 107th JNLEP comprises 345 questions, with multiple items allocated to each subject and question type. Therefore, the examination is considered sufficient to allow for a certain degree of interpretation.

With the progressive improvement of the models over time, the top-performing service shifted from ChatGPT to Claude, and subsequently to Gemini. Across OC-LLM services, such as ChatGPT, Gemini, Claude, and Perplexity, no consistent patterns were observed across subjects or question types. Considering that the key information, such as the volume of pretraining data, number of parameters, and tuning strategies of these OC-LLMs, is not publicly disclosed, fully discussing the factors that contribute to their improved performance in the pharmaceutical field is difficult. These factors include understanding of diagrams, chemical structures, and calculation-based questions.

Comparison With Prior Work

Numerous studies have evaluated the performance of OC-LLM in terms of knowledge of health care license examinations (Table 5). Early OC-LLMs failed the National Medical License Examination; however, the subsequent release of high-performance OC-LLMs met the passing criteria.

The reported OC-LLMs in Table 5 are biased toward ChatGPT, and the challenges and conditions vary according to each report on medical performance. Moreover, the performance of OC-LLM declines in languages other than English because of the smaller volume of training data [18,25,34-36]. Therefore, verifying the performance of OC-LLM in non-English languages is important. An important contribution of this study is its demonstration that multiple flagship OC-LLMs substantially outperform the passing criteria in areas where prior evidence is scarce, specifically in non-English languages and the pharmaceutical field. Achieving high response accuracy from OC-LLMs using non-English prompts has considerable implications for clinical implementation in health care settings in Japan (and other non-English–speaking regions).

One of the major strengths of this study is its systematic evaluation of multiple OC-LLMs released in 2024 under identical input conditions, such as the same prompt text and image resolution or size. To the best of our knowledge, this is the first study to evaluate the longitudinal improvement in generative AI performance in medical examinations.

[a]AI: artificial intelligence.

[b]OC-LLM: online chat-based large language model.

Conclusions

This study reveals that the performance of OC-LLMs in the pharmaceutical field has greatly improved as of 2024. Particularly, an increase in accuracy was observed for questions with diagrams. In the most recent version of the models, evaluated in 2024, the overall accuracy reached 85%, markedly exceeding the average examinee score, and indicating their potential as valuable support tools. Although caution is necessary due to the potentially serious impact of hallucinations on health care, the benefits of OC-LLMs outweigh the associated risks. Accordingly, health care professionals and medical educators must acquire the skills necessary to effectively use OC-LLMs, particularly the ability to recognize and manage hallucinations.

Data Availability

The datasets analyzed during this study are available in the Ministry of Health, Labour and Welfare in Japan repository [19].

Conflicts of Interest

None declared.

Abstract

Background: Artificial intelligence (AI) has revolutionized medical education by delivering tools that enhance and optimize learning. However, there is limited research on the medical students' perceptions regarding the effectiveness of AI as a learning tool, particularly in Sri Lanka.

Objective: The study aimed to explore students' perceived barriers and limitations to using AI for learning as well as their expectations in terms of future use of AI in medical education.

Methods: An exploratory qualitative study was conducted in September 2024, involving focus group discussions with medical students from two major universities in Sri Lanka. Reflexive thematic analysis was used to identify key themes and subthemes emerging from the discussions.

Results: Thirty-eight medical students participated in 5 focus group discussions. The majority of the participants were Sinhalese female students. The perceived benefits included saving time and effort and collecting and summarizing information. However, concerns and limitations centered around inaccuracies of information provided and the negative impacts on critical thinking, social interactions (peer and student teacher), and long-term retention of knowledge. Students were confused about contradictory messages received from educators regarding the use of AI for teaching and learning. However, participants showed an enthusiasm for learning more about the ethical use of AI to enhance learning and indicated that basic AI knowledge should be taught in their undergraduate program.

Conclusions: Participants recognized several benefits of AI-assisted learning but also expressed concerns and limitations requiring further studies for effective integration of AI into medical education. They expressed openness and enthusiasm for using AI while demonstrating confusion and reluctance due to the perspectives and stance of educators. We recommend educating both the educators and learners on the ethical use of AI, enabling a formal integration of AI tools into medical curricula.

medical students; AI in medical education; attitudes; perspectives; learning; qualitative study

Introduction

As the information age wanes with the rise of artificial intelligence (AI), a global trend has risen to implement AI to enhance the effectiveness of the health care system [1]. Notably, diagnosis and treatments for several diseases can now be performed faster and more precisely with the use of AI in clinical medicine [2,3], giving both doctors and patients easier pathways to navigate diseases than ever before. Consequently, attention is being drawn to how the medical workforce can be ready for this transition and, thus, to investigating how the education of future health care professionals can best be delivered to achieve the futuristic goals of clinical practice [4]. As evidenced by the COVID-19 pandemic, AI poses a significant impact on medical education, with the ability to provide medical students with an interactive learning environment, creating virtual simulations allowing learners to practice complex or risky clinical procedures on virtual patients without endangering actual patients [5-8]. The development of ChatGPT, a new AI-driven language model, showcased its potential for assisting learners in self-directed learning while highlighting ethical issues [9].

The World Medical Association and the Standing Committee of European Doctors advocate for the use of AI systems in basic and continuing medical education [10,11], highlighting the need for increasing awareness of the proper use of AI in graduate, postgraduate, and continuing medical education. However, existing literature on AI emphasizes the inability of today's

medical education to meet the needs of AI, proposing a fundamental change in education to achieve the goals stated by the World Medical Association [2,3,11-13]. An in-depth understanding of how the current medical student perceives the use of AI in their education and their comprehension of limitations, challenges, and future projections is vital for integrating AI into existing medical curricula. Many studies have investigated the students' perceptions regarding AI in medicine and medical education in countries such as the Republic of Korea [14], Germany [15,16], the United Kingdom [17,18], Canada [19,20], the United States [21], India [22], Pakistan [23], Australia and New Zealand [24], Malaysia [25], Turkey [26], Palestine [27], Saudi Arabia [28], Egypt [29], Syria [30], Jordan [31], the United Arab Emirates [32], and Kuwait [33], and it is worth noting that such examinations are still notably absent in the context of Sri Lanka, a developing island nation in the Asian continent. This scarcity is noteworthy, especially when considering Sri Lanka's recognized status as a quality health care provider and its contribution to skilled labor migration for developed countries [34]. Recognizing the overwhelming importance of incorporating AI into medical education, this study aims to explore medical students' perceptions toward AI in education, in terms of the barriers and challenges the students face when using AI in their education, and investigate the future projections of AI into medical education in the eye of the medical student. The findings will aid in making beneficial decisions regarding the inclusion of AI in medical curricula in the future while filling a niche in AI literature on undergraduate medical education.

Methods

Study Design

An exploratory qualitative study was conducted in September 2024 using focus group discussions to gather medical undergraduates' perspectives on using AI in their education. Our objective was to identify barriers and challenges the students face when using AI in their education and to investigate the future projections as perceived by learners to improve their learning experience. We adopted a constructivist approach with the understanding that meaning is constructed through dialog between the researcher and the researched [35]. Semi-structured focus group discussions enabled an in-depth exploration of the student participants' subjective reality and experiences [36] in using AI in their education and the freedom to consider different issues [37] as the discussions were co-constructed by the researcher and participant [38].

Ethical Considerations

After obtaining the ethics approval from the Ethics Review Committee, Faculty of Medicine, University of Peradeniya (ERC No: 2024/EC/27), general information about the study was shared with potential participants via WhatsApp groups. Third- and fourth-year medical students of the Faculty of Medicine, University of Peradeniya, and the Faculty of Medicine, University of Kelaniya, were recruited to the study. Students were informed via the information sheet of the voluntary nature of participation, their right to refuse to participate or answer any specific questions, and to withdraw from the study at any time. Informed consent was obtained from all participants. No personally identifiable information was collected, aside from participants' ethnicity and year of study. All data were securely stored on a password-protected platform, accessible only to the research team. All data collected was anonymized. Purposive sampling was carried out at this stage. To ensure maximal variation sampling, we recruited student volunteers of different genders and ethnic groups, including students from the foreign quota. The interviews were conducted in compliance with the standards for reporting qualitative research set by the Consolidated Criteria for Reporting Qualitative Research (COREQ) [39]. Participants did not receive any incentives for participating in the focus group discussions.

Designed Focus Group Discussion Protocol

The focus group discussions were facilitated by two trained researchers (KK and WP) in September 2024. The objectives of the present study were explained at the beginning of each focus group, and verbal consent was obtained from each participant. The participants were provided with essential background information. No extra questions were asked after the focus group discussions, no additional information was given by the facilitators, and no other questions were requested subsequently. Only the facilitator and the focus group participants were present for the focus group discussions. Other individuals were not allowed to attend the focus group discussions to ensure the privacy and confidentiality of the discussion. Before recording the responses, permission for audio recording was requested by the facilitator verbally and via the written consent form.

Data Collection

The participants in the focus group discussions met with a trained research assistant to provide their details and to hand over the consent forms. The time and venue of the focus group discussions were decided at this meeting. We conducted focus group discussions in English using a semi-structured interview guide, which explored how medical students felt about using AI in their education. The questions for the interview guide were extracted from previous similar research [19,27].

We investigated medical students' perceived barriers and limitations to using AI for learning, as well as their expectations in terms of future use of AI in medical education. The open-ended questions served to guide, but not constrain, the interview. We encouraged the participants to describe their experiences. We emboldened them to react to each other's opinions and generate new ideas from different points of view. We arranged and conducted focus group discussions, commencing with the first responders. When two successive focus group discussions yielded no novel themes and only repeated ideas, indicating thematic redundancy, we considered that data saturation had been reached [40]. Two trained researchers (KK and WP) conducted all the focus group discussions. Each focus group consisted of 7-9 students. Each focus group discussion lasted 1-1.5 hours and was held at the Faculties of Medicine, University of Peradeniya and University of Kelaniya. With the consent of the students, we audio taped the discussions for later transcription. We informed participants that their identities would remain confidential, and their views

and opinions would be anonymized. We removed all identifiable features during transcription. Participants were informed that the focus group discussions constituted part of a research project, and the findings might be published and used to improve medical education.

Data Analysis

Reflexive thematic analysis (TA) [41-43] was used to analyze the data from the focus group discussions. The qualitative data analysis coincided with the focus group discussions, allowing the researchers to gather information until data saturation. We removed all identifying features during transcription. In analyzing the focus group data, the reflexive element meant that we interpreted the data through our lens of experience as educators, centrally recognizing our subjectivity and seeking to develop a sense of meaning from our responses. As a result, our reflexive analysis of the data led to the output of codes, subthemes, and overarching themes through the coding process [43] and thus represents the reflexive TA approach. This method was structured around the common six-step process for TA as described by Braun and Clarke [41]. Using a sentence-by-sentence process, we manually coded each transcript and sorted the talk into categories and subcategories. All transcripts were coded by two authors (IA and WP). An open coding scheme was used for the first interview. After achieving consensus among the authors, this coding frame was used to code the remaining four transcripts. The authors compared coding for consistency to ensure a common language. We identified commonalities and differences across all interviews before regrouping the codes into themes. We compared interpretations and discussed them among all authors until there were no discrepancies. The authors reached a consensus regarding verbatim remarks selected to highlight the relevant subthemes arising from the analysis.

Research Team and Reflexivity

Project conception and survey design were performed by TS, who is a consultant pediatrician and a senior lecturer in Pharmacology who believes that AI training in medical education is important and has published similar work. KK is a lecturer in medical education who holds a PhD, with a qualitative and quantitative research background in medical education. Some of the focus group participants were personally known to TS, while all participants were unfamiliar to the second facilitator (KK) and the rest of the research team (IA and WP).

To enhance the credibility of this study, TS, who personally knew some participants and held a senior academic position, refrained from conducting the focus group discussions to minimize the influence of positional authority. KK and WP, to whom the participants were unknown, conducted the focus group discussions. Moreover, member checking on the accuracy of transcriptions was done. All transcripts were coded independently by two authors (IA and WP) who were not directly involved in prior AI-related research. Regular meetings were held to discuss coding decisions and reconcile discrepancies through consensus. We discussed the developed themes and subthemes with KK, an experienced qualitative researcher. TS participated in later stages of theme development, in order to enhance the neutrality and trustworthiness of the analysis. All four authors discussed our own biases to become aware of and be transparent about our perspectives, personal feelings, and preconceptions, and we considered these critically concerning the research being conducted [44]. All authors discussed and resolved any disagreements regarding coding or developing themes. All interpretations were critically reviewed by the entire research team to ensure they were grounded in the raw data. To contribute to the dependability of the data, we kept a reflexivity diary to reflect on the process [45]. We did this because TS is a senior lecturer who had previously contributed to the development of an AI tool used for assessing answers to short answer questions and who believes that AI training in medical education is important. We were cognizant, therefore, that TS may have a propensity to seek the positive elements of the data. In the focus group discussions, KK and WP encouraged participants to express both their positive and negative perceptions, and we consciously sought divergent opinions within the data during analysis. KK and WP emphasized to participants that whatever they mentioned in this study would not affect them in any way in their assessments. To further improve the validity of the findings, all coauthors cross-checked the analysis of all five transcripts.

Results

Participants' Characteristics

In the current study, 38 undergraduate medical students participated in the five focus group discussions. Twenty-two out of 38 (60%) participants were Sinhalese, complying with the composition of the student cohorts in the universities where the study was conducted. Table 1 shows the composition of the focus group discussion participants.

Table . Composition of focus group discussion participants.

FGD[a] no	Total number of participants	Gender		Year of study		Ethnicity			
		Male	Female	3	4	Sinhalese	Tamil	Muslim	Other
1	7	4	3	7	0	5	0	2	0
2	8	3	5	0	8	5	1	0	2
3	7	3	4	0	7	5	1	1	0
4	9	4	5	9	0	5	1	2	1
5	7	2	5	7	0	3	0	3	1

[a]FGD: focus group discussion.

Three major themes emerged from the qualitative analysis: satisfaction with the perceived benefits of using AI for learning, negative attitude toward AI for learning due to perceived limitations, and optimism about the future use of AI to enhance student learning. The themes, subthemes, and initial codes are shown in Table 2.

Table . Identified themes, subthemes, and codes.

Themes	Subthemes	Codes
Satisfaction with the perceived benefits of using AI[a] for learning,	Improvement of knowledge	AI for supplementary learning, AI enable identification of knowledge gaps, using AI for problem solving, Using AI for in-depth learning, AI as an enabler of exploration and knowledge expansion, using AI for learning new words/unfamiliar content, AI for preliminary learning, AI for foundational learning.
	Enhanced efficiency	Ease of use of AI tools, using AI is time-saving, AI enables ease of access to information, AI provides streamlined information, AI gives focused answers, AI is useful for organizing information, AI helps directed learning, AI gives quick solutions, AI helps faster reading, using AI requires fewer resources for learning, AI simplifies content.
Negative attitude towards AI due to perceived limitations	Issues with relevance and accuracy	AI gives contradictory information, reliability concerns, no personalization of AI-generated responses, selective applicability of AI, contextual limitations of AI data, AI is fact-centered, AI generates less precise information, AI provides over-generalized information, teachers' preference for authenticity, need for cross-checking AI information, AI emphasizes minor issues.
	Impact on critical thinking skills	AI promotes surface-level thinking, use of AI causes passive learning, use of AI reduces reasoning ability, use of AI reduces generative ability, AI hinders independent thinking, use of AI reduces creativity.
	Impact on knowledge retention	AI enables short-term memory; using AI reduces long-term memory.
	Impact on collaborative learning and motivation	Use of AI reduces engagement, use of AI reduced peer interactions and fear of social isolation, using AI limits active participation, AI reduces learner motivation for engagement, AI reduces motivation for learning, using AI undermines learner preparation.
Optimism about the future use of AI to enhance student learning	Emerging awareness to guide for better use of AI for learning	AI for objective tasks, selectivity of AI for proper use, not using AI to obtain visual content, use AI for self-evaluation, AI as preparation for lecturer encounters, selective applicability of AI.
	Experiential learning to expand use of AI for learning	Learning from experience, learning AI boundaries, lesser concerns with experience.
	Desire for formal education of AI in curricula	Including AI in teaching, formal teaching of AI, inclusion of AI in curricula, teaching how best to use AI by lecturers.

[a]AI: artificial intelligence.

Satisfaction With the Perceived Benefits of Using AI for Learning

The theme of satisfaction with the perceived benefits of using AI for learning developed over many references across all student participants. The participants explained that their motivation to use AI was driven by factors such as simplicity, time-saving qualities, and efficient access to information. The participants unanimously agreed that AI tools improve their knowledge. AI served as a starting point for understanding concepts and generating initial ideas, which participants refined or expanded later using textbooks or other sources:

> *AI is a good way to get a basic idea. Once we get that basic idea it is easy to build upon that base by referring to textbooks and other resources.* [P04]

Participants valued AI for its assistance in answering follow-up questions, clarifying concepts, and exploring unfamiliar theoretical concepts until the students understood thoroughly. As one participant pointed out:

> *We can ask the question and get an answer. We can follow up until we understand it. We can ask again and again.* [P22]

AI helped most students to learn new words and expand their knowledge by identifying gaps or what they may have overlooked when learning or answering questions. Students used ChatGPT to compare the answers and identify missing points:

> *Then I look at the ChatGPT answer and realize that I have missed some points, so then I can go back and find these points and add those as well.* [P03]

All the participants appreciated AI tools for their efficiency and ease of use. AI was seen as an easily accessible, easy-to-use tool that enabled obtaining new ideas and simplified learning, which created an appeal to engage with it for learning. As one participant expressed:

> *AI is a very easy method to get an idea about our answers and it's very interesting. I like to use it.* [P23]

AI tools were perceived to provide concise, filtered, and summarized information, which provided organized and structured answers to questions. The participants preferred AI tools like ChatGPT over other search engines such as Google because AI was identified to deliver organized and to-the-point answers to their queries:

> *Rather than Googling a question, we prefer to use AI...coz we usually get an organized, structured answer to our questions there.* [P35]

Moreover, all the student participants appreciated the time-saving nature of AI. AI helped direct learners to essential concepts, saving time by offering streamlined information. According to the participants, AI significantly reduced the time required to accomplish tasks such as answering questions:

> *It is just simple because it's time saving when we are writing answers to a theory question.* [P27]

> *It showed you the direction of where you should go when you are writing an answer or when trying to read up something more.* [P15]

The participants elaborated that the time invested in perusing multiple sources such as videos or scientific reports can now be foregone, with the use of AI that gives the required information much faster than before they used AI for learning:

> *ChatGPT gives precise and summarized answers, so it takes less time compared to things like going through Youtube to learn something….No need to refer to many resources to formulate an answer also. Therefore, it is very convenient.* [P33]

AI was used by almost all the study participants mostly as a shortcut to avoid effort in deeper understanding or problem solving. The quick solutions given by AI with focused answers were viewed as a time-saving method of learning:

> *If I have the AI tool I always just look it up and then I get the answer straight away.* [P19]

Negative Attitude Toward AI for Learning Due to Perceived Limitations

While all participants confirmed the regular use of AI tools for academic purposes, a recurring element was a lack of certainty regarding the information obtained through AI tools such as ChatGPT. All the participants described a hesitancy to use AI for obtaining factual information, stating concerns over reliability. The students described instances where the information provided by the AI tool differed significantly from textbooks and lecture notes.

> *Sometimes the facts they (AI tool) give are different from the facts in lecture notes or reference books.* [P12]

The participants were discouraged from using AI tools to learn about infections or diseases. The students did not want AI assistance to explain the clinical reasoning processes. The students noted that AI failed to account for geographic, regional, and contextual data, particularly in clinical and epidemiological aspects, and provided contradictory information when compared with trusted sources.

> *After a few tries, I have stopped using AI for clinical work. It is not that much fitting to our setting. Mostly I go according to the textbook but sometimes I clear it out with a lecturer.* [P28]

Some study participants stressed that AI-generated answers sometimes include irrelevant or rare information, which emphasized minor issues, which were viewed as unhelpful and misleading.

> *AI gives very minor details at times which are not taught during lectures, and which were not included as objectives in classes.* [P32]

Hence, the AI outputs were not accepted at face value, and the discussion revealed that students frequently resorted to cross-checking information obtained from AI tools with trusted sources such as Medscape, research articles, or lecture notes to ensure accuracy.

> *Most of the time we also cross-check with textbooks or with other articles on the internet like Medscape or research articles.* [P13]

Moreover, some students were highly dissatisfied with the lack of personalization of AI-generated answers to questions. Students found that the general, less precise, and mechanistic nature of AI-generated information is of lesser value for learning. This feeling intensified as the students felt that AI failed to account for additional details or their individual thought processes, which made students lean toward their teachers to obtain information. As one participant pointed out:

> *It is not very personified…might be a bit of a negative thing. Like a teacher would understand what you are trying to say and tell you how to get about it…. but AI can't recognize that.* [P04]

Another issue that dissatisfied some students about using AI for their learning was the perceived negative impact on their critical thinking skills. The students were reluctant to use AI as they felt that AI promoted passive learning as it merely encouraged surface-level thinking. Overreliance on AI was felt by students as leading to decreased effort in deeper thought processes, hindering independent thinking, creativity, and reasoning ability:

> *Sometimes I feel like we don't think enough, especially during clinicals. Then I get the answer straight away so when I get used to that I stop starting to think about why something is what it is… like that.* [P07]

> *Like it disturbs our thinking ability a lot because you get used to just get it from AI without doing anything of our own. We probably won't be developing…or doing any thinking of our own.* [P26]

A few participants were highly worried regarding the perceived impact AI had on their knowledge retention. Students felt that the use of AI promoted only short-term memory and worried that relying on AI would affect their long-term retention as they compared learning from AI with that of peers or their teachers:

> *When we are discussing it with others, we feel we can remember it more. If we discuss it with my friends or lecturers, it goes to long-term memory and help to remember things more clearly.* [P11]

> *Sometimes I feel reluctant to use because we don't think enough. It's like a flash in the pan.* [P33]

Another significant barrier to using AI for learning among most medical students was the perceived negative impact on collaborative learning and motivation. Use of AI by students within the classroom for readily obtaining information meant that it undermined the prior preparation of enthusiastic students, which led to demotivation, reduced engagement, and active participation in the classroom.

> *We don't have to prepare and come anymore. It (using AI) actually decreased our participation and motivation.* [P35]

The participants saw the overreliance on AI as a potential threat to peer interaction and teacher–student relationships, which culminated in fear of social isolation.

> *As of now, we still interact with all the students and the lecturers so it hasn't affected us that much yet… but if we entirely rely on those things only, it will reduce our social interactions it's highly probable that it will affect us.* [P29]

Most students were discouraged from using AI tools for their learning by the attitude the teachers showed. As one participant discussed:

> *Lectures are very unhappy if we use ChatGPT or anything of the sort. Like, if they feel like we used it for…maybe an essay or whatever, they will shout basically. It's really easy to just be away from it (AI assistance) than get shouted at you know.* [P05]

Optimism About the Future Use of AI to Enhance Student Learning

However, most of the study participants expressed an optimistic view toward the use of AI in the future. This sentiment emerged due to learning from experience that happened over time, which developed an emerging awareness about mitigating issues they encountered before. The students identified the selective applicability of AI, stating various ways in which AI can be used and where AI has failed.

> *AI is good to get answers for most MCQs and also for structured answers like one-word answers. But it can't give pictures… for example, things like that AI can't give us.* [P21]

For most of the participants, their initial concerns regarding AI reliability diminished as they gained experience with determining what to ask and how to interpret AI responses.

> *Previously we were worried. But it's not there now. Much. Like we know what should be asked from AI and what should not be asked of AI. It's good for self-evaluation because we can practice with it.* [P34]

Some participants of the study used optimism-building to prepare for lecturer encounters, which resulted in clarifying doubts and enabling deeper learning.

> *There's a limit to what you can learn from AI. But if you learn it and then come to a class, then you understand more with what the lecturer says.* [P01]

The students acknowledged that the age of AI is upon them and acutely felt the need to use AI for academic purposes.

> *It's like you can't not use it at all right? Everybody use AI for something or other so you would lose if you don't know how to use it right? So you have to learn one way or another.* [P13]

Building awareness for better use of AI resulted in a desire among the medical students for formal teaching of the ethical use of AI. Almost all students felt that if the teachers "taught" them how to use it to improve their learning, they would use it better in a more reliable manner. As one participant expressed not so eloquently:

> *If they (lecturers) taught us how to use AI properly rather than shouting at us for doing it, I think we would understand how to do it okay. Some of them (lecturers) talk sort of very… I mean look down on us completely, if they feel like we have used it in like in a presentation or anything. Is it such a big deal? Should we not use AI at all?* [P22]

Most participants of the study felt that formalizing AI learning by various means would facilitate ethical use of AI for both teaching by the teachers and learning by the students.

> *Teaching how to give the commands to ChatGPT, and like what can be done and what can't be done or things like what are the things that are okay to ask from AI… Also like what is okay to use AI for and what not to. Is it ok to get a title or a picture from AI*

or not? If you get that early on from the lecturers, then we can use it more effectively I think. [P09]

Discussion

Principal Results

AI has become increasingly integrated into educational settings, offering both opportunities and challenges. This qualitative analysis reveals a complex and nuanced picture of both enthusiasm and concerns. The majority of participating medical students believe that AI is important for enhanced learning and desire to learn more about AI for better use. We also found that despite these attitudes, there remains a reserve for using AI in education brought on by concerns about the reliability, privacy, and ethical issues and a lack of integration of AI into medical education in Sri Lanka. The clinical, scientific, economic, and ethical future of health care will be significantly impacted by AI [46]. The current generation of medical doctors is set to enter an industry that is significantly more AI - driven than it was when their training commenced. The current study opens the dialog for an inevitable yet successful implementation of AI in medical education.

The participants viewed AI tools as supplementary learning aids, helping students identify knowledge gaps and facilitating problem-solving. Additionally, AI facilitated exploration and aided learning new vocabulary and unfamiliar content, acting as both a preliminary and foundational learning resource. These capabilities align with findings that AI can provide personalized learning experiences, thereby enhancing knowledge acquisition and skill development [47]. The efficiency was identified as another significant benefit of AI tools. This was documented in previous studies where efficiency allowed students to allocate more time to higher-order thinking tasks, thereby enhancing the overall learning experience [48]. The enthusiasm shown by medical students in the global arena is reflected in the current study, who also report limited AI literacy and a wish for formal learning of AI to enhance student learning [15,49,50].

Despite its benefits, study participants were reluctant to use AI for learning mainly due to inaccuracies and contextually irrelevant information that arises from AI. Studies have revealed the necessity of learning how to manage AI-driven misinformation [51,52]. Although AI-assisted learning has been shown to promote active learning and learner engagement [53], the participants of this study perceived that relying on AI would affect long-term retention of knowledge negatively. Moreover, the study demonstrated concerns that reliance on AI may diminish critical thinking abilities. Consistently depending on AI tools has led to deteriorating basic foundational skills, critical thinking, and problem-solving skills [54]. Overdependence on AI tools has been shown to lead to cognitive offloading, where individuals rely on technology for tasks that require analytical thinking, potentially hindering the development of critical thinking skills [47]. This reliance may result in a superficial understanding of content, as students might accept AI-generated information without thorough evaluation.

Contrary to the evidence supporting enhanced collaborative learning in AI platforms [55], the present study reveals the negative impact of AI-assisted learning on collaborative learning. The participants of the study revealed a demotivation to engage with the peers and tutors for learning, due to the ease of accessing required information through AI platforms. Hence, students feared that the use of AI for learning might result in social isolation. However, students were adamant that the envisioned social isolation had only marginally affected them at present. It is important to note that these sentiments could negatively impact collaborative learning experiences and the development of communication skills, which are essential for critical thinking and knowledge application. Moreover, the participants were also concerned about the lack of personalization that human educators provide. Impersonal feedback may not address individual student needs effectively, leading to decreased motivation and engagement in learning activities [47]. These findings of this study demonstrate the importance of equipping medical students as well as educators with the tools necessary to enhance learner engagement in AI-assisted learning platforms [56].

Interestingly, the study participants appeared hopeful regarding the future use of AI to enhance their learning. The students emphasized the importance of emerging and building awareness and experiential learning to expand the use of AI for learning. The students identified the areas where AI tools fail, showing their growing awareness of the boundaries of AI-based assistance. However, they expected formal teaching of how best to use AI for learning by the faculty. This was amidst contradictory messages students received from educators that spanned a ban on incorporating AI into education to embracing AI-assisted learning. In a background where the evidence is overwhelmingly supportive of the ability of AI to enhance student learning [57], the overt reluctance of educators to accept that students are embracing the inevitable is questionable. This attitude may be because of regional factors or due to the traditional teaching/learning methods largely utilized in the education systems in Sri Lanka [58]. This sentiment may also stem from the apparent mistrust the educators may have on the reliability of AI-generated information [59] and doubts regarding students' misuse of AI tools for assignments and exams, affecting critical thinking and information retrieval skills [60]. Another study revealed that the educators were concerned about students' self-reliance on AI applications at the cost of traditional teaching methods, which might deprive them of skills best learned in person or group teaching [61]. However, overcoming such reservations is critical to keep abreast of the advancing technologies and ensure that educators facilitate medical students' learning in the age of technological revolution [62].

A recurring finding in this study was the strong student desire for guidance from faculty on how to use AI effectively for learning. However, this raises an important question: Should all medical educators, including clinicians like surgeons or pediatricians, be expected to teach AI-related content? Given the complex and evolving nature of AI and the already demanding responsibilities of clinical faculty, assigning this task universally may be unrealistic and potentially problematic. The concern is that untrained educators could unintentionally provide inaccurate or conflicting guidance, which was reflected in the confusion expressed by students in our study. Rather than

placing this responsibility on individual subject-area faculty, institutions should adopt a more structured and strategic approach. Drawing on Chan's AI Ecological Education Policy Framework, AI education should be delivered through dedicated units or trained personnel within the institution, ideally through interdisciplinary collaboration. This would ensure consistency, ethical alignment, and adaptability as AI technologies evolve [63]. Formal training and centralized resources for both faculty and students can support responsible AI use while relieving clinical educators of the expectation to independently master and teach AI tools.

While this study briefly referenced ethical concerns related to AI, it is important to more fully acknowledge the complex ethical landscape surrounding its use in medical education. Beyond data privacy and accuracy, there are deeper concerns regarding student development and equity. As Masters outlines in AMEE Guide No. 158, the use of AI tools may inadvertently undermine core competencies in learners, such as critical appraisal, summarization, and ethical decision-making, if overused or uncritically adopted. Furthermore, algorithmic bias, lack of transparency in AI-generated outputs, and passive data surveillance present significant risks to fairness, autonomy, and human dignity in the educational process. These tools can obscure the need for empathy, reflection, and professional judgment—essential traits of a medical practitioner [64].

Similarly, Alam et al argue that medical education must move beyond basic AI literacy to include a critical understanding of the ethical implications of AI-assisted learning and publishing. This includes interrogating how AI might alter authorship norms, contribute to inequities in access and performance, or even reinforce existing systemic biases if not carefully regulated [65]. The path forward, therefore, requires not just training students to use AI responsibly but also preparing institutions to adopt clear ethical guidelines and foster a culture of reflective, values-based technology use. As AI becomes increasingly integrated into medical education and health care, ethical fluency must be considered as essential as digital literacy for both students and educators.

Limitations

The present study has some limitations. The study did not quantitatively evaluate the impact of AI-assisted learning on achieving learning outcomes, satisfaction, or other measurable aspects of medical education, which could supplement the qualitative findings of this study. Additionally, since the study's focus was on understanding the perception of students, the perspectives of other stakeholders, such as the faculty and health care professionals, were not captured, and this could be explored in future research.

Conclusions

In a region where integrating AI into medical curricula is lacking, this study adds to our understanding of what medical students think about the challenges of AI tools in medical education. The present study highlights the improvement of knowledge and enhanced efficiency as the two primary advantages of AI-assisted learning as perceived by medical students. However, several concerns were interwoven within the widespread adoption of AI among the study participants. The reliance on AI was felt to have a negative impact on critical thinking and cognitive engagement, as students prioritized convenience over deep learning. Interestingly, students feared social isolation as a possible future impact of integrating AI into their learning. Students' lack of understanding of how much AI assistance is accepted at an institutional level and the need to "play" according to teacher preferences confused and hindered the students despite their enthusiasm to use AI for learning. A balanced approach is warranted to maximize the benefits of AI in education while mitigating its limitations. AI should complement, rather than replace, traditional learning methods, with educators guiding students on how to use AI effectively. Future research to explore the contextual factors and policy efforts is critical to refine AI's role in education, ensuring it enhances learning outcomes while preserving essential cognitive and social development.

Acknowledgments

All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Data Availability

The transcripts generated and analyzed during this study are not publicly available but can be obtained from the corresponding author on reasonable request.

Authors' Contributions

TS and KK contributed equally to conceptualization, designing, implementation, data analysis, writing, and revising the manuscript. IA and WP contributed equally to implementation, analysis, and revising the manuscript. All authors reviewed and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Large language models such as ChatGPT (OpenAI) have shown promise in medical education assessments, but the comparative effects of prompt engineering across optimized variants and relative performance against medical students remain unclear.

Objective: This study aims to systematically evaluate the impact of prompt engineering on five ChatGPT variants (GPT-3.5, GPT-4.0, GPT-4o, GPT-4o1-mini, and GPT-4o1) and benchmark their performance against fourth-year medical students in midterm and final examinations.

Methods: A 100-item examination dataset covering multiple choice questions, short answer questions, clinical case analysis, and image-based questions was administered to each model under no-prompt and prompt-engineering conditions over 5 independent runs. Student cohort scores (N=143) were collected for comparison. Responses were scored using standardized rubrics, converted to percentages, and analyzed in SPSS Statistics (v29.0) with paired *t* tests and Cohen *d* ($P<.05$).

Results: Baseline midterm scores ranged from 59.2% (GPT-3.5) to 94.1% (GPT-4o1), and final scores ranged from 55% to 92.4%. Fourth-year students averaged 89.4% (midterm) and 80.2% (final). Prompt engineering significantly improved GPT-3.5 (10.6%, $P<.001$) and GPT-4.0 (3.2%, $P=.002$) but yielded negligible gains for optimized variants ($P=.07$ - $.94$). Optimized models matched or exceeded student performance on both exams.

Conclusions: Prompt engineering enhances early-generation model performance, whereas advanced variants inherently achieve near-ceiling accuracy, surpassing medical students. As large language models mature, emphasis should shift from prompt design to model selection, multimodal integration, and critical use of artificial intelligence as a learning companion.

KEYWORDS

ChatGPT; prompt engineering; medical education; large language models; assessment performance

Introduction

The integration of large language models (LLMs), such as OpenAI's ChatGPT series, into medical education has generated considerable interest due to their potential for automating and enhancing assessment processes [1]. Initial investigations focused on foundational models—ChatGPT 3.5 and ChatGPT 4.0—to benchmark baseline performance in answering clinical and basic science questions representative of medical student examinations [2,3]. These early studies demonstrated that, compared to ChatGPT 3.5, ChatGPT 4.0 exhibited significant improvements in overall accuracy, reasoning ability, and contextual understanding, particularly in complex scenario-based items [3]. Prompt engineering—providing structured guidance within the input prompt—was shown to further augment performance for both models, yielding notable score increases and reducing variance across repeated trials [4].

Since the release of ChatGPT 4.0, OpenAI has introduced enhanced variants optimized for performance and generalization: GPT-4o (optimized for multimodal tasks), GPT-4o1-mini (a compact, latency-reduced iteration), and GPT-4o1 (the full-capacity optimized version) [5,6]. However, the comparative effects of prompt engineering on these advanced models remain unexplored. Given their architectural refinements and improved instruction-following capabilities, it is plausible that newer variants may naturally internalize prompt structures, diminishing the incremental benefit of explicit guidance.

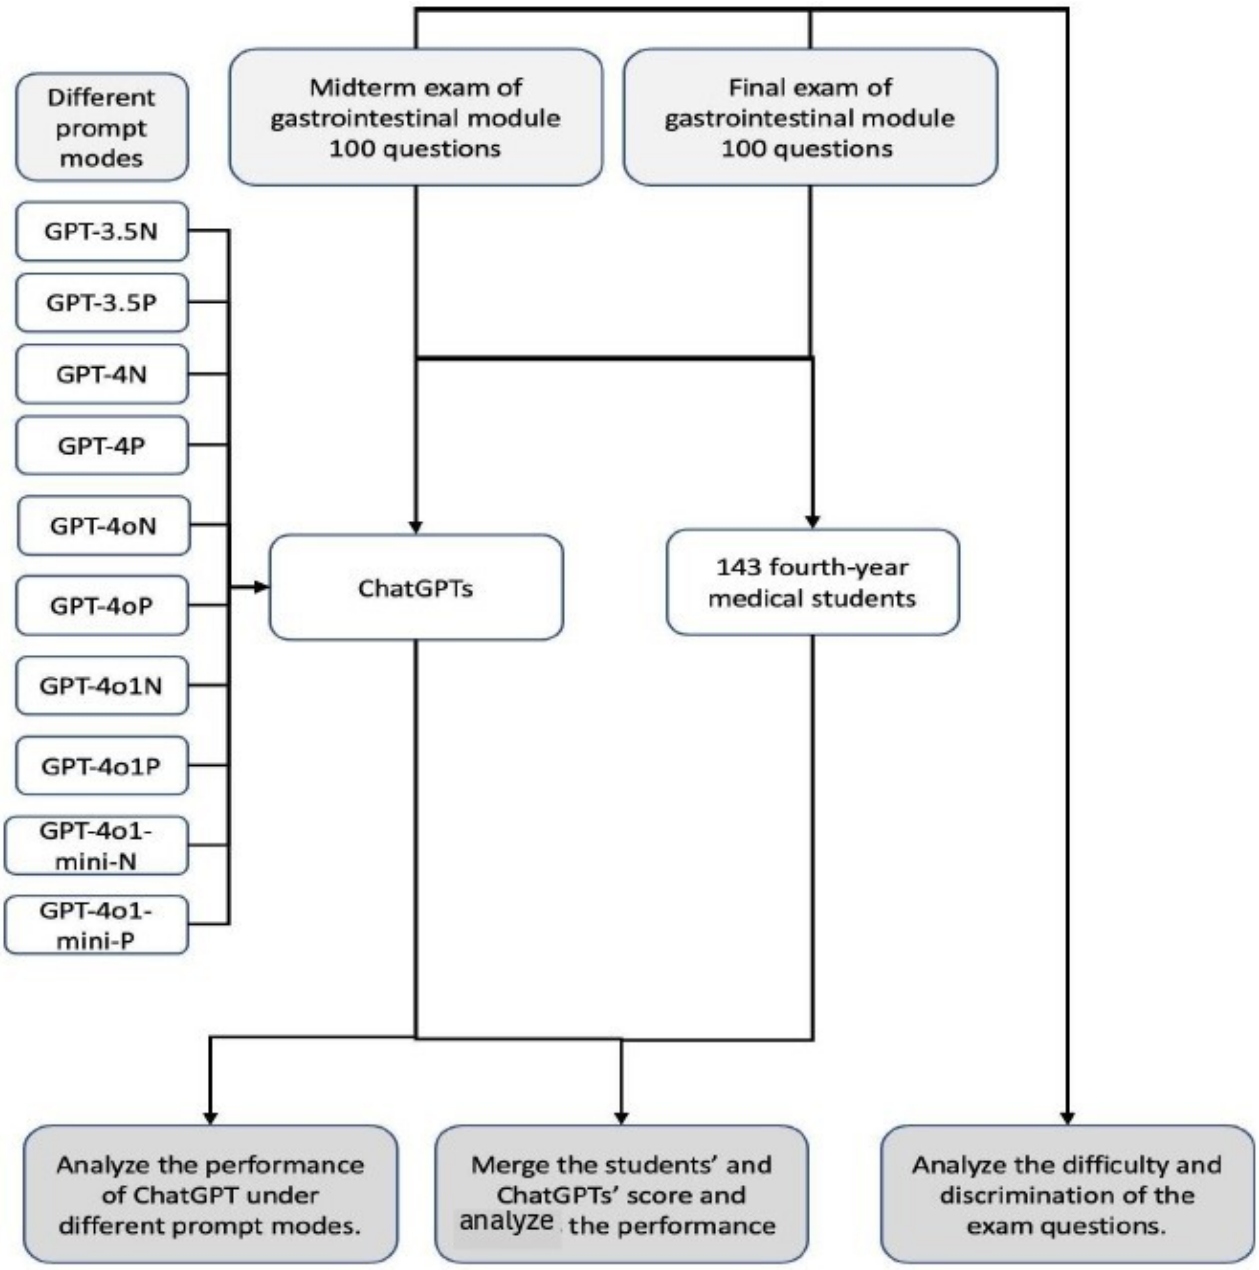
This study expands upon prior work by systematically evaluating the impact of prompt engineering across 5 ChatGPT variants—3.5, 4.0, 4o, 4o1mini, and 4o1—using a robust examination framework comprising multiple question types (multiple choice questions, MCQs; short answer questions, SAQs; clinical case analysis, CCA; and image-based interpretation, IBI). By comparing performance with and without structured prompts, we aim to quantify the degree to which prompt dependency has evolved alongside model iterations. The findings will inform best practices for leveraging LLMs in high-stakes medical education settings and contribute to understanding the maturation of prompt engineering as a methodology.

Methods

Study Design and Model Selection

This cross-sectional evaluation compared the performance of 5 OpenAI GPT variants: ChatGPT 3.5 (GPT-3.5-turbo), ChatGPT 4.0 (GPT-4), GPT-4o (optimized for multimodal tasks), GPT-4o1-mini (compact and latency-reduced), and GPT-4o1 (full-capacity optimized). Each variant was assessed under 2 prompting conditions: without a structured prompt (N) and with prompt engineering (P) (Figure 1).

Figure 1. Workflow of the study. Midterm and final gastrointestinal-module exams (100 items each) were administered to 143 fourth-year medical students and to 5 ChatGPT variants (GPT-3.5, GPT-4, GPT-4o, GPT-4o1-mini, and GPT-4o1) under 2 prompting conditions (no prompt vs prompt engineering). Each model or condition combination was run 5 times, responses were scored against the official key by 2 blinded reviewers, and performance metrics (mean, SD, *P* values, and effect sizes) as well as exam item difficulty and discrimination were analyzed.



Selecting the Student Cohort

Our curriculum uses modular teaching from the second semester of year 3 through the first semester of year 4. We selected fourth-year medical students to ensure participants had completed the modular clinical instruction, avoiding the variability introduced by students newly exposed to clinical modules. This choice ensures that the student cohort had comparable training before exam administration.

Examination Dataset and Question Types

We curated a 100-item question set drawn from the official medical student midterm and final examinations administered at Chung Shan Medical University in the 2024‐2025 academic year. The items encompassed 4 question types:

- MCQs: single-best-answer format (n=40)
- SAQs: 1‐2 sentence responses (n=20)
- CCA: open-ended diagnostic and management scenarios (n=20)
- IBI: radiographic or histologic images requiring identification or explanation (n=20)

Prompt Engineering

For the P condition, each item was prefaced with a standardized instruction prompt:

"You are an expert medical educator. Answer the following question concisely and justify your reasoning step by step."

In the N condition, only the question stem was presented.

Evaluation Procedure

For each model and condition, we conducted 5 independent runs (rounds) to account for stochastic variations. In each run, the model received the full 100-item set sequentially via the OpenAI API (v1) with default temperature settings (temperature=0.7, max_tokens=512). Outputs were recorded and collated.

Scoring and Outcome Measures

Responses were scored against the official answer key by 2 independent reviewers blinded to model and condition. MCQs were scored dichotomously (1 point for correct answer, otherwise 0). SAQs and IBI were scored on a 0‐2 scale (0=incorrect or missing, 1=partially correct, and 2=fully correct). CCA responses were scored on a 0‐3 rubric evaluating diagnostic accuracy, management plan, and justification. Total raw scores were converted to percentages of maximum possible scores.

Statistical Analysis

Statistical analyses were conducted in SPSS Statistics (version 29, IBM Corp). For each model and condition, descriptive statistics (mean scores and SD) were derived using the frequencies and descriptives procedures. Paired 2-tailed *t* tests (paired-samples *t* test) compared scores between the no-prompt (N) and prompt-engineering (P) conditions within each variant. Effect sizes (Cohen *d*) were calculated based on mean differences and pooled SDs. Statistical significance was set at $P<.05$, and all tests were 2-sided.

Ethical Considerations

The study protocol was reviewed and approved by the Institutional Review Board (IRB) of Chung Shan Medical University Hospital (approval number CSMU-2024-075), in accordance with institutional policies and the Declaration of Helsinki. The IRB granted a waiver of written informed consent because the research analyzed routinely collected deidentified examination records, involved no direct interaction or intervention with students, and posed minimal risk. Before transfer to the study team, all records were deidentified by the medical school; no direct identifiers (eg, names, student IDs, email, and IP addresses) were accessed. Analyses were performed on files labeled with random study codes, and only aggregate results are reported. Data were stored on password-protected institutional servers with access restricted to the research team and will be retained per institutional policy; no individual-level raw data will be publicly shared. Participants received no compensation, and inclusion in the dataset had no impact on grades, course standing, or academic evaluation.

Results

Overall Performance on Midterm and Final Examinations

As summarized in Table 1, baseline performance of ChatGPT 3.5 on the midterm examination was 59.2% (SD 2.1), whereas ChatGPT 4.0 achieved 81.4% (SD 1.8). The optimized variants—GPT-4o, GPT-4o1-mini, and GPT-4o1—further improved mean midterm scores to 91.3% (SD 0.8), 86.1% (SD 1), and 94.1% (SD 0.5), respectively (Table 1). A similar trend was observed for the final examination (Table 1), where GPT-3.5 scored 55% (SD 2.4) and GPT-4.0 scored 84.2% (SD 1.7), with GPT-4o, GPT-4o1-mini, and GPT-4o1 achieving 90.6% (SD 0.9), 82.1% (SD 0.6), and 92.4% (SD 0.6), respectively.

Table . Basic information of the exams: overall performance of ChatGPT variants on midterm and final examinations. Mean percentage scores (SD) for 5 GPT models (GPT-3.5, GPT-4.0, GPT-4o, GPT-4o1-mini, and GPT-4o1) under no-prompt and prompt-engineering conditions are listed, illustrating baseline accuracy and comparative gains across both examinations.

Exams	Midterm exams	Final exams
Total questions, N	100	100
Overall discrimination, mean (SD)	0.25 (0.18)	0.32 (0.21)
Overall difficulty level, mean (SD)	0.82 (0.14)	0.72 (0.18)
Memorization questions, n	66	63

Difficulty level, mean (SD)	0.84 (0.12)	0.74 (0.15)
Application questions, n	34	37
Discrimination, mean (SD)	0.21 (0.20)	0.29 (0.22)
Difficulty level, mean (SD)	0.78 (0.16)	0.69 (0.21)

Comparison With Medical Student Performance

A cohort of 143 fourth-year medical students took the identical midterm and final examinations, achieving a mean midterm score of 89.4% (SD 7.13) and a mean final score of 80.2% (SD 8.73) (Table 2). GPT-3.5 underperformed relative to students (59.2% vs 89.4%, $P<.001$; 55% vs 80.2%, $P<.001$), whereas advanced variants such as GPT-4o1 matched or exceeded student performance on both the midterm (94.1% vs 89.4%, $P<.001$) and final exams (92.4% vs 80.2%, $P<.001$) (Table 3).

Table . GPTs' performance in different question types.

ChatGPT versions	GPT-3.5N	GPT-3.5P	GPT-4N	GPT-4P	GPT-4oN	GPT-4oP	GPT-o1miniN	GPT-o1miniP	GPT-o1N	GPT-o1P	Students

Performance by Question Type

Table 2 presents model and student accuracy across 4 question types. All variants and students achieved the highest accuracy on MCQs, with GPT-4o1 reaching 98.5% (SD 1.2), students 92.3% (SD 5), and GPT-3.5 the lowest at 70.4% (SD 3). SAQs followed a similar pattern, ranging from 62.3% (SD 2.7) for GPT-3.5% to 92.1% (SD 1.5) for GPT-4o1, with students at 85.6% (SD 6.8). CCA yielded the greatest variability: GPT-3.5 scored 48.7% (SD 3.5) versus 88.4% (SD 2) for GPT-4o1 and 75.2% (SD 8.1) for students. IBI performance ranged from 55.2% (SD 3.1) to 90.2% (SD 1.8) for GPT-4o1, with student IBI at 78.5% (SD 7.5).

Error Analysis by Question Type

To further elucidate model performance nuances, we analyzed error rates across question types. CCA questions exhibited an error rate approximately 3 times higher than memory recall items when answered by early ChatGPT models (GPT-3.5 and GPT-4.0). Representative examples include:

- Memory recall: describing regulators of gastric acid secretion—GPT-3.5 misidentified pancreatic enzymes as inhibitory due to misinterpreting "major."

- CCA: a 65-year-old man with acute abdominal pain—GPT-3.5 attributed findings to pancreatitis; GPT-4o1-mini (no prompt) misdiagnosed cholecystitis.
- Short answer: advantages of laparoscopic appendectomy—GPT-4.0 only cited "smaller incision," omitting recovery and complication benefits.
- Image interpretation: abdominal X-ray—GPT-3.5 confused free air with pneumatosis intestinalis; GPT-4o (with prompt) correctly identified small-bowel obstruction. Subsequent optimized variants (GPT-4o, GPT-4o1-mini, and GPT-4o1) trained on broader multilingual corpora reduced CCA error rates, with GPT-4o1 achieving 88.4% accuracy (Table 2), approaching student performance (75.2%). This analysis highlights specific failure modes and improvements in reasoning and language comprehension.

Effect of Prompt Engineering

As shown in Table 4, prompt engineering significantly enhanced performance for early models. For the midterm, GPT-3.5 improved from 59.2% to 69.8% (Cohen d=1.5; P<.001), and GPT-4.0 from 81.4% to 84.6% (Cohen d=0.7; P=.002). In contrast, advanced variants exhibited no significant benefit: GPT-4o (91.3% vs 91.6%; P=.07), GPT-4o1-mini (86.1% vs 87.4%; P=.69), and GPT-4o1 (94.1% vs 94.2%; P=.55). Similar patterns were observed in the final exam (Table 4), where prompt-engineering scores for GPT-3.5 and GPT-4.0 increased significantly (P<.01), but not for GPT-4o (P=.94), GPT-4o1-mini (P=.58), or GPT-4o1 (P=.24).

Table . Investigation of the scores in different prompt modes: effect of prompt engineering on ChatGPT performance. Paired comparison of mean (SD) scores and *P* values is listed for each model variant under no-prompt versus prompt-engineering conditions, highlighting the variable benefit of structured prompts across model generations.

Rounds	1	2	3	4	5	Mean (SD)	*P* value
Midterm exams							
GPT-3.5N	60	59	58	60	59	59.2 (0.84)	<.001
GPT-3.5P	68	72	71	69	69	69.8 (1.64)	—[a]
GPT-4N	80	81	81	82	83	81.4 (1.14)	.002
GPT-4P	83	84	85	85	86	84.6 (1.14)	—
GPT-4oN	88	89	88	90	88	88.6 (0.89)	.07
GPT-4oP	89	90	90	89	90	89.6 (0.55)	—
GPT-4o1-miniN	91	90	92	90	91	90.8 (0.84)	.69
GPT-4o1-miniP	91	91	91	92	90	91 (0.71)	—
GPT-4o1N	92	92	91	92	92	91.8 (0.45)	.55
GPT-4oP	91	92	92	92	91	91.6 (0.55)	—
Final exams							
GPT-3.5N	54	56	55	54	56	55(1)	<.01
GPT-3.5P	61	60	60	60	60	60.2 (0.45)	—
GPT-4N	85	84	84	85	83	84.2 (0.84)	<.01
GPT-4P	89	87	87	88	88	87.8 (0.84)	—
GPT-4oN	89	90	90	90	90	89.8 (0.45)	.94
GPT-4oP	90	91	90	91	90	90.4 (0.55)	—
GPT-4o1-miniN	91	92	92	91	91	91.4 (0.55)	.58
GPT-4o1-miniP	92	91	92	92	91	91.6 (0.55)	—
GPT-4o1N	91	92	91	91	92	91.4 (0.55)	.24
GPT-4oP	91	92	92	92	92	91.8 (0.45)	—

[a]Not applicable.

Stability Across Runs

Coefficient of variation (CV) across the 5 independent runs decreased with model version. GPT-3.5 midterm CV was 3.5%, whereas GPT-4o1 recorded a CV of 0.6%. Prompt engineering reduced CV by an average of 0.4 percentage points for GPT-3.5 and GPT-4.0, but had a negligible impact on optimized variants.

These findings demonstrate not only a clear progression in raw performance and stability from GPT-3.5 to GPT-4o1, but also that the top-tier optimized models can match or surpass human student performance (Table 3), indicating their potential as both assessment tools and educational companions.

Discussion

Principal Findings

This study provides the first systematic evaluation of prompt engineering across multiple ChatGPT variants, highlighting the evolution of LLM capabilities in medical education settings. We observed that GPT-4 variants (GPT-4o, GPT-4o1-mini, and GPT-4o1) significantly outperformed earlier models, consistent with the findings by Kung et al [7] that ChatGPT 4.0 surpassed ChatGPT 3.5 on the United States Medical Licensing Examination, achieving accuracy at or near the passing threshold. In our work, advanced models not only exhibited higher baseline scores but also demonstrated greater stability across repeated runs, underscoring architectural improvements in reasoning and context retention.

Prompt engineering yielded substantial performance gains for early-generation models—GPT-3.5 and GPT-4—mirroring reports that structured guidance can boost LLM accuracy [4], but its use diminished for optimized variants. Safrai and Azaria [8] found that GPT-4 maintained performance even when confronted with extraneous "small talk" inserted into medical prompts, whereas GPT-3.5's performance degraded under similar conditions. Our findings extend this observation, showing that GPT-4o and its successors exhibit minimal dependency on explicit prompt structures, suggesting that these models have internalized reasoning scaffolds natively.

Our analysis by question type aligns with the in-depth evaluation by Knoedler et al [9], who reported variable ChatGPT performance across categories and a negative correlation with question difficulty (r_s=−0.306; P<.001) in the United States Medical Licensing Examination step 1 practice items. Similarly, we noted that CCA and IBI posed the greatest challenges for all models, although advanced variants narrowed the gap. These parallels reinforce the generalizability of LLM behavior across diverse educational assessment formats.

Our error analysis underscores the importance of evaluating LLMs not only by overall scores but also by question-type vulnerabilities. Early models' difficulties with multistep reasoning and complex Chinese phrasing, especially in clinical scenarios and image-based tasks, point to inherent limitations in contextual understanding. The marked reduction of these errors in optimized variants demonstrates progress but also indicates areas where artificial intelligence (AI) may still mislead learners. Educators should therefore integrate error-focused feedback loops when deploying LLMs: by exposing students to AI-generated mistakes in controlled settings, learners can develop critical appraisal skills and better discern AI hallucinations. This approach transforms AI from a mere answer engine into a pedagogical tool that actively fosters analytical thinking and deep learning.

Comparison With Medical Student Performance

The cohort of 143 fourth-year medical students achieved a mean midterm score of 89.4% (SD 7.13) and a mean final score of 80.2% (SD 8.73) (Table 3). GPT-3.5 underperformed relative to students (59.2% vs 89.4%; P<.001 and 55% vs 80.2%; P<.001), whereas advanced variants such as GPT-4o1 matched or exceeded student performance on both the midterm (94.02% vs 89.4%; P<.001) and final exams (92.75% vs 80.2%; P<.001). This indicates that top-tier LLMs can approach or surpass human proficiency in standardized medical assessments.

AI as a Learning Companion Beyond Assessment

Advanced LLMs show promise as AI-enabled educational tools, capable of rapidly synthesizing complex medical knowledge to aid student understanding. Studies have demonstrated AI's use in generating personalized explanations and feedback that enhance learning efficiency [2,4]. However, LLMs may still produce errors and "hallucinations" [10], underscoring the importance of maintaining critical appraisal and scholarly rigor when integrating AI into medical education.

Educational Value for Diagnosing Student Weaknesses

Although AI does not achieve 100% accuracy, its overall correctness surpassed that of most medical students in our cohort. Students spend significant time retrieving correct answers and understanding explanations; AI can serve as a learning companion by rapidly aggregating and summarizing complex medical knowledge, guiding step-by-step reasoning. Integrating our AI system into adaptive learning platforms could help students quickly identify weak areas, practice targeted question types, and maintain critical appraisal to avoid overreliance on AI outputs. This targeted approach not only enhances learning efficiency but also empowers students to become more self-directed learners, using AI as a diagnostic tool to identify knowledge gaps and focus their study efforts where they are most needed.

Strategies to Reduce AI Hallucinations

To mitigate risks of LLM-generated misinformation, future implementations should consider several evidence-based strategies. Cross-model consensus approaches—querying multiple LLMs (eg, GPT-4o1 and open-source alternatives) and adopting majority-vote answers—can increase reliability and reduce single-model biases. Expert fine-tuning using annotated medical datasets would strengthen domain-specific accuracy, particularly for specialized clinical scenarios. Integration of real-time evidence retrieval through literature and guideline search APIs would ensure responses include verifiable reference citations, enhancing transparency and trustworthiness. In addition, implementing confidence scoring systems coupled with human-AI collaboration frameworks would route low-confidence responses to human experts for review, creating a safety net against potential hallucinations while maintaining efficiency.

Collectively, these results underscore a maturation of LLMs: as model architectures advance, the marginal benefit of prompt engineering declines, and the potential educational role shifts from prompt design to strategic integration and fine-tuning. For practitioners and educators, this suggests a shift from elaborate

prompt design toward focusing on model selection and integration strategies—such as multimodal input handling and curriculum-specific fine-tuning—to maximize efficacy in high-stakes assessments. Future research should explore adaptive prompting frameworks that tailor AI guidance to learner needs and investigate real-world clinical scenario applications, while prioritizing the development of robust safeguards against AI hallucinations to ensure safe and effective integration into medical education curricula.

Conclusions

This comprehensive evaluation across 5 ChatGPT variants demonstrates a progressive enhancement in performance and stability in medical examination tasks. Notably, optimized LLMs (GPT-4o, GPT-4o1-mini, and GPT-4o1) not only matched but significantly exceeded the mean scores of fourth-year medical students on both midterm and final exams, underscoring their capacity to approach—or surpass—human proficiency in standardized assessments.

While prompt engineering substantially improved outcomes for early-generation models (GPT-3.5 and GPT-4.0), optimized variants achieved near-ceiling accuracy with negligible gains from structured prompts, indicating that these models inherently internalize contextual guidance. These findings suggest a strategic pivot for educators and assessment designers: from intricate prompt crafting toward thoughtful model selection, multimodal integration, and domain-specific fine-tuning.

Furthermore, the ability of advanced LLMs to rapidly synthesize and organize complex medical knowledge positions them as valuable AI-enabled learning companions. Educators should leverage AI's strengths in personalized explanation and feedback while maintaining rigorous critical appraisal to identify potential errors or "hallucinations."

Future research should investigate adaptive prompting frameworks tailored to individual learner needs and assess the educational impact of AI-augmented tools in real-world clinical training environments.

Abstract

Background: ChatGPT is a generative artificial intelligence–based chatbot developed by OpenAI. Since its release in the second half of 2022, it has been widely applied across various fields. In particular, the application of ChatGPT in medical education has become a significant trend. To gain a comprehensive understanding of the research developments and trends regarding ChatGPT in medical education, we conducted an extensive review and analysis of the current state of research in this field.

Objective: This study used bibliometric and visualization analysis to explore the current state of research and development trends regarding ChatGPT in medical education.

Methods: A bibliometric analysis of 407 articles on ChatGPT in medical education published between March 2023 and June 2025 was conducted using CiteSpace, VOSviewer, and Bibliometrix (RTool of RStudio). Visualization of countries, institutions, journals, authors, keywords, and references was also conducted.

Results: This bibliometric analysis included a total of 407 studies. Research in this field began in 2023, showing a notable surge in annual publications until June 2025. The United States, China, Türkiye, the United Kingdom, and Canada produced the most publications. Networks of collaboration also formed among institutions. The University of California system was a core research institution, with 3.4% (14/407) of the publications and 0.17 betweenness centrality. *BMC Medical Education*, *Medical Teacher*, and the *Journal of Medical Internet Research* were all among the top 10 journals in terms of both publication volume and citation frequency. The most prolific author was Yavuz Selim Kiyak, who has established a stable collaboration network with Isil Irem Budakoglu and Ozlem Coskun. Author collaboration in this field is usually limited, with most academic research conducted by independent teams and little communication between teams. The most frequent keywords were “AI,” “ChatGPT,” and “medical education.” Keyword analysis further revealed “educational assessment,” “exam,” and “clinical practice” as current research hot spots. The most cited paper was “Performance of ChatGPT on USMLE: Potential for AI-Assisted Medical Education Using Large Language Models,” and the paper with the strongest citation burst was “Are ChatGPT’s Knowledge and Interpretation Ability Comparable to Those of Medical Students in Korea for Taking a Parasitology Examination?: A Descriptive Study.” Both papers focus on evaluating ChatGPT’s performance in medical exams.

Conclusions: This study reveals the significant potential of ChatGPT in medical education. As the technology improves, its applications will expand into more fields. To promote the diversification and effectiveness of ChatGPT in medical education, future research should strengthen interregional collaboration and enhance research quality. These findings provide valuable insights for researchers to identify research perspectives and guide future research directions.

Introduction

Background

Large language models (LLMs) represent major progress in artificial intelligence (AI), especially for computational linguistics and natural language processing. These generative AI models are fundamentally based on the transformer neural network architecture [1]. Training is conducted using extensive text datasets, including books, documents, and website content. LLMs have been developed to predict subsequent words or tokens. Through this process, they learn to recognize complex language patterns, including vocabulary, grammar, semantics, and even specialized knowledge such as medicine [2].

ChatGPT, an AI chatbot developed by OpenAI [3], was launched in November 2022 as an LLM [4,5]. Built on the generative pretrained transformer architecture, it uses tens of billions of

parameters trained on massive internet text datasets [6]. ChatGPT excels at understanding and generating humanlike language, conducting natural dialogues, and delivering high-quality responses to user queries [7,8]. Its advanced text processing capabilities have driven unprecedented adoption: more than 1 billion monthly users within 4 months of release, demonstrating rapid societal integration [9].

ChatGPT demonstrates significant potential across diverse fields, such as translation, text summarization, and programming assistance [10]. Its effectiveness extends to specialized domains such as medical education [11]. In preclinical education, students use ChatGPT for medical knowledge acquisition and personalized learning [12,13]. Conversely, educators are able to use ChatGPT to implement innovative teaching methodologies and cultivate interactive learning environments [14-16]. In clinical education [17], ChatGPT simulates clinical environments to help students improve clinical skills [18-21]. Furthermore, the pass rates and accuracy in medical licensing exams and professional subject tests [22,23] in countries such as the United States [24-26], China [27,28], Japan [29,30], and Italy [31] have attracted significant attention [32]. ChatGPT is regarded as a significant instrument for promoting innovation and enhancing efficiency in the domain of medical education.

Objectives

While existing literature reviews have explored ChatGPT's applications and limitations in medical education, important questions remain unanswered. These include the collaboration networks among countries, institutions, and authors; the most influential journals; and the most cited publications. This study used bibliometric analysis to map collaboration networks and thematic evolution and provide a comprehensive understanding of the development of ChatGPT in medical education.

A bibliometric analysis is a rigorous scientific method that provides researchers across various fields with comprehensive guidance and support [33]. It allows researchers to gain in-depth insights into prevailing issues, key trends, and research limitations within their disciplines [34-36]. On the basis of recommendations from previous studies, this study proposes the following research questions (RQs):

1. Who are the most productive researchers and which are the most productive institutions and countries or regions in the field of ChatGPT in medical education?
2. What is the status of academic collaboration among researchers, countries, or regions in the field of ChatGPT in medical education?
3. Which are the most influential journals and articles in the field of ChatGPT in medical education?
4. What are the main research themes in the field of ChatGPT in medical education?
5. What are the research trends for ChatGPT in medical education?

Methods

Literature Sources and Search Strategy

The Web of Science database was chosen for this research due to its extensive coverage of more than 12,000 academic journals. When compared to other databases, including PubMed, MEDLINE, and Scopus, Web of Science offers a robust and reliable framework for bibliometric analysis [37]. After determining pertinent title keywords, a comprehensive bibliographic search was conducted online via the Web of Science database. The search was carried out in accordance with the following format:

> *((TS=(ChatGPT)) OR TS=(Chatbot*)) OR TS=(Chat Generative Pre-trained Transformer) and ((((((((((TS=(medic* educat*)) OR TS=(medic* student*)) OR TS=(clinical clerkship*)) OR TS=(medic* school*)) OR TS=(medic* learner*)) OR TS=(medic* trainee*)) OR TS=(medic*clerk*)) OR TS=(medical education)) OR TS=(medical student)) OR TS=(medical school)) OR TS=(medical student education)) OR TS=(healthcare). NOT ALL=(retracted)—Time: Tue Jul 01, 2025, 19:18:42 GMT+0800 (CST)*

A total of 1817 documents were retrieved. These documents were screened according to the inclusion and exclusion criteria. The inclusion criteria were as follows: (1) original research articles and review articles related to ChatGPT in medical education and (2) English-language articles. After screening, of the 1817 retrieved articles, 1610 (88.61%) were retained. Following application of the exclusion criteria (articles unrelated to ChatGPT in medical education and duplicate articles), of the remaining 1610 articles, 1203 (74.72%) were excluded. The research topics of the 1203 excluded articles are summarized as follows: 370 (30.76%) were non-ChatGPT studies, 298 (24.77%) involved ChatGPT and patients, 263 (21.86%) involved ChatGPT and clinical treatment, 144 (11.97%) involved ChatGPT and hospitals, 52 (4.32%) involved ChatGPT and nonmedicine, 36 (2.99%) were ChatGPT non–medical education review articles, 20 (1.66%) involved ChatGPT and health care professional perspectives, 14 (1.16%) involved ChatGPT and nonmedical interactions with students, and 5 (0.42%) involved ChatGPT and veterinary medicine. This resulted in 407 publications being selected for bibliometric analysis. A comprehensive dataset, along with the corresponding references, was subsequently extracted from the relevant publications and organized in plain-text format for future research endeavors. This process was conducted independently by 2 authors, who cross-verified their work. Any discrepancies were resolved by a senior author.

Data Collection and Statistics

The data were exported in plain-text file format using CiteSpace (version 6.3.R1; 64 bits; advanced) and R (version 4.5.0; R Foundation for Statistical Computing) with the *bibliometrix* package [38]. The data included the full record and cited references and were stored in the download format (.txt). The data extracted from the Bibliometric online platform [39] were exported in tab-delimited file format, with content and storage format identical to those described above.

CiteSpace, a bibliometric analysis software developed by Chaomei Chen, has achieved widespread use [40,41]. The software has been proven to provide feasible and reliable text mining and knowledge visualization methods. These methods

have been used to explore research performance allocation and collaboration, research status and frontiers, and future trends. In this study, CiteSpace was used to detect parameters and visually analyze institution distribution, the dual-map overlay of journals, and burst detection.

Burst detection, based on the Kleinberg algorithm, uses an infinite state automaton to model document streams, thereby extracting meaningful structures [42]. These analyses can reveal themes exhibiting rapid growth over extended periods, as well as those that are inherently more transient.

VOSviewer, released in 2010 by Nees Jan van Eck and Ludo Waltman (Leiden University), is mainly used for bibliometric network graph analysis [43]. We used VOSviewer version 1.6.20 to visualize and analyze the country distribution and collaboration, journal distribution, author distribution and collaboration, and keyword distribution.

In addition, Bibliometrix (RTool of RStudio; Posit PBC) was used to visualize the distribution of keywords over time in the form of a heat map [44]. Microsoft Excel 2024 was used to analyze the monthly publication trends of literature from March 2023 to June 2025.

Ethical Considerations

The study did not involve human participants, therefore the ethical approval was not required.

Results

Overview of Publication Status

Our search and screening efforts yielded 407 articles (Figure 1). The release of the AI chatbot ChatGPT in November 2022 was immediately followed by 2 review articles on ChatGPT published in March 2023, which provided an overview of ChatGPT in medical education and prediction of potential future applications for ChatGPT. The analysis of publication trends for this topic was conducted using Microsoft Excel 2024 and presented the number of publications in tabular form (Table 1). The number of articles showed a gradual increasing trend. In early 2023, the number of published articles per month was less than 10, and starting in September 2023, this number increased significantly. By 2024, the number of articles per month remained at more than 10, and in 2025, it was more than 20 articles per month. In May 2025, the number of articles per month reached 33. This implies that, over time, an increasing number of scholars are focusing their attention on this domain.

Figure 1. Flowchart of data collection and bibliometric analysis.

Table . Number of articles per month and cumulative number.

Month and year	Monthly publications, n	Cumulative publications, n
March 2023	2	2
April 2023	1	3
May 2023	2	5
June 2023	2	7
July 2023	2	9
August 2023	8	17
September 2023	14	31
October 2023	13	44
November 2023	7	51
December 2023	12	63
January 2024	14	77
February 2024	15	92
March 2024	9	101
April 2024	15	116
May 2024	19	135
June 2024	17	152
July 2024	15	167
August 2024	15	182
September 2024	17	199
October 2024	20	219
November 2024	16	235
December 2024	24	259
January 2025	23	282
February 2025	23	305
March 2025	26	331
April 2025	22	353
May 2025	33	386
June 2025	21	407

Analysis of National Publication Counts

Publication counts by country were used to analyze contributions in this field. According to the results, the publications originated from 66 countries. Visualizing the geographic distribution of the 66 countries using VOSviewer revealed that Asia, Europe, Africa, North America, South America, and Oceania were all represented and that the countries were mainly concentrated in the northern hemisphere (Figure 2). In total, 38% (25/66) of the countries were in Asia, and 33% (22/66) were from Europe, the 2 continents with the highest number of countries in this study. It is noteworthy that the linkages between countries or regions were concentrated between East Asia and North America, East Asia and Europe, North America and Europe, and North America and Oceania.

Figure 2. Countries and regions involved in the research in this field. The links between the countries and regions indicate their collaborations and connections.

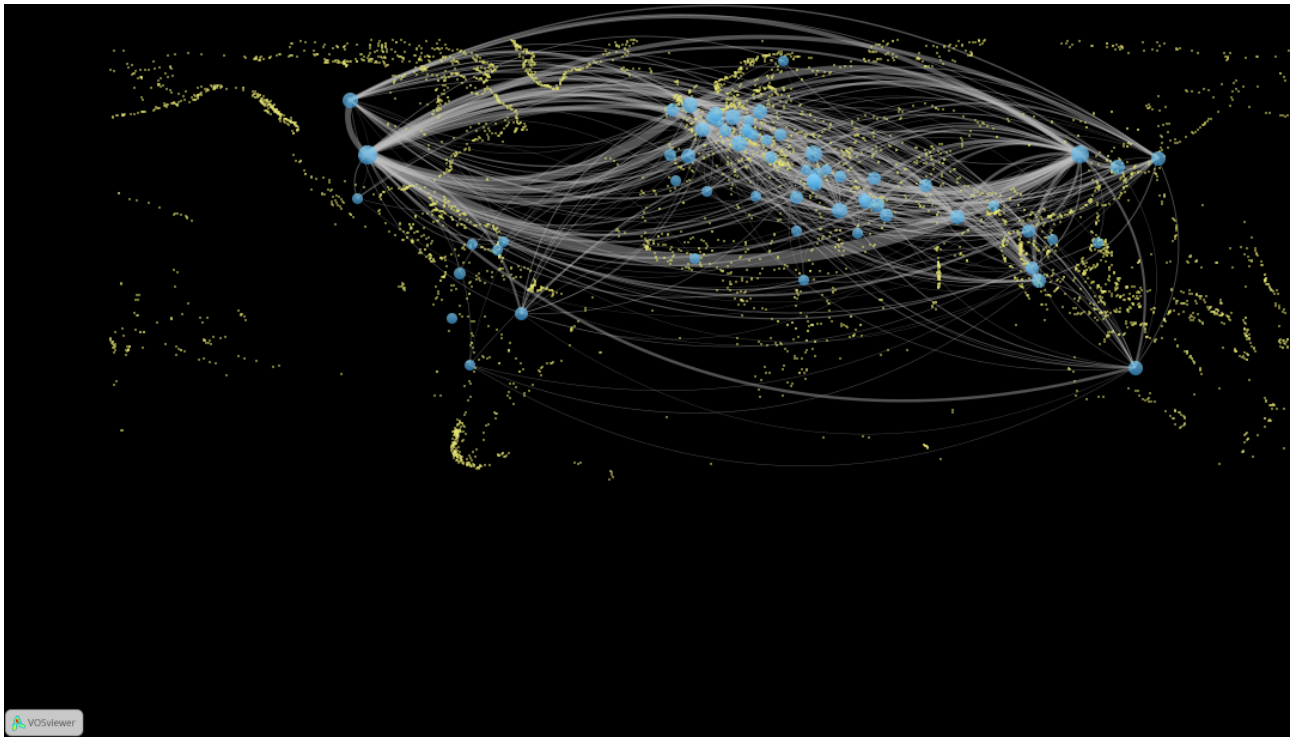

Table 2 shows the top 10 countries or regions in terms of number of publications and their corresponding citation frequency and centrality. The United States was the most prominent country with 31% (126/407) of the publications, closely followed by China, Türkiye, the United Kingdom, Canada, and Germany.

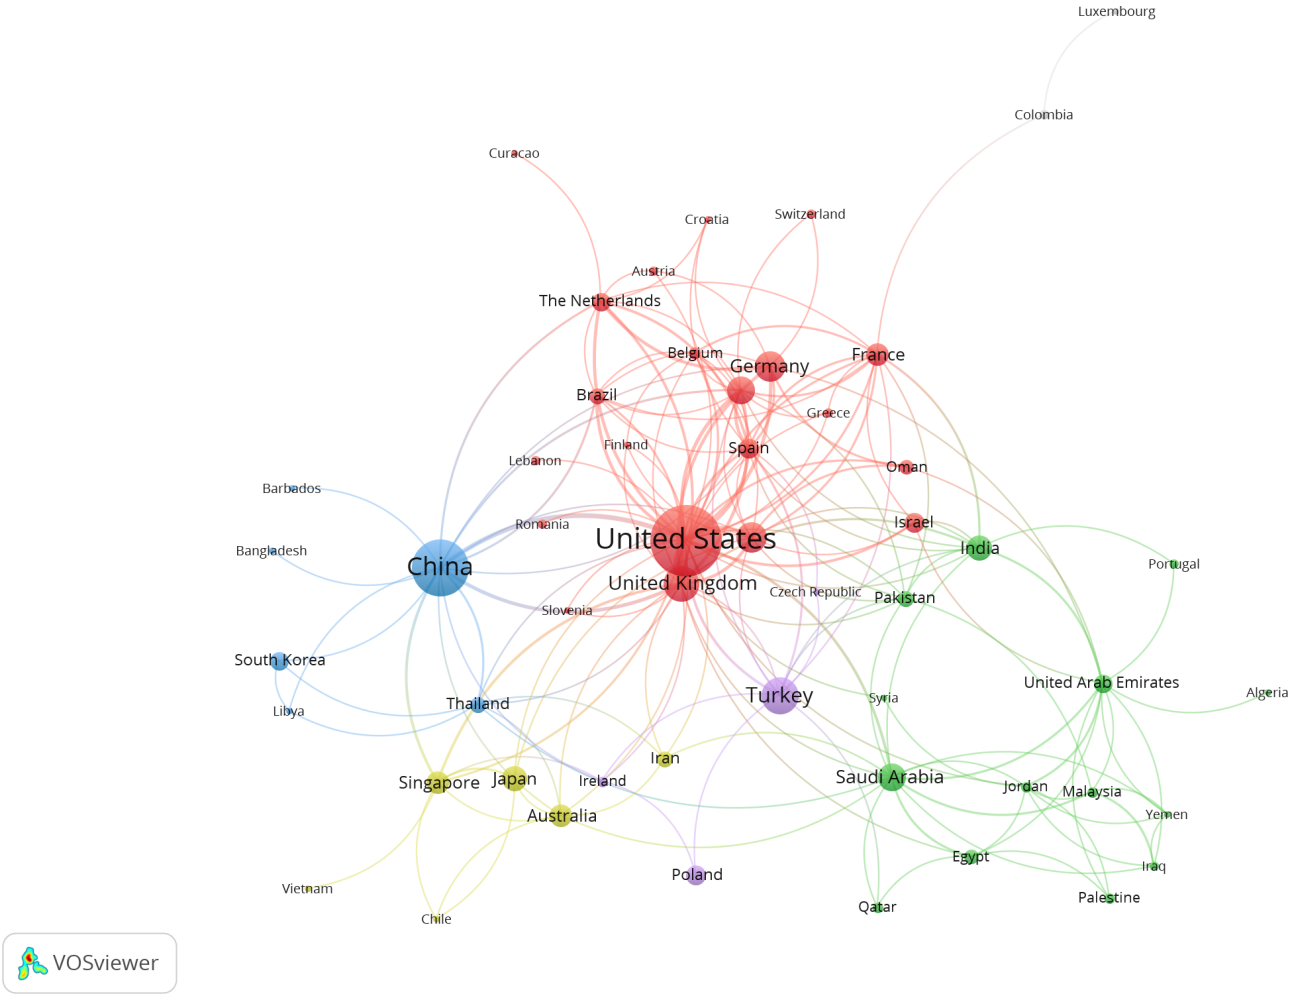
Table . Top 10 countries by number of publications and their number of citations and centrality (N=407).

Rank	Country	Publications, n (%)	Citations, n	Centrality
1	United States	126 (31)	3227	0.42
2	China	81 (19.9)	1026	0.19
3	Türkiye	35 (8.6)	215	0.08
4	United Kingdom	31 (7.6)	1844	0.17
5	Canada	24 (5.9)	668	0.05
6	Germany	22 (5.4)	463	0.06
7	Italy	19 (4.7)	730	0.06
8	Saudi Arabia	18 (4.4)	227	0.11
9	India	15 (3.7)	121	0.07
10	Japan	15 (3.7)	155	0.01

The results of the global collaboration network analysis show that countries and regions were roughly divided into 5 clusters in VOSviewer based on the closeness of collaboration and are indicated by different colors in Figure 3. The United States, China, Türkiye, the United Kingdom, and Canada were the top 5 countries in terms of the number of publications, and there were cooperative relationships between them. The betweenness centrality (BC) was calculated when analyzing the national and regional collaboration networks using CiteSpace, which represents the strength of association between nodes. Among the top 10 countries, the United States, China, the United Kingdom, and Saudi Arabia were the main research centers in this field.

Figure 3. Analysis of collaborative network visualization of countries and regions in VOSviewer.



Analysis of Publication Institutions

The scientific output came from 847 institutions. CiteSpace identified 147 institutions with 346 cooperative networks (Figure 4). The most productive institutions regarding research in this field were the University of California system (14/407, 3.4% of publications), Harvard University (11/407, 2.7% of publications), National University of Singapore (11/407, 2.7% of publications), the Commonwealth System of Higher Education (11/407, 2.7% of publications), the University of Toronto (10/407, 2.5% of publications), the University of London (8/407, 2% of publications), Gazi University (8/407, 2% of publications), the University of Pittsburgh (8/407, 2% of publications), Central South University (7/407, 1.7% of publications), and Stanford University (7/407, 1.7% of publications). Five of the top 10 institutions were from the United States. The remaining institutions were from Singapore, Canada, the United Kingdom, Türkiye, and China (Table 3).

Figure 4. Analysis of collaborative network visualization of institutions in CiteSpace.

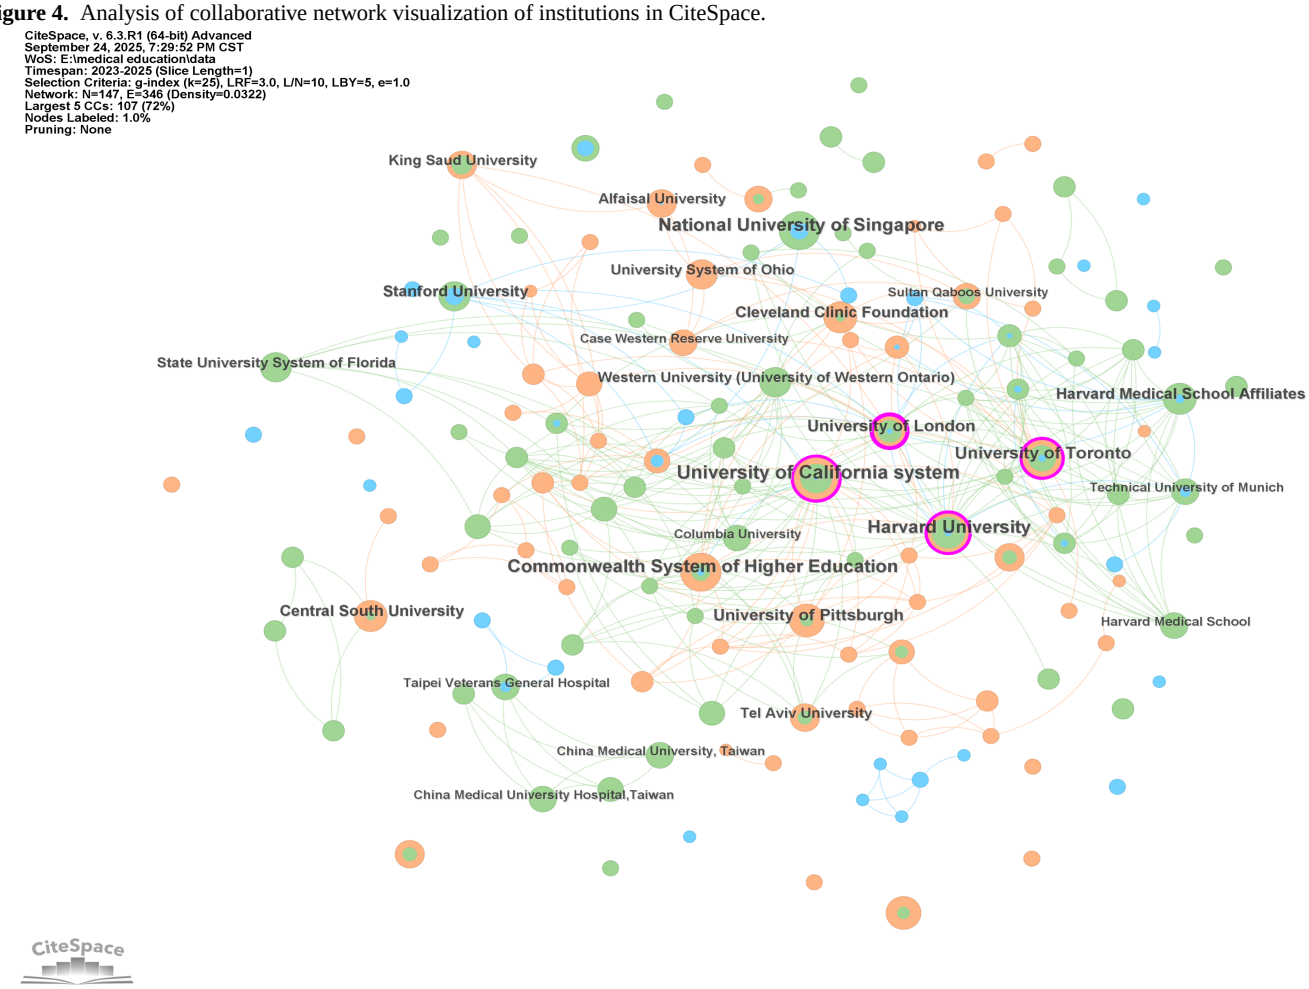


Table . Top 10 institutions and their centrality in CiteSpace (N=407).

Rank	Institution	Publications, n (%)	Centrality
1	University of California system	14 (3.4)	0.17
2	Harvard University	11 (2.7)	0.14
3	National University of Singapore	11 (2.7)	0
4	Commonwealth System of Higher Education	11 (2.7)	0.03
5	University of Toronto	10 (2.5)	0.1
6	University of London	8 (2)	0.22
7	Gazi University	8 (2)	0
8	University of Pittsburgh	8 (2)	0.01
9	Central South University	7 (1.7)	0
10	Stanford University	7 (1.7)	0.08

In CiteSpace, each node represents a institution, and the radius of a node increases with its contribution to research in the field, whereas the BC is proportional to the size of the purple ring around the nodes. The larger the purple circle, the larger the value of the betweenness centrality. Network visualization revealed that there were 4 central institutions: the University of California system (BC=0.17), Harvard University (BC=0.14), the University of Toronto (BC=0.10), and the University of London (BC=0.22; Figure 4). This reflects the significant bridging role of these institutions in the research on ChatGPT in medical education.

Analysis of Publication Quantity and Journal Impact

This study encompassed 407 articles published across 197 sources and journals. Table 4 lists the 10 most prolific sources and journals ranked by publication volume, along with their 2024 impact factor (IF). The top 10 journals published a total of 139 papers. Among these, *BMC Medical Education* (IF of

3.2; quartile 1; 40/407, 9.8% of publications) had the highest number of publications, followed by *Medical Teacher* (IF of 4.4; quartile 1; 32/407, 7.9% of publications), the *Journal of Medical Internet Research* (IF of 6.0; quartile 1; 11/407, 2.7% of publications), *Scientific Reports* (IF of 3.9; quartile 1; 11/407, 2.7% of publications), and *PLOS ONE* (IF of 2.6; quartile 2; 10/407, 2.5% of publications). Eight of the top 10 journals in terms of publications were distributed in quartile 1 of the Journal Citation Reports (Figure 5). The source or journal with the highest cocitation frequency was *arXiv*, followed by *JMIR Medical Education*, *Cureus*, *Medical Teacher*, *BMC Medical Education*, and the *Journal of Medical Internet Research* (Figure 6). Seven of the top 10 sources or journals in terms of cocitation frequency were distributed in quartile 1 of the Journal Citation Reports (Table 5). It is important to note that 3 of the top 10 journals in terms of publications were also among the top 10 journals in terms of cocitation frequency: *Medical Teacher*, *BMC Medical Education*, and the *Journal of Medical Internet Research*.

Table . Top 10 sources by number of publications and their corresponding journal impact factor (IF; Journal Citation Reports [JCR] 2024) and JCR quartile (N=407).

Rank	Source	Publications, n (%)	IF (JCR 2024)	JCR quartile
1	*BMC Medical Education*	40 (9.8)	3.2	1
2	*Medical Teacher*	32 (7.9)	4.4	1
3	*Journal of Medical Internet Research*	11 (2.7)	6.0	1
4	*Scientific Reports*	11 (2.7)	3.9	1
5	*PLOS ONE*	10 (2.5)	2.6	2
6	*Frontiers in Medicine*	9 (2.2)	3.0	1
7	*Digital Health*	7 (1.7)	3.3	1
8	*Healthcare*	7 (1.7)	2.7	2
9	*Nurse Education Today*	6 (1.5)	4.2	1
10	*Postgraduate Medical Journal*	6 (1.5)	2.7	1

Figure 6. Analysis of collaborative network visualization of journals' citations in VOSviewer.

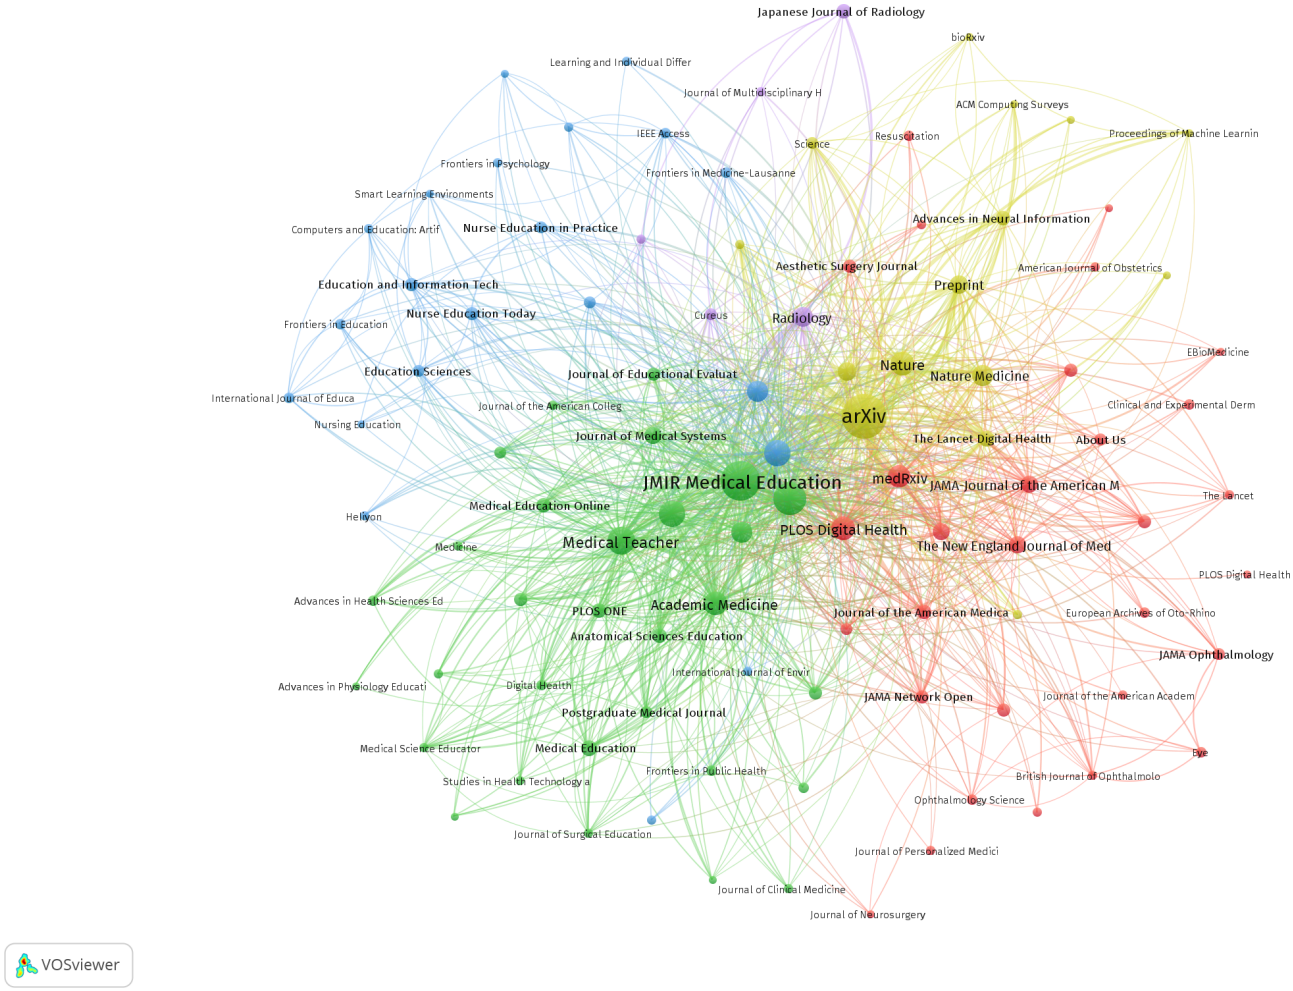

Figure 5. Analysis of collaborative network visualization of journals in VOSviewer.

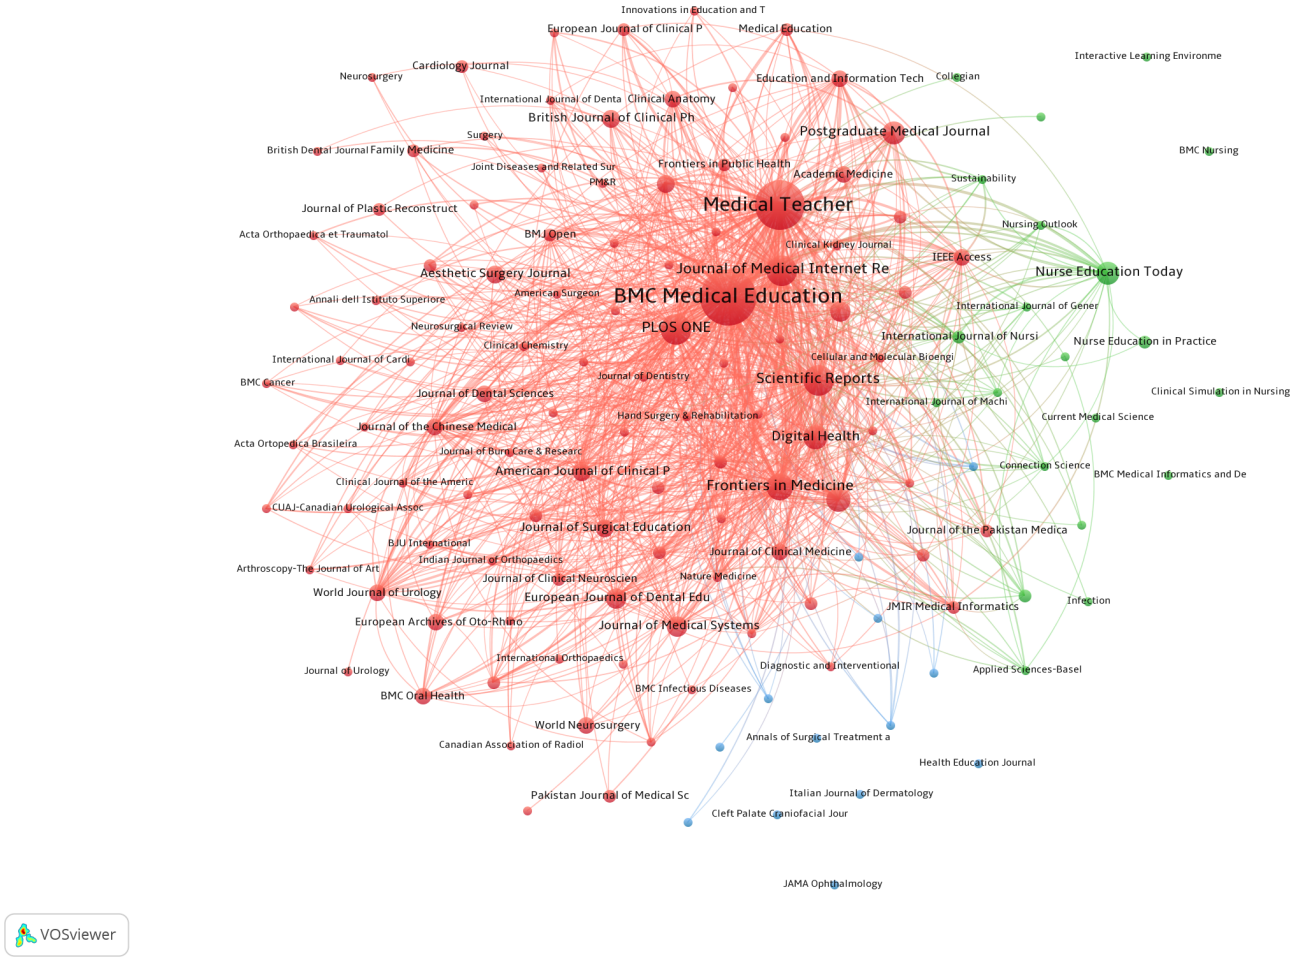

Table . Top 10 sources by number of cocitations and their corresponding journal impact factor (IF; Journal Citations Report [JCR] 2024) and JCR quartile.

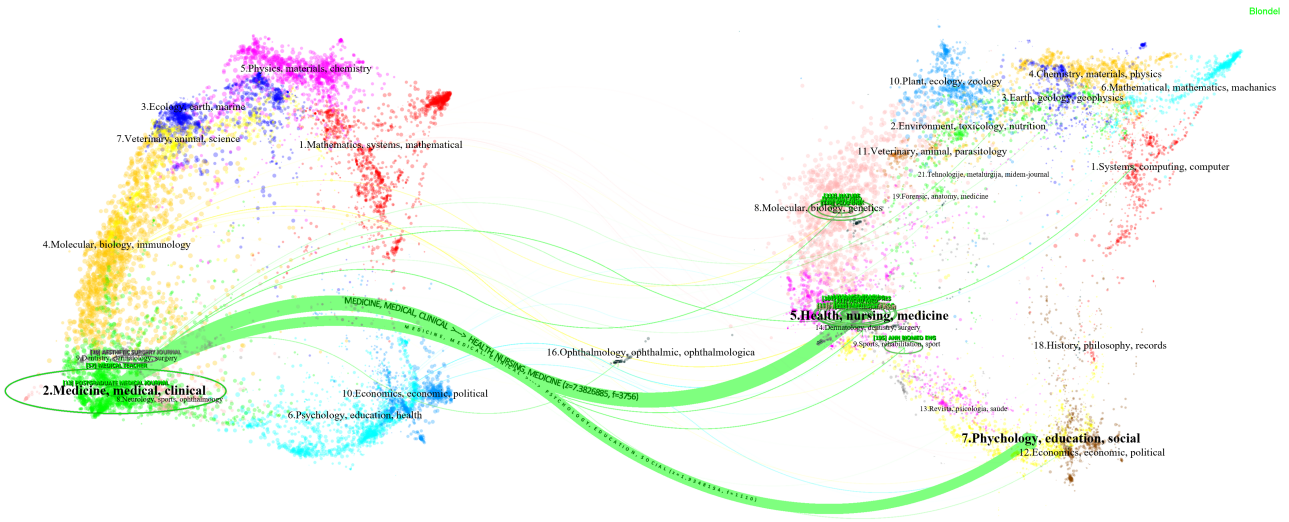
Rank	Source	Number of cocitations	IF (JCR 2024)	JCR quartile
1	*arXiv*	692	None	None
2	*JMIR Medical Education*	542	3.2	1
3	*Cureus Journal of Medical Science*	357	1.3	2
4	*Medical Teacher*	252	4.4	1
5	*BMC Medical Education*	237	3.2	1
6	*Journal of Medical Internet Research*	216	6.0	1
7	*PLOS Digital Health*	191	7.7	1
8	*Nature*	188	48.5	1
9	*Academic Medicine*	187	5.2	1
10	*medRxiv*	164	None	None

The visualization in VOSviewer showed the journals that have published articles on ChatGPT in medical education and the relationship between them. On the basis of the similarity between journals, they were divided into 3 categories: the red cluster focused on educational, technical, and basic research (eg, *BMC Medical Education* and *Medical Teacher*); the green cluster focused on the discipline of nursing and extended to nursing education, clinical simulation training, and health care informatics (eg, *Nurse Education Today* and *International Journal of Nursing Studies*); and the blue cluster focused on specialized clinical practice, particularly in surgery, obstetrics and gynecology, orthopedics, and ophthalmology (eg, *American Journal of Obstetrics and Gynecology* and *Cleft Palate Craniofacial Journal*).

Journals were among the most common sources for publishing research results. Figure 7 presents a dual-map overlay of all academic journals, illustrating the citation paths of various subject areas. This dual-map overlay consists of 2 base maps: one on the left for citing journals and one on the right for cited journals [45]. The disciplines represented by the citing journals are indicated by the labels on the left side of the dual map, whereas the disciplines of the cited journals are shown on the right [46].

Figure 7. The dual-map overlay of journals.



Notably, 2 primary citation trajectories can be identified on the map. They are from health, nursing, and medicine to medicine, medical, and clinical (green) and from psychology, education, and social to medicine, medical, and clinical (green). In addition, the leading-edge research results were mainly distributed in 2 (medicine, medical, and clinical). This suggests that research on ChatGPT in medical education is particularly active within these disciplines. In contrast, the knowledge base that frontier researchers rely on primarily stems from 5 (health, nursing, and medicine) and 7 (psychology, education, and social). Citing journals and cited journals were both from the field of medicine. This implies that the application of ChatGPT in fields where medical education intersects with other disciplines is still limited.

Analysis of the Author Collaboration Network Graph

Analyzing the coauthorship network of this study helped identify potential collaborators and authoritative figures in the field. The author with the highest number of publications was Yavuz Selim Kiyak (Table 6). He has formed a stable core collaboration group with Isil Irem Budakoglu and Ozlem Coskun, who are from the same institution (Figure 8). All 3 authors ranked among the top 10 in terms of publication volume. However, among the top 10 most prolific authors, the remaining 7 have each formed independent teams. The analysis of author collaboration suggests that most academic research was conducted in independent teams without cross-team communication. Therefore, large interinstitutional collaboration networks have yet to be established.

Table . Top 10 authors by number of publications and their institutions and total link strength (N=407).

Rank	Author	Publications, n (%)	Institution	Total link strength
1	Yavuz Selim Kiyak	8 (2)	Gazi University (Türkiye)	1372
2	Ken Masters	5 (1.2)	Sultan Qaboos University (Oman)	945
3	Isil Irem Budakoglu	4 (1)	Gazi University (Türkiye)	1081
4	Ozlem Coskun	4 (1)	Gazi University (Türkiye)	837
5	Chia-Hung Kao	4 (1)	China Medical University (China)	641
6	Michael Alfertshofer	3 (0.7)	Ludwig Maximilian University of Munich (Germany)	774
7	Shuji Awano	3 (0.7)	Kyushu Dental University (Japan)	748
8	Olena Bolgova	3 (0.7)	Alfaisal University (Saudi Arabia)	735
9	Tzeng-Ji Chen	3 (0.7)	Taipei Veterans General Hospital, Hsinchu Branch (China)	1041
10	Wisit Cheungpasitporn	3 (0.7)	Mayo Clinic (United States)	1087

Figure 8. Collaborative network visualization of authors in VOSviewer.

Co-citation refers to the situation in which different authors are cited by the same article. These authors then form a co-citation relationship.The increase in co-citation counts indicates a greater degree of similarity among different authors' research, with the analysis itself reflecting the research strength of the respective authors. Table 7 lists the top 10 authors in terms of cocitation

frequency. The most frequently cocited authors were Tiffany H Kung (n=176), Aidan Gilson (n=141), Malik Sallam (n=109), and Arun James Thirunavukarasu (n=58). It is noteworthy that Kung is highly influential in the field of research on ChatGPT in medical education.

Table . Top 10 authors by number of citations and their institutions and total link strength.

Rank	Author	Number of citations	Institution	Total link strength
1	Tiffany H Kung	176	Harvard Medical School (United States)	1945
2	Aidan Gilson	141	Yale School of Medicine (United States)	1577
3	Malik Sallam	109	The University of Jordan (Jordan)	1264
4	Arun James Thirunavukarasu	58	University of Cambridge (United Kingdom)	773
5	Gunther Eysenbach	53	JMIR Publications (Canada)	645
6	Hyunsu Lee	49	Keimyung University (South Korea)	775
7	Karan Singhal	49	Google Research (United States)	826
8	Yavuz Selim Kıyak	42	Gazi University (Türkiye)	389
9	Andrew Mihalache	42	University of Western Ontario (Canada)	549
10	Rehan Ahmed Khan	40	Riphah International University (Pakistan)	502

Keyword Analysis of Global Research

To provide an overview of the primary content of the articles, it is possible to use keywords to analyze the frontiers of research on ChatGPT in medical education. Table 8 lists the top 20 keywords by frequency. The most frequent keyword was “artificial intelligence (AI),” followed by “ChatGPT,” “medical education,” “large language models,” and “generative AI.” The keyword co-occurrence network was visualized using VOSviewer, where the connecting lines between different keywords indicate that they have co-occurrence relationships (Figure 9). The keywords that make up this network were categorized into 4 clusters. The keywords in the red cluster in Figure 9 were related to the foundational elements of medical education, core disciplines, and ethical issues, such as “academic writing,” “radiology,” “ethics-medical,” and “machine learning.” The keywords in the green cluster focused on assessment methods, exam systems, and clinical decision-making processes in medical education, such as “medical exam,” “clinical decision-making,” and “teaching and learning.” The keywords in the blue cluster focused on specific applications, challenges, and practical effects of generative AI in medical practice, medical education, and specialties, such as “clinical practice,” “nursing education,” and “clinical skills.” The keywords in the yellow cluster were related to the evaluation of different generative AI models and multiple research methods and practices, such as “google bard,” “meta-analysis,” and “diagnosis.”

Table . Top 20 keywords with the highest frequency of occurrence and their corresponding total link strength.

Rank	Keyword	Number of occurrences	Total link strength
1	“AI”	225	715
2	“ChatGPT”	216	676
3	“Medical education”	107	336
4	“Large language models”	101	338
5	“Generative AI”	29	108
6	“Education”	28	102
7	“Chatbot”	26	86
8	“Natural language processing”	22	110
9	“Medical student”	20	56
10	“Machine learning”	18	74
11	“Healthcare”	12	62
12	“Ethics”	9	48
13	“Gemini”	9	39
14	“Clinical decision-making”	9	26
15	“Medical exam”	9	48
16	“Bard”	8	40
17	“Nursing”	8	31
18	“Assessment”	8	40
19	“Clinical reasoning”	8	20
20	“Exam”	8	34

Figure 9. The co-occurrence of keywords in VOSviewer.

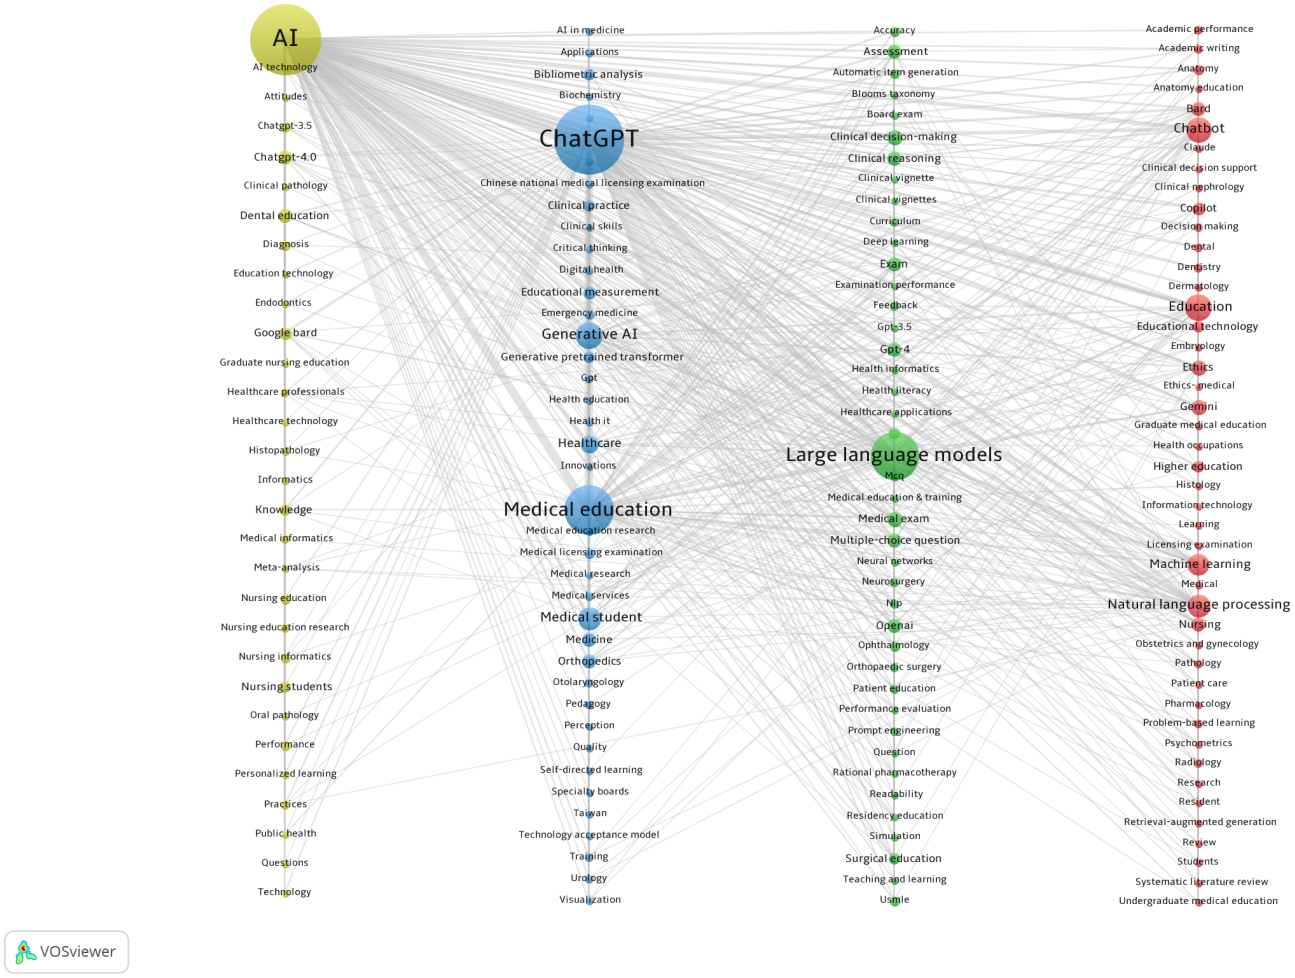


Figure 10 shows the monthly prevalence of the keywords from March 2023 to June 2025. Keywords such as “educational evaluation” and “medical disciplines” were research hot spots in 2023. Studies on GPT-4 continued throughout 2024. By 2025, research expanded to other LLMs such as Google Bard, Gemini, and Copilot. Research on medical exams continued from 2024 to 2025. Figure 11 shows the cumulative frequency of keywords between March 2023 and June 2025. Although research on clinical decision-making began in April 2023, related studies increased nearly in 2025. Ethics, starting in early 2024, rapidly became a research hot spot in a relatively short period.

Figure 10. Monthly distribution heat map of keywords in Bibliometrix.

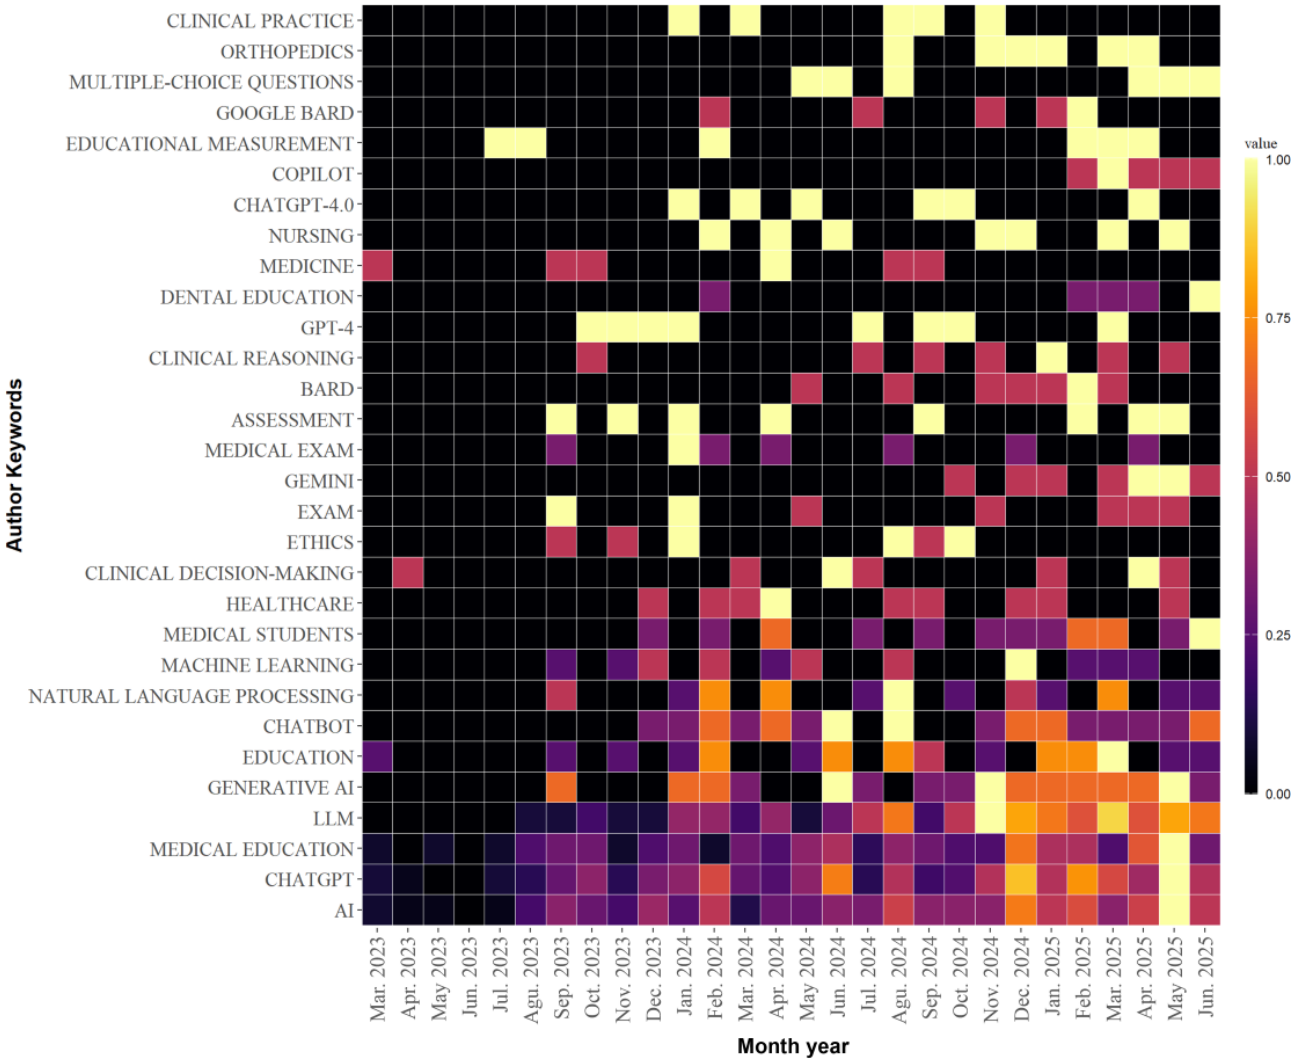

Figure 11. Cumulative distribution heat map of keywords in Bibliometrix.

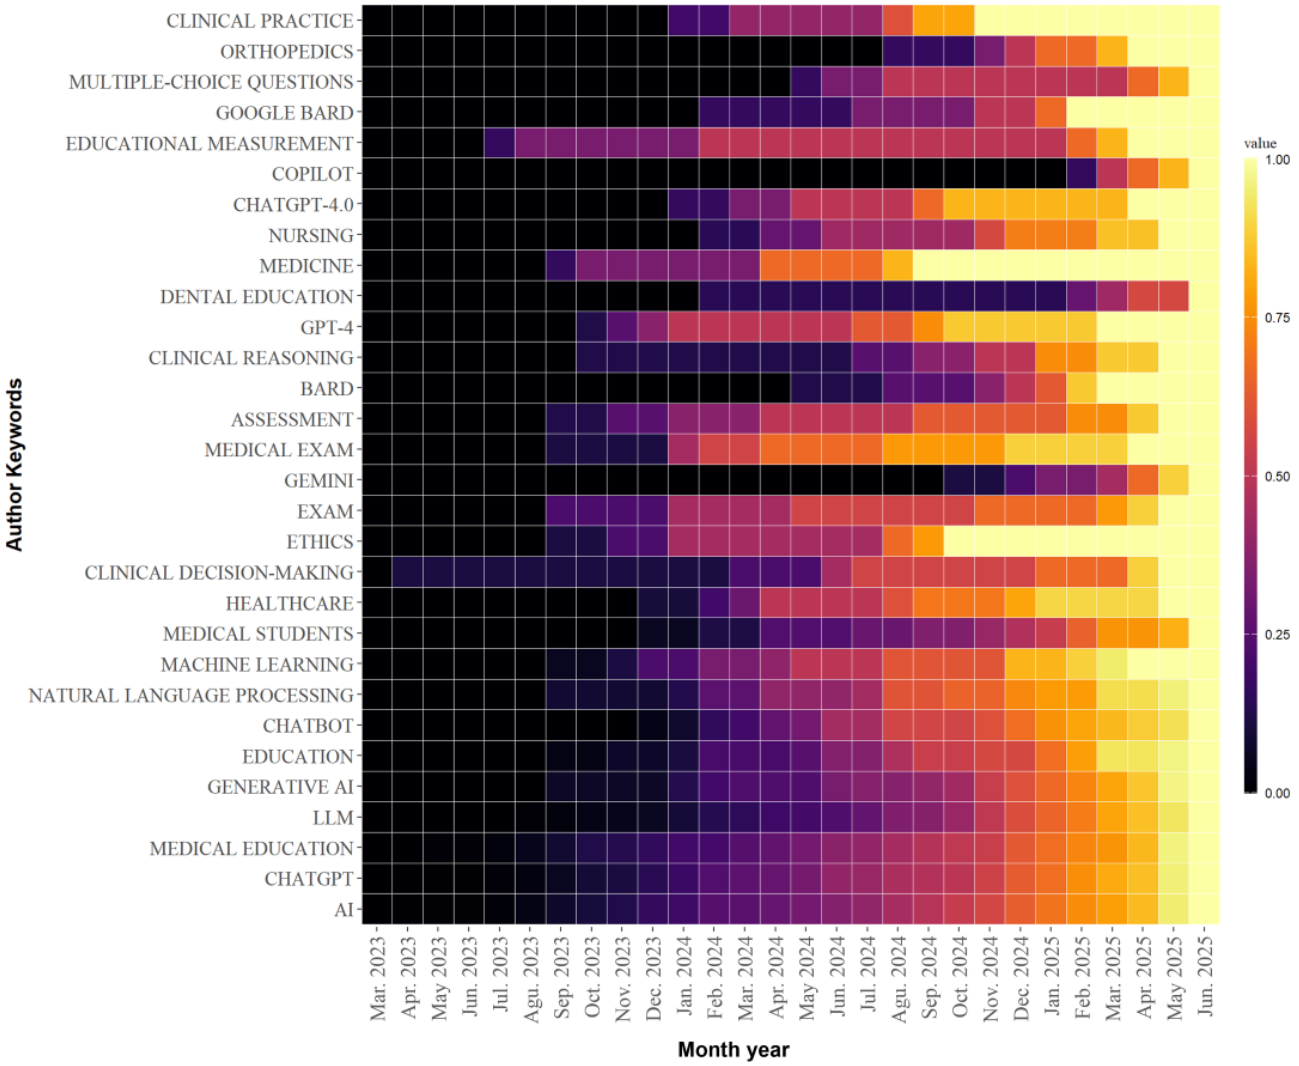

Characteristics of Cited Research Articles

Table 9 lists the top 10 articles in terms of citation frequency. The most frequently cited article was “Performance of ChatGPT on USMLE: Potential for AI-Assisted Medical Education Using Large Language Models” [47] (n=169). The second most cited article was “How Does ChatGPT Perform on the United States Medical Licensing Examination (USMLE)? The Implications of Large Language Models for Medical Education and Knowledge Assessment” [48] (n=125). Both articles were about ChatGPT’s participation in the United States Medical Licensing Examination (USMLE). They evaluated ChatGPT’s performance on the USMLE, reflecting strong researcher interest in AI’s exam capabilities during the 2023 to 2025 study period.

Table . Top 10 most cited references.

Table 10 shows the top 20 references with the strongest citation bursts. The first citation burst occurred in 2023. This was a study comparing ChatGPT and Korean medical students on a parasitology exam. An article published in 2023, titled "Chat Generative Pretrained Transformer Fails the Multiple-Choice American College of Gastroenterology Self-Assessment Test" [56], experienced a citation burst in 2024, with the burst lasting until 2025. Researchers have continued to study ChatGPT's ability to pass medical exams; the types of exams have ranged from the USMLE to basic subject exams. Furthermore, researchers have begun to evaluate ChatGPT's performance on different types of exam questions.

Table . Top 20 references with the strongest citation bursts.

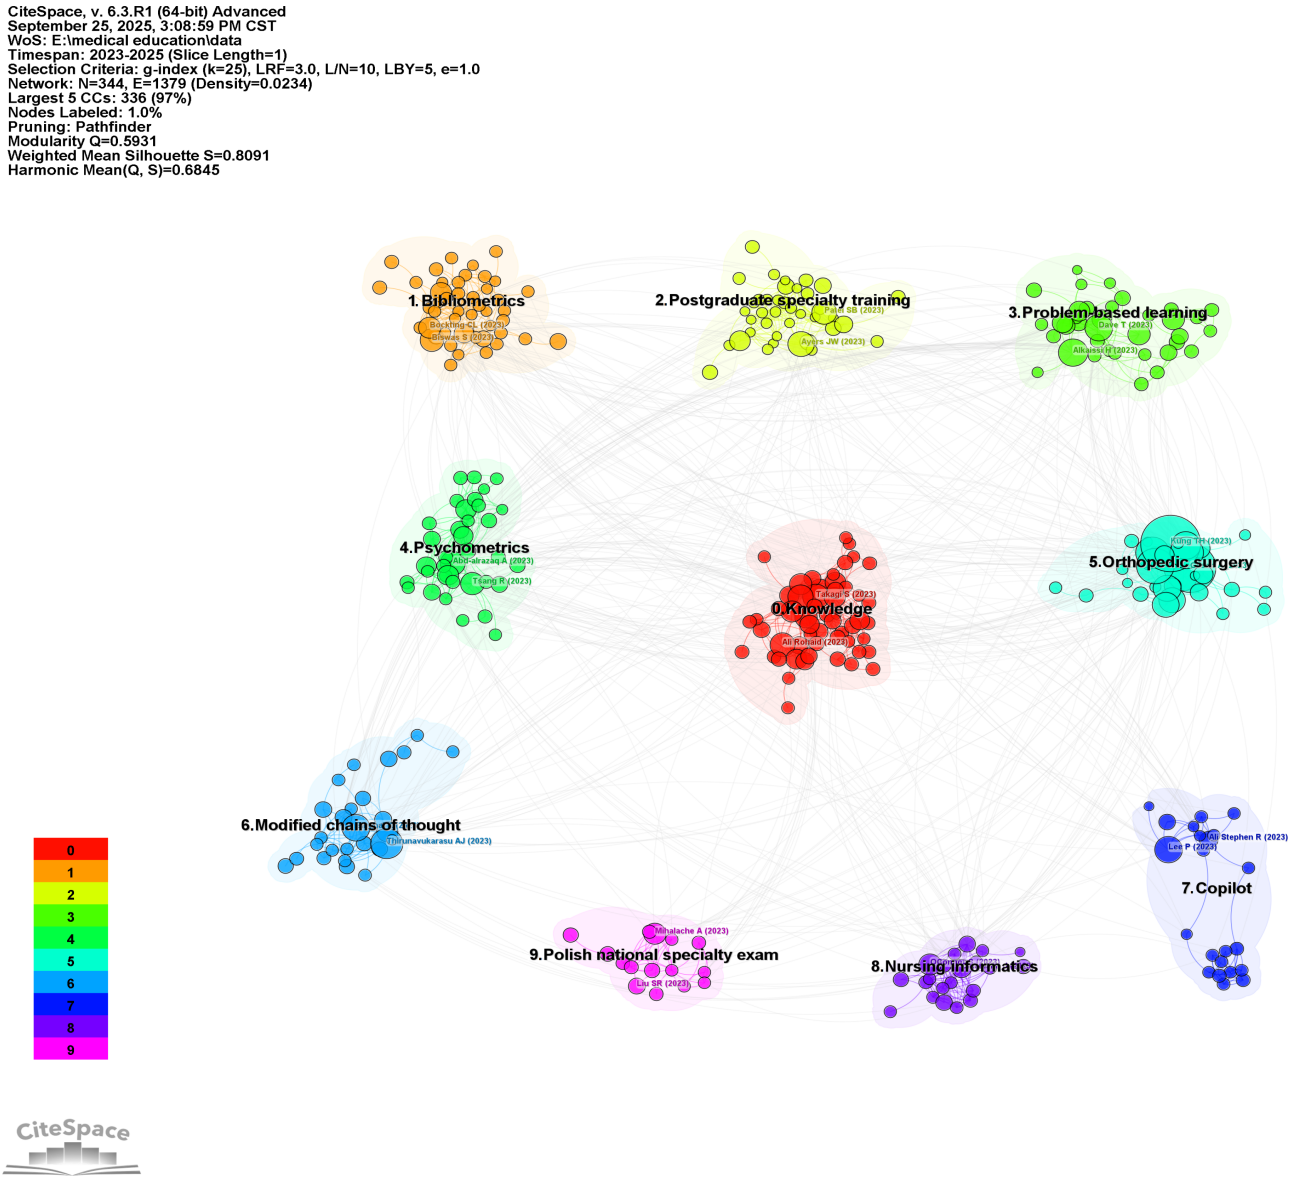
The process of clustering analysis was conducted based on the relevance between documents, with the result that the literature was divided into 9 categories (Figure 12), each of which was identified with a different color. The category with the highest number of publications was cluster 0. The term “knowledge” was a frequently occurring keyword in this category, indicating a concentration of studies evaluating ChatGPT’s medical knowledge. This finding is related to the research themes of the highly cited articles and burst articles. The cluster evolution shows that cluster 0 (knowledge) originated from clusters 2 (postgraduate specialty training) and 3 (problem-based learning), later developing into cluster 5 (orthopedic surgery). This progression reflects a research shift from foundational knowledge toward clinical applications. It is noteworthy that,

after Microsoft released Copilot in May 2023, studies expanded to cluster 7 (Copilot).

Figure 12. Clustering of references based on similarity.



Discussion

Principal Findings

We analyzed Web of Science literature on ChatGPT in medical education using VOSviewer and CiteSpace. The bibliometric results showed that researchers from 66 countries have participated in this field. The United States was the most prolific contributor, with 31% (126/407) of the published papers included in this study. Furthermore, the University of California system was ranked first with 3.4% (14/407) of the publications, reflecting the sustained investment of the United States in this area. Networks of countries and institutions have been established. This confirms active global communication and cooperation on the application of ChatGPT in medical education. Current research collaborations facilitate deeper international exchange in this field.

Notable contributors in this field include Yavuz Selim Kiyak, Ken Masters, Isil Irem Budakoglu, and Ozlem Coskun, all of whom are from academic institutions. Notably, 2 of the top 10 authors with the most publications are from hospitals or clinics. This indicates that clinicians are increasingly paying attention to the application of ChatGPT in clinical education. The results of the journal analysis showed that both citing and cited journals were from the field of medicine, and there was no emerging trend toward interdisciplinary research. The results of keyword analysis showed a shift in research focus from broader topics such as medical education assessment and medical exams to specific clinical disciplines such as dentistry and nephrology.

Comparison to the Literature

Our research findings are consistent with the existing literature. Research on ChatGPT in medical education primarily focuses on “medical knowledge,” “educational assessment,” “clinical decision-making,” and “exam performance” [50,71,72], with increasing attention to ethics concerns [73]. Previous studies have documented the increase in publications in the field, as well as the central role played by the United States [74].

Analyzing collaboration networks and journals may provide researchers in this field with a comprehensive understanding of institutional collaboration and journal publication information. Moreover, through thematic analysis, the evolution of research topics and recent research hot spots in this field were revealed.

Implications of the Findings

The findings of this study have a number of implications. The considerable increase in research on ChatGPT in medicine indicates its extensive integration into medical education and clinical practice. The strong international collaboration suggests that research outcomes related to ChatGPT in medical education are being shared worldwide. Authors conduct research in multiple small and isolated groups. This means that researchers in this field tend to work in independent teams and lack communication across different teams. The results of the dual-map overlay of the journals showed that both the citing and cited journals were from the field of medicine, indicating that research on ChatGPT in medical education has not yet been integrated with other disciplines, failing to form a cross-disciplinary trend.

Research themes evolved from preclinical education to clinical practice simulation, confirmed via keyword and citation analysis. As a learning tool, ChatGPT has passed medical licensing exams in the United States [75,76], India [77], the United Kingdom [78], and South Korea [79]. Its applications have expanded from basic exams to specialty tests, including the American Orthopaedic In-Training Examination [80], the Membership of the Royal Colleges of Physicians of the United Kingdom exam [81], and the Chinese Critical Care Examination [82]. Researchers test ChatGPT's medical knowledge through multiple exams. Nowadays, assessing the feasibility of ChatGPT as a learning tool is a research hot spot. Concurrently with the release of LLMs such as Microsoft Copilot, Google Gemini, and China's DeepSeek, studies have begun to compare different models' exam performance [83-85]. However, as LLMs keep evolving, we urgently need rigorous evidence of their reliability in medical testing. This proof remains essential before medical students fully adopt these learning tools.

In clinical teaching, ChatGPT has been used to emulate a range of clinical scenarios, including undiagnosed diabetes, kidney injury, and ophthalmic diseases [18-20]. This creates an interactive clinical reasoning environment for students, enhancing engagement during learning. However, it is important to note that ChatGPT sometimes generates inaccurate or fabricated information [86,87]. Medical educators and students need a clear understanding of ChatGPT's capabilities and limitations across medical specialties to effectively use AI tools for teaching and learning.

ChatGPT's integration into medical education raises ethical issues, highlighted by our keyword analysis. Researchers are concerned that it could unintentionally reveal a patient's personal information [88]. However, little research has been conducted on ChatGPT in medical ethics education (eg, medical ethics courses) and its educational impact [89]. While many studies have evaluated ChatGPT's performance in medical licensing exams across various countries, research on its ability to address medical ethics issues remains limited. The 2024 study by Danehy et al [90] showed that GPT-3.5 and ChatGPT-4 performed worse on ethics questions than on medical knowledge questions. This suggests that ChatGPT's training emphasizes medical knowledge over medical ethics. This training bias may be a potential trigger for ethical controversies involving ChatGPT in clinical practice.

Study Strengths and Limitations

This study has both strengths and limitations. To our knowledge, this is the first study to use bibliometric analysis to study the use of ChatGPT in medical education rather than general medicine. Furthermore, the visualization of quantitative results provides a comprehensive understanding of the current status of publications, research hot spots, and development trends related to ChatGPT in medical education.

Despite best efforts to include all the relevant terms and terminology in the literature search, some relevant papers may have been omitted. The search was confined to Web of Science, and only research articles written in English were included, with articles in other languages not being considered. In addition, due to the ongoing nature of the research, recent high-quality studies may not have been included.

Subsequently, the discussion focus on providing strong evidence to demonstrate the feasibility of ChatGPT as a learning tool, evaluating ChatGPT's medical ethics awareness in medical education, and offering evidence to support the application of ChatGPT in medical ethics.

Conclusions

In conclusion, this bibliometric analysis of ChatGPT in medical education reveals characteristics such as rapid publication growth, concentrated contributions from leading countries and institutions, decentralized author networks, and evolving thematic focuses. It will be crucial to enhance institution collaboration and cross-team partnerships in the future. This will promote the application potential of ChatGPT in various fields of medical education. Improving the effectiveness of ChatGPT is expected to provide educators and students with a more efficient medical teaching and learning process.
